Care has been taken to confirm the accuracy of the information presented and to describe generally accepted practices. However, the authors, editors, and publisher are not responsible for errors or omissions or for any consequences from application of the information in this book and make no warranty, express or implied, with respect to the content of the publication.

The authors, editors, and publisher have exerted every effort to ensure that drug selection and dosage set forth in this text are in accordance with the current recommendations and practice at the time of publication. However, in view of ongoing research, changes in government regulations, and the constant flow of information relating to drug therapy and drug reactions, the reader is urged to check the package insert for each drug for any change in indications and dosage and for added warnings and precautions. This is particularly important when the recommended agent is a new or infrequently employed drug.

Some drugs and medical devices presented in this publication have Food and Drug Administration (FDA) clearance for limited use in restricted research settings. It is the responsibility of the health care provider to ascertain the FDA status of each drug or device planned for use in his or her clinical practice.

Villanova, Pennsylvania

Chapter 13: Pain Management

Iris Woodard, BSN, RN-CS, ANP

Nurse Practitioner
Kaiser Permanente
Rockville, Maryland

Chapter 55: Assessment of Integumentary Function

Chapter 56: Management of Patients With Dermatologic Problems

Acknowledgments

The authors gratefully acknowledge the contributions and expertise of Dale Halsey Lea, MS, RN, MPH, FAAN.

The first edition of *Brunner & Suddarth's Textbook of Medical-Surgical Nursing* was published in 1964 under the leadership of Lillian Sholtis Brunner and Doris Smith Suddarth. Lillian and Doris pioneered a medical-surgical nursing textbook that has become a classic. Medical-surgical nursing has come a long way since 1964 but continues to be strongly influenced by the expansion of science, medicine, surgery, and technology, as well as a myriad of social, cultural, economic, and environmental changes throughout the world. Nurses must be particularly skilled in critical thinking and clinical decision-making as well as in consulting and collaborating with other members of the multidisciplinary health care team.

Along with the challenges that today's nurses confront, there are many opportunities to provide skilled, compassionate nursing care in a variety of health care settings, for patients in the various stages of illness, and for patients across the age continuum. At the same time, there are significant opportunities for fostering health promotion activities for individuals and groups; this is an integral part of providing nursing care.

Continuing the tradition of Lillian's and Doris's first edition, this 12th edition of *Brunner & Suddarth's Textbook of Medical-Surgical Nursing* is designed to assist nurses in preparing for their roles and responsibilities within the complex health care delivery system. A goal of the textbook is to provide balanced attention to the art and science of adult medical-surgical nursing. The textbook focuses on physiologic, pathophysiologic, and psychosocial concepts as they relate to nursing care, and emphasis is placed on integrating a variety of concepts from other disciplines such as nutrition, pharmacology, and gerontology. Content relative to health care needs of people with disabilities, nursing research findings, ethical considerations, and evidence-based practice has been expanded to provide opportunities for the nurse to refine clinical decision-making skills.

Organization

Brunner & Suddarth's Textbook of Medical-Surgical Nursing, 12th edition, is organized into 16 units. Units 1 through 4 cover core concepts related to medical-surgical nursing practice. Units 5 through 16 discuss adult health conditions that are treated medically or surgically. Each unit covering adult health conditions is structured in the following way, to facilitate understanding:

- The first chapter in the unit covers assessment and includes a review of normal anatomy and physiology of the body system being discussed.
- The subsequent chapters in the unit cover management of specific disorders. Pathophysiology, clinical manifestations, assessment and diagnostic findings, medical management, and nursing management are presented. Special "Nursing Process" sections, provided for selected conditions, clarify and expand on the nurse's role in caring for patients with these conditions.

Features

Practice-Oriented Features

Nurses assume many different roles when caring for patients. Many of the features in this textbook have been developed to help nurses fulfill these varied roles.

The Nurse as Practitioner

One of the central roles of the nurse is to provide holistic care to patients and their families, both independently and through collaboration with other health care professionals. Many features in *Brunner & Suddarth's Textbook of Medical-Surgical Nursing* are designed to assist students with clinical practice.

Nursing Process sections. The nursing process is the basis for all nursing practice. Special sections throughout the text, organized according to the nursing process framework, clarify the nurse's responsibilities in caring for patients with selected disorders.

 **Plans of Nursing Care.** These plans, provided for selected disorders, illustrate how the nursing process is applied to meet the person's health care and nursing needs.

 **Applying Concepts from NANDA, NIC, and NOC.** Each unit begins with a case study and a chart presenting examples of NANDA, NIC, and NOC terminologies related to the case study. Concept maps, which provide a visual representation of the NANDA, NIC, and NOC chart for each case study, are found on the accompanying Web site [thePoint](http://thePoint.lww.com/Smeltzer12e) to this book at thePoint.lww.com/Smeltzer12e. This feature introduces the student to the NIC and NOC language and classifications and brings them to life in graphic form.

 **Assessment charts.** These charts help to focus the student's attention on data that should be collected as part of the assessment step of the nursing process.

 **Risk Factor charts.** These charts draw the student's attention to factors that can impair health.

 **Guidelines charts.** These charts review key nursing interventions, and the rationales for those interventions, for specific patient care situations.

 **Pharmacology charts and tables.** Pharmacology charts and tables remind the student of important considerations relative to administering medications and monitoring drug therapy.

 **Nursing Alerts.** These special sections offer brief tips for clinical practice and red-flag warnings to help students avoid common mistakes.

 **Critical Care.** These special sections highlight nursing process considerations for the critically ill patient.

 **Gerontologic Considerations.** In the United States, older adults comprise the fastest-growing segment of the population. This icon is applied to headings, charts, and tables as appropriate to highlight information that pertains specifically to the care of the older adult patient.

 **Genetics in Nursing Practice charts.** These charts summarize and highlight the role that genetics play in many disorders.

Physiology/Pathophysiology figures. These illustrations and algorithms help students to understand normal physiologic and pathophysiologic processes.

The Nurse as Educator

Health education is a primary responsibility of the nursing profession. Nursing care is directed toward promoting, maintaining, and restoring health; preventing illness; and helping patients and families adapt to the residual effects of illness. Teaching, in the form of patient education and health promotion, is central to all of these nursing activities.

 **Patient Education charts.** These charts help the nurse to prepare the patient and family for procedures, assist them with understanding the patient's condition, and explain to them how to provide for self-care after discharge from the health care facility.

 **Home Care checklists.** These checklists review points that should be covered as part of patient education prior to discharge from the health care facility.

 **Health Promotion charts.** These charts review important points that the nurse should discuss with the patient to prevent common health problems from developing.

The Nurse as Patient Advocate

Nurses advocate for patients by protecting their rights (including the right to health care) and assisting patients and their families to make informed decisions about health care.

 **Ethics and Related Issues charts.** These charts present a scenario, a description of potential ethical dilemmas that could arise as a result of the scenario, and a list of questions about the scenario to stimulate thought and discussion.

The Nurse as Researcher

Nurses identify potential research problems and questions to increase nursing knowledge and improve patient care. Use and evaluation of research findings in nursing practice are essential to further the science of nursing.

Nursing Research Profiles. These charts identify the implications and applications of nursing research findings for nursing practice.

 **Evidence-Based Practice (EBP) questions.** This icon appears next to critical thinking exercises that encourage the student to think about the evidence base for specific nursing interventions. A journals supplement offers students free online access to over 70 journal articles that relate to the evidence-based practice questions in the text.

Pedagogical Features

Learning Objectives. Each chapter begins with a list of learning objectives. These give the student an overview of the chapter and help to focus his or her reading.

Glossaries. Glossaries provided at the beginning of each chapter let the student review vocabulary words before

reading the chapter, and also serve as a useful reference tool while reading.

Critical Thinking Exercises. These questions, which appear at the end of each chapter, foster critical thinking by challenging the student to apply textbook knowledge to clinical scenarios.

References and Selected Readings. A list of current references cited is given at the end of each chapter.

Resources. A resource list at the end of each chapter directs the reader to sources of additional information, Web sites, agencies, and patient education materials.

A Comprehensive Package for Teaching and Learning

To further facilitate teaching and learning, a carefully designed ancillary package is available. In addition to the usual print resources, we are pleased to present multimedia tools that have been developed in conjunction with the text.

Resources for Students

 **Interactive DVD-ROM.** Packaged with the textbook at no additional charge, this DVD helps students test their knowledge and enhance their understanding of medical-surgical nursing. This DVD includes:

- More than 700 study questions organized by unit
- 3,500 NCLEX-style cross-disciplinary questions
- Concepts in Action™ Animations
- Nursing in Action™ Videos
- Clinical Simulations
- Spanish-English Audioglossary
- Drug Monographs
- Other Learning Tools

Study Guide to Accompany Smeltzer, Bare, Hinkle & Cheever: Brunner & Suddarth's Textbook of Medical-Surgical Nursing, 12th edition. Available at student bookstores or at www.LWW.com, this study guide presents a variety of exercises to reinforce the textbook content and enhance learning.

Handbook to Accompany Smeltzer, Bare, Hinkle & Cheever: Brunner & Suddarth's Textbook of Medical-Surgical Nursing, 12th edition. Available at student bookstores or at www.LWW.com, this clinical reference presents need-to-know information on nearly 200 commonly encountered disorders in an easy-to-use alphabetized outline format.

Resources for Instructors

Instructor's Resource DVD-ROM. The instructor's resource DVD contains the following items:

- A thoroughly revised and augmented test generator, containing more than 2,000 NCLEX-style questions
- Sample syllabi for one-, two-, and three-semester courses
- Strategies for effective teaching
- PowerPoint™ lectures, guided lecture notes, and pre-lecture quizzes
- An image bank
- Discussion topics and assignments

Resources for Students and Instructors

ThePoint* (thepoint.lww.com) Students and instructors can visit thePoint to access supplemental multimedia resources to enhance their learning.

It is with pleasure that we introduce these resources—the textbook and the ancillary package—to you. One of our primary goals in creating these resources has been to help nurses and nursing students provide quality care to patients

and families across health care settings and in the home. We hope that we have succeeded in that goal, and we welcome feedback from our readers.

Clinical Assistant Professor
University of Massachusetts Amherst School of Nursing
Amherst, Massachusetts

Penny Y. Kessler, DNS(c), RN
Clinical Assistant Professor
University of Minnesota City
Minneapolis, Minnesota

Deborah R. Klinger, RN, MSN, MBA
Associate Professor
Manatee Community College
Bradenton, Florida

Catherine Lein, MS, FNP-BC
Assistant Professor
MSU College of Nursing
East Lansing, Michigan

Linda C. Lott, RN, MSN
AD Nursing Instructor
Itawamba Community College
Fulton, Mississippi

Tamar Jones Lucas, BSN, MSN, RN, BC
ADN Instructor
Itawamba Community College
Fulton, Mississippi

Billie A. Lynes, FNP, MSN
Professor/Gynecologic Oncology Nurse Practitioner
Mt. San Antonio College
Walnut, California

Shirley B. MacNeill, MSN, RN
ADN Nursing Instructor
Lamar State College, Port Arthur
Porth Arthur, Texas

Phyllis Magaletto, MS, RN, BC
Instructor
Cochran School of Nursing
Yonkers, New York

Gina Maiocco, PhD, RN, CCRN, CCNS
Assistant Professor
Coordinator BS/BA to BSN Program
West Virginia University
Morgantown, West Virginia

Andrea R. Mann, MSN, RN
Instructor, Third Level Chair at Frankford
Instructor Pharmacology at Penn State
Frankford Hospital School of Nursing
Penn State University
Philadelphia, Pennsylvania

Sharon McDonald, MSN, RN
Nursing Instructor
University of Southern Mississippi
Hattiesburg, Mississippi

Nancy Miller, MS, RN
Faculty
Minneapolis Community and Technical College
Minneapolis, Minnesota

Ildiko E. Monahan, MS, RN, ANP
Nurse Educator
St. Elizabeth College of Nursing
Utica, New York

Suzie Morrow, MSN, RN, CNE
Associate Professor
Southwest Baptist University
Springfield, Missouri

Mary Ellen Moyer-Hutcherson, RN, MSN
Professor
Florida Community College
Jacksonville, Florida

Janice A. Neil, RN, PhD
Associate Professor
East Carolina University
Greenville, North Carolina

Pamela S. Newton, RN, BSN
Traveling Nurse
Home Care RN Case Manager IV Team
Pathways Home Health and Hospice
Sunnyvale, California

Rebecca Otten, RN, MSN, EdD
Assistant Professor
California State University Fullerton
Fullerton, California

Verna C. Pangman, RN, MEd, MN
Senior Instructor
University of Manitoba
Winnipeg, Manitoba

Susan R. Parslow, RN, PhD
Associate Professor
Boise State University
Boise, Idaho

Linda Peake, MS, RN, C, CNE
Professor, Curriculum Coordinator
St. Mary's/Marshall University Cooperative and Program
Huntington, West Virginia

Lisa Peden, RN, MSN
Associate Professor
Dalton State College
Dalton, Georgia

Beverly Raway, PhD, RN
Assistant Professor
The College of St. Scholastica
Duluth, Minnesota

Marisue Rayno, RN, MSN, EdD(c)
Faculty
Luzerne County Community College
Nanticoke, Pennsylvania

Kathleen T. Rine, MSN, RN, OCN

Instructor
School of Nursing
Thomas Jefferson University
Philadelphia, Pennsylvania

Kathy Rodger, RN, BSN, MN

Faculty
Nursing Education Program of Saskatchewan (NEPS)
SIAST Wascana Campus
Regina, Saskatchewan

Donna Russo, RN, MSN, CCRN, CNE

Nursing Instructor
Frankford Hospital School of Nursing
Philadelphia, Pennsylvania

Lisa A. Streeter, MSRN, CNE

Nursing Instructor
St. Elizabeth College of Nursing
Utica, New York

Wendy J. Waldspurger Robb, PhD, RN, CNE

Assistant Professor
Director of the Graduate Nursing Program
Cedar Crest College
Allentown, Pennsylvania

Kristen J. Rogers, MSN, CNE, RN

Director, Service Excellence
The Washington Hospital
Washington, Pennsylvania

Tanya Lynn Rogers, APRN, BC, MSN

Associate Professor
Fairmont State University
Fairmont, West Virginia

Judith L. Samsel, RN, MSN

Professor/Chairperson, Nursing Department
Broome Community College
Binghamton, New York

Mary Ellen Santucci, PhD, RN

Assistant Professor
Widener University
Chester, Pennsylvania

Jo-Ann V. Sawatzky, RN, PhD

Associate Professor
University of Manitoba
Winnipeg, Manitoba

Ruth L. Schaffler, PhD, ARNP

Assistant Professor
Pacific Lutheran University
Tacoma, Washington

Donald G. Smith, Jr, MA, PhD, RN, ACRN

Assistant Professor
Hunter College, CUNY
New York, New York

Deborah Steele, PhD, RN, LMFT

Assistant Professor
California State University, Fresno
Fresno, California

Nancy Steffen, RN, MSN

Instructor
Century College
White Bear Lake, Minnesota

Marie H. Thomas, PhD, RN

Instructor
Forsyth Technical Community College
Winston-Salem, North Carolina

Linda Turchin, RN, MSN, CNE

Assistant Professor
Fairmont State University
Fairmont, West Virginia

Carol A. Velas, MSN, RN

Assistant Coordinator, Health Sciences
Associate Professor of Nursing
Moorpark College
Moorpark, California

Mary Walden, RN, MSN, DNP(c), CWOCN

Faculty
Itawamba Community College
Fulton, Mississippi

Terri L. Walker, MSN, RN

Professor
Oklahoma City Community College
Oklahoma City, Oklahoma

Mary Welhaven, PhD, RN

Professor
Winona State University, Rochester
Rochester, Minnesota

Stuart L. Whitney, EdD, RN, CNS

Clinical Associate Professor
University of Vermont
Burlington, Vermont

Donna Williams, RN, MSN, DNP(c)

Faculty
Itawamba Community College
Fulton, Mississippi

Emily Ray Wilson, RN, MSN, MA, AOCN

Instructor and Course Coordinator
Michigan State University
East Lansing, Michigan

Debra Wilson, MSN, FNP

Assistant Professor
California State University, Bakersfield
Bakersfield, California

Thomas Worms, MSN, RN

Professor
Truman College
Chicago, Illinois

Rebecca Yarnell, RN, MSN

Associate Professor
Roane State Community College
Harriman, Tennessee

Jean Yockey, MSN, FNP-BC, CNE

Associate Professor
University of South Dakota
Vermillion, South Dakota

CONTENTS

unit 1

Basic Concepts in Nursing 2

1 Health Care Delivery and Nursing Practice 4

- The Health Care Industry and the Nursing Profession 5
- Nursing Defined 5
- The Patient/Client: Consumer of Nursing and Health Care 5
- Health Care in Transition 5
- Health, Wellness, and Health Promotion 6
 - Health 6
 - Wellness 6
 - Health Promotion 6
- Influences on Health Care Delivery 6
 - Population Demographics 7
 - Changing Patterns of Disease 7
 - Advances in Technology and Genetics 8
 - Demand for Quality Health Care 8
 - Alternative Health Care Delivery Systems 9
- Roles of the Nurse 9
 - Practitioner Role 9
 - Leadership Role 10
 - Research Role 10
- Models of Nursing Care Delivery 10
- Community-Based Nursing and Community-Oriented/Public Health Nursing 10
- Expanded Nursing Roles 11
 - Interdisciplinary Collaborative Practice 12

2 Community-Based Nursing Practice 14

- Community-Based Care 15
- Home Health Care 15
 - Nursing in the Home Setting 16
 - Discharge Planning for Home Care 17
 - Community Resources and Referrals 17
 - Home Health Visits 17
- Other Community-Based Health Care Settings 19
 - Ambulatory Settings 19
 - Occupational Health Programs 19
 - School Health Programs 20
 - Community Nurse–Managed Centers 20
 - Care for the Homeless 20

3 Critical Thinking, Ethical Decision Making, and the Nursing Process 22

- Critical Thinking 23
 - Rationality and Insight 23
 - Components of Critical Thinking 23
 - Critical Thinking in Nursing Practice 23
- Ethical Nursing Care 25

- Ethics Versus Morality 25
- Ethics Theories 25
- Approaches to Ethics 25
- Moral Situations 25
- Types of Ethical Problems in Nursing 26
- Preventive Ethics 28
- Ethical Decision Making 29
- The Nursing Process 29
 - Definition 29
 - Using the Nursing Process 30

4 Health Education and Health Promotion 41

- Health Education Today 42
 - Purpose of Health Education 42
 - Adherence to the Therapeutic Regimen 42
 - Gerontologic Considerations 43
- The Nature of Teaching and Learning 43
 - Learning Readiness 43
 - The Learning Environment 45
 - Teaching Techniques 45
 - Teaching Special Populations 45
- The Nursing Process in Patient Teaching 47
 - Assessment 47
 - Nursing Diagnosis 47
 - Planning 48
 - Implementation 48
 - Evaluation 48
- Health Promotion 49
 - Definition 49
 - Health and Wellness 49
 - Health Promotion Models 49
 - Components of Health Promotion 50
- Health Promotion Throughout the Lifespan 51
 - Adolescents 51
 - Young and Middle-Aged Adults 51
 - Gerontologic Considerations 52
- Nursing Implications 53

5 Adult Health and Nutritional Assessment 55

- Considerations for Conducting a Health History and Physical Assessment 56
 - The Role of the Nurse 56
 - Communicating Effectively 56
 - Ethical Use of History or Physical Examination Data 56
 - Increasing Use of Technology 56
- Health History 57
 - The Informant 57
 - Components of the Health History 57
 - Other Health History Formats 64
- Physical Assessment 64
 - Examination Considerations 65

Components of the Physical Examination	65
Nutritional Assessment	67
Lifespan Considerations	68
Components of Nutritional Assessment	68
Factors Influencing Nutritional Status in Various Situations	71
Analysis of Nutritional Status	73
Assessment in the Home and Community	73

unit 2

Biophysical and Psychosocial Concepts in Nursing Practice 76

6 Homeostasis, Stress, and Adaptation 78

Fundamental Concepts	79
Steady State	79
Stress and Adaptation	79
Overview of Stress	80
Types of Stressors	80
Stress as a Stimulus for Disease	80
Psychological Responses to Stress	80
Physiologic Response to Stress	81
Maladaptive Responses to Stress	84
Indicators of Stress	84
Nursing Implications	85
Stress at the Cellular Level	85
Control of the Steady State	86
Cellular Adaptation	86
Cellular Injury	87
Cellular Response to Injury: Inflammation	89
Cellular Healing	90
Nursing Implications	91
Stress Management: Nursing Interventions	91
Promoting a Healthy Lifestyle	91
Enhancing Coping Strategies	92
Teaching Relaxation Techniques	92
Educating About Stress Management	93
Enhancing Social Support	93
Recommending Support and Therapy Groups	93

7 Individual and Family Considerations Related to Illness 96

Holistic Approach to Health and Health Care	97
The Brain and Physical and Emotional Health	97
Mental Health and Emotional Distress	97
Anxiety	98
Posttraumatic Stress Disorder	99
Depression	100
Substance Abuse	101
Family Health and Distress	103
Nursing Implications	103
Loss and Grief	104
Nursing Implications	104
Death and Dying	105
Spirituality and Spiritual Distress	105
Nursing Implications	105

8 Perspectives in Transcultural Nursing 108

Cultural Concepts	109
Subcultures	109
Minorities	110
Transcultural Nursing	110
Culturally Competent Nursing Care	110
Cross-Cultural Communication	111
Culturally Mediated Characteristics	112
Space and Distance	113
Eye Contact	113
Time	113
Touch	113
Observance of Holidays	113
Diet	114
Biologic Variations	114
Complementary and Alternative Therapies	114
Causes of Illness	115
Biomedical or Scientific	115
Naturalistic or Holistic	115
Magico-Religious	116
Folk Healers	116
Cultural Assessment	116
Additional Cultural Considerations:	
Know Thyself	116
Health Disparities	117
The Future of Transcultural Nursing Care	117

9 Genetics and Genomics Perspectives in Nursing 119

Genomic Framework for Nursing Practice	120
Integrating Genetic and Genomic Knowledge	121
Genes and Their Role in Human Variation	121
Inheritance Patterns	124
Chromosomal Differences and Genetic Conditions	126
Genetic and Genomic Technologies in Practice	127
Genetic Testing	128
Genetic Screening	128
Testing and Screening for Adult-Onset Conditions	128
Personalized Genomic Treatments	132
Applications of Genetics and Genomics in Nursing Practice	134
Genetics and Genomics in Health Assessment	134
Genetic Counseling and Evaluation Services	137
Ethical Issues	141

10 Chronic Illness and Disability 144

Overview of Chronicity	145
Definition of Chronic Conditions	145
Prevalence and Causes of Chronic Conditions	145
Characteristics of Chronic Conditions	147
Implications of Managing Chronic Conditions	148
Phases of Chronic Conditions	148
Nursing Care of Patients With Chronic Conditions	149
Applying the Nursing Process Using the Phases of the Chronic Illness System	150

Home and Community-Based Care	151	Other Aspects of Health Care of the Older Adult	222
Nursing Care for Special Populations With Chronic Illness	152	Elder Neglect and Abuse	222
Overview of Disability	152	Social Services	223
Definitions of Disability	152	Health Care Costs of Aging	223
Prevalence of Disability	153	Home Health Care	223
Characteristics of Disability	153	Hospice Services	224
Federal Legislation	155	Aging with a Disability	224
Right of Access to Health Care	155	Ethical and Legal Issues Affecting the Older Adult	224
Barriers to Health Care	157		
Federal Assistance Programs	160		
Nursing Care of Patients With Disabilities	160		
Nursing Considerations			
During Hospitalization	160		
Health Promotion and Prevention	161		
Significance of “People-First” Language	161		
Gerontologic Considerations	161		
Disability in Medical-Surgical Nursing Practice	162		
Home and Community-Based Care	162		
11 Principles and Practices of Rehabilitation	166		
Americans With Disabilities Act	168		
Patients’ Reactions to Disability	168		
The Rehabilitation Team	169		
Areas of Specialty Rehabilitation	169		
Assessment of Functional Ability	170		
Disability and Sexuality Issues	194		
Fatigue	194		
Complementary and Alternative Therapies	194		
Promoting Home and Community-Based Care	195		
Teaching Patients Self-Care	195		
Continuing Care	195		
12 Health Care of the Older Adult	200		
Overview of Aging	201		
Demographics of Aging	201		
Health Status of the Older Adult	201		
Nursing Care of the Older Adult	202		
Theories of Aging	202		
Age-Related Changes	202		
Physical Aspects of Aging	203		
Psychosocial Aspects of Aging	209		
Cognitive Aspects of Aging	211		
Pharmacologic Aspects of Aging	212		
Mental Health Problems in the Older Adult	213		
Depression	213		
Delirium	214		
Dementia	217		
Geriatric Syndromes	220		
Impaired Mobility	220		
Dizziness	220		
Falls and Falling	220		
Urinary Incontinence	221		
Increased Susceptibility to Infection	221		
Altered Pain and Febrile Responses	222		
Altered Emotional Impact	222		
Altered Systemic Response	222		
		unit 3	
		Concepts and Challenges in Patient Management	228
		13 Pain Management	230
		Importance of Pain Assessment and Management	231
		Types of Pain	231
		Classic Categories of Pain	231
		Pain Classified by Location	232
		Pain Classified by Etiology	232
		Harmful Effects of Pain	232
		Effects of Acute Pain	232
		Effects of Chronic Pain	232
		Pathophysiology of Pain	232
		Nociceptors	232
		Peripheral Nervous System	234
		Central Nervous System	234
		Gate Control Theory	235
		Factors Influencing Pain Response	235
		Past Experience	236
		Anxiety and Depression	236
		Culture	236
		Gerontologic Considerations	236
		Gender	237
		The Nurse’s Role in Assessment and Care of Patients with Pain	237
		Assessment	237
		Nursing Care	240
		Pain Management Strategies	242
		Premedication Assessment	242
		Agents Used to Treat Pain	244
		Approaches for Using Analgesic Agents	248
		Routes of Administration	251
		Placebo Effect	254
		Gerontologic Considerations	254
		Promoting Home and Community-Based Care	255
		Activities to Promote Comfort	256
		Neurologic and Neurosurgical Approaches to Pain Management	258
		Evaluating Pain Management Strategies	259
		14 Fluid and Electrolytes: Balance and Disturbance	263
		Fundamental Concepts	264
		Hypervolemia	273
		Sodium Imbalances	275
		Potassium Imbalances	280
		Calcium Imbalances	284

Magnesium Imbalances 288
 Phosphorus Imbalances 290
 Chloride Imbalances 292
 Acute and Chronic Metabolic Acidosis
 (Base Bicarbonate Deficit) 294
 Acute and Chronic Metabolic Alkalosis
 (Base Bicarbonate Excess) 295
 Acute and Chronic Respiratory Acidosis
 (Carbonic Acid Excess) 296
 Acute and Chronic Respiratory Alkalosis
 (Carbonic Acid Deficit) 296
 Mixed Acid–Base Disorders 297
 Parenteral Fluid Therapy 298

**15 Shock and Multiple Organ
 Dysfunction Syndrome 312**
 Overview of Shock 313
 Stages of Shock 314
 General Management Strategies in Shock 320
 Hypovolemic Shock 322
 Cardiogenic Shock 325
 Circulatory Shock 327
 Multiple Organ Dysfunction Syndrome 332
 Promoting Home and Community-Based Care 333

16 Oncology: Nursing Management in Cancer Care 336
 Epidemiology of Cancer 337
 Pathophysiology of the Malignant Process 338
 Detection and Prevention of Cancer 342
 Diagnosis of Cancer 345
 Tumor Staging and Grading 345
 Management of Cancer 346
 Nursing Care of Patients With Cancer 366
 Cancer Survivorship 391

17 End-of-Life Care 395
 Nursing and End-of-Life Care 396
 Settings for End-of-Life Care 398
 Nursing Care of Terminally Ill Patients 402
 Nursing Care of Patients Who Are Close to Death 414
 Coping With Death and Dying: Professional
 Caregiver Issues 418

unit 4

**Perioperative Concepts and Nursing
 Management 422**

18 Preoperative Nursing Management 424
 Preoperative Nursing 425
 Advances in Technology and Anesthesia 425
 Surgical Classifications 425
 Preadmission Testing 425
 Special Considerations During the
 Perioperative Period 425
 Informed Consent 428
 Preoperative Assessment 428
 General Preoperative Nursing Interventions 434

Immediate Preoperative Nursing Interventions 438
 Expected Patient Outcomes 439

19 Intraoperative Nursing Management 442

The Surgical Team 443
 The Surgical Environment 446
 The Surgical Experience 448
 Potential Intraoperative Complications 455

20 Postoperative Nursing Management 461

Care of the Patient in the Postanesthesia
 Care Unit 462
 Care of the Hospitalized Postoperative Patient 468

unit 5

**Gas Exchange and Respiratory
 Function 484**

21 Assessment of Respiratory Function 486

Anatomic and Physiologic Overview 487
 Assessment 495
 Diagnostic Evaluation 507

**22 Management of Patients With Upper Respiratory
 Tract Disorders 517**

Rhinitis 518
 Viral Rhinitis (Common Cold) 520
 Rhinosinusitis 521
 Pharyngitis 526
 Tonsillitis and Adenoiditis 528
 Peritonsillar Abscess 529
 Laryngitis 530
 Epistaxis (Nosebleed) 534
 Nasal Obstruction 535
 Fractures of the Nose 536
 Laryngeal Obstruction 537
 Cancer of the Larynx 537

**23 Management of Patients With Chest and Lower
 Respiratory Tract Disorders 551**

Pneumonia 554
 Aspiration 565
 Severe Acute Respiratory Syndrome 567
 Pulmonary Tuberculosis 567
 Lung Abscess 572
 Pleurisy 573
 Pleural Effusion 574
 Empyema 575
 Pulmonary Edema 576
 Acute Respiratory Failure 576
 Acute Respiratory Distress Syndrome 577
 Pulmonary Arterial Hypertension 579
 Pulmonary Heart Disease (Cor Pulmonale) 581
 Pulmonary Embolism 582
 Sarcoidosis 587
 Lung Cancer (Bronchogenic Carcinoma) 588
 Tumors of the Mediastinum 592

- Blunt Trauma 593
 - Penetrating Trauma: Gunshot and Stab Wounds 596
 - Pneumothorax 596
 - Cardiac Tamponade 599
 - Subcutaneous Emphysema 599
 - 24 Management of Patients With Chronic Pulmonary Disease 601**
 - Chronic Obstructive Pulmonary Disease 602
 - Bronchiectasis 614
 - Asthma 620
 - Status Asthmaticus 630
 - Cystic Fibrosis 631
 - 25 Respiratory Care Modalities 635**
 - Incentive Spirometry (Sustained Maximal Inspiration) 640
 - Mini-Nebulizer Therapy 641
 - Intermittent Positive-Pressure Breathing 642
 - Chest Physiotherapy 642
 - Emergency Management of Upper Airway Obstruction 645
 - Endotracheal Intubation 646
 - Tracheostomy 648
 - Mechanical Ventilation 651
 - Preoperative Management 664
 - Postoperative Management 666
- unit 6**
- Cardiovascular, Circulatory, and Hematologic Function 682**
- 26 Assessment of Cardiovascular Function 684**
 - Anatomic and Physiologic Overview 685
 - Anatomy of the Heart* 685
 - Function of the Heart* 687
 - Gerontologic Considerations 690
 - Gender Considerations 690
 - Assessment of the Cardiovascular System 691
 - Health History* 691
 - Physical Assessment* 697
 - Diagnostic Evaluation 705
 - Laboratory Tests* 705
 - Chest X-Ray and Fluoroscopy* 707
 - Electrocardiography* 707
 - Cardiac Stress Testing* 709
 - Echocardiography* 710
 - Radionuclide Imaging* 711
 - Cardiac Catheterization* 713
 - Electrophysiologic Testing* 715
 - Hemodynamic Monitoring* 715
 - 27 Management of Patients With Dysrhythmias and Conduction Problems 720**
 - Dysrhythmias 721
 - Normal Electrical Conduction* 721
 - The Electrocardiogram* 721
 - Analyzing the Electrocardiogram Rhythm Strip* 725
- Adjunctive Modalities and Management 741
 - Cardioversion and Defibrillation* 741
 - Pacemaker Therapy* 743
 - Implantable Cardioverter Defibrillator* 747
 - Electrophysiologic Studies* 751
 - Cardiac Conduction Surgery* 752
- 28 Management of Patients With Coronary Vascular Disorders 755**
 - Coronary Atherosclerosis 756
 - Angina Pectoris 762
 - Acute Coronary Syndrome and Myocardial Infarction 768
 - Surgical Procedures: Coronary Artery Revascularization 779
- 29 Management of Patients With Structural, Infectious, and Inflammatory Cardiac Disorders 797**
 - Mitral Valve Prolapse 798
 - Mitral Regurgitation 799
 - Mitral Stenosis 800
 - Aortic Regurgitation 801
 - Aortic Stenosis 801
 - Nursing Management: Valvular Heart Disorders 802
 - Valve Replacement 804
 - Nursing Management: Valvuloplasty and Replacement 806
 - Septal Defects 807
 - Cardiomyopathy 807
 - Rheumatic Endocarditis 814
 - Infective Endocarditis 815
 - Myocarditis 817
 - Pericarditis 818
- 30 Management of Patients With Complications From Heart Disease 823**
 - Cardiac Hemodynamics 824
 - Chronic Heart Failure 825
 - Pulmonary Edema 839
 - Thromboembolism 841
 - Pericardial Effusion and Cardiac Tamponade 842
 - Cardiac Arrest 843
- 31 Assessment and Management of Patients With Vascular Disorders and Problems of Peripheral Circulation 847**
 - Anatomic and Physiologic Overview 848
 - Assessment 852
 - Diagnostic Evaluation 852
 - Peripheral Arterial Occlusive Disease 863
 - Upper Extremity Arterial Occlusive Disease 866
 - Thromboangiitis Obliterans (Buerger's Disease) 866
 - Aortoiliac Disease 867

Aneurysms 868
 Other Aneurysms 871
 Dissecting Aorta 871
 Arterial Embolism and Arterial
 Thrombosis 872
 Raynaud's Phenomenon 873
 Chronic Venous Insufficiency/
 Postthrombotic Syndrome 880
 Leg Ulcers 881
 Varicose Veins 884
 Lymphangitis and Lymphadenitis 886
 Lymphedema and Elephantiasis 886

32 Assessment and Management of Patients With Hypertension 889

Hypertension 890
Pathophysiology 890
Clinical Manifestations 891
Assessment and Diagnostic Findings 892
Medical Management 892
 Hypertensive Crises 900

33 Assessment and Management of Patients With Hematologic Disorders 903

Assessment and Diagnostic Evaluation 909
 Hypoproliferative Anemias 914
 Hemolytic Anemias 920
 Polycythemia Vera 927
 Secondary Polycythemia 928
 Neutropenia 929
 Lymphopenia 930
 Acute Myeloid Leukemia 933
 Chronic Myeloid Leukemia 934
 Acute Lymphocytic Leukemia 935
 Chronic Lymphocytic Leukemia 936
 Hodgkin Lymphoma 941
 Non-Hodgkin Lymphomas 943
 Primary Thrombocytopenia 947
 Secondary Thrombocytopenia 948
 Thrombocytopenia 949
 Idiopathic Thrombocytopenic
 Purpura 950
 Platelet Defects 951
 Hemophilia 951
 Von Willebrand's Disease 954
 Vitamin K Deficiency 954
 Complications of Anticoagulant
 Therapy 955
 Disseminated Intravascular Coagulation 955
 Thrombotic Disorders 959
 Hyperhomocysteinemia 959
 Antithrombin Deficiency 959
 Protein C Deficiency 960
 Protein S Deficiency 960
 Activated Protein C Resistance and Factor V
 Leiden Mutation 960
 Acquired Thrombophilia 960

unit 7

Digestive and Gastrointestinal Function 976

34 Assessment of Digestive and Gastrointestinal Function 978

Anatomic and Physiologic Overview 979
Anatomy of the Gastrointestinal System 979
Function of the Digestive System 980
Gerontologic Considerations 982
 Assessment of the Gastrointestinal System 982
Health History 982
Physical Assessment 984
 Diagnostic Evaluation 986
Serum Laboratory Studies 986
Stool Tests 987
Breath Tests 987
Abdominal Ultrasonography 987
DNA Testing 988
Imaging Studies 988
Endoscopic Procedures 990
Manometry and Electrophysiologic Studies 994
*Gastric Analysis, Gastric Acid Stimulation Test, and
 pH Monitoring* 995
Laparoscopy (Peritoneoscopy) 995

35 Management of Patients With Oral and Esophageal Disorders 997

Dental Plaque and Caries 998
 Dentoalveolar Abscess or Periapical Abscess 1000
 Malocclusion 1001
 Temporomandibular Disorders 1002
 Jaw Disorders Requiring Surgical Management 1002
 Parotitis 1002
 Sialadenitis 1003
 Salivary Calculus (Sialolithiasis) 1003
 Neoplasms 1003
 Nursing Management of the Patient With Conditions
 of the Oral Cavity 1004
 Achalasia 1011
 Diffuse Esophageal Spasm 1011
 Hiatal Hernia 1012
 Diverticulum 1013
 Perforation 1013
 Foreign Bodies 1014
 Chemical Burns 1014
 Gastroesophageal Reflux Disease 1014
 Barrett's Esophagus 1015
 Benign Tumors of the Esophagus 1015
 Cancer of the Esophagus 1017

36 Gastrointestinal Intubation and Special Nutritional Modalities 1021

Gastrointestinal Intubation 1022
Tube Types 1022
Nursing Management 1023
 Gastrostomy and Jejunostomy 1031

- Parenteral Nutrition 1034
 - Establishing Positive Nitrogen Balance* 1034
 - Clinical Indications* 1035
 - Formulas* 1035
 - Initiating Therapy* 1035
 - Administration Methods* 1035
 - Discontinuing Parenteral Nutrition* 1037

37 Management of Patients With Gastric and Duodenal Disorders 1043

- Gastritis 1044
- Peptic Ulcer Disease 1047
- Morbid Obesity 1055
- Gastric Cancer 1056
- Gastric Surgery 1060
- Duodenal Tumors 1062

38 Management of Patients With Intestinal and Rectal Disorders 1067

- Constipation 1068
- Diarrhea 1070
- Fecal Incontinence 1072
- Irritable Bowel Syndrome 1073
- Conditions of Malabsorption 1074
- Appendicitis 1075
- Diverticular Disease 1077
- Peritonitis 1080
- Types of Inflammatory Bowel Disease 1082
- Management of Chronic Inflammatory Bowel Disease 1084
- Small Bowel Obstruction 1097
- Large Bowel Obstruction 1098
- Colorectal Cancer 1098
- Polyps of the Colon and Rectum 1107
- Diseases 1108
- Nursing Management of Patients With Anorectal Conditions 1110

unit 8

Metabolic and Endocrine Function 1114

39 Assessment and Management of Patients With Hepatic Disorders 1116

- Assessment 1119
- Diagnostic Evaluation 1120
- Jaundice 1123
- Portal Hypertension 1123
- Ascites 1124
- Esophageal Varices 1128
- Hepatic Encephalopathy and Coma 1133
- Other Manifestations of Hepatic Dysfunction 1137
- Hepatitis A Virus 1139
- Hepatitis B Virus 1141
- Hepatitis C Virus 1144

Basic Concepts in Nursing

Case Study • Applying Concepts from NANDA, NIC, and NOC

The Community with an Identified Health Problem

A nurse working in an urgent care clinic that serves an economically depressed urban area notes a high incidence of elderly patients with dehydration and heatstroke in the summer months. The nurse verifies the observations by accessing data about hospital admissions for dehydration and heatstroke. The nurse determines that many of the admitted patients live in the area served by the clinic and that many of the patients live alone and have other chronic illnesses. The nurse sees the need for a plan that includes a community response to this problem. The plan includes arranging an education program about the prevention of dehydration; a community support buddy system in which neighbors or volunteers call or visit homebound elders during critical periods in the summer; and economic support to air condition the senior citizens' center.

Visit thePoint to view a concept map that illustrates the relationships that exist between the nursing diagnoses, interventions, and outcomes for the patient's clinical problems.

Nursing Classifications and Languages

NANDA NURSING DIAGNOSES	NIC NURSING INTERVENTIONS	NOC NURSING OUTCOMES
		Return to functional baseline status, stabilization of, or improvement in:
INEFFECTIVE COMMUNITY THERAPEUTIC REGIMEN MANAGEMENT— Pattern of regulating and integrating into community processes programs for treatment of illness and the sequelae of illness that are unsatisfactory for meeting health-related goals	COMMUNITY HEALTH DEVELOPMENT— Assisting members of a community to identify a community's health concerns, mobilize resources, and implement solutions PROGRAM DEVELOPMENT— Planning, implementing, and evaluating a coordinated set of activities designed to enhance wellness, or to prevent, reduce or eliminate one or more health problems for a group or community	COMMUNITY COMPETENCE— Capacity of a community to collectively problem solve to achieve community goals
INEFFECTIVE COMMUNITY COPING— Pattern of community activities (for adaptation and problem solving) that is unsatisfactory for meeting the demands or needs of the community	SURVEILLANCE: COMMUNITY— Purposeful and ongoing acquisition, interpretation, and synthesis of data for decision making in the community	COMMUNITY HEALTH STATUS— The general state of well-being of a community or population
READINESS FOR ENHANCED COMMUNITY COPING— Pattern of community activities for adaptation and problem solving that is satisfactory for meeting the demands or needs of the community but can be improved for management of current and future problems/stressors	ENVIRONMENTAL RISK PROTECTION— Preventing and detecting disease and injury in populations at risk from environmental hazards

Health Care Delivery and Nursing Practice

LEARNING OBJECTIVES

On completion of this chapter, the learner will be able to:

- 1 Define health and wellness.
- 2 Describe factors causing significant changes in the health care delivery system and their impact on health care and the nursing profession.
- 3 Describe the practitioner, leadership, and research roles of nurses.
- 4 Describe nursing care delivery models.
- 5 Discuss expanded nursing roles.

GLOSSARY

Advanced Practice Nurse (APN): a title which encompasses the nurse practitioners (NPs), clinical nurse specialists (CNSs), certified nurse midwives (CNMs) and certified registered nurse anesthetists (CRNAs).

Collaborative practice model: involves nurses, physicians, and ancillary health personnel functioning within a decentralized organizational structure and collaboratively making clinical decisions.

Community-oriented nursing practice: nursing intervention that promotes wellness, reduces the spread of illness, and improves the health status of groups of citizens or the community at large with emphasis on primary, secondary, and tertiary prevention.

Continuous quality improvement (CQI): the ongoing examination of processes used to provide care, with the aim of improving quality by assessing and improving those processes that might improve patient care outcomes and patient satisfaction.

Health–illness continuum: description of a person’s health status as a range with anchors that include poor health or imminent death on one end of the continuum to high-level wellness on the other end.

Health care in the United States has undergone changes over the years as society has continued to change. Nursing, as a health care profession and a major component of the health care system, has been significantly affected by these changes. Nursing has played an important role in the health care system and will continue to do so.

The Health Care Industry and the Nursing Profession

Nursing Defined

Since the time of Florence Nightingale, who wrote in 1858 that the goal of nursing was “to put the patient in the best condition for nature to act upon him,” nursing leaders have described nursing as both an art and a science. However, the definition of nursing has evolved over time. In its Social Policy Statement (2003), the American Nurses Association (ANA) defined nursing as the diagnosis and treatment of human responses to health and illness. The ANA identifies the following phenomena as the focus for nursing care and research:

- Self-care processes
- Physiologic and pathophysiologic processes such as rest, sleep, respiration, circulation, reproduction, activity, nutrition, elimination, skin, sexuality, and communication
- Comfort, pain, and discomfort
- Emotions related to health and illness
- Meanings ascribed to health and illnesses
- Decision making and ability to make choices
- Perceptual orientations such as self-image and control over one’s body and environments
- Transitions across the lifespan, such as birth, growth, development, and death
- Affiliative relationships, including freedom from oppression and abuse
- Environmental systems

Nurses have a responsibility to carry out their role as described in the Social Policy Statement to comply with the nurse practice act of the state in which they practice, and to comply with the Code of Ethics for Nurses as spelled out by the ANA (2001) and the International Council of Nurses (ICN, 2006). To have a foundation for examining the delivery of nursing care, it is necessary to understand the needs of health care consumers and the health care delivery system, including the forces that affect nursing and health care delivery.

The Patient/Client: Consumer of Nursing and Health Care

The central figure in health care services is, of course, the patient. The term *patient*, which is derived from a Latin verb meaning “to suffer,” has traditionally been used to describe a person who is a recipient of care. The connotation commonly attached to the word is one of dependence. For this reason, many nurses prefer to use the term *client*, which is derived from a Latin verb meaning “to lean,” connoting alliance and interdependence. The term *patient* is used throughout this book, with the understanding that either term is acceptable.

The patient who seeks care for a health problem or problems (increasing numbers of people have multiple health problems) is also an individual person, a member of a family, and a citizen of the community. Patients’ needs vary depending on their problems, associated circumstances, and past experiences. Many patients, who as consumers of health care have become more knowledgeable about health care options, are assuming a collaborative approach with the nurse in the quest for optimal health (Hakesley-Brown & Malone, 2007). Among the nurse’s important functions in health care delivery are identifying the patient’s immediate needs and working in concert with the patient to address them.

The Patient’s Basic Needs

Certain needs are basic to all people. Some of these needs are more important than others. Once an essential need is met, people often experience a need on a higher level of priority. Addressing needs by priority reflects Maslow’s hierarchy of needs (Fig. 1-1).

Maslow’s Hierarchy

Maslow ranked human needs as follows: physiologic needs; safety and security; sense of belonging and affection; esteem and self-respect; and self-actualization, which includes self-fulfillment, desire to know and understand, and aesthetic needs. Lower-level needs always remain, but a person’s ability to pursue higher-level needs indicates movement toward psychological health and well-being. Such a hierarchy of needs is a useful framework that can be applied to the various nursing models for assessment of a patient’s strengths, limitations, and need for nursing interventions.

Health Care in Transition

Changes occurring in health care delivery and nursing are the result of societal, economic, technologic, scientific, and political forces that have evolved throughout the 20th and

Figure 1-1 This scheme of Maslow’s hierarchy of human needs shows how a person moves from fulfillment of basic needs to higher levels of needs, with the ultimate goal being integrated human functioning and health.

21st centuries. Among the most significant changes are shifts in population demographics, particularly the increase in the aging population and the cultural diversity of the population; changing patterns of diseases; increased technology; increased consumer expectations; higher costs of health care and changes in health care financing; and other health care reform efforts. These changes have led to institutional restructuring, staff reduction and cross-training, increased outpatient care services, decreased lengths of hospital stay, and increased health care in community and home settings. Such changes have dramatically influenced where nurses practice. These changes have influenced society's view of health and illness and affected the focus of nursing and health care.

As the proportion of the population reaching age 65 years has increased, and with the shift from acute illnesses to chronic illnesses, the traditional disease management and care focus of the health care professions has expanded. There is increasing concern about emerging infectious diseases, trauma, obesity, and bioterrorism. Thus, health care must focus more on disease prevention, health promotion, and management of chronic conditions and disability than in previous times. This shift in focus coincides with a nationwide emphasis on cost control and resource management directed toward providing safe, cost-efficient and cost-effective health care services to the population as a whole.

Health, Wellness, and Health Promotion

The health care system in the United States, which traditionally has been disease oriented, is placing increasing emphasis on health and its promotion. Similarly, a significant number of nurses in past decades focused on the care of patients with acute conditions, but now many are directing their efforts toward health promotion and illness prevention.

Health

How health is perceived depends on how health is defined. The World Health Organization (WHO) defines *health* in the preamble to its constitution as a “state of complete physical, mental, and social well-being and not merely the absence of disease and infirmity” (WHO, 2006 pg. 1). Although this definition of health does not allow for any variation in degrees of wellness or illness, the concept of a health–illness continuum allows for a greater range in describing a person's health status. By viewing health and illness on a continuum, it is possible to consider a person as being neither completely healthy nor completely ill. Instead, a person's state of health is ever-changing and has the potential to range from high-level wellness to extremely poor health and imminent death. Use of the health–illness continuum makes it possible to regard a person as simultaneously possessing degrees of both health and illness. On the **health–illness continuum**, even people with a chronic illness or disability may attain a high level of wellness if they are successful in meeting their health potential within the limits of their chronic illness or disability.

Wellness

Wellness has been defined as being equivalent to health. Wellness involves being proactive and being involved in self-care activities aimed toward a state of physical, psychological, and spiritual well-being (Clark, Stuijbergen, Gottlieb, et al., 2006). Hood and Leddy (2007) consider that wellness has four components: (1) the capacity to perform to the best of one's ability, (2) the ability to adjust and adapt to varying situations, (3) a reported feeling of well-being, and (4) a feeling that “everything is together” and harmonious. With this in mind, it becomes evident that the goal of health care providers is to promote positive changes that are directed toward health and well-being. The sense of wellness has a subjective aspect that addresses the importance of recognizing and responding to patient individuality and diversity in health care and nursing.

Health Promotion

Today, increasing emphasis is placed on health, health promotion, wellness, and self-care. Health is seen as resulting from a lifestyle oriented toward wellness. The result has been the evolution of a wide range of health promotion strategies, including multiphasic screening, genetic testing, lifetime health monitoring, environmental and mental health programs, risk reduction, and nutrition and health education. A growing interest in self-care skills is reflected by the large number of health-related publications, conferences, and workshops designed for the lay public.

People are increasingly knowledgeable about their health and take more interest in and responsibility for their health and well-being. Organized self-care education programs emphasize health promotion, disease prevention, management of illness, self-care, and judicious use of the professional health care system. In addition, numerous Web sites and chat groups promote sharing of experiences and information about self-care with others who have similar conditions, chronic diseases, or disabling conditions.

Special efforts are being made by health care professionals to reach and motivate members of various cultural and socioeconomic groups about lifestyle and health practices. Stress, unhealthy diet, lack of exercise, smoking, use of illicit drugs, high-risk behaviors (including risky sexual practices), and poor hygiene are all lifestyle behaviors known to affect health negatively. Health care professionals are concerned with encouraging behavior that promotes health. The goal is to motivate people to make improvements in the way they live, to modify risky behaviors, and to adopt healthy behaviors.

Influences on Health Care Delivery

The health care delivery system is constantly adapting as the population shifts its health care needs and expectations change. The shifting demographics of the population, the increase in chronic illnesses and disability, the greater emphasis on health care costs, and technologic advances have resulted in changing emphases in health care delivery and in nursing.

Population Demographics

Changes in the population in general are affecting the need for and the delivery of health care. The U.S. Bureau of the Census (2007) estimated that there were more than 303 million people in the country. Population growth is attributed in part to improved public health services and improved nutrition.

Not only is the population increasing, but also its composition is changing. The decline in birth rate and the increase in lifespan due to improved health care have resulted in fewer school-age children and more senior citizens, many of whom are women. Much of the population resides in highly congested urban areas, with a steady migration of members of ethnic minorities to the inner cities and a migration of members of the middle class to suburban areas. The number of homeless people, including entire families, has increased significantly. The population has become more culturally diverse as increasing numbers of people from different national backgrounds enter the country.

Because of population changes, the health care needs of people of specific ages, of women, and of diverse groups of people in specific geographic locations is altering the effectiveness of traditional means of providing health care. As a result, far-reaching changes in the overall health care delivery system are necessary.

Aging Population

The elderly population in the United States has increased significantly and will continue to grow in future years. In 2003, the 35.9 million adults who were older than 65 years of age constituted 12.4% of the U.S. population (U.S. Bureau of the Census, 2004). By the year 2030, 20% of the U.S. population is expected to be older than 65 years of age. According to the U.S. Bureau of the Census (2000), the number of people 65 to 74 years of age was 8 times larger in 1999 than in 1900, and the number of people 75 to 84 years of age was 16 times larger. In addition, people 85 years of age and older constituted one of the fastest-growing segments of the population; the number was 34 times larger in 1999 than in 1900.

The health care needs of older adults are complex and demand significant investments, both professional and financial, by the health care industry. Many elderly people suffer from multiple chronic conditions that are exacerbated by acute episodes. In particular, elderly women, whose conditions are frequently underdiagnosed and undertreated, are of concern. There are approximately three women for every two men in the older population, and elderly women are expected to continue to outnumber elderly men.

Cultural Diversity

An appreciation for the diverse characteristics and needs of people from varied ethnic and cultural backgrounds is important in health care and nursing. Some projections indicate that by 2030, racial and ethnic minority populations in the United States will triple. With increased immigration, both legal and illegal, this figure could approach 50% by the year 2030 (U.S. Bureaus of Census, 2004). As the cultural composition of the population changes, it is increasingly

important to address cultural considerations in the delivery of health care. Patients from diverse sociocultural groups not only bring various health care beliefs, values, and practices to the health care setting, but also have a variety of risk factors for some disease conditions and unique reactions to treatment. These factors significantly affect a person's responses to health care problems or illnesses, to caregivers, and to the care itself. Unless these factors are assessed for, understood, and respected by health care providers, the care delivered may be ineffective, and health care outcomes may be negatively affected.

Culture is defined as learned patterns of behavior, beliefs, and values that are shared by a particular group of people. Included among the many characteristics that distinguish cultural groups are the manner of dress, language spoken, values, rules or norms of behavior, gender-specific practices, economics, politics, law and social control, artifacts, technology, dietary practices, and health beliefs and practices. Health promotion, illness prevention, causes of sickness, treatment, coping, caring, dying, and death are part of every culture. Every person has a unique belief and value system that has been shaped at least in part by his or her cultural environment. This belief and value system guides the person's thinking, decisions, and actions. It provides direction for interpreting and responding to illness and disability and to health care.

To promote an effective nurse-patient relationship and positive outcomes of care, nursing care must be culturally competent, appropriate, and sensitive to cultural differences. All attempts should be made to help patients retain their unique cultural characteristics. Providing special foods that have significance and arranging for religious observances may enable patients to maintain a feeling of wholeness at a time when they may feel isolated from family and community.

Knowing the cultural and social significance that particular situations have for each patient helps the nurse avoid imposing a personal value system when the patient has a different point of view. In most cases, cooperation with the plan of care occurs when communication among the nurse, the patient, and the patient's family is directed toward understanding the situation or the problem and respecting each other's goals.

Changing Patterns of Disease

During the past 50 years, the health problems of the American people have changed significantly. Although many infectious diseases have been controlled or eradicated, others, such as tuberculosis, acquired immunodeficiency syndrome (AIDS), and sexually transmitted diseases/infections, are on the rise. An increasing number of infectious agents are becoming resistant to antibiotic therapy as a result of widespread and inappropriate use of antibiotics. Obesity has become a major health concern, and the multiple comorbidities that accompany it, such as hypertension, heart disease, diabetes, and cancer, add significantly to its associated mortality.

Conditions that were once easily treated have become more complex and life-threatening. The prevalence of chronic illnesses and disability is increasing because of the lengthening lifespan in the United States and the advances

in care and treatment options for conditions such as cancer, human immunodeficiency virus (HIV) infection, and cystic fibrosis. In addition, improvements in care for trauma and other serious acute health problems have meant that many people with these conditions live decades longer than in the past. People with chronic illness are the largest group of health care consumers in the United States. Because the majority of health problems seen today are chronic in nature, many people are learning to maximize their health within the constraints of chronic illness and disability.

As chronic conditions increase, health care broadens from a focus on cure and eradication of disease to include the prevention or rapid treatment of exacerbations of chronic conditions. Nursing, which has always encouraged patients to take control of their health and wellness, has a prominent role in the current focus on management of chronic illness and disability.

Advances in Technology and Genetics

Advances in technology and genetics have occurred more rapidly during the past several decades compared with other time periods. Sophisticated techniques and devices have revolutionized surgery and diagnostic testing, making it possible to perform many procedures and tests on an outpatient basis. Increased knowledge and understanding of genetics have resulted in expanded screening, diagnostic testing, and treatments for a variety of conditions. The sophisticated communication systems that connect most parts of the world, with the capability of rapid storage, retrieval, and dissemination of information, have stimulated brisk change as well as swift obsolescence in health care delivery strategies. Advances in genetics and technology have also resulted in many ethical issues for the health care system, health care providers, patients, families, and society.

Demand for Quality Health Care

Nurses in acute care settings must work with other health care team members to maintain quality care while facing pressures to discharge patients and decrease staffing costs. Nurses in hospitals now care for patients who are hospitalized for relatively few days. Nurses in the community care for patients who need high-technology acute care services as well as long-term care in the home. The importance of effective discharge planning and quality improvement cannot be overstated. Acute care nurses must also work with community-based nurses and others in community settings to ensure continuity of care.

The general public has become increasingly interested in and knowledgeable about health care and health promotion through television, newspapers, magazines, the Internet, and other communications media. Health care is a topic of political debate. The public has also become very health conscious and subscribes to the belief that health and quality health care constitute a basic right, rather than a privilege for a chosen few.

Quality Improvement and Evidence-Based Practice

In the 1980s, hospitals and other health care agencies implemented ongoing quality assurance (QA) programs. These programs were required for reimbursement for services and for accreditation by the Joint Commission (previously known as the Joint Commission for Accreditation of Healthcare Organizations [JCAHO]).

These QA programs sought to establish accountability to society on the part of the health professions for the quality, appropriateness, and cost of health services provided.

In the early 1990s, it was recognized that quality of care as defined by regulatory agencies is difficult to measure. QA criteria were identified as measures to ensure minimal expectations only; they did not provide mechanisms for identifying causes of problems or for determining systems or processes that needed improvement. **Continuous quality improvement (CQI)** was identified as a more effective mechanism for maintaining quality health care and its implementation was mandated in health care organizations in 1992. The Joint Commission specifies that patients have the right to health care (1) that is considerate and preserves dignity; (2) that respects cultural, psychosocial, and spiritual values; and (3) that is age specific (Joint Commission, 2007).

Unlike QA, which focuses on individual incidents or errors and minimal expectations, CQI focuses on the processes used to provide care, with the aim of improving quality by assessing and improving those processes that most affect patient care outcomes and patient satisfaction. CQI involves analyzing, understanding, and improving clinical, financial, and operational processes. Nurses directly involved in the delivery of care are engaged in analyzing data and refining the processes used in CQI. Their knowledge of the processes and conditions that affect patient care is critical in designing changes to improve the quality of the care provided.

Closely related to the implementation of CQI is the move to transform health care through evidence-based practice (EBP). The facilitation of EBP involves identifying and evaluating current literature and research, as well as incorporating the findings into patient care as a means of ensuring quality care (Bourgault, Ipe, Weaver, et al., 2007; Fineout-Overholt, Melnyk & Schultz, 2005). EBP includes the use of outcome assessment and standardized plans of care such as clinical guidelines, clinical pathways, and algorithms. Many of these measures are being implemented by nurses, particularly by nurse managers and **advanced practice nurses**, often in collaboration with other health care professionals.

Clinical Pathways and Care Mapping

Many health care facilities and home health services use clinical pathways or care mapping to coordinate care for patients (Kinsman, James & Ham, 2004). Clinical pathways are tools for tracking a patient's progress toward achieving positive outcomes within specified time frames. Clinical pathways based on current literature and clinical expertise have been developed for patients with certain diagnosis-related groups (DRGs) (eg, heart failure, ischemic stroke, fractured hip), for high-risk patients (eg, those receiving chemotherapy), and for patients with certain common health problems (eg, diabetes, chronic pain). The pathways indicate key events, such as diagnostic tests, treatments, activities, medications, consultation, and education, that must occur within specified times for patients to achieve the desired and timely outcomes.

A case manager often facilitates and coordinates interventions to ensure that the patient progresses through the key events and achieves the desired outcomes. Nurses who provide direct care have an important role in the development and use of clinical pathways through their participation in researching the literature and then developing, piloting, implementing, and revising clinical pathways. In addition, nurses monitor outcome achievement and document and analyze variances. Examples of clinical pathways can be found in Appendix B.

Other EBP tools used for planning patient care are care mapping, multidisciplinary action plans (MAPs), clinical guidelines, and algorithms. These tools are used to move patients toward predetermined outcome markers. Algorithms are used more often in acute situations to determine a particular treatment based on patient information or response. Care maps, clinical guidelines, and MAPs (the most detailed of these tools) help facilitate coordination of care and education throughout hospitalization and after discharge.

Because care mapping and guidelines are used for conditions in which a patient's progress often defies prediction, specific time frames for achieving outcomes are excluded. A patient with a highly complex condition or multiple underlying illnesses may benefit more from care mapping or guidelines than from clinical pathways, because the use of outcome milestones (rather than specific time frames) is more realistic.

Through case management and the use of clinical pathways or care mapping, patients and the care they receive are continually assessed from preadmission to discharge—and in many cases after discharge to the home care and community settings. Continuity of care, effective utilization of services, and cost containment are the major benefits for society and for the health care system.

Alternative Health Care Delivery Systems

The rising cost of health care over the past few decades has led to the use of managed health care and alternative health care delivery systems, including health maintenance organizations (HMOs) and preferred provider organizations (PPOs).

Managed Care

The continued escalation of health care costs over the course of the past several decades has prompted business, labor, and government to assume greater control over the financing and delivery of health care. The common features that characterize managed care include prenegotiated payment rates, mandatory precertification, utilization review, limited choice of providers, and fixed-price reimbursement. The scope of managed care has expanded from inpatient services to HMOs or variations such as PPOs; ambulatory, long-term, and home care services; and related diagnostic and therapeutic services.

Managed care has contributed to a dramatic reduction in inpatient hospital days, continuing expansion of ambulatory care, fierce competition, and marketing strategies that appeal to consumers as well as to insurers and regulators. Hospitals are faced with declining revenues, a declining number of patients, more severely ill patients with shorter lengths of

stay, and a need for cost-effective outpatient or ambulatory care services. As patients return to the community, they have more health care needs, many of which are complex. The demand for home care and community-based services is escalating. Despite their successes, managed care organizations are faced with the challenge of providing quality services under resource constraints. Case management is a strategy used by many organizations to meet this challenge.

Case Management

Case management is a system of coordinating health care services to ensure cost-effectiveness, accountability, and quality care. The premise of case management is that the responsibility for meeting patient needs rests with one person or team whose goals are to provide the patient and family with access to required services, to ensure coordination of these services, and to evaluate how effectively these services are delivered.

Case management has gained such prominence because of decreased costs of care associated with decreased lengths of hospital stays coupled with rapid and frequent interunit transfers from specialty to standard care units. The case manager role focuses on managing the care of a caseload of patients and collaborating with nurses and other health care personnel who provide care. In some settings, particularly the community setting, the focus of the nurse case manager is on managing the treatment plan of the patient with complex conditions. The case manager follows the patient throughout hospitalization and at home after discharge in an effort to coordinate health care services that will avert or delay rehospitalization. The caseload is usually limited in scope to patients with similar diagnoses, needs, and therapies.

Case management was designed to plan and coordinate the inpatient and outpatient services needed by patients. The goals of case management are quality, appropriateness, and timeliness of services as well as cost reduction. Evidence-based pathways or similar plans are often used in case management of similar patient populations (Craig & Huber, 2007; Huber & Craig, 2007).

Roles of the Nurse

As stated previously, nursing is the diagnosis and treatment of human responses to health and illness and therefore focuses on a broad array of phenomena. Professional nurses who work in institutional, community-oriented, or community-based settings have three major roles: the practitioner role, which includes providing care, teaching, and collaborating; the leadership role; and the research role. Although each role carries specific responsibilities, these roles are characteristic of all nursing positions, relate to one another, and are designed to meet the immediate and future needs of consumers who are the recipients of nursing care. Often, nurses act in a combination of roles to provide comprehensive patient care.

Practitioner Role

The practitioner role involves those actions taken by nurses to meet the health care and nursing needs of individual patients, their families, and significant others. This role is a

dominant one for nurses in primary, secondary, and tertiary health care settings and in home care and community nursing. It is achieved through use of critical thinking, clinical judgment, and the nursing process, all of which are key tools for nursing practice. Nurses help patients meet their needs by using direct intervention, by teaching patients and family members to perform care, and by coordinating and collaborating with other disciplines to provide needed services.

Leadership Role

The leadership role is often viewed as a role assumed by nurses who have titles that suggest leadership and who are the leaders of large groups of nurses or related health care professionals. However, because of the constant fluctuation of health care delivery demands and consumers, a broader definition of nursing leadership, one that identifies the leadership role as inherent within all nursing positions, is required. The leadership role involves those actions that nurses execute when they assume responsibility for the actions of others directed toward determining and achieving patient care goals. Many staff nurses now work in settings where they are held accountable for the nursing care delivered by unlicensed assistive personnel (UAPs) who work under their direct supervision.

Nursing leadership involves four components: decision making, relating, influencing, and facilitating. Each of these components promotes change and the ultimate outcome of goal achievement. Basic to the entire process is effective communication, which determines the success of the process and achievement of goals. The components of the leadership process are appropriate during all phases of the nursing process and in all settings. A new role, the clinical nurse leader (CNL) is a nurse generalist with a master's degree in nursing and a special background in clinical leadership to help patients navigate through complex health care systems (American Association of Colleges of Nursing [AACN], 2007).

Research Role

The primary task of nursing research is to contribute to the scientific base of nursing practice. Studies are needed to determine the effectiveness of nursing interventions and nursing care. The science of nursing grows through research, leading to the generation of scientifically based rationale for nursing practice and patient care. This process is the basis of EBP, with a resultant increase in the quality of patient care.

The research role is considered to be a responsibility of all nurses in clinical practice. Nurses are constantly alert for nursing problems and important issues related to patient care that can serve as a basis for the identification of researchable questions. Nurses with a background in research methods can use their research knowledge and skills to initiate and implement timely, relevant studies.

Nurses directly involved in patient care are often in the best position to identify potential research problems and questions, and their clinical insights are invaluable. Nurses also have a responsibility to become actively involved in ongoing research studies. This may involve facilitating the data collection process, or it may include actual collection

of data. Explaining the study to patients and their families and to other health care professionals is often of invaluable assistance to the researcher who is conducting the study.

Above all, nurses must use research findings in their nursing practice; the use, validation, replication, dissemination, and evaluation of research findings further the science of nursing. As stated previously, EBP requires the critique of the best evidence available in research-based studies and validating their saliency to nursing practice. Nurses must continually be aware of studies that are directly related to their own area of clinical practice and critically analyze those studies to determine the applicability of their implications for specific patient populations. Relevant conclusions and implications can be used to improve patient care.

Models of Nursing Care Delivery

Several organizational methods or models that vary greatly from one facility to another and from one set of patient circumstances to another may be used to carry out nursing care. These methods and models have changed over the years and have included functional nursing, team nursing, primary nursing, and patient-focused or patient-centered care. The models most commonly utilized today include primary nursing, which is characterized by assigning one primary nurse to accept overall responsibility for a given patient's individualized nursing care, and patient-focused care, which is characterized by assigning a nurse to manage the care of a caseload of patients during a given shift, who may then delegate care activities to other nursing personnel, including UAPs.

Community-Based Nursing and Community-Oriented/Public Health Nursing

Community health nursing, public health nursing, community-based nursing, and home health nursing may be discussed together. However, although aspects of patient care in each type do overlap, these terms are distinct from one another. The similar practice settings may blur these distinctions (Stanhope & Lancaster, 2008), and confusion exists regarding the differences. The central idea of **community-oriented nursing practice** is that nursing intervention can promote wellness, reduce the spread of illness, and improve the health status of groups of citizens or the community at large. Its emphasis is on primary, secondary, and tertiary prevention. Nurses in these settings have traditionally focused on health promotion, maternal and child health, and chronic care.

Community-based nursing occurs in a variety of settings within the community, including home settings, and is directed toward people and families (Stanhope & Lancaster, 2008). Most community-based and home health care is directed toward specific patient groups with identified needs, which usually relate to illness, injury, or disability, resulting most often from advanced age or chronic illness. However, nurses in the community are meeting the needs of groups of patients with a variety of problems and needs. Home health

care is a major aspect of community-based care discussed throughout this text. Community-based programs and agencies for specific populations (eg, the elderly, ventilator-dependent patients), as well as home health care agencies, hospices, independent professional nursing practices, and freestanding health care agencies, provide home health care services.

With shorter hospital stays and increased use of outpatient health care services, more nursing care is provided in the home and community setting. As a result, nurses have a choice of practicing in a variety of health care delivery settings. These settings include acute care medical centers, ambulatory care settings, clinics, urgent care centers, outpatient departments, neighborhood health centers, home health care agencies, independent or group nursing centers, and managed care agencies.

Community nursing centers are nurse managed and provide primary care services such as ambulatory and outpatient care, immunizations, health assessment and screening services, and patient and family education and counseling. These centers serve varied and often underserved populations that typically include a high proportion of patients who are rural, very young, very old, poor, or members of racial minorities.

Various agencies provide care in the home and community to meet the needs of patients who are discharged from acute care institutions to their homes and communities early in the recovery process and with complex needs. Many patients are elderly, and many have multiple medical and nursing diagnoses and multisystem health problems that require acute and intensive nursing care, including ventilatory support and intravenous (IV) or parenteral nutrition therapy.

As a result, there are many opportunities for employment for nurses in the community and home care settings. Home care nursing is a specialty area that requires advanced knowledge and skills in general nursing practice, with emphasis on community health and acute medical-surgical nursing. Also required are high-level assessment skills, critical thinking, and decision-making skills in a setting where other health care professionals are not available to validate observations, conclusions, and decisions.

Home care nurses often provide “high-tech, high-touch” services to patients with acute health care needs. In addition, they are responsible for patient and family teaching and for contacting community resources and coordinating the continuing care of patients. For these reasons, the scope of medical-surgical nursing encompasses not only the acute care setting within the hospital, but also the acute care setting as it expands into the community and the home. Throughout this textbook, the home health care needs of patients are addressed, with particular attention given to the teaching, self-care management, and health maintenance needs of patients and their families.

Expanded Nursing Roles

Professional nursing is adapting to meet changing health needs and expectations. The role of the nurse has expanded to improve the distribution of health care services

and to decrease the cost of health care. Nurses may receive advanced education in such specialties as family care, critical care, coronary care, respiratory care, oncologic care, maternal and child health care, neonatal intensive care, rehabilitation, trauma, rural health, and gerontologic nursing. In medical-surgical nursing, the most significant titles associated with an advanced specialized education include *nurse practitioner* (NP) and *clinical nurse specialist* (CNS), and the more recent title of *advanced practice nurse* (APN), which encompasses both NPs and CNSs. Certified nurse-midwives (CNMs) and certified registered nurse anesthetists (CRNAs) are also identified as APNs. Nurses who function in these roles provide direct care to patients through independent practice, practice within a health care agency, or collaboration with a physician. Specialization in nursing has evolved as a result of the recent explosion of technology and knowledge.

Most states require both NPs and CNSs to have graduate-level education. NPs are prepared as specialists (eg, family, acute care, pediatric, geriatric). They define their role in terms of direct provision of a broad range of health care services to patients and families. The focus is on providing direct health care to patients and collaborating with other health professionals. In most states, nurse practitioners have prescriptive authority and may receive direct Medicare reimbursement.

CNSs, on the other hand, are prepared as specialists who practice within a circumscribed area of care (eg, cardiovascular, oncology). They define their role as having five major components: clinical practice, education, management, consultation, and research. Studies have shown that CNSs often focus on their education and consultation roles, which involve education and counseling of patients and families, as well as education, counseling, and consultation with nursing staff. Some states have granted CNSs prescriptive authority if they have the required educational preparation. CNSs practice in a variety of settings, including the community and the home, although most practice in acute care settings. CNSs are ideal case managers because they have the educational background and the clinical expertise to organize and coordinate services and resources to meet the patient’s health care needs in a cost-effective and efficient manner. The expanding role of the nurse case manager has contributed to the designation of the APN case manager as an advanced practice role (Hamric, Spross & Hanson, 2005).

With advanced practice roles has come a continuing effort by professional nursing organizations to define more clearly the practice of nursing. States’ nurse practice acts give nurses the authority to perform functions that were previously restricted to the practice of medicine. These functions include diagnosis (nursing), treatment, performance of selected invasive procedures, and prescription of medications and treatments. The board of nursing in each state stipulates regulations regarding these functions, defines the education and experience required, and determines the clinical situations in which a nurse may perform these functions. Additionally, the introduction of the Doctor of Nursing Practice (DNP) as the terminal practice degree has generated considerable discussion

regarding the level of preparation needed for APNs (AACN, 2006).

Initial care, ambulatory health care, palliative care, and anticipatory guidance are all important in nursing practice. Advanced practice roles enable nurses to function interdependently with other health care professionals and to establish more collegial relationships with physicians. The role of advanced practice nurses is expected to continue to increase in terms of scope, responsibility, and recognition.

Interdisciplinary Collaborative Practice

This chapter has explored the changing role of nursing. Many references have been made to the significance of nurses as members of the health care team. As the unique competencies of nurses become more clearly articulated, there is increasing evidence that nurses provide health care services distinct to the profession. However, nursing continues to recognize the importance of collaboration with other health care disciplines in meeting the needs of patients.

Some institutions use the **collaborative practice model** (Fig. 1-2). Nurses, physicians, and ancillary health personnel function within a decentralized organizational structure, collaboratively making clinical decisions. A joint practice committee, with representation from all care providers, may function at the unit level to monitor, support, and foster collaboration. Collaborative practice is further enhanced with integration of the health or medical record and with joint patient care record reviews. The collaborative model, or a variation of it, promotes shared participation, responsibility, and accountability in a health care environment that is striving to meet the complex health care needs of the public.

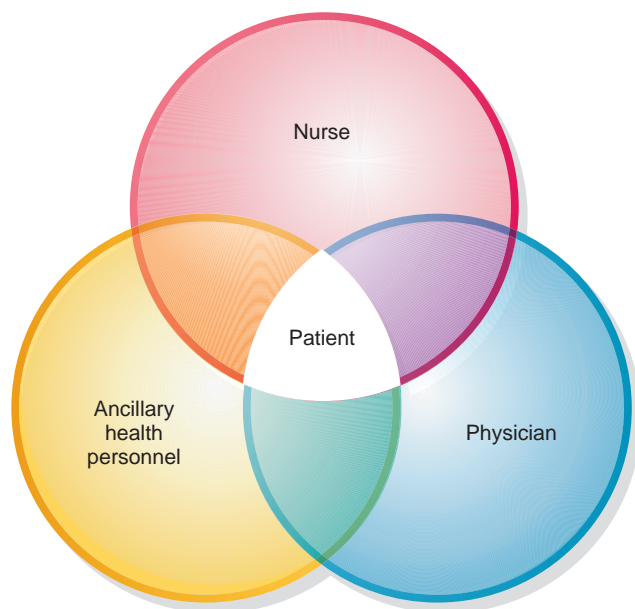

Figure 1-2 Collaborative practice model.

CRITICAL THINKING EXERCISES

1 Your clinical assignment is in a long-term care facility. Identify a patient care issue (eg, nutritional status) that could be improved. Describe the mechanism that is available within a clinical facility to address such quality improvement issues.

2 You are planning the discharge of an elderly patient who has several chronic medical conditions. A case manager has been assigned to this patient. How would you explain the role of the case manager to the patient and her husband?

EBP 3 You are assigned to care for a hospitalized patient who is obese, with a history of diabetes, and a new diagnosis of stable angina. There is a clinical nurse leader (CNL) assigned to provide consistent, quality care for this patient from hospital admission to discharge. Identify the evidence that supports the effectiveness of CNLs in supervising care of patients and promoting positive patient outcomes. What is the strength of the evidence? How might this specific patient's care be affected?

Community-Based Nursing Practice

LEARNING OBJECTIVES

On completion of this chapter, the learner will be able to:

- 1 Discuss the changes in the health care system that have increased the need for nurses to practice in community-based settings.
- 2 Compare the differences and similarities between community- and hospital-based nursing.
- 3 Describe the discharge planning process in relation to home care preparation.
- 4 Explain methods for identifying community resources and making referrals.
- 5 Discuss how to prepare for a home health care visit and how to conduct the visit.
- 6 Identify personal safety precautions a home care nurse should take when making home visits.
- 7 Describe the various types of nursing functions provided in ambulatory care facilities, in occupational health and school nursing programs, in community nurse-managed centers, in hospice care settings, and in facilities that provide services to the homeless.

GLOSSARY

community-based nursing: nursing care of individuals and families that is designed to (1) promote and maintain health and (2) prevent disease. It is provided as patients transition through the health care system to health-related services outside of the hospital setting

primary prevention: health care delivery focused on health promotion and prevention of illness or disease

secondary prevention: health care delivery centered on health maintenance and aimed at early detection of disease, with prompt intervention to prevent or minimize loss of function and independence

tertiary prevention: health care delivery focused on minimizing deterioration associated with disease and improving quality of life through rehabilitation measures

As described in Chapter 1, the shift in health care delivery from inpatient to outpatient settings is a result of multiple factors, including new population trends. Changes in federal legislation, tighter insurance regulations, decreasing hospital revenues, and alternative health care delivery systems have also affected the ways in which health care is delivered. The growing number of older adults in the United States increases the demand for medical, nursing, and social services within the public health system. Hospitals and other health care providers are reimbursed at a fixed rate for patients who have the same diagnosis as defined by diagnosis-related groups (DRGs). Under this system, hospitals and other health care providers can reduce costs and earn income by carefully monitoring the types of services they provide and discharging patients as soon as possible. Consequently, patients are being discharged from acute care facilities to their homes or to residential or long-term care facilities in early stages of recovery.

As health care delivery shifts into the community, more nurses are working in a variety of community-based settings. These settings include public health departments, ambulatory health clinics, long-term care facilities, hospice settings, industrial settings (as occupational nurses), homeless shelters and clinics, nursing centers, home health agencies, urgent care centers, same-day surgical centers, short-stay facilities, and patients' homes. In these settings, nurses often deliver care without direct on-site supervision or support of other health care personnel. They must be self-directed, flexible, adaptable, and accepting of various lifestyles and living conditions. To function effectively, nurses in these settings must have expertise in independent decision making, critical thinking, assessment, health education, and competence in basic nursing care (Stanhope & Lancaster, 2008).

In addition, nurses in community settings must be culturally competent, as culture plays a role in the delivery of care. Culture can be structured within the context of care through the utilization of a theoretical framework involving cultural competence (Jirwe, Gerrish & Emami, 2006).

Community-Based Care

Community-based nursing is a philosophy of care in which the care is provided as patients and their families move among various service providers outside of hospitals. This nursing practice focuses on promoting and maintaining the health of individuals and families, preventing and minimizing the progression of disease, and improving quality of life (Stanhope & Lancaster, 2008). Community health nurses provide direct care to patients and families and use political advocacy to secure resources for aggregate populations (eg, the aged population). Community health nurses have many roles, including epidemiologist, case manager for a group of patients, coordinator of services provided to a group of patients, occupational health nurse, school nurse (Fig. 2-1), visiting nurse, or parish nurse. (In parish nursing, the members of a religious community—the parish—are the recipients of care.) These roles have one element in common: a focus on community needs as well as on the needs of indi-

Figure 2-1 Community-based nursing takes many forms and focuses. Here the school nurse performs screening for scoliosis.

vidual patients. Community-based care is generally focused on individuals or their families, although efforts may be undertaken to improve the health of the entire community.

The primary concepts of community-based nursing care are self-care and preventive care within the context of culture and community. Two other important concepts are continuity of care and collaboration. Some community-based areas of nursing have become specialties in their own right, such as school health nursing and home health nursing.

Nurses in community-based practice provide preventive care at three levels—primary, secondary, and tertiary. **Primary prevention** focuses on health promotion and prevention of illness or disease, including interventions such as teaching about healthy lifestyles. **Secondary prevention** centers on health maintenance and is aimed at early detection and prompt intervention to prevent or minimize loss of function and independence, including interventions such as health screening and health risk appraisal. **Tertiary prevention** focuses on minimizing deterioration and improving quality of life, including rehabilitation to assist patients in achieving their maximum potential by working through their physical or psychological challenges. Home care nurses often focus on tertiary preventive nursing care, although primary and secondary prevention are also addressed.

Home Health Care

Home care nursing is a unique component of community-based nursing. Home care visits are made by nurses who work for home care agencies, public health agencies, and visiting nurse associations; by nurses who are employed by hospitals; and by parish nurses or faith community nurses

who work with the members of faith-based communities to promote health. Such visits may also be part of the responsibilities of school nurses, clinic nurses, or occupational health nurses. Home health care agencies are continuing to employ more nurses. Because of the high acuity level of patients, nurses with acute care and critical care experience are in demand in this field.

The type of nursing services provided to patients in their homes varies from agency to agency. Nurses from home care or hospice agencies make home visits to provide skilled nursing care, follow-up care, and teaching to promote health and prevent complications. Hospice nursing has become a specialty area of nursing practice in which nurses provide palliative care in patients' homes and within hospice centers, thus promoting comfort, peace, and dignity to patients who are dying. Clinic nurses may conduct home visits as part of patient follow-up. Public health, parish, and school nurses may make visits to provide anticipatory guidance to high-risk families and follow-up care to patients with communicable diseases. Many home care patients are acutely ill, and many have chronic health problems or disabilities, requiring that nurses provide more education and monitoring to patients and families. Holistic care is provided in the home through the collaboration of an interdisciplinary team that includes professional nurses; home health aides; social workers; physical, speech, and occupational therapists; and physicians. An interdisciplinary approach is used to provide health and social services with oversight of the total health care plan by a case manager, clinical nurse specialist, or nurse practitioner. Interdisciplinary collaboration is required if a home health agency is to receive Medicare certification (Stanhope & Lancaster, 2008).

Home health care services are provided by official, publicly funded agencies; nonprofit agencies; private businesses; proprietary chains; and hospital-based agencies. Some agencies specialize in high-technology services. Most agencies are reimbursed from a variety of sources, including Medicare and Medicaid programs, private insurance, and direct patient payment. Many home health care expenditures are financed by Medicare, which allows nurses to manage and evaluate patient care for seriously ill patients who have complex, labile conditions and are at high risk for rehospitalization. Each funding source has its own requirements for services rendered, number of visits allowed, and amount of reimbursement the agency receives. The elderly are the most frequent users of home care services. To be eligible for service, the patient must be acutely ill, homebound, and in need of skilled nursing services.

Health care visits may be intermittent or periodic, and case management via telephone or via Internet may be used to promote communication with home care consumers. The nurse instructs the patient and family about skills and self-care strategies and about health maintenance and promotion activities (eg, nutritional counseling, exercise programs, stress management). Nursing care includes skilled assessment of the patient's physical, psychological, social, and environmental status (Fig. 2-2). Nursing interventions may include intravenous (IV) therapy and injections, parenteral nutrition, venipuncture, catheter insertion, pressure ulcer treatment, wound care, ostomy care, and patient and family

Figure 2-2 Assessment is an important part of any home health visit.

teaching. Complex technical equipment, such as dialysis machines and ventilators, is often part of home health care (Stanhope & Lancaster, 2008). Nurses have a role in evaluating the safety and effectiveness of technology in the home setting. In addition, “tele-health” is an emerging trend in home health care; this facilitates exchange of information via telephone lines between patients and nurses regarding health information such as blood glucose readings, vital signs, and cardiac parameters (Stanhope & Lancaster, 2008). Use of a broad spectrum of computer and Internet resources, such as Web cams, also facilitates exchange of information.

Nursing in the Home Setting

The home care nurse is a guest in the patient's home and must have permission to visit and give care. The nurse has minimal control over the lifestyle, living situation, and health practices of the patients he or she visits. This lack of full decision-making authority can create a conflict for the nurse and lead to problems in the nurse–patient relationship. To work successfully with patients in any setting, the nurse must be nonjudgmental and convey respect for patients' beliefs, even if they differ sharply from the nurse's. This can be difficult when a patient's lifestyle involves activities that a nurse considers harmful or unacceptable, such as smoking, use of alcohol, drug abuse, or overeating.

The cleanliness of a patient's home may not meet the standards of a hospital. Although the nurse can provide teaching points about maintaining clean surroundings, the patient and family decide if they will implement the nurse's suggestions. The nurse must accept their decisions and deliver the care required regardless of the conditions of the setting.

The kind of equipment and the supplies or resources that usually are available in acute care settings are often unavailable in the patient's home. The nurse has to learn to improvise when providing care, such as when changing a dressing or catheterizing a patient in a regular bed that is

not adjustable and lacks a bedside table (Smith-Temple & Johnson, 2005).

Infection control is as important in the home as it is in the hospital, but it can be more challenging in the home and requires creative approaches. As in any situation, it is important to clean one's hands before and after giving direct patient care, even in a home that does not have running water. If aseptic technique is required, the nurse must have a plan for implementing this technique before going to the home. This applies to universal precautions, transmission-based precautions, and disposal of bodily secretions and excretions. If injections are given, the nurse must use a closed container to dispose of syringes. Injectable and other medications must be kept out of the reach of children during visits and must be stored in a safe place if they are to remain in the house.

Friends, neighbors, or family members may ask the nurse about the patient's condition. The patient has a right to confidentiality, and information should be shared only with the patient's permission. If the nurse carries a patient's medical record into a house, he or she must put it in a secure place to prevent it from being picked up by others or from being misplaced.

Discharge Planning for Home Care

Discharge planning is an important part of making the transition from the acute to the home care setting, and it is mandated for Medicare reimbursement. Discharge planning begins with the patient's admission to the hospital and must consider the possible need for follow-up home care. Several different personnel (eg, social workers, home care nurses, and case managers) or agencies may be involved in the planning process.

The development of a comprehensive discharge plan requires collaboration with professionals at both the referring agency and the home care agency, as well as other community agencies that provide specific resources upon discharge. The process involves identifying the patient's needs and developing a thorough plan to meet them. It is essential to have open lines of communication with family members to ensure their understanding and cooperation.

Community Resources and Referrals

As case managers, community-based nurses may make referrals to other team members, such as home health aides and social workers. These nurses work collaboratively with the health team and the referring agency or person. Continuous coordinated care among all health care providers involved in a patient's care is essential to avoid duplication of effort by the various personnel caring for the patient.

A community-based nurse must be knowledgeable about community resources available to patients as well as services provided by local agencies, eligibility requirements, and any possible charges for the services. Most communities have directories of health and social service agencies that the nurse can consult. These directories must be updated as resources change. If a community does not have a resource booklet, an agency may develop one for its staff. It should include the commonly used community resources that patients need, as well as the costs of the services and eligibility requirements. The telephone book and the Internet are often

useful in helping patients identify the location and accessibility of grocery and drug stores, banks, health care facilities, ambulances, physicians, dentists, pharmacists, social service agencies, and senior citizens' programs. In addition, a patient's place of worship or parish may be an important resource for services.

The community-based nurse is responsible for informing the patient and family about the community resources available to meet their needs. During initial and subsequent home visits, the nurse helps the patient and family identify these community services and encourages them to contact the appropriate agencies. When appropriate, nurses may make the initial contact.

Home Health Visits

Preparing for a Home Visit

Most agencies have a policy manual that identifies the agency's philosophy and procedures and defines the services provided. Becoming familiar with these policies is essential before initiating a home visit. It is also important to know the agency's policies and the state law regarding what actions to take if the nurse finds a patient dead, suspects abuse, determines that a patient cannot safely remain at home, or observes a situation that possibly indicates malicious harm to the community at large.

Before making a home visit, the nurse should review the patient's referral form and other pertinent data concerning the patient. It may be necessary to contact the referring agency if the purpose for the referral is unclear or if important information is missing. The first step is to call the patient to obtain permission to visit, schedule a time for the visit, and verify the address. This initial phone conversation provides an opportunity to introduce oneself, identify the agency, and explain the reason for the visit. If the patient does not have a telephone, the nurse should see if the people who made the referral have a number where a phone message can be left for the patient. If an unannounced visit to a patient's home must be made, the nurse should ask permission to come in before entering the house. Explaining the purpose of the referral at the outset and setting up the times for future visits before leaving are also recommended.

Most agencies provide nurses with bags that contain standard supplies and equipment needed during home visits. It is important to keep the bag properly supplied and to bring any additional items that might be needed for the visit. Patients rarely have the medical supplies needed for treatment.

Conducting a Home Visit

Personal Safety Precautions

Community nurses must pay particular attention to personal safety, because their practice settings are often in unknown environments. Based on the principle of due diligence, agencies must inform employees of at-risk working environments. Agencies have policies and procedures concerning the promotion of safety for clinical staff, and training is provided to facilitate personal safety. Environments must be proactively assessed for safety by the individual nurse and agency.

Chart 2-1 • Safety Precautions in Home Health Care

- Learn or preprogram a cell phone with the telephone numbers of the agency and police and emergency services. Most agencies provide cell phones for their nurses so that the agency can contact the nurse, and so that the nurse can contact the agency in case of an emergency or unexpected situation.
- Carry agency identification and a charged cell phone to make telephone calls in case you become lost or have problems.
- Let the agency know your daily schedule and the telephone numbers of your patients so that you can be located if you do not return when expected.
- Know where the patient lives before leaving to make the visit and carry a map for quick referral.
- Keep your car in good working order and have sufficient gas in the tank.
- Park the car near the patient's home and lock the car during the visit.
- Do not drive an expensive car or wear expensive jewelry when making visits.
- Know the regular bus schedule and know the routes when using public transportation or walking to the patient's house.
- When making visits in high-crime areas, visit with another person rather than alone.
- Schedule visits only during daylight hours.
- Never walk into a patient's home uninvited.
- If you do not feel safe entering a patient's home, leave the area.
- Become familiar with the layout of the house, including exits from the house.
- If a patient or family member is intoxicated, hostile, or obnoxious, reschedule the visit and leave.
- If a family is having a serious argument or abusing the patient or anyone else in the household, reschedule the visit, contact your supervisor, and report the abuse to the appropriate authorities.

Whenever a nurse makes a home visit, the agency should know the nurse's schedule and the locations of the visits. The nurse should learn about the neighborhood and obtain directions to the destination. A plan of action should always be established in case of emergencies. If a dangerous situation is encountered during the visit, the nurse should return to the agency and contact his or her supervisor or law enforcement officials, or both. Suggested precautions to take when making a home visit are presented in Chart 2-1.

Initial Home Visit

The first visit sets the tone for subsequent visits and is crucial in establishing the nurse-patient relationship. The situations encountered depend on numerous factors. Patients may be in pain and unable to care for themselves. Family members may be overwhelmed and doubt their ability to care for their loved ones. They may not understand why the patient was sent home from the hospital before being totally rehabilitated. They may not comprehend what home care is or why they cannot have 24-hour nursing services. It is critical that the nurse conveys an understanding of what patients and families are experiencing and how the illness is affecting their lives.

During the initial home visit, which usually lasts less than an hour, the individual patient is evaluated and a plan of care is established to be followed or modified on subsequent visits. The nurse informs the patient of the agency's practices, policies, and hours of operation. If the agency is to be reimbursed for the visit, the nurse asks for insurance information, such as a Medicare or Medicaid card.

The initial assessment includes evaluating the patient, the home environment, the patient's self-care abilities or the family's ability to provide care, and the patient's need for additional resources. Identification of possible hazards, such as cluttered walk areas, potential fire risks, air or water pollution, or inadequate sanitation facilities, is also part of the initial assessment.

Documentation considerations for home visits follow fairly specific regulations. The patient's needs and the nurs-

ing care provided must be documented to ensure that the agency qualifies for payment for the visit. Medicare, Medicaid, and third-party payers require documentation of the patient's homebound status and the need for skilled professional nursing care. The medical diagnosis and specific detailed information on the functional limitations of the patient are usually part of the documentation. The goals and the actions appropriate for attaining them must be identified. Expected outcomes of the nursing interventions must be stated in terms of patient behaviors and must be realistic and measurable. They must reflect the nursing diagnosis or the patient's problems and must specify those actions that address the patient's problems. Inadequate documentation may result in nonpayment for the visit and care services.

Determining the Need for Future Visits

While conducting an assessment of a patient's situation, the home care nurse evaluates the need for future visits and the frequency with which those visits may need to be made. To make these judgments, the nurse should consider the questions listed in Chart 2-2. With each subsequent visit, these same factors are evaluated to determine the continuing health needs of the patient. As progress is made and the patient, with or without the help of significant others, becomes more capable of self-care and more independent, the need for home visits may decline.

Ending the Visit

As the visit comes to a close, it is important to summarize the main points of the visit for the patient and family and to identify expectations for future visits or patient achievements. The following points should be considered at the end of each visit:

- What are the main points the patient or family should remember from the visit?
- What positive attributes have been noted about the patient and the family that will give them a sense of accomplishment?

Chart 2-2 • Assessing the Need for Home Visits

Current Health Status

- How well is the patient progressing?
- How serious are the present signs and symptoms?
- Has the patient shown signs of progressing as expected, or does it seem that recovery will be delayed?

Home Environment

- Are worrisome safety factors apparent?
- Are family or friends available to provide care, or is the patient alone?

Level of Self-Care Ability

- Is the patient capable of self-care?
- What is the patient's level of independence?
- Is the patient ambulatory or bedridden?
- Does the patient have sufficient energy, or is he or she frail and easily fatigued?
- Does the patient need and use assistive devices?

Level of Nursing Care Needed

- What level of nursing care does the patient require?
- Does the care require basic skills or more complex interventions?

Prognosis

- What is the expectation for recovery in this particular instance?
- What are the chances that complications may develop if nursing care is not provided?

Educational Needs

- How well has the patient or family grasped the teaching points made?
- Is there a need for further follow-up and retraining?
- What level of proficiency does the patient or family show in carrying out the necessary care?

Mental Status

- How alert is the patient?
- Are there signs of confusion or thinking difficulties?
- Does the patient tend to be forgetful or have a limited attention span?

Level of Adherence

- Is the patient following the instructions provided?
- Does the patient seem capable of following the instructions?
- Are the family members helpful, or are they unwilling or unable to assist in caring for the patient as expected?

- What were the main points of the teaching plan or the treatments needed to ensure that the patient and family understand what they must do? A written set of instructions should be left with the patient or family, provided they can read and see (alternative formats include video or audio recordings). Printed material must be in the patient's primary language and in large print when indicated.
- Whom should the patient or family call if they need to contact someone immediately? Are current emergency telephone numbers readily available? Is tele-

phone service available, or can an emergency cell phone service be provided?

- What signs of complications should be reported immediately?
- How frequently will visits be made? How long will they last (approximately)?
- What is the day and time of the next visit? Will a different nurse make the visit?

Other Community-Based Health Care Settings

Ambulatory Settings

Ambulatory health care is provided for patients in community- or hospital-based settings. The types of agencies that provide such care are medical clinics, ambulatory care units, urgent care centers, cardiac rehabilitation programs, mental health centers, student health centers, community outreach programs, and nursing centers. Some ambulatory centers provide care to a specific population, such as migrant workers or Native Americans. Neighborhood health centers provide services to patients who live in a geographically defined area. The centers may operate in freestanding buildings, storefronts, or mobile units. Agencies may provide ambulatory health care in addition to other services, such as an adult day care or health program. The kinds of services offered and the patients served depend on the agency's mission.

Nursing responsibilities in ambulatory health care settings include providing direct patient care, conducting patient intake screenings, treating patients with acute or chronic illnesses or emergency conditions, referring patients to other agencies for additional services, teaching patients self-care activities, and offering health education programs that promote health maintenance. A useful tool for community-based nurses might be the classification scheme developed by the Visiting Nurses Association of Omaha, which contains patient-focused problems in one of four domains: environmental, psychosocial, physiologic, and health-related behaviors (Barton, Clark & Baramée, 2004).

Nurses also work as clinic managers, direct the operation of clinics, and supervise other health team members. Nurse practitioners, educated in primary care, often practice in ambulatory care settings that focus on gerontology, pediatrics, family or adult health, or women's health. Constraints imposed by federal legislation and ambulatory payment classifications require efficient and effective management of patients in ambulatory settings. Nurses can play an important part in facilitating the function of ambulatory care facilities.

Occupational Health Programs

Federal legislation, especially the Occupational Safety and Health Act (OSHA), has been enacted to ensure safe and healthy work conditions. A safe working environment results in decreased employee absenteeism, hospitalization, and disability, as well as reduced costs.

Occupational nurses may work in solo units in industrial settings, or they may serve as consultants on a limited or part-time basis. They may be members of an interdisciplinary team composed of a variety of personnel such as nurses,

physicians, exercise physiologists, health educators, counselors, nutritionists, safety engineers, and industrial hygienists. Occupational health nurses may:

- Provide direct care to employees who become ill or injured
- Conduct health education programs for company staff members
- Set up programs aimed at establishing specific health outcomes, such as healthy eating and regular exercise
- Monitor employees' hearing, vision, blood pressure, or blood glucose
- Track exposure to radiation, infectious diseases, and toxic substances, reporting results to government agencies as necessary

Occupational health nurses must be knowledgeable about federal regulations pertaining to occupational health and familiar with other pertinent legislation, such as the Americans With Disabilities Act.

School Health Programs

School health programs provide services to students and may also serve the school's community. School-age children and adolescents with health problems are at major risk for underachieving or failing in school. The leading health problems of elementary school children are injuries, infections (including influenza and pneumonia), malnutrition, dental disease, and cancer. The leading problems of high school students are alcohol and drug abuse, injuries, homicide, pregnancy, eating disorders, sexually transmitted diseases/infections (STDs/STIs), sports injuries, dental disease, and mental and emotional problems. Contemporary school health issues that are being examined include school violence, which may affect students' and teachers' physical and emotional health, and the increasing numbers of overweight and obese children and adolescents.

Ideally, school health programs have an interdisciplinary health team consisting of physicians, nurses, dentists, social workers, counselors, school administrators, parents, and students. The school may serve as the site for a family health clinic that offers primary health and mental health services to children and adolescents as well as to all family members in the community. Advanced practice nurses perform physical examinations and diagnose and treat students and families for acute and chronic illnesses within the scope of their practice. These clinics are cost-effective and benefit students from low-income families who lack access to traditional health care or have no health insurance.

School nurses play a number of roles, including care provider, health educator, consultant, and counselor. They collaborate with students, parents, administrators, and other health and social service professionals regarding student health problems. School nurses perform health screenings, provide basic care for minor injuries and complaints, administer medications, monitor the immunization status of students and families, identify children with health problems, provide teaching related to health maintenance and safety, and monitor the weight of children in order to facilitate prevention and treatment of obesity. They need to be knowledgeable about state and local regulations affecting school-age children, such as ordinances for excluding stu-

dents from school because of communicable diseases or parasites such as lice or scabies.

School nurses are also health education consultants for teachers. In addition to providing information on health practices, teaching health classes, and participating in the development of the health education curriculum, school nurses educate teachers and classes when a student has a special problem, a disability, or a disease such as hemophilia, asthma, or human immunodeficiency virus (HIV) infection.

Community Nurse-Managed Centers

Community nurse-managed centers are a relatively new concept in community-based nursing, having appeared only in recent decades. Frequently sponsored by academic institutions, these centers typically are designed for the delivery of primary health care and typically serve people who are vulnerable, uninsured, and without access to health services. Community nurse-managed centers, which are usually run by advanced practice nurses, serve a large number of patients who are poor, members of minority groups, women, elderly, or homeless. The nurses provide health teaching, wellness and illness care, case management services, and psychosocial counseling (Pohl, Barkauskas, Benkert, et al., 2007). In some areas, various community partnership models facilitate care for the growing number of migrant workers.

Care for the Homeless

Homelessness is a growing problem. The homeless population is heterogeneous and includes members of both dysfunctional and intact families, the unemployed, and those who cannot find affordable housing. In addition, increasing numbers of women with children (often victims of domestic abuse), elderly people, and veterans since the military action following the terrorist attacks of September 11, 2001, are homeless. Some people are temporarily homeless as a result of catastrophic natural disasters.

Homeless people are often underinsured or uninsured and have limited or no access to health care. Because of numerous barriers, they seek health care late in the course of a disease and deteriorate more quickly than patients who are not homeless. Many of their health problems are related in large part to their living situation. Street life exposes people to the extremes of hot and cold environments and it compounds their health risks. Homeless people have high rates of trauma, tuberculosis, upper respiratory tract infections, poor nutrition and anemia, lice, scabies, peripheral vascular disorders, STDs/STIs, dental problems, arthritis, hypothermia, skin disorders, and foot problems. Common chronic health problems also include diabetes, hypertension, heart disease, acquired immunodeficiency syndrome (AIDS), mental illness, and abuse of alcohol or other drugs (National Coalition for the Homeless, 2007a). These problems are made more difficult by living on the streets or discharge to a transitory, homeless situation in which follow-up care is unlikely. Shelters frequently are overcrowded and unventilated, promoting the spread of communicable diseases such as tuberculosis. Homeless people also tend to have a higher incidence of death prior to the age of 62 (National Coalition for the Homeless, 2006a, 2006b).

Community-based nurses who work with homeless people must be nonjudgmental, patient, and understanding. They must be skilled in dealing with people who have a wide variety of health problems and needs and must recognize that individualized treatment strategies are required in highly unpredictable environments. Nursing interventions are aimed at evaluating the health care needs of people who live in shelters and attempting to obtain health care services for all homeless people.

CRITICAL THINKING EXERCISES

1 You are a nurse employed at the health clinic of a community college. The dean asks you to organize a series of health fairs for the school year that focus on key problems of teenagers and young adults. How might you determine the key issues and trends that need to be addressed? Name the top five areas of concern that you will address.

EBP 2 A 27-year-old woman with newly diagnosed diabetes is being referred for home care after discharge from the hospital, and she needs glucose monitoring and teaching. She has several family members at home, but they all work. You are concerned about her ability to understand the basic information and applications for around-the-clock management. What resources could you use to assess her health literacy? How would you go about obtaining this information? What is the evidence base that supports conducting a literacy assessment to determine what is needed for appropriate home care follow-up in facilitating self-care measures in diabetes home care management? What is the strength of the evidence?

Critical Thinking, Ethical Decision Making, and the Nursing Process

LEARNING OBJECTIVES

On completion of this chapter, the learner will be able to:

- 1 Define the characteristics of critical thinking and critical thinkers.
- 2 Describe the critical thinking process.
- 3 Define ethics and nursing ethics.
- 4 Identify several ethical dilemmas common to the medical-surgical area of nursing practice.
- 5 Specify strategies that can be helpful to nurses in ethical decision making.
- 6 Describe the components of the nursing process.
- 7 Develop a plan of nursing care for a patient using strategies of critical thinking.

GLOSSARY

- assessment:** the systematic collection of data to determine the patient's health status and any actual or potential health problems
- collaborative problems:** specific pathophysiologic manifestations that nurses monitor to detect onset or changes in status
- critical thinking:** a process of insightful thinking that utilizes multiple dimensions of one's cognition to develop conclusions, solutions, and alternatives that are appropriate for the given situation
- deontologic or formalist theory:** an ethical theory maintaining that ethical standards or principles exist independently of the ends or consequences
- ethics:** the formal, systematic study of moral beliefs

GLOSSARY (Continued)

- evaluation:** determination of the patient's responses to the nursing interventions and the extent to which the outcomes have been achieved
- implementation:** actualization or carrying out of the plan of care through nursing interventions
- moral dilemma:** situation in which a clear conflict exists between two or more moral principles or competing moral claims
- moral distress:** conflict that arises within oneself when a person is aware of the correct course of action but institutional constraints stand in the way of pursuing the correct action
- moral problem:** competing moral claim or principle; one claim or principle is clearly dominant
- moral uncertainty:** conflict that arises within a person when he or she cannot accurately define what the moral situation is or what moral principles apply but has a strong feeling that something is not right
- morality:** the adherence to informal personal values
- nursing diagnoses:** actual or potential health problems that can be managed by independent nursing interventions
- nursing process:** a deliberate problem-solving approach for meeting people's health care and nursing needs; common components are assessment, diagnosis, planning, implementation, and evaluation
- planning:** development of goals and outcomes, as well as a plan of care designed to assist the patient in resolving the diagnosed problems and achieving the identified goals and desired outcomes
- teleologic theory or consequentialism:** the theoretical basis of ethics, which focuses on the ends or consequences of actions, such as utilitarianism
- utilitarianism:** a teleologic theory of ethics based on the concept of "the greatest good for the greatest number"

In today's health care arena, nurses face increasingly complex issues and situations resulting from advanced technology, greater acuity of patients in both hospital and community settings, an aging population, and complex disease processes, as well as ethical issues and cultural factors. The decision-making part of the problem-solving activities of nurses has become increasingly multifaceted and requires critical thinking.

Critical Thinking

Critical thinking is a multidimensional skill, a cognitive or mental process or set of procedures. It involves reasoning and purposeful, systematic, reflective, rational, outcome-directed thinking based on a body of knowledge, as well as examination and analysis of all available information and ideas. Critical thinking leads to the formulation of conclusions and alternatives that are the most appropriate for the situation. Although many definitions of critical thinking have been offered in various disciplines, some consistent themes within those definitions are (1) a strong formal and informal foundation of knowledge; (2) willingness to pursue or ask questions; and (3) ability to develop solutions that are new, even those that do not fit the standard or current state of knowledge or attitudes. Willingness and openness to various viewpoints are inherent in critical thinking, and it is also important to reflect on the current situation (Banning, 2006). Critical thinking includes metacognition, the examination of one's own reasoning or thought processes, to help refine thinking skills. Independent judgments and decisions evolve from a sound knowledge base and the ability to synthesize information within the context in which it is presented. Nursing practice in today's society requires the use of high-level critical thinking skills. Critical thinking enhances clinical decision making, helping to identify patient needs and the best nursing actions that will assist patients in meeting those needs.

As previously stated, critical thinking is a conscious, outcome-oriented activity. It is not erratic but rather is systematic and organized. Critical thinkers are inquisitive truth seekers who are open to the alternative solutions that might surface. Alfaro-LeFevre (2008) identified critical thinkers as people who ideally are active thinkers, fair minded, open minded, persistent, empathic, independent in thought, good communicators, honest, organized and systematic, proactive, flexible, realistic, humble, cognizant of the rules of logic, curious and insightful, and creative and committed to excellence. The skills involved in critical thinking are developed over time through effort, practice, and experience.

Rationality and Insight

Skills needed in critical thinking include interpretation, analysis, evaluation, inference, explanation, and self-regulation. Critical thinking requires background knowledge and knowledge of key concepts as well as logical thinking. Nurses use this disciplined process to validate the accuracy of data and the reliability of any assumptions they have made, and they then carefully evaluate the effectiveness of what they have identified as the necessary actions to take. Nurses also evaluate the reliability of sources, being mind-

ful of and questioning inconsistencies. Nurses use interpretation to determine the significance of data that are gathered, analysis to identify patient problems suggested by the data, and inference to draw conclusions. Explanation is the justification of actions or interventions used to address patient problems and to help patients move toward desired outcomes. Evaluation is the process of determining whether outcomes have been or are being met. Self-regulation is the process of examining the care provided and adjusting the interventions as needed.

Critical thinking is also reflective, involving metacognition, active evaluation, and refinement of the thinking process. Nurses engaged in critical thinking consider the possibility of personal bias when interpreting data and determining appropriate actions. Critical thinkers must be insightful and have a sense of fairness and integrity, the courage to question personal ethics, and the perseverance to strive continuously to minimize the effects of egocentricity, ethnocentricity, and other biases on the decision-making process (Alfaro-LeFevre, 2008).

Components of Critical Thinking

Certain cognitive or mental activities are key components of critical thinking. Critical thinkers:

- Ask questions to determine why certain developments have occurred and to see whether more information is needed to understand the situation accurately
- Gather as much relevant information as possible to consider as many factors as possible
- Validate the information presented to make sure that it is accurate (not just supposition or opinion), that it makes sense, and that it is based on fact and evidence
- Analyze the information to determine what it means and to see whether it forms clusters or patterns that point to certain conclusions
- Draw on past clinical experience and knowledge to explain what is happening and to anticipate what might happen next, acknowledging personal bias and cultural influences
- Maintain a flexible attitude that allows the facts to guide thinking and take into account all possibilities
- Consider available options and examine each in terms of its advantages and disadvantages
- Formulate decisions that reflect creativity and independent decision making

Critical thinking requires going beyond basic problem solving into a realm of inquisitive exploration, looking for all relevant factors that affect the issue, and being an "out-of-the-box" thinker. It includes questioning all findings until a comprehensive picture emerges that explains the phenomenon, possible solutions, and creative methods for proceeding (Wilkinson, 2007). Critical thinking in nursing practice results in a comprehensive plan of care with maximized potential for success.

Critical Thinking in Nursing Practice

Critical thinking and decision making are thought to be associated with improved clinical expertise. Critical thinking is at the center of the process of clinical reasoning and clinical judgment (Jackson, 2006). Using critical thinking to

develop a plan of nursing care requires considering the human factors that might influence the plan. Nurses interact with patients, families, and other health care providers in the process of providing appropriate, individualized nursing care. The culture, attitude, and thought processes of nurses, patients, and others affect the critical thinking process from the data-gathering stage through the decision-making stage; therefore, aspects of the nurse–patient interaction must be considered (Wilkinson, 2007).

Nurses must use critical thinking skills in all practice settings—acute care, ambulatory care, extended care, and the home and community. Regardless of the setting, each patient situation is viewed as unique and dynamic. Key components of critical thinking behavior are withholding judgment and being open to options and explanations from one patient to another in similar circumstances (Jackson, 2006). The unique factors that patients and nurses bring to the health care situation are considered, studied, analyzed, and interpreted. Interpretation of the information then allows nurses to focus on those factors that are most relevant and most significant to the clinical situation. Decisions about what to do and how to do it are then developed into a plan of action.

In decision making related to the nursing process, nurses use intellectual skills in critical thinking. These skills include systematic and comprehensive assessment, recognition of assumptions and inconsistencies, verification of reliability and accuracy, identification of missing information, distinguishing relevant from irrelevant information, support of the evidence with facts and conclusions, priority setting with timely decision making, determination of patient-specific outcomes, and reassessment of responses and out-

comes (Alfaro-LeFevre, 2008). For example, nurses use critical thinking and decision-making skills in providing genetics-related nursing care when they:

- Assess and analyze family history data for genetic risk factors
- Identify those individuals and families in need of referral for genetic testing or counseling
- Ensure the privacy and confidentiality of genetic information

To depict the process of “thinking like a nurse,” Tanner (2006) developed a model known as the clinical judgment model. This model supports the idea that nurses engage in a complex process of clinical reasoning when caring for patients. Nurses draw on personal knowledge and experience from a variety of situations and consider the contextual background of the clinical culture. As nursing students develop their clinical reasoning skills and become professional nurses, their ability to reason clinically and to make sound clinical nursing judgments becomes more refined.

Because developing the skill of critical thinking takes time and practice, critical thinking exercises are offered at the end of each chapter as a means of honing the reader’s ability to think critically. Some exercises include questions that stimulate the reader to seek information about evidence-based practice relative to the clinical situation described. Additional exercises may be found in the study guide that accompanies the text. The questions listed in Chart 3-1 can serve as a guide in working through the exercises. It is important to remember that each clinical situation is unique and calls for an individualized approach that fits its unique set of circumstances.

Chart 3-1 • *The Inquiring Mind: Critical Thinking in Action*

Throughout the critical thinking process, a continuous flow of questions evolves in the thinker’s mind. Although the questions will vary according to the particular clinical situation, certain general inquiries can serve as a basis for reaching conclusions and determining a course of action.

When faced with a patient situation, it is often helpful to seek answers to some or all of the following questions in an attempt to determine those actions that are most appropriate:

- What relevant assessment information do I need, and how do I interpret this information? What does this information tell me? What contextual factors must be considered when gathering this information?
- To what problems does this information point? Have I identified the most important ones? Does the information point to any other problems that I should consider?
- Have I gathered all the information I need (signs and symptoms, laboratory values, medication history, emotional factors, mental status)? Is anything missing?
- Is there anything that needs to be reported immediately? Do I need to seek additional assistance?
- Does this patient have any special risk factors? Which ones are most significant? What must I do to minimize these risks?
- What possible complications must I anticipate?
- What are the most important problems in this situation? Do the patient and the patient’s family recognize the same problems?
- What are the desired outcomes for this patient? Which have the highest priority? Do the patient and I agree on these points?
- What is going to be my first action in this situation?
- How can I construct a plan of care to achieve the goals?
- Are there any age-related factors involved, and will they require some special approach? Will I need to make some change in the plan of care to take these factors into account?
- How do the family dynamics affect this situation, and will they have an effect on my actions or the plan of care?
- Are there cultural factors that I must address and consider?
- Am I dealing with an ethical issue here? If so, how am I going to resolve it?
- Has any nursing research been conducted on this subject? What are the nursing implications of this research for care of this patient?

Ethical Nursing Care

In the complex modern world, we are surrounded by ethical issues in all facets of our lives. Consequently, there has been a heightened interest in the field of ethics in an attempt to gain a better understanding of how these issues influence us. Specifically, the focus on ethics in health care has intensified in response to controversial developments, including advances in technology and genetics, as well as diminished health care and financial resources.

Today, sophisticated technology can prolong life well beyond the time when death would have occurred in the past. Expensive experimental procedures, medications, equipment, and devices are available for attempting to preserve life, even when such attempts are likely to fail. The development of technologic support has influenced the quality and delivery of nursing care at all stages of life and also has contributed to an increase in average life expectancy. For example, the prenatal period has been influenced by genetic screening, in vitro fertilization, the harvesting and freezing of embryos, and prenatal surgery. Premature infants who once would have died early in life now may survive because of advances in technology. Children and adults who would have died of organ failure are living longer because of organ transplantation.

These advances in technology have been a mixed blessing. Questions have been raised about whether it is appropriate to use such technology, and if so, under what circumstances. Although many patients do achieve a better quality of life, others face extended suffering as a result of efforts to prolong life, usually at great expense. Ethical issues also surround those practices or policies that seem to allocate health care resources unjustly on the basis of age, race, gender, disability, or social mores.

The ethical dilemmas nurses may encounter in the medical-surgical nursing arena are numerous and diverse and occur in all settings. An awareness of underlying philosophical concepts helps nurses use reason to work through these dilemmas. Basic concepts related to moral philosophy, such as ethics and its terminology, theories, and approaches, are included in this chapter. Understanding the role of the professional nurse in ethical decision making helps nurses articulate their ethical positions and develop the skills needed to make ethical decisions.

Ethics Versus Morality

The terms *ethics* and *morality* are used to describe beliefs about right and wrong and to suggest appropriate guidelines for action. In essence, **ethics** is the formal, systematic study of moral beliefs, whereas **morality** is the adherence to informal personal values. Because the distinction between *ethics* and *morality* is slight, the two terms are often used interchangeably.

Ethics Theories

One classic theory in ethics is **teleologic theory or consequentialism**, which focuses on the ends or consequences of actions. The best-known form of this theory, **utilitarianism**, is based on the concept of “the greatest good for the greatest number.” The choice of action is clear under this theory,

because the action that maximizes good over bad is the correct one. The theory poses difficulty when one must judge intrinsic values and determine whose good is the greatest. In addition, it is important to ask whether good consequences can justify any amoral actions that might be used to achieve them.

Another theory in ethics is the **deontologic or formalist theory**, which argues that ethical standards or principles exist independently of the ends or consequences. In a given situation, one or more ethical principles may apply. Nurses have a duty to act based on the one relevant principle, or the most relevant of several ethical principles. Problems arise with this theory when personal and cultural biases influence the choice of the most primary ethical principle.

Approaches to Ethics

Two approaches to ethics are meta-ethics and applied ethics. An example of meta-ethics (understanding the concepts and linguistic terminology used in ethics) in the health care environment is analysis of the concept of informed consent. Nurses are aware that patients must give consent before surgery, but sometimes a question arises as to whether a patient is truly informed. Delving more deeply into the concept of informed consent would be a meta-ethical inquiry.

An example of applied ethics is when a specific discipline identifies ethical problems within that discipline’s practice. Various disciplines use the frameworks of general ethical theories and principles and apply them to specific problems within their domain. Common ethical principles that apply in nursing include autonomy, beneficence, confidentiality, double effect, fidelity, justice, nonmaleficence, paternalism, respect for people, sanctity of life, and veracity. Brief definitions of these important principles can be found in Chart 3-2.

Nursing ethics may be considered a form of applied ethics because it addresses moral situations that are specific to the nursing profession and patient care. Some ethical problems that affect nursing may also apply to the broader area of bioethics and health care ethics. Nursing has its own professional code of ethics.

Moral Situations

Many situations exist in which ethical analysis is needed. Some are **moral dilemmas**, situations in which a clear conflict exists between two or more moral principles or competing moral claims, and nurses must choose the lesser of two evils. Other situations represent **moral problems**, in which there may be competing moral claims or principles, but one claim or principle is clearly dominant. Some situations result in **moral uncertainty**, when one cannot accurately define what the moral situation is or what moral principles apply but has a strong feeling that something is not right. Still other situations may result in **moral distress**, in which one is aware of the correct course of action but constraints stand in the way of pursuing the correct action.

For example, a patient tells a nurse that if he is dying he wants all possible measures taken to save his life. However, the surgeon and family have made the decision not to tell the patient that he is terminally ill and not to resuscitate him if he stops breathing. From an ethical

Chart 3-2 • Common Ethical Principles

The following common ethical principles may be used to validate moral claims.

Autonomy

This word is derived from the Greek words *autos* ("self") and *nomos* ("rule" or "law"), and therefore refers to self-rule. In contemporary discourse it has broad meanings, including individual rights, privacy, and choice. Autonomy entails the ability to make a choice free from external constraints.

Beneficence

Beneficence is the duty to do good and the active promotion of benevolent acts (eg, goodness, kindness, charity). It may also include the injunction not to inflict harm (see nonmaleficence).

Confidentiality

Confidentiality relates to the concept of privacy. Information obtained from an individual will not be disclosed to another unless it will benefit the person or there is a direct threat to the social good.

Double Effect

This is a principle that may morally justify some actions that produce both good and evil effects.

All four of the following criteria must be fulfilled:

1. The action itself is good or morally neutral.
2. The agent sincerely intends the good and not the evil effect (the evil effect may be foreseen but is not intended).
3. The good effect is not achieved by means of the evil effect.
4. There is proportionate or favorable balance of good over evil.

Fidelity

Fidelity is promise keeping; the duty to be faithful to one's commitments. It includes both explicit and implicit promises to another person.

Justice

From a broad perspective, justice states that like cases should be treated alike. A more restricted version of justice is *distributive justice*, which refers to the distribution of social

benefits and burdens based on various criteria that may include the following:

- Equality
- Individual need
- Individual effort
- Societal contribution
- Individual merit
- Legal entitlement

Retributive justice is concerned with the distribution of punishment.

Nonmaleficence

This is the duty not to inflict harm as well as to prevent and remove harm. Nonmaleficence may be included within the principle of beneficence, in which case nonmaleficence would be more binding.

Paternalism

Paternalism is the intentional limitation of another's autonomy, justified by an appeal to beneficence or the welfare or needs of another. Under this principle, the prevention of evil or harm takes precedence over any potential evil caused by interference with the individual's autonomy or liberty.

Respect for Persons

Respect for persons is frequently used synonymously with *autonomy*. However, it goes beyond accepting the notion or attitude that people have autonomous choices, to treating others in such a way that enables them to make choices.

Sanctity of Life

This is the perspective that life is the highest good. Therefore, all forms of life, including mere biologic existence, should take precedence over external criteria for judging quality of life.

Veracity

Veracity is the obligation to tell the truth and not to lie or deceive others.

perspective, the patient should be told the truth about his diagnosis and should have the opportunity to make decisions about treatment. Ideally, this information should come from the physician, with the nurse present to assist the patient in understanding the terminology and to provide further support, if necessary. In this situation, a moral problem exists because of the competing moral claims of the family and physician, who wish to spare the patient distress, and the nurse, who wishes to be truthful with the patient. If the patient's competency were questionable, a moral dilemma would exist because no dominant principle would be evident. The nurse could experience moral distress if the hospital threatened disciplinary action or job termination because the information is disclosed to the patient without the agreement of the physician or the family, or both.

It is essential that nurses freely engage in dialogue concerning moral situations, even though such dialogue is difficult for everyone involved. Improved interdisciplinary communication is supported when all members of the health care team can voice their concerns and come to an understanding of the moral situation. The use of an ethics consultant or consultation team could be helpful to assist the health care team, patient, and family to identify the moral dilemma and possible approaches to the dilemma. Nurses should be familiar with agency policy supporting patient self-determination and resolution of ethical issues.

Types of Ethical Problems in Nursing

As a profession, nursing is accountable to society. This accountability is spelled out in the American Hospital

Association's Patient Care Partnership, which reflects social beliefs about health and health care. In addition to accepting this document as one measure of accountability, nursing has further defined its standards of accountability through a formal code of ethics that explicitly states the profession's values and goals. The code (Chart 3-3), established by the American Nurses Association (ANA), consists of ethical standards, each with its own interpretive statements (ANA, 2001). The interpretive statements provide guidance to address and resolve ethical dilemmas by incorporating universal moral principles. The code is an ideal framework for nurses to use in ethical decision making.

Ethical issues have always affected the role of professional nurses. The accepted definition of professional nursing supports the advocacy role for nurses. The ANA, in *Nursing's Social Policy Statement* (2003, p. 6), defines nursing as "the protection, promotion, and optimization of health and abilities, prevention of illness and injury, alleviation of suffering through the diagnosis and treatment of human response, and advocacy in the care of individuals, families, communities, and populations." This definition supports the claim that nurses must be actively involved in the decision-making process regarding ethical concerns surrounding health care and human responses. Efforts to enact this standard may cause conflict in health care settings in which the traditional roles of nurses are delineated within a bureaucratic structure. However, if nurses learn to present ethical conflicts within a logical, systematic framework, struggles over jurisdictional boundaries may decrease. Health care settings in which nurses are valued members of the team promote interdisciplinary communication and may enhance patient care. To practice effectively in these settings, nurses must be aware of ethical issues and assist patients in voicing their moral concerns.

Nursing theories that incorporate the biopsychosocial-spiritual dimensions emphasize a holistic viewpoint, with humanism or caring at the core. As the nursing profession strives to delineate its own theory of ethics, caring is often cited as the moral foundation. For nurses to embrace this professional ethos, they must be aware not only of major ethical dilemmas, but also of those daily interactions with health care consumers that frequently give rise to less easily identifiable ethical challenges. Although technologic advances and diminished resources have been instrumental in raising numerous ethical questions and controversies, including life-and-death issues, nurses should not ignore the many routine situations that involve ethical considerations. Some of the most common issues faced by nurses today include confidentiality, use of restraints, trust, refusing care, and end-of-life concerns.

Confidentiality

All nurses should be aware of the confidential nature of information obtained in daily practice. If information is not pertinent, they should question whether it is prudent to document it in a patient's record. In the practice setting, discussion of patients with other members of the health care team is often necessary. However, these discussions should occur in a private area where it is unlikely that the conversation will be overheard. Nurses should also be aware that the use of family members as interpreters for patients who are not fluent in the English language or who are deaf violates patients' rights of confidentiality. Translation services should be provided for non-English-speaking patients and interpreters should be provided for those who use sign language.

Another threat to confidentiality is the widespread use of computer-based technologies and people's easy access to them. The growing demand for tele-health innovations and the increasing use of this new method can result in unchecked access to health information. In addition, personal

Chart 3-3 • American Nurses Association Code of Ethics for Nurses

1. The nurse, in all professional relationships, practices with compassion and respect for the inherent dignity, worth, and uniqueness of every individual, unrestricted by considerations of social or economic status, personal attributes, or the nature of health problems.
2. The nurse's primary commitment is to the patient, whether an individual, family, group, or community.
3. The nurse promotes, advocates for, and strives to protect the health, safety, and rights of the patient.
4. The nurse is responsible and accountable for individual nursing practice and determines the appropriate delegation of tasks consistent with the nurse's obligation to provide optimum patient care.
5. The nurse owes the same duties to self as to others, including the responsibility to preserve integrity and safety, to maintain competence, and to continue personal and professional growth.
6. The nurse participates in establishing, maintaining, and improving health care environments and conditions of employment conducive to the provision of quality health care and consistent with the values of the profession through individual and collective action.
7. The nurse participates in the advancement of the profession through contributions to practice, education, administration, and knowledge development.
8. The nurse collaborates with other health professionals and the public in promoting community, national, and international efforts to meet health needs.
9. The profession of nursing, as represented by associations and their members, is responsible for articulating nursing values, for maintaining the integrity of the profession and its practice, and for shaping social policy.

and health information is often made available to numerous individuals and corporate stakeholders, which may increase the potential for misuse of health care information. Because of these possibilities of maleficence (see Chart 3-2), sensitivity to the principle of confidentiality is essential. Federal legislation has been developed to protect the right of confidentiality. According to the Health Insurance Portability and Accountability Act (HIPAA) (U.S. Department of Health and Human Services [USDHHS], 2003), efforts must be made to protect each patient's private information, whether it is transmitted by verbal, written, or electronic means of communication. Communication should be confined to the appropriate settings and with appropriate individuals, and occur for the appropriate purposes of facilitating patient care. Violations of protection of any patient's privacy could result in criminal or civil litigation (USDHHS, 2007).

Restraints

The use of restraints (including physical and pharmacologic measures) is another issue with ethical overtones because of the perception of imprisonment when restraints are used. It is important to weigh carefully the risks of limiting a person's autonomy and increasing the risk of injury by using restraints against the risks of not using restraints; they have been documented as resulting in physical harm and death. Before restraints are used, other strategies, such as asking family members to sit with the patient or utilizing a specially trained sitter, should be tried. The Joint Commission (formerly the Joint Commission on Accreditation of Healthcare Organizations [JCAHO]) and the Centers for Medicare and Medicaid Services (CMS) have designated standards for use of restraints; these standards are available on the Web site listed at the end of this chapter.

Trust Issues

Telling the truth (veracity) is one of the basic principles of our culture. Three ethical dilemmas in clinical practice that can directly conflict with this principle are the use of placebos (nonactive substances used for treatment), not revealing a diagnosis to a patient, and revealing a diagnosis to people other than the patient with the diagnosis. All involve the issue of trust, which is an essential element in the nurse-patient relationship.

Placebos may be used in experimental research, in which a patient is involved in the decision-making process and is aware that placebos are being used in the treatment regimen. However, the use of a placebo as a substitute for an active drug to show that a patient does not have actual symptoms of a disease is deceptive, and this practice may severely undermine the nurse-patient relationship.

Informing a patient of his or her diagnosis when the family and physician have chosen to withhold information is a common ethical situation in nursing practice. The nursing staff may often use evasive comments with the patient as a means of maintaining professional relationships with other health practitioners. This area is indeed complex, because it challenges a nurse's integrity. Strategies nurses could consider include the following:

- Not lying to the patient
- Providing all information related to nursing procedures and diagnoses

- Communicating the patient's requests for information to the family and physician. The family is often unaware of the patient's repeated questions to the nurse. With a better understanding of the situation, the family members may change their perspective

Although providing the information may be the morally appropriate behavior, the manner in which the patient is told is important. Nurses must be compassionate and caring while informing patients; disclosure of information merely for the sake of patient autonomy does not convey respect for others.

Disclosing the patient's diagnosis to others without the patient's consent is a HIPAA violation and, therefore, is not only unethical, but also illegal.

Refusing to Provide Care

Any nurse who feels compelled to refuse to provide care for a particular type of patient faces an ethical dilemma. The reasons given for refusal range from a conflict of personal values to fear of personal injury. Feelings related to care of people of different cultures also surface as changes emerge in the cultural makeup of the U.S. population. For example, a highly publicized case in 2007 involved a Latina patient who died after she hemorrhaged in the emergency department of an urban California hospital (MSNBC News, June 13, 2007). The ethical dilemmas surrounding this case relative to lack of care of the patient put many health care personnel, including nurses, under close scrutiny. The ethical obligation to care for all patients is clearly identified in the first statement of the *Code of Ethics for Nurses* (ANA, 2001). To avoid facing ethical dilemmas, nurses can follow certain strategies. For example, when applying for a job, a nurse should ask questions regarding the patient population. If a nurse is uncomfortable with a particular situation, then not accepting the position would be an option. Denial of care, or providing substandard nursing care to some members of society, is not acceptable nursing practice.

End-of-Life Issues

Dilemmas that center on death and dying are prevalent in medical-surgical nursing practice and frequently initiate discussion. With the availability of increasingly sophisticated and advanced technology, it may be difficult to accept that nothing more can be done to prolong life or that technology may prolong life but at the expense of the patient's comfort and quality of life. Nurses are being faced with increasingly controversial dilemmas concerning patients' desires to avoid prolongation of life. Many people who are terminally ill seek legal options for a peaceful and dignified death.

End-of-life issues shift the focus from curative care to palliative and end-of-life care. Focusing on the caring as well as the curing role may help nurses deal with these difficult moral situations. Needs of patients and families require holistic and interdisciplinary approaches. End-of-life issues that often involve ethical dilemmas include pain control, "do not resuscitate" orders, life support measures, and administration of food and fluids. These are discussed in detail in Chapter 17.

Preventive Ethics

When a nurse is faced with two conflicting alternatives, it is his or her moral decision to choose the lesser of the

two evils. Various preventive strategies are available to help nurses anticipate or avoid certain kinds of ethical dilemmas.

Frequently, dilemmas occur when health care practitioners are unsure of the patient's wishes because the patient is unconscious or too cognitively impaired to communicate directly. The Patient Self-Determination Act, enacted in December 1991, encourages people to prepare advance directives in which they indicate their wishes concerning the degree of supportive care they wish if they become incapacitated. This legislation requires that patients be informed about advance directives by the staff of the health care facility.

In 2005, the highly publicized case of Terri Schiavo focused national attention on the importance of advance directives. Schiavo was a young woman who suffered severe brain damage in 1990 after her heart stopped because of a chemical imbalance that was believed to have been caused by an eating disorder. Court-appointed physicians ruled she was in a persistent vegetative state with no chance of recovery. She left no living will or advance directive. Her husband requested that her feeding tube be removed to allow her to die, but her parents opposed this for 7 years. They involved the courts, Congress, and the president. After the courts ruled that her feeding tube could be removed, Terri Schiavo died in 2005. This case represents an area in which nurses can play a significant role in patient education about the significance of advance directives.

Advance Directives

Advance directives are legal documents that specify a person's wishes before hospitalization and provide valuable information that may assist health care providers in decision making. A living will is one type of advance directive. In most situations, living wills are limited to situations in which the patient's medical condition is deemed terminal. Because it is difficult to define "terminal" accurately, living wills are not always honored. Another potential drawback is that living wills are frequently written while people are in good health. It is not unusual for people to change their minds as an illness progresses; therefore, patients retain the option to nullify these documents.

Durable power of attorney for health care, in which one person identifies another person to make health care decisions on his or her behalf, is another type of advance directive. Patients may have clarified their wishes concerning a variety of medical situations. The power of attorney for health care is a less restrictive type of advance directive. Laws concerning advance directives vary among state jurisdictions. However, even in states where these documents are not legally binding, they provide helpful information to determine the patient's prior expressed wishes in situations in which this information can no longer be obtained. (See Chapter 17 for further discussion of end-of-life care.)

Ethics Committees

Institutional ethics committees exist in many hospitals to assist clinicians with ethical dilemmas. The purpose of these multidisciplinary committees varies among institutions. In some hospitals, the committees exist solely for the purpose

of developing policies, whereas in others, they may have a strong educational or consultation focus. These committees usually are composed of people with some advanced training in ethics and are important resources for the health care team, patient, and family. Nurses with a particular interest or expertise in the area of ethics can serve as members of these committees, which are valuable resources for staff nurses.

The heightened interest in ethical decision making has resulted in many continuing education programs, ranging from small seminars or workshops to full-semester courses offered by local colleges or professional organizations. In addition, nursing and medical journals contain articles on ethical issues, and numerous textbooks on clinical ethics or nursing ethics are available. The resources listed at the end of this chapter are valuable because they discuss ethical theory and dilemmas of practice in greater depth.

Ethical Decision Making

As noted in the preceding discussions, ethical dilemmas are common and diverse in nursing practice. Situations vary, and experience indicates that there are no clear solutions to these dilemmas. However, the fundamental philosophical principles are the same, and the process of moral reflection helps nurses justify their actions. The approach to ethical decision making can follow the steps of the nursing process. Chart 3-4 outlines the steps of an ethical analysis.

The Nursing Process

Definition

The **nursing process** is a deliberate problem-solving approach for meeting people's health care and nursing needs. Although the steps of the nursing process have been stated in various ways by different writers, the common components cited are assessment, diagnosis, planning, implementation, and evaluation. ANA's *Standards of Clinical Nursing Practice* (2004) includes an additional component entitled outcome identification and establishes the sequence of steps in the following order: **assessment**, diagnosis, outcome identification, **planning**, **implementation**, and **evaluation**. For the purposes of this text, the nursing process is based on the traditional five steps and delineates two components in the diagnosis step: **nursing diagnoses** and **collaborative problems**. After the diagnoses or problems have been determined, the desired outcomes are often evident. The traditional steps are defined as follows:

1. **Assessment**: The systematic collection of data to determine the patient's health status and any actual or potential health problems. (Analysis of data is included as part of the assessment. Analysis may also be identified as a separate step of the nursing process.)
2. **Diagnosis**: Identification of the following two types of patient problems:
 - **Nursing diagnoses**: Actual or potential health problems that can be managed by independent nursing interventions
 - **Collaborative problems**: "Certain physiologic complications that nurses monitor to detect onset or

Chart 3-4 • Steps of an Ethical Analysis

The following are guidelines to assist nurses in ethical decision making. These guidelines reflect an active process in decision making, similar to the nursing process detailed in this chapter.

Assessment

1. Assess the ethical/moral situations of the problem. This step entails recognition of the ethical, legal, and professional dimensions involved.
 - a. Does the situation entail substantive moral problems (conflicts among ethical principles or professional obligations)?
 - b. Are there procedural conflicts? (For example, who should make the decisions? Any conflicts among the patient, health care providers, family and guardians?)
 - c. Identify the significant people involved and those affected by the decision.

Planning

2. Collect information.
 - a. Include the following information: the medical facts, treatment options, nursing diagnoses, legal data, and the values, beliefs, and religious components.
 - b. Make a distinction between the factual information and the values/beliefs.
 - c. Validate the patient's capacity, or lack of capacity, to make decisions.

- d. Identify any other relevant information that should be elicited.
- e. Identify the ethical/moral issues and the competing claims.

Implementation

3. List the alternatives. Compare alternatives with applicable ethical principles and professional code of ethics. Choose either of the frameworks below, or other frameworks, and compare outcomes.
 - a. *Utilitarian approach*: Predict the consequences of the alternatives; assign a positive or negative value to each consequence; choose the consequence that predicts the highest positive value or "the greatest good for the greatest number."
 - b. *Deontologic approach*: Identify the relevant moral principles; compare alternatives with moral principles; appeal to the "higher-level" moral principle if there is a conflict.

Evaluation

4. Decide and evaluate the decision.
 - a. What is the best or morally correct action?
 - b. Give the ethical reasons for your decision.
 - c. What are the ethical reasons against your decision?
 - d. How do you respond to the reasons against your decision?

changes in status. Nurses manage collaborative problems using physician-prescribed and nurse-prescribed interventions to minimize the complications of the events" (Carpenito-Moyet, 2008 pg. 19).

3. *Planning*: Development of goals and outcomes, as well as a plan of care designed to assist the patient in resolving the diagnosed problems and achieving the identified goals and desired outcomes
4. *Implementation*: Actualization of the plan of care through nursing interventions
5. *Evaluation*: Determination of the patient's responses to the nursing interventions and the extent to which the outcomes have been achieved

Dividing the nursing process into distinct steps serves to emphasize the essential nursing actions that must be taken to address the patient's nursing diagnoses and manage any collaborative problems or complications. However, dividing the process into separate steps is artificial: The process functions as an integrated whole, with the steps being interrelated, interdependent, and recurrent (Fig. 3-1). Chart 3-5 presents an overview of the nursing activities involved in applying the nursing process.

Using the Nursing Process

Assessment

Assessment data are gathered through the health history and the physical assessment. In addition, ongoing monitoring is crucial to remain aware of changing patient needs and the effectiveness of nursing care.

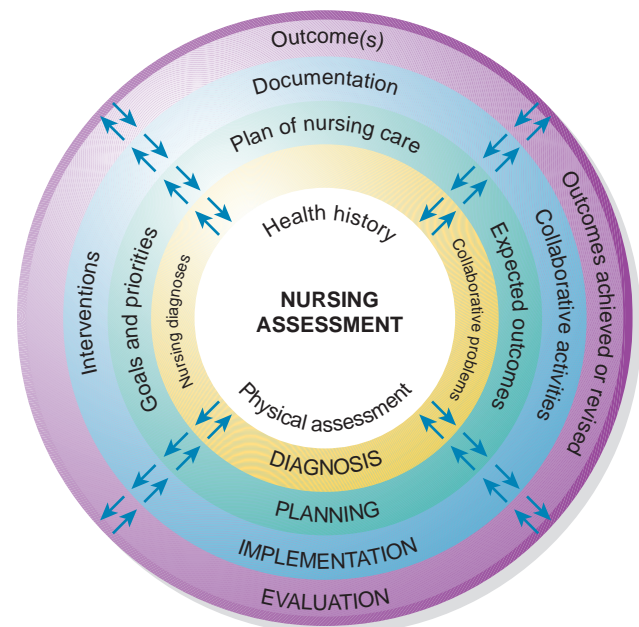

Figure 3-1 The nursing process is depicted schematically in this circle. Starting from the innermost circle, nursing assessment, the process moves outward through the formulation of nursing diagnoses and collaborative problems; planning, with setting of goals and priorities in the nursing plan of care; implementation and documentation; and, finally, the ongoing process of evaluation and outcomes.

Chart 3-5 • Steps of the Nursing Process**Assessment**

1. Conduct the health history.
2. Perform the physical assessment.
3. Interview the patient's family or significant others.
4. Study the health record.
5. Organize, analyze, synthesize, and summarize the collected data.

Diagnosis**Nursing Diagnosis**

1. Identify the patient's nursing problems.
2. Identify the defining characteristics of the nursing problems.
3. Identify the etiology of the nursing problems.
4. State nursing diagnoses concisely and precisely.

Collaborative Problems

1. Identify potential problems or complications that require collaborative interventions.
2. Identify health team members with whom collaboration is essential.

Planning

1. Assign priority to the nursing diagnoses.
2. Specify the goals.
 - a. Develop immediate, intermediate, and long-term goals.
 - b. State the goals in realistic and measurable terms.
3. Identify nursing interventions appropriate for goal attainment.
4. Establish expected outcomes.
 - a. Make sure that the outcomes are realistic and measurable.
 - b. Identify critical times for the attainment of outcomes.

5. Develop the written plan of nursing care.
 - a. Include nursing diagnoses, goals, nursing interventions, expected outcomes, and critical times.
 - b. Write all entries precisely, concisely, and systematically.
 - c. Keep the plan current and flexible to meet the patient's changing problems and needs.
6. Involve the patient, family or significant others, nursing team members, and other health team members in all aspects of planning.

Implementation

1. Put the plan of nursing care into action.
2. Coordinate the activities of the patient, family or significant others, nursing team members, and other health team members.
3. Record the patient's responses to the nursing actions.

Evaluation

1. Collect data.
2. Compare the patient's actual outcomes with the expected outcomes. Determine the extent to which the expected outcomes were achieved.
3. Include the patient, family or significant others, nursing team members, and other health care team members in the evaluation.
4. Identify alterations that need to be made in the nursing diagnoses, collaborative problems, goals, nursing interventions, and expected outcomes.
5. Continue all steps of the nursing process: assessment, diagnosis, planning, implementation, and evaluation.

Health History

The health history is conducted to determine a person's state of wellness or illness and is best accomplished as part of a planned interview. The interview is a personal dialogue between a patient and a nurse that is conducted to obtain information. The nurse's approach to the patient largely determines the amount and quality of the information that is received. To achieve a relationship of mutual trust and respect, the nurse must have the ability to communicate a sincere interest in the patient. Examples of effective therapeutic communication techniques that can be used to achieve this goal are found in Table 3-1.

The use of a health history guide may help in obtaining pertinent information and in directing the course of the interview. A variety of health history formats designed to guide the interview are available, but they must be adapted to the responses, problems, and needs of the person. See Chapter 5 for further information about the health history.

Physical Assessment

A physical assessment may be carried out before, during, or after the health history, depending on a patient's physical and emotional status and the immediate priorities of the sit-

uation. The purpose of the physical assessment is to identify those aspects of a patient's physical, psychological, and emotional state that indicate a need for nursing care. It requires the use of sight, hearing, touch, and smell, as well as appropriate interview skills and techniques. Physical examination techniques as well as techniques and strategies for assessing behaviors and role changes are presented in Chapters 5 and 7 and in each unit of this book.

Other Components of the Assessment

Additional relevant information should be obtained from the patient's family or significant others, from other members of the health team, and from the patient's health record or chart. Depending on the patient's immediate needs, this information may have been completed before the health history and the physical assessment were obtained. Whatever the sequence of events, it is important to use all available sources of pertinent data to complete the nursing assessment.

Recording the Data

After the health history and physical assessment are completed, the information obtained is recorded in the patient's permanent record. This record provides a means of

Technique	Definition	Therapeutic Value
Listening	Active process of receiving information and examining one's reactions to the messages received	Nonverbally communicates nurse's interest in patient
Silence	Periods of no verbal communication among participants for therapeutic reasons	Gives patient time to think and gain insights, slows the pace of the interaction, and encourages the patient to initiate conversation, while conveying the nurse's support, understanding, and acceptance
Restating	Repeating to the patient what the nurse believes is the main thought or idea expressed	Demonstrates that the nurse is listening and validates, reinforces, or calls attention to something important that has been said
Reflection	Directing back to the patient his or her feelings, ideas, questions, or content	Validates the nurse's understanding of what the patient is saying and signifies empathy, interest, and respect for the patient
Clarification	Asking the patient to explain what he or she means or attempting to verbalize vague ideas or unclear thoughts of the patient to enhance the nurse's understanding	Helps to clarify the patient's feelings, ideas, and perceptions and to provide an explicit correlation between them and the patient's actions
Focusing	Questions or statements to help the patient develop or expand an idea	Allows the patient to discuss central issues and keeps communication goal-directed
Broad openings	Encouraging the patient to select topics for discussion	Indicates acceptance by the nurse and the value of the patient's initiative
Humor	Discharge of energy through the comic enjoyment of the imperfect	Promotes insight by bringing repressed material to consciousness, resolving paradoxes, tempering aggression, and revealing new options; a socially acceptable form of sublimation
Informing	Providing information	Helpful in health teaching or patient education about relevant aspects of patient's well-being and self-care
Sharing perceptions	Asking the patient to verify the nurse's understanding of what the patient is thinking or feeling	Conveys the nurse's understanding to the patient and has the potential to clarify confusing communication
Theme identification	Underlying issues or problems experienced by the patient that emerge repeatedly during the course of the nurse-patient relationship	Allows the nurse to best promote the patient's exploration and understanding of important problems
Suggesting	Presentation of alternative ideas for the patient's consideration relative to problem solving	Increases the patient's perceived options or choices

Adapted from Stuart, G. W. & Laraia, M. T. (2005). *Principles and practice of psychiatric nursing* (8th ed.). St Louis: CV Mosby.

communication among members of the health care team and facilitates coordinated planning and continuity of care. The record fulfills other functions as well:

- It serves as the legal and business record for a health care agency and for the professional staff members who are responsible for the patient's care. A variety of systems are used for documenting patient care, and each health care agency selects the system that best meets its needs.
- It serves as a basis for evaluating the quality and appropriateness of care and for reviewing the effective use of patient care services.
- It provides data that are useful in research, education, and short- and long-range planning.

Diagnosis

The assessment component of the nursing process serves as the basis for identifying nursing diagnoses and collaborative problems. Soon after the completion of the health history and the physical assessment, nurses organize, analyze, synthesize, and summarize the data collected and determine the patient's need for nursing care.

Nursing Diagnosis

Nursing diagnoses, the first taxonomy created in nursing, have fostered autonomy and accountability in nursing and have helped delineate the scope of practice. Many state nurse practice acts include nursing diagnosis as a nursing function, and nursing diagnosis is included in the ANA's *Standards of Clinical Nursing Practice* (ANA, 2004) and the standards of nursing specialty organizations.

North American Nursing Diagnosis Association (NANDA) International is the official organization responsible for developing the taxonomy of nursing diagnoses and formulating nursing diagnoses acceptable for study. Approved nursing diagnoses are compiled and categorized by NANDA International in a taxonomy that is updated to maintain currency. The diagnostic labels identified by NANDA International (2008) have been generally accepted, but ongoing validation, refinement, and expansion based on clinical use and research are encouraged. They are not yet complete or mutually exclusive, and more research is needed to determine their validity and clinical applicability.

Choosing a Nursing Diagnosis

When choosing the nursing diagnoses for a particular patient, nurses must first identify the commonalities among the assessment data collected. These common features lead to the categorization of related data that reveal the existence of a problem and the need for nursing intervention. The identified problems are then defined as specific nursing diagnoses. Nursing diagnoses represent actual or potential health problems that can be managed by independent nursing actions.

It is important to remember that nursing diagnoses are not medical diagnoses; they are not medical treatments prescribed by the physician, and they are not diagnostic studies. Rather, they are succinct statements in terms of specific patient problems that guide nurses in the development of the nursing plan of care.

To give additional meaning to the nursing diagnosis, the characteristics and the etiology of the problem are identified and included as part of the diagnosis. For example, the nursing diagnoses and their defining characteristics and etiology for a patient who has anemia may include the following:

- Activity intolerance related to weakness and fatigue
- Ineffective tissue perfusion related to inadequate blood volume
- Imbalanced nutrition: Less than body requirements related to fatigue and inadequate intake of essential nutrients

Collaborative Problems

In addition to nursing diagnoses and their related nursing interventions, nursing practice involves certain situations and interventions that do not fall within the definition of nursing diagnoses. These activities pertain to potential problems or complications that are medical in origin and require collaborative interventions with the physician and other members of the health care team. The term *collaborative problem* is used to identify these situations.

Collaborative problems are certain physiologic complications that nurses monitor to detect changes in status or onset of complications. Nurses manage collaborative problems using physician-prescribed and nurse-prescribed interventions to minimize complications (Carpenito-Moyet, 2008). When treating collaborative problems, a primary nursing focus is monitoring patients for the onset of complications or changes in the status of existing complications. The complications are usually related to the disease process, treatments, medications, or diagnostic studies. The nurse recommends nursing interventions that are appropriate for managing the complications and implements the treatments prescribed by the physician. The algorithm in Figure 3-2 depicts the differences between nursing diagnoses and collaborative problems. After the nursing diagnoses and collaborative problems have been identified, they are recorded on the plan of nursing care.

Planning

Once the nursing diagnoses have been identified, the planning component of the nursing process begins. This phase involves the following steps:

1. Assigning priorities to the nursing diagnoses and collaborative problems

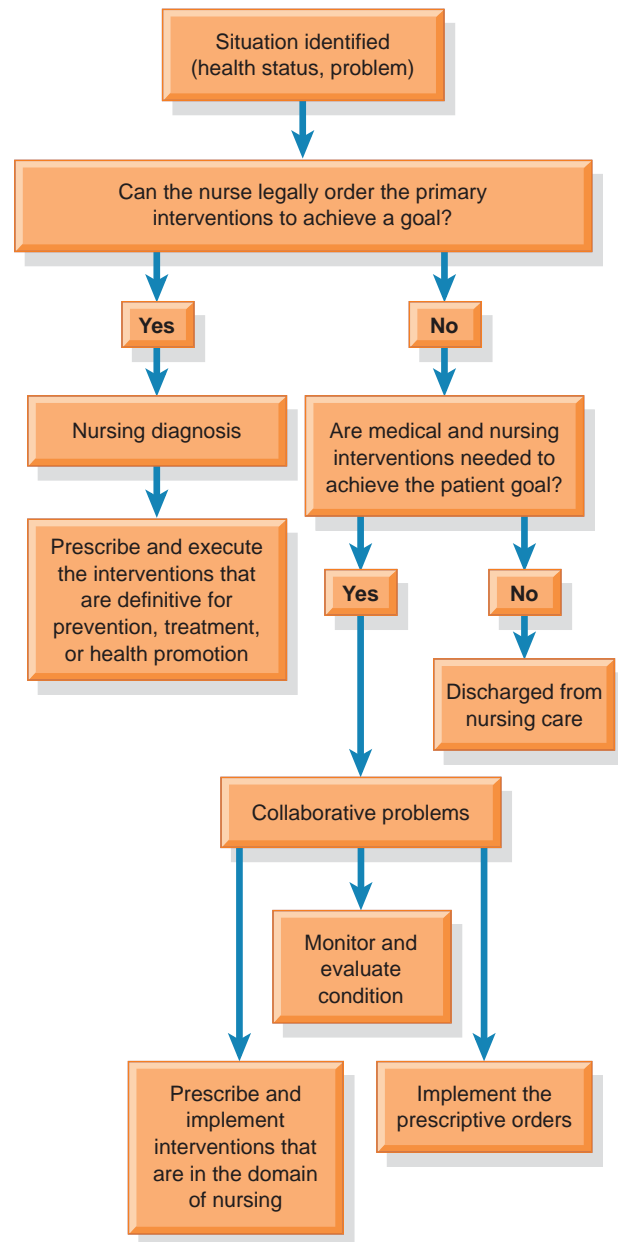

Figure 3-2 Differentiating nursing diagnoses and collaborative problems. Redrawn from Carpenito-Moyet, L. J. (2008). *Nursing diagnosis: Application to clinical practice* (12th ed., p. 28). Philadelphia: Lippincott Williams & Wilkins.

2. Specifying expected outcomes
3. Specifying the immediate, intermediate, and long-term goals of nursing action
4. Identifying specific nursing interventions appropriate for attaining the outcomes
5. Identifying interdependent interventions
6. Documenting the nursing diagnoses, collaborative problems, expected outcomes, nursing goals, and nursing interventions on the plan of nursing care
7. Communicating to appropriate personnel any assessment data that point to health care needs that can

best be met by other members of the health care team

Setting Priorities

Assigning priorities to the nursing diagnoses and collaborative problems is a joint effort by the nurse and the patient or family members. Any disagreement about priorities is resolved in a way that is mutually acceptable. Consideration must be given to the urgency of the problems, with the most critical problems receiving the highest priority. The Maslow hierarchy of needs provides one framework for prioritizing problems, with importance being given first to physical needs; once those basic needs are met, higher-level needs can be addressed. See Chapter 1 for a further discussion of the Maslow hierarchy.

Establishing Expected Outcomes

Expected outcomes of the nursing interventions are expressed in terms of the patient’s behaviors and the time period in which the outcomes are to be achieved, as well as any special circumstances related to achieving the outcome (Smith-Temple & Johnson, 2005). These outcomes must be realistic and measurable. Resources for identifying appropriate expected outcomes include the Nursing-Sensitive Outcomes Classification (NOC) (Chart 3-6) and standard outcome criteria established by health care agencies for people with specific health problems. These outcomes can be associated with nursing diagnoses and interventions and can be used when appropriate. However, the NOC may need to be adapted to establish realistic criteria for the specific patient involved.

Chart 3-6 • Nursing-Sensitive Outcomes Classification (NOC)

The NOC is a classification of patient outcomes sensitive to nursing interventions. Each outcome is a neutral statement about a variable patient condition, behavior, or perception, coupled with a rating scale. The outcome statement and scale can be used to identify baseline functioning, expected outcomes, and actual outcomes for individual patients. The following table is an example of a nursing-sensitive outcome.

Respiratory Status: Gas Exchange (0402)

Domain—Physiologic Health (II)
Class—Cardiopulmonary (E)
Scale(s)—Severe deviation from normal range to No deviation from normal range (b) and Severe to None (n)
Definition: Alveolar exchange of carbon dioxide and oxygen to maintain arterial blood gas concentrations.

OUTCOME TARGET RATING Maintain at ____ Increase to ____

Respiratory Status:		Severe	Substantial	Moderate	Mild	No	
Gas Exchange		Deviation from Normal Range	Deviation from Normal Range	Deviation from Normal Range	Deviation from Normal Range	Deviation from Normal Range	
Overall Rating		1	2	3	4	5	
Indicators							
040208	Partial pressure of oxygen in arterial blood (PaO ₂)	1	2	3	4	5	NA
040209	Partial pressure of carbon dioxide in arterial blood (PaCO ₂)	1	2	3	4	5	NA
040210	Arterial pH	1	2	3	4	5	NA
040211	Oxygen saturation	1	2	3	4	5	NA
040212	End-tidal carbon dioxide	1	2	3	4	5	NA
040213	Chest x-ray findings	1	2	3	4	5	NA
040214	Ventilation–perfusion balance	1	2	3	4	5	NA
		Severe	Substantial	Moderate	Mild	None	
040203	Dyspnea at rest	1	2	3	4	5	NA
040204	Dyspnea with mild exertion	1	2	3	4	5	NA
040205	Restlessness	1	2	3	4	5	NA
040206	Cyanosis	1	2	3	4	5	NA
040207	Somnolence	1	2	3	4	5	NA
040216	Impaired cognition	1	2	3	4	5	NA

With permission from Moorhead, S., Johnson, M., Maas, M. L., et al. (Eds.). (2008). *Nursing outcomes classification (NOC)* (4th ed.). St. Louis: Mosby–Elsevier.

The expected outcomes that define the desired behavior of the patient are used to measure the progress made toward resolving the problem. The expected outcomes also serve as the basis for evaluating the effectiveness of the nursing interventions and for deciding whether additional nursing care is needed or whether the plan of care needs to be revised.

Establishing Goals

After the priorities of the nursing diagnoses and expected outcomes have been established, goals (immediate, intermediate, and long-term) and the nursing actions appropriate for attaining the goals are identified. The patient and family are included in establishing goals for the nursing actions. Immediate goals are those that can be attained within a short period. Intermediate and long-term goals require a longer time to be achieved and usually involve preventing complications and other health problems and promoting self-care and rehabilitation. For example, goals for a patient with a nursing diagnosis of impaired physical mobility related to pain and edema following total knee replacement may be stated as follows:

- Immediate goal: Stands at bedside for 5 minutes 6 to 12 hours after surgery
- Intermediate goal: Ambulates with walker or crutches in hospital and home
- Long-term goal: Ambulates independently 1 to 2 miles each day

Determining Nursing Actions

In planning appropriate nursing actions to achieve the desired goals and outcomes, the nurse, with input from the pa-

tient and significant others, identifies individualized interventions based on the patient's circumstances and preferences that address each outcome. Interventions should identify the activities needed and who will implement them. Determination of interdisciplinary activities is made in collaboration with other health care providers as needed.

The nurse identifies and plans patient teaching and demonstration as needed to assist the patient in learning certain self-care activities. Planned interventions should be ethical and appropriate to the patient's culture, age, and gender. Standardized interventions, such as those found on institutional care plans or in the Nursing Interventions Classification (NIC) (Bulechek, Butcher & Dochterman, 2008) can be used. Chart 3-7 describes the NIC system and provides an example of an NIC system intervention. It is important to individualize prewritten interventions to promote optimal effectiveness for each patient. Actions of nurses should be based on established standards.

Implementation

The implementation phase of the nursing process involves carrying out the proposed plan of nursing care. The nurse assumes responsibility for the implementation and coordinates the activities of all those involved in implementation, including the patient and family, other members of the nursing team, and other members of the health care team, so that the schedule of activities facilitates the patient's recovery. The plan of nursing care serves as the basis for implementation, as described below:

- The immediate, intermediate, and long-term goals are used as a focus for the implementation of the designated nursing interventions.

Chart 3-7 • Nursing Interventions Classification (NIC)

The NIC is a standardized classification of nursing treatments (interventions) that includes independent and collaborative interventions. Intervention labels are terms such as hemorrhage control, medication administration, or pain management. Listed under each intervention are multiple discrete nursing actions that together constitute a comprehensive approach to the treatment of a particular condition. Not all actions are applicable to every patient; nursing judgment will determine which actions to implement. The following is an example of a nursing intervention:

Ventilation Assistance

Definition

Promotion of an optimal spontaneous breathing pattern that maximizes oxygen and carbon dioxide exchange in the lungs

Activities

Maintain a patent airway.
Position to alleviate dyspnea.
Position to facilitate ventilation-perfusion matching ("good lung down"), as appropriate.
Assist with frequent position changes, as appropriate.

Position to minimize respiratory efforts (eg, elevate the head of the bed and provide overbed table for patient to lean on).
Monitor the effects of position change on oxygenation (eg, arterial blood gases, SaO₂, SvO₂).
Encourage slow deep breathing, turning, and coughing.
Assist with incentive spirometer, as appropriate.
Auscultate breath sounds, noting areas of decreased or absent ventilation and presence of adventitious sounds.
Monitor for respiratory muscle fatigue.
Initiate and maintain supplemental oxygen, as prescribed.
Administer appropriate pain medication to prevent hypoventilation.
Ambulate three to four times per day, as appropriate.
Monitor respiratory and oxygenation status.
Administer medications (eg, bronchodilators and inhalers) that promote airway patency and gas exchange.
Teach pursed lips breathing techniques, as appropriate.
Teach breathing techniques, as appropriate.
Initiate a program of respiratory muscle strength and/or endurance training, as appropriate.
Initiate resuscitation efforts, as appropriate.

- While implementing nursing care, the nurse continually assesses the patient and his or her response to the nursing care.
- Revisions are made in the plan of care as the patient's condition, problems, and responses change and when reordering of priorities is required.

Implementation includes direct or indirect execution of the planned interventions. It is focused on resolving the patient's nursing diagnoses and collaborative problems and achieving expected outcomes, thus meeting the patient's health needs. Examples of nursing interventions are assisting with hygiene care; promoting physical and psychological comfort; supporting respiratory and elimination functions; facilitating the ingestion of food, fluids, and nutrients; managing the patient's immediate surroundings; providing health teaching; promoting a therapeutic relationship; and carrying out a variety of therapeutic nursing activities. Judgment, critical thinking, and good decision-making skills are essential in the selection of appropriate evidence-based and ethical nursing interventions. All nursing interventions are patient-focused and outcome-directed and are implemented with compassion, confidence, and a willingness to accept and understand the patient's responses.

Although many nursing actions are independent, others are interdependent, such as carrying out prescribed treatments, administering medications and therapies, and collaborating with other health care team members to accomplish specific expected outcomes and to monitor and manage potential complications. Such interdependent functioning is just that—interdependent. Requests or orders from other health care team members should not be followed blindly but should be assessed critically and questioned when necessary. The implementation phase of the nursing process ends when the nursing interventions have been completed.

Evaluation

Evaluation, the final step of the nursing process, allows the nurse to determine the patient's response to the nursing interventions and the extent to which the objectives have been achieved. The plan of nursing care is the basis for evaluation. The nursing diagnoses, collaborative problems, priorities, nursing interventions, and expected outcomes provide the specific guidelines that dictate the focus of the evaluation. Through evaluation, the nurse can answer the following questions:

- Were the nursing diagnoses and collaborative problems accurate?
- Did the patient achieve the expected outcomes within the critical time periods?
- Have the patient's nursing diagnoses been resolved?
- Have the collaborative problems been resolved?
- Do priorities need to be reordered?
- Have the patient's nursing needs been met?
- Should the nursing interventions be continued, revised, or discontinued?

- Have new problems evolved for which nursing interventions have not been planned or implemented?
- What factors influenced the achievement or lack of achievement of the objectives?
- Should changes be made in the expected outcomes and outcome criteria?

Objective data that provide answers to these questions are collected from all available sources (eg, patients, families, significant others, health care team members). These data are included in patients' records and must be substantiated by direct patient observation before the outcomes are documented.

Documentation of Outcomes and Revision of Plan

Outcomes are documented concisely and objectively. Documentation should relate outcomes to the nursing diagnoses and collaborative problems, describe the patient's responses to the interventions, indicate whether the outcomes were met, and include any additional pertinent data. An example of an individualized plan of nursing care is given in Chart 3-8.

The plan of care is subject to change as a patient's needs change, as the priorities of needs shift, as needs are resolved, and as additional information about a patient's state of health is collected. As the nursing interventions are implemented, the patient's responses are evaluated and documented, and the plan of care is revised accordingly. A well-developed, continuously updated plan of care is the greatest assurance that the patient's nursing diagnoses and collaborative problems are addressed and his or her basic needs are met.

Framework for a Common Nursing Language: Combining NANDA, NIC, and NOC

Various frameworks or taxonomies can be used for determining nursing diagnoses (eg, NANDA), establishing outcomes (eg, NOC), and designing interventions (eg, NIC). Ultimately, a framework that uses a language common to all aspects of nursing, regardless of the classification system, is desirable. Although still controversial and in its infancy, significant efforts have been made toward accomplishing this goal of unifying the language of nursing. In 2001, a taxonomy of nursing practice was developed for the harmonization of NANDA, NIC, and NOC. This three-part combination links nursing diagnoses, accompanying interventions, and outcomes, organizing them in the same way. Such organization of concepts in a common language may facilitate the process of critical thinking, because interventions and outcomes are more accurately matched with appropriately developed nursing diagnoses (Johnson, Bulechek, Butcher, et al., 2006). The final taxonomic scheme identifies four clinical domains (functional, physiologic, psychosocial, and environmental), which contain numerous classes of diagnoses, outcomes, and interventions. Chart 3-9 presents the taxonomy of nursing practice.

CHART
3-8
PLAN OF NURSING CARE**Example of an Individualized Plan of Nursing Care**

Mrs. T.C., a 52-year-old elementary school teacher, was admitted to the nursing unit from the emergency department. She had had a gnawing pain on her right side radiating to her back for 3 days. She now describes her pain as “excruciating after eating or drinking.” In the past 48 hours she has been vomiting about 2 to 3 hours after she eats. She has not had anything to eat or drink for the past 12 hours.

Mrs. T.C. stated that she had not been successful in adhering to the weight reduction diet that had been prescribed by her physician and that she had rapidly lost, then regained, weight several times in the past year and a half. She stated, “My life is just too busy—I work late hours planning lessons and have to buy my meals out a lot.” She indicated that in addition to her work, she and her husband share the responsibility for raising their three young children.

Admission physical examination revealed BP 132/84, P 104, R 22, T 100.1°F, height 5'7", weight 205 lbs, skin warm, no jaundice. She stated that her urine has been “a strange gold color” and her stools were “grayish.” She was admitted with the diagnosis of acute cholecystitis. The physician’s orders on admission included: monitor vital signs every 4 hours; IV of D₅ Ringer’s lactate 125 mL per hour; 1500-calorie, low-fat liquid diet and progress to low-fat soft diet if no pain in 16 hours; morphine sulfate 2 mg IV every 2 hours as needed; notify physician for sudden increase in frequency or intensity of pain; promethazine 12.5 mg IV every 4 hours as needed for nausea or vomiting.

Nursing Diagnoses

- Acute pain related to distended cystic duct and inflamed or infected gallbladder
- Risk for deficient fluid volume related to vomiting and decreased intake
- Ineffective coping related to role and responsibilities at work and home
- Imbalanced nutrition: More than body requirements, related to knowledge deficit about sedentary lifestyle, poor food choices and eating pattern

Collaborative Problems

- Risk for cystic duct necrosis or perforation
- Obesity

Goals**Immediate:**

- Relief of pain
- Prevent fluid volume deficit and electrolyte imbalance
- Promote rest
- Early detection of any complications

Intermediate:

- Initiation of lifestyle alterations to decrease stress and facilitate rest

Long-term:

- Alteration of lifestyle to reduce emotional and environmental stressors
- Compliance with dietary regimen
- Weight reduction

Nursing Interventions

1. Monitor BP, pulse, temperature, and respirations every 4 hours.
2. Monitor pain status with accompanying abdominal assessment every 2 hours, or more frequently, as needed.
 - a. Assess pain characteristics every 2 hours or as needed.
 - b. Assess abdomen every 2 hours or with pain assessment.
 - c. Use nonpharmacologic measures (pillows, repositioning, etc.) as desired and tolerated by patient for pain relief.
 - d. Administer analgesic at regular intervals as needed, and assess response.

Expected Outcomes

1. Vital signs within normal limits
2. Experiences pain relief; abdominal assessment within normal limits

Outcomes

1. BP range 110/62–128/78 with pain relief measures; temperature 98°–98.8°F; pulse range 74–88; respirations 18–22
2. Verbalized decrease in pain from severe (8) to low (2) intensity within 10 minutes after morphine administered; no pain radiation to back
Abdomen soft and nontender

 CHART
3-8

PLAN OF NURSING CARE
Example of an Individualized Plan of Nursing Care (Continued)

Nursing Interventions	Expected Outcomes	Outcomes
3. Monitor and support fluid and electrolyte status: <ol style="list-style-type: none"> Monitor weight. I&O Monitor skin turgor and temperature. Monitor serum electrolytes. Monitor color and consistency of urine and stool output. Encourage low-fat liquid intake if pain-free. Administer promethazine as prescribed to control or relieve vomiting. 4. Promote atmosphere conducive to physical and mental rest: <ol style="list-style-type: none"> Encourage alternation of rest and activity. Encourage limitation of visitors and interactions that are stress producing. 5. Assist patient to alter lifestyle to decrease stress: <ol style="list-style-type: none"> Discuss relationship between emotional stress and physiologic function. Encourage patient to identify stress-producing stimuli. Encourage patient to identify adjustments necessary to reduce stress relative to the home and work setting. 6. Encourage patient to identify sedentary lifestyle, obesity, and repetitive weight loss and gain as physiologic and emotional stressors; request consultation with dietitian and reinforce instructions given. 7. Teach importance of maintaining low-fat liquid diet and progression toward long-term low-fat diet. Teach food and menu choices low in fat.	3. Fluid balance maintained; electrolytes within normal limits 4. Alternates periods of rest and activity Limits visitors to family in the evenings Avoids stress-producing interactions 5. Describes stress, sedentary lifestyle, and obesity as precursors to alteration in physiologic functioning Identifies lifestyle factors that produce stress 6. Identifies lifestyle adjustments necessary to reduce stress Discusses lifestyle adjustments with family 7. Identifies harmful effects of obesity and high-fat foods Makes plans for losing weight Makes plans for preplanned meals Identifies foods/menu choices low in fat	3. Weight 205 on admission and 199 after 2-day period Urinary output adequate in relation to oral and IV intake Skin warm and supple, good recoil Electrolytes in normal range Urine dark amber in color, no sediment; stools soft, formed, light brown No vomiting reported 4. Rested in bed 2 hours in morning and 2 hours in afternoon; disconnected phone during rest periods. 8 hours uninterrupted sleep at night; husband and children visit 2 hours in evening; patient calm and relaxed after visits Accurately described relationship between stress, sedentary lifestyle, and obesity 5. Identified the following stressors: Demands of job Excessive involvement in children's school and recreational activities 6. Identified need to stop taking work home with her Consulted with husband and children; will alternate with husband in attending children's activities; all family members supportive 7. Accurately described effects of obesity and intake of high-fat foods on overall physical health and well-being Plans to attend Weight Watchers; has had success with this program in the past Identified that preparing low-fat lunches at home the night before work is a good preplanning option

Chart 3-9 • Hierarchy of Taxonomy in Nursing Practice: A Unified Structure of Nursing Language

- I. The **functional domain** is defined as the diagnoses, outcomes, and interventions that promote basic needs and includes the following eight classes:
- Activity/exercise:** physical activity, including energy conservation and expenditure
 - Comfort:** a sense of emotional, physical, and spiritual well-being and relative freedom from distress
 - Growth and development:** physical, emotional, and social growth and developmental milestones
 - Nutrition:** processes related to taking in, assimilating, and using nutrients
 - Self-care:** ability to accomplish basic and instrumental activities of daily living
 - Sexuality:** maintenance or modification of sexual identity and patterns
 - Sleep/rest:** the quantity and quality of sleep, rest, and relaxation patterns
 - Values/beliefs:** ideas, goals, perceptions, and spiritual and other beliefs that influence choices or decisions
- II. The **physiologic domain** is defined as the diagnoses, outcomes, and interventions to promote optimal biophysical health and includes the following 10 classes:
- Cardiac function:** cardiac mechanisms used to maintain tissue perfusion
 - Elimination:** processes related to secretion and excretion of body wastes
 - Fluid and electrolyte:** regulation of fluid/electrolytes and acid-base balance
 - Neurocognition:** mechanisms related to the nervous system and neurocognitive functioning, including memory, thinking, and judgment
 - Pharmacologic function:** effects (therapeutic or adverse) of medications or drugs and other pharmacologically active products
 - Physical regulation:** body temperature, endocrine, and immune system responses to regulate cellular processes.
 - Reproduction:** processes related to human procreation and birth
- Respiratory function:** ventilation adequate to maintain arterial blood gases within normal limits
- Sensation/perception:** intake and interpretation of information through the senses, including seeing, hearing, touching, tasting, and smelling
- Tissue integrity:** skin and mucous membrane protection to support secretion, excretion, and healing
- III. The **psychosocial domain** is defined as the diagnoses, outcomes, and interventions to promote optimal mental and emotional health and social functioning and includes the following seven classes:
- Behavior:** actions that promote, maintain, or restore health
 - Communication:** receiving, interpreting, and expressing spoken, written, and nonverbal messages
 - Coping:** adjusting or adapting to stressful events
 - Emotional:** a mental state of feeling that may influence perception of the world
 - Knowledge:** understanding and skill in applying information to promote, maintain, and restore health
 - Roles/relationships:** maintenance and/or modification of expected social behaviors and emotional connectedness with others
 - Self-perception:** awareness of one's body and personal identity
- IV. The **environmental domain** is defined as the diagnoses, outcomes, and interventions that promote and protect the environmental health and safety of individuals, systems, and communities and includes the following three classes:
- Health care system:** social, political, and economic structures and processes for delivery of health care services
 - Populations:** aggregates of individuals or communities having characteristics in common
 - Risk management:** avoidance or control of identifiable health threats

CRITICAL THINKING EXERCISES

1 A 50-year-old, morbidly obese man is admitted to your unit with a severe asthma attack. He is complaining of extreme shortness of breath and chest pain. What are the priorities for data collection for this patient's current condition? How would these priorities change if the client is in no acute distress and not having chest pain?

2 You are at the bedside of a 93-year-old patient who has no advance directives. The patient has been comatose for 3 days and the physician has not prescribed any feedings. When you ask the physician about an enteral nutritional supplement (tube feeding), he responds, "No, I don't think so." What actions should be taken in this situation? What ethical and legal dilemmas exist? What

other health professionals could be helpful in resolving any issues?

EBP 3 You are caring for a patient with another nursing student, and the student shares that he administered a wrong medication to the patient but is afraid to share this with the faculty and nurses. The patient was given an antihypertensive agent that was not due for another 12 hours. The patient appears to be "OK" at this time, and it is 2 hours after the medication was given. What actions should be taken? Should this information be communicated to your faculty supervisor? What is the care priority for the patient? What evidence supports or does not support disclosure of medication administration errors to patients? What steps would you take and in what order?

Health Education and Health Promotion

LEARNING OBJECTIVES

On completion of this chapter, the learner will be able to:

- 1 Describe the purposes and significance of health education.
- 2 Describe the concept of adherence to a therapeutic regimen.
- 3 Identify variables that affect learning readiness and adult learning abilities.
- 4 Describe the relationship of the teaching–learning process to the nursing process.
- 5 Develop a teaching plan for a patient.
- 6 Identify modifications indicated when teaching patients with disabilities.
- 7 Define the concepts of health, wellness, and health promotion.
- 8 Discuss major health promotion theories.
- 9 Describe the components of health promotion: self-responsibility, nutritional awareness, stress reduction and management, and physical fitness.
- 10 Specify the variables that affect health promotion activities for adolescents, young and middle-aged adults, and elderly adults.
- 11 Describe the role of the nurse in health promotion.

GLOSSARY

adherence: the process of faithfully following guidelines or directions

community: an interacting population of individuals living together within a larger society

feedback: the return of information about the results of input given to a person or a system

health education: a variety of learning experiences designed to promote behaviors that facilitate health

health promotion: the art and science of assisting people to change their lifestyle toward a higher state of wellness

learning: the act of gaining knowledge and skill

learning readiness: the optimum time for learning to occur; usually corresponds to the learner's perceived need and desire to obtain specific knowledge

nutrition: the science that deals with food and nourishment in humans

physical fitness: the condition of being physically healthy as a result of proper exercise and nutrition

reinforcement: the process of strengthening a given response or behavior to increase the likelihood that the behavior will continue

self-responsibility: personal accountability for one's actions or behavior

stress management: behaviors and techniques used to strengthen a person's resources against stress

teaching: the imparting of knowledge

therapeutic regimen: a routine that promotes health and healing

wellness: a condition of good physical and emotional health sustained by a healthy lifestyle

Effective **health education** lays a solid foundation for individual and **community** wellness. Teaching is an integral tool that all nurses use to assist patients and families in developing effective health behaviors and altering lifestyle patterns that predispose people to health risks. Health education is an influential factor directly related to positive patient care outcomes.

Health Education Today

Today's health care environment mandates the use of an organized approach to health education so that patients can meet their specific health care needs. Significant factors for nurses to consider when planning patient education include the availability of health care outside the hospital setting, the use of diverse health care providers to accomplish care management goals, and the increased use of complementary and alternative strategies rather than traditional approaches to care. Careful consideration of these factors can provide patients with the comprehensive information that is essential for making informed decisions about health care. Demands from consumers for comprehensive information about their health issues throughout the life cycle accentuate the need for holistic health education to occur in every patient–nurse encounter.

Teaching, as a function of nursing, is included in all state nurse practice acts and in the *Standards of Clinical Nursing Practice* of the American Nurses Association (ANA, 2004). Health education is an independent function of nursing practice and is a primary nursing responsibility. All nursing care is directed toward promoting, maintaining, and restoring health; preventing illness; and helping people adapt to the residual effects of illness. Many of these nursing activities are accomplished through health education or patient teaching. Nurses who serve as teachers are challenged to focus on the educational needs of communities and to provide specific patient and family education. Health education is important to nursing care because it affects the abilities of people and families to perform important self-care activities.

Every contact an individual nurse has with a health care consumer, whether or not that person is ill or has a disability, should be considered an opportunity for health teaching. Although people have a right to decide whether or not to learn, nurses have the responsibility to present information that motivates people to recognize the need to learn. Therefore, nurses must use opportunities in all health care settings to promote **wellness**. Educational environments may include homes, hospitals, community health centers, schools, places of business, service agencies, shelters, and consumer action or support groups.

Purpose of Health Education

This emphasis on health education stems in part from the public's right to comprehensive health care, which includes up-to-date health information. It also reflects the emergence of an informed public that is asking more significant questions about health and health care. Because of the importance American society places on health and the responsibility each person has to maintain and promote his or

her own health, members of the health care team, specifically nurses, are obligated to make health education available. Without adequate knowledge and training in self-care skills, consumers cannot make informed decisions about their health.

People with chronic illnesses and disabilities are among those most in need of health education. As the lifespan of the population increases, the number of people with such illnesses also increases. People with chronic illness need health care information to participate actively in and assume responsibility for self-care. Health education can help those with chronic illness adapt to their illness, prevent complications, carry out prescribed therapy, and solve problems when confronted with new situations. It can also help prevent crisis situations and reduce the potential for rehospitalization resulting from inadequate information about self-care. The goal of health education is to teach people to live life to its healthiest—that is, to strive toward achieving their maximum health potential.

In addition to the public's right to and desire for health education, patient education is also a strategy for promoting self-care at home and in the community, reducing health care costs by preventing illness, effectively managing necessary therapies, avoiding expensive medical interventions, decreasing hospital lengths of stay, and facilitating earlier discharge. For health care agencies, offering community wellness programs is a public relations tool for increasing patient satisfaction and for developing a positive image of the institution. Patient education is also a cost-avoidance strategy in that positive staff–patient relationships may avert malpractice suits.

Adherence to the Therapeutic Regimen

One of the goals of patient education is to encourage people to adhere to their **therapeutic regimen**. **Adherence** to treatment usually requires that a person make one or more lifestyle changes to carry out specific activities that promote and maintain health. Common examples of behaviors facilitating health include taking prescribed medications, maintaining a healthy diet, increasing daily activities and exercise, self-monitoring for signs and symptoms of illness, practicing specific hygiene measures, seeking recommended health evaluations and screening, and performing other therapeutic and preventive measures.

Many people do not adhere to their prescribed regimens; rates of adherence are generally low, especially when the regimens are complex or of long duration (eg, therapy for tuberculosis, multiple sclerosis, and human immunodeficiency virus [HIV] infection and hemodialysis). Nonadherence to prescribed therapy has been the subject of many studies (Belguzar, Kayser & Selim, 2007; Gelmanova, Keshavjee, Golubchikova, et al., 2007; Vik, Hogan, Patten, et al., 2006). For the most part, findings have been inconclusive, and no one predominant causative factor has been identified. Instead, a wide range of variables appears to influence the degree of adherence, including the following:

- Demographic variables, such as age, gender, race, socioeconomic status, and level of education
- Illness variables, such as the severity of the illness and the relief of symptoms afforded by the therapy

- Therapeutic regimen variables, such as the complexity of the regimen and uncomfortable side effects
- Psychosocial variables, such as intelligence, motivation, availability of significant and supportive people (especially family members), attitudes toward health professionals, acceptance or denial of illness, substance abuse, and religious or cultural beliefs
- Financial variables, especially the direct and indirect costs associated with a prescribed regimen

Nurses' success with health education is determined by ongoing assessment of the variables that affect patients' ability to adopt specific behaviors, to obtain resources, and to maintain a healthy social environment (Edelman & Mandle, 2006). Teaching programs are more likely to succeed if the variables affecting patient adherence are identified and considered in the teaching plan.

The problem of nonadherence to therapeutic regimens is a substantial one that must be addressed before patients can achieve their maximum health potential. Surprisingly, patients' need for knowledge has not been found to be a sufficient stimulus for acquiring knowledge and thereby enabling complete adherence to a health regimen. Teaching directed toward stimulating patient motivation results in varying degrees of adherence. The variables of choice, establishment of mutual goals, and quality of the patient-provider relationship directly influence the behavioral changes that can result from patient education. These factors are directly linked to motivation for learning.

Using a learning contract or agreement can also be a motivator for learning. Such a contract is based on assessment of patient needs; health care data; and specific, measurable goals (Redman, 2007). A well-designed learning contract is realistic and positive; it includes measurable goals, with a specific time frame and reward system for goal achievement. The learning contract is recorded in writing and contains methods for ongoing evaluation.

The value of the contract lies in its clarity, its specific description of what is to be accomplished, and its usefulness for evaluating behavioral change. In a typical learning contract, a series of goals is established, beginning with small, easily attainable objectives and progressing to more advanced goals. Frequent, positive **reinforcement** is provided as the person moves from one goal to the next. For example, incremental goals such as weight loss of 1 to 2 pounds per week are more appropriate in a weight reduction program than a general goal such as a 30-pound weight loss.

Gerontologic Considerations

Nonadherence to therapeutic regimens is a significant problem for elderly people, leading to increased morbidity, mortality, and cost of treatment (U.S. Public Health Service, 2005). Many admissions to nursing homes and hospitals are associated with nonadherence.

Elderly people frequently have one or more chronic illnesses that are managed with numerous medications and complicated by periodic acute episodes. Elderly people may also have other problems that affect adherence to therapeutic regimens, such as increased sensitivity to medications and their side effects, difficulty in adjusting to change and stress, financial constraints, forgetfulness, inadequate support systems, lifetime habits of self-treatment with over-

Figure 4-1 Taking time to teach patients about their medication and treatment program promotes interest and cooperation. Older adults who are actively involved in learning about their medication and treatment program and the expected effects may be more likely to adhere to the therapeutic regimen.

the-counter medications, visual and hearing impairments, and mobility limitations. To promote adherence among the elderly, all variables that may affect health behavior should be assessed (Fig. 4-1). Nurses must also consider that cognitive impairment may be manifested by the elderly person's inability to draw inferences, apply information, or understand the major teaching points (Ebersole & Touhy, 2006). The person's strengths and limitations must be assessed to encourage use of existing strengths to compensate for limitations. Above all, health care professionals must work together to provide continuous, coordinated care; otherwise, the efforts of one health care professional may be negated by those of another.

The Nature of Teaching and Learning

Learning can be defined as acquiring knowledge, attitudes, or skills. **Teaching** is defined as helping another person learn. These definitions indicate that the teaching-learning process is an active one, requiring the involvement of both teacher and learner in the effort to reach the desired outcome, a change in behavior. The teacher does not simply give knowledge to the learner but instead serves as a facilitator of learning.

In general, there is no definitive theory about how learning occurs and how it is affected by teaching. However, learning can be affected by factors such as readiness to learn, the learning environment, and the teaching techniques used (Bastable, 2008; London, 2007).

Learning Readiness

One of the most significant factors influencing learning is a person's **learning readiness**. For adults, readiness is based on culture, personal values, physical and emotional status, and past experiences in learning. The "teachable moment" occurs when the content and skills being taught are congruent with the task to be accomplished (Redman, 2007).

NURSING RESEARCH PROFILE

4-1

Health and Health Promotion Behaviors Among Amish Families

Armer, J. M. & Radina, M. E. (2006). Definition of health and health promotion behaviors among midwestern Old Order Amish families. *Journal of Multicultural Nursing and Health*, 12(3), 44–53.

Purpose

The purpose of this study was to explore health promotion practices and well-being among three generations of Old Order Amish people. The study specifically investigated the responses of the participants to measures of health perceptions, health practices, affective experiences, perceived control, locus of control, health-promoting lifestyle, perceived social support of family and friends, self-rated health, and morale.

Design

The study used a mixed method design, with the collection of both quantitative and qualitative data. Researchers interviewed 78 participants who also completed the research tools. The instruments used included the Wallston and Wallston's 18-item Multidimensional Health Locus of Control Scale, Pender's 48-item Health-Promoting Lifestyle Profile, and Procidano and Heller's 20-item Perceived Social Support–Family and Friends Scale.

Findings

The qualitative findings of this study revealed six themes about the Old Order Amish definition of health: the

importance of being healthy, the ability to work hard, a sense of freedom to enjoy life, family responsibility, and physical and spiritual well-being. On the Multidimensional Health Locus of Control Scale, the mean responses were the same across the generations. On the Health-Promoting Lifestyle Profile, the nutrition subscale ranked the highest and the exercise scale ranked the lowest. On the Perceived Social Support–Family and Friends Scale, all three generations scored higher on the family subscale than on the friend subscale. Extended family members provide assistance and support to each of the three generations as needed.

Nursing Implications

Nurses need to consider unique perspectives, needs, and choices of the Old Order Amish. By developing an understanding of this culture and a definition of what constitutes health, the nurse is in a better position to provide culturally sensitive care. The importance of the family and the community in making health care decisions must be recognized. Family involvement in individual health decisions is essential if a person is to obtain the care required. Health promotion programs in Amish communities should be developed only after establishing strong and sensitive communication with the elders and family leaders. It is essential for the nurse to recognize that health promotion and health maintenance activities among culturally diverse rural populations often differ from those of urban and suburban middle-class populations.

Culture encompasses values, ideals, and behaviors, and the traditions within each culture provide the framework for solving the issues and concerns of daily living. Because people with different cultural backgrounds have different values and lifestyles, choices about health care vary. Culture is a major variable influencing readiness to learn because it affects how people learn and what information can be learned. Sometimes people do not accept health teaching because it conflicts with culturally mediated values. Before beginning health teaching, nurses must conduct an individual cultural assessment instead of relying only on generalized assumptions about a particular culture. A patient's social and cultural patterns must be appropriately incorporated into the teaching–learning interaction. Chapter 8 (Chart 8-3) describes cultural assessment components to consider when formulating a teaching plan. Chart 4-1 summarizes a research study exploring health promotion practices among Old Order Amish families.

A person's values include beliefs about behaviors that are desirable and undesirable. The nurse must know what value the patient places on health and health care. In clinical situations, patients express their values through their actions and the level of knowledge pursued (Andrews & Boyle, 2007). When the nurse is unaware of the patient's cultural values, misunderstanding, lack of cooperation, and negative health outcomes may occur (Leininger & McFarland, 2006). A person's values and behaviors can be either an asset or a deterrent to readiness to learn. Therefore, patients are unlikely to accept health education unless their values and beliefs about health and illness are respected (Giger & Davidhizar, 2008).

Physical readiness is of vital importance, because until the person is physically capable of learning, attempts at teaching and learning may be both futile and frustrating. For example, a person in acute pain is unable to focus attention away from the pain long enough to concentrate on learning. Likewise, a person who is short of breath concentrates on breathing rather than on learning.

Emotional readiness also affects the motivation to learn. A person who has not accepted an existing illness or the threat of illness is not motivated to learn. A person who does not accept a therapeutic regimen, or who views it as conflicting with his or her present lifestyle, may consciously avoid learning about it. Until the person recognizes the need to learn and demonstrates an ability to learn, teaching efforts may be thwarted. However, it is not always wise to wait for the person to become emotionally ready to learn, because that time may never come unless the nurse makes an effort to stimulate the person's motivation.

Illness and the threat of illness are usually accompanied by anxiety and stress. Nurses who recognize such reactions can use simple explanations and instructions to alleviate these anxieties and provide further motivation to learn. Because learning involves behavior change, it often produces mild anxiety, which can be a useful motivating factor.

Emotional readiness can be promoted by creating a warm, accepting, positive atmosphere and by establishing realistic learning goals. When learners achieve success and a feeling of accomplishment, they are often motivated to participate in additional learning opportunities.

Feedback about progress also motivates learning. Such feedback should be presented in the form of positive reinforcement when the learner is successful, and in the form of constructive suggestions for improvement when the learner is unsuccessful.

Experiential readiness refers to past experiences that influence a person's ability to learn. Previous educational experiences and life experiences in general are significant determinants of a person's approach to learning. People with little or no formal education may not be able to understand the instructional materials presented. People who have had difficulty learning in the past may be hesitant to try again. Many behaviors required for reaching maximum health potential require knowledge, physical skills, and positive attitudes. In their absence, learning may be very difficult and very slow. For example, a person who does not understand the basics of normal nutrition may not be able to understand the restrictions of a specific diet. A person who does not view the desired learning as personally meaningful may reject teaching efforts. A person who is not future-oriented may be unable to appreciate many aspects of preventive health teaching. Experiential readiness is closely related to emotional readiness, because motivation tends to be stimulated by an appreciation for the need to learn and by those learning tasks that are familiar, interesting, and meaningful.

The Learning Environment

Although learning can take place without teachers, most people who are attempting to learn new or altered health behaviors benefit from contact with a nurse. The interpersonal interaction between the person and the nurse who is attempting to meet the person's learning needs may be formal or informal, depending on the method and techniques of teaching.

Learning may be optimized by minimizing factors that interfere with the learning process. For example, the room temperature, lighting, noise levels, and other environmental conditions should be appropriate to the learning situation. In addition, the time selected for teaching should be suited to the needs of the individual person. Scheduling a teaching session at a time of day when a patient is fatigued, uncomfortable, or anxious about a pending diagnostic or therapeutic procedure, or when visitors are present, is not conducive to learning. However, if the family is to participate in providing care, the sessions should be scheduled when family members are present so that they can learn any necessary skills or techniques.

Teaching Techniques

Teaching techniques and methods enhance learning if they are appropriate to the patient's needs. Numerous techniques are available, including lectures, group teaching, and demonstrations, all of which can be enhanced with specially prepared teaching materials. The lecture or explanation method of teaching is commonly used but should be accompanied by discussion. Discussion is important because it affords learners opportunities to express their feelings and concerns, to ask questions, and to receive clarification.

Group teaching is appropriate for some people because it allows them not only to receive needed information, but also to feel secure as members of a group. People with similar problems or learning needs have the opportunity to

identify with each other and gain moral support and encouragement. However, not everyone relates or learns well in groups or benefits from such experiences. Also, if group teaching is used, assessment and follow-up are imperative to ensure that each person has gained sufficient knowledge and skills.

Demonstration and practice are essential ingredients of a teaching program, especially when teaching skills. It is best to demonstrate the skill and then give the learner ample opportunity for practice. When special equipment is involved, such as syringes, colostomy bags, dialysis equipment, dressings, or suction apparatus, it is important to teach with the same equipment that will be used in the home setting. Learning to perform a skill with one kind of equipment and then having to change to a different kind may lead to confusion, frustration, and mistakes.

Teaching aids used to enhance learning include books, pamphlets, pictures, films, slides, audio tapes, models, programmed instruction, other visual aids (eg. charts), and computer-assisted learning modules. These are made available as needed for home, clinic, or hospital use, and they allow review and reinforcement of content and enhanced visual and auditory learning. Such teaching aids are invaluable when used appropriately and can save a significant amount of personnel time and related cost. However, all such aids should be reviewed before use to ensure that they meet the person's learning needs and are free of advertisements that may confuse the patient. Human interaction and discussion cannot be replaced by teaching technologies but may be enhanced by them.

Reinforcement and follow-up are important because learning takes time. Allowing ample time to learn and reinforcing what is learned are important teaching strategies; a single teaching session is rarely adequate. Follow-up sessions are imperative to promote the learner's confidence in his or her abilities and to plan for additional teaching sessions. For hospitalized patients who may not be able to transfer what they have learned in the hospital to the home setting, follow-up after discharge is essential to ensure that they have realized the full benefits of a teaching program.

Teaching Special Populations

People With Disabilities

When providing health information to people with disabilities, the individual needs of each person must be assessed and incorporated into the teaching plan. Teaching techniques and the imparting of information may need to be altered. The nurse must be aware of the health promotion needs when teaching specific groups of people with physical disabilities; emotional, psychiatric, or mental health disabilities; hearing, visual, or sensory impairments; learning disabilities; and developmental disabilities. It may be necessary to institute new or modified approaches to teach these people with disabilities about their health. Table 4-1 outlines some of the teaching strategies to use when teaching people with disabilities.

Elderly

Nurses caring for elderly people must be aware of how the normal changes that occur with aging may affect learning abilities and how they can help elderly people age well.

Table 4-1 TEACHING PEOPLE WITH DISABILITIES	
Type of Disability	Teaching Strategy
Physical, Emotional, or Cognitive Disability	Adapt information to accommodate the person's cognitive, perceptual, and behavioral disabilities. Give clear written and oral information. Highlight significant information for easy reference. Avoid medical terminology or "jargon."
Hearing Impairment	Use slow, directed, deliberate speech. Use sign language or interpreter services if appropriate. Position yourself so that the person can see your mouth if speech reading. Use telecommunication devices (TTY or TDD) for the person with hearing impairment. Use written materials and visual aids, such as models and diagrams. Use captioned videos, films, and computer-generated materials. Teach on the side of the "good ear" if unilateral deafness is present.
Visual Impairment	Use optical devices such as a magnifying lens. Use proper lighting and proper contrast of colors on materials and equipment. Use large-print materials. Use Braille materials if appropriate. Convert information to auditory and tactile formats. Obtain audiotapes and talking books. Explain noises associated with procedures, equipment, and treatments. Arrange materials in clockwise pattern.
Learning Disabilities	
Input disability	If visual perceptual disorder: <ul style="list-style-type: none"> • Explain information verbally, repeat, and reinforce frequently. • Use audiotapes. • Encourage learner to verbalize information received. If auditory perceptual disorder: <ul style="list-style-type: none"> • Speak slowly with as few words as possible, repeat, and reinforce frequently. • Use direct eye contact to focus person on task. • Use demonstration and return demonstration such as modeling, role playing, and hands-on experiences. • Use visual tools, written materials, and computers.
Output disability	Use all senses as appropriate. Use written, audiotape, and computer information. Review information and give time verbally, repeat, interact and ask questions. Use hand gestures and motions.
Developmental disability	Base information and teaching on developmental stage, not chronologic age. Use nonverbal cues, gestures, signing, and symbols as needed. Use simple explanations and concrete examples with repetition. Encourage active participation. Demonstrate information and have the person perform return demonstrations.

Above all, it is important to recognize that just because a person is elderly does not mean that he or she cannot learn. Older adults *can* learn and remember if information is paced appropriately, relevant, and followed by the appropriate feedback strategies that apply to all learners (Miller, 2009). Because changes associated with aging vary significantly among elderly people, the nurse should conduct a thorough assessment of each person's level of physiologic and psychological functioning before beginning teaching. More information on the physiologic effects of aging can be found in Chapter 12.

Changes in cognition with age may include slowed mental functioning; decreased short-term memory, abstract thinking, and concentration; and slowed reaction time. These changes are often accentuated by the health problems that cause the elderly person to seek health care in the first place. Effective teaching strategies include slow-paced presentation of small amounts of material at a time; frequent repetition of information; and the use of reinforcement techniques, such as audiovisual and written materials and repeated practice sessions. Distracting stimuli should be

minimized as much as possible in the teaching environment.

Sensory changes associated with aging also affect teaching and learning. Teaching strategies to accommodate decreased visual acuity include large-print and easy-to-read materials printed on nonglare paper. Because color discrimination is often impaired, the use of color-coded or high-lighted materials may not be effective. To maximize hearing, teachers must speak distinctly with a normal or lowered pitch, facing the person so that speech reading can occur as needed. Visual cues often help reinforce verbal teaching.

Family members should be involved in teaching sessions when possible and appropriate. They provide another source for reinforcement of material and can help the elderly person recall instructions later. Family members can also provide valuable assessment information about the person's living situation and related learning needs.

The chance of success is maximized when nurses, families, and other health care professionals work collaboratively to facilitate the elderly person's learning. Successful learning should result in improved self-care management

skills, enhanced self-esteem, confidence, and a willingness to learn in the future.

The Nursing Process in Patient Teaching

The steps of the nursing process are used when constructing a teaching plan to meet people's teaching and learning needs (Chart 4-2).

Assessment

Assessment in the teaching–learning process is directed toward the systematic collection of data about the person and family's learning needs and readiness to learn. All internal and external variables that affect the patient's readiness to learn are identified. A learning assessment guide may be used for this purpose. Some of the available guides are directed toward the collection of general health information (eg, smoking cessation), whereas others are specific to med-

ication regimens or disease processes (eg, stroke risk assessments). Such guides facilitate assessment but must be adapted to the responses, problems, and needs of each person. The nurse organizes, analyzes, synthesizes, and summarizes the assessment data collected and determines the patient's need for teaching.

Nursing Diagnosis

The process of formulating nursing diagnoses makes educational goals and evaluations of progress more specific and meaningful. Teaching is an integral intervention implied by all nursing diagnoses, and for some diagnoses, education is the primary intervention. Examples of nursing diagnoses that help in planning for educational needs are ineffective therapeutic regimen management, impaired or ineffective home maintenance, health-seeking behaviors (specify), and decisional conflict (specify). The diagnosis "deficient knowledge" should be used cautiously, because knowledge deficit is not a human response but a factor relating to or causing the diagnosis. For example, "ineffective therapeutic

Chart 4-2 • A Guide to Patient Education

Assessment

1. Assess the person's readiness for health education.
 - a. What are the person's health beliefs and behaviors?
 - b. What physical and psychosocial adaptations does the person need to make?
 - c. Is the learner ready to learn?
 - d. Is the person able to learn these behaviors?
 - e. What additional information about the person is needed?
 - f. Are there any variables (eg, hearing or visual impairment, cognitive issues, literacy issues) that will affect the choice of teaching strategy or approach?
 - g. What are the person's expectations?
 - h. What does the person want to learn?
2. Organize, analyze, synthesize, and summarize the collected data.

Nursing Diagnosis

1. Formulate the nursing diagnoses that relate to the person's learning needs.
2. Identify the learning needs, their characteristics, and their etiology.
3. State nursing diagnoses concisely and precisely.

Planning and Goals

1. Assign priority to the nursing diagnoses that relate to the individual's learning needs.
2. Specify the immediate, intermediate, and long-term learning goals established by teacher and learner together.
3. Identify teaching strategies appropriate for goal attainment.
4. Establish expected outcomes.
5. Develop the written teaching plan.
 - a. Include diagnoses, goals, teaching strategies, and expected outcomes.
 - b. Put the information to be taught in logical sequence.
 - c. Write down the key points.

- d. Select appropriate teaching aids.
 - e. Keep the plan current and flexible to meet the person's changing learning needs.
6. Involve the learner, family or significant others, nursing team members, and other health care team members in all aspects of planning.

Implementation

1. Put the teaching plan into action.
2. Use language the person can understand.
3. Use appropriate teaching aids and provide Internet resources if appropriate.
4. Use the same equipment that the person will use after discharge.
5. Encourage the person to participate actively in learning.
6. Record the learner's responses to the teaching actions.
7. Provide feedback.

Evaluation

1. Collect objective data.
 - a. Observe the person.
 - b. Ask questions to determine whether the person understands.
 - c. Use rating scales, checklists, anecdotal notes, and written tests when appropriate.
2. Compare the person's behavioral responses with the expected outcomes. Determine the extent to which the goals were achieved.
3. Include the person, family or significant others, nursing team members, and other health care team members in the evaluation.
4. Identify alterations that need to be made in the teaching plan.
5. Make referrals to appropriate sources or agencies for reinforcement of learning after discharge.
6. Continue all steps of the teaching process: assessment, diagnosis, planning, implementation, and evaluation.

regimen management related to a lack of information about wound care” is a more appropriate nursing diagnosis than “deficient knowledge” (Carpenito-Moyet, 2008; NANDA International, 2007). A nursing diagnosis that relates specifically to a patient’s and family’s learning needs serves as a guide in the development of the teaching plan.

Planning

Once the nursing diagnoses have been identified, the planning component of the teaching–learning process is established in accordance with the steps of the nursing process:

1. Assigning priorities to the diagnoses
2. Specifying the immediate, intermediate, and long-term goals of learning
3. Identifying specific teaching strategies appropriate for attaining goals
4. Specifying the expected outcomes
5. Documenting the diagnoses, goals, teaching strategies, and expected outcomes of the teaching plan

The assignment of priorities to the diagnoses should be a collaborative effort by the nurse and the patient or family members. Consideration must be given to the urgency of the patient’s learning needs; the most critical needs should receive the highest priority.

After the diagnostic priorities have been mutually established, it is important to identify the immediate and long-term goals and the teaching strategies appropriate for attaining the goals. Teaching is most effective when the objectives of both the patient and nurse are in agreement (Bastable, 2006). Learning begins with the establishment of goals that are appropriate to the situation and realistic in terms of the patient’s ability and desire to achieve them. Involving the patient and family in establishing goals and in planning teaching strategies promotes their cooperation in the implementation of the teaching plan.

Outcomes of teaching strategies can be stated in terms of expected behaviors of patients, families, or both. Outcomes should be realistic and measurable, and the critical time periods for attaining them should also be identified. The desired outcomes and the critical time periods serve as a basis for evaluating the effectiveness of the teaching strategies.

During the planning phase, the nurse must consider the sequence in which the subject matter is presented. Critical information (eg, survival skills for a patient with diabetes) and material that the person or family identifies to be of particular importance must receive high priority. An outline is often helpful for arranging the subject matter and for ensuring that all necessary information is included. In addition, appropriate teaching aids to be used in implementing teaching strategies are prepared or selected at this time.

The entire planning phase concludes with the formulation of the teaching plan. This teaching plan communicates the following information to all members of the nursing team:

- The nursing diagnoses that specifically relate to the patient’s learning needs and the priorities of these diagnoses
- The goals of the teaching strategies
- The teaching strategies that are appropriate for goal attainment
- The expected outcomes, which identify the desired behavioral responses of the learner

- The critical time period within which each outcome is expected to be met
- The patient’s behavioral responses (which are documented on the teaching plan)

The same rules that apply to writing and revising the plan of nursing care apply to the teaching plan.

Implementation

In the implementation phase of the teaching–learning process, the patient, the family, and other members of the nursing and health care team carry out the activities outlined in the teaching plan. The nurse coordinates these activities.

Flexibility during the implementation phase of the teaching–learning process and ongoing assessment of patient responses to the teaching strategies support modification of the teaching plan as necessary. Creativity in promoting and sustaining the patient’s motivation to learn is essential. New learning needs that may arise after discharge from the hospital or after home care visits have ended should also be taken into account.

The implementation phase ends when the teaching strategies have been completed and when the patient’s responses to the actions have been recorded. This serves as the basis for evaluating how well the defined goals and expected outcomes have been achieved.

Evaluation

Evaluation of the teaching–learning process determines how effectively the patient has responded to teaching and to what extent the goals have been achieved. An evaluation must be made to determine what was effective and what needs to be changed or reinforced. It cannot be assumed that patients have learned just because teaching has occurred; learning does not automatically follow teaching. An important part of the evaluation phase addresses the question, “What can be done to improve teaching and enhance learning?” Answers to this question direct the changes to be made in the teaching plan.

A variety of measurement techniques can be used to identify changes in patient behavior as evidence that learning has taken place. These techniques include directly observing the behavior; using rating scales, checklists, or anecdotal notes to document the behavior; and indirectly measuring results using oral questioning and written tests. All direct measurements should be supplemented with indirect measurements whenever possible. Using more than one measuring technique enhances the reliability of the resulting data and decreases the potential for error from a measurement strategy.

In many situations, measurement of actual behavior is the most accurate and appropriate evaluation technique. Nurses often perform comparative analyses using patient admission data as the baseline: Selected data points observed when nursing care is given and self-care is initiated are compared with the patient’s baseline data. In other cases, indirect measurement may be used. Some examples of indirect measurement are patient satisfaction surveys, attitude surveys, and instruments that evaluate specific health status variables.

Measurement is only the beginning of evaluation, which must be followed by data interpretation and value judgments about learning and teaching. These aspects of

evaluation should be conducted periodically throughout the teaching–learning program, at its conclusion, and at varying periods after the teaching has ended.

Evaluation of learning after teaching that occurs in any setting (eg, clinics, offices, nursing centers, hospitals) is essential, because the analysis of teaching outcomes must extend into aftercare. With shortened hospital lengths of stay and with short-stay and same-day surgical procedures, follow-up evaluation is especially important. Coordination of efforts and sharing of information between hospital-based and community-based nursing personnel facilitate postdischarge teaching and home care evaluation.

Evaluation is not the final step in the teaching–learning process but is the beginning of a new patient assessment. The information gathered during evaluation should be used to redirect teaching actions, with the goal of improving the patient’s responses and outcomes.

Health Promotion

Health teaching and **health promotion** are linked by a common goal—to encourage people to achieve as high a level of wellness as possible so that they can live maximally healthy lives and avoid preventable illnesses. The call for health promotion has become a cornerstone in health policy because of the need to control costs and reduce unnecessary sickness and death.

Health goals for the nation were established in the publication *Healthy People 2000*. The priorities from this initiative were identified as health promotion, health protection, and the use of preventive services. *Healthy People 2010* defines the current national health promotion and disease prevention initiative for the nation. The two essential goals from this report are (1) to increase the quality and years of healthy life for people and (2) to eliminate health disparities among various segments of the population (U.S. Public Health Service, 2005) (Chart 4-3).

Definition

Health promotion may be defined as those activities that assist people in developing resources that maintain or enhance well-being and improve their quality of life. These

activities involve people’s efforts to remain healthy in the absence of symptoms and do not require the assistance of a health care team member.

The purpose of health promotion is to focus on the person’s potential for wellness and to encourage appropriate alterations in personal habits, lifestyle, and environment in ways that reduce risks and enhance health and well-being. Health promotion is an active process; that is, it is not something that can be prescribed or dictated. It is up to each person to decide whether to make changes to promote a higher level of wellness. Only the individual can make these choices.

Health and Wellness

The concept of health promotion has evolved because of a changing definition of health and an awareness that wellness exists at many levels of functioning. Health is viewed as a dynamic, ever-changing condition that enables people to function at an optimal potential at any given time. The ideal health status is one in which people are successful in achieving their full potential, regardless of any limitations they might have.

Wellness, a reflection of health, involves a conscious and deliberate attempt to maximize one’s health. Wellness does not just happen; it requires planning and conscious commitment and is the result of adopting lifestyle behaviors for the purpose of attaining one’s highest potential for well-being. Wellness is not the same for every person. The person with a chronic illness or disability may still be able to achieve a desirable level of wellness. The key to wellness is to function at the highest potential within the limitations over which there is no control, such as a lifelong disability or genetic disorders (Chart 4-4).

A significant amount of research has shown that people, by virtue of what they do or fail to do, influence their own health. Today, many of the major causes of illness are chronic diseases that have been closely related to lifestyle behaviors (eg, type 2 diabetes mellitus, heart disease, lung and colon cancer, chronic obstructive pulmonary diseases, hypertension, cirrhosis, traumatic injury, and HIV infection). To a large extent, a person’s health status may be reflective of his or her lifestyle.

Health Promotion Models

Several health promotion models identify health-protecting behaviors and seek to explain what makes people engage in preventive behaviors. A health-protecting behavior is defined as any behavior performed by people, regardless of their actual or perceived health condition, for the purpose of promoting or maintaining their health, whether or not the behavior produces the desired outcome (Keleher, MacDougall & Murphy, 2007). One model, the Health Belief Model, was designed to foster understanding of why some healthy people choose actions to prevent illness while others do not. Another model, the resource model of preventive health behavior, addresses the ways in which people use resources to promote health (Keleher, et al., 2007). Nurse educators can use this model to assess how demographic variables, health behaviors, and social and health resources influence health promotion.

The Canadian health promotion initiative, Achieving Health for All, builds on the work of Lalonde (1977), in

GENETICS IN NURSING PRACTICE

Genetics Aspects of Health Education and Promotion

Nurses in all settings should be prepared to incorporate genetics into health education and promotion by:

- Inquiring about patients' and families' desired health outcomes with regard to genetics-related conditions or risk factors

- Referring patients for genetics services when indicated
- Identifying barriers to accessing genetics-related health services
- Offering appropriate genetics information and resources

which four determinants of health—human biology, environment, lifestyle, and the health care delivery system—were identified. Determinants of health were defined as factors and conditions that have an influence on the health of individuals and communities. Since the 1970s, a total of 12 health determinants have been identified, and this number will continue to increase as population health research progresses. Determinants of health provide a framework for assessing and evaluating the population's health.

The Health Belief Model developed by Becker and colleagues (1974) is based on the premise that four variables influence the selection and use of health promotion behaviors. Demographic and disease factors, the first variable, include patient characteristics such as age, gender, education, employment, severity of illness or disability, and length of illness. Barriers, the second variable, are defined as factors leading to unavailability or difficulty in gaining access to a specific health promotion alternative. Resources, the third variable, encompass such factors as financial and social support. Perceptual factors, the fourth variable, consist of how the person views his or her health status, self-efficacy, and the perceived demands of the illness. Becker and colleagues demonstrated that these four variables have a positive correlation with a person's quality of life.

The health promotion model described by Pender, Murdaugh and Parsons (2006) is based on social learning theory and emphasizes the importance of motivational factors in acquiring and sustaining health promotion behaviors. This model explores how cognitive-perceptual factors affect the person's view of the importance of health. It also examines perceived control of health, self-efficacy, health status, and the benefits and barriers to health-promoting behaviors.

The Transtheoretical Model of Change, also known as the stages of change model, is a framework that focuses on the motivation of a person to make decisions that promote healthy behavior change (Miller, 2009; DiClemente, 2007). Table 4-2 shows the six stages of the model. Research indicates that people seeking assistance from professionals or self-help groups progress through these stages of change (Kim, 2007).

Any of the models can serve as an organizing framework for clinical work and research that support the enhancement of health. Research and other literature that support health promotion concepts and frameworks increase the nurse's understanding of the health promotion behaviors of families and communities (Betz, 2007; Chen, Shiao & Gau, 2007; Rowley, Dixon & Palk, 2007; Seals, 2007).

Components of Health Promotion

There are several components of health promotion as an active process: self-responsibility, nutritional awareness, stress reduction and management, and physical fitness.

Self-Responsibility

Taking responsibility for oneself is the key to successful health promotion. The concept of **self-responsibility** is based on the understanding that the individual controls his or her life. Each person alone must make the choices that determine how healthy his or her lifestyle is. As more people recognize that lifestyle and behavior significantly affect health, they may assume responsibility for avoiding high-risk behaviors such as smoking, alcohol and drug abuse, overeating, driving while intoxicated, risky sexual practices, and other unhealthy habits. They may also assume responsibility for adopting routines that have been found to have a positive influence on health, such as engaging in regular exercise, wearing seat belts, and eating a healthy diet.

A variety of techniques have been used to encourage people to accept responsibility for their health, ranging from extensive educational programs to reward systems. No one technique has been found to be superior to any other. Instead, self-responsibility for health promotion is individualized and depends on a person's desires and inner motivations. Health promotion programs are important tools for encouraging people to assume responsibility for their health and to develop behaviors that improve health.

Nutritional Awareness

Nutrition, as a component of health promotion, has become the focus of considerable attention and publicity with the growing epidemic of obesity in the United States. A vast array of books and magazine articles address the topics of special diets; natural foods; and the hazards associated with certain substances, such as sugar, salt, cholesterol,

Table 4-2 STAGES IN THE TRANSTHEORETICAL MODEL OF CHANGE

Stage	Description
1. Precontemplative	The person is not thinking about making a change.
2. Contemplative	The person is only thinking about change in the near future.
3. Decision making	The person constructs a plan to change behavior.
4. Action	The person takes steps to operationalize the plan of action.
5. Maintenance	The person works to prevent relapse and to sustain the gains made from the actions taken.
6. Termination	The person has the ability to resist relapse back to unhealthy behavior(s).

Adapted from DiClemente, C. (2007). The transtheoretical model of intentional behavior change. *Drugs & Alcohol Today*, 7(1), 29–33; and Miller, C. A. (2009). *Nursing wellness in older adults* (5th ed.). Philadelphia: Lippincott Williams & Wilkins.

trans fats, carbohydrates, artificial colors, and food additives. It has been suggested that good nutrition is the single most significant factor in determining health status, longevity, and weight control.

Nutritional awareness involves an understanding of the importance of a healthy diet that supplies all of the essential nutrients. Understanding the relationship between diet and disease is an important facet of a person's self-care. Some clinicians believe that a healthy diet is one that substitutes "natural" foods for processed and refined ones and reduces the intake of sugar, salt, fat, cholesterol, caffeine, alcohol, food additives, and preservatives.

Chapter 5 contains further information about the assessment of a person's nutritional status. It describes the physical signs indicating nutritional status, assessment of food intake (food record, 24-hour recall), the dietary guidelines presented in the MyPyramid plan, and calculation of ideal body weight.

Stress Reduction and Management

Stress management and stress reduction are important aspects of health promotion. Studies have shown the negative effects of stress on health and a cause-and-effect relationship between stress and infectious diseases, traumatic injuries (eg, motor vehicle crashes), and some chronic illnesses. Stress has become inevitable in contemporary societies in which demands for productivity have become excessive. More and more emphasis is placed on encouraging people to manage stress appropriately and to reduce the pressures that are counterproductive. Techniques such as relaxation training, exercise, and modification of stressful situations are often included in health promotion programs dealing with stress. Further information on stress management, including health risk appraisal and stress reduction methods such as biofeedback and the relaxation response, can be found in Chapter 6.

Physical Fitness

Physical fitness is another important component of health promotion. Clinicians and researchers (Perry, Rosenfeld, Bennett, et al., 2007; Chao, Lian, Yu, et al., 2007) who have examined the relationship between health and physical fitness have found that a regular exercise program can promote health in the following ways:

- Improve the function of the circulatory system and the lungs
- Decrease cholesterol and low-density lipoprotein levels
- Decrease body weight by increasing calorie expenditure
- Delay degenerative changes such as osteoporosis
- Improve flexibility and overall muscle strength and endurance

An appropriate exercise program can have a positive effect on a person's performance capacity, appearance, and level of stress and fatigue, as well as his or her general state of physical, mental, and emotional health. An exercise program should be designed specifically for a given person, with consideration given to age, physical condition, and any known cardiovascular or other risk factors. Exercise can be harmful if it is not started gradually and increased slowly in accordance with a person's response.

Health Promotion Throughout the Lifespan

Health promotion is a concept and a process that extends throughout the lifespan. The health of a child can be affected either positively or negatively by the health practices of the mother during the prenatal period. Therefore, health promotion starts before birth and extends through childhood, adolescence, adulthood, and old age.

Health promotion includes health screening. The American Academy of Family Physicians has developed recommendations for periodic health examinations that identify the age groups for which specific screening interventions are appropriate. Table 4-3 presents general population guidelines. Specific population standards and guidelines have also been recommended, including adult immunization recommendations (Centers for Disease Control and Prevention [CDC], 2007).

Adolescents

Health screening has traditionally been an important aspect of adolescent health care. The goal has been to detect health problems at an early age so that they can be treated at this time. Today, health promotion goes beyond the mere screening for disabilities and includes extensive efforts to promote positive health practices at an early age. Because health habits and practices are formed early in life, adolescents should be encouraged to develop positive health attitudes. For this reason, more and more programs are being offered to adolescents to help them develop good health habits. Although the negative results of practices such as smoking, risky sexual activities, alcohol and drug abuse, and poor nutrition are explained in these educational programs, emphasis is also placed on values training, self-esteem, and healthy lifestyle practices. The projects are designed to appeal to a particular age group, with emphasis on learning experiences that are fun, interesting, and relevant.

Young and Middle-Aged Adults

Young and middle-aged adults represent an age group that not only expresses an interest in health and health promotion, but also responds enthusiastically to suggestions that show how lifestyle practices can improve health. Adults are frequently motivated to change their lifestyles in ways that are believed to enhance their health and wellness. Many adults who wish to improve their health turn to health promotion programs to help them make the desired changes in their lifestyles. Many have responded to programs that focus on topics such as general wellness, smoking cessation, exercise, physical conditioning, weight control, conflict resolution, and stress management. Because of the nationwide emphasis on health during the reproductive years, young adults actively seek programs that address prenatal health, parenting, family planning, and women's health issues.

Programs that provide health screening, such as those that screen for cancer, high cholesterol, hypertension, diabetes, abdominal aneurysm, and visual and hearing impairments, are quite popular with young and middle-aged adults. Programs that involve health promotion for people with specific chronic illnesses such as cancer, diabetes, heart

Table 4-3 ROUTINE HEALTH PROMOTION SCREENING FOR ADULTS

Type of Screening	Suggested Time Frame
Routine health examination	Yearly
Blood chemistry profile	Baseline at age 20, then as mutually determined by patient and clinician
Complete blood count	Baseline at age 20, then as mutually determined by patient and clinician
Lipid profile	Baseline at age 20, then as mutually determined by patient and clinician
Hemocult screening	Yearly after age 50
Electrocardiogram	Baseline at age 40, then as mutually determined by patient and clinician
Blood pressure	Yearly, then as mutually determined by patient and clinician
Tuberculosis skin test	Every 2 years or as mutually determined by patient and clinician
Chest x-ray film	For positive PPD results
Breast self-examination	Monthly
Mammogram	Yearly for women over 40, or earlier or more often if indicated
Clinical breast examination	Yearly
Gynecologic examination	Yearly
Pap test	Yearly
Bone density screening	Based on identification of primary and secondary risk factors (prior to onset of menopause, if indicated)
Nutritional screening	As mutually determined by patient and clinician
Digital rectal examination	Yearly
Colonoscopy	Every 3–5 years after age 50 or as mutually determined by patient and clinician
Prostate examination	Yearly
Prostate-specific antigen	Every 1–2 years after age 50
Testicular examination	Monthly
Skin examination	Yearly or as mutually determined by patient and clinician
Vision screening	Every 2–3 years
Glaucoma	Baseline at age 40, then every 2–3 years until age 70, then yearly
Dental screening	Every 6 months
Hearing screening	As needed
Health risk appraisal	As needed
Adult Immunizations	
Hepatitis B (if not received as a child)	Series of three doses (now, 1 month later, then 5 months after the second date)
Influenza vaccine	Yearly

Note: Any of these screenings may be performed more frequently if deemed necessary by the patient or recommended by the health care provider.

disease, and pulmonary disease are also popular. Chronic disease and disability do not preclude health and wellness; rather, positive health attitudes and practices can promote optimal health for people who must live with the limitations imposed by their chronic illnesses and disabilities.

Health promotion programs can be offered almost anywhere in the community. Common sites include local clinics, schools, colleges, recreation centers, churches, and even private homes. Health fairs are frequently held in civic centers and shopping malls. The outreach idea for health promotion programs has served to meet the needs of many adults who otherwise would not avail themselves of opportunities to strive toward a healthier lifestyle.

The workplace has become a center for health promotion activity for several reasons. Employers have become increasingly concerned about the rising costs of health care insurance to treat illnesses related to lifestyle behaviors, and they are also concerned about increased absenteeism and lost productivity. Some employers use health promotion specialists to develop and implement these programs, and others purchase packaged programs that have already been developed by health care agencies or private health promotion corporations.

Programs offered at the workplace usually include employee health screening and counseling, physical fitness, nutritional awareness, work safety, and stress management and stress reduction. In addition, efforts are made to pro-

mote a safe and healthy work environment. Many large businesses provide exercise facilities for their employees and offer their health promotion programs to retirees.

Gerontologic Considerations

Health promotion is as important for the elderly as it is for others. Although 80% of people older than 65 years have one or more chronic illnesses and many are limited in their activity, the elderly as a group experience significant gains from health promotion. The elderly are very health-conscious, and most view their health positively and are willing to adopt practices that will improve their health and well-being (Ebersole & Hess, 2005). Although their chronic illnesses and disabilities cannot be eliminated, these adults can benefit from activities that help them maintain independence and achieve an optimal level of health.

Various health promotion programs have been developed to meet the needs of older Americans. Both public and private organizations continue to be responsive to health promotion, and more programs that serve the elderly are emerging. Many of these programs are offered by health care agencies, churches, community centers, senior citizen residences, and a variety of other organizations. The activities directed toward health promotion for the elderly are the same as those for other age groups: physical fitness and exercise, nutrition, safety, and stress management (Fig. 4-2).

Figure 4-2 Health promotion for the elderly includes physical fitness. Here, a nurse teaches simple exercises at a senior center.

Nursing Implications

By virtue of their expertise in health and health care and their long-established credibility with consumers, nurses play a vital role in health promotion. In many instances, they have initiated health promotion and health screening programs or have participated with other health care personnel in developing and providing wellness services in a variety of settings.

As health care professionals, nurses have a responsibility to promote activities that foster well-being, self-actualization, and personal fulfillment. Every interaction with consumers of health care must be viewed as an opportunity to promote positive health attitudes and behaviors.

CRITICAL THINKING EXERCISES

EBP 1 A female college student with a 2-year history of irritable bowel syndrome makes an appointment to speak with the nurse practitioner at the college health center to discuss her increased use of antidiarrheal medication. The student states, “I’ve been very busy with my studies and several activities this semester, and I haven’t been eating right.” What health promotion components guide the nurse in assessing the student’s situation? What is the evidence base for offering information and health programs to help this young adult make appropriate health decisions and establish positive health behaviors? Identify the criteria used to evaluate the strength of the evidence for this practice.

2 After falling from a piece of machinery at a construction site, a 40-year-old man is recuperating at home after being in the hospital. A home health nurse visits three times a week to perform abdominal wound care. During a visit, the man complains that he misses his daily exercise routine and asks when he will be able to resume exercising. Determine the factors that influence his ability to engage in exercise. What factors support the overall relationship between fitness and health? Develop a plan to assist the man to maintain muscle tone and promote well-being.

EBP 3 A 74-year-old woman is volunteering at a local health fair being held at her granddaughter’s high school. When the nurse coordinator asks the woman if she would like to participate in the screening events and other informational activities, she replies, “No, thank you. I’m too old to think about health promotion. I just need to take care of the health problems that I already have.” What evidence supports the importance of health promotion strategies for the older adult? What information should you include in a discussion with this woman about promoting health in the elderly? What type of information, available at various booths at the health fair, would be appropriate for this woman to obtain?

Adult Health and Nutritional Assessment

LEARNING OBJECTIVES

On completion of this chapter, the learner will be able to:

- 1 Identify ethical considerations necessary for protecting a person's rights related to data collected in the health history and physical assessment.
- 2 Describe the components of the health history.
- 3 Apply culturally sensitive interviewing skills and techniques to conduct a successful health history, physical examination, and nutritional assessment.
- 4 Identify genetic aspects nurses should incorporate into the health history and physical assessment.
- 5 Identify modifications needed to obtain a health history and conduct a physical assessment for a person with a disability.
- 6 Describe the techniques of inspection, palpation, percussion, and auscultation to perform a basic physical assessment.
- 7 Discuss the techniques of measurement of body mass index, biochemical assessment, clinical examination, and assessment of food intake to assess a person's nutritional status.
- 8 Describe factors that may contribute to altered nutritional status in high-risk groups such as adolescents and the elderly.
- 9 Conduct a health history and physical and nutritional assessment of a person at home.

GLOSSARY

- auscultation:** listening to sounds produced within different body structures created by the movement of air or fluid
- body mass index (BMI):** a calculation done to estimate the amount of body fat of a person
- health history:** a series of questions that provides an overview of the patient's current health status
- inspection:** visual assessment of different aspects of the patient
- palpation:** examination of different organs of the body using the sense of touch
- percussion:** the use of sound to examine different organs of the body

The ability to assess patients is a skill integral to nursing, regardless of the practice setting. In all settings in which nurses interact with patients and provide care, eliciting a complete health history and using appropriate assessment skills are critical to identifying physical and psychological problems and concerns experienced by the patient. As the first step in the nursing process, patient assessment is necessary to obtain data that enable the nurse to make an accurate nursing diagnosis, identify and implement appropriate interventions, and assess their effectiveness. This chapter covers the complete health history and basic assessment techniques. Because a patient's nutritional status is an important factor in overall health and well-being, a section on nutritional assessment is also addressed.

Considerations for Conducting a Health History and Physical Assessment

The Role of the Nurse

All members of the health care team use their unique skills and knowledge to contribute to the resolution of patient problems by first obtaining some level of history and assessment (Weber & Kelley, 2007). Because the focus of each member of the health care team is unique, a variety of health history and physical examination formats have been developed. Regardless of the format, the information obtained by the nurse complements the data obtained by other members of the health care team and focuses on nursing's unique concerns for the patient. In health assessment, the nurse obtains the patient's health history and performs a physical assessment, which can be carried out in a variety of settings, including the acute care setting, clinic or outpatient office, school, long-term care facility, or home. Nurses use a growing list of nursing diagnoses to identify and categorize patient problems that nurses have the knowledge, skills, and responsibility to treat independently (NANDA International, 2007).

Communicating Effectively

People who seek health care for a specific problem are often anxious. Their anxiety may be increased by fear about potential diagnoses, possible disruption of lifestyle, and other concerns. With this in mind, the nurse attempts to establish rapport, put the patient at ease, encourage honest communication, make eye contact, and listen carefully to the patient's responses to questions about health issues (Fig. 5-1).

When obtaining a health history or performing a physical examination, the nurse must be aware of his or her own nonverbal communication, as well as that of the patient. The nurse should take into consideration the patient's educational and cultural background as well as language proficiency. Questions and instructions to the patient are phrased in a way that is easily understandable. Technical terms and medical jargon are avoided. In addition, the nurse must take into consideration the patient's disabilities or impairments (hearing, vision, cognitive, and physical limitations). At the end of the assessment, the nurse may summarize and clarify the information obtained and ask the

Figure 5-1 A comfortable, relaxed atmosphere and an attentive interviewer are essential for a successful clinical interview.

patient if he or she has any questions; this gives the nurse the opportunity to correct misinformation and add facts that may have been omitted.

Ethical Use of History or Physical Examination Data

Whenever information is elicited from a person through a health history or physical examination, the person has the right to know why the information is sought and how it will be used. For this reason, it is important to explain what the history and physical examination are, how the information will be obtained, and how it will be used (Bickley, 2007; Weber & Kelley, 2007). It is also important that the person be aware that the decision to participate is voluntary. A private setting for the history interview and physical examination promotes trust and encourages open, honest communication. After the history and examination are completed, the nurse selectively records the data pertinent to the patient's health status. This written record of the patient's history and physical examination findings is then maintained in a secure place and made available only to those health professionals directly involved in the care of the patient. This protects confidentiality and promotes professional conduct.

Increasing Use of Technology

The use of technology to augment the information-gathering process has become an increasingly important aspect of obtaining a health history and physical examination. Computerization of medical records is becoming more common in private health care providers' offices as well as in medical centers as the Institute of Medicine has called for the implementation of the computerized patient health record (Simpson, 2007). Electronic health records are thought to improve the quality of care, reduce medical errors, and help reduce health care costs; therefore, their implementation is moving forward on a global scale (Arnold, Wagner, Hyatt, et al., 2007). Assessments such as the nutrition assessment (Vereecken, Covents, Matthys, et al., 2005) and screening for intimate partner violence (MacMillan, Wathen, Jamieson, et al., 2006) can be completed on a computer. Nurses must be sensitive to the needs of older adults and

others who may not be comfortable with computer technology. Nurses may need to allow extra time and provide detailed instructions or assistance.

Health History

The **health history** is a series of questions used to provide an overview of the current health status of the patient. When obtaining the health history, attention is focused on the impact of psychosocial, ethnic, and cultural background on a person's health, illness, and health promotion behaviors. The interpersonal and physical environments, as well as the person's lifestyle and activities of daily living, are explored in depth. Many nurses are responsible for obtaining a detailed history of the person's current health problems, past medical history, and family history and a review of the person's functional status. This results in a total health profile that focuses on health as well as illness.

The format of the health history traditionally combines the medical history and the nursing assessment, although formats based on nursing frameworks, such as functional health patterns, have also become standard. Both the review of systems and the patient profile are expanded to include individual and family relationships, lifestyle patterns, health practices, and coping strategies. These components of the health history are the basis of nursing assessment and can be easily adapted to address the needs of any patient population in any setting, institution, or agency (Bickley, 2007; Weber & Kelley, 2007). Combining the information obtained by the physician and the nurse into one health history prevents duplication of information and minimizes efforts on the part of the patient to provide this information repeatedly. This also encourages collaboration among members of the health care team who share in the collection and interpretation of the data.

The Informant

The informant, or the person providing the health history, may not always be the patient, as in the case of a developmentally delayed, mentally impaired, disoriented, confused, unconscious, or comatose patient. The interviewer assesses the reliability of the informant and the usefulness of the information provided. For example, a disoriented patient is often unable to provide reliable information; people who use alcohol and illicit drugs often deny using these substances. The interviewer must make a clinical judgment about the reliability of the information (based on the context of the entire interview) and include this assessment in the record. Chart 5-1 provides special considerations for obtaining a health history from an older adult.

Components of the Health History

When a patient is seen for the first time by a member of the health care team, the first requirement is that baseline information be obtained (except in emergency situations). The sequence and format of obtaining data about a patient may vary, but the content, regardless of format, usually addresses the same general topics. A traditional approach includes the following: biographical data, chief complaint, present health concern (or present illness), past history, family history, review of systems, and patient profile.

CHART
5-1

Health Assessment in the Older Adult

A health history should be obtained from elderly patients in a calm, unrushed manner. Because of the increased incidence of impaired vision and hearing in the elderly, lighting should be adequate but not glaring, and distracting noises should be kept to a minimum. The interviewer should assume a position that enables the person to read lips and facial expressions. People who normally use a hearing aid are asked to use it during the interview. The interviewer should also recognize that there is wide diversity among the elderly and that differences exist in health practices, gender, income, and functional status (Mai & Eng, 2007).

Elderly people often assume that new physical problems are a result of age rather than a treatable illness. In addition, the signs and symptoms of illness in the elderly are often more subtle than those in younger people and may go unreported. Therefore, a question such as, "What interferes most in your daily activities?" may be useful in focusing the clinical evaluation (Soriano, Fernandes, Cassel, et al., 2007). Special care is taken in obtaining a complete history of medications used, because many elderly people take many different kinds of prescription and over-the-counter (OTC) medications. Although elderly people may experience a decline in mental function, it should not be assumed that they are unable to provide an adequate history (Soriano, et al., 2007). Nevertheless, including a member of the family in the interview process (eg, spouse, adult child, sibling, caretaker) may validate information and provide missing details. However, this should be done after obtaining the patient's permission. Further details about assessment of the older adult are provided in Chapter 12.

Biographical Data

Biographical information puts the patient's health history into context. This information includes the person's name, address, age, gender, marital status, occupation, and ethnic origins. Some interviewers prefer to ask more personal questions at this part of the interview, whereas others wait until more trust and confidence have been established or until a patient's immediate or urgent needs are first addressed. A patient who is in severe pain or has another urgent problem is unlikely to have a great deal of patience for an interviewer who is more concerned about marital or occupational status than with quickly addressing the problem at hand.

Chief Complaint

The chief complaint is the issue that brings a person to the attention of the health care provider. Questions such as, "Why have you come to the health center today?" or "Why were you admitted to the hospital?" usually elicit the chief complaint. In the home setting, the initial question might be, "What is bothering you most today?" When a problem is identified, the person's exact words are usually recorded in quotation marks. However, a statement such as, "My doctor sent me," should be followed up with a question that identifies the probable reason why the person is seeking health care; this reason is then identified as the chief complaint (Bickley, 2007; Weber & Kelley, 2007).

Present Health Concern or Illness

The history of the present health concern or illness is the single most important factor in helping the health care team arrive at a diagnosis or determine the patient's needs. The physical examination is helpful but often only validates the information obtained from the history. A careful history assists in correct selection of appropriate diagnostic tests. Although diagnostic test results can be helpful, they often support rather than establish the diagnosis.

If the present illness is only one episode in a series of episodes, the entire sequence of events is recorded. For example, a history from a patient whose chief complaint is an episode of insulin shock describes the entire course of the diabetes to put the current episode in context. The details of the health concern or present illness are described from onset until the time of contact with the health care team. These facts are recorded in chronologic order, beginning with, for example, "The patient was in good health until . . ." or "The patient first experienced abdominal pain 2 months prior to seeking help."

The history of the present illness or problem includes such information as the date and manner (sudden or gradual) in which the problem occurred, the setting in which the problem occurred (at home, at work, after an argument, after exercise), manifestations of the problem, and the course of the illness or problem. This includes self-treatment (including complementary and alternative therapies), medical interventions, progress and effects of treatment, and the patient's perceptions of the cause or meaning of the problem.

Specific symptoms (pain, headache, fever, change in bowel habits) are described in detail, along with the location and radiation (if pain), quality, severity, and duration. The interviewer also asks whether the problem is persistent

or intermittent, what factors aggravate or alleviate it, and whether any associated manifestations exist.

Associated manifestations are symptoms that occur simultaneously with the chief complaint. The presence or absence of such symptoms may shed light on the origin or extent of the problem, as well as on the diagnosis. These symptoms are referred to as significant positive or negative findings and are obtained from a review of systems directly related to the chief complaint. For example, if a patient reports a vague symptom such as fatigue or weight loss, all body systems are reviewed and included in this section of the history. If, on the other hand, a patient's chief complaint is chest pain, only the cardiopulmonary and gastrointestinal systems may be included in the history of the present illness. In either situation, both positive and negative findings are recorded to define the problem further.

Past Health History

A detailed summary of a person's past health is an important part of the health history. After determining the general health status, the interviewer should inquire about immunization status according to the recommendations of the adult immunization schedule and record the dates of immunization (if known). The Advisory Committee on Immunization Practices (ACIP) updates the schedule each year (Centers for Disease Control and Prevention [CDC], 2007). The interviewer should also inquire about any known allergies to medications or other substances, along with the type of allergy and adverse reactions. Other relevant material includes information, if known, about the patient's last physical examination, chest x-ray, electrocardiogram, eye examination, hearing test, dental checkup (Chart 5-2), Papanicolaou

CHART 5-2 NURSING RESEARCH PROFILE Oral Health Assessment

Chen, C. C.-H., Chyun, D. A., Li, C., et al. (2007). A single-item approach to screening elders for oral health assessment. *Nursing Research*, 56(5), 332–338.

Purpose

When performing health assessments for elderly patients, nurses are aware that oral health is an important indicator of overall health. The main purpose of this study was to evaluate the usefulness of asking the question, "Do you have regular dental checkups?" as a means of determining whether an oral health assessment or further referral is indicated for elders.

Design

The study was a secondary analysis using a nutritional survey of 240 elderly participants who were living in the community. A gerontologic nurse practitioner was trained to rate each participant on three oral indices: the Kayser-Jones Brief Oral Health Status Examination, the self-reported General Oral Health Assessment Index, and the number of remaining teeth. During an assessment in their home, the participants were also asked about their pattern of dental checkups (regular versus irregular).

Findings

Approximately half (55%) of participants reported a dental visit within the past year for any reason, but only 81 (33.8%) reported having regular dental checkups. For participants with teeth ($n = 147$), an irregular dental checkup was associated with lower educational level, Protestant faith, and black race. Participants with a pattern of irregular dental checkups scored lower on all three oral indices. The question, "Do you have regular dental checkups?" was found to be valid for identifying those with teeth and good oral health; it was less effective for those participants without teeth.

Nursing Implications

During the general health assessment for the elderly, the nurse should be aware that a single question, "Do you have regular dental checkups?" can be used effectively to identify those with teeth and good oral health and not in need of further oral health assessment or referral. This one question was less effective in identifying those in need of further oral health assessment or referral.

(Pap) smear and mammogram (if female), digital rectal examination of the prostate gland (if male), bone density testing, colon cancer screening, and any other pertinent tests. The interviewer then discusses previous illnesses and records negative as well as positive responses to a list of specific diseases. Dates of illness, or the age of the patient at the time, as well as the names of the primary health care provider and hospital, the diagnosis, and the treatment are noted. The interviewer elicits a history of the following areas:

- Childhood illnesses—rubeola, rubella, polio, whooping cough, mumps, measles, chickenpox, scarlet fever, rheumatic fever, strep throat
- Adult illnesses
- Psychiatric illnesses
- Injuries—burns, fractures, head injuries
- Hospitalizations
- Surgical and diagnostic procedures
- Current medications—prescription, over-the-counter (OTC), home remedies, complementary and alternative therapies
- Use of alcohol and other drugs

If a particular hospitalization or major medical intervention is related to the present illness, the account of it is not repeated; rather, the report refers to the appropriate part of the record, such as “See history of present illness” on the data sheet.

Family History

To identify diseases that may be genetic, communicable, or possibly environmental in origin, the interviewer asks about the age and health status, or the age and cause of death, of first-order relatives (parents, siblings, spouse, children) and second-order relatives (grandparents, cousins). In general, the following conditions are included: cancer, hypertension, heart disease, diabetes, epilepsy, mental illness, tuberculosis, kidney disease, arthritis, allergies, asthma, alcoholism, and obesity. One of the easiest methods of recording such data is by using the family tree, genogram, or pedigree (Fig. 5-2). The results of genetic testing or screening, if known, are recorded. Chart 5-3 provides genetic considerations related to health assessment; see also Chapter 9 for a detailed discussion of genetics.

Review of Systems

The review of systems includes an overview of general health as well as symptoms related to each body system. Questions are asked about each of the major body systems

Figure 5-2 Diagram (called a genogram) used to record history of family members, including their age and cause of death or, if living, their current health status.

for information about past and present symptoms. Reviewing each body system helps reveal relevant data. Negative as well as positive answers are recorded. If a patient responds positively to questions about a particular system, the information is analyzed carefully. If any illnesses were previously mentioned or recorded, it is not necessary to repeat them in this part of the history. Instead, reference is made to the appropriate place in the health history where the information can be found.

A review of systems can be organized in a formal checklist, which becomes a part of the health history. One advantage of a checklist is that it can be easily audited and is less subject to error than a system that relies heavily on the interviewer's memory.

CHART 5-3

GENETICS IN NURSING PRACTICE Genetics Aspects of Health Assessment

Nurses incorporate a genetics focus into the following health assessments:

- Family history—assess for genetics-related risk factors.
- Cultural, social, and spiritual assessment—assess for individual and family perceptions and beliefs around genetics topics.
- Physical assessment—assess for clinical features that may suggest a genetic condition is present (eg, unusually tall stature—Marfan syndrome).

- Ethnic background—since many conditions are more common in specific ethnic populations, the nurse gathers information about ethnic background (eg, Tay-Sachs disease in Ashkenazi Jewish populations or thalassemia in Southeast Asian populations).

Patient Profile

In the patient profile, more biographical information is gathered. A complete composite, or profile, of the patient is critical to analysis of the chief complaint and of the person's ability to deal with the problem. A complete patient profile is summarized in Chart 5-4.

At this point in the interview, the information elicited is highly personal and subjective. People are encouraged to express feelings honestly and to discuss personal experiences. It is best to begin with general, open-ended questions and to move to direct questioning when specific facts are needed. Interviews that progress from information that is less personal (birthplace, occupation, education) to information that is more personal (sexuality, body image, coping abilities) often reduce anxiety.

A general patient profile consists of the following content areas: past life events related to health, education and occupation, environment (physical, spiritual, cultural), lifestyle (patterns and habits), presence of a physical or mental disability, self-concept, sexuality, risk for abuse, and stress and coping response.

Past Life Events Related to Health

The patient profile begins with a brief life history. Questions about place of birth and past places of residence help focus attention on the earlier years of life. Personal experiences during childhood or adolescence that have special significance may be elicited by asking a question such as, “Was there anything that you experienced as a child or adolescent that would be helpful for me to know about?” The interviewer's intent is to encourage the patient to make a quick review of his or her earlier life, highlighting information of particular significance. Although many patients may not recall anything significant, others may share information such as a personal achievement, a failure, a developmental crisis, or an instance of physical, emotional, or sexual abuse. The life history should include a brief medication history as appropriate for the patient.

Education and Occupation

Inquiring about current occupation can reveal much about a person's economic status and educational preparation. A statement such as, “Tell me about your job,” often elicits information about role, job tasks, and satisfaction with the

position. Direct questions about past employment and career goals may be asked if the person does not provide this information.

It is important to learn about a person's educational background. Asking a person what kind of educational requirements were necessary to attain his or her present job is a more sensitive approach than asking whether he or she graduated from high school. Information about the patient's general financial status may be obtained by questions such as, "Do you have any financial concerns at this time?" or "Sometimes there just doesn't seem to be enough money to make ends meet. Are you finding this true?" Inquiries about the person's insurance coverage and plans for health care payment are also appropriate.

Environment

The concept of environment includes a person's physical environment and its potential hazards, spiritual awareness, cultural background, interpersonal relationships, and support system.

Physical Environment. Information is elicited about the type of housing (apartment, duplex, single-family) in which the person lives, its location, the level of safety and comfort within the home and neighborhood, and the presence of environmental hazards (eg, isolation, potential fire risks, inadequate sanitation). If the patient is homeless or living in a homeless shelter or has a disability, the patient's environment assumes special importance (Mai & Eng, 2007).

Spiritual Environment. The term *spiritual environment* refers to the degree to which a person thinks about or contemplates his or her existence, accepts challenges in life, and seeks and finds answers to personal questions. Spirituality may be expressed through identification with a particular religion. Spiritual values and beliefs often direct a person's behavior and approach to health problems and can influence responses to sickness. Illness may create a spiritual crisis and can place considerable stress on a person's internal resources and beliefs. Inquiring about spirituality can identify possible support systems as well as beliefs and customs that need to be considered in planning care. Information is gathered about the extent to which religion is a part of the person's life as well as religious beliefs and practices related to health and illness.

A spiritual assessment may involve asking the following questions:

- Is religion or God important to you?
- If yes, in what way?
- If no, what is the most important thing in your life?
- Are there any religious practices that are important to you?
- Do you have any spiritual concerns because of your present health problem?

Cultural Environment. When obtaining the health history, the person's cultural and religious backgrounds are taken into account. Cultural attitudes and beliefs about health, illness, health care, hospitalization, the use of medications, and use of complementary and alternative therapies, which are derived from personal experiences, vary according to ethnic, cultural, and religious background. A person from another culture may

have different views of personal health practices from those of the health care practitioner (Bickley, 2007; Weber & Kelley, 2007). See Chapter 8 for more cultural considerations.

The beliefs and practices that have been shared from generation to generation are known as cultural or ethnic patterns. They are expressed through language, dress, dietary choices, and role behaviors; in perceptions of health and illness; and in health-related behaviors. The influence of these beliefs and customs on how a person reacts to health problems and interacts with health care providers cannot be underestimated. The following questions may assist in obtaining relevant information:

- Where did your parents or ancestors come from? When?
- What language do you speak at home?
- Are there certain customs or values that are important to you?
- Is there anything special you do to keep in good health?
- Do you have any specific practices for treating illness?

Family Relationships and Support System. An assessment of family structure (members, ages, and roles), patterns of communication, and the presence or absence of a support system is an integral part of the patient profile. Although the traditional family is recognized as a mother, a father, and children, many different types of living arrangements exist within our society. "Family" may mean two or more people bound by emotional ties or commitments. Live-in companions, roommates, and close friends can all play a significant role in a person's support system.

Lifestyle

The lifestyle section of the patient profile provides information about health-related behaviors. These behaviors include patterns of sleep, exercise, nutrition, and recreation, as well as personal habits such as smoking and the use of illicit drugs, alcohol, and caffeine. Although most people readily describe their exercise patterns or recreational activities, many are unwilling to report their smoking, alcohol use, and illicit drug use, and many deny or understate the degree to which they use such substances. Questions such as, "What kind of alcohol do you enjoy drinking at a party?" may elicit more accurate information than, "Do you drink?" The specific type of alcohol (eg, wine, liquor, beer) and the amount ingested per day or per week (eg, 1 pint of whiskey daily for 2 years) should be described (Lussier-Cushing, Repper-DeLisi, Mitchell, et al., 2007).

If alcohol abuse is suspected, additional information may be obtained by using common alcohol screening questionnaires such as the CAGE (Cutting down, Annoyance by criticism, Guilty feelings, and Eye-openers) (Ewing, 1984), AUDIT (Alcohol Use Disorders Identification Test), TWEAK (Tolerance, Worry, Eye-opener, Amnesia, Kut down) (Chan, Pristach, Welte, et al. 1993), or SMAST (Short Michigan Alcohol Screening Test). Chart 5-5 shows the CAGE Questions Adapted to Include Drugs (CAGEAID). The MAST (Michigan Alcohol Screening Test) has been updated to include drug use and has a geriatric version (The New York State Office of Alcoholism and Substance Abuse Services [OASAS], 2007).

CHART
5-5

Assessing for Alcohol or Drug Use

CAGE Questions Adapted to Include Drugs (CAGEAID)*

Have you felt you ought to cut down on your drinking (or drug use)?

___Yes ___No

Have people annoyed you by criticizing your drinking (or drug use)?

___Yes ___No

Have you felt bad or guilty about your drinking (or drug use)?

___Yes ___No

Have you ever had a drink (or used drugs) first thing in the morning to steady your nerves or get rid of a hangover (or to get the day started)?

___Yes ___No

*Boldface text shows the original CAGE questions; boldface italic text shows modifications of the CAGE questions used to screen for drug disorders. In a general population, two or more positive answers indicate a need for more in-depth assessment.

From Fleming, M. F. & Barry, K. L. (1992). *Addictive disorders*. St. Louis: Mosby; and Ewing, J. A. (1984). Detecting alcoholism: The CAGE questionnaire. *Journal of the American Medical Association*, 252(14), 1905–1907.

Similar questions can be used to elicit information about smoking and caffeine consumption. Questions about illicit drug use follow naturally after questions about smoking, caffeine consumption, and alcohol use. A non-judgmental approach makes it easier for a person to respond truthfully and factually. If street names or unfamiliar terms are used to describe drugs, the person is asked to define the terms used.

Investigation of lifestyle should also include questions about complementary and alternative therapies. It is estimated that as many as 40% of Americans use some type of complementary or alternative therapies, including special diets, prayer, visualization or guided imagery, massage, meditation, herbal products, and many others. Marijuana is used for management of symptoms, especially pain, in a number of chronic conditions.

Disability

The general patient profile needs to contain questions about any hearing, vision, or other type of physical disability. Mental, sensory, or cognitive disabilities need to be inquired about as well. The presence of an obvious physical limitation (eg, using crutches to walk or using a wheelchair to get around) necessitates further investigation. The etiology of the disability should be elicited, and the length of time the patient has had the disability, the impact on function, and health access are important to assess (Smeltzer, Sharts-Hopko, Ott, et al., 2007). Chart 5-6 presents specific issues that the nurse should consider when obtaining health histories and conducting physical assessments of patients with disabilities.

Self-Concept

Self-concept refers to a person's view of himself or herself, an image that has developed over many years. To assess

self-concept, the interviewer might ask how a person views life, using a question such as, "How do you feel about your life in general?" A person's self-concept can be threatened very easily by changes in physical function or appearance or other threats to health. The impact of certain medical conditions or surgical interventions, such as a colostomy or a mastectomy, can threaten body image. The question, "Do you have any particular concerns about your body?" may elicit useful information about self-image.

Sexuality

No area of assessment is more personal than the sexual history. Interviewers are frequently uncomfortable with such questions and ignore this area of the patient profile or conduct a very cursory interview about this subject. Lack of knowledge about sexuality, preconceived notions (eg, assuming all people are heterosexual), and anxiety about one's own sexuality may hamper the interviewer's effectiveness in dealing with this subject (Neville & Henrickson, 2006).

Sexual assessment can be approached at the end of the interview, at the time interpersonal or lifestyle factors are assessed, or it may be easier to discuss sexuality as a part of the genitourinary history within the review of systems. In female patients, a discussion of sexuality would follow questions about menstruation. In male patients, a similar discussion would follow questions about the urinary system.

Obtaining the sexual history provides an opportunity to discuss sexual matters openly and gives the person permission to express sexual concerns to an informed professional. The interviewer must be nonjudgmental and must use language appropriate to the patient's age and background (Neville & Henrickson, 2006). The assessment begins with an orienting sentence such as, "Next, I would like to ask about your sexual health and practices." Such an opening may lead to a discussion of concerns related to sexual expression or the quality of a relationship, or to questions about contraception, risky sexual behaviors, and safer sex practices. Examples of other questions are, "Do you have one or more sexual partners?" and "Are you satisfied with your sexual relationships?"

Determining whether a person is sexually active should precede any attempts to explore issues related to sexuality and sexual function. Care should be taken to initiate conversations about sexuality with elderly patients and patients with disabilities and not to treat them as asexual people. Questions are worded in such a way that the person feels free to discuss his or her sexuality regardless of marital status or sexual preference. Direct questions are usually less threatening when prefaced with such statements as, "Most people feel that . . ." or "Many people worry about . . ." This suggests the normalcy of such feelings or behavior and encourages the person to share information that might otherwise be omitted because of fear of seeming "different."

If a person answers abruptly or does not wish to carry the discussion any further, then the interviewer should move to the next topic. However, introducing the subject of sexuality indicates to the person that a discussion of sexual

Chart 5-6 • Health Assessment of People With Disabilities**Overview**

People with disabilities are entitled to the same level of health assessment and physical examination as people without disabilities. The nurse needs to be aware of the patient's disabilities or impairments (hearing, vision, cognitive, and physical limitations) and take these into consideration when obtaining a health history and conducting a physical assessment. It is appropriate to ask the patient what assistance he or she needs rather than assuming that help is needed for all activities or that, if assistance is needed, the patient will ask for it.

Health History

Communication between the nurse and the patient is essential. To ensure that the patient is able to respond to assessment questions and provide needed information, interpreters, assistive listening devices, or other alternative formats (eg, Braille, large-print forms) may be required.

When interpreters are needed, interpretation services should be arranged. Health care facilities have a responsibility to provide these services without charge to the patient. Family members (especially children) should *not* be used as interpreters, because doing so violates the patient's right to privacy and confidentiality.

The nurse should speak directly to the patient and not to family members or others who have accompanied the patient. If the patient has vision or hearing loss, normal tone and volume of the voice should be used when conducting the assessment. The patient should be able to see the nurse's face clearly during the health history, so that speech reading and nonverbal clues can be used to aid communication.

The health history should address general health issues that are important to all patients, including sexual history and risk for abuse. It should also address the impact of the patient's disability on health issues and access to care and the effect of the patient's current health problem on his or her disability.

The nurse should verify what the patient has said; if the patient has difficulty communicating verbally, the nurse should ask for clarification rather than assume that it is too difficult for the patient to do so. Most people would rather be asked to explain again than run the risk of being misunderstood (Smeltzer, et al., 2007).

Physical Examination

Inaccessible facilities remain a major barrier to health care for people with disabilities. Barriers include lack of ramps and grab bars, inaccessible restrooms, small examination rooms, and examination tables that cannot be lowered to allow the patient to move himself or herself onto, or be transferred easily and safely to, the examination table. The patient may

need help getting undressed for the physical examination (and dressed again), moving on and off the examination table, and maintaining positions usually required during physical examination maneuvers. It is important to ask the patient what assistance is needed.

If the patient has impaired sensory function (eg, lack of sensation, hearing or vision loss), it is important to inform the patient that you will be touching him or her. Furthermore, it is important to explain all procedures and maneuvers.

Gynecologic examinations should *not* be deferred because a patient has a disability or is assumed to be sexually inactive. Explanations of the examination are important for all women, and even more so for women with disabilities, because they may have had previous negative experiences. Slow, gentle moving and positioning of the patient for the gynecologic examination and warming the speculum before attempting insertion often minimize spasticity in women with neurologically related disabilities.

Health Screening and Testing

Many people with disabilities report that they have not been weighed for years or even decades because they are unable to stand for this measurement. Alternative methods (eg, use of wheelchair scales) are needed to monitor weight and body mass index. This is particularly important because of the increased incidence of obesity and its effects on health status and transfer of persons with disabilities.

Patients with disabilities may require special assistance if urine specimens are to be obtained as part of the visit. They are often able to suggest strategies to obtain urine specimens based on previous experience.

If it is necessary for the nurse to wear a mask during a procedure or if the patient is unable to see the face of the nurse during a procedure, it is important to explain the procedure and the expected role of the patient ahead of time. If the patient is unable to hear or is unable to communicate with the nurse or other health care provider verbally during an examination or diagnostic test, a method of communication (eg, signaling the patient by tapping his or her arm, signaling the nurse by using a bell) should be established beforehand.

Inaccessible facilities have resulted in decreased participation of people with disabilities in recommended preventive screening, including gynecologic examinations, mammograms, and bone density testing (Smeltzer, Zimmerman & Capriotti, 2005). Therefore, it is important to ask about health screening and recommendations for screening. In addition, people with disabilities should be asked about their participation in health promotion activities, because inaccessible environments may limit their participation in exercise, health programs, and other health promotion efforts.

concerns is acceptable and can be approached again in the future if so desired. Further discussion of the sexual history is presented in Chapters 46 and 49.

Risk for Abuse

Physical, sexual, and psychological abuse is a topic of growing importance in today's society. Such abuse occurs to people of both genders, of all ages, and from all socioeconomic, ethnic, and cultural groups. Patients rarely discuss this topic unless specifically asked about it. In fact, research shows that the majority of women currently in an abusive relationship have never told a health care provider. Therefore, it is important to ask direct questions, such as:

- Is anyone physically hurting you or forcing you to have sexual activities?
- Has anyone ever hurt you physically or threatened to do so?
- Are you ever afraid of anyone close to you (your partner, caregiver, or other family members)?

Patients who are elderly or have disabilities are at increased risk for abuse and should be asked about it as a routine part of assessment. However, when elderly patients are questioned directly, they rarely admit to abuse. Health care professionals should assess for risk factors, such as high levels of stress or alcoholism in caregivers, evidence of violence, and emotional outbursts, as well as financial, emotional, or physical dependency.

Two additional questions have been found to be effective in uncovering specific types of abuse that may occur only in people with disabilities:

- Does anyone prevent you from using a wheelchair, cane, respirator, or other assistive device?
- Does anyone you depend on refuse to help you with an important personal need, such as taking your medicine, getting to the bathroom, getting in or out of bed, bathing, dressing, or getting food or drink?

If a person's response indicates that abuse is a risk, further assessment is warranted, and efforts are made to ensure the patient's safety and provide access to appropriate community and professional resources and support systems. Further discussion of domestic violence and abuse is presented in Chapter 46.

Stress and Coping Responses

Each person handles stress differently. How well people adapt depends on their ability to cope. During a health history, past coping patterns and perceptions of current stresses and anticipated outcomes are explored to identify the person's overall ability to handle stress. It is especially important to identify expectations that a person may have of family, friends, and caregivers in providing financial, emotional, or physical support. Further discussion of stress and coping is presented in Chapter 6.

Other Health History Formats

The health history format discussed in this chapter is only one possible approach that is useful in obtaining and organizing information about a person's health status. Some experts consider this traditional format to be inappropriate for nurses, because it does not focus exclusively on the assessment of human responses to actual or potential health prob-

lems. Several attempts have been made to develop an assessment format and database with this focus in mind. One example is a nursing database based on the North American Nursing Diagnosis Association and its 13 domains: health promotion, nutrition, elimination/exchange, activity/rest, perception/cognition, self-perception, role relationship, sexuality, coping/stress tolerance, life principles, safety/protection, comfort, and growth/development (NANDA International, 2007). Although there is support in nursing for using this approach, no consensus for its use has been reached. Other examples include electronic systems specific to home care and perioperative nursing (Simpson, 2007).

The National Center for Health Services Research of the U.S. Department of Health and Human Services (USDHHS) and other groups from the public and private sectors have focused on assessing not only biologic health, but also other dimensions of health. These dimensions include physical, functional, emotional, mental, and social health. Efforts to assess health status have focused on the manner in which disease or disability affects a patient's functional status—that is, the ability of the person to function normally and perform his or her usual physical, mental, and social activities. An emphasis on functional assessment is viewed as more holistic than the traditional health or medical history. Instruments to assess health status in these ways may be used by nurses along with their own clinical assessment skills to determine the impact of illness, disease, disability, and health problems on functional status.

Health concerns that are not complex (eg, earache, sinusitis) and can be resolved in a short period usually do not require the depth or detail that is necessary when a person is experiencing a major illness or health problem. Additional assessments that go beyond the general patient profile may be used if the patient's health problems are acute and complex or if the illness is chronic (Bickley, 2007; Weber & Kelley, 2007).

The person should be asked about continuing health promotion and screening practices. If the person has not been involved in these practices in the past, he or she should be educated about their importance and referred to appropriate health care providers. Research has shown that health promotion is beneficial even for frail older home care clients. One study found that proactively providing older people with health promotion compared to providing standard nursing home care services resulted in better mental health functioning, decreased depression, and enhanced perceptions of social support with no increase in costs (Markle-Reid, Weir, Browne, et al., 2006).

Regardless of the assessment format used, the focus of nurses during data collection is different from that of physicians and other health team members. However, the nursing focus complements these other approaches and encourages collaboration among the health care providers, with each member bringing his or her own expertise and focus to the situation.

Physical Assessment

Physical assessment, or the physical examination, is an integral part of nursing assessment. The basic techniques and tools used in performing a physical examination are

described in general in this chapter. The examinations of specific systems, including special maneuvers, are described in the appropriate chapters throughout the book.

Examination Considerations

The physical examination is usually performed after the health history is obtained. It is carried out in a well-lighted, warm area. The patient is asked to (or helped to) undress and is draped appropriately so that only the area to be examined is exposed. The person's physical and psychological comfort are considered at all times. It is necessary to describe procedures to the patient and explain what sensations to expect before each part of the examination. The examiner's hands are washed before and immediately after the examination. Fingernails are kept short to avoid injuring the patient. If there is a possibility of coming into contact with blood or other body secretions during the physical examination, gloves should be worn.

An organized and systematic examination is the key to obtaining appropriate data in the shortest time. Such an approach encourages cooperation and trust on the part of the patient. The person's health history provides the examiner with a health profile that guides all aspects of the physical examination.

A "complete" physical examination is not routine. Many of the body systems are selectively assessed on the basis of the presenting problem. For example, if a healthy 20-year-old college student requires an examination to study abroad and reports no history of neurologic abnormality, the neurologic assessment is brief. Conversely, a history of transient numbness and diplopia (double vision) usually necessitates a complete neurologic investigation. Similarly, a patient with chest pain receives a much more intensive examination of the chest and heart than one with an earache. In general, the health history guides the examiner in obtaining additional data for a complete picture of the patient's health.

The process of learning to perform a physical examination requires repetition and reinforcement in a clinical setting. Only after basic physical assessment techniques are mastered can the examiner tailor the routine screening examination to include thorough assessments of particular systems, including special maneuvers (Bickley, 2007; Weber & Kelley, 2007).

Components of the Physical Examination

The components of a physical examination include general observations and then a more focused assessment of the pertinent body systems. The tools of the physical examination are the human senses of vision, hearing, touch, and smell. These may be augmented by special tools (eg, stethoscope, ophthalmoscope, reflex hammer) that are extensions of the human senses; they are simple tools that anyone can learn to use well. Expertise comes with practice, and sophistication comes with the interpretation of what is seen and heard.

Initial Observations

General inspection begins with the first contact with the patient. Introducing oneself and shaking hands provide opportunities for making initial observations: Is the person old

or young? How old? How young? Does the person appear to be his or her stated age? Is the person thin or obese? Does the person appear anxious or depressed? Is the person's body structure normal or abnormal? In what way, and how different from normal? It is essential to pay attention to the details in observation. Vague, general statements are not a substitute for specific descriptions based on careful observation. Consider the following examples:

- "The person appears sick." In what way does he or she appear sick? Is the skin clammy, pale, jaundiced, or cyanotic? Is the person grimacing in pain or having difficulty breathing? Does he or she have edema? What specific physical features or behavioral manifestations indicate that the person is "sick"?
- "The person appears chronically ill." In what way does he or she appear chronically ill? Does the person appear to have lost weight? People who lose weight secondary to muscle-wasting diseases (eg, acquired immunodeficiency syndrome [AIDS], malignancy) have a different appearance than those who are merely thin, and weight loss may be accompanied by loss of muscle mass or atrophy. Does the skin have the appearance of chronic illness (ie, is it pale, or does it give the appearance of dehydration or loss of subcutaneous tissue)?

These important specific observations are documented in the patient's chart or health record. Among general observations that should be noted in the initial examination of the patient are posture and stature, body movements, nutritional status, speech pattern, and vital signs.

Posture

The posture that a person assumes often provides valuable information. Patients who have breathing difficulties (dyspnea) secondary to cardiac disease prefer to sit and may report feeling short of breath when lying flat for even a brief time. Patients with abdominal pain due to peritonitis prefer to lie perfectly still; even slight jarring of the bed causes agonizing pain. In contrast, patients with abdominal pain due to renal or biliary colic are often restless and may pace the room.

Body Movements

Abnormalities of body movement are of two kinds: generalized disruption of voluntary or involuntary movement and asymmetry of movement. The first category includes tremors of a wide variety; some tremors may occur at rest (Parkinson's disease), whereas others occur only on voluntary movement (cerebellar ataxia). Other tremors may exist during both rest and activity (alcohol withdrawal syndrome, thyrotoxicosis). Some voluntary or involuntary movements are fine, and others are quite coarse. At the extreme are the convulsive movements of epilepsy or tetanus and the choreiform (involuntary and irregular) movements of patients with rheumatic fever or Huntington disease.

Asymmetry of movement, in which only one side of the body is affected, may occur with disorders of the central nervous system (CNS), primarily in those patients who have had a cerebrovascular accident (stroke). Patients may have drooping of one side of the face, weakness or paralysis of the extremities on one side of the body, and a

foot-dragging gait. Spasticity (increased muscle tone) may also be present, particularly in patients with multiple sclerosis.

Nutritional Status

Nutritional status is important to note. Obesity may be generalized as a result of excessive intake of calories, or it may be specifically localized to the trunk in patients who have an endocrine disorder (Cushing's disease) or who have been taking corticosteroids for long periods. Loss of weight may be generalized as a result of inadequate caloric intake, or it may be seen in loss of muscle mass with disorders that affect protein synthesis. Nutritional assessment is discussed in more detail later in this chapter.

Speech Pattern

Speech may be slurred because of CNS disease or because of damage to cranial nerves. Recurrent damage to the laryngeal nerve results in hoarseness, as do disorders that produce edema or swelling of the vocal cords. Speech may be halting, slurred, or interrupted in flow in patients with some CNS disorders (eg, multiple sclerosis, stroke).

Vital Signs

The recording of vital signs is a part of every physical examination (Bickley, 2007). Blood pressure, pulse rate, respiratory rate, and body temperature measurements are obtained and recorded. Acute changes and trends over time are documented, and unexpected changes and values that deviate significantly from a patient's normal values are brought to the attention of the patient's primary health care provider. The "fifth vital sign," pain, is also assessed and documented, if indicated.

A normal oral temperature for most people is 37.0°C (98.6°F); however, some variation is normal. Some people's temperatures are quite normal at 36.6°C (98°F) or 37.3°C (99°F). There is a normal diurnal variation of a degree or two in body temperature throughout the day; temperature is usually lowest in the morning and increases during the day to between 37.3° and 37.5°C (99° to 99.5°F), and it then decreases during the night (Bickley, 2007; Weber & Kelley, 2007).

Focused Assessment

Following the general inspection, a more focused assessment is conducted. Although the sequence of physical examination depends on the circumstances and on the patient's reason for seeking health care, the complete examination usually proceeds as follows:

- Skin
- Head and neck
- Thorax and lungs
- Breasts
- Cardiovascular system
- Abdomen
- Rectum
- Genitalia
- Neurologic system
- Musculoskeletal system

In clinical practice, all relevant body systems are tested throughout the physical examination, not necessarily in the sequence described (Weber & Kelley, 2007). For example, when the face is examined, it is appropriate to check for facial asymmetry and, thus, for the integrity of the fifth and seventh cranial nerves; the examiner does not need to repeat this as part of a neurologic examination. When systems are combined in this manner, the patient does not need to change positions repeatedly, which can be exhausting and time-consuming.

The traditional sequence in the focused portion of the examination is inspection, palpation, percussion, and then auscultation, except in the case of an abdominal examination.

Inspection

The first fundamental technique is **inspection** or observation of each relevant body system in more detail as indicated from the health history or the general inspection. Characteristics such as skin color, presence and size of lesions, edema, erythema, symmetry, and pulsations are noted. Specific body movements that are noted on inspection include spasticity, muscle spasms, and an abnormal gait (Porth & Matfin, 2009).

Palpation

Palpation is a vital part of the physical examination. Many structures of the body, although not visible, may be assessed through the techniques of light and deep palpation (Fig. 5-3).

Figure 5-3 A, Light palpation. B, Deep palpation.

Examples include the superficial blood vessels, lymph nodes, thyroid gland, organs of the abdomen and pelvis, and rectum. When the abdomen is examined, auscultation is performed before palpation and percussion to avoid altering bowel sounds (Bickley, 2007; Weber & Kelley, 2010).

Sounds generated within the body, if within specified frequency ranges, also may be detected through touch. For example, certain murmurs generated in the heart or within blood vessels (thrills) may be detected. Thrills cause a sensation to the hand much like the purring of a cat. Voice sounds are transmitted along the bronchi to the periphery of the lung. These may be perceived by touch and may be altered by disorders affecting the lungs. The phenomenon is called *tactile fremitus* and is useful in assessing diseases of the chest. The significance of these findings is discussed in Chapters 21 and 26.

Percussion

The technique of **percussion** translates the application of physical force into sound (Fig. 5-4). It is a skill requiring practice that yields much information about disease processes in the chest and abdomen (Bickley, 2007; Weber & Kelley, 2007). The principle is to set the chest wall or abdominal wall into vibration by striking it with a firm object. The sound produced reflects the density of the underlying structure. Certain densities produce sounds as percussion notes. These sounds, listed in a sequence that proceeds from the least to the most dense, are tympany, hyperresonance, resonance, dullness, and flatness. Tympany is the drumlike sound produced by percussing the air-filled stomach. Hyperresonance is audible when one percusses over inflated lung tissue in a person with emphysema. Resonance is the sound elicited over air-filled lungs. Percussion of the liver produces a dull sound, whereas percussion of the thigh produces a flat sound.

Percussion allows the examiner to assess such normal anatomic details as the borders of the heart and the movement of the diaphragm during inspiration. It is also possible to determine the level of a pleural effusion (fluid in the pleural cavity) and the location of a consolidated area

caused by pneumonia or atelectasis (collapse of alveoli). The use of percussion is described further with disorders of the thorax and abdomen (see Chapters 21 and 34).

Auscultation

Auscultation is the skill of listening to sounds produced within the body created by the movement of air or fluid. Examples include breath sounds, the spoken voice, bowel sounds, heart sounds, and cardiac murmurs. Physiologic sounds may be normal (eg, first and second heart sounds) or pathologic (eg, heart murmurs in diastole, crackles in the lung). Some normal sounds may be distorted by abnormalities of structures through which the sound must travel (eg, changes in the character of breath sounds as they travel through the consolidated lung of a patient with lobar pneumonia).

Sound produced within the body, if of sufficient amplitude, may be detected with the stethoscope, which functions as an extension of the human ear and channels sound. The nurse must avoid touching the tubing or rubbing other surfaces (hair, clothing) during auscultation to minimize extraneous noises.

Sound produced by the body, like any other sound, is characterized by intensity, frequency, and quality. The *intensity*, or loudness, associated with physiologic sound is low; therefore, the use of the stethoscope is needed. The *frequency*, or pitch, of physiologic sound is in reality “noise,” in that most sounds consist of a frequency spectrum, as opposed to the single-frequency sounds that we associate with music or a tuning fork. The frequency spectrum may be quite low, yielding a rumbling noise, or comparatively high, producing a harsh or blowing sound. *Quality* of sound relates to overtones that allow one to distinguish among various sounds. Sound quality enables the examiner to distinguish between the musical quality of high-pitched wheezing and the low-pitched rumbling of a diastolic murmur (Bickley, 2007; Weber & Kelley, 2007).

Nutritional Assessment

Nutrition is important to maintain health and to prevent disease and death. When illness or injury occurs, optimal nutrition is essential for healing and resisting infection and other complications. An in-depth nutritional assessment is often integrated into the health history and physical examination. Assessment of nutritional status provides information about obesity, weight loss, undernutrition, malnutrition, deficiencies in specific nutrients, metabolic abnormalities, the effects of medications on nutrition, and special problems affecting patients both in hospitals and in the home and other community settings (Chen, 2005).

Disorders caused by nutritional deficiency, overeating, or eating unhealthy meals are among the leading causes of illness and death in the United States today. The three leading causes of death—heart disease, cancer, and stroke—are related, in part, to consequences of unhealthy nutrition (Lear, Humphries, Kohl, et al., 2007). Other examples of health problems associated with poor nutrition include obesity, osteoporosis, cirrhosis, diverticulitis, and eating disorders.

Figure 5-4 Percussion technique. The middle finger of one hand strikes the terminal phalanx of the middle finger of the other hand, which is placed firmly against the body. If the action is performed sharply, a brief, resonant tone will be produced. The clarity of the tone depends on the brevity of the action. The intensity of the tone varies with the force used.

Certain signs and symptoms that suggest possible nutritional deficiency, such as muscle wasting, poor skin integrity, loss of subcutaneous tissue, and obesity, are easy to note because they are specific; these should be pursued further. Other physical signs may be subtle and must be carefully assessed. For example, certain signs that appear to indicate nutritional deficiency may actually reflect other systemic conditions (eg, endocrine disorders, infectious disease). Others may result from impaired digestion, absorption, excretion, or storage of nutrients in the body (Porth & Matfin, 2009; Weber & Kelley, 2007).

Lifespan Considerations

Adolescence is a time of critical growth and acquisition of lifelong eating habits, and therefore nutritional assessment, analysis, and intervention are critical (Vereecken et al., 2005). In the past two decades rates of obesity in adolescents have increased at an alarming rate.

Adolescent girls are at particular nutritional risk, because iron, folate, and calcium intakes are below recommended levels and they are a less physically active group compared to adolescent males. Adolescents with other nutritional disorders, such as anorexia and bulimia, have a better chance of recovery if these disorders are identified and treated in the adolescent years rather than in adulthood.

The elderly are also at risk for altered nutrition. Special considerations for nutritional assessment in the older adult are presented in Chart 5-7.

Components of Nutritional Assessment

The sequence of assessment of parameters may vary, but evaluation of nutritional status includes one or more of the

following methods: measurement of body mass index and waist circumference, biochemical measurements, clinical examination findings, and dietary data.

Body Mass Index

Body mass index (BMI) is a ratio based on body weight and height. The obtained value is compared to the established standards; however, trends or changes in values over time are considered more useful than isolated or one-time measurements. BMI (Fig. 5-5) is highly correlated with body fat, but increased lean body mass or a large body frame can also increase the BMI. People who have a BMI lower than 24 (or who are 80% or less of their desirable body weight for height) are at increased risk for problems associated with poor nutritional status. In addition, a low BMI is associated with a higher mortality rate among hospitalized patients and community-dwelling elderly. Those who have a BMI of 25 to 29 are considered overweight; those with a BMI of 30 to 39, obese; and those with a BMI greater than 40, extremely obese (Dudek, 2006). In analyzing BMI, the nurse must be aware that cutoff scores for normal, overweight, and obese may differ for different ethnic groups.

It is important to assess for usual body weight and height and to compare these values with ideal weight (Chart 5-8). Current weight does not provide information about recent changes in weight; therefore, patients are asked about their usual body weight. Loss of height may be due to osteoporosis, an important problem related to nutrition, especially in postmenopausal women. A loss of 2 or 3 inches of height may indicate osteoporosis (Bickley, 2007; Weber & Kelley, 2007).

In addition to the calculation of BMI, waist circumference measurement is particularly useful for adult patients who are categorized as being of normal weight or over-

CHART
5-7

Nutritional Assessment in the Older Adult

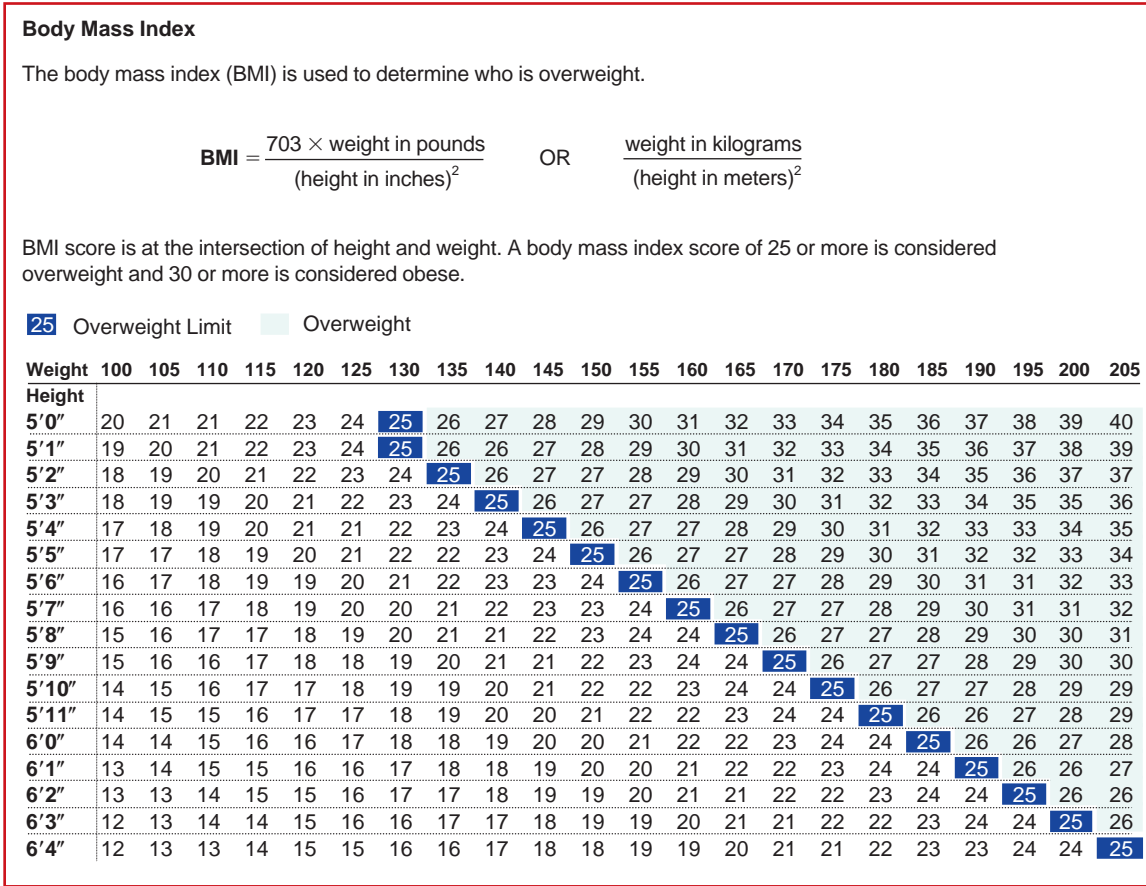

Nutritional screening in the elderly is a first step in maintaining adequate nutrition and replacing nutrient losses to maintain the individual's health and well-being. Aging is associated with increases in the incidence of weight loss, being underweight, and having protein-energy malnutrition (Soriano, et al., 2007). Elderly people who are malnourished tend to have longer and more expensive hospital stays than those who are adequately nourished; the risk of costly complications is also increased in malnourished patients (Dudek, 2006).

Inadequate dietary intake in the elderly may result from physiologic changes in the gastrointestinal tract, social and economic factors, drug interactions, disease, excessive use of alcohol, and poor dentition or missing teeth. Malnutrition is a common consequence of these factors and in turn leads to illness and frailty of the elderly. Important aspects of care of the elderly in the hospital, home, outpatient setting, or extended care facility include recognizing risk factors and identifying those who are at risk for inadequate nutrition (Soriano, et al., 2007).

Many elderly people take excessive and inappropriate medications; this is referred to as polypharmacy. The number of adverse reactions increases proportionately with the number of prescribed and over-the-counter medications taken. Age-related physiologic and pathophysiologic changes may

alter the metabolism and elimination of many medications. Medications can influence food intake by producing side effects such as nausea, vomiting, decreased appetite, and changes in sensorium. They may also interfere with the distribution, utilization, and storage of nutrients. Disorders affecting any part of the gastrointestinal tract can alter nutritional requirements and health status in people of any age; however, they are likely to occur more quickly and more frequently in the elderly.

Nutritional problems in the elderly often occur or are precipitated by such illnesses as pneumonia and urinary tract infections. Acute and chronic diseases may affect the metabolism and utilization of nutrients, which already are altered by the aging process. Up-to-date immunizations, prompt treatment of bacterial infections, and social programs such as Meals on Wheels may reduce the risk of illness-associated malnutrition. Alcohol and substance abuse are potential factors in the elderly population that should not be overlooked (OASAS, 2007). Even the well elderly may be nutritionally at risk because of decreased odor perception, poor dental health, limited ability to shop and cook, financial hardship, and the fact that they often eat alone. Also, reduction in exercise with age without concomitant changes in carbohydrate intake places the elderly at risk for obesity.

Figure 5-5 Body mass index.

weight (Dudek, 2006). To measure waist circumference, a tape measure is placed in a horizontal plane around the abdomen at the level of the iliac crest. A waist circumference greater than 40 inches for men or 35 inches for women indicates excess abdominal fat. Those with a high waist cir-

cumference are at increased risk for diabetes, dyslipidemias, hypertension, cardiovascular disease, and atrial fibrillation (Bickley, 2007; Weber & Kelley, 2009).

Biochemical Assessment

Biochemical assessment reflects both the tissue level of a given nutrient and any abnormality of metabolism in the utilization of nutrients. These determinations are made from studies of serum (albumin, transferrin, retinol-binding protein, electrolytes, hemoglobin, vitamin A, carotene, vitamin C, and total lymphocyte count) and studies of urine (creatinine, thiamine, riboflavin, niacin, and iodine). See Appendix A for normal serum and urine biochemical values. Some of these tests, while reflecting recent intake of the elements detected, can also identify below-normal levels when there are no clinical symptoms of deficiency.

Low serum albumin and prealbumin levels are most often used as measures of protein deficit in adults. Albumin synthesis depends on normal liver function and an adequate supply of amino acids. Because the body stores a large amount of albumin, the serum albumin level may not decrease until malnutrition is severe; therefore, its usefulness in detecting recent protein depletion is limited. Decreased albumin levels may be caused by overhydration, liver or renal disease, or excessive protein loss due to burns, major surgery, infection, or cancer. Serial measurements of prealbumin

Chart 5-8 • Calculating Ideal Body Weight

Women

- Allow 100 lb for 5 feet of height.
- Add 5 lb for each additional inch over 5 feet.
- Subtract 10% for small frame; add 10% for large frame.

Men

- Allow 106 lb for 5 feet of height.
- Add 6 lb for each additional inch over 5 feet.
- Subtract 10% for small frame, add 10% for large frame.

Example: Ideal body weight for a 5'6" adult is

	Female	Male
5' of height	100 lb	106 lb
Per additional inch	6" × 5 lb/inch = 30 lb	6" × 6 lb/inch = 36 lb
Ideal body weight	130 lb ± 13 lb depending on frame size	142 lb ± 14 lb depending on frame size

levels are also used to assess the results of nutritional therapy. Prealbumin, also called thyroxin-binding protein, is a more sensitive indicator of protein status than albumin, but the test is more expensive and therefore less frequently ordered (Dudek, 2006; Kuszajewski & Clontz, 2005).

Additional laboratory data, such as levels of transferrin and retinol-binding protein, anergy panels, and lymphocyte and electrolyte counts, are used in many institutions. Transferrin is a protein that binds and carries iron from the intestine through the serum. Because of its short half-life, transferrin levels decrease more quickly than albumin levels in response to protein depletion. Although measurement of retinol-binding protein is not available from many laboratories, it may be a useful means of monitoring acute, short-term changes in protein status. The total lymphocyte count may be reduced in people who are acutely malnourished as a result of stress and low-calorie feeding and in those with impaired cellular immunity. Anergy, the absence of an immune response to injection of small concentrations of recall antigen under the skin, may also indicate malnutrition because of delayed antibody synthesis and response. Serum electrolyte levels provide information about fluid and electrolyte balance and kidney function. The creatinine/height index calculated over a 24-hour period assesses the metabolically active tissue and indicates the degree of protein depletion, comparing expected body mass for height with actual body cell mass. A 24-hour urine sample is obtained, and the amount of creatinine is measured and compared to normal ranges based on the patient's height and gender. Values lower than normal may indicate loss of lean body mass and protein malnutrition.

Clinical Examination

The state of nutrition is often reflected in a person's appearance. Although the most obvious physical sign of good

nutrition is a normal body weight with respect to height, body frame, and age, other tissues can serve as indicators of general nutritional status and adequate intake of specific nutrients; these include the hair, skin, teeth, gums, mucous membranes, mouth and tongue, skeletal muscles, abdomen, lower extremities, and thyroid gland (Table 5-1). Specific aspects of clinical examination that are useful in identifying nutritional deficits include an examination (Chen, Chyun, Li, et al., 2007) and assessment of skin for turgor, edema, elasticity, dryness, subcutaneous tone, poorly healing wounds and ulcers, purpura, and bruises (Porth & Matfin, 2009). The musculoskeletal examination also provides information about muscle wasting and weakness.

Dietary Data

Commonly used methods of determining individual eating patterns include the food record, the 24-hour food recall, and a dietary interview. Each of these methods helps estimate whether food intake is adequate and appropriate. If these methods are used to obtain the dietary history, instructions must be given to the patient about measuring and recording food intake.

Methods of Collecting Data

Food Record. The food record is used most often in nutritional status studies. A person is instructed to keep a record of food actually consumed over a period of time, varying from 3 to 7 days, and to accurately estimate and describe the specific foods consumed. Food records are fairly accurate if the person is willing to provide factual information and is able to estimate food quantities.

24-Hour Recall. As the name implies, the 24-hour recall method is a recall of food intake over a 24-hour period. A person is asked to recall all foods eaten during the previous day and to estimate the quantities of each food consumed.

Table 5-1 PHYSICAL INDICATORS OF NUTRITIONAL STATUS

Indicator	Signs of Good Nutrition	Signs of Poor Nutrition
General appearance	Alert, responsive	Listless, appears acutely or chronically ill
Hair	Shiny, lustrous; firm, healthy scalp	Dull and dry, brittle, depigmented, easily plucked; thin and sparse
Face	Skin color uniform; healthy appearance	Skin dark over cheeks and under eyes, skin flaky, face swollen or hollow/sunken cheeks
Eyes	Bright, clear, moist	Eye membranes pale, dry (xerophthalmia); increased vascularity, cornea soft (keratomalacia)
Lips	Good color (pink), smooth	Swollen and puffy; angular lesion at corners of mouth (cheilosis)
Tongue	Deep red in appearance; surface papillae present	Smooth appearance, swollen, beefy-red, sores, atrophic papillae
Teeth	Straight, no crowding, no dental caries, bright	Dental caries, mottled appearance (fluorosis), malpositioned
Gums	Firm, good color (pink)	Spongy, bleed easily, marginal redness, recession
Thyroid	No enlargement of the thyroid	Thyroid enlargement (simple goiter)
Skin	Smooth, good color, moist	Rough, dry, flaky, swollen, pale, pigmented; lack of fat under skin
Nails	Firm, pink	Spoon-shaped, ridged, brittle
Skeleton	Good posture, no malformation	Poor posture, beading of ribs, bowed legs or knock knees
Muscles	Well developed, firm	Flaccid, poor tone, wasted, underdeveloped
Extremities	No tenderness	Weak and tender; edematous
Abdomen	Flat	Swollen
Nervous system	Normal reflexes	Decreased or absent ankle and knee reflexes
Weight	Normal for height, age, and body build	Overweight or underweight

Because information does not always represent usual intake, at the end of the interview the patient is asked whether the previous day's food intake was typical. To obtain supplementary information about the typical diet, it is also necessary to ask how frequently the person eats foods from the major food groups.

Dietary Interview. The success of the interviewer in obtaining information for dietary assessment depends on effective communication, which requires that good rapport be established to promote respect and trust. The interviewer explains the purpose of the interview. The interview is conducted in a nondirective and exploratory way, allowing the respondent to express feelings and thoughts while encouraging him or her to answer specific questions. The manner in which questions are asked influences the respondent's cooperation. The interviewer must be nonjudgmental and avoid expressing disapproval, either by verbal comments or by facial expression.

Character of General Intake Several questions may be necessary to elicit the information needed. When attempting to elicit information about the type and quantity of food eaten at a particular time, leading questions such as, "Do you use sugar or cream in your coffee?" should be avoided. In addition, assumptions are not made about the size of servings; instead, questions are phrased so that quantities are more clearly determined. For example, to help determine the size of one hamburger, the patient may be asked, "How many servings were prepared with the pound of meat you bought?" Another approach to determining quantities is to use food models of known sizes in estimating portions of meat, cake, or pie, or to record quantities in common measurements, such as cups or spoonfuls (or the size of containers, when discussing intake of bottled beverages).

In recording a particular combination dish, such as a casserole, it is useful to ask about the ingredients, recording the largest quantities first. When recording quantities of ingredients, the interviewer notes whether the food item was raw or cooked and the number of servings provided by the recipe. When a patient lists the foods for the recall questionnaire, it may help to read back the list of foods and ask whether anything was forgotten, such as fruit, cake, candy, between-meal snacks, or alcoholic beverages.

Additional information obtained during the interview should include methods of preparing food, sources available for food (including donated foods and food stamps), food-buying practices, use of vitamin and mineral supplements, and income range (Chen, 2005; Gilliam, 2006).

Cultural and Religious Considerations An individual's culture determines to a large extent which foods are eaten and how they are prepared and served. Culture and religious practices together often determine whether certain foods are prohibited and whether certain foods and spices are eaten on certain holidays or at specific family gatherings. Because of the importance of culture and religious beliefs to many individuals, it is important to be sensitive to these factors when obtaining a dietary history. It is, however, equally important not to stereotype individuals and assume that because they are from a certain culture or religious group, they adhere to specific dietary customs. One particular area of consideration is the presence of fish and shellfish in the diet,

where they come from (farmed versus wild), and the method of preparation. These methods may put certain populations at risk for toxicity due to contaminants. Culturally sensitive materials, such as the food pagoda and the Mediterranean Pyramid, are available for making appropriate dietary recommendations (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2005).

Evaluating Dietary Information

After obtaining basic dietary information, the nurse evaluates the patient's dietary intake and communicates the information to the dietitian and the rest of the health care team for more detailed assessment and for clinical nutrition intervention. If the goal is to determine whether the patient generally eats a healthful diet, his or her food intake may be compared with the dietary guidelines outlined in the U.S. Department of Agriculture's Food Guide Pyramid (Fig. 5-6). The pyramid divides foods into five major groups (grains, vegetables, fruits, milk products, and meat and beans), plus fats and oils. Recommendations are provided for variety in the diet, proportion of food from each food group, and moderation in eating fats, oils, and sweets. A person's food intake is compared with recommendations based on various food groups for different age groups and activity levels (Weber & Kelley, 2007).

If nurses or dietitians are interested in knowing about the intake of specific nutrients, such as vitamin A, iron, or calcium, the patient's food intake is analyzed by consulting a list of foods and their composition and nutrient content. The diet is analyzed in terms of grams and milligrams of specific nutrients. The total nutritive value is then compared with the recommended dietary allowances specific for the patient's age category, gender, and special circumstances such as pregnancy or lactation.

Fat intake and cholesterol levels are additional aspects of the nutritional assessment. Trans fats are produced when hydrogen atoms are added to monounsaturated or polyunsaturated fats to produce a semisolid product, such as margarine. Trans fats, which are contained in many baked goods and restaurant foods, are a concern, because increased amounts of trans fats have been associated with increased risk for heart disease and stroke. Since 2006, the U.S. Food and Drug Administration has required the inclusion of trans fats information on food labels.

Factors Influencing Nutritional Status in Various Situations

One sensitive indicator of the body's gain or loss of protein is its nitrogen balance. An adult is said to be in nitrogen equilibrium when the nitrogen intake (from food) equals the nitrogen output (in urine, feces, and perspiration); it is a sign of health. A positive nitrogen balance exists when nitrogen intake exceeds nitrogen output and indicates tissue growth, such as occurs during pregnancy, childhood, recovery from surgery, and rebuilding of wasted tissue. A negative nitrogen balance indicates that tissue is breaking down faster than it is being replaced. In the absence of an adequate intake of protein, the body converts protein to glucose for energy. This can occur with fever, starvation, surgery, burns, and debilitating diseases. Each gram of nitrogen

Figure 5-6 MyPyramid emphasizes foods from the five major food groups. Each of these food groups provides some, but not all, of the nutrients an adult needs. Foods in one group cannot replace those in another. No one of these major food groups is more important than another. From U.S. Department of Agriculture, Center for Nutrition Policy and Promotion. (2005). *MyPyramid: Steps to a healthier you* (5th ed.). Available at: www.MyPyramid.gov.

loss in excess of intake represents the depletion of 6.25 g of protein or 25 g of muscle tissue. Therefore, a negative nitrogen balance of 10 g/day for 10 days could mean the wasting of 2.5 kg (5.5 pounds) of muscle tissue as it is converted to glucose for energy.

When conditions that result in negative nitrogen balance are combined with anorexia (loss of appetite), they can lead to malnutrition. Malnutrition interferes with wound healing, increases susceptibility to infection, and contributes to an increased incidence of complications,

longer hospital stays, and prolonged confinement of patients to bed (Morton, Fontaine, Hudak, et al., 2005).

Patients who are hospitalized may have an inadequate dietary intake because of the illness or disorder that necessitated the hospital stay or because the hospital's food is unfamiliar or unappealing. Patients who are cared for at home may feel too sick or fatigued to shop and prepare food, or they may be unable to eat because of other physical problems or limitations. Limited or fixed incomes or the high costs of medications may result in insufficient money to

Table 5-2 FACTORS ASSOCIATED WITH POTENTIAL NUTRITIONAL DEFICITS

Factor	Possible Consequences
Dental and oral problems (missing teeth, ill-fitting dentures, impaired swallowing or chewing)	Inadequate intake of high-fiber foods
NPO for diagnostic testing	Inadequate caloric and protein intake; dehydration
Prolonged use of glucose and saline IV fluids	Inadequate caloric and protein intake
Nausea and vomiting	Inadequate caloric and protein intake; loss of fluid, electrolytes, and minerals
Stress of illness, surgery, and/or hospitalization	Increased protein and caloric requirement; increased catabolism
Wound drainage	Loss of protein, fluid, electrolytes, and minerals
Pain	Loss of appetite; inability to shop, cook, eat
Fever	Increased caloric and fluid requirement; increased catabolism
Gastrointestinal intubation	Loss of protein, fluid, and minerals
Tube feedings	Inadequate amounts; various nutrients in each formula
Gastrointestinal disease	Inadequate intake and malabsorption of nutrients
Alcoholism	Inadequate intake of nutrients; increased consumption of calories without other nutrients; vitamin deficiencies
Depression	Loss of appetite; inability to shop, cook, eat
Eating disorders (anorexia, bulimia)	Inadequate caloric and protein intake; loss of fluid, electrolytes, and minerals
Medications	Inadequate intake due to medication side effects, such as dry mouth, loss of appetite, decreased taste perception, difficulty swallowing, nausea and vomiting, physical problems that limit shopping, cooking, eating; malabsorption of nutrients
Restricted ambulation or disability	Inability to help self to food, liquids, other nutrients

buy nutritious foods. Patients with inadequate housing or inadequate cooking facilities are unlikely to have an adequate nutritional intake (Mai & Eng, 2007). Because complex treatments (eg, mechanical ventilation, intravenous infusions, chemotherapy), once used only in the hospital setting, are now being provided in the home and outpatient settings, nutritional assessment of patients in these settings is an important aspect of home and community-based care.

Many medications influence nutritional status by suppressing the appetite, irritating the oral or gastric mucosa, or causing nausea and vomiting. Others may influence bacterial flora in the intestine or directly affect nutrient absorption so that secondary malnutrition results. People who must take many medications in a single day often report feeling too full to eat. A patient's use of prescription and OTC medications and their effects on appetite and dietary intake are assessed. Many of the factors that contribute to poor nutritional status are identified in Table 5-2.

Analysis of Nutritional Status

Physical measurements (BMI, waist circumference) and biochemical, clinical, and dietary data are used in combination to determine a patient's nutritional status. Often, these data provide more information about the patient's nutritional status than the clinical examination, which may not detect subclinical deficiencies unless they become so advanced that overt signs develop. A low intake of nutrients over a long period may lead to low biochemical levels and, without nutritional intervention, may result in characteristic and observable signs and symptoms (see Table 5-2). A plan of action for nutritional intervention is based on the results of the dietary assessment and

the patient's clinical profile. To be effective, the plan must meet the patient's need for a healthy diet, maintain (or control) weight, and compensate for increased nutritional needs.

Assessment in the Home and Community

Assessment of people in community settings, including the home, consists of collecting information specific to existing health problems, including data on the patient's physiologic and emotional status, the community and home environment, the adequacy of support systems or care given by family and other care providers, and the availability of needed resources. In addition, it is important to evaluate the ability of the individual and family to cope with and address their respective needs. The physical assessment in the community and home consists of the same techniques used in the hospital, outpatient clinic, or office setting. Privacy is provided, and the person is made as comfortable as possible.

Before the first home visit, the nurse usually calls the patient's home to let the patient know when to expect the home care nurse; this also gives the patient's primary caregiver the opportunity to be available. During the home visit, assessment is not limited to physical assessment of the patient. Other aspects of assessment are related to the home environment and support systems (Chart 5-9). The patient may not have family members available to assist him or her and may live alone in substandard housing or in a shelter for the homeless (Mai & Eng, 2007). Therefore, the nurse must be aware of resources available in the community and methods of obtaining those resources for the patient.

CHART
5-9

Assessing the Home Environment

Physical Facilities (check all that apply)

Exterior

- steps
- unsafe steps
- porch
- litter
- noise
- inadequate lighting
- other _____

Interior

- accessible bathroom
- level, safe floor surface
- number of rooms
- privacy
- sleeping arrangements
- refrigeration
- trash management
- animals
- adequate lighting
- steps/stairs
- other _____

Safety Hazards found in the patient's current residence (check all that apply)

- none
- inadequate floor, roof, or windows
- inadequate lighting
- unsafe gas/electric appliances
- inadequate heating
- inadequate cooling
- lack of fire safety devices
- unsafe floor coverings
- inadequate stair rails
- lead-based paint
- improperly stored hazardous material
- improper wiring/electrical cords
- other _____

Safety factors (check all that apply)

- fire/smoke detectors
- telephone
- placement of electrical cords
- emergency plan
- emergency phone numbers displayed
- safe portable heaters
- obstacle-free paths
- other _____

CRITICAL THINKING EXERCISES

EBP 1 Your health history and physical examination of a young adult male patient alerts you to the possibility of substance abuse. Explain how you would pursue this. What is the evidence base for available assessments to assist in a more comprehensive evaluation? Identify the criteria used to evaluate the strength of the evidence for this practice.

EBP 2 Your health assessment of a female college freshman reveals that she has a high fat intake, has a minimal calcium intake, and gets little exercise. What recommendations would you make for this patient? If the patient is a vegetarian, what dietary instructions would you develop for her? What is the evidence base for the type of instructional method to use with a college student? Identify the criteria used to evaluate the strength of the evidence for this practice.

3 How would you modify your health history and physical assessment technique if your patient has the following disabilities: (1) impaired communication due to aphasia secondary to stroke, (2) impaired mobility due to spinal cord injury, or (3) cognitive impairment?

Biophysical and Psychosocial Concepts in Nursing Practice

Case Study • Applying Concepts from NANDA, NIC, and NOC

A Patient with Fear Accompanied By Somatic Complaints Unsubstantiated By Physical Findings

Mr. Roberts is a 40-year-old man who comes to the emergency department (ED) for treatment of high blood pressure. On his previous visit to the ED he reported chest pressure, feelings of numbness and tingling in his arms, and extreme fearfulness that he was having a heart attack. Even though a myocardial infarction was ruled out and subsequent testing revealed that he had no heart disease, Mr. Roberts continues to have feelings of chest pressure and fear that he is having a heart attack. The only abnormal finding has been an elevation of blood pressure (158/88 mm Hg). The nurse interviews Mr. Roberts, who reveals he is under intense financial pressure. The nurse assesses his compliance with his antihypertensive therapy and suggests interventions to help with Mr. Robert's anxiety.

Visit thePoint to view a concept map that illustrates the relationships that exist between the nursing diagnoses, interventions, and outcomes for the patient's clinical problems.

Nursing Classifications and Languages

NANDA NURSING DIAGNOSES	NIC NURSING INTERVENTIONS	NOC NURSING OUTCOMES
		Return to functional baseline status, stabilization of, or improvement in:
ANXIETY —Vague uneasy feeling of discomfort or dread accompanied by an autonomic response (the source often nonspecific or unknown to the individual); a feeling of apprehension caused by anticipation of danger. It is an alerting signal that warns of impending danger and enables the individual to take measures to deal with threat.	ANXIETY REDUCTION —Minimizing apprehension, dread, foreboding, or uneasiness related to unidentified source of anticipated danger	ANXIETY SELF-CONTROL —Personal actions to eliminate or reduce feelings of apprehension, tension, or uneasiness from an unidentifiable source
INEFFECTIVE COPING —Inability to form a valid appraisal of the stressors, inadequate choices of practiced responses, and/or inability to use available resources	COPING ENHANCEMENT —Assisting a patient to adapt to perceived stressors, changes, or threats that interfere with meeting life demands and roles COUNSELING —Use of an interactive helping process focusing on the needs, problems, or feelings of the patient and significant others to enhance or support coping, problem-solving, and interpersonal relationships SUPPORT SYSTEM ENHANCEMENT —Facilitation of support to patient by family, friends, and community	COPING —Personal actions to manage stressors that tax an individual's resources

Homeostasis, Stress, and Adaptation

LEARNING OBJECTIVES

On completion of this chapter, the learner will be able to:

- 1 Relate the principles of internal constancy, homeostasis, stress, and adaptation to the concept of steady state.
- 2 Identify the significance of the body's compensatory mechanisms in promoting adaptation and maintaining the steady state.
- 3 Identify physiologic and psychosocial stressors.
- 4 Compare the sympathetic-adrenal-medullary and hypothalamic-pituitary responses to stress.
- 5 Describe the general adaptation syndrome as a theory of adaptation to biologic stress.
- 6 Describe the relationship of the process of negative feedback to the maintenance of the steady state.
- 7 Compare the adaptive processes of hypertrophy, atrophy, hyperplasia, dysplasia, and metaplasia.
- 8 Describe the inflammatory and reparative processes.
- 9 Assess the health patterns of a person and determine their effects on maintenance of the steady state.
- 10 Identify ways in which maladaptive responses to stress can increase the risk of illness and cause disease.
- 11 Identify individual and group measures that are useful in reducing stress.

GLOSSARY

- adaptation:** a change or alteration designed to assist in adapting to a new situation or environment
- adrenocorticotrophic hormone (ACTH):** a hormone produced by the anterior lobe of the pituitary gland that stimulates the secretion of cortisol and other hormones by the adrenal cortex
- antidiuretic hormone (ADH):** a hormone secreted by the posterior lobe of the pituitary gland that constricts blood vessels, elevates blood pressure, and reduces the excretion of urine
- catecholamines:** any of the group of amines (such as epinephrine, norepinephrine, or dopamine) that serve as neurotransmitters
- coping:** the cognitive and behavioral strategies used to manage the stressors that tax a person's resources
- dysplasia:** bizarre cell growth resulting in cells that differ in size, shape, or arrangement from other cells of the same tissue type
- glucocorticoids:** the group of steroid hormones, such as cortisol, that are produced by the adrenal cortex; they are involved in carbohydrate, protein, and fat metabolism and have anti-inflammatory properties
- gluconeogenesis:** the formation of glucose by the liver from noncarbohydrate sources, such as amino acids and the glycerol portion of fats
- guided imagery:** the mindful use of a word, phrase, or visual image to achieve relaxation or direct attention away from uncomfortable sensations or situations
- homeostasis:** a steady state within the body; the stability of the internal environment
- hyperplasia:** an increase in the number of new cells of a tissue
- hypoxia:** inadequate supply of oxygen to the cell
- inflammation:** a localized, protective reaction of tissue to injury, irritation, or infection, manifested by pain, redness, heat, swelling, and sometimes loss of function
- metaplasia:** a cell transformation in which there is conversion of one type of mature cell into another type of cell
- negative feedback:** feedback that decreases the output of a system
- positive feedback:** feedback that increases the output of a system
- steady state:** a stable condition that does not change over time, or when change in one direction is balanced by change in an opposite direction
- stress:** a disruptive condition that occurs in response to adverse influences from the internal or external environments

When the body is threatened or suffers an injury, its response may involve functional and structural changes; these changes may be adaptive (having a positive effect) or maladaptive (having a negative effect). The defense mechanisms that the body uses determine the difference between adaptation and maladaptation—health and disease. This chapter discusses homeostasis, stress, adaptation, health problems associated with maladaptation, and ways nurses can intervene to reduce stress and its health-related effects.

Fundamental Concepts

Each body system performs specific functions to sustain optimal life for an organism. Mechanisms for adjusting internal conditions promote the normal steady state of the organism and its survival. These mechanisms are compensatory in nature and work to restore balance in the body. An example of this restorative effort is the development of rapid breathing (hyperpnea) after intense exercise in an attempt to compensate for an oxygen deficit and excess lactic acid accumulated in the muscle tissue.

Pathophysiologic processes result when cellular injury occurs at such a rapid rate that the body's compensatory mechanisms can no longer make the adaptive changes necessary to remain healthy. An example of a pathophysiologic change is the development of heart failure; the body reacts by retaining sodium and water and increasing venous pressure, which worsens the condition. These pathophysiologic responses give rise to symptoms that are reported by patients or signs that are observed by patients, nurses, or other health care providers. These observations, plus a sound knowledge of physiologic and pathophysiologic processes, can assist in determining the existence of a problem and can guide nurses in planning the appropriate course of action.

Steady State

Physiologic mechanisms must be understood in the context of the body as a whole. Each person, as a living system, has both an internal and an external environment, between which information and matter are continuously exchanged. Within the internal environment, each organ, tissue, and cell is also a system or subsystem of the whole, each with its own internal and external environment, each exchanging information and matter (Fig. 6-1). The goal of the interaction of the body's subsystems is to produce a dynamic balance or **steady state** (even in the presence of change), so that all subsystems are in harmony with each other. Four concepts—constancy, homeostasis, stress, and adaptation—are key to the understanding of steady state.

Claude Bernard, a 19th-century French physiologist, developed the biologic principle that for life there must be a constancy or “fixity of the internal milieu” despite changes in the external environment. The internal milieu was the fluid that bathed the cells, and the constancy was the balanced internal state maintained by physiologic and biochemical processes. His principle implied a static process.

Homeostasis refers to a steady state within the body. When a change or stress occurs that causes a body function to deviate from its stable range, processes are initiated to restore and maintain dynamic balance. When these adjust-

Figure 6-1 Constellation of systems. Each system is a subsystem of the larger system (suprasystem) of which it is a part. In this figure the cells represent the smallest system and are a subsystem of all other systems.

ment processes or compensatory mechanisms are not adequate, steady state is threatened, function becomes disordered, and dysfunctional responses occur. This can lead to disease, which is a threat to steady state. Disease is an abnormal variation in the structure or function of any part of the body. It disrupts function and therefore can limit freedom of action.

Stress and Adaptation

Stress is a state produced by a change in the environment that is perceived as challenging, threatening, or damaging to a person's dynamic balance or equilibrium. The person may feel unable to meet the demands of the new situation. The change or stimulus that evokes this state is the stressor. The nature of the stressor is variable; an event or change that is stressful for one person may not be stressful for another, and an event that produces stress at one time and place may not do so at another time and place. A person appraises and copes with changing situations. The desired goal is **adaptation** or adjustment to the change so that the person is again in equilibrium and has the energy and ability to meet new demands. This is the process of **cop**ing with the stress, a compensatory process that has physiologic and psychological components.

Adaptation is a constant, ongoing process that requires a change in structure, function, or behavior so that a person is better suited to the environment; it involves an interaction between the person and the environment. The outcome depends on the degree of “fit” between the skills and capacities of the person, the type of social support available, and the various challenges or stressors encountered. As such, adaptation is an individual process: Each person has varying abilities to cope or respond. As new challenges are

met, this ability to cope and adapt can change, thereby providing the person with a wide range of adaptive ability. Adaptation occurs throughout the lifespan as the person encounters many developmental and situational challenges, especially related to health and illness. The goal of adaptation is optimal wellness.

Because both stress and adaptation may exist at different levels of a system, it is possible to study these reactions at the cellular, tissue, and organ levels. Biologists are concerned mainly with subcellular components or with subsystems of the total body. Behavioral scientists, including many nurse researchers, study stress and adaptation in individuals, families, groups, and societies; they focus on how a group's organizational features are modified to meet the requirements of the social and physical environment in which the group exists. In any system, the desired goals of adaptation are survival, growth, and reproduction.

Overview of Stress

Types of Stressors

Each person operates at a certain level of adaptation and regularly encounters a certain amount of change. Such change is expected; it contributes to growth and enhances life. A stressor can upset this equilibrium. A stressor may be defined as an internal or external event or situation that creates the potential for physiologic, emotional, cognitive, or behavioral changes in an individual.

Stressors exist in many forms and categories. They may be described as physical, physiologic, or psychosocial. Physical stressors include cold, heat, and chemical agents; physiologic stressors include pain and fatigue. An example of a psychosocial stressor is fear (eg, fear of failing an examination, losing a job, and waiting for a diagnostic test result). Stressors can also occur as normal life transitions that require some adjustment, such as going from childhood into puberty, getting married, or giving birth.

Stressors have also been classified as (1) day-to-day frustrations or hassles, (2) major complex occurrences involving large groups, and (3) stressors that occur less frequently and involve fewer people. The first group, the day-to-day stressors, includes such common occurrences as getting caught in a traffic jam, experiencing computer downtime, and having an argument with a spouse or roommate. These experiences vary in effect. For example, encountering a rainstorm while you are vacationing at the beach will most likely evoke a more negative response than it might at another time. These daily hassles have been shown to have a greater health impact than major life events because of the cumulative effect they have over time. They can lead to high blood pressure, palpitations, or other physiologic problems (Rice, 2005).

The second group of stressors influences larger groups of people, sometimes even entire nations. These include events of history, such as terrorism and war, experienced either directly in the war zone or indirectly through live news coverage. The demographic, economic, and technologic changes occurring in society also serve as stressors. The tension produced by any stressor is sometimes a result not only

of the change itself, but also of the speed with which the change occurs.

The third group of stressors has been studied most extensively and concerns relatively infrequent situations that directly affect people. This category includes the influence of life events such as death, birth, marriage, divorce, and retirement. It also includes the psychosocial crises that occur in the life cycle stages of the human experience. More enduring chronic stressors may include having a permanent disability or coping with the need to provide long-term care to a frail elderly parent.

Duration may also be used to categorize stressors, as in the following:

- An acute, time-limited stressor, such as studying for final examinations
- A stressor sequence—a series of stressful events that result from an initial event such as job loss or divorce
- A chronic intermittent stressor, such as daily hassles
- A chronic enduring stressor that persists over time, such as chronic illness, a disability, or poverty

Stress as a Stimulus for Disease

Relating life events to illness (the theoretical approach that defines stress as a stimulus) has been a major focus of psychosocial studies. Research has revealed that people under constant stress have a high incidence of psychosomatic disease.

Holmes and Rahe (1967) developed life events scales that assign numerical values, called life-change units, to typical life events. Because the items in the scales reflect events that require a change in a person's life pattern, and stress is defined as an accumulation of changes in one's life that require psychological adaptation, one can theoretically predict the likelihood of illness by checking off the number of recent events and deriving a total score. The Recent Life Changes Questionnaire (Tausig, 1982) contains 118 items such as death, birth, marriage, divorce, promotions, serious arguments, and vacations. The items include both desirable and undesirable events.

Sources of stress for people have been well researched (Barnard, Street & Love, 2006; Lunney, 2006; Tak, 2006). People typically experience distress related to alterations in their physical and emotional health status, changes in their level of daily functioning, and decreased social support or the loss of significant others. Fears of immobilization, isolation, loneliness, sensory changes, financial problems, and death or disability increase a person's anxiety level. Loss of one's role or perceived purpose in life can cause intense discomfort. Any of these identified variables, plus myriad other conditions or overwhelming demands, are likely to cause ineffective coping, and a lack of necessary coping skills is often a source of additional distress for the person. When a person endures prolonged or unrelenting suffering, the outcome is frequently the development of a stress-related illness. Nurses have the skills to assist people to alter their distressing circumstances and manage their responses to stress.

Psychological Responses to Stress

After recognizing a stressor, a person consciously or unconsciously reacts to manage the situation. This is termed the mediating process. A theory developed by Lazarus (1991a)

emphasizes cognitive appraisal and coping as important mediators of stress. Appraisal and coping are influenced by antecedent variables, including the internal and external resources of the individual person.

Appraisal of the Stressful Event

Cognitive appraisal (Lazarus, 1991a; Lazarus & Folkman, 1984) is a process by which an event is evaluated with respect to what is at stake (primary appraisal) and what might and can be done (secondary appraisal). What a person sees as being at stake is influenced by his or her personal goals, commitments, or motivations. Important factors include how important or relevant the event is to the person, whether the event conflicts with what the person wants or desires, and whether the situation threatens the person's own sense of strength and ego identity.

Primary appraisal results in the situation being identified as either nonstressful or stressful. Secondary appraisal is an evaluation of what might and can be done about the situation. Reappraisal, a change of opinion based on new information, may occur. The appraisal process is not necessarily sequential; primary and secondary appraisal and reappraisal may occur simultaneously.

The appraisal process contributes to the development of an emotion. Negative emotions such as fear and anger accompany harm/loss appraisals, and positive emotions accompany challenge. In addition to the subjective component or feeling that accompanies a particular emotion, each emotion also includes a tendency to act in a certain way. For example, unprepared students may view an unexpected quiz as threatening. They might feel fear, anger, and resentment and might express these emotions through hostile behavior or comments.

Lazarus (1991a) expanded his initial ideas about stress, appraisal, and coping into a more complex model relating emotion to adaptation. He called this model a “cognitive-motivational-relational theory,” with the term *relational* “standing for a focus on negotiation with a physical and social world” (p. 13). A theory of emotion was proposed as the bridge to connect psychology, physiology, and sociology: “More than any other arena of psychological thought, emotion is an integrative, organismic concept that subsumes psychological stress and coping within itself and unites motivation, cognition, and adaptation in a complex configuration” (p. 40).

Coping With the Stressful Event

Coping consists of the cognitive and behavioral efforts made to manage the specific external or internal demands that tax a person's resources and may be emotion-focused or problem-focused. Coping that is emotion-focused seeks to make the person feel better by lessening the emotional distress. Problem-focused coping aims to make direct changes in the environment so that the situation can be managed more effectively. Both types of coping usually occur in a stressful situation. Even if the situation is viewed as challenging or beneficial, coping efforts may be required to develop and sustain the challenge—that is, to maintain the positive benefits of the challenge and to ward off any threats. In harmful or threatening situations, successful coping reduces or eliminates the source of stress and relieves the emotion generated.

Appraisal and coping are affected by internal characteristics such as health, energy, personal belief systems, commitments or life goals, self-esteem, control, mastery, knowledge, problem-solving skills, and social skills. The characteristics that have been studied most often in nursing research are health-promoting lifestyles and hardiness. A health-promoting lifestyle buffers the effect of stressors. From a nursing practice standpoint, this outcome—buffering the effect of stressors—supports nursing's goal of promoting health. In many circumstances, promoting a healthy lifestyle is more achievable than altering the stressors.

Hardiness is a general quality that comes from having rich, varied, and rewarding experiences. Hardy people perceive stressors as something they can change and therefore control. To them, potentially stressful situations are interesting and meaningful; change and new situations are viewed as challenging opportunities for growth. Researchers have found positive support for hardiness as a significant variable that positively influences rehabilitation and overall improvement after an onset of an illness (Ayalon & Covinsky, 2007; Baumgartner, 2007; Greeff & Holtkamp, 2007; Travis, 2007).

Physiologic Response to Stress

The physiologic response to a stressor, whether it is physical or psychological, is a protective and adaptive mechanism to maintain the homeostatic balance of the body. When a stress response occurs, it activates a series of neurologic and hormonal processes within the brain and body systems. The duration and intensity of the stress can cause both short-term and long-term effects. A stressor can disrupt homeostasis to the point where adaptation to the stressor fails, and a disease process results.

Selye's Theory of Adaptation

Hans Selye developed a theory of adaptation that profoundly influenced the scientific study of stress (1976). Selye first described a syndrome consisting of enlargement of the adrenal cortex; shrinkage of the thymus, spleen, lymph nodes, and other lymphatic structures; and the appearance of deep, bleeding ulcers in the stomach and duodenum. He identified this as a nonspecific response to diverse, noxious stimuli.

General Adaptation Syndrome

Selye then developed a theory of adaptation to biologic stress that he named the general adaptation syndrome (GAS), which has three phases: alarm, resistance, and exhaustion. During the alarm phase, the sympathetic “fight-or-flight” response is activated with release of **catecholamines** and the onset of the **adrenocorticotrophic hormone** (ACTH)—adrenal cortical response. The alarm reaction is defensive and anti-inflammatory but self-limited. Because living in a continuous state of alarm would result in death, people move into the second stage, resistance. During the resistance stage, adaptation to the noxious stressor occurs, and cortisol activity is still increased. If exposure to the stressor is prolonged, the third stage, exhaustion, occurs. During the exhaustion stage, endocrine activity increases, and this has negative effects on the body systems (especially the circulatory, digestive, and immune systems) that can

lead to death. Stages one and two of this syndrome are repeated, in different degrees, throughout life as the person encounters stressors.

Selye compared the GAS with the life process. During childhood, too few encounters with stress occur to promote the development of adaptive functioning, and children are vulnerable. During adulthood, a number of stressful events occur, and people develop resistance or adaptation. During the later years, the accumulation of life's stressors and wear and tear on the organism again decrease people's ability to adapt, resistance falls, and eventually death occurs.

Local Adaptation Syndrome

According to Selye, a local adaptation syndrome also occurs. This syndrome includes the inflammatory response and repair processes that occur at the local site of tissue injury. The local adaptation syndrome occurs in small, topical injuries, such as contact dermatitis. If the local injury is severe enough, the general adaptation syndrome is activated as well.

Selye emphasized that stress is the nonspecific response common to all stressors, regardless of whether they are physiologic, psychological, or social. The many conditioning factors in each person's environment account for why different demands are experienced by different people as stressors. Conditioning factors also account for differences in the tolerance of different people for stress: Some people may develop diseases of adaptation, such as hypertension and migraine headaches, whereas others are unaffected.

Interpretation of Stressful Stimuli by the Brain

Physiologic responses to stress are mediated by the brain through a complex network of chemical and electrical messages. The neural and hormonal actions that maintain homeostatic balance are integrated by the hypothalamus, which is located in the center of the brain, surrounded by the limbic system and the cerebral hemispheres. The hypothalamus is made up of a number of nuclei and integrates autonomic nervous system mechanisms that maintain the chemical constancy of the internal environment of the body. Together with the limbic system, which contains the amygdala, hippocampus, and septal nuclei, along with other structures, the hypothalamus regulates emotions and many visceral behaviors necessary for survival (eg, eating, drinking, temperature control, reproduction, defense, aggression).

Each of the brain structures responds differently to stimuli. The cerebral hemispheres are concerned with cognitive functions: thought processes, learning, and memory. The limbic system has connections with both the cerebral hemispheres and the brain stem. In addition, the reticular activating system (RAS), a network of cells that forms a two-way communication system, extends from the brain stem into the midbrain and limbic system. This network controls the alert or waking state of the body.

In the stress response, afferent impulses are carried from sensory organs (eye, ear, nose, skin) and internal sensors (baroreceptors, chemoreceptors) to nerve centers in the brain. The response to the perception of stress is integrated in the hypothalamus, which coordinates the adjustments necessary to return to homeostatic balance. The degree and duration of the response vary; major stress evokes both sympathetic and pituitary adrenal responses.

Physiology Pathophysiology

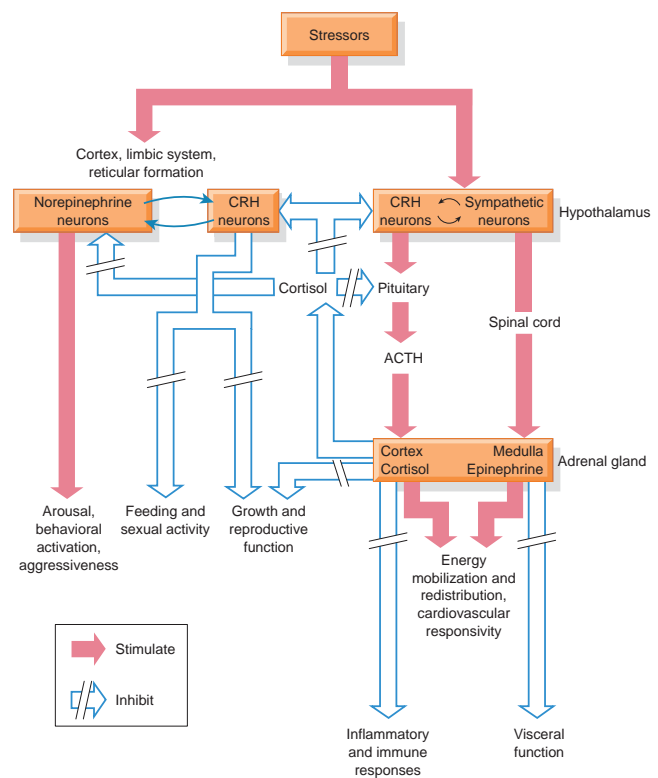

Figure 6-2 Integrated responses to stress mediated by the sympathetic nervous system and the hypothalamic-pituitary-adrenal axis. The responses are mutually reinforcing at both the central and peripheral levels. Negative feedback by cortisol also can limit an overresponse that might be harmful to the individual. Colored arrows represent stimulation, open arrows, inhibition. CRH, corticotropin-releasing hormone; ACTH, adrenocorticotropic hormone. Reproduced with permission from Berne, R. M. & Levy, M. N. (2003). *Physiology*. St. Louis: C. V. Mosby.

Neural and neuroendocrine pathways under the control of the hypothalamus are also activated in the stress response. Initially, there is a sympathetic nervous system discharge, followed by a sympathetic-adrenal-medullary discharge. If the stress persists, the hypothalamic-pituitary system is activated (Fig. 6-2).

Sympathetic Nervous System Response

The sympathetic nervous system response is rapid and short-lived. Norepinephrine is released at nerve endings that are in direct contact with their respective end organs to cause an increase in function of the vital organs and a state of general body arousal. The heart rate is increased and peripheral vasoconstriction occurs, raising the blood pressure. Blood is also shunted away from abdominal organs. The purpose of these responses is to provide better perfusion of vital organs (brain, heart, skeletal muscles). Blood glucose is increased, supplying more readily available energy. The pupils are dilated, and mental activity is increased; a greater sense of awareness exists. Constriction of the blood vessels of the skin limits bleeding in the event of trauma. The person is likely to experience cold feet, clammy skin

and hands, chills, palpitations, and “knots” in the stomach. Typically, the person appears tense, with the muscles of the neck, upper back, and shoulders tightened; respirations may be rapid and shallow, with the diaphragm tense.

Sympathetic-Adrenal-Medullary Response

In addition to its direct effect on major end organs, the sympathetic nervous system stimulates the medulla of the adrenal gland to release the hormones epinephrine and norepinephrine into the bloodstream. The action of these hormones is similar to that of the sympathetic nervous system and has the effect of sustaining and prolonging its actions. Epinephrine and norepinephrine are catecholamines that stimulate the nervous system and produce metabolic effects that increase the blood glucose level and increase the metabolic rate. The effect of the sympathetic-adrenal-medullary responses is summarized in Table 6-1. This effect is called the “fight-or-flight” reaction.

Hypothalamic-Pituitary Response

The longest-acting phase of the physiologic response, which is more likely to occur in persistent stress, involves the hypothalamic-pituitary pathway. The hypothalamus secretes corticotropin-releasing factor, which stimulates the anterior pituitary to produce ACTH, which in turn stimulates the adrenal cortex to produce **glucocorticoids**, primarily cortisol. Cortisol stimulates protein catabolism, releasing amino acids; stimulates liver uptake of amino acids and their conversion to glucose (**gluconeogenesis**); and inhibits glucose uptake (anti-insulin action) by many body cells but not those of the brain and heart. These cortisol-induced metabolic effects provide the body with a ready source of energy during a stressful situation. This effect has some important implications. For example, a person with diabetes who is under stress, such as that caused

by an infection, needs more insulin than usual. Any patient who is under stress (eg, illness, surgery, trauma, or prolonged psychological stress) catabolizes body protein and needs supplements.

The actions of the catecholamines (epinephrine and norepinephrine) and cortisol are the most important in the general response to stress. Other hormones that play a role are **antidiuretic hormone** (ADH) released from the posterior pituitary and aldosterone released from the adrenal cortex. ADH and aldosterone promote sodium and water retention, which is an adaptive mechanism in the event of hemorrhage or loss of fluids through excessive perspiration. ADH has also been shown to influence learning and may thus facilitate coping in new and threatening situations. Secretion of growth hormone and glucagon stimulates the uptake of amino acids by cells, helping to mobilize energy resources. Endorphins, which are endogenous opioids, increase during stress and enhance the threshold for tolerance of painful stimuli. They may also affect mood and have been implicated in the so-called high that long-distance runners experience. The secretion of other hormones is also affected, but their adaptive function is less clear.

Immunologic Response

Research findings show that the immune system is connected to the neuroendocrine and autonomic systems. Lymphoid tissue is richly supplied by autonomic nerves capable of releasing a number of different neuropeptides that can have a direct effect on leukocyte regulation and the inflammatory response. Neuroendocrine hormones released by the central nervous system and endocrine tissues can inhibit or stimulate leukocyte function. The wide variety of stressors a person experiences may result in different alterations in autonomic activity and subtle variations in neurohormone

Table 6-1 SYMPATHETIC-ADRENAL-MEDULLARY RESPONSE TO STRESS

Effect	Purpose	Mechanism
Increased heart rate and blood pressure	Better perfusion of vital organs	Increased cardiac output due to increased myocardial contractility and heart rate; increased venous return (peripheral vasoconstriction)
Increased blood glucose level	Increased available energy	Increased liver and muscle glycogen breakdown; increased breakdown of adipose tissue triglycerides
Mental acuity	Alert state	Increase in amount of blood shunted to the brain from the abdominal viscera and skin
Dilated pupils	Increased awareness	Contraction of radial muscle of iris
Increased tension of skeletal muscles	Preparedness for activity, decreased fatigue	Excitation of muscles; increase in amount of blood shunted to the muscles from the abdominal viscera and skin
Increased ventilation (may be rapid and shallow)	Provision of oxygen for energy	Stimulation of respiratory centre in medulla; bronchodilation
Increased coagulability of blood	Prevention of hemorrhage in event of trauma	Vasoconstriction of surface vessels

and neuropeptide synthesis. All of these possible autonomic and neuroendocrine responses can interact to initiate, weaken, enhance, or terminate an immune response.

The study of the relationships among the neuroendocrine system, the central and autonomic nervous systems, and the immune system and the effects of these relationships on overall health outcomes is called *psychoneuroimmunology*. Because one's perception of events and one's coping styles determine whether, and to what extent, an event activates the stress response system, and because the stress response affects immune activity, one's perceptions, ideas, and thoughts can have profound neurochemical and immunologic consequences. Studies have demonstrated alteration of immune function in people who are under stress (Kendall-Tackett, 2007; Leserman & Drossman, 2007; Mertin, Sawatzky, Diehl-Jones, et al., 2007). Other studies have identified certain personality traits, such as optimism and active coping, as having positive effects on health (Dilworth-Anderson, Boswell & Cohen, 2007; Krucoff, 2007; Verhaeghe, van Zuuren, DeFloor, et al., 2007). As research continues, this field of study will likely uncover to what extent and by what mechanisms people can consciously influence their immunity.

Maladaptive Responses to Stress

The stress response, as indicated earlier, facilitates adaptation to threatening situations, and is retained from humans' evolutionary past. The "fight-or-flight" response, for example, is an anticipatory response that mobilized the bodily resources of our ancestors to deal with predators and other harsh factors in their environment. This same mobilization comes into play in response to emotional stimuli unrelated to danger. For example, a person may get an "adrenaline rush" when competing over a decisive point in a ball game, or when excited about attending a party.

When responses to stress are ineffective, they are referred to as *maladaptive*. Maladaptive responses are chronic, recurrent responses or patterns of response that do not promote the goals of adaptation. The goals of adaptation are somatic or physical health (optimal wellness); psychological health or having a sense of well-being (happiness, satisfaction with life, morale); and enhanced social functioning, which includes work, social life, and family (positive relationships). Maladaptive responses that threaten these goals include faulty appraisals and inappropriate coping (Lazarus, 1991a).

The frequency, intensity, and duration of stressful situations contribute to the development of emotions and subsequent patterns of neurochemical discharge. By appraising situations adequately and coping appropriately, it is possible to anticipate and defuse some of these situations. For example, frequent stressful encounters (eg, marital discord) might be avoided with better communication and problem solving, or a pattern of procrastination (eg, delaying work on tasks) could be corrected to reduce stress when deadlines approach.

Coping processes that include the use of alcohol or drugs to reduce stress increase the risk of illness. Other inappropriate coping patterns may increase the risk of illness less directly. For example, people who demonstrate "type A" behaviors, including impatience, competitiveness, and

achievement orientation, have an underlying aggressive approach to life and are more prone than others to develop stress-related illnesses. Type A behaviors increase the output of catecholamines, the adrenal-medullary hormones, with their attendant effects on the body.

Other forms of inappropriate coping include denial, avoidance, and distancing. Denial may be illustrated by the woman who feels a lump in her breast but downplays its seriousness and delays seeking medical attention. The intent of denial is to control the threat, but it may also endanger life.

Models of illness frequently include stress and maladaptation as precursors to disease. A general model of illness, based on Selye's theory, suggests that any stressor elicits a state of disturbed physiologic equilibrium. If this state is prolonged or the response is excessive, it increases the susceptibility of the person to illness. This susceptibility, coupled with a predisposition in the person (from genetic traits, health, or age), leads to illness. If the sympathetic adrenal-medullary response is prolonged or excessive, a state of chronic arousal develops that may lead to high blood pressure, arteriosclerotic changes, and cardiovascular disease. If the production of ACTH is prolonged or excessive, behavior patterns of withdrawal and depression are seen. In addition, the immune response is decreased, and infections and tumors may develop.

Selye (1976) proposed a list of disorders known as diseases of maladaptation: high blood pressure (including hypertension of pregnancy), diseases of the heart and blood vessels, diseases of the kidney, rheumatic and rheumatoid arthritis, inflammatory diseases of the skin and eyes, infections, allergic and hypersensitivity diseases, nervous and mental diseases, sexual dysfunction, digestive diseases, metabolic diseases, and cancer.

Indicators of Stress

Indicators of stress and the stress response include both subjective and objective measures. Chart 6-1 lists signs and symptoms that may be observed directly or reported by a person. They are psychological, physiologic, or behavioral and reflect social behaviors and thought processes. Some of these reactions may be coping behaviors. Over time, each person tends to develop a characteristic pattern of behavior during stress to warn that the system is out of balance.

Laboratory measurements of indicators of stress have helped in understanding this complex process. Blood and urine analyses can be used to demonstrate changes in hormonal levels and hormonal breakdown products. Blood levels of catecholamines, glucocorticoids, ACTH, and eosinophils are reliable measures of stress. Serum cholesterol and free fatty acid levels can be used to measure stress. When the body experiences distress, there are changes in adrenal hormones such as cortisol and aldosterone. As the levels of these chemicals increase, there is a simultaneous release of additional cholesterol into the general circulation. Both physical and psychological distress can trigger an elevated cholesterol level. In addition, the results of immunoglobulin assays are increased when a person is exposed to a variety of stressors, especially infections and immunodeficiency conditions. With greater attention to the field of neuroimmunology, improved laboratory measures are likely to follow.

CHART
6-1

Assessing for Stress

Be alert for the following signs and symptoms:

- Restlessness
- Depression
- Dry mouth
- Overpowering urge to act out
- Fatigue
- Loss of interest in life activities
- Intense periods of anxiety
- Strong startle response
- Hyperactivity
- Gastrointestinal distress
- Diarrhea
- Nausea or vomiting
- Changes in menstrual cycle
- Change in appetite
- Injury-prone
- Palpitations
- Impulsive behaviors
- Emotional lability
- Concentration difficulties
- Feeling weak or dizzy
- Increased body tension
- Tremors
- Nervous habits
- Nervous laughter
- Bruxism (grinding of teeth)
- Difficulty sleeping
- Excessive perspiration
- Urinary frequency
- Headaches
- Pain in back, neck, or other parts of the body
- Increased use of tobacco
- Substance use or abuse
- Unintentional weight loss or gain

In addition to using laboratory tests, researchers have developed questionnaires to identify and assess stressors, stress, and coping strategies. The work of Rice (2005), a compilation of information gained from research on stress, coping, and health, includes some of these questionnaires. Research reports also contain examples of instruments that nurses use to measure levels of patient distress and patient functioning (Caetano, Ramisetty-Miller, Caetano-Vaeth, et al., 2007; Weisel, Most & Michael, 2007). Miller and Smith (1993) provided a stress audit and a stress profile measurement tool that is available in the popular lay literature.

Nursing Implications

It is important for nurses to realize that the optimal point of intervention to promote health is during the stage when a person's own compensatory processes are still functioning effectively. A major role of nurses is the early identification of both physiologic and psychological stressors. Nurses should be able to relate the presenting signs and symptoms of distress to the physiology they represent and identify a person's position on the continuum of function, from health and compensation to pathophysiology and disease.

For example, if an anxious, middle-aged woman presented for a checkup and was found to be overweight with

a blood pressure of 150/85 mm Hg, the nurse would counsel her with respect to diet, stress management, and activity. The nurse would also encourage weight loss and discuss the woman's intake of salt (which affects fluid balance) and caffeine (which provides a stimulant effect). The patient and the nurse would identify both individual and environmental stressors and discuss strategies to decrease her lifestyle stress, with the ultimate goal being to create a healthy lifestyle and prevent hypertension and its sequelae.

Stress at the Cellular Level

Pathologic processes may occur at all levels of the biologic organism. If the cell is considered the smallest unit or subsystem (tissues being aggregates of cells, organs aggregates of tissues, and so on), the processes of health and disease or adaptation and maladaptation can all occur at the cellular level. Indeed, pathologic processes are often described by scientists at the subcellular or molecular level.

The cell exists on a continuum of function and structure, ranging from the normal cell, to the adapted cell, to the injured or diseased cell, to the dead cell (Fig. 6-3). Changes from one state to another may occur rapidly and may not be readily detectable, because each state does not have discrete boundaries, and disease represents disruption of normal processes. The earliest changes occur at the molecular or subcellular level and are not perceptible until steady-state functions or structures are altered. With cell injury, some changes may be reversible; in other instances, the injuries are lethal. For example, tanning of the skin is an adaptive, morphologic response to exposure to the rays of the sun. However, if the exposure is continued, sunburn and injury occur, and some cells may die, as evidenced by desquamation ("peeling").

Different cells and tissues respond to stimuli with different patterns and rates of response, and some cells are more vulnerable to one type of stimulus or stressor than others. The cell involved, its ability to adapt, and its physiologic state are determinants of the response. For example, cardiac muscle cells respond to **hypoxia** (inadequate oxygenation) more quickly than do smooth muscle cells.

Other determinants of cellular response are the type or nature of the stimulus, its duration, and its severity. For

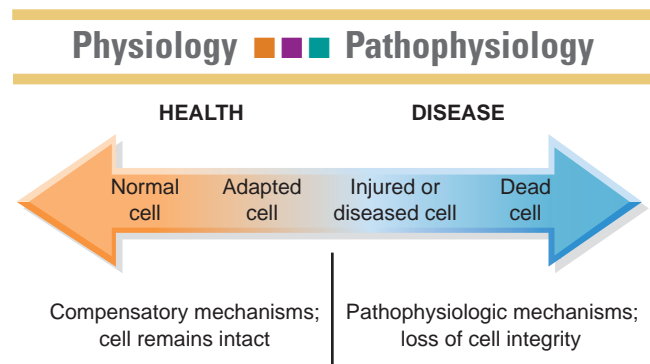

Figure 6-3 The cell on a continuum of function and structure. Changes in the cell are not as easily discerned as the diagram depicts, and the point at which compensation subsides and pathophysiology begins is not clearly defined.

example, neurons that control respiration can develop a tolerance to regular, small amounts of a barbiturate, but one large dose may result in respiratory depression and death.

Control of the Steady State

The concept of the cell as existing on a continuum of function and structure includes the relationship of the cell to compensatory mechanisms, which occur continuously in the body to maintain the steady state. Compensatory processes are regulated primarily by the autonomic nervous system and the endocrine system, with control achieved through negative feedback.

Negative Feedback

Negative feedback mechanisms throughout the body monitor the internal environment and restore homeostasis when conditions shift out of the normal range. These mechanisms work by sensing deviations from a predetermined set point or range of adaptability and triggering a response aimed at offsetting the deviation. Blood pressure, acid–base balance, blood glucose level, body temperature, and fluid and electrolyte balance are examples of functions regulated through such compensatory mechanisms.

Most of the human body's control systems are integrated by the brain with feedback from the nervous and endocrine systems. Control activities involve detecting deviations from the predetermined reference point and stimulating compensatory responses in the muscles and glands of the body. The major organs affected are the heart, lungs, kidneys, liver, gastrointestinal tract, and skin. When stimulated, these organs alter their rate of activity or the amount of secretions they produce. Because of this, they have been called the “organs of homeostasis or adjustment.”

In addition to the responses influenced by the nervous and endocrine systems, local responses consisting of small feedback loops in a group of cells or tissues are possible. The cells detect a change in their immediate environment and initiate an action to counteract its effect. For example, the accumulation of lactic acid in an exercised muscle stimulates dilation of blood vessels in the area to increase blood flow and improve the delivery of oxygen and removal of waste products.

The net result of the activities of feedback loops is homeostasis. A steady state is achieved by the continuous, variable action of the organs involved in making the adjustments and by the continuous exchange of chemical substances among cells, interstitial fluid, and blood. For example, an increase in the CO₂ concentration of the extracellular fluid leads to increased pulmonary ventilation, which decreases the CO₂ level. On a cellular level, increased CO₂ raises the hydrogen ion concentration of the blood. This is detected by chemosensitive receptors in the respiratory control center of the medulla of the brain. The chemoreceptors stimulate an increase in the rate of discharge of the neurons that innervate the diaphragm and intercostal muscles, which increases the rate of respiration. Excess CO₂ is exhaled, the hydrogen ion concentration returns to normal, and the chemically sensitive neurons are no longer stimulated (Porth & Matfin, 2009).

Positive Feedback

Another type of feedback, **positive feedback**, perpetuates the chain of events set in motion by the original disturbance instead of compensating for it. As the system becomes more unbalanced, disorder and disintegration occur. There are some exceptions to this; blood clotting in humans, for example, is an important positive feedback mechanism.

Cellular Adaptation

Cells are complex units that dynamically respond to the changing demands and stresses of daily life. They possess a maintenance function and a specialized function. The maintenance function refers to the activities that the cell must perform with respect to itself; specialized functions are those that the cell performs in relation to the tissues and organs of which it is a part. Individual cells may cease to function without posing a threat to the organism. However, as the number of dead cells increases, the specialized functions of the tissues are altered, and health is threatened.

Cells can adapt to environmental stress through structural and functional changes. Some of these adaptations include cellular hypertrophy, atrophy, hyperplasia, dysplasia, and metaplasia (Table 6-2). These adaptations reflect changes in the normal cell in response to stress. If the stress is unrelenting, cellular injury and death may occur.

Hypertrophy and atrophy lead to changes in the size of cells and hence the size of the organs they form. Compensatory hypertrophy is the result of an enlarged muscle mass and commonly occurs in skeletal and cardiac muscle that experiences a prolonged, increased workload. One example is the bulging muscles of the athlete who engages in body building.

Atrophy can be the consequence of disease, decreased use, decreased blood supply, loss of nerve supply, or inadequate nutrition. Disuse of a body part is often associated with the aging process and immobilization. Cell size and organ size decrease, and the structures principally affected are the skeletal muscles, the secondary sex organs, the heart, and the brain.

Hyperplasia is an increase in the number of new cells in an organ or tissue. As cells multiply and are subjected to increased stimulation, the tissue mass enlarges. This mitotic response (a change occurring with mitosis) is reversible when the stimulus is removed. This distinguishes hyperplasia from neoplasia or malignant growth, which continues after the stimulus is removed. Hyperplasia may be hormonally induced. An example is the increased size of the thyroid gland caused by thyroid-stimulating hormone (secreted from the pituitary gland) when a deficit in thyroid hormone occurs.

Dysplasia is bizarre cell growth resulting in cells that differ in size, shape, or arrangement from other cells of the same tissue type. Dysplastic cells have a tendency to become malignant; dysplasia is seen commonly in epithelial cells in the bronchi of people who smoke.

Metaplasia is a cell transformation in which there is a conversion of one type of mature cell into another type of cell. This serves a protective function, because less transformed cells are more resistant to the stress that stimulated

Table 6-2 CELLULAR ADAPTATION TO STRESSORS

Adaptation	Stimulus	Example
Hypertrophy—increase in cell size leading to increase in organ size	Increased workload	Leg muscles of runner Arm muscles in tennis player Cardiac muscle in person with hypertension
Atrophy—shrinkage in size of cell, leading to decrease in organ size	Decrease in: Use Blood supply Nutrition Hormonal stimulation Innervation	Secondary sex organs in aging person Extremity immobilized in cast
Hyperplasia—increase in number of new cells (increase in mitosis)	Hormonal influence	Breast changes of girl in puberty or of pregnant woman Regeneration of liver cells New red blood cells in blood loss
Dysplasia—bizarre changes in the appearance of cells	Reproduction of cells with resulting alteration of their size and shape	Alterations in epithelial cells of the skin or the cervix, producing irregular tissue changes that could be the precursors of a malignancy
Metaplasia—transformation of one adult cell type to another (reversible)	Stress applied to highly specialized cell	Changes in epithelial cells lining bronchi in response to smoke irritation (cells become less specialized)

the change. For example, the ciliated columnar epithelium lining the bronchi of people who smoke is replaced by squamous epithelium. The squamous cells can survive; loss of the cilia and protective mucus, however, can have damaging consequences.

Cellular Injury

Injury is defined as a disorder in steady-state regulation. Any stressor that alters the ability of the cell or system to maintain optimal balance of its adjustment processes leads to injury. Structural and functional damage then occurs, which may be reversible (permitting recovery) or irreversible (leading to disability or death). Homeostatic adjustments are concerned with the small changes within the body's systems. With adaptive changes, compensation occurs and a new steady state may be achieved. With injury, steady-state regulation is lost, and changes in functioning ensue.

Causes of disorder and injury in the system (cell, tissue, organ, body) may arise from the external or internal environment (Fig. 6-4) and include hypoxia, nutritional imbalance, physical agents, chemical agents, infectious agents, immune mechanisms, genetic defects, and psychogenic factors. The most common causes are hypoxia (oxygen deficiency), chemical injury, and infectious agents. In addition, the presence of one injury makes the system more susceptible to another injury. For example, inadequate oxygenation and nutritional deficiencies make the system vulnerable to infection. These agents act at the cellular level by damaging or destroying:

- The integrity of the cell membrane, necessary for ionic balance
- The ability of the cell to transform energy (aerobic respiration, production of adenosine triphosphate)
- The ability of the cell to synthesize enzymes and other necessary proteins

- The ability of the cell to grow and reproduce (genetic integrity)

Hypoxia

Inadequate cellular oxygenation (hypoxia) interferes with the cell's ability to transform energy. Hypoxia may be caused by a decrease in blood supply to an area, a decrease in the oxygen-carrying capacity of the blood (decreased hemoglobin), a ventilation/perfusion or respiratory problem that reduces the

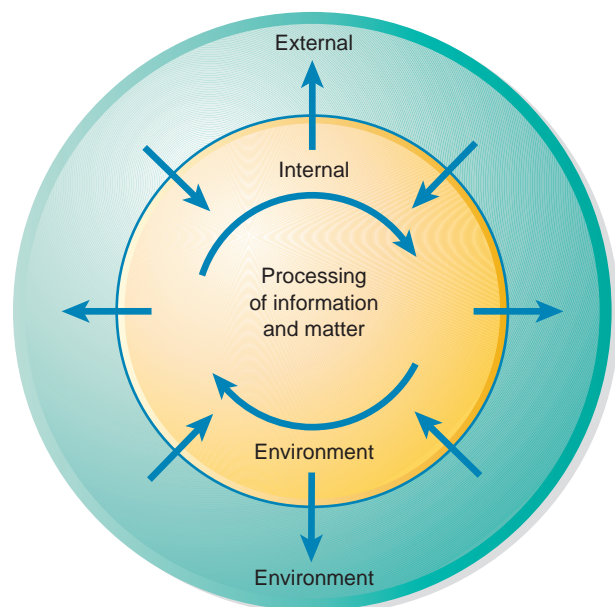

Figure 6-4 Influences leading to disorder may arise from the internal environment and the external environment of the system. Excesses or deficits of information and matter may occur, or there may be faulty regulation of processing.

amount of arterial oxygen available, or a problem in the cell's enzyme system that makes it unable to use oxygen.

The usual cause of hypoxia is ischemia, or deficient blood supply. Ischemia is commonly seen in myocardial cell injury in which arterial blood flow is decreased because of atherosclerotic narrowing of blood vessels. Ischemia also results from intravascular clots (thrombi or emboli) that may form and interfere with blood supply. Thrombi and emboli are common causes of cerebrovascular accidents (strokes, brain attacks). The length of time different tissues can survive without oxygen varies. For example, brain cells most often succumb in 3 to 6 minutes. If the condition leading to hypoxia is slow and progressive, collateral circulation may develop, whereby blood is supplied by other blood vessels in the area. However, this mechanism is not highly reliable.

Nutritional Imbalance

Nutritional imbalance refers to a relative or absolute deficiency or excess of one or more essential nutrients. This may be manifested as undernutrition (inadequate consumption of food or calories) or overnutrition (caloric excess). Caloric excess to the point of obesity overloads cells in the body with lipids. By requiring more energy to maintain the extra tissue, obesity places a strain on the body and has been associated with the development of disease, especially pulmonary and cardiovascular disease.

Specific deficiencies arise when an essential nutrient is deficient or when there is an imbalance of nutrients. Protein deficiencies and avitaminosis (deficiency of vitamins) are typical examples. An energy deficit leading to cell injury can occur if there is insufficient glucose, or insufficient oxygen to transform the glucose into energy. A lack of insulin, or the inability to use insulin, may also prevent glucose from entering the cell from the blood. This occurs in diabetes mellitus, a metabolic disorder that can lead to nutritional deficiency, as well as a host of short-term and long-term life-threatening complications.

Physical Agents

Physical agents, including temperature extremes, radiation, electrical shock, and mechanical trauma, can cause injury to the cells or to the entire body. The duration of exposure and the intensity of the stressor determine the severity of damage.

Temperature

When a person's temperature is elevated, hypermetabolism occurs and the respiratory rate, heart rate, and basal metabolic rate all increase. With fever induced by infections, the hypothalamic thermostat may be reset at a higher temperature and then return to normal when the fever abates. The increase in body temperature is achieved through physiologic mechanisms. Body temperatures greater than 41°C (106°F) indicate hyperthermia, because the physiologic function of the thermoregulatory center breaks down and the temperature soars. This physiologic condition occurs in people who have heat stroke. Eventually, the high temperature causes coagulation of cell proteins, and cells die. The body must be cooled rapidly to prevent brain damage.

The local response to burn injury is similar. There is an increase in metabolic activity, and, as heat increases, proteins coagulate and enzyme systems are destroyed. In extreme situations, charring or carbonization occurs. For more information about burn injuries, see Chapter 57.

Extremes of low temperature, or cold, cause vasoconstriction. Blood flow becomes sluggish and clots form, leading to ischemic damage in the involved tissues. With still lower temperatures, ice crystals may form, and cells may burst.

Radiation and Electrical Shock

Radiation is used for diagnosis and treatment of diseases. Ionizing forms of radiation may cause injury by their destructive action. Radiation decreases the protective inflammatory response of the cell, creating a favorable environment for opportunistic infections. Electrical shock produces burns as a result of the heat generated when electrical current travels through the body. It may also abnormally stimulate nerves, leading, for example, to fibrillation of the heart.

Mechanical Trauma

Mechanical trauma can result in wounds that disrupt the cells and tissues of the body. The severity of the wound, the amount of blood loss, and the extent of nerve damage are significant factors in the outcome.

Chemical Agents

Chemical injuries are caused by poisons, such as lye, which have a corrosive action on epithelial tissue, or by heavy metals, such as mercury, arsenic, and lead, each of which has its own specific destructive action. Many other chemicals are toxic in certain amounts, in certain people, and in specific tissues. For example, excessive secretion of hydrochloric acid can damage the stomach lining; large amounts of glucose can cause osmotic shifts, affecting the fluid and electrolyte balance; and too much insulin can cause subnormal levels of glucose in the blood (hypoglycemia) and can lead to coma.

Drugs, including prescribed medications, can also cause chemical poisoning. Some people are less tolerant of medications than others and manifest toxic reactions at the usual or customary dosages. Aging tends to decrease tolerance to medications. Polypharmacy (taking many medications at one time) also occurs frequently in the aging population and is a problem because of the unpredictable effects of the resulting medication interactions.

Alcohol (ethanol) is also a chemical irritant. In the body, alcohol is broken down into acetaldehyde, which has a direct toxic effect on liver cells that leads to a variety of liver abnormalities, including cirrhosis in susceptible people. Disordered liver cell function leads to complications in other organs of the body.

Infectious Agents

Biologic agents known to cause disease in humans are viruses, bacteria, rickettsiae, mycoplasmas, fungi, protozoa, and nematodes. The severity of the infectious disease depends on the number of microorganisms entering the body, their virulence, and the host's defenses (eg, health, age, immune responses).

Some bacteria, such as those that cause tetanus and diphtheria, produce exotoxins that circulate and create cell damage. Others, such as gram-negative bacteria, produce endotoxins when they die. Tubercle bacilli induce an immune reaction.

Viruses, the smallest living organisms known, survive as parasites of the living cells they invade. Viruses infect specific cells. Through a complex mechanism, viruses replicate within cells and then invade other cells, where they continue to replicate. An immune response is mounted by the body to eliminate the viruses, and the cells harboring the viruses can be injured in the process. Typically, an inflammatory response and immune reaction are the physiologic responses of the body to viral infection.

Disordered Immune Responses

The immune system is an exceedingly complex system, the purpose of which is to defend the body from invasion by any foreign object or foreign cell type, such as cancerous cells. This is a steady-state mechanism, but like other adjustment processes it can become disordered, and cellular injury results. The immune response detects foreign bodies by distinguishing non-self substances from self substances and destroying the non-self entities. The entrance of an antigen (foreign substance) into the body evokes the production of antibodies that attack and destroy the antigen (antigen-antibody reaction).

The immune system may function normally or it may be hypoactive or hyperactive. When it is hypoactive, immunodeficiency diseases occur; when it is hyperactive, hypersensitivity disorders occur. A disorder of the immune system itself can result in damage to the body's own tissues. Such disorders are labeled autoimmune diseases (see Unit 11).

Genetic Disorders

There is intense research interest in genetic defects as causes of disease and modifiers of genetic structure. Many of these defects produce mutations that have no recognizable effect, such as lack of a single enzyme; others contribute to more obvious congenital abnormalities, such as Down syndrome. People can be assessed for many genetic conditions (or the risk for such conditions) such as sickle cell disease, cystic fibrosis, hemophilia A and B, breast cancer, obesity, cardiovascular disease, phenylketonuria, and Alzheimer's disease. The availability of genetic information and technology enables health care providers to perform screening, testing, and counseling for people with genetics concerns. Knowledge obtained from the Human Genome Project has also created opportunities for assessing a person's genetic profile and preventing or treating diseases. Diagnostic genetics and gene therapy have the potential to identify and modify genes before they begin to express traits that would lead to disease or disability. (For further information, see Chapter 9.)

Cellular Response to Injury: Inflammation

Cells or tissues of the body may be injured or killed by any of the agents (physical, chemical, infectious) described earlier. When this happens, an inflammatory response (or in-

flammation) naturally occurs in the healthy tissues adjacent to the site of injury. **Inflammation** is a defensive reaction intended to neutralize, control, or eliminate the offending agent and to prepare the site for repair. It is a nonspecific response (not dependent on a particular cause) that is meant to serve a protective function. For example, inflammation may be observed at the site of a bee sting, in a sore throat, in a surgical incision, and at the site of a burn. Inflammation also occurs in cell injury events, such as strokes and myocardial infarctions.

Inflammation is not the same as infection. An infectious agent is only one of several agents that may trigger an inflammatory response. An infection exists when the infectious agent is living, growing, and multiplying in the tissues and is able to overcome the body's normal defenses.

Regardless of the cause, a general sequence of events occurs in the local inflammatory response. This sequence involves changes in the microcirculation, including vasodilation, increased vascular permeability, and leukocytic cellular infiltration (Fig. 6-5). As these changes take place, five cardinal signs of inflammation are produced: redness, heat, swelling, pain, and loss of function.

The transient vasoconstriction that occurs immediately after injury is followed by vasodilation and an increased rate of blood flow through the microcirculation to the area of

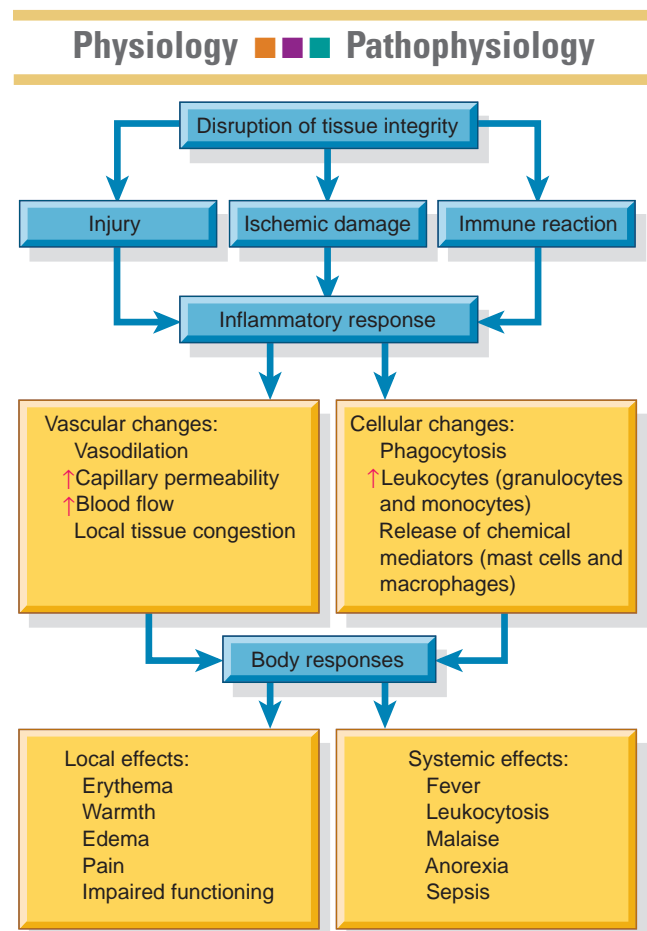

Figure 6-5 Inflammatory response.

tissue damage. Local heat and redness result. Next, the structure of the microvascular system changes to accommodate the movement of plasma protein from the blood into the tissues. Following this increase in vascular permeability, plasma fluids (including proteins and solutes) leak into the inflamed tissues, producing swelling. Leukocytes migrate through the endothelium and accumulate in the tissue at the site of the injury. The pain that occurs is attributed to the pressure of fluids or swelling on nerve endings and to the irritation of nerve endings by chemical mediators released at the site. Bradykinin is one of the chemical mediators suspected of causing pain. Loss of function is most likely related to the pain and swelling, but the exact mechanism is not completely known.

As blood flow increases and fluid leaks into the surrounding tissues, the formed elements (red blood cells, white blood cells, and platelets) remain in the blood, causing it to become more viscous. Leukocytes (white blood cells) collect in the vessels, exit, and migrate to the site of injury to engulf offending organisms and to remove cellular debris in a process called phagocytosis. Fibrinogen in the leaked plasma fluid coagulates, forming fibrin for clot formation, which serves to wall off the injured area and prevent the spread of infection.

Chemical Mediators of Inflammation

Injury initiates the inflammatory response, but chemical substances released at the site induce vascular changes. Foremost among these chemicals are histamine and kinins. Histamine is present in many tissues of the body but is concentrated in the mast cells. It is released when injury occurs and is responsible for the early changes in vasodilation and vascular permeability. Kinins increase vascular dilations and permeability and attract neutrophils to the area. Prostaglandins, another group of chemical substances, are also suspected of causing increased vascular permeability (Porth & Matfin, 2009).

Systemic Response to Inflammation

The inflammatory response is often confined to the site, causing only local signs and symptoms. However, systemic responses can also occur. Fever is the most common sign of a systemic response to injury, and it is most likely caused by endogenous pyrogens (internal substances that cause fever) released from neutrophils and macrophages (specialized forms of leukocytes). These substances reset the hypothalamic thermostat, which controls body temperature, and produce fever. Leukocytosis, an increase in the synthesis and release of neutrophils from bone marrow, may occur to provide the body with greater ability to fight infection. During this process, general, nonspecific symptoms develop, including malaise, loss of appetite, aching, and weakness.

Types of Inflammation

Inflammation is categorized primarily by its duration and the type of exudate produced. It may be acute, subacute, or chronic. Acute inflammation is characterized by the local vascular and exudative changes described previously and usually lasts less than 2 weeks. An acute inflammatory response is immediate and serves a protective function. After the causative agent is removed, the inflammation subsides

and healing takes place with the return of normal or near-normal structure and function.

Chronic inflammation develops if the injurious agent persists and the acute response is perpetuated. Symptoms are present for many months or years. Chronic inflammation may also begin insidiously and never have an acute phase. The chronic response does not serve a beneficial and protective function; on the contrary, it is debilitating and can produce long-lasting effects. As the inflammation becomes chronic, changes occur at the site of injury and the nature of the exudate becomes proliferative. A cycle of cellular infiltration, necrosis, and fibrosis begins, with repair and breakdown occurring simultaneously. Considerable scarring may occur, resulting in permanent tissue damage.

Subacute inflammation falls between acute and chronic inflammation. It includes elements of the active exudative phase of the acute response as well as elements of repair, as in the chronic phase. The term *subacute inflammation* is not widely used.

Cellular Healing

The reparative process begins at approximately the same time as the injury. Healing proceeds after the inflammatory debris has been removed. Healing may occur by regeneration, in which gradual repair of the defect occurs by proliferation of cells of the same type as those destroyed, or by replacement, in which cells of another type, usually connective tissue, fill in the tissue defect and result in scar formation.

Regeneration

The ability of cells to regenerate depends on whether they are labile, permanent, or stable. Labile cells multiply constantly to replace cells worn out by normal physiologic processes; these include epithelial cells of the skin and those lining the gastrointestinal tract. Permanent cells include neurons—the nerve cell bodies, not their axons. Destruction of neurons is permanent, but axons may regenerate. If normal activity is to return, tissue regeneration must occur in a functional pattern, especially in the growth of several axons. Stable cells in some organ systems have a latent ability to regenerate. Under normal physiologic processes, they are not shed and do not need replacement, but if they are damaged or destroyed, they are able to regenerate. Examples include functional cells of the kidney, liver, and pancreas. Cells in other organs, such as the brain, for example, do not regenerate.

Replacement

The condition of the host, the environment, and the nature and severity of the injury affect the processes of inflammation, repair, and replacement. Depending on the extent of damage, repair and replacement may occur by first-, second-, or third-intention healing. In first-intention healing, the wound edges are approximated, as in a surgical wound. Little scar formation occurs, and the wound healing occurs without granulation. In second-intention healing, the edges are not approximated and the wound fills with granulation tissue. The process of repair takes longer and may result in scar formation, with loss of specialized function. For example, people who have recovered from myocardial infarction have abnormal electrocardiographic tracings because the

electrical signal cannot be conducted through the connective tissue that has replaced the infarcted area. In third-intention healing, the wound edges are not approximated and healing is delayed. For more information about wound healing see Chapter 20.

Nursing Implications

In the assessment of people who seek health care, both objective signs and subjective symptoms are the primary indicators of existing physiologic processes. The following questions are addressed:

- Are the heart rate, respiratory rate, and temperature normal?
- What emotional distress may be contributing to the patient's health problems?
- Are there other indicators of steady-state deviation?
- What are the patient's blood pressure, height, and weight?
- Are there any problems in movement or sensation?
- Are there any problems with affect, behavior, speech, cognitive ability, orientation, or memory?
- Are there obvious impairments, lesions, or deformities?

Objective evidence can be obtained from laboratory data, such as electrolytes, blood urea nitrogen, blood glucose, and urinalysis results. Further signs of change are seen in diagnostic studies such as computed tomography (CT), magnetic resonance imaging (MRI), and positron emission tomography (PET). Further information on diagnostic studies can be found in assessment chapters of each unit of the book.

In making a nursing diagnosis, the nurse must relate the symptoms or problems reported by the patient to the existing physical signs. Management of specific biologic disorders is discussed in subsequent chapters; however, nurses can assist any patient to respond to stress-inducing biologic or psychological disorders with stress management interventions.

Stress Management: Nursing Interventions

Stress or the potential for stress is ubiquitous; that is, it is both everywhere and anywhere. Anxiety, frustration, anger, and feelings of inadequacy, helplessness, or powerlessness are emotions often associated with stress. In the presence of these emotions, the customary activities of daily living may be disrupted; for example, a sleep disturbance may occur, eating and activity patterns may be altered, and family processes or role performance may be disrupted.

Many nursing diagnoses are possible for patients suffering from stress. One nursing diagnosis related to stress is Anxiety, which is defined as a vague, uneasy feeling, the source of which may be nonspecific or not known to the person. Stress may also be manifested as ineffective coping patterns, impaired thought processes, or disrupted relationships. These human responses are reflected in the nursing diagnoses of Risk-prone health behavior, Ineffective coping, Defensive coping, and Ineffective denial, all of which indicate poor adaptive responses (NANDA International,

2007). Other possible nursing diagnoses include Social isolation, Risk for impaired parenting, Risk for spiritual distress, Readiness for enhanced family coping, Decisional conflict, Situational low self-esteem, and Risk for powerlessness, among others. Because human responses to stress are varied, as are the sources of stress, arriving at an accurate diagnosis allows interventions and goals to be more specific and leads to improved outcomes.

Stress management is directed toward reducing and controlling stress and improving coping. The need to prevent illness, improve the quality of life, and decrease the cost of health care makes efforts to promote health essential, and stress control is a significant health promotion goal. Stress reduction methods and coping enhancements can derive from either internal or external sources. For example, healthy eating habits and relaxation techniques are internal resources that help reduce stress, and a broad social network is an external resource that helps reduce stress. Goods and services that can be purchased are also external resources for stress management. It may be easier for people with adequate financial resources to cope with constraints in the environment, because their sense of vulnerability to threat is decreased compared to those without adequate financial resources.

Promoting a Healthy Lifestyle

A health-promoting lifestyle provides internal resources that aid in coping, and it buffers or cushions the impact of stressors. Lifestyles or habits that contribute to the risk of illness can be identified through a health risk appraisal, an assessment method designed to promote health by examining a person's habits and recommending changes when a health risk is identified.

Health risk appraisals involve the use of health risk questionnaires to estimate the likelihood that people with a given set of characteristics will become ill. It is hoped that if people are provided with this information, they will adopt healthy behaviors (eg, stop smoking, have periodic screening examinations) to improve their health. Questionnaires typically address the information presented in Chart 6-2.

The personal information is compared with average population risk data, and the risk factors are identified and weighted. From this analysis, a person's risks and major

Chart 6-2 • Information Addressed in Health Risk Questionnaires

- Demographic data: age, gender, race, ethnic background
- Personal and family history of diseases and health problems
- Lifestyle choices
 - Eating, sleeping, exercise, smoking, drinking, sexual activity, and driving habits
 - Stressors at home and on the job
 - Role relationships and associated stressors
- Physical measurements
 - Blood pressure
 - Height, weight, body mass index (BMI)
 - Laboratory analyses of blood and urine
- Participation in high-risk behaviors

Chart 6-3 • Coping Enhancement: Nursing Interventions**Definition**

Assisting a patient to adapt to perceived stressors, changes, or threats that interfere with meeting life demands and roles.

Selected Activities

Use a calm, reassuring approach and provide an atmosphere of acceptance for patients and families.

Assist the patient and family in developing an objective appraisal of the event.

Provide factual information concerning diagnosis, treatment, and prognosis as needed.

Encourage an attitude of realistic hope as a way of dealing with feelings of helplessness.

Acknowledge the patient's spiritual/cultural background and encourage the use of spiritual resources if desired.

Foster constructive methods of dealing with life problems for patients and families.

Assist the patient and family to identify appropriate short- and long-term goals.

Appraise the needs and desires for social support and assist the patient and family to identify available support systems.

Assist the patient to identify positive strategies to deal with limitations, manage needed lifestyle or role changes, and work through the losses of chronic illness and/or disability if appropriate.

Adapted from Bulechek, G. M., Butcher, H. K. & Dochterman, J. C. (Eds.). (2008). *Nursing interventions classification (NIC)* (5th ed.). St. Louis: Mosby.

health hazards are identified. Further comparisons with population data can estimate how many years will be added to a person's lifespan if the suggested changes are made. However, research has not yet demonstrated that providing people with such information ensures that they will change their behaviors. The single most important factor for determining health status is social class, and within a social class the research suggests that the major factor influencing health is level of education (Bastable, 2008).

Enhancing Coping Strategies

Bulechek, Butcher, and Dochterman (2008, p. 228) identified "coping enhancement" as a nursing intervention and defined it as "assisting a patient to adapt to perceived stressors, changes, or threats that interfere with meeting life demands and roles" (Chart 6-3). The nurse can build on the patient's existing coping strategies, as identified in the health appraisal, or teach new strategies for coping if necessary.

The five predominant ways of coping with illness identified in a review of 57 nursing research studies were as follows (Jalowiec, 1993):

- Trying to be optimistic about the outcome
- Using social support
- Using spiritual resources
- Trying to maintain control either over the situation or over feelings
- Trying to accept the situation

Other ways of coping included seeking information, reprioritizing needs and roles, lowering expectations, making compromises, comparing oneself to others, planning activities to conserve energy, taking things one step at a time, listening to one's body, and using self-talk for encouragement.

Teaching Relaxation Techniques

Relaxation techniques are a major method used to relieve stress. Commonly used techniques include progressive muscle relaxation, the Benson Relaxation Response, and relaxation with guided imagery. The goal of relaxation training is to produce a response that counters the stress response. When this goal is achieved, the action of the hypothalamus adjusts and decreases the activity of the sympathetic and

parasympathetic nervous systems. The sequence of physiologic effects and their signs and symptoms are interrupted, and psychological stress is reduced. This is a learned response and requires practice to achieve.

The different relaxation techniques share four similar elements: (1) a quiet environment, (2) a comfortable position, (3) a passive attitude, and (4) a mental device (something on which to focus one's attention, such as a word, phrase, or sound).

Progressive Muscle Relaxation

Progressive muscle relaxation involves tensing and releasing the muscles of the body in sequence and sensing the difference in feeling. It is best if the person lies on a soft cushion, in a quiet room, breathing easily. Someone usually reads the instructions in a low tone in a slow and relaxed manner, or a recording of the instructions may be played. The person tenses the muscles in the entire body (one muscle group at a time), holds, senses the tension, and then relaxes. As each muscle group is tensed, the person keeps the rest of the body relaxed. Each time the focus is on feeling the tension and relaxation. When the exercise is completed, the entire body should be relaxed (Benson, 1993; Benson & Stark, 1996).

Benson's Relaxation Response

Benson (1993) described the following steps of the Benson Relaxation Response:

1. Pick a brief phrase or word that reflects your basic belief system.
2. Choose a comfortable position.
3. Close your eyes.
4. Relax your muscles.
5. Become aware of your breathing, and start using your selected focus word.
6. Maintain a passive demeanor.
7. Continue for a set period of time.
8. Practice the technique twice daily.

This response combines meditation with relaxation. Along with the repeated word or phrase, a passive demeanor is essential. If other thoughts or distractions (noises,

pain) occur, Benson recommends not fighting the distraction but simply continuing to repeat the focus phrase. Time of day is not important, but the exercise works best on an empty stomach.

Relaxation With Guided Imagery

Simple **guided imagery** is the mindful use of a word, phrase, or visual image for the purpose of distracting oneself from distressing situations or consciously taking time to relax or reenergize. A nurse can help a person select a pleasant scene or experience, such as watching the ocean or dabbling the feet in a cool stream. This image serves as the mental device in this technique. As the person sits comfortably and quietly, the nurse guides the person to review the scene, trying to feel and relive the imagery with all of the senses. A recording may be made of the description of the image, or commercial recordings for guided imagery and relaxation can be used. Other relaxation techniques include meditation, breathing techniques, massage, Reiki, music therapy, biofeedback, and the use of humor.

Educating About Stress Management

Two commonly prescribed nursing educational interventions—providing sensory information and providing procedural information (eg, preoperative teaching)—have the goal of reducing stress and improving the patient's coping ability. This preparatory education includes giving structured content, such as a lesson in childbirth preparation to expectant parents, a review of cardiovascular anatomy to a cardiac patient, or a description of sensations a patient will experience during cardiac catheterization. These techniques may alter the person–environment relationship such that something that might have been viewed as harmful or a threat will now be perceived more positively. Giving patients information also reduces the emotional response so that they can concentrate and solve problems more effectively (Eggenberger & Nelms, 2007; Kasper, Köpke, Mühlhauser, et al., 2006).

Enhancing Social Support

The nature of social support and its influence on coping have been studied extensively. Social support has been demonstrated to be an effective moderator of life stress. Social support has been found to provide people with several different types of emotional information (Glass, Perrin, Campbell, et al., 2007; Wilsey & Shear, 2007). The first type of information leads people to believe that they are cared for and loved. This emotional support appears most often in a relationship between two people in which mutual trust and attachment are expressed by helping one another meet their emotional needs. The second type of information leads people to believe that they are esteemed and valued. This is most effective when there is recognition demonstrating a person's favorable position in the group. Known as esteem support, this elevates the person's sense of self-worth. The third type of information leads people to feel that they belong to a network of communication and mutual obligation. Members of this network share information and make goods and services available to the members as needed.

Social support also facilitates a person's coping behaviors; however, this depends on the nature of the social support. People can have extensive relationships and interact frequently, but the necessary support comes only when there is a deep level of involvement and concern, not when people merely touch the surface of each other's lives. The critical qualities within a social network are the exchange of intimate communications and the presence of solidarity and trust.

Emotional support from family and significant others provides love and a sense of sharing the burden. The emotions that accompany stress are unpleasant and often increase in a spiraling fashion if relief is not provided. Being able to talk with someone and express feelings openly may help a person gain mastery of the situation. Nurses can provide this support; however, it is important to identify the person's social support system and encourage its use. People who are "loners," who are isolated, or who withdraw in times of stress have a high risk of coping failure.

Because anxiety can also distort a person's ability to process information, it helps to seek information and advice from others who can assist with analyzing the threat and developing a strategy to manage it. Again, this use of others helps people maintain mastery of a situation and self-esteem.

Thus, social networks assist with management of stress by providing people with:

- A positive social identity
- Emotional support
- Material aid and tangible services
- Access to information
- Access to new social contacts and new social roles

Recommending Support and Therapy Groups

Support groups exist especially for people in similar stressful situations. Groups have been formed by parents of children with leukemia; people with ostomies; women who have had mastectomies; and people with other kinds of cancer or other serious diseases, chronic illnesses, and disabilities. There are groups for single parents, substance abusers and their family members, and victims of child abuse. Professional, civic, and religious support groups are active in many communities. There are also encounter groups, assertiveness training programs, and consciousness-raising groups to help people modify their usual behaviors in their transactions with their environment. Being a member of a group with similar problems or goals has a releasing effect on a person that promotes freedom of expression and exchange of ideas.

As previously noted, a person's psychological and biologic health, internal and external sources of stress management, and relationships with the environment are predictors of health outcomes. These factors are directly related to the person's health patterns. The nurse has a significant role and responsibility in identifying the health patterns of the patient receiving care. If those patterns are not achieving physiologic, psychological, and social balance, the nurse is obligated, with the assistance and agreement of the patient, to seek ways to promote balance.

Although this chapter has presented some physiologic mechanisms and perspectives on health and disease, the way that one copes with stress, the way one relates to others, and the values and goals held are also interwoven into those physiologic patterns. To evaluate a patient's health patterns and to intervene if a disorder exists requires a total assessment of the person. Specific disorders and their nursing management are addressed in greater depth in other chapters.

CRITICAL THINKING EXERCISES

1 A woman was carjacked, raped, and left on the shoulder of the road, where she was hit by a car. She is hospitalized with injuries related to her sexual assault and the hit-and-run vehicle crash. Describe the physiologic and psychological trauma she has experienced. Discuss the parameters that should be assessed. Identify appropriate nursing interventions used to alleviate the patient's physiologic and emotional stressors. Address the need for emotional support from both the nursing staff and the family.

2 A 50-year-old woman had a successful kidney transplant 18 months ago. She developed an intimate relationship with a man in her neighborhood. Several months later she was diagnosed with genital herpes. The woman verbalized to the nurse that this new illness only added to her health problems as well as to her financial, personal, and relational stressors. Discuss the methods the nurse would use to help this patient effectively cope with the multitude of stressors that she is experiencing. Address health care referrals to support groups or social networks that are appropriate for this patient.

EBP 3 A patient experiences burns to the upper extremities after being involved in a kitchen fire. Describe the manner in which homeostasis has been disrupted and the compensatory mechanisms that are evident. How does the patient's medical treatment support the body's compensatory mechanisms? Determine the evidence-based nursing interventions that are appropriate for promoting the healing process.

EBP 4 A 70-year-old woman recently moved to a retirement community where she lives independently. A nurse practitioner assesses this patient's health promotion needs. The family's health history reveals that her mother had type 2 diabetes and thyroid disease, and that her father had hypertension and coronary artery disease. This patient has limited resources and support networks for making necessary lifestyle changes. What evidence exists to support the nurse practitioner's initiating strategies to promote a healthy lifestyle? What is the evidence that supports intervention to limit or prevent maladaptive responses from occurring with this woman? Describe the strength of the evidence regarding the effectiveness of lifestyle changes in promoting health in older adults.

Individual and Family Considerations Related to Illness

LEARNING OBJECTIVES

On completion of this chapter, the learner will be able to:

- 1 Describe the holistic approach to maintaining health and well-being.
- 2 Discuss the concepts of emotional well-being and emotional distress.
- 3 Identify variables that influence the ability to cope with stress and that are antecedents to emotional disorders.
- 4 Explain the concepts of anxiety, posttraumatic stress disorder, depression, loss, and grief.
- 5 Determine the role of the nurse in identifying substance abuse problems and in helping families to cope.
- 6 Assess the impact of illness on the patient's family and on family functioning.
- 7 Explore the concept of spirituality and address the spiritual needs of patients.
- 8 Identify nursing actions that promote effective coping for both patients and families.

GLOSSARY

anxiety: an emotional state characterized by feelings of apprehension, discomfort, restlessness, or worry

bereavement: feelings, thoughts, and responses that occur after a loss

depression: state in which a person feels sad, distressed, and hopeless, with little to no energy for normal activities

faith: belief and trust in God or a higher power

family: a group whose members are related by reciprocal caring, mutual responsibilities, and loyalties

grief: a universal response to any loss

holistic health: promotion of the total health of mind, body, and spirit

mental disorder: a state in which a person has deficits in functioning, has a distorted sense of self or the world, is unable to sustain relationships, or cannot handle stress or conflict effectively

mental health: a state in which a person can meet basic needs, assume responsibilities, sustain relationships, resolve conflicts, and grow throughout life

posttraumatic stress disorder (PTSD): the development of severe anxiety-type symptoms after the experience of a traumatic life event

spirituality: connectedness with self, others, a life force, or God that allows people to find meaning in life

substance abuse: a maladaptive pattern of drug use that causes physical and emotional harm with the potential for disruption of daily life

When people experience threats to their health, they seek out various care providers for the purpose of maintaining or restoring health. In recent years, both patients and families have become increasingly involved in health care and health promotion activities. This chapter discusses the holistic approach to health and wellness, how a person's emotional state contributes to health and illness, and how nurses can help individuals and families prevent the recurrence or exacerbation of health problems and develop strategies to improve their future health status.

Holistic Approach to Health and Health Care

Since the 1980s, holistic therapies often accompany traditional health care. It is estimated that approximately 35% to 45% of consumers in the United States follow **holistic health** practices. More than 50% of people supplement traditional health care treatments with complementary and alternative therapies. In ambulatory care settings, more consumers request these therapies, and increasing numbers of clinicians integrate them into their clinical practice (Hardy-Pickering, Adams, Sim, et al., 2007; Sood, 2007; van Tulder, 2007). In all settings, it is imperative that during clinical assessments the use of complementary and alternative therapies be assessed. Complementary and alternative therapies are discussed in Chapter 8.

For some people, the holistic approach is viewed as a way to capitalize on personal strengths and recultivate the values and beliefs about health that were common before the age of technologic innovations and the sophistication of biomedical science. A lack of focus on individuals, families, and their environments by some health care providers has created feelings of disillusionment and depersonalization.

Active participation by individuals and families in health promotion supports the self-care model historically embraced by the nursing profession. This model is congruent with the philosophy that seeks to balance and integrate the use of traditional medicine and advanced technology with the influence of the mind and spirit on healing. A holistic approach to health reconnects the traditionally separate approaches to mind and body. Factors such as the physical environment, economic conditions, sociocultural issues, emotional state, interpersonal relationships, and support systems can influence health. The connections among physical health, emotional health, and spiritual well-being must be understood and considered when providing health care. It is the nurse's conceptual integration of the physiologic health condition within the emotional and social context, along with the patient's developmental life stage, that allows for the development of a holistic plan of nursing care.

The Brain and Physical and Emotional Health

Research findings suggest fundamental relationships between the brain's environment and mood, behavior, and resistance to disease. One focus of brain research has been the biologic basis of mental disturbances and the relationship

between mental disorders and changes in the brain. The field of psychoneuroimmunology examines connections between the emotions and the central nervous, neuroendocrine, and immune systems and has established compelling evidence that psychosocial variables can affect the functioning of the immune system.

As neuroscientific research continues, data about neurotransmitters and brain functioning contribute to increased understanding of emotions, intelligence, memory, and many aspects of physical functioning. Increased knowledge about the brain and nervous system has led to breakthroughs in the treatment of both symptoms and illnesses.

These findings suggest the need for health care providers to recognize how biologic, emotional, and societal problems combine to affect individuals, families, and communities. Some problems that nurses and other health care providers must address include substance abuse, homelessness, family violence, eating disorders, trauma, and chronic **mental health** conditions such as anxiety and depression. To focus attention on these and other mental health problems, the U.S. Department of Health and Human Services initiated a mental health agenda for the nation in *Healthy People 2010* (U.S. Public Health Service, 2005). The objectives identified are summarized in Chart 7-1.

Mental Health and Emotional Distress

Emotional health involves the ability to function as comfortably and productively as possible. Typically, people who are mentally healthy are satisfied with themselves and their life situations. In the usual course of living, emotionally healthy people focus on activities geared to meet their needs and attempt to accomplish personal goals while managing everyday challenges and problems. Often, people must work hard to balance their feelings, thoughts, and behaviors to alleviate emotional distress, and much energy is used to change, adapt, or manage the obstacles inherent in daily living. A mentally healthy person accepts reality and has a positive sense of self. Emotional health is also manifested by having moral and humanistic values and beliefs, having satisfying interpersonal relationships, doing productive work, and maintaining a realistic sense of hope.

When people have unmet emotional needs or distress, they experience an overall feeling of unhappiness. As tension escalates, security and survival are threatened. How different people respond to these troublesome situations reflects their level of coping and maturity. Emotionally healthy people endeavor to meet the demands of distressing situations while still coping with the typical issues that emerge in their lives. The ways in which people respond to uncomfortable stimuli reflect their exposure to various biologic, emotional, and sociocultural experiences.

When stress interferes with a person's ability to function comfortably and inhibits the effective management of personal needs, that person is at risk for emotional problems. The use of ineffective and unhealthy methods of coping is manifested by dysfunctional behaviors, thoughts, and feelings. These behaviors are aimed at relieving the overwhelming stress, even though they may cause further problems.

Chart 7-1 • Major Mental Health Objectives for Healthy People in the Year 2010

- Reduce the proportion of children and adolescents with disabilities who are reported to be sad, unhappy, or depressed.
- Reduce the proportion of adults with disabilities who report feelings such as sadness, unhappiness, or depression that prevent them from being active.
- Increase the proportion of adults with disabilities reporting sufficient emotional support.
- Increase the proportion of adults with disabilities reporting satisfaction with life.
- Reduce the suicide rate.
- Reduce the rate of suicide attempts by adolescents.
- Reduce the proportion of homeless adults who have serious mental illness.
- Increase the proportion of persons with serious mental illness who are employed.
- Reduce the relapse rates for persons with eating disorders including anorexia nervosa and bulimia nervosa.
- Increase the number of persons in primary care who receive mental health screening and assessment.
- Increase the proportion of children with mental health problems who receive treatment.
- Increase the proportion of juvenile justice facilities that screen admissions for mental health problems.
- Increase the proportion of adults with mental disorders who receive treatment.
- Increase the proportion of persons with co-occurring substance abuse and mental disorders who receive treatment for both disorders.
- Increase the number of states and the District of Columbia that track consumer satisfaction with the mental health services they receive.
- Increase the number of states, territories, and the District of Columbia with an operational mental health plan that addresses cultural competence.

U.S. Public Health Service. (2005). *Healthy people 2010: Understanding and improving health*. Washington, DC: U.S. Government Printing Office. Available at: <http://healthypeople.gov>

Coping ability is strongly influenced by biologic or genetic factors, physical and emotional growth and development, family and childhood experiences, and learning. Typically, people revert to the strategies observed early in life that were modeled by family members, caregivers, and others to resolve conflicts. If these strategies were not adaptive, the person exhibits a range of unproductive behaviors. Dysfunctional behavior in one person not only seriously affects that person's emotional health but can also put others at risk for injury or death. As these destructive behaviors are repeated, a cyclic pattern becomes evident: impaired thinking, negative feelings, and more dysfunctional actions that prevent the person from meeting the demands of daily living.

No universally accepted definition of what constitutes an emotional disorder exists, but many views and theories share the idea that a number of variables can interfere with emotional growth and development and impede successful adaptation to the environment. Most clinicians have adopted the statement from the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders (DSM-IV-TR)*, which defines the term **mental disorder** as a group of behavioral or psychological symptoms or a pattern that manifests itself in significant distress, impaired functioning, or accentuated risk of enduring severe suffering or possible death (American Psychiatric Association, 2000). Risk factors for mental health problems are listed in Chart 7-2.

Patients seen in medical-surgical settings often struggle with psychosocial issues of anxiety, depression, loss, and grief. Abuse, addiction, chemical dependency, body image disturbances, and eating disorders are a few examples of issues that require extensive physical and emotional care to restore optimal functioning. The dual challenge for the health care team is to understand how the patient's emotions influence physical conditions and to identify the best care for the patient experiencing underlying emotional and spiritual distress.

Anxiety

All people experience some degree of **anxiety** (a tense emotional state) as they face new, challenging, or threatening life situations. In clinical settings, fear of the unknown, unexpected news about one's health, and impairment of bodily functions engenders anxiety. Although a mild level of anxiety can mobilize a person to take a position, act on the task that needs to be done, or learn to alter lifestyle habits, more severe anxiety can be paralyzing. Anxiety that escalates to a near panic state can be incapacitating. When patients receive unwelcome news about results of diagnostic studies, they are certain to experience anxiety. Different patients manifest physiologic, emotional, and behavioral signs and symptoms of anxiety in different ways.

CHART
7-2

Risk Factors for Mental Health Problems

Nonmodifiable Risk Factors

- Age
- Gender
- Genetic background
- Family history

Modifiable Risk Factors

- Marital status
- Family environment
- Housing problems
- Poverty or economic difficulties
- Physical health
- Nutritional status
- Stress level
- Social environment and activities
- Exposure to trauma
- Alcohol and drug misuse
- Environmental toxins or other pollutants
- Availability, accessibility, and cost of health services

CHART
7-3

Assessing for Anxiety

Be on the alert for the following assessment findings:

Physiologic Indicators

- Appetite change
- Headaches
- Muscle tension
- Fatigue or lethargy
- Weight change
- Cold and flu symptoms
- Digestive upsets
- Grinding teeth
- Palpitations
- Hypertension
- Restlessness
- Difficulty sleeping
- Skin irritations
- Injury prone
- Increased use of any alcohol or drugs

Emotional Indicators

- Forgetfulness
- Low productivity
- Feeling dull
- Poor concentration
- Negative attitude
- Confusion
- Whirling mind
- No new ideas
- Boredom
- Negative self-talk
- Anxiety

- Frustration
- Depression
- Crying periods
- Irritability
- Worrying
- Feeling discouraged
- Nervous laughter

Relational Indicators

- Isolation
- Intolerance
- Resentment
- Loneliness
- Lashing out
- “Clamming up”
- Nagging
- Distrust
- Few friends
- No intimacy
- Using people

Spiritual Indicators

- Emptiness
- Loss of meaning
- Doubt
- Unforgiving attitude
- Martyrdom
- Loss of direction
- Cynicism
- Apathy

Nursing Implications

Early clinical observations of anxiety are essential components of nursing care (Chart 7-3). A high level of anxiety in a patient probably exacerbates physiologic distress. For example, a postoperative patient who is in pain may discover that anxiety intensifies the sensation of pain. A patient newly diagnosed with type 1 diabetes mellitus may be worried and fearful and therefore unable to focus on or complete essential self-care activities. Many medical conditions (eg, a breast lump or heart condition) cause anxiety. Many assessment findings alert the nurse to patients with moderate to severe anxiety.

All nurses must be vigilant about patients who worry excessively and deteriorate in emotional, social, or occupational functioning. If participation in the therapeutic regimen (eg, administration of insulin) becomes a problem because of extreme anxiety, nursing interventions must be immediately initiated. Caring strategies emphasize ways for the patient to verbalize feelings and fears and to identify sources of anxiety. The need to teach and promote effective coping abilities and the use of relaxation techniques are the priorities of care. In some cases, antianxiety medication may be prescribed. Chart 7-4 provides a list of basic nursing principles that are useful to assist patients in managing

Chart 7-4 • Managing Anxiety

- Listen actively and focus on having the patient discuss personal feelings.
- Use positive remarks and focus on the positive aspects of life in the “here and now.”
- Use appropriate touch (with patient permission) to demonstrate support.
- Discuss the importance of safety and the patient’s overall sense of well-being.
- Explain all procedures, policies, diagnostic studies, medications, treatments, or protocols for care.
- Explore coping strategies and work with the patient to practice and use them effectively (eg, breathing, progressive relaxation, visualization, imagery).
- Use distraction as indicated to relax and prevent self from being overwhelmed.

severe anxiety. Chapter 6 presents additional information about stress and the relaxation response.

Posttraumatic Stress Disorder

In medical-surgical settings, especially in emergency departments, burn units, and rehabilitation centers, nurses care for extremely anxious patients who have experienced overwhelming events that may be outside the range of normal human experience. Patients can suffer from **posttraumatic stress disorder** (PTSD), a condition that generates waves of anxiety, anger, aggression, depression, and suspicion; threatens a person’s sense of self; and interferes with daily functioning. Specific examples of events that place people at risk for PTSD are rape, family violence, torture, terrorist attacks, fire, earthquake, and military combat. Patients who have experienced a traumatic event are often frequent users of the health care system, seeking treatment for the overall emotional and physical trauma that they experienced.

The physiologic responses of people who have been severely traumatized include increased activity of the sympathetic nervous system, increased plasma catecholamine levels, and increased urinary epinephrine and norepinephrine levels. People with PTSD may lose the ability to control their response to stimuli (Loseke, Gelles & Cavanaugh, 2005). The resulting excessive arousal can increase overall body metabolism and trigger emotional reactivity. In this situation, patients have difficulty sleeping, have an exaggerated startle response, and are excessively vigilant.

Symptoms of PTSD can occur hours to years after the trauma is experienced. Acute PTSD is defined as the experience of symptoms for less than a 3-month period. Chronic PTSD is defined as the experience of symptoms lasting longer than 3 months. In the case of delayed PTSD, up to 6 months may elapse between the trauma and the manifestation of symptoms (American Psychiatric Association, 2000). For more information, see Chart 7-5.

Nursing Implications

It is often thought that the incidence of PTSD is very low in the overall population. However, when high-risk groups are studied, the results indicate that more than 50% of study participants have PTSD (McKenny & Price, 2005). Therefore, it is important that nurses consider which of their

 CHART
7-5

Assessing for Posttraumatic Stress Disorder (PTSD)

Be on the alert for the following assessment findings:

Physiologic Indicators

- Dilated pupils
- Headaches
- Sleep pattern disturbances
- Tremors
- Elevated blood pressure
- Tachycardia or palpitations
- Diaphoresis with cold, clammy skin
- Hyperventilation
- Dyspnea
- Smothering or choking sensation
- Nausea, vomiting, or diarrhea
- Stomach ulcers
- Dry mouth
- Abdominal pain
- Muscle tension or soreness
- Exhaustion

Psychological Indicators

- Anxiety
- Anger
- Depression
- Fears or phobias
- Survivor guilt
- Hypervigilance
- Nightmares or flashbacks
- Intrusive thoughts about the trauma
- Impaired memory
- Dissociative states
- Restlessness or irritability
- Strong startle response
- Substance abuse
- Self-hatred
- Feelings of estrangement
- Feelings of helplessness, hopelessness, or powerlessness
- Lack of interest in life
- Inability to concentrate
- Difficulty communicating, caring, and expressing love
- Problems with relationships
- Sexual problems ranging from acting out to impotence
- Difficulty with intimacy
- Inability to trust
- Lack of impulse control
- Aggressive, abusive, or violent behavior, including suicide
- Thrill-seeking behaviors

Copel, L. C. (2000). *Nurse's clinical guide: Psychiatric and mental health care* (2nd ed.). Springhouse, PA: Springhouse.

patients are at risk for PTSD and be knowledgeable about the common symptoms associated with it. Older people are more susceptible to the physical effects of trauma and the effects of PTSD because of the neural inactivation associated with aging. One study reported that people with strong support networks were less likely to experience PTSD after a natural disaster than people without a strong support system (Acierno, Ruggiero, Kilpatrick, et al., 2006).

The sensitivity and caring of the nurse creates the interpersonal relationship necessary to work with patients who

have PTSD. These patients are physically compromised and are struggling emotionally with situations that are not considered part of normal human experience, situations that violate the commonly held perceptions of human social justice. Treatment of patients with PTSD includes several essential components: establishing a trusting relationship, addressing and working through the trauma experience, and teaching the coping skills needed for recovery and self-care. The patient's progress can be influenced by the ability to cope with the various aspects of both the physical and the emotional distress.

Depression

Depression is a common response to health problems and is an underdiagnosed problem, particularly in hospitalized patients. People may become depressed as a result of injury or illness; may be suffering from an earlier loss that is compounded by a new health problem; or may seek health care for somatic manifestations of depression.

Clinical depression is distinguished from everyday feelings of sadness by its duration and severity. Most people occasionally feel down or depressed, but these feelings are short-lived and do not result in impaired functioning. Clinically depressed people usually have had signs of a depressed mood or a decreased interest in pleasurable activities for at least a 2-week period. An obvious impairment in social, occupational, and overall daily functioning occurs in some people. Others function appropriately in their interactions with the outside world by exerting great effort and forcing themselves to mask their distress. Sometimes they are successful at hiding their depression for months or years and astonish family members and others when they finally admit that they are seriously depressed.

Many people experience depression but seek treatment for somatic complaints. The leading somatic complaints of patients struggling with depression are headache, backache, abdominal pain, fatigue, malaise, anxiety, and decreased desire or problems with sexual functioning (Vaccarolis, Carson & Shoemaker, 2006). It is estimated that depression is undiagnosed about half of the time and masquerades as physical health problems (Townsend, 2005). People with depression also exhibit poor functioning with frequent absences from work and school.

Specific symptoms of clinical depression include feelings of sadness, worthlessness, fatigue, guilt, and difficulty concentrating or making decisions. Changes in appetite, weight gain or loss, sleep disturbances, and psychomotor retardation or agitation are also common. Often, patients have recurrent thoughts about death or suicide or have made suicide attempts. A diagnosis of clinical depression is made when a person presents with at least five of nine diagnostic criteria for depression (Chart 7-6). Unfortunately, only one of three depressed people is properly diagnosed and appropriately treated (American Psychiatric Association, 2000).

Nursing Implications

Because any loss in function, change in role, or alteration in body image is a possible antecedent to depression, nurses in all settings encounter patients who are depressed or who have thought about suicide. Depression is suspected if changes in the patient's thoughts or feelings and a loss of

Chart 7-6 • Diagnostic Criteria for Depression Based on the DSM-IV-TR

A person experiences at least five out of nine characteristics, with one of the first two symptoms present most of the time:

1. Depressed mood
2. Loss of pleasure or interest
3. Weight gain or loss
4. Sleeping difficulties
5. Psychomotor agitation or retardation
6. Fatigue
7. Feeling worthless
8. Inability to concentrate
9. Thoughts of suicide or death

American Psychiatric Association. (2000). *Diagnostic and statistical manual of mental disorders (DSM-IV-TR)* (4th ed.). Washington, DC: Author.

self-esteem are noted. Chart 7-7 lists risk factors for depression. Depression can occur at any age, and it is diagnosed more frequently in women than in men. In elderly patients, nurses should be aware that decreased mental alertness or withdrawal-type responses may be indicative of depression. Consultation with an advanced practice psychiatric mental health nurse to assess and differentiate between dementia-like symptoms and depression is often helpful.

Talking with the patient about his or her fears, frustration, anger, and despair can help alleviate a sense of helplessness and lead to necessary treatment. Helping the patient learn to cope effectively with conflict, interpersonal problems, and grief and encouraging the patient to discuss actual and potential losses may hasten his or her recovery from depression. It may also be possible to help the patient identify and decrease negative self-talk and unrealistic expectations and show how these contribute to depression. The nurse should monitor the patient for the onset of new problems because depression adversely affects physical health and self-care activities (Chart 7-8). All patients with depression should be evaluated to determine if they would benefit from antidepressant therapy.

In addition to the measures previously listed, psychoeducational programs, establishment of support systems, and counseling can reduce anxiety- and depression-related distress (McKenny & Price, 2005). Psychoeducational pro-

grams can help patients and their families understand depression, treatment options, and coping strategies. (In crisis situations, it is imperative that patients be referred to psychiatrists, psychiatric nurse specialists, advanced practice psychiatric mental health nurses, or crisis centers.) Explaining to patients that depression is a medical illness and not a sign of personal weakness, and that effective treatment will allow them to feel better and stay emotionally healthy, is an important aspect of care (Varcariolis, et al., 2006).

In the United States, 1% of deaths are due to suicide, and screening in primary care settings helps reduce mortality (Bickley, 2007). When patients make statements that are self-deprecating, express feelings of failure, or are convinced that things are hopeless and will not improve, they may be at risk for suicide. Risk factors for suicide are listed in Chart 7-9.

Substance Abuse

Some people use mood-altering substances as a coping mechanism. People who engage in **substance abuse** use illegally obtained drugs, prescribed or over-the-counter medications, and alcohol alone or in combination with other drugs in ineffective attempts to cope with the pressures, strains, and burdens of life. They are unable to make healthy decisions and to solve problems effectively. Typically, they are also unable to identify and implement adaptive behaviors. Some people may respond to personal illness or the illness of a loved one by using those substances to decrease emotional pain. Over time, physiologic, emotional, cognitive, and behavioral problems develop as a result of continuous substance abuse. These problems cause distress for people, their families, and their communities.

Nursing Implications

Substance abuse is encountered in all clinical settings. Intoxication and withdrawal are two common substance abuse problems. Nurses may treat patients who have experienced trauma as a result of intoxication. Other patients who are active substance abusers enter the primary care setting with a diagnosis other than that of substance abuse. Many do not disclose the extent of their substance use. The nurse who performs a substance use assessment can detect the patient's use of denial or lack of knowledge about the harmful effects of psychoactive substances.

A number of tools are available to nurses to assess drug and alcohol abuse. Examples of such instruments are the CAGE Questionnaire (Ewing, 1984), the Michigan Alcohol Screening Test (MAST) (Selzer, 1971), the Addiction Severity Index (McLellan, Kushner, Metzger, et al., 1992), the Drug Abuse Screening Test for Adolescents (Martino, Grilo & Fehon, 2000), and the TWEAK alcohol screening test (Chan, Pristach, Welte, et al., 1993). The MAST has been updated to include drug use and has a geriatric version (The New York State Office of Alcoholism and Substance Abuse Services [OASAS], 2007). The CAGE Questions Adapted to Include Drugs (CAGEAID) instrument is presented in Chapter 5, Chart 5-5. Information that is commonly addressed in substance abuse questionnaires is summarized in Chart 7-10.

Health care professionals are in a pivotal position to identify substance abuse problems, institute treatment

CHART
7-7

Risk Factors for Depression

- Family history
- Stressful situations
- Female gender
- Prior episodes of depression
- Onset before age 40 years
- Medical comorbidity
- Past suicide attempts
- Lack of support systems
- History of physical or sexual abuse
- Current substance abuse

CHART
7-8 **NURSING RESEARCH PROFILE**
Loneliness and Social Support in MS

Beal, C. C. & Stuijbergen, A. (2007). Loneliness in women with multiple sclerosis. *Rehabilitation Nursing, 32*(4), 165–171.

Purpose

Women diagnosed with multiple sclerosis (MS) are at risk for loneliness due to the changes that frequently occur in their social activities and networks. This study was designed to (1) examine the relationship between loneliness, social support, functional limitations, self-rated health status, social responses to illness, and marital status, as well as to (2) determine the extent that the previously mentioned variables could predict loneliness.

Design

A secondary analysis examined data collected from 659 women in 1996. Participants, from the southwest region of the United States, were members of the National Multiple Sclerosis Society. The women provided information on age, gender, ethnicity, education, employment, marital status, and type of MS. The participants completed a longitudinal survey concerning health promotion behaviors and quality of life for people with MS. The researchers used descriptive statistics to describe the subjects. Pearson correlations and regression analysis were used to identify the variables that explained the variance for loneliness.

Findings

The subjects reported few problems with activities of daily living. Ninety-eight of the women (approximately 15%) revealed that they experienced fatigue, with 48% indicating that the fatigue was frequent or disabling. The majority of the participants reported that they were less social as a result of the MS because it was difficult to plan social activities.

These women believed that other people did not understand what they were going through, and they felt obligated to help others learn about and understand their illness. Approximately 67% of the participants stated that other people treated them differently because of their chronic illness. Fifty percent of the women reported feeling lonely at some time in the past week. Loneliness was positively correlated with all the study variables, although the correlations with functional limitation, self-rated health status, and marital status were weak. Researchers noted that there was a negative relationship between loneliness and social support. They found a positive correlation between loneliness and social responses to illness.

Nursing Implications

Loneliness occurs in women with MS who have low levels of social support, low self-rated health status, and increased social demands of illness. In this study, loneliness was a frequent experience in women with MS and was also more common in those who were unmarried.

Health care providers must be aware that women with MS need to be assessed for loneliness, because loneliness is a precursor to depression. Loneliness may not be easily recognized. Astute nurses are able to determine if social isolation exists; this situation is essential to determine if women are at risk for loneliness. Nurses also need to recognize that social support must be assessed and social networks encouraged. For women with MS, another significant nursing intervention is the strengthening of interpersonal resources. It is necessary to develop programs that increase social interaction. These women need opportunities to participate in activities that allow them to form new friendships. Nurses can assist in promoting the overall emotional health of women with MS.

protocols, and make referrals. Because substance abuse severely affects families, nurses can help family members confront the situation, decrease enabling behaviors, and motivate the person with the substance abuse problem to obtain treatment.

Caring for codependent family members is another nursing priority. Codependent people tend to manifest unhealthy patterns in relationships with others. Codependents struggle with a need to be needed, an urge to control others, and a willingness to remain involved and suffer with a person who has a drug problem.

Families may approach the health care team to help set limits on the dysfunctional behavior of people who abuse substances. At these times, a therapeutic intervention is organized for the purpose of confronting the patient about

CHART
7-9  **Risk Factors for Suicide**

- Age younger than 20 or older than 45 years, especially older than 65 years
- Gender—women make more attempts, men are more successful
- Dysfunctional family—members have experienced cumulative multiple losses and possess limited coping skills
- Family history of suicide
- Severe depression
- Severe, intractable pain
- Chronic, debilitating medical problems
- Substance abuse
- Severe anxiety
- Overwhelming problems
- Severe alteration in self-esteem or body image
- Lethal suicide plan

CHART
7-10

Assessing for Substance Abuse

- Past and recurrent use of the substance
- Patient's view of substance use as a problem
- Age when substance was first used and last used
- Length and duration of use of substance
- Preferred method of use of substance
- Amount of substance used
- How substance is procured
- Effect of or reaction to substance
- Previous attempts to cease or decrease substance use

substance use and the need to obtain drug or alcohol treatment. Nurses or other skilled addiction counselors help families present the addicted person with a realistic perspective about the problem, their concerns about and caring for the person, and a specific plan for treatment. This therapeutic intervention works on the premise that honest and caring confrontation can break through a person's denial of the addiction. If a person refuses to participate in the designed plan, the family members define the consequences and state their commitment to follow through with them. This intervention is empowering to the family and usually provides the structure needed to secure treatment.

However, even with treatment, the patient may experience relapse. The nurse works with the patient and family to prevent relapse and to be prepared if relapse occurs. Relapse is considered a part of the illness process and therefore must be viewed and addressed in the same way that chronic illness is treated.

Nurses who work with patients and families struggling with addiction must dispel the myth that addiction is a defect in character or a moral fault. Views on substance abuse vary within society. A person's background may help determine whether he or she uses drugs, what drugs are used, and when they are used. The combination of factors, such as values and beliefs, family and personal norms, spiritual convictions, and conditions of the current social environment, predisposes a person to the possibility of drug use, motivation for treatment, and continual recovery. It has also been said that a person's attitude, especially toward alcohol, reflects the overall beliefs and attitudes of that person's culture (Giger & Davidhizar, 2008).

Family Health and Distress

The **family** (a group related by reciprocal caring, mutual responsibilities, and loyalties) plays a central role in the life of the patient and is a major part of the context of the patient's life. It is within families that people grow, are nurtured, acquire a sense of self, develop beliefs and values about life, and progress through life's developmental stages (Fig. 7-1). Families are also the first source for socialization and teaching about health and illness. Families prepare their own

Figure 7-1 There are many types of families.

members with strategies for balancing closeness with separateness and togetherness with individuality. A major role of families is to provide physical and emotional resources to maintain health and a system of support in times of crises, such as in illness and disability.

Health problems often affect the family's ability to function. Five family functions are viewed as essential to the growth of individuals and families. The first function, *management*, involves the use of power, decision making about resources, establishment of rules, provision of finances, and future planning—responsibilities assumed by the adults of the family. The second function, *boundary setting*, makes clear distinctions between the generations and the roles of adults and children within the family structure. The third function, *communication*, is important to individual and family growth; healthy families have a full range of clear, direct, and meaningful communication among their members. The fourth function is *education and support*. Education involves modeling skills for living a physically, emotionally, and socially healthy life. Support is manifested by actions that tell family members they are cared about and loved; it promotes health and is seen as a critical factor in coping with crises and illness situations. The fifth function, *socialization*, involves families' transmission of culture and the acceptable behaviors needed to perform adequately in the home and in the world (Wright & Leahey, 2005).

Nursing Implications

When a family member becomes ill, injured, or disabled, all members of the family are affected. Depending on the nature of the health problem, family members may need to modify their existing lifestyles or even restructure their lives.

There are many degrees of family functioning. Nurses assess family functioning to determine how a particular family copes with the impact of the health condition. If the family is chaotic or disorganized, promoting coping skills becomes a priority in the plan of care. The family with pre-existing problems may require additional assistance before participating fully in the current health situation. In performing a family assessment, the nurse must evaluate the present family structure and function. Areas of appraisal include demographic data, developmental information (keeping in mind that different family members can be in different developmental stages simultaneously), family structure, family functioning, and coping abilities. The role the environment plays in family health is also assessed.

Interventions with family members are based on strengthening coping skills through direct care, fostering communication skills, and providing education. Healthy family communication has a strong influence on the quality of family life and can help the family make appropriate choices, consider alternative strategies, or persevere through complex circumstances. Within a family system, for example, a particular patient may be undergoing extensive surgery for cancer while the partner has cardiac disease, an adolescent has type 1 diabetes mellitus, and a child has a fractured arm. In this situation, there are multiple health concerns along with competing developmental tasks and needs. Despite the obvious concerns of the family members, both individually and collectively, a crisis may or may not be present. The family may be coping effectively, or it may

be in crisis or unable to handle the situation. Ideally, the health care team conducts a careful and comprehensive family assessment, develops interventions tailored to handle the stressors, implements the specified treatment protocols, and facilitates the construction of social support systems.

The use of existing family strengths, resources, and education is augmented by therapeutic family interventions. The primary goals of the nurse are to maintain and improve the patient's present level of health and to prevent physical and emotional deterioration. Next, the nurse intervenes in the cycle that the illness creates: patient illness, stress for other family members, new illness in other family members, and additional patient stress.

Helping the family members handle the myriad stressors that bombard them daily involves working with family members to develop coping skills. Seven traits that enhance coping of family members under stress have been identified (Burr, Klein, Burr, et al., 1994). Communication skills and spirituality were the most useful traits. Cognitive abilities, emotional strengths, relationship capabilities, willingness to use community resources, and individual strengths and talents were also associated with effective coping. As nurses work with families, they must not underestimate the impact their therapeutic interactions, educational information, positive role modeling, provision of direct care, and teaching have on promoting health.

Without the active support of the family members by the health care team, the potential for maladaptive coping increases. Often, denial and blaming of others occur. Sometimes, physiologic illness, emotional withdrawal, and physical distancing are the results of severe family conflict, violent behavior, or addiction to drugs and alcohol. Substance abuse may develop in family members who feel unable to cope or solve problems. Frequently, people engage in these dysfunctional behaviors when faced with difficult or problematic situations.

Loss and Grief

Loss is a part of the life cycle. All people experience loss in the form of change, growth, and transition. The experience of loss and **grief** is painful, frightening, and lonely, and it triggers an array of emotional responses (Chart 7-11). People may vacillate between denial, shock, disbelief, anger, inertia, intense yearning, loneliness, sadness, loss of control, depression, and spiritual despair (Kubler-Ross & Kessler, 2005).

In addition to normal losses associated with life cycle stages, there are the potential losses of health, a body part, self-image, self-esteem, and even one's life. When loss is not acknowledged or there are multiple losses, anxiety, depression, and health problems may occur. People with physical health problems, such as diabetes mellitus, human immunodeficiency virus (HIV) infection/acquired immunodeficiency syndrome (AIDS), cardiac disorders, gastrointestinal disorders, disabilities, and neurologic impairments, tend to respond to these conditions with feelings of loss and grief.

People grieve in different ways, and there is no timeline for completing the **bereavement** process. The time of griev-

CHART
7-11

Assessing for Grieving

Be on the alert for the following assessment findings:

Physiologic Indicators

- Heart rate changes
- Blood pressure alterations
- Gastrointestinal disturbances
- Chest discomfort
- Shortness of breath
- Weakness
- Appetite changes
- Sleep problems
- Vague, but distressing, physical symptoms

Emotional Indicators

- Sadness
- Depression
- Anger
- Social withdrawal
- Loneliness
- Apathy
- Longing for who or what was lost
- Blaming of self or others
- Questioning of beliefs

Behavioral Indicators

- Slow movements
- Forgetfulness
- Purposeless activity
- Crying
- Sighing
- Lack of interest
- Easily distracted from tasks

ing often depends on the significance of the loss, the anticipation of or preparation for the loss, the person's emotional stability and maturity, and the person's coping ability.

Regardless of the duration of the grieving process, there are two basic goals: (1) healing the self and (2) recovering from the loss. Other factors that influence grieving are the type of loss, life experiences with various changes and transitions, religious beliefs, cultural background, and personality type. Some patients may resort to abuse of prescription medications, illegal drugs, or alcohol if they find it difficult to cope with the loss; the grief process is then complicated by the use of addictive substances.

Nursing Implications

Nurses identify patients and family members who are grieving and work with them to accomplish the four major tasks of the grief process: (1) acceptance of the loss, (2) acknowledgment of the intensity of the pain of the loss, (3) adaptation to life after the loss, and (4) cultivation of new relationships and activities. Nurses also assess and differentiate between grief and depression by knowing the common thoughts, feelings, physical or bodily reactions, and behaviors associated with grief compared with depression.

The physical response to grief includes the sensation of somatic distress, a tightness in the throat followed by a choking sensation or shortness of breath, the need to sigh,

an empty feeling inside the abdomen, a lack of muscle power, and intense disabling distress. Grief can further debilitate already compromised patients and can have a strong impact on family functioning.

Death and Dying

Coping with the death of a loved one or with anticipation of one's own death is considered the ultimate challenge. The idea of death is threatening and anxiety provoking to many people. Kubler-Ross (1975, p. 1) stated: "The key to the question of death unlocks the door of life. . . . For those who seek to understand it, death is a highly creative force." Common fears of those who are dying are fear of the unknown, pain, suffering, loneliness, loss of the body, and loss of personal control.

In recent years, the experience of dying has changed as advances have been made in the care of chronically and terminally ill patients. Technologic innovations and modern therapeutic treatments have prolonged the lifespan, and many deaths are now the result of chronic illnesses that result in progressive physiologic deterioration and subsequent multisystem failure. For more information on end-of-life care and death and dying, see Chapter 17.

Spirituality and Spiritual Distress

Spirituality is defined as connectedness with self, others, a life force, or God that allows people to experience self-transcendence and find meaning in life. Spirituality helps people discover a purpose in life, understand the ever-changing qualities of life, and develop their relationship with God or a higher power. Within the framework of spirituality, people may discover truths about the self, about the world, and about concepts such as love, compassion, wisdom, honesty, commitment, imagination, reverence, and morality. Sacred texts for the major religious traditions offer guidelines for personal conduct and social and spiritual behavior. It is important that the spiritual beliefs of people and families be acknowledged, valued, and respected for the comfort and guidance they provide.

Spiritual behavior can be expressed through sacrifice, self-discipline, and spending time in activities that focus on the inner self or the soul. Although religion and nature are two vehicles that people use to connect themselves with God or a higher power, bonds to religious institutions, beliefs, or dogma are not required to experience the spiritual sense of self. **Faith**, considered the foundation of spirituality, is a belief in something that a person cannot see. The spiritual part of a person views life as a mystery that unfolds over one's lifetime, encompassing questions about meaning, hope, relatedness to God, acceptance or forgiveness, and transcendence.

A strong sense of spirituality or religious faith can have a positive impact on health (Hovey & Seligman, 2007; McManus, 2007). Spirituality is also a component of hope, and, especially during chronic, serious, or terminal illness, patients and their families often find comfort and emotional strength in their religious traditions or spiritual beliefs. At other times, illness and loss can cause a loss of faith or

meaning in life and a spiritual crisis. The nursing diagnosis of spiritual distress is applicable to those who have a disturbance in the belief or value system that provides strength, hope, and meaning in life.

Nursing Implications

Spiritually distressed patients (or family members) may show despair, discouragement, ambivalence, detachment, anger, resentment, or fear. They may question the meaning of suffering, life, and death and express a sense of emptiness. The nurse assesses spiritual strength by inquiring about the patient's sense of spiritual well-being, hope, and peacefulness and assesses whether spiritual beliefs and values have changed in response to illness or loss. In addition, the nurse assesses current and past participation in religious or spiritual practices and notes the patient's responses to questions about spiritual needs—grief, anger, guilt, depression, doubt, anxiety, or calmness—to help determine the patient's need for spiritual care. Another simple assessment technique is to inquire about the patient's and family's desire for spiritual support.

For nurses to provide spiritual care, they must be open to being present and supportive when patients experience doubt, fearfulness, suffering, despair, or other difficult psychological states of being. Interventions that foster spiritual growth or reconciliation include being fully present; listening actively; conveying a sense of caring, respect, and acceptance; using therapeutic communication techniques to encourage expression; suggesting the use of prayer, meditation, or imagery; and facilitating contact with spiritual leaders or performance of spiritual rituals.

Patients with serious, chronic, or terminal illnesses face physical and emotional losses that threaten their spiritual integrity. During acute and chronic illness, rehabilitation, or the dying process, spiritual support can stimulate patients to regain or strengthen their connections with their inner selves, their loved ones, and God or a higher power to transcend suffering and find meaning. Nurses can alleviate distress and suffering and enhance wellness by meeting their patients' spiritual needs.

CRITICAL THINKING EXERCISES

EBP 1 A 60-year-old woman who survived an earthquake is in a hospital emergency department for treatment of severe lacerations. She tells the nurse she is fearful that her spouse, who was already admitted to the hospital with a fractured hip, is alone and suffering. She states, "I am nervous about his condition and that he will go to surgery before I see him. I know that he will be better if he knows that I am all right, too. Please, let me see him!" What assessment data should be collected to determine measures that will most likely allay this patient's anxiety? What evidenced-based nursing interventions are appropriate for assisting the woman through the trauma that she experienced? What complementary or alternative interventions might be helpful to this woman? Discuss the strength of the evidence. Identify the criteria used to evaluate the strength of the evidence for the strategies.

2 The night before a patient's major cardiac surgery, the nurse learns her patient has lost both his wife and his adult son in the past 6 months. What physiologic, emotional, and behavioral indicators should the nurse be alert for in assessing grieving? Generate a list of possible nursing diagnoses for this patient. Identify the nursing interventions that would be most appropriate for each of the possible nursing diagnoses and evaluation criteria for these interventions.

Perspectives in Transcultural Nursing

LEARNING OBJECTIVES

On completion of this chapter, the learner will be able to:

- 1 Identify key components of cultural assessment.
- 2 Apply transcultural nursing principles, concepts, and theories when providing nursing care to individuals, families, groups, and communities.
- 3 Develop strategies for planning, providing, and evaluating culturally competent nursing care for patients from diverse backgrounds.
- 4 Critically analyze the influence of culture on nursing care decisions and actions for patients.
- 5 Discuss the impact of diversity and health care disparities on health care delivery.

GLOSSARY

culture: the knowledge, belief, art, morals, laws, customs, and any other capabilities and habits acquired by humans as members of society

culturally competent nursing care: effective, individualized care that demonstrates respect for the dignity, personal rights, preferences, beliefs, and practices of the person receiving care, while acknowledging the biases of the caregiver and preventing these biases from interfering with the care provided

cultural nursing assessment: a systematic appraisal or examination of individuals, families, groups, and communities in terms of their cultural beliefs, values, and practices

minority: group of people whose physical or cultural characteristics differ from the majority of people in a society

subculture: relatively large groups of people who share characteristics that identify them as a distinct entity

transcultural nursing: nursing care to clients and families across cultural variations

In the health care delivery system, as in society, nurses interact with people of similar as well as diverse cultural backgrounds. People may have different frames of reference and varied preferences regarding their health and health care needs. Nurses must often practice **transcultural nursing**, providing care to clients and families across cultural variations. Acknowledging, respecting, and adapting to the cultural needs of patients and significant others are important components of nursing care. In addition, facilitating access to culturally appropriate health care is critical to ensure holistic nursing care. To plan and deliver culturally appropriate and competent care, nurses must understand the language of culture, culturally appropriate care, and cultural competence and the various aspects of culture that should be explored for each patient.

Cultural Concepts

The concept of culture and its relationship to the health care beliefs and practices of the patient and his or her family or significant others provide the foundation for transcultural nursing. This awareness of culture in the delivery of nursing care has been described in different terms and phrases, including respect for cultural diversity; culturally sensitive or comprehensive care; and culturally competent, appropriate (Giger, Davidhizar, Purnell, et al., 2007b), or culturally congruent nursing care (Leininger, 2002). Two important concepts are cultural diversity and culturally competent care.

Culture is commonly defined as the knowledge, belief, art, morals, laws, customs, and any other capabilities and habits acquired by humans as members of society. During the past century, and especially during recent decades, hundreds of definitions of culture have been offered that integrate these themes and the themes of ethnic variations of a population based on race, nationality, religion, language, physical characteristics, and geography (Underwood, 2006). To fully appreciate the broad impact of culture, factors such as disabilities, gender, social class, physical appearance (eg, weight, height), ideologies (political views), or sexual orientation must be integrated into the definition of culture as well (Underwood, 2006).

Madeleine Leininger (2002), founder of the specialty called transcultural nursing, writes that culture involves learned and transmitted knowledge about values, beliefs, rules of behavior, and lifestyle practices that guide designated groups in their thinking and actions in patterned ways. Giger and Davidhizar (2008) define transcultural nursing as a research-focused, client-based practice field of culturally competent nursing. Transcultural nursing addresses the differences and similarities among cultures in relation to health, health care, and illness, with consideration of patient values, beliefs, and practices. Culture develops over time as a result of exposure to social and religious structures and intellectual and artistic manifestations, and each individual person, including each nurse, is culturally unique (Giger & Davidhizar, 2008).

Ethnic culture has four basic characteristics:

- It is learned from birth through language and socialization.
- It is shared by members of the same cultural group, and it includes an internal sense and external perception of distinctiveness.
- It is influenced by specific conditions related to environmental and technical factors and to the availability of resources.
- It is dynamic and everchanging.

With the exception of the first characteristic, cultures related to aging, physical appearance, lifestyle, and other less frequently acknowledged aspects also share the above characteristics.

Cultural diversity has also been defined in a number of ways. Often, differences in skin color, religion, and geographic area are the only elements used to identify diversity, with ethnic minorities being considered the primary sources of cultural diversity. However, there are many other possible sources of cultural diversity. To truly acknowledge the cultural differences that may influence health care delivery, the nurse must confront bias and recognize the influence of his or her own culture and cultural heritage (Evans, 2007).

Culturally competent nursing care is defined as effective, individualized care that demonstrates respect for the dignity, personal rights, preferences, beliefs, and practices of the person receiving care, while acknowledging the biases of the caregiver and preventing these biases from interfering with the care provided. Culturally competent nursing care is a dynamic process that requires comprehensive knowledge of culture-specific information and an awareness of, and sensitivity to, the effect that culture has on the care situation. It requires that the nurse integrate cultural knowledge, awareness of his or her own cultural perspective, and the patient's cultural perspectives when preparing and implementing a plan of care (Giger & Davidhizar, 2008). Exploring one's own cultural beliefs and how they might conflict with the beliefs of the patients being cared for is a first step toward becoming culturally competent. Understanding the diversity within cultures, such as subcultures, is also important. In addition, culturally competent care involves facilitating patient access to culturally appropriate resources (Cutilli, 2006).

Subcultures

Although culture is a universal phenomenon, it takes on specific and distinctive features for a particular group because it encompasses all of the knowledge, beliefs, customs, and skills acquired by the members of that group. When such groups function within a larger cultural group, they are referred to as subcultures.

The term **subculture** is used for relatively large groups of people who share characteristics that identify them as a distinct entity. Examples of American subcultures based on ethnicity (ie, subcultures with common traits such as physical characteristics, language, or ancestry) include African Americans, Hispanic/Latino Americans, Asian/Pacific Islanders, and Native Americans. Each of these subcultures may be further divided; for example, Native Americans consist of American Indians and Alaska Natives, who represent more than 500 federally and state-recognized tribes in addition to an unknown number of tribes that are not officially recognized.

Subcultures may also be based on religion (more than 1200 religions exist in the United States), occupation (eg, nurses, physicians, other members of the health care team), disability (eg, the deaf community), or illness. In addition, subcultures may be based on age (eg, infants, children, adolescents, adults, older adults), gender (eg, male, female), sexual orientation (eg, homosexual, bisexual, heterosexual), or geographic location (eg, Texan, Southern, Appalachian).

Nurses should also be sensitive to the interracial applications of cultural competence. Differences between individuals in subcultures in a designated group add to the challenge to plan and provide culturally competent care. Focusing on cultural “norms” while ignoring individual uniqueness could offend or anger patients and result in stereotyped care that is not truly culturally appropriate for that patient (Gray & Thomas, 2006). Nurses must refrain from culturally stereotyping patients. Instead, nurses should consult patients or significant others regarding personal values, beliefs, preferences, and cultural identification. This strategy is also applicable for members of nonethnic subcultures.

Minorities

The term **minority** refers to a group of people whose physical or cultural characteristics differ from the majority of people in a society. At times, minorities may be singled out or isolated from others in society or treated in different or unequal ways. Although there are four generally identified minority groups—blacks/African Americans, Hispanics, Asian/Pacific Islanders, and Native Americans (Baldwin, 2004; Sullivan Commission, 2004)—the concept of “minority” varies widely and must be understood in a cultural context. For example, men may be considered a minority in the nursing profession, but they constitute a majority in the field of medicine. In addition, Caucasians may be in the minority in some communities in the United States, but they are currently the majority group in the country (although it has been projected that by the middle to late 21st century, Caucasians will no longer be in the majority in the United States). Because the term minority often connotes inferiority, members of many racial and ethnic groups object to being identified as minorities.

Transcultural Nursing

Transcultural nursing, a term sometimes used interchangeably with cross-cultural, intercultural, or multicultural nursing, refers to research-focused practice that focuses on patient-centered, culturally competent nursing. Transcultural nursing incorporates the care (caring) values, beliefs, and practices of people and groups from a particular culture without imposing the nurse’s cultural perspective on the patient. The underlying focus of transcultural nursing is to provide culture-specific and culture-universal care that promotes the well-being or health of individuals, families, groups, communities, and institutions (Giger & Davidhizar, 2008; Leininger, 2002). All people as well as the community or institution at large benefit when culturally competent care is provided. When the care is delivered beyond a nurse’s national boundaries, the term *international* or *transnational nursing* is often used.

Although many nurses, anthropologists, and others have written about the cultural aspects of nursing and health care, Leininger (2002) developed a comprehensive research-based theory called Culture Care Diversity and Universality to promote culturally congruent nursing for people of different or similar cultures. This means promoting recovery from illness, preventing conditions that would limit the patient’s health or well-being, or facilitating a peaceful death in ways that are culturally meaningful and appropriate. Nursing care needs to be tailored to fit the patient’s cultural values, beliefs, and lifestyles.

Leininger’s theory stresses the importance of providing culturally congruent nursing care (meaningful and beneficial health care tailored to fit the patient’s cultural values) through culture care accommodation and culture care restructuring. *Culture care accommodation* refers to professional actions and decisions that nurses make on behalf of those in their care to help people of a designated culture achieve a beneficial or satisfying health outcome. *Culture care restructuring* or repatterning refers to professional actions and decisions that help patients reorder, change, or modify their lifestyles toward new, different, or more beneficial health care patterns (Fig. 8-1). At the same time, the patient’s cultural values and beliefs are respected, and a better or healthier lifestyle results. Other terms and definitions that provide further insight into culture and health care include the following:

- *Acculturation*: the process by which members of a cultural group adapt to or take on the behaviors of another group
- *Cultural blindness*: the inability of people to recognize their own values, beliefs, and practices and those of others because of strong ethnocentric tendencies (the tendency to view one’s own culture as superior to others)
- *Cultural imposition*: the tendency to impose one’s cultural beliefs, values, and patterns of behavior on a person or people from a different culture
- *Cultural taboos*: activities or behaviors that are avoided, forbidden, or prohibited by a particular cultural group

Culturally Competent Nursing Care

Culturally competent nursing care is the delivery of interventions that are congruent with a given culture. It involves a complex integration of attitudes, knowledge, and skills (including assessment, decision making, judgments, critical thinking, and evaluation) that enables nurses to provide culturally sensitive and appropriate care. Agency policies are important to achieve culturally competent care. Policies that promote culturally competent care establish flexible regulations pertaining to visitors (number, frequency, and length of visits), provide translation services for non-English-speaking patients, and train staff to provide care for patients with different cultural values (Purnell & Paulanka, 2005). Culturally competent policies are developed to promote an environment in which the traditional healing, spiritual, and religious practices of patients are respected and encouraged and to recognize the special dietary practices of patients from selected cultural groups.

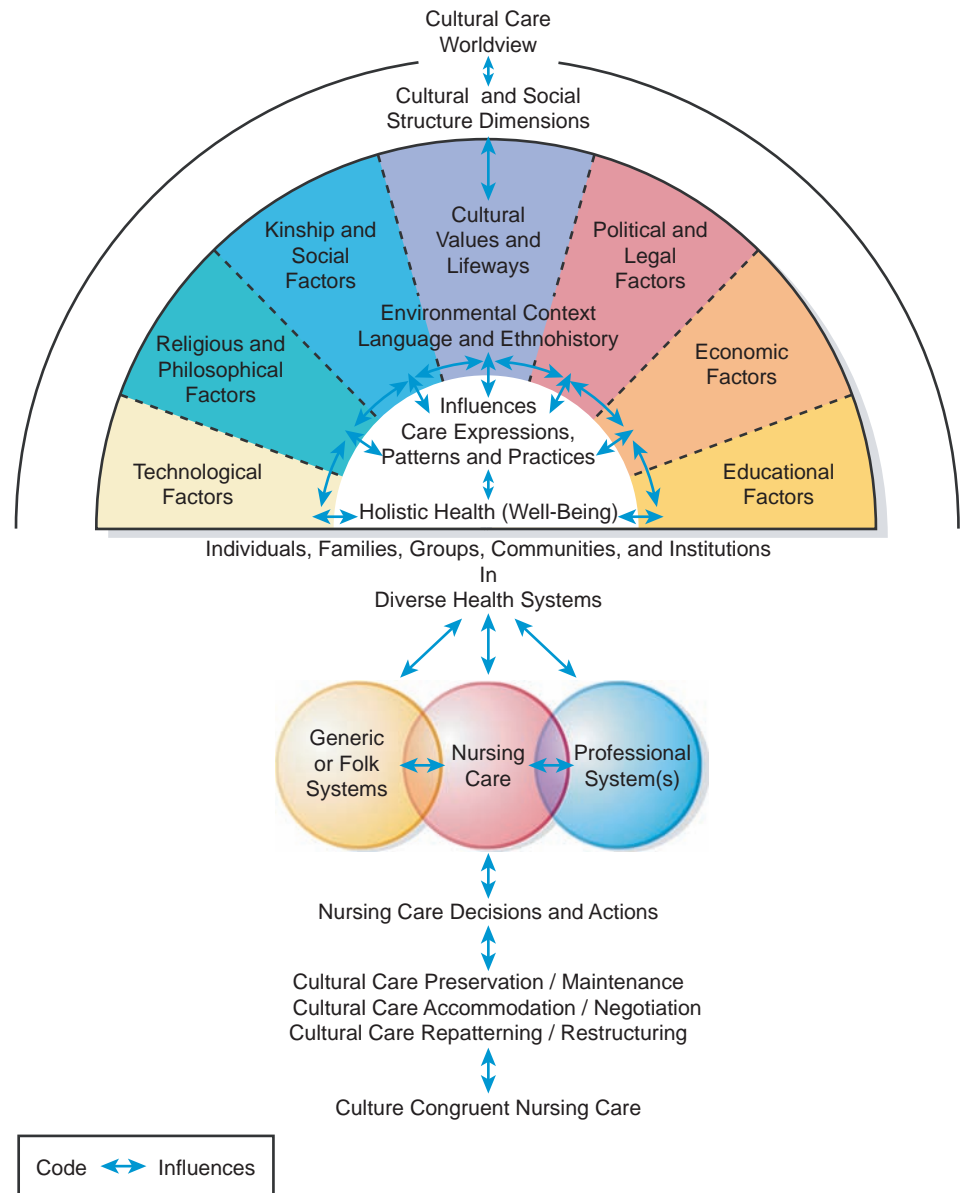

Figure 8-1 Leininger's Sunrise Model depicts her theory of cultural care diversity and universality. From Leininger, M. M. (Ed.). (2001). *Culture care diversity and universality: A theory of nursing*. New York: National League for Nursing Press.

Giger and Davidhizar (2008) created an assessment model to guide nurses in exploring cultural phenomena that might affect nursing care. They identified communication, space, time orientation, social organization, environmental control, and biologic variations as relevant phenomena. This model has been used in various patient care settings to provide data essential to the provision of culturally competent care.

Cross-Cultural Communication

Establishment of an environment of culturally congruent care and respect begins with effective communication, which occurs not only through words, but also through body language and other cues, such as voice, tone, and loudness. Nurse-patient interactions, as well as communication among members of a multicultural health care team,

are dependent on the ability to understand and be understood.

Approximately 150 different languages are spoken in the United States, with Spanish accounting for the largest percentage after English. Obviously, nurses cannot become fluent in all languages, but certain strategies for fostering effective cross-cultural communication are necessary when providing care for patients who are not fluent in English. Cultural needs should be considered when choosing an interpreter; for instance, fluency in varied dialects is beneficial (Cutilli, 2006). The interpreter's voice quality, pronunciation, use of silence, use of touch, and use of nonverbal communication should also be considered (Giger & Davidhizar, 2008). The interpreter should not be a member of the patient's family because that could violate the patient's right to privacy.

Chart 8-1 • Overcoming Language Barriers

- Greet the patient using the last or complete name. Avoid being too casual or familiar. Point to yourself and say your name. Smile.
- Proceed in an unhurried manner. Pay attention to any effort by the patient or family to communicate.
- Speak in a low, moderate voice. Avoid talking loudly. Remember that there is a tendency to raise the volume and pitch of your voice when the listener appears not to understand. The listener may perceive that you are shouting or angry.
- Organize your thoughts. Repeat and summarize frequently. Use audiovisual aids when feasible.
- Use short, simple sentence structure and speak in the active voice.
- Use simple words, such as “pain” rather than “discomfort.” Avoid medical jargon, idioms, and slang. Avoid using contractions, such as don’t, can’t, won’t.
- Use nouns repeatedly instead of pronouns. *Example:* Do not say: “He has been taking his medicine, hasn’t he?” Do say: “Does Juan take his medicine?”
- Pantomime words (use gestures) and simple actions while verbalizing them.
- Give instructions in the proper sequence. *Example:* Do not say: “Before you rinse the bottle, sterilize it.” Do say: “First, wash the bottle. Second, rinse the bottle.”
- Discuss one topic at a time, and avoid giving too much information in a single conversation. Avoid using conjunctions. *Example:* Do not say: “Are you cold and in pain?” Do say (while pantomiming/gesturing): “Are you cold?” “Are you in pain?”
- Talk directly to the patient rather than to the person who accompanied him or her.
- Validate whether the person understands by having him or her repeat instructions, demonstrate the procedure, or act out the meaning.
- Use any words you know in the person’s language. This indicates that you are aware of and respect the patient’s primary means of communicating.
- Try a third language. Many Indo-Chinese speak French. Europeans often know three or four languages. Try Latin words or phrases, if you are familiar with the language.
- Be aware of culturally based gender and age differences and diverse socioeconomic, educational, and tribal or regional differences when choosing an interpreter.
- Obtain phrase books from a library or bookstore, make or purchase flash cards, contact hospitals for a list of interpreters, and use both formal and informal networking to locate a suitable interpreter. Although they are costly, some telecommunication companies provide translation services.

During illness, patients of all ages tend to regress, and the regression often involves language skills. Chart 8-1 summarizes suggested strategies for overcoming language barriers. Nurses should also assess how well patients and families have understood what has been said. The following cues may signify a lack of effective communication:

- Efforts to change the subject: This could indicate that the listener does not understand what was said and is attempting to talk about something more familiar.
- Absence of questions: Paradoxically, this often means that the listener is not grasping the message and therefore has difficulty formulating questions to ask.
- Inappropriate laughter: A self-conscious giggle may signal poor comprehension and may be an attempt to disguise embarrassment.
- Nonverbal cues: A blank expression may signal poor understanding. However, among some Asian Americans, it may reflect a desire to avoid overt expression of emotion. Avoidance of eye contact may be a cultural expression of respect for the speaker in some Native Americans and Asian Americans.

Culturally Mediated Characteristics

Nurses should be aware that patients act and behave in a variety of ways, in part because of the influence of culture on behaviors and attitudes. However, although certain attributes and attitudes are frequently associated with particular cultural groups, as described in the rest of this chapter, it is important to remember that not all people from the same cultural background share the same behaviors and views. Although nurses who fail to consider patients’

cultural preferences and beliefs are considered insensitive and possibly indifferent, nurses who assume that all members of any one culture act and behave in the same way run the risk of stereotyping people. As previously stated, the best way to avoid stereotyping is to view each patient as an individual and to assess the patient’s cultural preferences. A thorough culture assessment using a culture assessment tool or questionnaire (see later discussion) is very beneficial.

Many aspects of care may be influenced by the diverse cultural perspectives held by health care providers, patients, families, or significant others. One example is the issue of informed consent and full disclosure. In general, nurses may argue that patients have the right to full disclosure concerning their disease and prognosis and may believe that advocacy means working to provide that disclosure. However, family members in some cultural backgrounds may believe it is their responsibility to protect and spare the patient (their loved one) knowledge about a terminal illness. Similarly, patients may in fact not want to know about their condition and may expect their family members to “take the burden” of that knowledge and related decision making. Nurses should not decide that a family or patient is simply wrong or that a patient must know all of the details of his or her illness regardless of the patient’s preference. Similar concerns may be noted when patients refuse pain medication or treatment because of cultural beliefs regarding pain or beliefs in divine intervention or faith healing.

Determining the most appropriate and ethical approach to patient care requires an exploration of the cultural aspects of these situations. Self-examination and recognition of one’s own cultural bias and worldview, as discussed earlier, play a major part in helping the nurse resolve cultural and ethical conflicts. Nurses must promote open dialogue

and work with patients, families, physicians, and other health care providers to reach the culturally appropriate solution for the individual patient.

Space and Distance

People tend to regard the space in their immediate vicinity as an extension of themselves. The amount of space they need between themselves and others to feel comfortable is a culturally determined phenomenon.

Because nurses and patients usually are not consciously aware of their personal space requirements, they frequently have difficulty understanding different behaviors in this regard. For example, one patient may perceive the nurse sitting close to him or her as an expression of warmth and care; another patient may perceive the nurse's act as a threatening invasion of personal space. Research reveals that people from the United States, Canada, and Great Britain require the most personal space between themselves and others, whereas those from Latin America, Japan, and the Middle East need the least amount of space and feel comfortable standing close to others (Giger & Davidhizar, 2008).

If the patient appears to position himself or herself too close or too far away, the nurse should consider cultural preferences for space and distance. Ideally, the patient should be permitted to assume a position that is comfortable to him or her in terms of personal space and distance. The nurse should be aware that the wheelchair of a person with a disability is considered an extension of the person; therefore, the nurse should ask the person's permission before moving or touching the wheelchair. Because a significant amount of communication during nursing care requires close physical contact, the nurse should be aware of these important cultural differences and consider them when providing care (Smith-Temple & Johnson, 2006).

Eye Contact

Eye contact is also a culturally determined behavior. Although most nurses have been taught to maintain eye contact when speaking with patients, some people from certain cultural backgrounds may interpret this behavior differently. For example, some Asians, Native Americans, Indo-Chinese, Arabs, and Appalachians may consider direct eye contact impolite or aggressive, and they may avert their own eyes when talking with nurses and others whom they perceive to be in positions of authority. Some Native Americans stare at the floor during conversations, a cultural behavior conveying respect and indicating that the listener is paying close attention to the speaker. Some Hispanic patients maintain downcast eyes as a sign of culturally appropriate deferential behavior toward others on the basis of age, gender, social position, economic status, and position of authority (Giger & Davidhizar, 2008). The nurse who is aware that eye contact may be culturally determined can better understand the patient's behavior and provide an atmosphere in which the patient can feel comfortable.

Time

Attitudes about time vary widely among cultures and can be a barrier to effective communication between nurses and patients. Views about punctuality and the use of time are

culturally determined, as is the concept of waiting. Symbols of time, such as watches, sunrises, and sunsets, represent methods for measuring the duration and passage of time (Giger & Davidhizar, 2008).

For most health care providers, time and promptness are extremely important. For example, nurses frequently expect patients to arrive at an exact time for an appointment, although patients are often kept waiting by health care providers who are running late. Health care providers are likely to function according to an appointment system in which there are short intervals of perhaps only a few minutes. However, for patients from some cultures, time is a relative phenomenon, with little attention paid to the exact hour or minute. For example, some Hispanic people consider time in a wider frame of reference and make the primary distinction between day and night. Time may also be determined according to traditional times for meals, sleep, and other activities or events. For people from some cultures, the present is of the greatest importance, and time is viewed in broad ranges rather than in terms of a fixed hour. Being flexible in regard to schedules is the best way to accommodate these differences.

Value differences also may influence a person's sense of priority when it comes to time. For example, responding to a family matter may be more important to a patient than meeting a scheduled health care appointment. Allowing for these different views is essential in maintaining an effective nurse-patient relationship. Scolding or acting annoyed at patients for being late undermines their confidence and may result in further missed appointments or indifference to health care suggestions.

Touch

The meaning people associate with touching is culturally determined to a great degree. In some cultures (eg, Hispanic, Arab), male health care providers may be prohibited from touching or examining certain parts of the female body. Similarly, it may be inappropriate for females to care for males. Among many Asian Americans, it is impolite to touch a person's head because the spirit is believed to reside there. Therefore, assessment of the head or evaluation of a head injury requires permission of the patient or a family member, if the patient is not able to give permission.

The patient's culturally defined sense of modesty must also be considered when providing nursing care. For example, some Jewish and Muslim women believe that modesty requires covering their head, arms, and legs with clothing.

Observance of Holidays

People from all cultures observe certain civil and religious holidays. Nurses should familiarize themselves with major observances for members of the cultural groups they serve. Information about these observances is available from various sources, including religious organizations, hospital chaplains, and patients themselves. Routine health appointments, diagnostic tests, surgery, and other major procedures should be scheduled to avoid observances patients identify as significant. If not contraindicated, efforts should also be made to accommodate patients and families or significant others who wish to perform cultural and religious rituals in the health care setting.

Diet

The cultural meanings associated with food vary widely but usually include one or more of the following: relief of hunger; promotion of health and healing; prevention of disease or illness; expression of caring for another; promotion of interpersonal closeness among individual people, families, groups, communities, or nations; and promotion of kinship and family alliances. Food may also be associated with strengthening of social ties; celebration of life events (eg, birthdays, marriages, funerals); expression of gratitude or appreciation; recognition of achievement or accomplishment; validation of social, cultural, or religious ceremonial functions; facilitation of business negotiations; and expression of affluence, wealth, or social status.

Culture determines which foods are served and when they are served, the number and frequency of meals, who eats with whom, and who receives the choicest portions. Culture also determines how foods are prepared and served, how they are eaten (with chopsticks, hands, or fork, knife, and spoon), and where people shop (eg, ethnic grocery stores, specialty food markets). Culture also determines the impact of excess weight and obesity on self-esteem and social standing. In some cultures, physical bulk is viewed as a sign of affluence and health (eg, a healthy baby is a chubby baby).

Religious practices may include fasting (eg, Mormons, Catholics, Buddhists, Jews, Muslims) and abstaining from selected foods at particular times (eg, Catholics abstain from meat on Ash Wednesday and on Fridays during Lent). Practices may also include the ritualistic use of food and beverages (eg, Passover dinner, consumption of bread and wine during religious ceremonies). Chart 8-2 summarizes some dietary practices of selected religious groups.

Many groups tend to feast, often in the company of family and friends, on selected holidays. For example, many Christians eat large dinners on Christmas and Easter and

consume other traditional high-calorie, high-fat foods, such as seasonal cookies, pastries, and candies. These culturally based dietary practices are especially significant in the care of patients with diabetes, hypertension, gastrointestinal disorders, obesity, and other conditions in which diet plays a key role in the treatment and health maintenance regimen.

Biologic Variations

Along with psychosocial adaptations, nurses must also consider the physiologic impact of culture on patients' response to treatment, particularly medications. Data have been collected for many years regarding differences in the effect some medications have on people of diverse ethnic or cultural origins. Genetic predispositions to different rates of metabolism cause some patients to be prone to adverse reactions to the standard dose of a medication, whereas other patients are likely to experience a greatly reduced benefit from the standard dose of the medication. For example, an antihypertensive agent may work well for a Caucasian man within a 4-week time span but may take much longer to work or not work at all for an African American man with hypertension. General polymorphism—biologic variation in response to medications resulting from patient age, gender, size, and body composition—has long been acknowledged by the health care community. Nurses must be aware that ethnicity and related factors such as values and beliefs regarding the use of herbal supplements, dietary intake, and genetic factors can affect the effectiveness of treatment and compliance with the treatment regimen (Giger & Davidhizar, 2008).

Complementary and Alternative Therapies

Interventions for alterations in health and wellness vary among cultures. Interventions most commonly used in the United States have been labeled as *conventional medicine* by

Chart 8-2 • Prohibited Foods and Beverages of Selected Religious Groups

<p>Hinduism</p> <p>All meats Animal shortenings</p>	<p>Mixing milk and meat dishes at same meal Blood by ingestion (eg, blood sausage, raw meat). <i>Note:</i> Packaged foods will contain labels identifying kosher ("properly preserved" or "fitting") and pareve (made without meat or milk) items.</p>
<p>Islam</p> <p>Pork Alcoholic products and beverages (including extracts, such as vanilla and lemon) Animal shortenings Gelatin made with pork, marshmallow, and other confections made with gelatin <i>Note:</i> <i>Halal</i> food is lawful food that may be consumed according to tenets of the Koran whereas <i>Haram</i> is food that is unlawful to consume</p>	<p>Mormonism (Church of Jesus Christ of Latter-Day Saints)</p> <p>Alcohol Beverages containing caffeine stimulants (coffee, tea, colas, and selected carbonated soft drinks)</p>
<p>Judaism</p> <p>Pork Predatory fowl Shellfish and scavenger fish (eg, shrimp, crab, lobster, eel, catfish). Fish with fins and scales are permissible.</p>	<p>Seventh-Day Adventism</p> <p>Alcohol Beverages containing caffeine stimulants (coffee, tea, colas, and selected carbonated soft drinks) Pork Certain seafood, including shellfish Fermented beverages <i>Note:</i> Optional vegetarianism is encouraged.</p>

the National Institutes of Health (National Center for Complementary and Alternative Medicine [NCCAM], 2007). Other names for conventional medicine are allopathy, Western medicine, regular medicine, mainstream medicine, and biomedicine. Alternative therapy used to supplement conventional medicine may be referred to as *complementary therapy*. Interest in interventions that are not an integral part of conventional medicine prompted the National Institutes of Health to create the Office of Alternative Medicine and then to establish NCCAM.

According to a nationwide survey, 36% of adults in the United States use some form of complementary and alternative medicine. This percentage increases to 75% when prayer specifically for health reasons is included in the definition. Complementary and alternative interventions are classified into five main categories: alternative medical systems, mind–body interventions, biologically based therapies, manipulative and body-based methods, and energy therapies (NCCAM, 2007):

- *Alternative medical systems* are defined as complete systems of theory and practice that are different from conventional medicine. Some examples are traditional Eastern medicine (including acupuncture, herbal medicine, Oriental massage, and Qi gong); India's traditional medicine, Ayurveda (including diet, exercise, meditation, herbal medicine, massage, exposure to sunlight, and controlled breathing to restore harmony of a person's body, mind, and spirit); homeopathic medicine (including use of herbal medicine and minerals); and naturopathic medicine (including diet, acupuncture, herbal medicine, hydrotherapy, spinal and soft-tissue manipulation, electrical currents, ultrasound and light therapy, therapeutic counseling, and pharmacology).
- *Mind–body interventions* are defined as techniques to facilitate the mind's ability to affect symptoms and bodily functions. Some examples are meditation, dance, music, art therapy, prayer, and mental healing.
- *Biologically based therapies* are defined as natural and biologically based practices, interventions, and products. Some examples are herbal therapies (a plant or plant part that produces and contains chemical substances that act on the body), special diet therapies (such as those of Drs. Atkins, Ornish, and Pritikin), orthomolecular therapies (magnesium, melatonin, megadoses of vitamins), and biologic therapies (shark cartilage, bee pollen).
- *Manipulative and body-based methods* are defined as interventions based on body movement. Some examples are chiropractic (primarily manipulation of the spine), osteopathic manipulation, massage therapy (soft-tissue manipulation), and reflexology.
- *Energy therapies* are defined as interventions that focus on energy fields within the body (biofields) or externally (electromagnetic fields). Some examples are Qi gong, Reiki, therapeutic touch, pulsed electromagnetic fields, magnetic fields, alternating electrical current, and direct electrical current.

Patients may choose to seek an alternative to conventional medical or surgical therapies. Many of these alternative therapies are becoming widely accepted as feasible

treatment options. Therapies such as acupuncture and herbal treatments may be recommended by physicians to address aspects of a condition that are unresponsive to conventional medical treatment or to minimize the side effects associated with conventional medical therapy. Physicians and advanced practice nurses may work in collaboration with herbalists or with spiritualists or shamans to provide a comprehensive treatment plan. Out of respect for the way of life and beliefs of patients from different cultures, it is often necessary that healers and health care providers respect the strengths of each approach (NCCAM, 2007).

Complementary therapy is becoming more common as health care consumers learn what information is available in printed media and on the Internet. As patients become more informed, they are more likely to participate in a variety of therapies in conjunction with their conventional medical treatments (Hart, 2007). Nurses must assess all patients for use of complementary therapies, be alert to the danger of herb–drug interactions or conflicting treatments, and be prepared to provide information to patients about treatments that may be harmful. However, nurses must be accepting of patients' beliefs and right to control their own care. As patient advocates, nurses facilitate the integration of conventional medical, complementary, and alternative therapies.

Causes of Illness

People may view illness differently. Three major views, or paradigms, attempt to explain the causes of disease and illness: the biomedical or scientific view, the naturalistic or holistic perspective, and the magico-religious view.

Biomedical or Scientific

The biomedical or scientific worldview prevails in most health care settings and is embraced by most nurses and other health care providers. The basic assumptions underlying the biomedical perspective are that all events in life have a cause and effect, that the human body functions much like a machine, and that all of reality can be observed and measured (eg, blood pressures, partial pressure of arterial oxygen [PaO₂] levels, intelligence tests). One example of the biomedical or scientific view is the bacterial or viral explanation of communicable diseases.

Naturalistic or Holistic

The naturalistic or holistic perspective is another viewpoint that explains the cause of illness and is commonly embraced by many Native Americans, Asians, and others. According to this view, the forces of nature must be kept in natural balance or harmony.

One example of a naturalistic belief, held by many Asian groups, is the yin/yang theory, in which health is believed to exist when all aspects of a person are in perfect balance or harmony. Rooted in the ancient Chinese philosophy of Taoism (which translates as “The Way”), the yin/yang theory proposes that all organisms and objects in the universe consist of yin and yang energy. The seat of the energy forces is within the autonomic nervous system, where balance between the opposing forces is maintained during health. Yin

energy represents the female and negative forces, such as emptiness, darkness, and cold, whereas the yang forces are male and positive, emitting warmth and fullness. Foods are classified as cold (yin) or hot (yang) in this theory and are transformed into yin and yang energy when metabolized by the body. Cold foods are eaten when a person has a hot illness (eg, fever, rash, sore throat, ulcer, infection), and hot foods are eaten when a person has a cold illness (eg, cancer, headache, stomach cramps, “cold”). The yin/yang theory is the basis for Eastern or Chinese medicine and is embraced by some Asian Americans.

Many Hispanic, African American, and Arab groups also embrace the hot/cold theory of health and illness. The four humors of the body—blood, phlegm, black bile, and yellow bile—regulate basic bodily functions and are described in terms of temperature and moisture. The treatment of disease consists of adding or subtracting cold, heat, dryness, or wetness to restore the balance of these humors. Beverages, foods, herbs, medicines, and diseases are classified as hot or cold according to their perceived effects on the body, not their physical characteristics. According to the hot/cold theory, the person as a whole, not just a particular ailment, is significant. People who embrace the hot/cold theory maintain that health consists of a positive state of total well-being, including physical, psychological, spiritual, and social aspects of the person.

According to the naturalistic worldview, breaking the laws of nature creates imbalances, chaos, and disease. People who embrace the naturalistic paradigm use metaphors such as “the healing power of nature.” For example, from the perspective of many Chinese people, illness is viewed not as an intruding agent but as a part of life’s rhythmic course and an outward sign of disharmony within.

Magico-Religious

The third major way in which people view the world and explain the causes of illness is the magico-religious worldview. This view’s basic premise is that the world is an arena in which supernatural forces dominate, and that the fate of the world and those in it depends on the action of supernatural forces for good or evil. Examples of magical causes of illness include belief in voodoo or witchcraft among some African Americans and people from Caribbean countries. Faith healing is based on religious beliefs and is most prevalent among selected Christian religions, including Christian Science, whereas various healing rituals may be found in many other religions, such as Roman Catholicism and Mormonism (Church of Jesus Christ of Latter-Day Saints).

Of course, it is possible to hold a combination of worldviews, and many patients offer more than one explanation for the cause of their illness. As a profession, nursing largely embraces the scientific or biomedical worldview, but some aspects of holism have begun to gain popularity, including a wide variety of techniques for managing chronic pain, such as hypnosis, therapeutic touch, and biofeedback. Belief in spiritual power is also held by many nurses who credit supernatural forces with various unexplained phenomena related to patients’ health and illness states. Regardless of the view held and whether the nurse agrees with the patient’s beliefs in this regard, it is important to be aware of how the

person views illness and health and to work within this framework to promote patient care and well-being.

Folk Healers

People of some cultures believe in folk or indigenous healers. For example, nurses may find that some Hispanic patients may seek help from a *curandero* or *curandera*, *espiritualista* (spiritualist), *yerbo* (herbalist), or *sabador* (healer who manipulates bones and muscles). Some African American patients may seek assistance from a *hougan* (voodoo priest or priestess), spiritualist, root doctor (usually a woman who uses magic rituals to treat diseases), or “old lady” (an older woman who has successfully raised a family and who specializes in child care and folk remedies). Native American patients may seek assistance from a shaman or medicine man or woman. Asian patients may mention that they have visited herbalists, acupuncturists, or bone setters. Several cultures have their own healers, most of whom speak the native tongue of that culture, make house calls, and charge significantly less than healers practicing in the conventional medical health care system.

People seeking complementary and alternative therapies have expanded the practices of folk healers beyond their traditional populations, so the nurse should ask the patient about use of folk healers regardless of the patient’s cultural background. It is best not to disregard the patient’s belief in folk healers or try to undermine trust in the healers. To do so may alienate the patient and drive him or her away from receiving the prescribed care. Nurses should make an effort to accommodate the patient’s beliefs while also advocating the treatment proposed by health science.

Cultural Assessment

Cultural nursing assessment refers to a systematic appraisal or examination of individuals, families, groups, and communities in terms of their cultural beliefs, values, and practices. The purpose of such an assessment is to provide culturally competent care (Giger & Davidhizar, 2008). In an effort to establish a database for determining a patient’s cultural background, nurses have developed cultural assessment tools or modified existing assessment tools (Leininger, 2002) to ensure that transcultural considerations are included in the plan of care. Giger and Davidhizar’s model has been used to design nursing care from health promotion to nursing skills activities (Giger & Davidhizar, 2008; Smith-Temple & Johnson, 2006). The information presented in this chapter and the general guidelines presented in Chart 8-3 can be used to direct nursing assessment of culture and its influence on a patient’s health beliefs and practices.

Additional Cultural Considerations: Know Thyself

Because the nurse–patient interaction is the focal point of nursing, nurses should consider their own cultural orientation when conducting assessments of patients and their

Chart 8-3 • Assessing for Patients' Cultural Beliefs

- What is the patient's country of origin? How long has the patient lived in this country? What is the patient's primary language and literacy level?
- What is the patient's ethnic background? Does he or she identify strongly with others from the same cultural background?
- What is the patient's religion, and how important is it to his or her daily life?
- Does the patient participate in cultural activities such as dressing in traditional clothing and observing traditional holidays and festivals?
- Are there any food preferences or restrictions?
- What are the patient's communication styles? Is eye contact avoided? How much physical distance is maintained? Is the patient open and verbal about symptoms?
- Who is the head of the family, and is he or she involved in decision making about the patient?
- What does the patient do to maintain his or her health?
- What does the patient think caused the current problem?
- Has the advice of traditional healers been sought?
- Have complementary and alternative therapies been used?
- What kind of treatment does the patient think will help? What are the most important results he or she hopes to get from this treatment?
- Are there cultural or religious rituals related to health, sickness, or death that the patient observes?

families and friends. The following guidelines may prove useful to nurses who want to provide culturally appropriate care:

- Know your own cultural attitudes, values, beliefs, and practices.
- Regardless of "good intentions," recognize that everyone has cultural "baggage" that ultimately results in ethnocentrism.
- In general, it is easier to understand those whose cultural heritage is similar to your own, while viewing those who are unlike you as strange and different.
- Maintain a broad, open attitude. Expect the unexpected. Enjoy surprises.
- Avoid seeing all people as alike; that is, avoid cultural stereotypes, such as "all Chinese like rice" or "all Italians eat spaghetti."
- Try to understand the reasons for any behavior by discussing commonalities and differences with representative of ethnic groups different from your own.
- If a patient has said or done something that you do not understand, ask for clarification. Be a good listener. Most patients will respond positively to questions that arise from a genuine concern for and interest in them.
- If at all possible, speak the patient's language (even simple greetings and social courtesies are appreciated). Avoid feigning an accent or using words that are ordinarily not part of your vocabulary.
- Be yourself. There are no right or wrong ways to learn about cultural diversity.

Health Disparities

Health disparities—higher rates of morbidity, mortality, and burden of disease in a population or community than found in the overall population—are significant in ethnic and racial minorities. Key health indicators in the United States reveal a significant gap in health status between the overall American population and people of specific ethnic backgrounds (Sullivan Commission, 2004). Ethnic and racial minorities are disproportionately burdened with cancer, heart disease, diabetes, human immunodeficiency virus (HIV) infection/acquired immunodeficiency syndrome (AIDS), and other conditions. They receive a lower quality of health care than nonminorities and are at a greater risk for declining health. Health disparities also occur with women, gays and lesbians, and people with disabilities. Many reasons are cited for these disparities, including low socioeconomic status; health behaviors; limited access to health care because of poverty or disability; environmental factors; and direct and indirect manifestations of discrimination. Other causes include lack of health insurance; overdependence on publicly funded facilities; and barriers to health care such as insufficient transportation, geographic location (not enough providers in an area), cost of services, and the low numbers of minority health care providers (Baldwin, 2004; Cutilli, 2006; Institute of Medicine, 2003; Sullivan Commission, 2004).

The Future of Transcultural Nursing Care

By the middle of the 21st century, half of all Americans will trace their ancestry to Africa, Asia, the Pacific Islands, or the Hispanic or Arab worlds, rather than to Europe (Cutilli, 2006). As indicated previously, the concept of culturally competent care applies to health care institutions, which must develop culturally sensitive policies and provide a climate that fosters the provision of culturally competent care by nurses. Nurses must learn to acknowledge and adapt to diversity among their colleagues in the workplace (Evans, 2007).

As the population becomes more culturally diverse, efforts to increase the number of ethnic minority nurses must continue and accelerate (Sullivan Commission, 2004). Today more than 87% of all nurses are Caucasian. Progress toward increasing the percentage of culturally diverse nurses has been significantly slower than the increasing percentage of ethnic minorities in the United States. Greater efforts must be made to facilitate the recruitment and program completion of nursing students who are members of ethnic minorities. In addition, educational institutions must prepare nurses to deliver culturally competent care and must work to increase the number of ethnic minority providers in the nursing workforce. Nursing programs are exploring creative ways to promote cultural competence and humanistic care in nursing students, including offering multicultural health studies in their curricula (Kleiman, 2007; Underwood, 2006).

Cultural diversity remains one of the foremost issues in health care today. Nurses are expected to provide culturally competent care for patients. Nurses must work effectively with the increasing number of patients, other nurses, and

other health care team members whose ancestry reflects the multicultural complexion of contemporary society.

CRITICAL THINKING EXERCISES

EBP 1 You are assigned to care for a hospitalized patient whose cultural background is Hispanic. You know little about this culture. What is the evidence base for use of a cultural assessment tool to ensure that cultural considerations are included in the nursing plan of care? What is the strength of that evidence? What resources are available to you to promote culturally competent care? Explain why it is important to examine your own feelings about each patient's cultural beliefs and practices.

2 An 84-year-old man who is originally from Vietnam is hospitalized in the neurosurgical intensive care unit with a cerebrovascular accident (CVA, stroke). His immediate family members insist on staying with him around the clock, and many extended family members visit each day, staying late into the night. His prognosis is poor, and when his attending physician discusses discontinuing his life support therapy with his family members who are his legal next of kin, they acquiesce but request that all family members be allowed to remain present to witness his death. Policies in the intensive care unit do not permit more than three family members to be with a patient at any given time. The staff members complain that they have difficulty completing their tasks with other critically ill patients because of the distractions they face from the multiple family members visiting this man. How can you help the nursing staff explore the meaning of the family's behavior and understand their own negative feelings about this behavior? Devise a strategy that will help resolve this situation.

3 As a diabetes educator, you are consulted about providing initial teaching services for a young Arab woman who is admitted to the hospital with a new diagnosis of diabetes. Her husband insists that he must be present for any teaching you perform. During your initial meeting with the patient and her husband, you note that the patient does not make eye contact and defers all questions you pose to her husband. You wish to initiate her diabetes teaching and begin a teaching plan for her. What aspects of the patient's and family's background would you want to further assess to determine the need for continuing assessment and care? Identify culturally sensitive methods you might use to ensure that the patient receives the diabetes teaching she requires. What resources might you use to assist you in providing the teaching?

The Smeltzer suite offers these additional resources to enhance learning and facilitate understanding of this chapter:

Genetics and Genomics Perspectives in Nursing

LEARNING OBJECTIVES

On completion of this chapter, the learner will be able to:

- 1 Describe the role of the nurse in integrating genetics and genomics in nursing care.
- 2 Conduct a genetics- and genomics-based assessment.
- 3 Identify the common patterns of inheritance of genetic disorders.
- 4 Identify ethical issues in nursing related to genetics and genomics.

GLOSSARY

carrier: person who is heterozygous; possessing two different alleles of a gene pair

chromosome: microscopic structures in the cell nucleus that contain genetic information and are constant in number in a species (eg, humans have 46 chromosomes)

deoxyribonucleic acid (DNA): the primary genetic material in humans consisting of nitrogenous bases, a sugar group, and phosphate combined into a double helix

dominant: a genetic trait that is normally expressed when a person has a gene mutation on one of a pair of chromosomes and the “normal” form of the gene is on the other chromosome

genetics: the scientific study of heredity; how specific traits or predispositions are transmitted from parents to offspring

genome: the total genetic complement of an individual genotype

genomics: the study of the human genome, including gene sequencing, mapping, and function

genotype: the genes and the variations therein that a person inherits from his or her parents

Human Genome Project: an international research effort aimed at identifying and characterizing the order of every base in the human genome

mutation: a heritable alteration in the genetic material

nondisjunction: the failure of a chromosome pair to separate appropriately during meiosis, resulting in abnormal chromosome numbers in reproductive cells (gametes)

pedigree: a diagrammatic representation of a family history

phenotype: a person’s entire physical, biochemical, and physiologic makeup, as determined by the person’s genotype and environmental factors

predisposition testing: testing that is used to determine the likelihood that a healthy person with or without a family history of a condition will develop a disorder

prenatal screening: testing that is used to identify whether a fetus is at risk for a birth defect such as Down syndrome or spina bifida (eg, multiple marker maternal serum screening in pregnancy)

presymptomatic testing: genetic testing that is used to determine whether persons with a family history of a disorder, but no current symptoms, have the gene mutation (eg, testing for Huntington disease)

recessive: a genetic trait that is expressed only when a person has two copies of a mutant autosomal gene or a single copy of a mutant X-linked gene in the absence of another X chromosome

variable expression: variation in the degree to which a trait is manifested; clinical severity

X-linked: located on the X chromosome

The **Human Genome Project** has ushered in a new type of medicine, personalized medicine that includes the influence of both genetic and genomic factors in disease causation, response to treatment, and health outcomes (Feetham, Thomson & Hinshaw, 2005). The term **genetics** applies to single genes and their impact on relatively rare single gene disorders (American Nurses Association [ANA], 2006). The term **genomics** involves “all of the genes in the human genome together, including their interactions with each other, the environment, and the influence of other psychosocial and cultural factors” (ANA, 2006, p. 9). Personalized medicine aims to tailor health care at the individual level by using a patient’s genomic information, often called genetic makeup or genomic profile. Identification of the genetic and genomic factors associated with disease, including gene–gene function and gene–environment interactions, contributes to the development of more effective therapies customized to that particular patient’s genetic makeup and the genomic profile of his or her disease. Genetic and genomic profiles allow health care providers to prescribe more specific and effective treatment for each patient; to identify and follow individuals at high risk for disease; and to avoid adverse drug reactions (National Human Genome Research Institute, 2007a). New genomic-based strategies for disease detection, management, and treatment are being utilized, making personalized medicine a reality (Table 9-1).

To meet the challenges of personalized medicine, nurses must understand the new technologies and treatments of genetic-based and genomic-based health care. Nurses also must recognize that they are a vital link between the patient and health care services; patients often turn to nurses first with questions about a family history of risk factors, genetics information, and genetic tests and interpretations. The incorporation of genetics and genomics into nursing means including genetics and genomics in health assessments, planning, and interventions that support identification of and response to the changing genetics-related health needs of people (ANA, 2006). This chapter offers a foundation for the clinical application of genetic and genomic principles in medical and surgical nursing, outlines the nurse’s role in genetic counseling and evaluation, addresses important ethical issues, and provides related information for nurses and patients. The foundation for this information is based on the ANA document, *Essential Nursing Competencies and Curricula Guidelines for Genetics and Genomics* (ANA, 2006).

Genomic Framework for Nursing Practice

The unique contribution of nursing to genomic medicine is its holistic perspective that takes into account each person’s intellectual, physical, spiritual, social, cultural, biopsychologic, ethical, and aesthetic experiences. Because genomics addresses all of the genes of a given individual’s human **genome** working together as a whole, genomics expands nursing’s holistic view. Genetics and genomics are the basis of normal and pathophysiologic development, human health and disease, and health outcomes. Knowledge and interpretation of genetic and genomic information, gene-based testing, diagnosis, and treatment broaden the holistic view of nursing. Such expertise in genetics and genomics is basic to nursing practice and its holistic approach to patient care (ANA, 2006).

The *Essential Nursing Competencies and Curricula Guidelines for Genetics and Genomics* provides a framework for integrating genetics and genomics into nursing practice (Chart 9-1). This document includes a philosophy of care that recognizes when genetic and genomic factors play a role or could play a role in a person’s health. This means assessing predictive genetic and genomic factors using family history and the results of genetic tests effectively, informing patients about genetics and genomic concepts, understanding the personal and societal impact of genetics and genomic information, and valuing the privacy and confidentiality of genetics and genomic information (ANA, 2006).

A person’s response to genetics and genomics information, genetic testing, or genetics-related conditions may be either empowering or disabling. Genetic and genomic information may stigmatize people if it affects how they view themselves or how others view them. Nurses help individuals and families learn how genetic traits and conditions are passed on within families as well as how genetic and environmental factors influence health and disease (ANA, 2006). Nurses facilitate communication among family members, the health care system, and community resources, and they offer valuable support to patients and families. All nurses should be able to recognize when a patient is asking a question related to genetic or genomic information and should know how to obtain genetics information by gathering family and health histories and conducting physical and developmental assessments. This allows nurses to provide

Table 9-1 TRANSITION FROM THE MEDICAL ERA TO THE GENOMIC ERA OF PERSONALIZED MEDICINE

	Medical Era	Genomic Era of Personalized Medicine
Defining characteristics	<ul style="list-style-type: none"> • Consider single genes • Wait for disease symptoms to appear • Treat symptoms of presenting disease • Use trial-and-error approach to treatment 	<ul style="list-style-type: none"> • Consider interaction of genes with one another and the environment • Identify genetic predisposition and optimize risk reduction to prevent disease • Treat underlying genetic cause of disease • Use personalized approach tailored to the genetic/genomic profile of the individual and the disease

Chart 9-1 • Essential Nursing Competencies for Genetics and Genomics

Professional Responsibilities

1. Recognition of attitudes and beliefs related to genetic and genomic science
2. Advocacy for genetic and genomic services
3. Incorporation of genetic and genomic technologies and information into practice
4. Demonstration of personalizing genetic and genomic information and services
5. Provide autonomous, informed genetic-related and genomic-related decision making

Professional Practice

1. Integrate and apply genetic and genomic knowledge to nursing assessment
2. Identify clients who may benefit from specific genetic and genomic resources, services, or technologies
3. Facilitate referrals for genetic and genomic services
4. Provide education, care, and support related to the interpretation of genetic or genomic tests, services, interventions, or treatments

American Nurses Association. (2006). *Essential nursing competencies and curricula guidelines for genetics and genomics*. Washington, DC: Author.

appropriate genetics resources and support to patients and families (ANA, 2006; Jenkins & Lea, 2005).

For example, when nurses assess patients' cardiovascular risk, they can expand their assessment to include information about family history of hypertension, hypercholesterolemia, and clotting disorders. Knowledge that genes are involved in the control of lipid metabolism, insulin resistance, blood pressure regulation, clotting factors, and vascular lining function helps individualize care based on the patient's genetic and genomic risk profile (Moss, Ryan, Oakes, et al., 2005).

Essential to a genetic and genomic framework in nursing is the awareness of one's attitudes, experience, and assumptions about genetics and genomics concepts and how these are manifested in one's own practice (ANA, 2006). To develop awareness of these attitudes, experiences, and assumptions, the nurse must examine his or her own:

- Beliefs or values about health as well as family, religious, or cultural beliefs about the cause of illness; and how one's values or biases affect understanding of genetic conditions
- Philosophical, theological, cultural, and ethical perspectives related to health and how these perspectives influence one's use of genetics information or services
- Level of expertise about genetics and genomics
- Experiences with birth defects, chronic illnesses, and genetic conditions along with one's view of such conditions as disabling or empowering
- Attitudes about the right to access and other rights of individuals with genetic disorders
- View and assumptions about DNA and beliefs about the value of information about one's risk for genetic disorders
- Beliefs about reproductive options

- View of genetic testing and engineering
- Approach to patients with disabilities

Integrating Genetic and Genomic Knowledge

Scientific developments and advances in technology have increased the understanding of genetics, resulting in better understanding of relatively rare diseases such as phenylketonuria (PKU) or hemophilia that are related to mutations of a single gene inherited in families. Scientists are able to characterize inherited metabolic variations that interact over time and lead to common diseases such as cancer, heart disease, and dementia. The transition from genetics to genomics has increased understanding of how multiple genes act and control biologic processes. Most health conditions are now believed to be the result of a combination of genetic and environmental influences (Guttmacher & Collins, 2004).

Genes and Their Role in Human Variation

Genes are central components of human health and disease. The Human Genome Project has shown how basic human genetics is to human development, health, and disease. Knowledge that specific genes are associated with specific genetic conditions makes diagnosis possible, even in the unborn. Many common conditions have genetic causes and many more associations between genetics, health, and disease are likely to be identified. Genomics is the study of the interaction of genes with other genes and environmental factors.

Genes and Chromosomes

A person's unique genetic constitution, called a **genotype**, is made up of some 30,000 to 40,000 genes (Guttmacher & Collins, 2004). A person's **phenotype**, the observable characteristics of his or her genotype, includes physical appearance and other biologic, physiologic, and molecular traits. Environmental influences modify every person's phenotype, even phenotypes with a major genetic component. This concept of genotype and phenotype applies to a person's total genome and the respective traits of his or her genetic makeup.

The concept of genotype and phenotype also applies to specific diseases. For example, in hypercholesterolemia, the genotype refers to the genes that control lipid metabolism, and the phenotype may be manifested in various corresponding ways. The genotype involves mutations in low-density lipoprotein (LDL) receptors and in one of the apolipoprotein genes (Dedoussis, 2007). The phenotype is characterized by early onset of cardiovascular disease, high levels of LDL, skin xanthomas, and a family history of heart disease. An individual's genotype, consisting of normal functioning genes as well as some mutations, is characterized by physical and biologic traits that may predispose to disease.

Human growth, development, and disease occur as a result of both genetic and environmental influences and interactions. The contribution of genetic factors may be large or small. For example, in a person with cystic fibrosis or PKU, the genetic contribution is significant. In contrast,

the genetic contribution underlying a person's response to infection may be less applicable.

A single gene is conceptualized as a unit of heredity. A gene is composed of a segment of **deoxyribonucleic acid (DNA)** that contains a specific set of instructions for making the protein or proteins needed by body cells for proper functioning. Genes regulate both the types of proteins made and the rate at which proteins are produced. The structure of the DNA molecule is referred to as a double helix. The essential components of the DNA molecule are sugar-phosphate molecules and pairs of nitrogenous bases. Each nucleotide contains a sugar (deoxyribose), a phosphate group, and one of four nitrogenous bases: adenine (A), cytosine (C), guanine (G), and thymine (T). DNA is composed of two paired strands, each made up of a number of nucleotides. The strands are held together by hydrogen bonds between pairs of bases (Fig. 9-1).

Genes are arranged in a linear order within **chromosomes**, which are located in the cell nucleus. In humans, 46 chromosomes occur in pairs in all body cells except oocytes (eggs) and sperm, which each contain only 23 chromosomes. Twenty-two pairs of chromosomes, called autosomes, are the same in females and males. The 23rd pair is referred to as the gender chromosome. A female has two X chromosomes, whereas a male has one X and one Y chromosome. At conception, each parent normally gives one chromosome of each pair to his or her child. As a result, children receive half of their chromosomes from their fathers and half from their mothers (Fig. 9-2).

Careful examination of DNA sequences from many people shows that these sequences have multiple versions in a population. The different versions of these sequences are called alleles. Sequences found in many forms are said to be polymorphic, meaning that there are at least two common forms of a particular gene.

Figure 9-1 DNA is a double helix formed by base pairs attached to a sugar-phosphate backbone. DNA carries the instructions that allow cells to make proteins. DNA is made up of four chemical bases. Redrawn from Genetic Home Reference <http://ghr.nlm.nih.gov/handbook/illustrations/dnastructure>

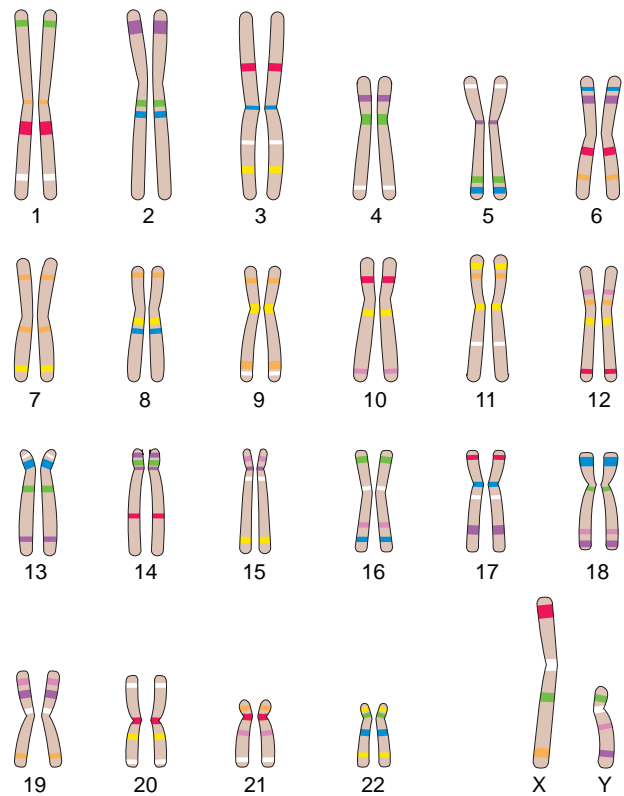

Figure 9-2 Each human cell contains 23 pairs of chromosomes, which can be distinguished by their size and unique banding patterns. This set is from a male, because it contains a Y chromosome. Females have two X chromosomes. Redrawn from Genetics Home Reference, <http://ghr.nlm.nih.gov/handbook/basics/howmanychromosomes>

Cell Division

The human body grows and develops as a result of the process of cell division. Mitosis and meiosis are two distinctly different types of cell division.

Mitosis is involved in cell growth, differentiation, and repair. During mitosis, the chromosomes of each cell duplicate. The result is two cells, called daughter cells, each of which contains the same number of chromosomes as the parent cell. The daughter cells are said to be diploid because they contain 46 chromosomes in 23 pairs. Mitosis occurs in all cells of the body except oocytes and sperm.

Meiosis, in contrast, occurs only in reproductive cells and is the process by which oocytes and sperm are formed. During meiosis, a reduction in the number of chromosomes takes place, resulting in oocytes or sperm that contain half the usual number, or 23 chromosomes. Oocytes and sperm are referred to as haploid because they contain a single copy of each chromosome, compared to the usual two copies in all other body cells. During meiosis, as the paired chromosomes come together in preparation for cell division, portions cross over, and an exchange of genetic material occurs before the chromosomes separate. This event, called recombination, creates greater diversity in the makeup of oocytes and sperm.

During the process of meiosis, a pair of chromosomes may fail to separate completely, creating a sperm or oocyte

Figure 9-3 When a gene contains a mutation, the protein encoded by that gene is likely to be abnormal. Sometimes the protein is able to function, although it does so imperfectly. In other cases, it is totally disabled. The outcome depends not only on how the mutation alters the protein's function but also on how vital that particular protein is to survival.

that contains either two copies or no copy of a particular chromosome. This sporadic event, called **nondisjunction**, can lead to either a trisomy or a monosomy. Down syndrome is an example of trisomy, in which people have three copies of chromosome number 21. Turner's syndrome is an example of monosomy, in which girls have a single X chromosome, causing them to have short stature and infertility (National Human Genome Research Institute, 2007b).

Gene Mutations

Within each cell, many intricate and complex interactions regulate and express human genes. Gene structure and function, transcription and translation, and protein synthesis are all involved. Alterations in gene structure and function and the process of protein synthesis may influence a person's health. Changes in gene structure, called **mutations**, permanently change the sequence of DNA, which in turn can alter the nature and type of proteins made (Fig. 9-3).

Some gene mutations have no significant effect on the protein product, whereas others cause partial or complete changes. How a protein is altered and its importance to body functioning determine the impact of the mutation. Gene mutations may occur in hormones, enzymes, or other important protein products, with significant implications for health and disease. Sickle cell anemia is a genetic condition caused by a small gene mutation that affects protein structure, producing hemoglobin S. A person who inherits two copies of the hemoglobin S gene mutation has sickle cell anemia and experiences the symptoms of severe anemia and thrombotic organ damage resulting from hypoxia (National Human Genome Research Institute, 2007c).

Other gene mutations include deletion (loss), insertion (addition), duplication (multiplication), or rearrangement (translocation) of a longer DNA segment. Duchenne muscular dystrophy, myotonic dystrophy, Huntington disease, and fragile X syndrome are examples of conditions caused by gene mutations.

Figure 9-4 Hereditary mutations are carried in the DNA of the reproductive cells. When reproductive cells containing mutations combine to produce offspring, the mutation is present in all of the offspring's body cells. Redrawn from National Cancer Institute, www.cancer.gov/cancertopics/understandingcancer/genetesting/Slide11

Gene mutations may be inherited or acquired. Inherited or germline gene mutations are present in the DNA of all body cells and are passed on in reproductive cells from parent to child. Germline or hereditary mutations are passed on to all daughter cells when body cells replicate (Fig. 9-4). The gene that causes Huntington disease is one example of a germline mutation.

Spontaneous mutations take place in individual oocytes or sperm at the time of conception. A person who carries the new "spontaneous" mutation may pass on the mutation to his or her children. Achondroplasia, Marfan syndrome, and neurofibromatosis type 1 are examples of genetic conditions that may occur in a single family member as a result of spontaneous mutation.

Acquired mutations take place in somatic cells and involve changes in DNA that occur after conception, during a person's lifetime. Acquired mutations develop as a result of cumulative changes in body cells other than reproductive cells (Fig. 9-5). Somatic gene mutations are passed on to the daughter cells derived from that particular cell line.

Gene mutations occur in the human body all the time. Cells have built-in mechanisms by which they can recognize mutations in DNA, and in most situations, they correct the changes before they are passed on by cell division. However, over time, body cells may lose their ability to repair damage from gene mutations, causing an accumulation of genetic changes that may ultimately result in diseases such as cancer and possibly other conditions of aging, such as Alzheimer's disease (Jenkins & Lea, 2005).

Genetic Variation

Research is ongoing to sort out the genetic components of complex conditions (eg, heart disease, diabetes, common

Figure 9-5 Acquired mutations develop in DNA during a person's lifetime. If the mutation arises in a body cell, copies of the mutation will exist only in the descendants of that particular cell. Redrawn from the National Cancer Institute, www.cancer.gov/cancertopics/understandingcancer/genetesting/Slide12

cancers, psychiatric disorders) that result from the interaction of environment, lifestyle, and genetic effects and to develop a map of common DNA variants. Genetic variations occur among people of all populations. Polymorphisms and single nucleotide polymorphisms (SNPs, or “snips”) are the terms used for common genetic variations that occur most frequently throughout the human genome. Some SNPs may contribute directly to a trait or disease expression by altering function. SNPs are becoming increasingly important for the discovery of DNA sequence variations that affect biologic function. Such knowledge allows clinicians to subclassify diseases and adapt therapies to individual patients (Gutmacher & Collins, 2004). For example, a polymorphism or SNP can alter protein or enzyme activity, and thereby affect drug efficacy and safety, if it occurs in proteins that are targets of medication regimens or that are involved in drug transport or drug metabolism.

Inheritance Patterns

Nursing assessment of the patient's health includes obtaining and recording family history information in the form of a **pedigree**. This is a first step in establishing the pattern of inheritance. Nurses must be familiar with mendelian patterns of inheritance and pedigree construction and analysis to help identify patients and families who may benefit from further genetic counseling, testing, and treatment (ANA, 2006; Jenkins & Lea, 2005).

Mendelian conditions are genetic conditions that are inherited in fixed proportions among generations. They result from gene mutations that are present on one or both chromosomes of a pair. A single gene inherited from one or both parents can cause a mendelian condition. Mendelian conditions are classified according to their pattern of inheritance: autosomal dominant, autosomal recessive, and **X-linked**. The terms **dominant** and **recessive** refer to the trait,

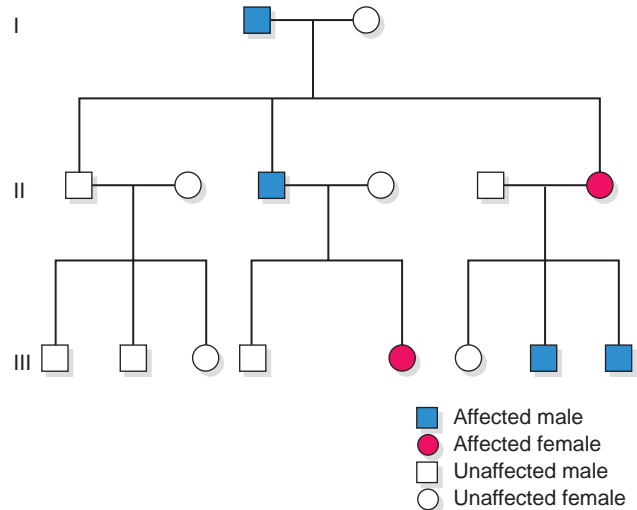

Figure 9-6 Three-generation pedigree illustrating autosomal dominant inheritance.

genetic condition, or phenotype but not to the genes or alleles that cause the observable characteristics (Nussbaum, McInnes & Willard, 2004).

Autosomal Dominant Inheritance

Autosomal dominant inherited conditions affect female and male family members equally and follow a vertical pattern of inheritance in families (Fig. 9-6). A person who has an autosomal dominant inherited condition carries a gene mutation for that condition on one chromosome of a pair. Each of that person's offspring has a 50% chance of inheriting the gene mutation for the condition and a 50% chance of inheriting the normal version of the gene (Fig. 9-7). Offspring who do not inherit the gene mutation do not develop the condition and do not have an increased chance of having children with the same condition. Table 9-2 presents characteristics and examples of different patterns of inherited conditions.

Autosomal dominant conditions often manifest with varying degrees of severity. Some affected people may have significant symptoms, whereas others may have only mild ones. This characteristic is referred to as **variable expression**; it results from the influences of genetic and environmental factors on clinical presentation.

Another phenomenon observed in autosomal dominant inheritance is penetrance, or the percentage of persons known to have a particular gene mutation who actually show the trait. Almost complete penetrance is observed in conditions such as achondroplasia, in which nearly 100% of people with the gene mutation typically display traits of the disease. However, in some conditions, the presence of a gene mutation does not invariably mean that a person has or will develop an autosomal inherited condition. For example, a woman who has the *BRCA1* hereditary breast cancer gene mutation has a lifetime risk of breast cancer that can be as high as 80%, not 100%. This quality, known as **incomplete penetrance**, indicates the probability that a given gene will produce disease. In other words, a person may inherit the

Figure 9-7 In dominant genetic disorders, if one affected parent has a disease-causing allele that dominates its normal counterpart, each child in the family has a 50% chance of inheriting the disease allele and the disorder. Redrawn from Genetics Home Reference, <http://ghr.nlm.nih.gov/handbook/illustrations/autodominant>

gene mutation that causes an autosomal dominant condition but may not have any of the observable physical or developmental features of that condition. However, this person carries the gene mutation and still has a 50% chance of passing the gene for the condition to each of his or her children.

One of the effects of incomplete penetrance is that the gene appears to “skip” a generation, thus leading to errors in interpreting family history and in genetic counseling. Examples of other genetic conditions with incomplete penetrance include otosclerosis (40%) and retinoblastoma (80%) (Nussbaum, et al., 2004).

Autosomal Recessive Inheritance

In contrast to autosomal dominant conditions, autosomal recessive conditions have a pattern that is more horizontal than vertical; relatives of a single generation tend to have the condition (Fig. 9-8). Autosomal recessive conditions are frequently seen among particular ethnic groups and usually occur more often in children of parents who are related by blood, such as first cousins (see Table 9-2).

In autosomal recessive inheritance, each parent carries a gene mutation on one chromosome of the pair and a normal gene on the other chromosome. The parents are said to be **carriers** of the gene mutation. Unlike people with an autosomal dominant condition, carriers of a gene mutation for a

recessive condition do not have symptoms of the genetic condition. When carriers have children together, there is a 25% chance that each child may inherit the gene mutation from both parents and have the condition (Fig. 9-9). Gaucher’s disease, cystic fibrosis, sickle cell anemia, and PKU are examples of autosomal recessive conditions (National Human Genome Research Institute, 2007d).

X-Linked Inheritance

X-linked conditions may be inherited in recessive or dominant patterns (see Table 9-2). In both, the gene mutation is located on the X chromosome. All males inherit an X chromosome from their mothers and a Y chromosome from their fathers for a normal sex constitution of 46,XY. Because males have only one X chromosome, they do not have a counterpart for its genes, as do females. This means that a gene mutation on the X chromosome of a male is expressed even though it is present in only one copy. Females, on the other hand, inherit one X chromosome from each parent for a normal sex constitution of 46,XX. A female may be an unaffected carrier of a gene mutation, or she may be affected if the condition results from a gene mutation causing an X-linked dominant condition. Either the X chromosome that she received from her mother or the X chromosome she received from her father may be passed on to each of her offspring, and this is a random occurrence.

The most common pattern of X-linked inheritance is that in which a female is a carrier for a gene mutation on one of her X chromosomes. This is referred to as X-linked recessive inheritance in which a female carrier has a 50% chance of passing on the gene mutation to a son, who would be affected, or to a daughter, who would be a carrier like her mother (Fig. 9-10). Examples of X-linked recessive conditions include factor VIII and factor IX hemophilia, severe combined immunodeficiency, and Duchenne muscular dystrophy.

Nontraditional Inheritance

Although mendelian conditions manifest with a specific pattern of inheritance in some families, many diseases and traits do not follow these simple patterns. A variety of factors influence how a gene performs and is expressed. Different mutations in the same gene can produce variable symptoms in different people, as in cystic fibrosis. Different mutations in several genes can lead to identical outcomes, as in Alzheimer’s disease. Some traits involve simultaneous mutation in two or more genes. A recently observed phenomenon, imprinting, can determine which of a pair of genes (the mother’s or the father’s) is silenced or activated. This form of inheritance has been observed in Angelman syndrome, a severe form of mental retardation and ataxia (Nussbaum, et al., 2004).

Multifactorial Inheritance and Complex Genetic Conditions

Many birth defects and common health conditions such as heart disease, high blood pressure, cancer, osteoarthritis, and diabetes occur as a result of interactions of multiple gene mutations and environmental influences. Thus, they

Table 9-2 PATTERNS OF MENDELIAN INHERITANCE

Characteristics	Examples
Autosomal Dominant Inherited Conditions	
Vertical transmission in families	Hereditary breast/ovarian cancer syndrome
Males and females equally affected	Familial hypercholesterolemia
Variable expression among family members and others with condition	Hereditary non-polyposis colorectal cancer
Reduced penetrance (in some conditions)	Huntington disease
Advanced paternal age associated with sporadic cases	Marfan syndrome
	Neurofibromatosis
Autosomal Recessive Inherited Conditions	
Horizontal pattern of transmission seen in families	Cystic fibrosis
Males and females equally affected	Galactosemia
Associated with consanguinity (genetic relatedness)	Phenylketonuria
Associated with particular ethnic groups	Sickle cell anemia
	Tay-Sachs disease
	Canavan disease
X-Linked Recessive Inherited Conditions	
Vertical transmission in families	Duchenne muscular dystrophy
Males predominantly affected	Hemophilia A and B
	Wiscott-Aldrich syndrome
	Protan and Deutan forms of color blindness
Multifactorial Inherited Conditions	
Occur as a result of combination of genetic and environmental factors	Congenital heart defects
May recur in families	Cleft lip and/or palate
Inheritance pattern does not demonstrate characteristic pattern of inheritance seen with other mendelian conditions	Neural tube defects (anencephaly and spina bifida)
	Diabetes mellitus
	Osteoarthritis
	High blood pressure

Adapted from Jenkins, J. & Lea, D. H. (2005). *Nursing care in the genomic era: A case-based approach*. Sudbury, MA: Jones & Bartlett Publishers. Skirton, H, Patch, C. & Williams, J. (2005). *Applied genetics in healthcare: A handbook for specialists*. New York: Taylor and Francis Group.

are called multifactorial or complex conditions (see Table 9-2). Other examples of multifactorial genetic conditions include neural tube defects such as spina bifida and anencephaly. Multifactorial conditions may cluster in families,

but they do not always result in the characteristic pattern of inheritance seen in families who have mendelian inherited conditions (Fig. 9-11).

Chromosomal Differences and Genetic Conditions

Differences in the number or structure of chromosomes are a major cause of birth defects, mental retardation, and malignancies. Chromosomal differences are present in approximately 1 of every 160 liveborn infants and are the cause of greater than 50% of all spontaneous first-trimester pregnancy losses (Nussbaum, et al., 2004). Chromosomal differences most commonly involve an extra or missing chromosome; this is called aneuploidy. Whenever there is an extra or missing chromosome, there is always associated mental or physical disability to some degree.

Down syndrome, or trisomy 21, is a common chromosomal condition that occurs with greater frequency in pregnancies of women who are 35 years of age or older. A person with trisomy 21 has a complete extra chromosome 21, which causes a particular facial appearance and increased risk of congenital heart defects, thyroid and vision problems, and mental retardation. Other examples of chromosomal differences include trisomy 13 and trisomy 18, both more severe than Down syndrome, and conditions involving extra or missing sex chromosomes, such as Turner's syndrome (Nussbaum, et al., 2004).

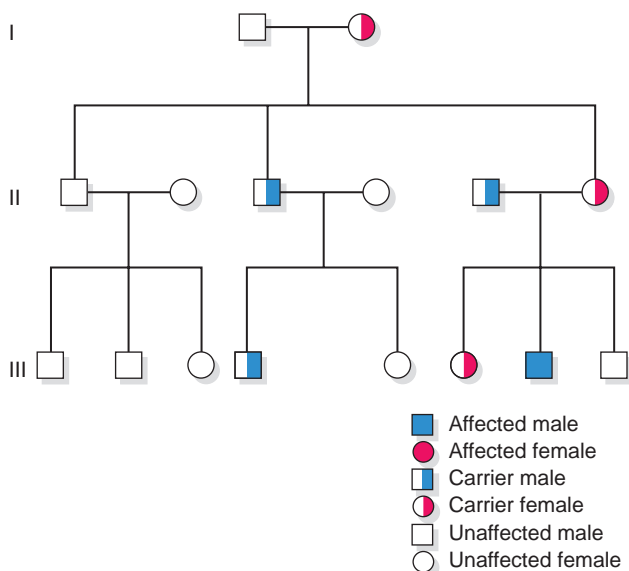

Figure 9-8 Three-generation pedigree illustrating autosomal recessive inheritance.

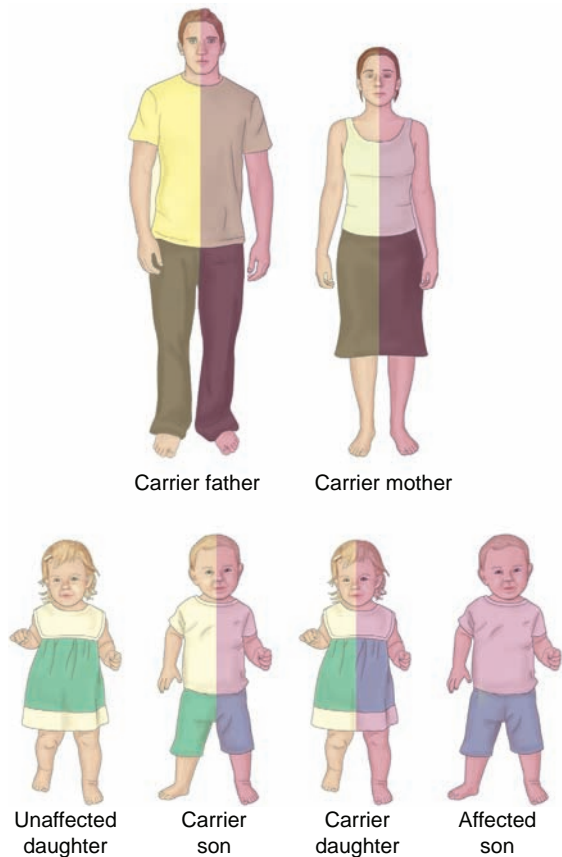

Figure 9-9 In diseases associated with altered recessive genes, both parents—although disease-free themselves—carry one normal allele and one altered allele. Each child has one chance in four of inheriting two abnormal alleles and developing the disorder; one chance in four of inheriting two normal alleles; and two chances in four of inheriting one normal and one altered allele, and therefore being a carrier like both parents. Redrawn from Genetics Home Reference, <http://ghr.nlm.nih.gov/handbook/illustrations/autorecessive>

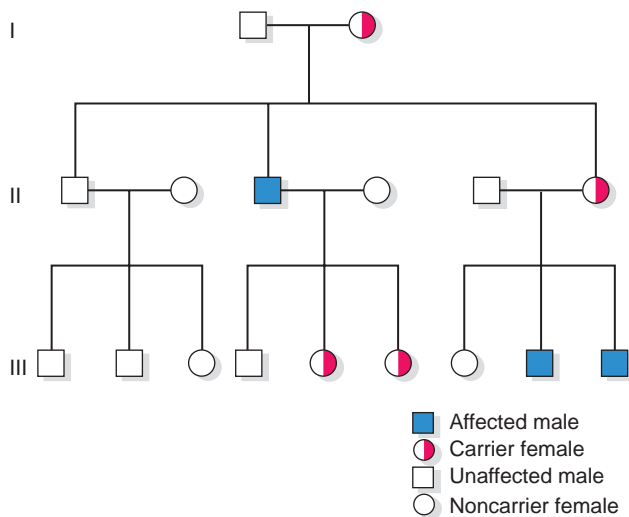

Figure 9-10 Three-generation pedigree illustrating X-linked recessive inheritance.

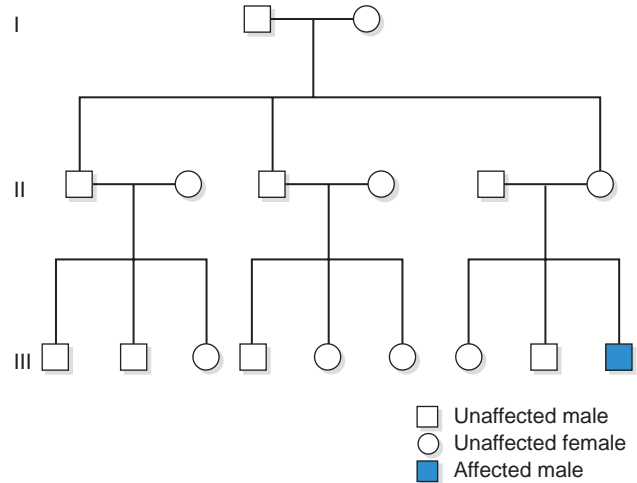

Figure 9-11 Three-generation pedigree illustrating multifactorial conditions.

Chromosomal differences may also involve a structural rearrangement within or between chromosomes. These are less common than chromosomal conditions in which there is an extra or missing chromosome, but they still occur in 1 of every 500 newborns (Nussbaum, et al., 2004). People who carry “balanced” chromosome rearrangements have all of their chromosomal material, but it is rearranged. Women with a “balanced” chromosomal rearrangement have an increased risk of spontaneous pregnancy loss and of having children with an unbalanced chromosomal arrangement that may result in physical or mental disabilities. Known carriers of these chromosomal differences are offered prenatal counseling and testing.

Chromosome studies may be needed at any age, depending on the indication. Two common indications are a suspected diagnosis such as Down syndrome and a history of two or more unexplained pregnancy losses. Chromosome studies are accomplished by obtaining a tissue sample (eg, blood, skin, amniotic fluid), preparing and staining the chromosomes, and analyzing them under a microscope. The microscopic study of chromosomes, called cytogenetics, is used with new molecular techniques such as fluorescent in situ hybridization (FISH), which permits more detailed examination of chromosomes. FISH is useful to detect small abnormalities and to characterize chromosomal rearrangements (Skirton, Patch & Williams, 2005).

Genetic and Genomic Technologies in Practice

One of the most immediate applications of new genetic and genomic discoveries is the development of genetic tests that can be used to detect a trait, diagnose a genetic condition, and identify people who have a genetic predisposition to a disease such as cancer or heart disease. Another emerging application is pharmacogenetics, which

involves the use of genetic testing to identify genetic variations that relate to the safety and efficacy of medications and gene-based treatments, so that individualized treatment can be developed. Future applications may include the use of gene chips to map a person's individual genome for genetic variations that may lead to disease. Some nurses are involved in caring for patients who are undergoing genetic testing and gene-based treatments. Knowledge of the clinical applications of modern genetic and genomic technologies enables nurses to inform and support patients and to provide high-quality genetics-related health care (ANA, 2006).

Genetic Testing

Genetic testing is the primary tool used to identify individuals predisposed to specific genetic diseases. Genetic tests provide information that can lead to the diagnosis of inherited conditions or other conditions with a known genetic contribution.

In genetic testing, approaches may be genotypic or phenotypic. Genotypic methods involve analysis of the chromosomes and genes directly, using specific laboratory techniques to learn whether a genetic alteration related to a specific disease or condition is present. This testing may be DNA based, chromosomal, or biochemical. Phenotypic methods examine the familial or biologic presentation of disease and include assessment of the patient's personal or family history and medical factors influencing his or her disease as well as testing for gene products such as protein markers in body fluids or diseased tissues. The family history, which is considered the first genetic test, is discussed later in this chapter (see Family History Assessment). It is expected that all nurses will know how to use this genetic tool.

Another phenotypic approach involves searching for gene products, such as proteins and enzymes that can clinically indicate a genetic abnormality. For example, germline mutations in the repair genes *MLH1*, *MSH2*, *MSH6*, and *PMS2* are responsible for hereditary early-onset colorectal cancer. Colorectal tumors are now tested to measure the presence or absence of these proteins using immunohistochemistry, a routine type of pathology test. Tumors that stain negative for one of those proteins signify malfunction of the gene whose protein is missing. Patients with absent or negative protein expression in their tumors (eg, *MLH1* protein-negative) can proceed with genetic testing for a germline *MLH1* mutation (Southey, Jenkins, Mead, et al., 2005).

Genetic testing can be used for a variety of purposes in prenatal, pediatric, and adult populations (Skirton, et al., 2005). Prenatal testing is widely used for **prenatal screening** and diagnosis of such conditions as Down syndrome. Carrier testing is used to determine if a person carries a recessive allele for an inherited condition (eg, cystic fibrosis, sickle cell anemia, Tay-Sachs disease) and therefore risks passing it on to his or her children. Genetic testing is also used widely in newborn screening. In the United States, it is available for an increasing number of genetic conditions (eg, PKU, galactosemia) (Therrell & Adams, 2007).

Diagnostic testing is used to detect the presence or absence of a particular genetic alteration or allele to iden-

tify or confirm a diagnosis of a disease or condition (eg, myotonic dystrophy, fragile X syndrome). Increasingly, genetic tests are being used to predict drug response and to design specific and individualized treatment plans, or personalized medicine. For example, genetic testing is used to identify specific gene variants that can predict the effectiveness of treatments for human immunodeficiency virus (HIV) infection and the use of tacrine for Alzheimer's disease (Weinshilboum & Wang, 2006). Examples of current uses of genetic tests are shown in Table 9-3.

Nurses are increasingly participating in patient's genetic testing, especially in the area of taking family histories and patient education. They contribute by ensuring informed health choices and consent, advocating for privacy and confidentiality with regard to genetic test results, and helping patients understand the complex issues involved (ANA, 2006; Skirton, et al., 2005).

Genetic Screening

Genetic screening, in contrast to genetic testing, applies to testing of populations or groups independent of a positive family history or symptom manifestation. Genetic screening, as defined in 1975 by the Committee for the Study of Inborn Errors of Metabolism of the National Academy of Sciences (Secretary's Advisory Committee on Genetic Testing, 2000), has several major aims. The first aim is to improve management; that is, to identify people with treatable genetic conditions that could prove dangerous to their health if left untreated. For example, newborns are screened for an increasing number of conditions, including PKU, congenital hypothyroidism, and galactosemia. The second aim is to provide reproductive options to people with a high probability of having children with severe, untreatable diseases and for whom genetic counseling, prenatal diagnosis, and other reproductive options could be helpful and of interest. For example, people of Ashkenazi Jewish descent (Jews of Eastern European origin) are screened for conditions such as Tay-Sachs disease and Canavan disease. The third aim is to screen pregnant women to detect birth defects such as neural tube defects and Down syndrome. Genetic screening may also be used for public health purposes to determine the incidence and prevalence of a birth defect or to investigate the feasibility and value of new genetic testing methods. Most commonly, genetic screening occurs in prenatal and newborn programs. Table 9-4 gives examples of types of genetic screening.

Testing and Screening for Adult-Onset Conditions

Adult-onset conditions with a genetic or genomic basis are manifested in later life. Often clinical signs or symptoms occur only in late adolescence or adulthood, and disease is clearly observed to run in families. Some of these conditions are attributed to specific genetic mutations and follow either an autosomal dominant or an autosomal recessive inheritance pattern. However, the majority of adult-onset conditions are considered to be genomic or multifactorial. Examples of multifactorial conditions include heart disease, diabetes, and arthritis. Genomic or multifactorial influences

Table 9-3 GENETIC TESTS: EXAMPLES OF CURRENT USES

Purpose of Genetic Test	Type of Genetic Test
Carrier Testing	
Cystic fibrosis	DNA analysis
Tay-Sachs disease	Hexosaminidase A activity testing and DNA analysis
Canavan disease	DNA analysis
Sickle cell anemia	Hemoglobin electrophoresis
Thalassemia	Complete blood count and hemoglobin electrophoresis
Prenatal Diagnosis —amniocentesis is often performed when there is a risk for a chromosomal or genetic disorder:	
Risk of Down syndrome	Chromosomal analysis
Risk of cystic fibrosis	DNA analysis
Risk of Tay-Sachs disease	Hexosaminidase A activity testing and/or DNA analysis
Risk of open neural tube defect	Protein analysis
Diagnosis	
Down syndrome	Chromosomal analysis
Fragile X syndrome	DNA analysis
Myotonic dystrophy	DNA analysis
Presymptomatic Testing	
Huntington disease	DNA analysis
Myotonic dystrophy	DNA analysis
Susceptibility Testing	
Hereditary breast/ovarian cancer	DNA analysis
Hereditary non-polyposis colorectal cancer	DNA analysis

involve interactions among several genes (gene–gene interactions) and between genes and the environment (gene–environment interactions), as well as the individual’s lifestyle (Gutmacher & Collins, 2004).

Nursing assessment for adult-onset conditions is based on family history, personal and medical risk factors, and identification of associated diseases or clinical manifestations (the phenotype). Knowledge of adult-onset conditions and their genetic bases (ie, mendelian versus multifactorial conditions) influences the nursing considerations for genetic testing and health promotion. Table 9-5 de-

scribes selected adult-onset conditions, their age of onset, pattern of inheritance, and risk factors, both genetic and environmental.

If a single gene accounts for an adult-onset condition in a symptomatic person, diagnostic testing is used to confirm a diagnosis to assist in the plan of care and management. Diagnostic testing for adult-onset conditions is most frequently used with autosomal dominant conditions, such as Huntington disease or factor V Leiden thrombophilia, and with autosomal recessive conditions such as hemochromatosis. In families with known adult-onset conditions or

Table 9-4 APPLICATIONS FOR GENETIC SCREENING

Timing of Screening	Purpose	Examples
Preconception screening	For autosomal recessive inherited genetic conditions that occur with greater frequency among individuals of certain ethnic groups	Cystic fibrosis—all couples, but especially Northern European Caucasian, and Ashkenazi Jewish Tay-Sachs disease—Ashkenazi Jewish Sickle cell anemia—African American, Puerto Rican, Mediterranean, Middle Eastern Alpha-thalassemia—Southeast Asian, African American
Prenatal screening	For genetic conditions that are common and for which prenatal diagnosis is available when a pregnancy is identified at increased risk	Neural tube defects—spina bifida, anencephaly Down syndrome Other chromosomal abnormalities—trisomy 18
Newborn screening	For genetic conditions for which there is specific treatment	Phenylketonuria (PKU) Galactosemia Homocystinuria Biotinidase deficiency

Table 9-5 ADULT-ONSET DISORDERS			
Clinical Description	Age of Onset (y)	Inheritance	Risk Factors
Neurologic Conditions			
Early-Onset Familial Alzheimer's Disease			
Progressive dementia, memory failure, personality disturbance, loss of intellectual functioning associated with cerebral cortical atrophy, beta-amyloid plaque formation, intra-neuronal neurofibrillary tangles	<60–65 and often before 55	A.D. <2%	Mutations on preslin 1 (PSEN1), preslin 2 (PSEN2), and/or beta-amyloid precursor protein (APP)
Late-Onset Familial Alzheimer's Disease			
Progressive dementia, cognitive decline	>60–65	A.D. ~25% M.F. ~75%	Gene-gene interactions Carriers of apolipoprotein E4 Down syndrome
Huntington Disease			
Widespread degenerative brain change with progressive motor loss, both voluntary and involuntary disability, cognitive decline, chorea (involuntary movements) at later stage, psychiatric disturbances	35–44 (mean)	A.D. 100%	HD gene
Hematologic Conditions			
Hereditary Hemochromatosis (HHC)			
High absorption of iron by gastrointestinal mucosa, resulting in excessive iron storage in liver, skin, pancreas, heart, joints, and testes Early symptoms of abdominal pain, weakness, lethargy, weight loss Possible pigmentation, diabetes mellitus, hepatic fibrosis or cirrhosis, heart failure, and dysrhythmias or arthritis in untreated people	40–60 in males; after menopause in females	A.R. ~60–90% M.F. ~10–30%	Carrier or sibling of carrier of HFE gene mutations Liver disease such as alcoholic liver disease, acute viral hepatitis, or chronic hepatitis C Iron overload resulting from ingested iron in foods, cookware, and medicines, as well as parenteral iron from iron injections or transfusions for a chronic anemia such as beta-thalassemia or sickle cell disease
Factor V Leiden Thrombophilia			
Poor anticoagulant response to activated protein C with increased risk for venous thrombosis and risk for increased fetal loss during pregnancy	30s; during pregnancy in females	A.D.	Carriers or relatives of individuals known to have factor V Leiden mutations Family or personal history of high rates of venous thromboembolism, deep venous thrombosis, or pulmonary embolism, especially if age <50 y Women with recurrent pregnancy loss or venous thromboembolism during pregnancy or who use oral contraceptives
Diabetes Mellitus Type 2			
Insulin resistance, impaired glucose tolerance	Variable onset; most often 40–60	M.F.	Gene-gene interactions TCF7L2 variant Obesity Hypertension Hyperlipidemia High intake of refined carbohydrates
Cardiovascular Disease			
Familial hypercholesterolemia Elevated LDL levels leading to coronary artery disease, xanthomas, and corneal arcus Atherosclerotic plaque	35–50	A.D.	Family or personal history of coronary heart disease at <45 y in women or <40 y in men Elevated LDL
Oncology Conditions			
Multiple Endocrine Neoplasia			
Familial medullary thyroid cancer, pheochromocytoma, and parathyroid abnormalities	Early adulthood	A.D.	Carrier or relative of carrier of a RET mutation Family history of medullary thyroid cancer, pheochromocytoma, and parathyroid abnormalities

Table 9-5 ADULT-ONSET DISORDERS (Continued)

Clinical Description	Age of Onset (y)	Inheritance	Risk Factors
Breast Cancer			
BRCA1 and BRCA2 hereditary breast/ovarian cancer Breast, ovarian, and prostate (BRCA1) Breast, ovarian, and other cancer (BRCA2)	30–70; often <50	A.D. ~5–10% of breast and ovarian cancers M.F. >75%	Carrier of BRCA1, BRCA2 mutations Older age Early menses (<11 y) Nulliparity Family history of breast, ovarian, or prostate cancer Breast biopsies
Hereditary Non-Polyposis Colorectal Cancer (HNPCC)			
Colorectal, ovarian, endometrial, gastric, small intestines, hepato-biliary, and renal cell cancers	<50	A.D. ~1–3% of colorectal colon cancer; ~1% of endometrial cancers M.F. >75%	Mutations in family of repair genes Older age Personal or family history of colon cancer or adenomas High-fat, low-fiber diet Inflammatory bowel disease

From Bird, 2007; Kohlmann & Gruber, 2006; Kowdley, Tait, Bennett, et al., 2006; Kujovich, 2007; Online Mendelian Inheritance in Man, 2007; Petrucelli, Daly, Bars Culver, et al., 2007; Warby, Graham, & Hayden, 2007; Wiesner & Snow-Bailey, 2005.

A.D. = autosomal dominant, A.R. = autosomal recessive, M.F. = multifactorial

with a confirmed genetic mutation in an affected family member, **presymptomatic testing** provides asymptomatic people with information about the presence of a genetic mutation and about the likelihood of developing the disease. Presymptomatic testing is considered for people in families with a known adult-onset condition in which either a positive or a negative test result indicates an increased or reduced risk of developing the disease, affects medical management, or allows earlier treatment of a condition.

Huntington disease has served as the model for presymptomatic testing because the presence of the genetic mutation predicts disease onset and progression. Although preventive measures are not yet available for Huntington disease, the genetics information enables health care providers to develop a clinical, supportive, and psychological plan of care.

The foremost factor that may influence the development and severity of disease is a person's genomic makeup. In the absence of a single disease-causing gene, it is thought that multiple genes and other environmental factors are related to the onset of most adult diseases. For some diseases, the interactions among several genes and other environmental or metabolic events affect disease onset and progression. Specific gene–gene interactions or SNPs can confer susceptibility to disease. Most susceptibility testing is conducted in the research setting to identify candidate genes for diseases such as Alzheimer's disease, psychiatric conditions, heart disease, hypertension, and hypercholesterolemia. Susceptibility testing helps distinguish variations within the same disease or response to treatment. For example, no single gene is associated with osteoporosis. Several polymorphisms on candidate genes related to the vitamin D receptor, estrogen and androgen receptors, and regulation of bone mineral density (BMD) have been shown to contribute to osteo-

porosis and fracture risk. Moreover, diet and exercise have a strong interaction with the polymorphisms regulating BMD (Ralston, 2007).

Some susceptibility genes may predict treatment response. For example, people may present with similar clinical signs and symptoms of asthma but have different responses to glucocorticoid (GC) treatment. Mutations in genes that regulate GC receptors are helpful to classify people with asthma as sensitive or resistant to treatment with corticosteroids (Pujols, Mullol & Picado, 2007).

Population screening, the use of genetic testing for large groups or entire populations, to identify late-onset conditions is under development. For a test to be considered for population screening, there must be (1) sufficient information about gene distribution within populations, (2) accurate prediction about the development and progression of disease, and (3) appropriate medical management for asymptomatic people with a mutation. Currently, population screening is offered in some ethnic groups to identify cancer-predisposing genes. For example, the Ashkenazi Jewish have a greater chance of having a specific genetic mutation in the BRCA1 or BRCA2 gene. People with one of these BRCA mutations have approximately an 80% risk of breast cancer, a 40% to 65% risk of ovarian cancer (BRCA1 carriers), a 20% risk of ovarian cancer (BRCA2 carriers), and a 16% risk of prostate cancer (Chen, Iversen, Friebel, et al., 2006). The identification of one of these mutations gives patients options for cancer screening as well as chemoprevention or prophylactic mastectomy or oophorectomy. Population screening is also being explored for other adult-onset conditions such as type 2 diabetes, heart disease, and hereditary hemochromatosis (iron overload disorder).

Nurses will be expected to participate in explaining risk and genetic predisposition, supporting informed health

decisions and opportunities for prevention and early intervention, and protecting patients' privacy (Skirton, et al., 2005). Nurses must be alert for family histories that indicate multiple generations (autosomal dominant inheritance) or multiple siblings (autosomal recessive inheritance) are affected with the same condition or that onset of disease is earlier than expected (eg, multiple generations with early-onset hyperlipidemia). Possible adult-onset conditions are discussed with other members of the health care team for appropriate resources and referral. When a family history of disease is identified, a patient is made aware that this is a risk factor for disease; resources and referral are then provided. It is the patient's decision whether or not to pursue a genetic testing workup. For example, if a 45-year-old woman presents for her annual gynecology visit and reports a family history of colon cancer in multiple paternal relatives, including her father, the nurse should discuss the family history with the gynecologist. In addition, the woman should be alerted to the risk of colon cancer based on the family history and given information about possible genetic testing and referral for a colonoscopy.

If the existence of a mutation for an adult-onset condition in a family is identified, at-risk family members can be referred for **predisposition testing**. If the patient is found to carry the mutation, the nurse provides him or her with information and referral for risk-reduction measures and information about the risk to other family members. In that discussion, the nurse assures the patient that the test results are private and confidential and will not be shared with others, including family members, without the patient's permission. If the patient is an unaffected family member, the nurse discusses inheritance and the risk of developing the disease, provides support for the decision-making process, and offers referral for genetics services.

Personalized Genomic Treatments

Information about genes and their variations is helping researchers identify genetic differences that predispose certain people to more aggressive diseases and affect their responses to treatment. Genetics and genomics have revolutionized the field of oncology because genetic mutations are the basis for the development and progression of all cancers. Until recently, individuals with cancer faced treatment based on the stage of the cancer, lymph node involvement, and spread to distant organs. Treatments for a particular type of cancer, stage for stage, were similar. However, studies have shown that individuals with the same type and stage of cancer who received the same treatment did not always have the same response or survival rate. The differences in a given cancer are due to genetic differences in that cancer (Calzone, Lea & Masny, 2006). For example, women with early-stage breast cancer (ie, tumor diameter less than 2 cm, estrogen receptor-positive tumors, no lymph node involvement) have often received chemotherapy. In the past, deciding which of these women would benefit the most from chemotherapy was unclear. Currently, a gene tumor profile of these women's tumors can be used to predict which women are

more likely to have an aggressive cancer. This genetic test allows clinicians to recognize which early breast cancers pose a higher risk for recurrence and respond to chemotherapy (Paik, 2007). Other patients who need treatment are receiving personalized cancer treatment based on the genetic signature of the tumor. This treatment, called targeted therapy, tries to match the treatment to the specific malfunctioning genes expressed in the tumor or to selectively inhibit genetic factors that promote cancer growth (Kalyn, 2007).

The use of individualized genetic and genomic data is rapidly resulting in personalized treatment for some common diseases. It has long been known that patients differ in their response to medications. The genetic and genomic variations in drug metabolism account largely for the differences in drug response and drug-related toxicities. Drug metabolism involves genetically controlled protein/enzyme activity for absorption, distribution, drug-cell interaction, inactivation, and excretion, metabolic processes that are known as pharmacokinetics. The cytochrome P450 (CYP) family genes play a key role in the pharmacokinetic process of drug metabolism. Once a drug reaches its target cell, other genes such as those regulating cell receptors and cell signaling control the drug's effect, known as pharmacodynamics. Single genes may affect drug response. More commonly, drug response involves the interaction of multiple genes, the host, and the effects of other drugs. Figure 9-12 is a schematic display of the genetic and genomic influences on drug metabolism and treatment effect.

The difference between genetics and genomics, described earlier in this chapter, aptly corresponds to the terms pharmacogenetics and pharmacogenomics, which combine pharmacology and genetics/genomics. Pharmacogenetics refers to the study of the effect of variations in a single gene on drug response and toxicity. The field of pharmacogenetics has evolved so that it has become a broader genomic-based approach that recognizes the interaction of multiple genes and the environment on drug response. Pharmacogenomics refers to the study of the combined effect of variations in many genes on drug response and toxicity and involves methods that rapidly identify which genetic variations influence a drug's effect. Pharmacogenomics involves the search for genetic variations associated with medication metabolism and efficacy, with the goal of tailoring treatment to each individual's genomic makeup (National Human Genome Research Institute, 2007e).

SNPs, described earlier, are common genetic variations that occur most frequently throughout the human genome and often contribute to variations in enzymatic activity that affect drug metabolism. The CYPs, a family of enzymes, play a key role in the pharmacokinetic process of drug metabolism. More than 200 variations (SNPs) of genes that control CYP activation and deactivation have been identified. Researchers have created a catalog of CYP variations because of their role in drug metabolism (Sim & Ingelman-Sundberg, 2006).

Four classes of CYP metabolic activity levels have been identified based on a person's CYP genotype and the corresponding drug response: (1) poor metabolizers, (2) intermediate

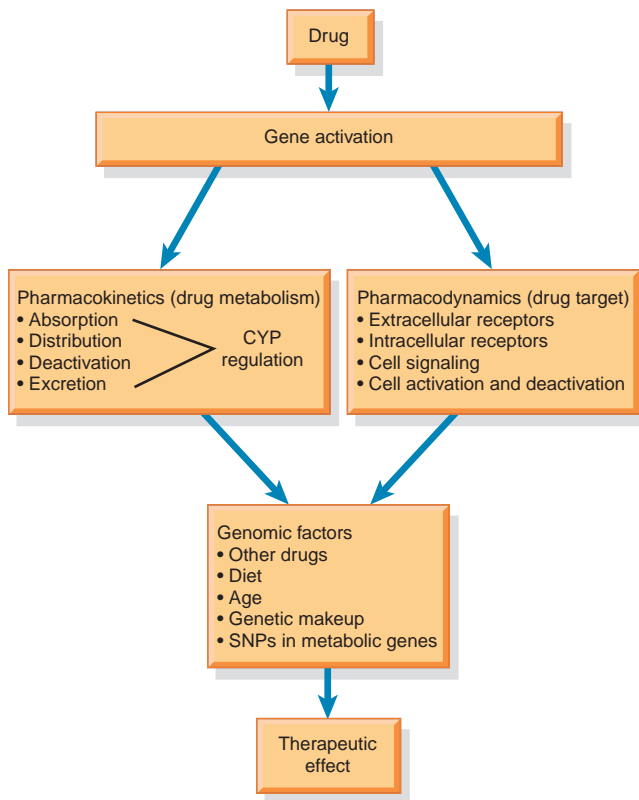

Figure 9-12 Simplified schematic representation of the multiple, complex, genetic-regulated mechanisms involved in pharmacokinetics (cytochrome [CYP]-dependent) and pharmacodynamics, along with other genomic and environmental factors affecting drug metabolism and treatment effect. SNP, single nucleotide polymorphism.

metabolizers, (3) extensive metabolizers, and (4) ultrarapid metabolizers (Ingelman-Sundberg, 2004). Poor metabolizers have a specific SNP variation in a CYP gene that causes little or no enzyme function, resulting in very little or no drug metabolism and higher blood levels of active drug because the drug cannot be absorbed or excreted. Conversely, ultrarapid metabolizers have SNP variations that cause in-

creased enzyme activity, resulting in rapid absorption, distribution, and excretion of a drug. Ultrarapid metabolizers have lower drug blood levels, usually with inadequate therapeutic response or longer treatment time to achieve therapeutic results. Both poor metabolizers and ultrarapid metabolizers are predisposed to adverse drug reactions. Poor metabolizers may have adverse effects or toxicities from high blood levels of drugs and need a lower dose, whereas ultrarapid metabolizers have inadequate treatment response because of lower drug blood levels and may need a higher dose or more frequent dosing. Table 9-6 shows examples of differences in drug response in poor versus ultrarapid metabolizers. Intermediate metabolizers have reduced enzyme activity levels and metabolize drugs at a slower than normal rate. Because intermediate metabolizers have some enzyme activity, they may have differences in treatment response. Extensive metabolizers have normal enzyme activity levels and normal drug metabolism. Differences in metabolism of other medications occur with other genetic variations.

Nurses have traditionally monitored and reported drug response and drug adverse effects. In the future, pharmacogenetic testing for such genetic variations will give patients more information about drug dosage, time to achieve response, and risk of adverse effects. Nurses will be expected to provide education about a particular patient's profile for drug metabolism and explain the rationale for the recommended dosage and likelihood of adverse effects. Nurses will continue to incorporate information about gender differences, food interactions, and drug compliance into patient education (Prows & Prows, 2004).

Clinical guidelines for pharmacogenomic testing for several drugs are being tested and will soon be part of clinical practice. Examples include warfarin (Coumadin) (Millican, Lenzini, Milligan, et al., 2007; Sconce, Kahn, Wynne, et al., 2005), tricyclic antidepressants (deLeon, Armstrong, Cozza, 2006), and vitamin K (Pestka, Hale, Johnson, et al., 2007). Once pharmacogenomic guidelines for drug dosing are established, it is expected that nurses will advocate for testing and educate patients about the rationale for pharmacogenetic testing prior to treatment with these medications.

Table 9-6 CLINICAL EFFECTS OF CYTOCHROME P450 ENZYME VARIATIONS

Enzyme	Drug	Effects	
		Poor Metabolizer	Ultrarapid Metabolizer
CYP2C9	Warfarin	Bleeding	Longer treatment time to achieve stable dosing
	Phenytoin	Ataxia	Not established
CYP2C19	Diazepam	Sedation	Poor response
CYP2D6	Tricyclic antidepressants	Cardiotoxicity	No response to recommended dose; need 10-fold increase in dose
	Selective serotonin reuptake inhibitors	Nausea	Not established
	Antipsychotics	Parkinson-like effects	Longer treatment time and higher drug costs

Applications of Genetics and Genomics in Nursing Practice

Nurses who provide genetics-related and genomics-related health care blend the principles of human genetics with nursing care in collaboration with other professionals, including genetics specialists, to foster improvement, maintenance, and restoration of patients' health. In all nursing practice settings, nurses have five main tasks (ANA, 2006): (1) help collect and interpret relevant family and medical histories, (2) identify patients and families who need further genetics evaluation and counseling and refer them to appropriate genetics services, (3) offer genetics information and resources to patients and families, (4) collaborate with genetics specialists, and (5) participate in the management and coordination of care of patients with genetic conditions. Genetics-related nursing practice involves the care of people who have genetic conditions, those who may be predisposed to develop or pass on genetic conditions, and those who are seeking genetics information and referral for additional genetics services (Jenkins & Lea, 2005; Skirton, et al., 2005).

Nurses support patients and families with genetics-related and genomics-related health concerns by ensuring that their health choices are informed ones and by advocating for the privacy and confidentiality of genetic and genomic information and for equal access to genetic testing and treatments (ANA, 2006).

Genetics and Genomics in Health Assessment

Assessment of a person's genetic and genomic health status is an ongoing process. Nurses collect information that can help identify individuals and families who have actual or potential genetics-related or genomics-related health con-

cerns or who may benefit from further genetics information, counseling, testing, and treatment. This process can begin before conception and continue throughout the lifespan. Nurses evaluate family and past medical histories, including prenatal history, childhood illnesses, developmental history, adult-onset conditions (in adults), past surgeries, treatments, and medications; this information may relate to the genetic or genomic condition at hand or to a condition being considered. (See Chapter 5 for more information on assessing past medical history.) Nurses also identify the patient's ethnic background and conduct a physical assessment to gather pertinent genetics information. The assessment also includes information about culture, spiritual beliefs, and ancestry. Health assessment includes determining a patient's or family's understanding of actual or potential genetics-related or genomics-related health concerns and awareness of how these issues are communicated within a family (ANA, 2006; Jenkins & Lea, 2005).

Family History Assessment

Nurses in any practice setting can assess families' genetics histories to identify the presence of a genetic trait, inherited condition, or predisposition. Targeted questions are used to identify genetic and genomic conditions for which further information, education, testing, or treatment can be offered (Chart 9-2). After consultation and collaboration with other health care providers and specialists, further genetic testing and evaluation is offered for the trait or condition in question. The genetics family history is used to make a diagnosis, identify testing strategies, and establish a pattern of inheritance. It includes at least three generations, as well as information about the current and past health status of all family members, including the age at onset of any illnesses, cause of death, and age at death. Nurses also can inquire about medical conditions that are known to have a heritable component and for which genetic testing may be

Chart 9-2 • Genetics Family History: An Essential Tool for All Nurses

A well-documented family history can be used to:

- Assess risk of certain diseases
- Decide on testing strategies, such as what genetic and other diagnostic tests to order
- Establish a pattern of inheritance
- Identify other family members who are at increased risk
- Identify shared environmental risk factors
- Calculate risks
- Assess risk of passing on conditions to children
- Determine and recommend treatments that modify disease risk
- Making decisions about management or surveillance
- Develop patient rapport
- Educate patients

Key questions to ask about each family member include:

- What is the current age or what was the age at death?
- What is the ethnic background (some genetic conditions are more common in certain ethnic groups)?

- Is there a history of:

- Multiple pregnancy losses/stillbirths?
- Unexplained infertility?
- Birth defects?
- Mental retardation or developmental delay?
- Learning disabilities?
- Medical problems in children whose parents are closely related (second cousins or closer)?
- Congenital or juvenile blindness, cataracts, hearing loss, or deafness?
- Very short or very tall stature?
- Several close relatives with the same or related conditions (eg, breast or colon cancer, diabetes, heart disease, asthma, stroke, high blood pressure, kidney disease)?
- Occurrence of a common condition with earlier age of onset than is usual (eg, breast or colon cancer, hearing loss, dementia, heart disease)?

Adapted from Centers for Disease Control and Prevention, Frequently asked questions about family history, www.hhs.gov/familyhistory/docs/FAQs.pdf and Mayo Clinic, Medical history: How to compile your medical family tree, www.mayoclinic.com/health/medical-history/HQ01707

available. Nurses obtain information about the presence of birth defects, mental retardation, familial traits, or similarly affected family members (Jenkins & Lea, 2005; Skirton, et al., 2005).

Nurses also consider the closeness of the relationship (genetic relatedness or consanguinity) among family members when assessing the risk of genetic conditions in couples or families. For example, when obtaining a preconception or prenatal family history, it is important for the nurse to ask if the prospective parents have common ancestors (ie, are they first cousins?). This is important because people who are related have more genes in common than those who are unrelated, thus increasing their chance of having children with an autosomal recessive inherited condition such as cystic fibrosis. Ascertaining genetic relatedness provides direction for genetic counseling and evaluation. It may also serve as an explanation for parents who have a child with a rare autosomal recessive inherited condition or for a person who is similarly affected.

When the assessment of family history reveals that a patient has been adopted, genetics-based and genomics-based health assessment becomes more challenging. Every effort is made to help the patient obtain as much information as possible about his or her biologic parents, including their ethnic backgrounds.

Questions about previous miscarriage or stillbirth are included in genetics health assessments to identify possible chromosomal conditions. Nurses can also inquire about any history of family members with inherited conditions or birth defects; maternal health conditions such as type 1 diabetes, seizure disorders, or PKU, which may increase the risk for birth defects in children; and about exposure to alcohol or other drugs during pregnancy. Maternal age is also noted; women who are 35 years of age or older who are considering pregnancy and childbearing or who are already pregnant should be offered prenatal diagnosis (eg, testing through amniocentesis) because of the association between advanced maternal age and chromosomal abnormalities such as Down syndrome (Skirton, et al., 2005).

Physical Assessment

Physical assessment may provide clues that a particular genetic or genomic condition is present in a person and family. Family history assessment may serve as a guide to focus the physical assessment. For example, a history of familial hypercholesterolemia would alert the nurse to assess for symptoms of hyperlipidemias (xanthomas, corneal arcus, abdominal pain of unexplained origin). As another example, a family history of neurofibromatosis type 1, an inherited condition involving tumors of the central nervous system, would prompt the nurse to carry out a detailed assessment of closely related family members. Skin findings such as *café-au-lait* spots, axillary freckling, or tumors of the skin (neurofibromas) would warrant referral for further evaluation, including genetic evaluation and counseling (Skirton, et al., 2005).

If a genetic or genomic condition is suspected as a result of a family history or physical assessment, the nurse, as a part of his or her role, and in collaboration with the health care team, may initiate further discussion of genetics and genomic information, offering and discussing genetic tests

Chart 9-3 • Indications for Making a Genetics Referral

Prepregnancy and Prenatal

- Maternal age of 35 years or greater at expected time of delivery
- Previous child with a chromosome problem
- Positive alpha-fetoprotein profile screening test
- Previous child with a birth defect or family history of birth defects
- Pregnancy history of two or more unexplained miscarriages
- Maternal conditions such as diabetes, epilepsy, or alcoholism
- Exposures to certain medications or drugs during pregnancy
- Family history of mental retardation
- Either member of the couple has a birth defect such as cleft lip or palate, spina bifida, or congenital heart defect
- Either member of the couple has a chromosome abnormality

Pediatric

- Positive newborn screening test
- One or more major birth defects
- Unusual (dysmorphic) facial features
- Developmental delay/mental retardation
- Suspicion of a metabolic disorder
- Unusually tall or short stature, or growth delays
- Known chromosomal abnormality

Adult

- Mental retardation without a known cause
- Unexplained infertility or multiple pregnancy losses
- A personal or family history of thrombotic events
- Adult-onset conditions such as hemochromatosis, hearing loss, visual impairment
- Family history of an adult-onset neurodegenerative disorder (eg, Huntington disease)
- Features of a genetic condition such as neurofibromatosis (*café-au-lait* spots, neurofibromas on the skin), Marfan syndrome (unusually tall stature, dilation of the aortic root), others
- Personal or family history of cardiovascular disorders known to be associated with genetic factors such as cardiomyopathy or long QT syndrome
- Family history of cancers known to be associated with specific genes such as hereditary breast/ovarian cancer or hereditary nonpolyposis colorectal cancer (HNPCC)
- Family history of early onset cancers and familial clustering of related tumors

Adapted from Pletcher, B. A., Toriello, H. V., Noblin, S. J., et al. (2007). Indications for genetic referral: A guide for healthcare providers. *Genetics in Medicine*, 9(6), 385–389.

and suggesting a referral for further genetic evaluation. (Chart 9-3).

Ancestry, Cultural, Social, and Spiritual Assessment

Genetics assessment addresses the ancestry of patients and families, as well as their ethnicity. This information helps identify individual patients and groups who could benefit

from genetic testing for carrier identification, prenatal diagnosis, and susceptibility testing. For example, carrier testing for sickle cell anemia is routinely offered to people of African American descent, and carrier testing for Tay-Sachs disease and Canavan disease is offered to people of Ashkenazi Jewish descent. The American College of Obstetrics and Gynecology (ACOG) recommends that members of at-risk racial and ethnic populations be offered carrier testing (ACOG Committee on Genetics, 2004). ACOG and the American College of Medical Genetics (ACMG) recommend that all couples, particularly those of Northern European and Ashkenazi Jewish ancestry, be offered carrier screening for cystic fibrosis (ACOG, 2004; Watson, et al., 2004). Ideally, carrier testing is offered before conception to allow people who are carriers to make decisions about reproduction. Prenatal diagnosis is offered and discussed when both partners of a couple are found to be carriers.

It is also important to inquire about the patient's ethnic backgrounds when assessing for susceptibilities to adult-onset conditions such as hereditary breast or ovarian cancer. For example, a *BRCA1* cancer-predisposing gene mutation seems to occur more frequently in women of Ashkenazi Jewish descent. Therefore, asking about ethnicity can help identify people with an increased risk of cancer gene mutations (American Medical Association, 2006).

Nurses also should consider their patients' views about the significance of a genetic condition and its effect on self-concept, as well as patients' perception of the role of genet-

ics in health and illness, reproduction, and disability. Patients' social and cultural backgrounds determine their interpretations and values about information obtained from genetic testing and evaluation and thus influence their perceptions of health, illness, and risk (Chart 9-4). Family structure, decision making, and educational background contribute in the same way (Jenkins & Lea, 2005; Skirton, et al., 2005).

Assessment of the patients' beliefs, values, and expectations regarding genetic testing and genetic and genomic information helps nurses provide appropriate information about the specific genetics or genomics topic. For example, in some cultures, people believe that health means the absence of symptoms and that the cause of illness is supernatural. Patients with these beliefs may initially reject suggestions for presymptomatic or carrier testing. However, by including resources such as family, cultural, and religious community leaders when providing genetics-related or genomics-related health care, nurses can help ensure that patients receive information in a way that transcends social, cultural, and economic barriers (Tranin, Masny & Jenkins, 2003).

Psychosocial Assessment

Psychosocial assessment is an essential nursing component of the genetics health assessment to understand the potential impact of new genetic and genomic information on the patient and family and how they may cope with this information (Chart 9-5).

CHART 9.4

NURSING RESEARCH PROFILE

Knowledge of Hereditary Prostate Cancer among High-Risk African American Men

Weinrich, S., Svinivasan, V., Powell, I. J., et al. (2007). Knowledge of hereditary prostate cancer among high-risk African American men. *Oncology Nursing Forum*, 35(4), 854–860.

Purpose

Hereditary prostate cancer accounts for 5% to 10% of all reported cases of prostate cancer. African American men develop prostate cancer 50% to 60% more often than Caucasian men and die from it at twice the rate of any other ethnic group. The purpose of this study was to assess knowledge about hereditary prostate cancer in a group of African American men at high risk for prostate cancer because of family history.

Design

This pilot study used a cross-sectional, correlational design. O'Connor's Decision Support Framework served as the basis for the study. This framework addresses three steps in decision making: assessing determinants (a person's perceptions, resources, and individual characteristics), support, and decision making. A total of 79 men were recruited from four U.S. sites that were part of the African American Hereditary Prostate Cancer Study. Of these, 38 men had been diagnosed with prostate cancer. Telephone interviews were conducted using the nine true-false questions that make up the Knowledge of Hereditary Prostate Cancer Scale. Each participant's answers were scored as correct or incorrect

based on the known correct answer for each item and then totaled to provide a score. The possible range of scores was 0 to 9.

Findings

The mean score was 6.34, with an average of 67% of answers correct; this was interpreted by the authors as a low level of overall knowledge about hereditary prostate cancer. The authors reported a high percentage of incorrect answers on questions related to genetic testing, prevention of prostate cancer, and risk based on a positive family history of prostate cancer. Older men had more knowledge than younger men, and responses did not differ by educational level.

Nursing Implications

The finding of a low level of knowledge of hereditary prostate cancer emphasizes the need for nurses to address the knowledge of hereditary prostate cancer among African American men, particularly those at high risk because of a family history of the disease. Nurses can use the Knowledge of Hereditary Prostate Cancer Scale to assist in assessing patients' baseline knowledge level and to guide teaching about risk of prostate cancer. Nurses need to be aware that genetic disorders, such as hereditary prostate cancer, affect families as well as individual patients and also be aware of the ethical implications of genetic testing for both individual patients and their families when such testing is available.

CHART
9-5

Assessing Psychosocial Genetic Health

The assessment of a client's psychosocial genetic health is based on the nurse's professional responsibility to "demonstrate in practice the importance of tailoring genetic and genomic information and services to clients based on their culture, religion, knowledge level, literacy and preferred language."

The nurse assesses:

- Educational level and understanding of the genetic condition or concern in the family
- Desired goals and health outcomes in relation to the genetic condition or concern
- Family rules regarding disclosure of medical information (eg, some families may not reveal a history of a disease such as cancer or mental illness during the family history assessment)
- Family rules, boundaries, and cultural practices as well as personal preference about knowing genetic information
- Past coping mechanisms and social support
- Ability to make an informed decision (eg, is the patient under stress from family situations, acute or chronic illness, or medications that may impair the patient's ability to make an informed decision?)

Adapted from American Nurses Association. (2006). *Essential nursing competencies and curricula guidelines for genetics and genomics*. Silver Spring, MD: Author, p. 11. Skirton, H., Patch, C. & Williams, J. (2005). *Applied genetics in healthcare: A handbook for specialist practitioners*. New York: Taylor and Francis Group.

Genetic Counseling and Evaluation Services

People seek genetic counseling for a variety of reasons and at different stages of life. Some are seeking preconception or prenatal information, others are referred after the birth of a child who has a birth defect or suspected genetic condition, and still others are seeking information for themselves or their families because of the presence of, or a family history of, a genetic condition. Regardless of the timing or setting, genetic counseling is offered to all people who have questions about genetics or genomics and their health. In collaboration with the health care team, nurses consider referral for genetic counseling for any patient who belongs to a family with a hereditary condition and who asks questions such as, "What are my chances for having this condition? Is there a genetic test that will tell me? Is there a gene-based treatment or cure? What are my options?" (Skirton, et al., 2005).

As the contribution of genetics and genomics to the health-illness continuum is recognized, genetic counseling will become a responsibility of all health care professionals in clinical practice. Nurses are in an ideal position to assess the patient's health and genetics family history and to make referrals for specialized diagnosis and treatment. They offer anticipatory guidance by explaining the purpose and goals of a referral. They collaborate with other health care providers in giving supportive and follow-up counseling and coordinating follow-up and case management.

Genetics Services

Genetics services provide genetics information, education, and support to patients and families. Medical geneticists, genetics counselors, and advanced practice nurses in genetics provide specific genetics services to patients and families who are referred by their primary or specialty health care providers. A team approach is often used to obtain and interpret complex family history information, evaluate and diagnose genetic conditions, interpret and discuss complicated genetic test results, support patients throughout the evaluation process, and offer professional and family support. Patients participate as team members and decision makers throughout the process. Genetics services enable patients and their families to learn and understand relevant aspects of genetics and genomics, to make informed health decisions, and to receive support as they integrate personal and family genetic and genomic information into daily living (Jenkins & Lea, 2005).

Genetic counseling may take place over an extended period and may entail more than one counseling session, which may include other family members. The components of genetic counseling are outlined in Chart 9-6. Although genetic counseling may be offered at any point during a patient's lifespan, counseling issues are often relevant to the life stage in which counseling is sought (Jenkins & Lea, 2005). Some examples are presented in Chart 9-7.

Nursing Care and Interventions in Genetic Counseling

The process of genetic counseling and evaluation often involves additional genetic testing and procedures as well as decisions by patients and families about reproduction, fertility, testing of children, and management options such as prophylactic surgery. In each of these areas, nurses provide psychosocial interventions and information as family members consider their genetic testing and treatment options. Nurses consider individual patients in the context of the family.

When a patient undergoes presymptomatic genetic testing for hereditary breast and ovarian cancer and tests positive for a cancer-causing mutation, the nurse provides information and support as the patient makes decisions about treatment and interventions.

Decision-making support is an important nursing intervention in many genetic counseling situations. Examples include consideration of pregnancy termination, presymptomatic testing for conditions such as Huntington disease, or predisposition testing for a hereditary cancer. Nurses help patients and families obtain information about options, identify the pros and cons of each option, and explore their values and beliefs. In addition, nurses respect each person's right to receive or not to receive information and help them explain their decision to other family members (Bulechek, Butcher & Dochterman, 2008).

Another essential component of nursing care and genetic counseling is coping enhancement. Coping enhancement involves helping people adapt to stressors or changes that interfere with daily living and functioning (Bulechek, et al., 2008). Coping enhancement is essential throughout the entire genetic counseling, evaluation, and testing process. Nurses can use indicators of patient

Chart 9-6 • Components of Genetic Counseling**Information and Assessment Sources**

- Reason for referral
- Family history
- Medical history/records
- Relevant test results and other medical evaluations
- Social and emotional concerns
- Relevant cultural, educational, and financial factors

Analysis of Data

- Family history
- Physical examination as needed
- Additional laboratory testing and procedures (eg, echocardiogram, ophthalmology or neurologic examination)

Communication of Genetic Finding

- Natural history of disorder
- Pattern of inheritance

- Reproductive and family health issues and options
- Testing options
- Management and treatment issues

Counseling and Support

- Identify individual and family questions and concerns
- Identify existing support systems
- Provide emotional and social support
- Refer for additional support and counseling as indicated

Follow-Up

- Written summary to referring primary care providers and family
- Coordination of care with primary care providers and specialists
- Additional discussions of test results or diagnosis

knowledge, decision making, and coping outcomes to document nursing care provided to families and its effectiveness. These activities are carried out in collaboration with patients and families and help ensure that they receive the most benefit from genetic counseling (ANA, 2006).

Advocacy in Genetic and Genomic Decisions

Respecting the patient's right to self-determination—that is, supporting decisions that reflect the patient's personal beliefs, values, and interests—is a central principle in directing how nurses provide genetic and genomic information and counseling. Nurses and others participating in genetic counseling make every attempt to respect the patient's ability to make autonomous decisions. A first step in providing such nondirective counseling is recognizing one's own values (see Chart 9-1) and how communication of genetic and genomic information may be influenced by those values.

Confidentiality of genetic and genomic information and respect for privacy are other essential principles underlying genetic counseling. Patients have the right to have testing without having the results divulged to anyone, including insurers, physicians, employers, or family members. Some patients pay for testing themselves so that insurers will not learn of the test, and others use a different name for testing to protect their privacy.

A nurse may want to disclose genetics information to family members who could experience significant harm if they do not know such information. However, the patient may have other views and may wish to keep this information from the family, resulting in an ethical dilemma for both patient and nurse (Chart 9-8). The nurse must honor the patient's wishes, while explaining to the patient the potential benefit this information may have for other family members (International Society of Nurses in Genetics, 2005).

CHART
9-8

Ethics and Related Issues: Sharing of Genetic Information

Are Individuals Who Are Identified to Have a Disease-Causing Gene Mutation Obligated to Share This Information With Other At-Risk Family Members?

Situation

Genetic technologies are creating new sources of medical information for individuals, families, and communities that raise important ethical, legal, and social issues. Genetic information is defined as heritable, biological information (National Human Genome Research Institute, 2007a), and it can be identified at any point throughout a person's lifespan from preconception until after death. In addition to heritable, biological information, the family history, genetic test results, and medical records are also sources of genetic information.

Privacy involves the right of the individual to control his or her own body, actions, and personal information. Confidentiality refers to the nurse's obligation to protect, and not to disclose, personal information provided in confidence to another. However, genetic information obtained from family history and genetic testing may reveal information not only about the health risks to the individual patient, but also of other family members who may not be aware of the health concern.

Dilemma

An ethical dilemma arises for nurses and other health care providers when a patient chooses not to share genetic information with other family members when it may be important to their health. This creates a dilemma for the nurse, who on the one hand must respect the patient's confidentiality, while on the other hand has the duty to warn other family members of the potential health risks. For example, a

woman who tests positive for *BRCA1* informs the nurse that she does not wish to share this information with her sisters and her mother because she does not get along with them and has not spoken to them in more than 5 years. The nurse is aware that mutations in *BRCA1* or *BRCA2* predispose those who carry one of these gene mutations to breast cancer, ovarian cancer, prostate cancer (*BRCA1*), and other cancers (*BRCA2*). When a family member such as a sibling or parent is found to have a mutation in one of these genes, other family members have an increased risk of also having that same gene mutation. The ethical concern in this example is for the patient's sisters and mother. Each of them now has a 1 in 2 chance of having the same breast/ovarian cancer gene mutation that confers a significantly increased risk of developing breast/ovarian and other cancers.

Discussion

1. What arguments would you offer for informing the patient's family members about their risk of having a hereditary breast/ovarian cancer gene mutation?
2. What arguments would you offer against informing the patient's family members about their risk of having a hereditary breast/ovarian cancer gene mutation?
3. Are there any professional guidelines that you can turn to for help in resolving this ethical dilemma? If so, what are they, and how can they help?
4. What would you do if the patient with the *BRCA1* gene mutation ultimately refuses to share the information with family members based on her beliefs about confidentiality of genetic information?
5. How would you respond if the patient with the *BRCA1* mutation says that she is afraid to let her family know because she feels guilty about bringing them bad news?

Schneider, K. A., Chittenden, A. B., Branda, K. J., et al. (2006). Ethical issues in cancer genetics: I 1) Whose information is it? *Journal of Genetic Counseling*, 15(6), 491–503.

The Health Insurance Portability and Accountability Act (HIPAA) of 1996 prohibits the use of genetics information to establish insurance eligibility. However, HIPAA does not prohibit group plans from increasing premiums, excluding coverage for a specific condition, or imposing a lifetime cap on benefits. The National Human Genome Research Institute, Policy and Public Affairs and Legislative Activities Branch (2009a), has a summary of each state's legislation on employment and insurance discrimination. (See also the Resources list at the end of this chapter.)

Most lawmakers, scientists, and health advocacy groups strongly believe that there is a need for federal legislation to prevent genetic discrimination. Nurses need to become familiar with the Genetic Information Nondiscrimination Act (GINA), which was signed into law in 2008. Its purpose is to protect Americans against improper use of genetic and genomic information in insurance and employment decisions. The act prohibits health insurers from denying coverage to a healthy person or charging higher insurance rates based on a person's genetic predisposition to a disease. The act also prevents employers from using a person's genetic

and genomic information to make decisions about hiring, job placement, promotion, or firing. As a result, most Americans are free to use genetics and genomics information in health care without the fear of misuse (National Human Genome Research Institute, 2009b). However, GINA does not cover life, disability, or long-term care insurance. Furthermore, GINA and other state and federal protections do not extend to genetic testing of active duty military personnel or genetic information obtained from active military personnel (Baruch & Hudson, 2008).

All genetics specialists, including nurses who participate in the genetic counseling process and those with access to a person's genetics information, must honor a patient's desire for confidentiality. Genetics information should not be revealed to family members, insurance companies, employers, and schools if the patient so desires, even if keeping the information confidential is difficult.

Providing Precounseling Information

Preparing the patient and family, promoting informed decision making, and obtaining informed consent are essential in genetic counseling. Nurses assess the patient's capacity

and ability to give voluntary consent. This includes assessment of factors that may interfere with informed consent, such as hearing loss, language differences, cognitive impairment, and the effects of medication. Nurses make sure that a person's decision to undergo testing is not affected by coercion, persuasion, or manipulation. Because information may need to be repeated over time, nurses offer follow-up discussion as needed (Tranin, et al., 2003).

The genetics service to which a patient or family is referred for genetic counseling will ask the nurse for background information for evaluation. Genetics specialists need to know the reason for referral, the patient's or family's reason for seeking genetic counseling, and potential genetics-related health concerns. For example, a nurse may refer a family with a new diagnosis of hereditary breast or ovarian cancer for counseling or to discuss the likelihood of developing the disease and the implications for other family members. The family may have concerns about confidentiality and privacy. The nurse and the genetics specialist tailor the genetic counseling to respond to these concerns.

With the patient's permission, genetics specialists will request the relevant test results and medical evaluations. Nurses obtain permission from the patient and, if applicable, from other family members to provide medical records that document the genetic condition of concern. In some situations, evaluation of more than one family member may be necessary to establish a diagnosis of a genetic disorder. Nurses explain that the medical information is needed to ensure that appropriate information and counseling (including risk interpretation) are provided.

The genetics service asks nurses about the emotional and social status of the patient and family. Genetics specialists want to know the coping skills of patients and families who have recently learned of the diagnosis of a genetic disorder as well as what type of genetics information is being sought. Nurses help identify cultural and other issues that may influence how information is provided and by whom. For example, for patients with hearing loss, a sign interpreter's services may have to be arranged. For those with vision loss, alternative forms of communication may be necessary. Genetics professionals prepare for the genetic counseling and evaluation with these relevant issues in mind (Jenkins & Lea, 2005).

Preparing Patients for Genetics Evaluation

Before a genetic counseling appointment, the nurse discusses with the patient and family the type of family history information that will be collected during the consultation. Family history collection and analysis are comprehensive and focus on information that may be relevant to the genetics-related or genomics-related concern in question. The genetic analysis always includes assessment for any other potentially inherited conditions for which testing, prevention, and treatment may be possible.

A physical examination may be performed by the medical geneticist to identify specific clinical features that are diagnostic of a genetic condition. The examination also helps determine if further testing is needed to diagnose a genetic disorder. This examination generally involves assessment of all body systems, with a focus on specific physical characteristics considered for diagnosis. Nurses de-

scribe the diagnostic evaluations that are part of a genetics consultation and explains their purposes (Skirton, et al., 2005).

Communicating Genetic and Genomic Information to Patients

After the family history and physical examination are completed, the genetics team reviews the information gathered before beginning genetic counseling with the patient and family. The genetics specialists meet with the patient and family to discuss their findings. If the information gathered confirms the presence of a genetic condition in a family, genetics specialists discuss with the patient the natural history of the condition, the pattern of inheritance, and the implications of the condition for reproductive and general health. When appropriate, specialists also discuss relevant testing and management options.

Providing Support

The genetics team provides support throughout the counseling session and identifies personal and family concerns. Genetics specialists use active listening to interpret patient concerns and emotions, seek and provide feedback, and demonstrate understanding of those concerns. Genetics specialists suggest referral for additional social and emotional support. Genetics specialists discuss pertinent patient and family concerns and needs with nurses and primary health care teams so that they can provide additional support and guidance (Jenkins & Lea, 2005; Skirton, et al., 2005). Nurses assess the patient's understanding of the information given during the counseling session, clarify information, answer questions, assess patient reactions, and identify support systems.

Follow-Up After Genetic Evaluation

As follow-up to genetic evaluation and counseling, genetics specialists prepare a written summary of the evaluation and counseling session for the patient and, with the patient's consent, send this summary to the primary health care provider as well as other providers identified by the patient as participants in care. The consultation summary outlines the results of the family history and physical and laboratory assessments, provides a discussion of the specific diagnosis (if made), reviews the inheritance and associated risk of recurrence for the patient and his or her family, presents reproductive and general health options, and makes recommendations for further testing and management. The nurse reviews the summary with the patient and identifies information, education, and counseling for which follow-up genetic counseling may be useful (Skirton, et al., 2005).

Follow-up genetic counseling is always offered because some patients and families need more time to understand and discuss the specifics of a genetic test or diagnosis, or they may wish to review reproductive options again later, when pregnancy is being considered. Follow-up counseling is also offered to patients when further evaluation and counseling of extended family members is recommended (Skirton, et al., 2005).

As part of follow-up, nurses can educate patients about sources of information about genetic and genomic

issues. Some resources that provide the most up-to-date and reliable genetic and genomic information are available on the Internet (see Resources at the end of this chapter).

Ethical Issues

Nurses must consider their responsibilities in handling genetic and genomic information and potential ethical issues such as informed decision making, privacy and confidentiality of such information, and access to and justice in health care. The ethical principles of autonomy, fidelity, and veracity are also important (ANA, 2008).

Ethical questions relating to genetics and genomics occur in all settings and at all levels of nursing practice. At the level of direct patient care, nurses participate in providing genetics information, testing, and gene-based therapeutics. They offer patient care based on the values of self-determination and personal autonomy. To be as fully informed as possible, patients need appropriate, accurate, and complete information given at such a level and in such a form that they and their families can make well-informed personal, medical, and reproductive health decisions. Nurses can help patients clarify values and goals, assess understanding of information, protect patients' rights, and support their decisions. Nurses can advocate for patient autonomy in health decisions. Several resources and position statements have been developed to guide nursing practice (ANA, 2006). These position statements are listed at the end of this chapter.

Many people are increasingly concerned about threats to their personal privacy and the confidentiality of genetic and genomic information. An ethical foundation provides nurses with a holistic framework for handling ethical issues with integrity and a basis for communicating genetic and genomic information to a patient, a family, other care providers, community agencies and organizations, and society. Ethical principles of beneficence (to do good) and nonmaleficence (to do no harm), as well as autonomy, justice, fidelity, and veracity, are used to resolve ethical dilemmas that may arise in clinical care. Respect for people is the ethical principle underlying all nursing care. Using these principles and the values of caring, nurses can promote thoughtful discussions that are useful when patients and families are facing genetic-related and genomic-related health and reproductive decisions and consequences (ISONG, 2000; Tranin, et al., 2003). Further information about ethics is included in Chapter 3.

CRITICAL THINKING EXERCISES

EBP 1 A 42-year-old man has biopsy-proven, right-sided colon cancer. The pathology report shows a 3-cm poorly differentiated tumor that is negative for *MLH1* by immunohistochemistry. His father had colon cancer at age 48 and his sister had uterine cancer at age 52. Clinicians present the patient with options for genetic testing

and surgical consideration of a colon resection. He reports that he does not understand why he should have genetic testing. What evidence about the patient's phenotype (ie, age and tumor characteristics) is the basis for the recommendation for genetic testing and what is the strength of that evidence? What information about his family history supports having genetic testing? What genetic resources or referrals would you suggest for this patient? What professional guidelines support your recommendation for genetic testing?

EBP 2 A 32-year-old woman has been admitted to your nursing unit after having orthopedic surgery—open reduction with internal fixation—to stabilize a right ankle fracture. Your nursing intervention includes a pain assessment. The patient is already asking questions about when her parenteral opioids will be changed to oral ones. She reports having had poor pain control with oral opioids after a prior fracture; she describes having to ask more frequently for pain medication than was recommended. During that recovery period, she felt very discouraged because she was accused of “drug-seeking behavior.” What pharmacogenomic evidence-based information would you give this patient about her past experience with pain medications? What evidence related to pain medications supports your discussion? How would you determine the strength of that evidence? What pharmacologic measures would you discuss with the surgical team to plan for effective pain control?

3 A 50-year-old woman is seen in the clinic for concerns about recent episodes of forgetfulness. She has a strong family history of early-onset Alzheimer's disease (AD). Her father recently died at the age of 68 after having AD for 10 years. Her physician wants her to see a genetic counselor to discuss the pros and cons of being tested to see if she carries one of the genes for AD. She sees you for patient education and asks how she would cope with knowing that AD may be in her future. In addition, she has concerns about the privacy of genetic information and what that would mean in terms of her health insurance. What further nursing assessment would you pursue regarding this patient's psychosocial, coping, and support mechanisms? What information could you provide about preparation for genetic counseling, autonomous decision making, and genetic privacy? What resources and referrals would you make available?

The Smeltzer suite offers these additional resources to enhance learning and facilitate understanding of this chapter:

Chronic Illness and Disability

LEARNING OBJECTIVES

On completion of this chapter, the learner will be able to:

- 1 Define “chronic conditions.”
- 2 Identify factors related to the increasing incidence of chronic conditions.
- 3 Describe characteristics of chronic conditions and implications for people with chronic conditions and for their families.
- 4 Describe advantages and disadvantages of various models of disability.
- 5 Describe implications of disability for nursing practice.

GLOSSARY

chronic conditions: medical or health problems with associated symptoms or disabilities that require long-term management (3 months or longer)

disability: restriction or lack of ability to perform an activity in a normal manner; the consequences of impairment in terms of an individual’s functional performance and activity. Disabilities represent disturbances at the level of the person (eg, bathing, dressing, communication, walking, grooming)

impairment: loss or abnormality of psychological, physiologic, or anatomic structure or function at the organ level (eg, dysphagia, hemiparesis); an abnormality of body structure, appearance, and organ or system function resulting from any cause

secondary conditions or disorders: any physical, mental, or social disorders resulting directly or indirectly from an initial disabling condition; a condition to which a person with a disability is more susceptible because of having a primary disabling condition

Chronic illness and disability affect people of all ages—the very young, the middle aged, and the very old. Chronic illnesses and disability are found in all ethnic, cultural, and racial groups, although some disorders occur more frequently in some groups than in others (Centers for Disease Control and Prevention [CDC], 2006). Chronic diseases account for 7 of the 10 leading causes of death in the United States, including the three most frequently occurring diseases that result from preventable causes (tobacco use, improper diet and physical inactivity, and alcohol use). Chronic diseases accounted for about 88% of deaths in the United States in 2002 (World Health Organization [WHO], 2005). Chronic disease occurs in all socioeconomic groups, but people who have low incomes and disadvantaged backgrounds are more likely to report poor health. Factors such as poverty and inadequate health insurance decrease the likelihood that people with chronic illness or disability receive health care and health screening measures such as mammography, cholesterol testing, and routine checkups (U.S. Department of Health and Human Services [USDHHS], 2005a). In addition, chronic disease can lead to poverty at the level of the patient and family, a society, or country as a whole because deaths due to chronic illness occur most often during a person's most productive years (WHO, 2006).

Many people with chronic health conditions and disability function independently with only minor inconvenience to their everyday lives; others require frequent and close monitoring or placement in long-term care facilities. Certain conditions require advanced technology for survival, as in the late stages of amyotrophic lateral sclerosis or end-stage renal disease, or intensive care or mechanical ventilation for periods of weeks or months. People with disorders such as these have been described as chronically critically ill (Lipson, Kelley, Higgins, et al., 2006). Some chronic conditions have little effect on quality of life, but others have a considerable effect because they result in disability. However, not all disabilities are a result of chronic illness, and not all chronic illnesses cause disability. In this chapter, chronic illness is discussed, followed by a discussion of disability and the implications for nursing practice.

Overview of Chronicity

Although each chronic condition has its own specific physiologic characteristics, chronic conditions do share common features. Many chronic conditions, for example, have pain and fatigue as associated symptoms. Some degree of disability is usually present in severe or advanced chronic illness, limiting the patient's participation in many activities. Many chronic conditions require therapeutic regimens to keep them under control. Unlike the term *acute*, which implies a curable and relatively short disease course, the term *chronic* describes a long disease course and conditions that may be incurable. This often makes managing chronic conditions difficult for those who must live with them.

Psychological and emotional reactions of patients to acute and chronic conditions and changes in their health status are described in detail in Chapter 7. People who develop chronic conditions or disabilities may react with

shock, disbelief, depression, anger, resentment, or a number of other emotions. How people react to and cope with chronic illness is usually similar to how they react to other events in their lives, depending, in part, on their understanding of the condition and their perceptions of its potential impact on their own and their families' lives. Adjustment to chronic illness (and disability) is affected by various factors:

- Suddenness, extent, and duration of lifestyle changes necessitated by the illness
- Family and individual resources for dealing with stress
- Stages of individual/family life cycle
- Previous experience with illness and crises
- Underlying personality characteristics
- Unresolved anger or grief from the past

Psychological, emotional, and cognitive reactions to chronic conditions are likely to occur at their onset and recur if symptoms worsen or after a period of remission. Symptoms associated with chronic health conditions are often unpredictable and may be perceived as crisis events by patients and their families who must contend with both the uncertainty of chronic illness and the changes it brings to their lives. These possible effects of chronic conditions can guide nursing assessment and interventions for the patient who has a chronic illness.

Definition of Chronic Conditions

Chronic conditions are often defined as medical conditions or health problems with associated symptoms or disabilities that require long-term management (3 months or longer). Chronic conditions can also be defined as illnesses or diseases that have a prolonged course, that do not resolve spontaneously, and for which complete cures are unlikely or rare. The specific condition may be a result of illness, genetic factors, or injury; or it could be a consequence of conditions or unhealthy behaviors that began during childhood or young adulthood. Management of chronic conditions includes learning to live with symptoms or disabilities and coming to terms with identity changes resulting from having a chronic condition. It also consists of carrying out the lifestyle changes and regimens designed to control symptoms and prevent complications. Although some people assume what might be called a "sick role" identity, most people with chronic conditions do not consider themselves to be sick or ill and try to live as normal a life as possible. Only when complications develop or symptoms interfere with activities of daily living (ADLs) do most people with chronic health conditions think of themselves as being sick or disabled.

Prevalence and Causes of Chronic Conditions

Chronic conditions occur in people of every age group, socioeconomic level, race, and culture. In 2000, an estimated 125 million people in the United States had one or more chronic conditions, and 61 million people (21% of the population) had multiple chronic conditions. It is predicted that by the year 2050, about 167 million people (about 50% of the population) will have a chronic illness, with 81 million (24%) having two or more chronic health conditions (Anderson & Horvath, 2004). As the incidence of chronic

Table 10-1 MYTHS AND TRUTHS ABOUT CHRONIC DISEASE

Common Misconceptions About Chronic Disease	The Reality About Chronic Disease
1. Everyone has to die of something.	Chronic illnesses typically do not result in sudden death but often result in progressive illness and disability. People with chronic disease often die slowly, painfully, and prematurely.
2. People can live to old age even if they lead unhealthy lives (smoke, are obese).	Although there are exceptions (some people who live unhealthy lives live to old age and some people who live healthy lives develop chronic illnesses), the majority of chronic illnesses can be traced to common risk factors and can be prevented by eliminating these risks.
3. Solutions for chronic disease prevention and control are too expensive to be feasible for low-income and middle-income countries.	A full range of chronic disease interventions are very cost-effective for all regions of the world, including the poorest. Many of these interventions are inexpensive to implement.
4. There is nothing that can be done anyway; chronic diseases cannot be prevented.	The major causes of chronic diseases are known, and if these risk factors were eliminated, over 80% of heart disease, stroke, and type 2 diabetes would be prevented; and over 40% of cancer would be prevented.
5. If individuals develop chronic disease as a result of unhealthy “lifestyles,” they have no one to blame but themselves.	Individual responsibility can have its full effect only if individuals have equal access to a healthy life and are supported to make healthy choices. Poor people often have limited choices about the food they eat, their living conditions, and access to education and health care.
6. Certain chronic diseases, especially heart disease, primarily affect men.	Chronic diseases, including heart disease, affect women and men almost equally. Almost half of all deaths due to chronic illness occur in women.
7. Chronic diseases primarily affect the elderly.	Almost half of chronic disease deaths occur prematurely, in people under 70 years of age.
8. Chronic diseases mainly affect people who are rich (affluent).	People who are poor are much more likely than the wealthy to develop chronic diseases and are more likely to die as a result. Chronic diseases cause substantial financial burden and can push people and families into poverty.
9. The priority of low-income and middle-income countries should be on control of infectious diseases.	Although infectious diseases are an issue, low-income and middle-income countries are experiencing a rapid increase in chronic disease risk factors and deaths, especially in urban settings.
10. Chronic diseases affect mostly high-income countries.	Eighty percent of deaths due to chronic disease are in low-income and middle-income countries.

Based on World Health Organization (2005). Widespread misunderstandings about chronic disease—and the reality. Facing the facts #2. Available at: www.who.int/entity/chp/chronic_disease_report/media/Factsheet2.pdf

illnesses increases, the costs associated with these illnesses (ie, hospital costs, equipment, medications, supportive services) also increase. Expenditures for health care for people with chronic conditions exceed billions of dollars every year; these costs represent four of every five health care dollars expended. Chronic disease is associated with 78% of health care costs in the United States. It accounts for 96% of home health care, 88% of prescriptions, 72% of physician visits, and 76% of hospital stays. Most of these health care costs are associated with having two or more chronic conditions (Anderson & Horvath, 2004).

Although some chronic health conditions cause little or no inconvenience, others are severe enough to cause major activity limitations. When people with activity limitations are unable to meet their needs for health care and personal services, they may be unable to carry out their therapeutic regimens or have their prescriptions filled on time, may miss appointments and office visits with their health care providers, and may be unable to carry out ADLs.

Chronic disease is a global issue that affects both rich and poor nations. Chronic conditions have become the major cause of health-related problems in developed countries as well as in developing countries, which are also trying to cope with new and emerging infectious diseases. In almost all countries, chronic diseases are currently the major cause of death among adults. More than 35 million people died of chronic diseases worldwide in 2005. Four of every five deaths occurred in countries characterized as low or middle income, where people tend to develop chronic diseases at younger ages, suffer longer, and die sooner than people in

high-income countries. In contrast to common belief, the total number of people dying from chronic disease is twice that of patients dying from infectious (including human immunodeficiency virus [HIV] infection), maternal and perinatal conditions, and nutritional deficiencies combined (WHO, 2005). The majority of these chronic diseases and complications of chronic illness are preventable. Although chronic diseases or illnesses are common, people have many myths or misunderstandings about them (Table 10-1).

Causes of the increasing number of people with chronic conditions include the following:

- A decrease in mortality from infectious diseases (eg, smallpox, diphtheria, acquired immunodeficiency syndrome [AIDS]–related infections) and from acute conditions because of prompt and aggressive management of acute conditions (eg, myocardial infarction, trauma).
- Lifestyle factors, such as smoking, chronic stress, and sedentary lifestyle, which increase the risk of chronic health problems such as respiratory disease, hypertension, cardiovascular disease, and obesity. Although signs and symptoms of chronic illness often first appear during older age, risks may begin earlier, even during fetal development.
- Longer lifespans because of advances in technology and pharmacology, improved nutrition, safer working conditions, and greater access (for some people) to health care.
- Improved screening and diagnostic procedures, enabling early detection and treatment of diseases, re-

sulting in improved outcomes of management of cancer and other disorders (Oeffinger, Mertens, Sklar, et al., 2006).

Consequences of unhealthy lifestyles include an alarming increase in the incidence of diabetes, hypertension, obesity, and cardiac and chronic respiratory disorders (WHO, 2005). Physiologic changes in the body often occur before the appearance of symptoms of chronic disease. Therefore, the goal of emphasizing healthy lifestyles early in life is to improve overall health status and slow the development of such disorders. Major risk factors for chronic disease, which represent a growing challenge to public health, include unhealthy eating habits, decreased energy expenditure associated with a sedentary lifestyle, increasing age, and tobacco use and alcohol consumption (WHO, 2005). In addition, serious psychiatric or mental illness puts people at greater risk for chronic illness than the general population and leads to higher morbidity and mortality rates of chronic diseases (Robson & Gray, 2007).

Characteristics of Chronic Conditions

Sometimes it is difficult for people who are disease free to understand the profound effect that chronic illness often has on the lives of patients and their families. It is easy for health professionals to focus on the illness or disability itself while overlooking the person who has the disorder. In all illnesses, but even more so with chronic conditions, the illness cannot be separated from the person. People with chronic illness must contend with it daily. To relate to what people must cope with or to plan effective interventions, nurses must understand what it means to have a chronic illness. Characteristics of chronic illness include the following:

- Managing chronic illness involves more than treating medical problems. Associated psychological and social problems must also be addressed, because living for long periods with illness symptoms and disability can threaten identity, bring about role changes, alter body image, and disrupt lifestyles. These changes require continuous adaptation and accommodation, depending on age and situation in life. Each decline in functional ability requires physical, emotional, and social adaptation for patients and their families (Corbin, 2003).
- Chronic conditions usually involve many different phases over the course of a person's lifetime. There can be acute periods, stable and unstable periods, flare-ups, and remissions. Each phase brings its own set of physical, psychological, and social problems, and each requires its own regimens and types of management.
- Keeping chronic conditions under control requires persistent adherence to therapeutic regimens. Failure to adhere to a treatment plan or to do so consistently increases the risk of developing complications and accelerating the disease process. However, the realities of daily life, including the impact of culture, values, and socioeconomic factors, affect the degree to which people adhere to a treatment regimen. Managing a chronic illness takes time, requires knowledge and planning, and can be uncomfortable and inconvenient. It is not unusual for patients to stop taking medications or alter dosages because of side effects that are more disturbing or disruptive than symptoms of the illness, or to cut back on regimens they consider overly time consuming, fatiguing, or costly (Corbin, 2003).
- One chronic disease can lead to the development of other chronic conditions. Diabetes, for example, can eventually lead to neurologic and vascular changes that may result in visual, cardiac, and kidney diseases and erectile dysfunction. The presence of a chronic illness also contributes to a higher risk of morbidity and mortality in patients admitted to the intensive care unit with acute health conditions as well as greater utilization of clinical services during hospitalization (Dartmouth Atlas of Health Care Working Group, 2006).
- Chronic illness affects the entire family. Family life can be dramatically altered as a result of role reversals, unfilled roles, loss of income, time required to manage the illness, decreases in family socialization activities, and the costs of treatment. Stress and caretaker fatigue are common with severe chronic conditions, and the entire family rather than just the patient may need care (Ray & Street, 2007). However, some families are able to master the treatment regimen and changes that accompany chronic illness as well as make the treatment regimen a routine part of life. Furthermore, they are able to keep the chronic illness from becoming the focal point of family life.
- The day-to-day management of illness is largely the responsibility of people with chronic disorders and their families. As a result, the home, rather than the hospital, is the center of care in chronic conditions. Hospitals, clinics, physicians' offices, nursing homes, nursing centers, and community agencies (home care services, social services, and disease-specific associations and societies) are considered adjuncts or backup services to daily home management.
- The management of chronic conditions is a process of discovery. People can be taught how to manage their conditions. However, each person must discover how his or her own body reacts under varying circumstances—for example, what it is like to be hypoglycemic, what activities are likely to bring on angina, and how these or other conditions can best be prevented and managed.
- Managing chronic conditions must be a collaborative process that involves many different health care professionals working together with patients and their families to provide the full range of services that are often needed for management at home. The medical, social, and psychological aspects of chronic health problems are often complex, especially in severe conditions.
- The management of chronic conditions is expensive. Many of the expenses incurred by an individual patient (eg, costs for hospital stays, diagnostic tests, equipment, medications, supportive services) may be covered by health insurance and by federal and state agencies. However, the cost increases affect society as

a whole as insurance premiums increase to cover these costs. Cost increases at the government level decrease resources that might benefit society. In addition, many out-of-pocket expenses are not reimbursed. Many people with chronic disorders, including the elderly and people who are working, are uninsured or underinsured and may be unable to afford the high costs of care often associated with chronic illnesses (CDC, 2006). Absence from work because of chronic disorders may jeopardize job security and income.

- Chronic conditions raise difficult ethical issues for patients, families, health care professionals, and society. Problematic questions include how to establish cost controls, how to allocate scarce resources (eg, organs for transplantation), and what constitutes quality of life and when life support should be withdrawn.
- Living with chronic illness means living with uncertainty. Although health care providers may be aware of the usual progression of a chronic disease such as Parkinson's disease or multiple sclerosis, no one can predict with certainty a person's illness course because of individual variation. Even when a patient is in remission or symptom free, he or she often fears that the illness will reappear.

Implications of Managing Chronic Conditions

Chronic conditions have implications for everyday living and management for those affected and their families as well as for society at large. Most importantly, individual efforts should be directed at preventing chronic conditions, since many chronic illnesses or disorders are linked to unhealthy lifestyles or behaviors such as smoking and overeating. Therefore, changes in lifestyle can prevent some chronic disorders, or at least delay onset until a later age. Because most people resist change, bringing about alterations in people's lifestyles is a major challenge for nurses today.

Once a chronic condition has occurred, the focus shifts to managing symptoms, avoiding complications (eg, eye complications in a person with diabetes), and avoiding the development of other acute illnesses (eg, pneumonia in a person with chronic obstructive lung disease). Quality of life, often overlooked by health professionals in their approach to people with chronic conditions, is also important. Health-promoting behaviors, such as exercise, are essential to quality of life even in people who have chronic illnesses and disabilities, because they help to maintain functional status (USDHHS, 2005a; Stuijbergen, Seraphine, Harrison, et al., 2005).

Although coworkers, extended family, and health care professionals are affected by chronic illnesses, the problems of living with chronic conditions are most acutely experienced by patients and their immediate families. They experience the greatest impact, with lifestyle changes that directly affect quality of life. Nurses provide direct care, especially during acute episodes, but they also provide the teaching and secure the resources and other supports that enable people to integrate their illnesses into their lives and to have an acceptable quality of life despite the illness. To understand what nursing care is needed, it is important to

recognize and appreciate the issues that people with chronic illness and their families contend with and manage, often on a daily basis. The challenges of living with chronic conditions include the need to accomplish the following:

- Alleviate and manage symptoms
- Psychologically adjust to and physically accommodate disabilities
- Prevent and manage crises and complications
- Carry out regimens as prescribed
- Validate individual self-worth and family functioning
- Manage threats to identity
- Normalize personal and family life as much as possible
- Live with altered time, social isolation, and loneliness
- Establish the networks of support and resources that can enhance quality of life
- Return to a satisfactory way of life after an acute debilitating episode (eg, another myocardial infarction or stroke) or reactivation of a chronic condition
- Die with dignity and comfort

Many people with chronic illness must face an additional challenge: the need to deal with more than one chronic illness at a time. The symptoms or treatment of a second chronic condition may aggravate the first chronic condition. Patients need to be able to deal with their various chronic conditions separately as well as in combination. Some Medicare beneficiaries have five or more chronic conditions, see an average of 13 physicians per year, and fill an average of 50 prescriptions per year (Anderson, 2005). Furthermore, the effects of increasing longevity among Americans are likely to increase health care costs in the future.

Even more challenging for many people with chronic illness is the need to hire and oversee caregivers who come into their homes to assist with ADLs and instrumental activities of daily living (IADLs). It is difficult for many people to be in a position of hiring, supervising, and sometimes firing people who may provide them with intimate physical care. The need to balance the role of recipient of care and oversight of the person providing care may lead to blurring of role boundaries.

The challenges of living with and managing a chronic illness are well known, and people with chronic illnesses often report receiving inadequate care, information, services, and counseling (Chart 10-1). This provides an opportunity for nurses to assume a more active role in addressing many of the issues experienced, coordinating care, and serving as an advocate for patients who need additional assistance to manage their illnesses while maintaining a quality of life that is acceptable to them.

Phases of Chronic Conditions

Chronic conditions can pass through different phases, as described in Table 10-2. However, this course may be too uncertain to predict with any degree of accuracy. The course of an illness can be thought of as a trajectory that can be managed or shaped over time, to some extent, through proper illness management strategies (Corbin, 1998). It is important to keep in mind that not all phases occur in all patients; some phases do not occur at all, and some phases may recur. Each phase is characterized by different medical and psychosocial issues. For example, the needs of a patient with a stroke who is a good candidate for rehabilitation are

Chart 10-1 • Characteristics of Patients With Chronic Illness in America

A representative sample of 24,053 people with one of six chronic health conditions (arthritis, asthma, hypertension, cardiovascular disease, depression, type 2 diabetes) or family caregivers of people with chronic illness were invited to participate in an online survey.

A total of 6447 people (4013 patients and 2434 family caregivers) completed the online survey. The findings reveal that people with chronic illnesses

- Experience greater gaps in economic and cultural access to the health care system than those without chronic illness
- Report having increasing difficulty affording health care
- Have high rates of unmet needs for support services, including home care and transportation, rehabilitation services, referral, and counseling
- Lack financial access to health care and to insurance coverage and affordability, as well as physical access
- Report poorer quality of life, fewer visits to health care providers, less knowledge about how to manage their illness, poorer relationships with their physicians, and less complete benefit from modern standards of care if they are uninsured or underinsured when compared with those who have adequate insurance
- Do not receive the information and services needed to manage their illness successfully
- Are infrequently advised by their physicians to make healthy behavior choices
- Do not receive recommended condition-specific tests and treatments about one half of the time
- Are at high risk for having unmet health-related needs
- Are less likely to receive appropriate levels of care, information, and attention from their physicians if they are members of minority groups, especially Hispanics, are poor, or are younger than 25 years of age
- Report that they do not receive adequate information and counseling about self-care from their physician, including information about medication therapy needed to avoid complications
- Report being confused about self-care activities even if they receive counseling about self-care from their physicians
- Report that treatment options and their pros and cons are not discussed with them by their physicians
- Report that their preferences regarding treatment are not taken into account and they do not feel that their physicians collaborate with them about management of their illness
- Do not feel fully involved in decisions about their own care and do not feel a sense of confidence about managing their illness
- Report that they were never advised or are confused about how to manage their illness
- Report having little sense of control over their lives and their illness
- Report infrequently receiving information or recommendations from their physicians about healthy behaviors (eg, exercise, weight control, smoking avoidance, misuse of alcohol, healthy eating)

Adapted from Robert Wood Johnson Foundation (2001). *A portrait of the chronically ill in America, 2001*. Report from the Robert Wood Johnson Foundation National Strategic Indicator Survey. Princeton, NJ: Robert Wood Johnson Foundation.

very different from those of a patient with terminal cancer. By thinking in terms of phases and individual patients within a phase, nurses can target their care more specifically to each person. Not every chronic condition is necessarily life-threatening, and not every patient passes through each possible phase of a chronic condition in the same order.

Using the trajectory model enables the nurse to put the present situation into the context of what might have happened to the patient in the past—that is, the life factors and understandings that might have contributed to the present state of the illness. In this way, the nurse can more readily address the underlying issues and problems.

Nursing Care of Patients With Chronic Conditions

Nursing care of patients with chronic conditions is varied and occurs in a variety of settings. Care may be direct or supportive. Direct care may be provided in the clinic or physician's office, a nurse-managed center or clinic, the hospital, or the patient's home, depending on the status of the illness. Examples of direct care include assessing the patient's physical status, providing wound care, managing and overseeing medication regimens, and performing other technical tasks. The availability of this type of nursing care may allow the patient to remain at home and return to a more normal life after an acute episode of illness. Nurses have also used "tele-

health" care (use of the telephone in health care) to monitor patients with chronic illnesses, deliver selected nursing interventions (eg, counseling), and provide ongoing education and support (Coyle, Duffy & Martin, 2007).

Because much of the day-to-day responsibility for managing chronic conditions rests with the patient and family, nurses often provide supportive care at home. Supportive care may include ongoing monitoring, teaching, counseling, serving as an advocate for the patient, making referrals, and managing the case. Giving supportive care is just as important as giving technical care. For example, through ongoing monitoring either in the home or in a clinic, a nurse might detect early signs of impending complications and make a referral (ie, contact the physician or consult the medical protocol in a clinic) for medical evaluation, thereby preventing a lengthy and costly hospitalization.

Working with people with chronic illness or disability requires not just dealing with the medical aspects of their disorder, but also working with the whole person—physically, emotionally, and socially. This holistic approach to care requires nurses to draw on their knowledge and skills, including knowledge from the social sciences and psychology in particular. People often respond to illness, health teaching, and regimens in ways that differ from the expectations of health care providers. Although quality of life is usually affected by chronic illness, especially if the illness is severe, patients' perceptions of what constitutes quality of life often drive their management behaviors or affect how they view

Phase	Description	Focus of Nursing Care
Pretrajectory	Genetic factors or lifestyle behaviors that place a person or community at risk for a chronic condition	Refer for genetic testing and counseling if indicated; provide education about prevention of modifiable risk factors and behaviors
Trajectory onset	Appearance or onset of noticeable symptoms associated with a chronic disorder; includes period of diagnostic workup and announcement of diagnosis; may be accompanied by uncertainty as patient awaits a diagnosis and begins to discover and cope with implications of diagnosis	Provide explanations of diagnostic tests and procedures and reinforce information and explanations given by primary health care provider; provide emotional support to patient and family
Stable	Illness course and symptoms are under control as symptoms, resulting disability and everyday life activities are being managed within limitations of illness; illness management centered in the home	Reinforce positive behaviors and offer ongoing monitoring; provide education about health promotion and encourage participation in health promoting activities and health screening
Unstable	Characterized by an exacerbation of illness symptoms, development of complications, or reactivation of an illness in remission Period of inability to keep symptoms under control or reactivation of illness; difficulty in carrying out everyday life activities May require more diagnostic testing and trial of new treatment regimens or adjustment of current regimen, with care usually taking place at home	Provide guidance and support; reinforce previous teaching
Acute	Severe and unrelieved symptoms or the development of illness complications necessitating hospitalization, bed rest, or interruption of the person's usual activities to bring illness course under control	Provide direct care and emotional support to the patient and family members
Crisis	Critical or life-threatening situation requiring emergency treatment or care and suspension of everyday life activities until the crisis has passed	Provide direct care, collaborate with other health care team members to stabilize patient's condition
Comeback	Gradual recovery after an acute period and learning to live with or to overcome disabilities and return to an acceptable way of life within the limitations imposed by the chronic condition or disability; involves physical healing, limitations stretching through rehabilitative procedures, psychosocial coming-to-terms, and biographical reengagement with adjustments in everyday life activities	Assist in coordination of care; rehabilitative focus may require care from other health care providers; provide positive reinforcement for goals identified and accomplished
Downward	Illness course characterized by rapid or gradual worsening of a condition; physical decline accompanied by increasing disability or difficulty in controlling symptoms; requires biographical adjustment and alterations in everyday life activities with each major downward step	Provide home care and other community-based care to help patient and family adjust to changes and come to terms with these changes; assist patient and family to integrate new treatment and management strategies; encourage identification of end-of-life preferences and planning
Dying	Final days or weeks before death; characterized by gradual or rapid shutting down of body processes, biographical disengagement and closure, and relinquishment of everyday life interests and activities	Provide direct and supportive care to patients and their families through hospice programs

Adapted from Corbin, J. M. (1998). The Corbin and Strauss Chronic Illness Trajectory Model: An update. *Scholarly Inquiry for Nursing Practice*, 12(1), 33–41.

advice about health care. Nurses and other health care professionals need to recognize this, even though it may be difficult to see patients make unwise choices and decisions about lifestyles and disease management. People have the right to receive care without fearing ridicule or refusal of treatment, even if their behaviors (eg, smoking, substance abuse, overeating, failure to follow health care providers' recommendations) may have contributed to their chronic disorders.

Applying the Nursing Process Using the Phases of the Chronic Illness System

The focus of care for patients with chronic conditions is determined largely by the phase of the illness and is directed by the nursing process, which includes assessment, diagnosis, planning, implementation, and evaluation.

Step 1: Identifying Specific Problems and the Trajectory Phase

The first step is assessment of the patient to determine the specific problems identified by the patient, family, nurse, and other health care providers. Assessment enables the nurse to identify the specific medical, social, and psychological problems likely to be encountered in a phase. For instance, the problems of a patient with an acute myocardial infarction are very different from those likely to occur with the same patient, 10 years later, dying at home of heart failure. The types of direct care, referrals, teaching, and emotional support needed in each situation are different as well. Because complementary and alternative therapies are often used by people with chronic illness, it is important to determine whether a patient with a chronic illness is using these regimens.

Step 2: Establishing and Prioritizing Goals

Once the phase of illness has been identified for a specific patient, along with the specific medical problems and related social and psychological problems, the nurse helps prioritize problems and establish the goals of care. Identification of goals must be a collaborative effort, with the patient, family, and nurse working together, and the goals must be consistent with the abilities, desires, motivations, and resources of those involved.

Step 3: Defining the Plan of Action to Achieve Desired Outcomes

Once goals have been established, it is necessary to identify a realistic and mutually agreed-on plan for achieving them, including specific criteria that will be used to assess the patient's progress. The identification of the person responsible for each task in the action plan is also essential.

In addition, identification of the environmental, social, and psychological factors that might interfere with or facilitate achieving the desired outcome is an important part of planning.

Step 4: Implementing the Plan and Interventions

This step addresses implementation of the plan. Possible nursing interventions include providing direct care, serving as an advocate for the patient, teaching, counseling, making referrals, and managing the case (eg, arranging for resources). Nurses can help patients implement the actions that allow patients to live with the symptoms and therapies associated with chronic conditions, thus helping them to gain independence. The nurse works with each patient and family to identify the best ways to integrate treatment regimens into their ADLs to accomplish two tasks: (1) adhering to regimens to control symptoms and keep the illness stable, and (2) dealing with the psychosocial issues that can hinder illness management and affect quality of life. Helping patients and their families to understand and implement regimens and to carry out ADLs within the limits of the chronic illness or disability is an important aspect of nursing care for patients with chronic disorders and disabilities and their families.

Step 5: Following Up and Evaluating Outcomes

The final step involves following up to determine if the problem is resolving or being managed and if the patient and family are adhering to the plan. This follow-up may uncover the existence of new problems resulting from the intervention, problems that interfere with the ability of the patient and family to carry out the plan, or previously unexpected problems. Maintaining the stability of the chronic condition while preserving the patient's control over his or her life and the patient's sense of identity and accomplishment is a primary goal. Based on the follow-up and evaluation, consideration of alternative strategies or revision of the initial plan may be warranted.

Helping the patient and family to integrate changes into their lifestyle is an important part of the process. Change takes time, patience, and creativity and often requires encouragement from the nurse. Validation by the nurse for each small increment toward goal accomplishment is im-

portant for enhancing self-esteem and reinforcing behaviors. Success may be defined as making some progress toward a goal when a patient is unable to implement rapid and dramatic changes in his or her life. If no progress is made, or if progress toward goals seems too slow, it may be necessary to redefine the goals, the intervention, or the time frame. The nurse must realize and accept that some people will not change. Patients share responsibility for management of their conditions, and outcomes are as much related to their ability to accommodate the illness and carry out regimens as they are to nursing intervention.

Home and Community-Based Care

Teaching Patients Self-Care

Because chronic conditions are so costly to people, families, and society, one of the major goals of nursing today should be the prevention of chronic conditions and the care of people with them. This requires promoting healthy lifestyles and encouraging the use of safety and disease-prevention measures, such as wearing seat belts and obtaining immunizations. Prevention should also begin early in life and continue throughout life. Self-care teaching may need to address interactions among the patient's chronic conditions as well as skills necessary to care for the individual diseases and their interactive effects.

Patient and family teaching is an important nursing role that may make the difference in the ability of the patient and family to adapt to chronic conditions. Well-informed, educated patients are more likely than uninformed patients to be concerned about their health and to do what is necessary to maintain it. They are also more likely to manage symptoms, recognize the onset of complications, and seek health care early. Knowledge is the key to making informed choices and decisions during all phases of the chronic illness trajectory.

Despite the importance of teaching the patient and family, the nurse must recognize that patients recently diagnosed with serious chronic conditions and their families may need time to understand the significance of their condition and its effect on their lives. Teaching must be planned carefully so that it is not overwhelming. Furthermore, it is important to assess the impact of a new diagnosis of chronic illness on a patient's life and the meaning of self-management to the patient (Kocaman, Kutlu, Özkan, et al., 2007).

The nurse who cares for patients with chronic conditions in the hospital, clinic, or home should assess each patient's knowledge about his or her illness and its management; the nurse cannot assume that a patient with a long-standing chronic condition has the knowledge necessary to manage the condition. Learning needs change as the trajectory phase and the patient's personal situation change. The nurse must also recognize that patients may know how their body responds under certain conditions and how best to manage their symptoms. Contact with patients in the hospital, clinic, nursing center, home, or long-term care facility offers nurses the ideal opportunity to reassess patients' learning needs and to provide additional teaching about an illness and its management.

Teaching strategies and teaching materials should be adapted to the individual patient, so that the patient and

family can understand and follow recommendations from health care providers. For instance, teaching materials should be tailored for people with low literacy levels and available in several languages and in various alternative formats (eg, Braille, large print, audiotapes). It may be necessary to provide sign interpreters.

Continuing Care

Chronic illness management is a collaborative process between the patient, family, nurse, and other health care providers. Collaboration extends to all settings and throughout the illness trajectory. Keeping an illness stable over time requires careful monitoring of symptoms and attention to management regimens. Detecting problems early and helping patients develop appropriate management strategies can make a significant difference in outcomes.

Most chronic conditions are managed in the home. Therefore, care and teaching during hospitalization should focus on essential information about the condition so that management can continue once the patient is discharged home. Nurses in all settings should be aware of the resources and services available in a community and should make the arrangements (before hospital discharge, if the patient is hospitalized) that are necessary to secure those resources and services. When appropriate, home care services are contacted directly. The home care nurse reassesses how the patient and family are adapting to the chronic condition and its treatment and continues or revises the plan of care accordingly.

Because chronic conditions occur worldwide and the world is increasingly interconnected, nurses should think beyond the personal level to the community and global levels. In terms of illness prevention and health promotion, this entails wide-ranging efforts to assess people for risks of chronic illness (eg, blood pressure and diabetes screening, stroke risk assessments) and group teaching related to illness prevention and management.

In addition, nurses should also remind patients with chronic illnesses or disabilities and their families about the need for ongoing health promotion and screening recommended for all people, because chronic illness and disability are often considered the main concern while other health-related issues are ignored.

Nursing Care for Special Populations With Chronic Illness

When providing care and teaching, the nurse must consider a variety of factors (eg, age, gender, culture and ethnicity, cognitive status, the presence of physical and sensory limitations) that influence susceptibility to chronic illness and the ways patients respond to chronic disorders. Certain populations, for example, tend to be more susceptible to certain chronic conditions. Populations at high risk for specific conditions can be targeted for special teaching and monitoring programs; this includes those at risk because of their genetic profile (see Chapter 9 for further discussion of genetics). People of different cultures and genders may respond to illness differently, and being aware of these differences is essential. For cultures in which patients rely heavily on the support of their families, the families must be involved and

made part of the nursing plan of care. As the United States becomes more multicultural and ethnically diverse, and as the general population ages, nurses need to be aware of how a person's culture and age affect chronic illness management and be prepared to adapt their care accordingly.

It is also important to consider the effect of a preexisting disability, or a disability associated with recurrence of a chronic condition, on the patient's ability to manage ADLs, self-care, and the therapeutic regimen. These issues are discussed in the following section.

Overview of Disability

Definitions of Disability

A person is considered to have a disability such as a limitation in performance or function in everyday activities if he or she has difficulty talking, hearing, seeing, walking, climbing stairs, lifting or carrying objects, performing ADLs, doing school work, or working at a job. A severe disability is present if a person is unable to perform one or more activities, uses an assistive device for mobility, or needs help from another person to accomplish basic activities. People are also considered severely disabled if they receive federal benefits because of an inability to work.

The World Health Organization (WHO) once defined a disability as a limitation in a person's abilities (eg, mobility, personal care, communication, behavior), an **impairment** as a body system or function affected (eg, neurologic, respiratory, urologic), and a **handicap** as a disadvantage experienced by a person in his or her environment (eg, workplace, economic sufficiency, independence) (WHO, 1980). In an effort to change the focus from a classification based on *disease* to one based on *health*, these definitions were revised in 2001. According to the WHO, *disability* is an umbrella term for impairments, activity limitations, participation restrictions, and environmental factors, and *impairment* is a loss or abnormality in body structure or physiologic function, including mental function. A person's functioning or disability is viewed as a dynamic interaction between health conditions (ie, diseases, disorders, injuries, trauma) and contextual factors (ie, personal and environmental factors) (WHO, 2001).

The term *handicap* is no longer included in the revised WHO classification system: *International Classification of Functioning, Disability and Health—ICF* (WHO, 2001). The term was used previously to identify those circumstances in which the environment played a role in limiting the participation of people with disabilities in activities. The term *societal participation* is used in the revised WHO classification system in place of *handicap* to acknowledge the fact that the environment is always interacting with people to either assist or hinder participation in life activities. The revision of the classification system acknowledges that the environment may have a greater impact on the ability of an individual to participate in life activities than does the physical, mental, or emotional condition.

Federal legislation uses more than 50 definitions of disability, which illustrates how difficult it is to define the term. The Americans With Disabilities Act of 1990 (ADA; discussed later) defines a person with a **disability** as one who

(1) has a physical or mental impairment that substantially limits one or more major life activities, (2) has a record of such an impairment, or (3) is regarded as having such an impairment. Other terms used to describe people with disabilities that are not universally accepted or understood are “people who are physically challenged,” and “people with special needs.”

Another approach to disability is described by Lutz and Bowers (2005), who stated that none of the existing definitions adequately addresses disability in everyday life. They defined disability as a multifaceted, complex experience that is integrated into the lives of people with disabilities. The degree of the integration is influenced by three disability-related factors: (1) the effects of the disabling condition, (2) others’ perceptions of disability, and (3) the need for and use of resources by the person with a disability.

Prevalence of Disability

An estimated 54 to 60 million people in the United States have disabilities (U.S. Census Bureau, 2005); they compose the nation’s third largest minority. The number of people with disabilities is expected to increase over time as people with early-onset disabilities, chronic disorders, and severe trauma survive and have normal or near-normal lifespans (Cristian, 2005). In addition, changes in the demographic profile are resulting in an increased number of older people with chronic illnesses and disabilities. As the population ages, the prevalence of disability is expected to increase. Although disability is often perceived as being associated only with old age, national data demonstrate that disability occurs across the lifespan; however, its incidence increases with age (U.S. Census Bureau, 2005; USDHHS, 2005a).

The U.S. Census, last conducted in 2000, indicates that 20% of people have a disability and 10% have a severe disability. More than 32 million Americans, or 1 in every 10 Americans, have a severe disability. A total of 72.3 million families have at least one family member with a disability. More than 46% of people with one disability have other disabilities. More than 50% of people with a disability are women. Although the prevalence of disability is higher in males than in females for people younger than 65 years of age, the prevalence is higher in women than in men for people older than 65 years of age. Among people 65 years of age and older, almost 60% of those with disabilities are women (U.S. Census Bureau, 2005).

Currently, more than 10 million people need personal assistance with one or more ADLs, which include bathing, dressing, feeding, and toileting, or IADLs, which include grocery shopping, meal preparation, housekeeping, transportation, and managing finances. In addition, more than 9.3 million people have sensory disabilities that affect hearing or vision. About 5 million people use a cane, more than 2 million use a wheelchair, and at least 1 million use crutches or a walker.

Among all people 21 to 64 years of age (the prime employable years), approximately 33% of people with a severe disability and 77% of those with a nonsevere disability are employed, compared with 82% of people without a disability. However, employed people with a disability earn less money than people without disabilities (U.S. Census Bureau, 2005). Furthermore, 17.5% of people with disabilities live in poverty. Many people with disabilities who are unemployed want to work; however, they are often unable to

do so because of the limited access to work settings, lack of accommodations in the workplace, reluctance of employers to hire them, and financial risk if their income exceeds eligibility limits to qualify for disability benefits.

Characteristics of Disability

Categories and Types of Disability

Disabilities can be categorized as developmental disabilities, acquired disabilities, and age-associated disabilities. Developmental disabilities are those that occur any time from birth to 22 years of age and result in impairment of physical or mental health, cognition, speech, language, or self-care. Examples of developmental disabilities are spina bifida, cerebral palsy, Down syndrome, and muscular dystrophy (Chart 10-2). Some developmental disabilities occur as a result of birth trauma or severe illness or injury at a very young age, whereas many developmental disabilities are genetic in origin (see Chapter 9). Acquired disabilities may occur as a result of an acute and sudden injury (eg, traumatic brain injury, spinal cord injury, traumatic amputation), acute nontraumatic disorders (eg, stroke, myocardial infarction), or progression of a chronic disorder (eg, arthritis, multiple sclerosis, chronic obstructive pulmonary disease, blindness due to diabetic retinopathy). Age-related disabilities are those that occur in the elderly population and are thought to be due to the aging process. Examples of age-related disabilities include osteoarthritis, osteoporosis, and hearing loss. Because people with disabilities, including those with severe developmental disabilities, are surviving longer than ever before, there is a growing number of young, middle-age, and elderly adults with disabilities, including developmental disabilities.

Types of disability include sensory disabilities that affect hearing or vision; learning disabilities that affect the ability to learn, remember, or concentrate; disabilities that affect the ability to speak or communicate; and disabilities that affect the ability to work, shop, care for oneself, or obtain health care (U.S. Census Bureau, 2005). Many disabilities are visible, but invisible disabilities are often as disabling as those that can be seen. Some disabilities affect only IADLs, whereas others affect ADLs. People can be temporarily disabled because of an injury or acute exacerbation of a chronic disorder but later return to full functioning; this definition of disability may not apply for legal purposes.

Although different impairments may result from different types of disabilities, there are some similarities across disabilities. People with disabilities are often considered by society to be dependent and in need of care from others; however, many people with disabilities are highly functioning, independent, productive people who are capable of caring for themselves and others, having children and raising families, holding a full-time job, and making significant and major contributions to society (Fig. 10-1). Like other people, those with disabilities often prefer to live in their own homes with family members. Most people with disabilities are able to live at home independently. Some patients live alone in their own homes and use home care services. However, alternative living arrangements may be necessary; these include assisted living facilities, long-term care facilities, and group homes.

NURSING RESEARCH PROFILE

Health Experiences of Adults With Neural Tube Defects

Nehring, W. M. & Faux, S. A. (2006). Transitional and health issues of adults with neural tube defects. *Journal of Nursing Scholarship*, 38(1), 63–70.

Purpose

Increasing numbers of people with neural tube defects (NTDs; eg, spina bifida) are living well into adulthood because of better health care and medical management. However, although survival rates of people born with NTDs have increased, the experiences of people with NTDs are largely unexplored. Furthermore, the experiences of adults with NTDs from minority populations are unknown. The purpose of this study was to explore the health-related and life experiences of Caucasian, African American, and Mexican American adults with NTDs.

Design

A descriptive, qualitative research design was used in which individual interviews were conducted with 16 Caucasian, 11 African American, and 15 Mexican American adults with NTDs at the thoracic, sacral, or lumbar areas of the spine. Most interviews were conducted in person; three were conducted by telephone. A semistructured interview guide was used to obtain data about each study participant, including information about health status and secondary conditions, health care management, current physical functioning, sexuality, independence, self-care, mobility, social activities and relationships, and cultural and religious influences. Qualitative data analysis methods were used to analyze the interview transcripts.

Findings

Three themes identified across all three groups were uncertainty about the future, access to health care and information, and advocacy. Concerns regarding uncertainty about the future related to health, mortality and lifespan, sexuality, marriage and family, mobility, and self-care. Participants in all groups identified sexuality and pregnancy as important issues. Issues of mobility and deterioration of health status with aging were major concerns. Concerns about access to health care and information related in part to barriers to care as well as to the need for health care providers who were knowledgeable about their conditions and about their complex medical histories. Concerns about the ability to advocate for themselves for information, independence, and acceptance by others, including family members, were also issues.

Nursing Implications

Nurses in contact with adults with developmental disabilities need to assess these people's concerns and assist them in identifying and accessing appropriate health care and services. Although adults with developmental disabilities have usually received information about management of conditions associated with their disability as children, the transitions that occur throughout life mandate that current learning needs be assessed and addressed. Learning needs include self-advocacy skills.

Models of Disability

Several models of disability have been used to address or explain the issues encountered by people with disabilities (Smeltzer, 2007a). These include the medical and rehabilitation models, the social model, the biopsychosocial model,

Figure 10-1 Many people with disabilities lead full, productive lives. A woman attends college classes.

and the interface model. Chart 10-3 briefly describes these models of disability. Of these, the interface model (Goodall, 1995) may be the most appropriate for use by nurses to provide care that is empowering rather than care that promotes dependency. The interface model does not ignore the disabling condition or its disabling effects; instead, it promotes the view that people with disabilities are capable, responsible people who are able to function effectively despite having a disability. The interface model can serve as a basis for the role of nurses as advocates for removal of barriers to health care and for examination of how society and health care professionals contribute to discrimination by viewing disability as an abnormal state.

Disability Versus Disabling Disorders

Regardless of which definition or model of disability is adopted, it is important to realize that it is possible to understand the pathophysiology of a disabling condition or injury or be very knowledgeable about the physical changes resulting from a disorder without understanding the concept of disability. The nurse who cares for patients with pre-existing disabilities or new disabilities must recognize the impact of a disability on current and future health and well-being, the ability to participate in self-care or self-management, and the ability to obtain required health care and health screening. Nursing management, from assessment through evaluation of the effectiveness of nursing interventions, must be examined to determine whether appropriate modifications have been made to ensure that those with

Chart 10-3 • Models of Disability

Medical Model

This model equates people who are disabled with their disabilities and views disability as a problem of the person, directly caused by disease, trauma, or other health condition, which requires medical care provided in the form of individual treatment by professionals. Health care providers, rather than people with disabilities, are viewed as the experts or authorities. Management of the disability is aimed at cure or the person's adjustment and behavior change. The model is viewed as promoting passivity and dependency. People with disabilities are viewed as tragic (Goodall, 1995; Scullion, 1999, 2000; World Health Organization, 2001; Lollar & Crews, 2003).

Rehabilitation Model

The rehabilitation model emerged from the medical model. It regards disability as a deficiency that requires a rehabilitation specialist or other helping professional to fix the problem. People with disabilities are often perceived as having failed if they do not overcome the disability (Lollar & Crews, 2003).

Social Model

The social model, which is also referred to as the barriers or disability model, views disability as socially constructed and

as a political issue that is a result of social and physical barriers in the environment. Its perspective is that disability can be overcome by removal of these barriers (French, 1992; Richardson, 1997; Shakespeare & Watson, 1997; World Health Organization, 2001).

Biopsychosocial Model

The biopsychosocial model integrates the medical and social models to address perspectives of health from a biologic, individual, and social perspective (World Health Organization, 2001; USDHHS, 2005a). Critiques of this model have suggested that the disabling condition, rather than the person and the experience of the person with a disability, remains the defining construct of the biopsychosocial model (Lutz & Bowers, 2005).

Interface Model

The interface model is based on the life experience of the person with a disability and views disability at the intersection (ie, interface) of the medical diagnosis of a disability and environmental barriers. It considers rather than ignores the diagnosis. The person with a disability, rather than others, defines the problems and seeks or directs solutions (Goodall, 1995).

disabilities receive health care equal to that of people without disabilities. Furthermore, nurses as well as other health care providers need to examine their facilities and procedures to ensure that the needs of people with a variety of disabilities can be adequately addressed. Although the health care needs of people with disabilities generally do not differ from those of the general population, some disabilities create special needs and necessitate the use of special accommodations. Chart 10-4 reviews specific areas of assessment when caring for people with disabilities.

Federal Legislation

Because of widespread discrimination against people with disabilities, the U.S. Congress has enacted legislation to address health care disparities in this population. This legislation includes the Rehabilitation Act of 1973 and the ADA. Health care in people with disabilities has received further national attention through the first-time inclusion of specific national objectives that address health care for people with disabilities in *Healthy People 2010* (USDHHS, 2005b). In 2005, the U.S. surgeon general called for action to improve the health and wellness of people with disabilities (Smeltzer, 2007a; USDHHS, 2005a).

The Rehabilitation Act of 1973 is a law that protects people from discrimination based on their disabilities. The act applies to employers and organizations that receive financial assistance from any federal department or agency; this includes many hospitals, long-term care facilities, mental health centers, and human service programs. It forbids organizations from excluding or denying people with disabilities equal access to program benefits and services. It also prohibits discrimination related to availability, accessibility, and delivery of services, including health care services.

The ADA of 1990 mandates that people with disabilities have access to job opportunities and to the community. It requires that employers evaluate an applicant's ability to perform the job and not discriminate on the basis of a disability. According to the ADA, communities must provide public transportation that is accessible to people with disabilities. The ADA also requires that "reasonable accommodations" be provided to facilitate employment of a person with a disability. Facilities used by the public must be accessible and accommodate those with disabilities. Examples of reasonable accommodations in health care settings include accessible facilities and equipment (eg, accessible restrooms, adjustable examination tables, access ramps, grab bars, elevated toilet seats) and alternative communication methods (eg, telecommunication devices and sign interpreters for use by people who are deaf).

Although the ADA took effect in 1992, compliance has been slow, and some facilities continue to be inaccessible. However, all new construction and modifications of public facilities must address access for people with disabilities. Examples of modifications that are needed to provide equal access to health care to people with disabilities are identified in Chart 10-4.

Right of Access to Health Care

People with disabilities have the right of access to health care that is equal in quality to that of other people. For years, people with disabilities have been discriminated against in employment, public accommodations, and public and private services, including health care. The needs of the people with disabilities in health care settings present

Chart 10-4 • Strategies to Ensure Quality Health Care for People With Disabilities**Communication Strategies**

- Does the patient with a disability require or prefer accommodations (eg, a sign interpreter) to ensure full participation in conversations about his or her own health care?
- Are appropriate accommodations made to communicate with the patient?
- Are efforts made to direct all conversations to the patient rather than to others who have accompanied the patient to the health care facility?

Accessibility of the Health Care Facility

- Are clinics, hospital rooms, offices, restrooms, laboratories, and imaging facilities accessible to people with disabilities, as legally required by the Americans With Disabilities Act and Rehabilitation Act?
- Has accessibility been verified by a person with a disability?
- Is a sign interpreter other than family member available to assist in obtaining a patient's health history and in conducting a physical assessment?
- Does the facility include appropriate equipment to permit people with disabilities to obtain health care (including mammography, gynecologic examination and care, dental care) in a dignified and safe manner?

Assessment**Usual Health Considerations**

- Does the health history address the same issues that would be included when obtaining a history from a person without disabilities, including sexuality, sexual function, and reproductive health issues?

Disability-Related Considerations

- Does the health history address the patient's specific disability and the effect of disability on the patient's ability to obtain health care, manage self-care activities, and obtain preventive health screening and follow-up care?
- What physical modifications and positioning are needed to ensure a thorough physical examination, including pelvic or testicular and rectal examination?

Abuse

- Is the increased risk for abuse (physical, emotional, financial, and sexual) by a variety of people (family, paid care providers, strangers) addressed in the assessment?
- If abuse is detected, are men and women with disabilities who are survivors of abuse directed to appropriate resources, including accessible shelters and hotlines?

Depression

- Is the patient experiencing depression? If so, is treatment offered just as it would be to a patient without a disability, without assuming that depression is normal and a result of having a disability?

Aging

- What concerns does the patient have about aging with a preexisting disability?
- What effect has aging had on the patient's disability and what effect has the disability had on the patient's aging?

Secondary Conditions

- Does the patient have secondary conditions related to his or her disability or its treatment?

- Is the patient at risk for secondary conditions because of environmental barriers or lack of access to health care or health promotion activities?
- Are strategies in place to reduce the risk for secondary conditions or to treat existing secondary conditions?

Accommodations in the Home

- What accommodations does the patient have at home to encourage or permit self-care?
- What additional accommodations does the patient need at home to encourage or permit self-care?

Cognitive Status

- Is it assumed that the patient is able to participate in discussion and conversation rather than assuming that he or she is unable to do so because of a disability?
- Are appropriate modifications made in written and verbal communication strategies?

Modifications in Nursing Care

- Are modifications made during hospital stays, acute illness or injury, and other health care encounters to enable a patient with disability to be as independent as he or she prefers?
- Is "person-first language" used in referring to a patient with disability, and do nurses and other staff talk directly to the patient rather than to those who accompanied the patient?
- Are all staff informed about the activities of daily living (ADLs) for which the patient will require assistance?
- Are accommodations made to enable the patient to use his or her assistive devices (hearing/visual aids, prostheses, limb support devices, ventilators, service animals)?
- If a patient with disability is immobilized because of surgery, illness, injury, or treatments, are risks of immobility addressed and strategies implemented to minimize those risks?
- Is the patient with a disability assessed for other illnesses and health issues (eg, other acute or chronic illness, depression, psychiatric/mental health and cognitive disorders) not related to his or her primary disability?

Patient Teaching

- Are accommodations and alternative formats of teaching materials (large print, Braille, visual materials, audiotapes) provided for patients with disabilities?
- Does patient teaching address the modifications (eg, use of assistive devices) needed by patients with disabilities to enable them to adhere to recommendations?
- Are modifications made in teaching strategies to address learning needs, cognitive changes, and communication impairment?

Health Promotion and Disease Prevention

- Are health promotion strategies discussed with people with disabilities along with their potential benefits: improving quality of life and preventing secondary conditions (health problems that result because of preexisting disability)?
- Are patients aware of accessible community-based facilities (eg, health care facilities, imaging centers, public

Continued

Chart 10-4 • Strategies to Ensure Quality Health Care for People With Disabilities (Continued)

exercise settings, transportation) to enable them to participate in health promotion?

Independence Versus Dependence

- Is independence, rather than dependence, of the person with a disability the focus of nursing care and interaction?
- Are care and interaction with the patient focused on empowerment rather than promoting dependence of the patient?

Insurance Coverage

- Does the patient have access to the health insurance coverage and other services for which he or she qualifies?
- Is the patient aware of various insurance and other available programs?
- Would the patient benefit from talking to a social worker about eligibility for Medicaid, Medicare, Disability Insurance, and other services?

many challenges to health care providers: how to communicate effectively if there are communication deficits, the additional physical requirements for mobility, and time required to provide assistance with self-care routines during hospitalization. Health care providers, including nurses, may not be aware of the specific needs of people with disabilities and may fail to provide appropriate care and services for them. However, it is essential that health care providers, including nurses, realize that people with disabilities have a legally mandated right to accessible health care facilities for all medical care and screening procedures. Furthermore, people with disabilities have the right to health care provided by professionals who are knowledgeable about and sensitive to the effects of disability on access to health care, including care that addresses their reproductive issues and sexuality. Reasonable accommodations are mandated by law and are the financial responsibility of the health care provider or facility. People with disabilities should not be expected to provide their own accommodations (eg, sign interpreters, assistants). Family members should not be expected to serve as interpreters because of concern for the patient's privacy and confidentiality and the risk of errors in interpreting information by either the patient or the health care provider. Chart 10-5 identifies strategies to communicate effectively with people with disabilities.

In response to continued accessibility issues, the U.S. surgeon general issued a *Call to Action to Improve the Health and Wellness of Persons with Disabilities* (USDHHS, 2005a). This report recognized that all persons with disabilities need to have access to comprehensive health care so that they are able to have full, engaged, and productive lives in their own communities. Among strategies to accomplish this, the document stipulated that health care professionals need to become knowledgeable about disability. It further recommended that schools training people for the health professions teach about disability and address the need for increased availability of methods to screen, diagnose, and treat the whole person with a disability with dignity.

In an effort to improve the health care of people with disabilities, Senator Thomas Harkin proposed bill S. 1050, "Promoting Wellness for Individuals with Disabilities Act of 2007" in the U.S. Senate in 2007. This bill would amend the Rehabilitation Act of 1973 to require that standards be set for medical diagnostic equipment to ensure that such equipment is accessible to and usable by individuals with

disabilities. The amended act would apply to examination tables and chairs, weight scales, mammography equipment, and other equipment commonly used for diagnostic purposes by health professionals (Congressional Record, 2007). The bill would also increase training programs to improve competency and clinical skills of health care professionals who provide health care and communicate with patients with disabilities by integrating the topic of disability into curricula.

Barriers to Health Care

Many people with disabilities encounter barriers to full participation in life, including health care, health screening, and health promotion (Nehring & Faux, 2006; Smeltzer, Sharts-Hopko, Ott, et al., 2007). Some of these barriers are structural and make certain facilities inaccessible. Examples of structural barriers include stairs, lack of ramps, narrow doorways that do not permit entry of a wheelchair, and restroom facilities that cannot be used by people with disabilities (eg, restrooms that lack grab bars and those that lack larger restroom stalls designed for people using wheelchairs) (Kirschner, Breslin & Iezzoni, 2007).

Structural barriers to accessibility are most easily identified and eliminated. Other, less visible barriers include negative and stereotypic attitudes (eg, believing that all people with disabilities have a poor quality of life and are dependent and nonproductive) on the part of the public. Health care providers with similar negative attitudes make it difficult for people with disabilities to obtain health care equal in quality to that of people without disabilities. The Rehabilitation Act and the ADA were enacted more than 30 and 15 years ago, respectively, to ensure equal access to people with disabilities, but people with disabilities continue to encounter and report multiple barriers to health care facilities and providers (Smeltzer, et al., 2007). This legislation and the U.S. surgeon general's call to improve the health and wellness of people with disabilities (USDHHS, 2005a) are examples of efforts to eliminate barriers encountered by people with disabilities.

People with disabilities have reported that they often encounter barriers that prevent them from obtaining recommended health care screening and care. They have also reported lack of access to information, transportation difficulties, inability to pay because of limited income, difficulty finding a health care provider knowledgeable about their particular disability, previous negative health care encounters, reliance on caregivers, and the demands

Chart 10-5 • Interacting and Communicating With People With Disabilities

Patients will feel most comfortable receiving health care if you consider the following suggestions.

General Considerations

- Do not be afraid to make a mistake when interacting and communicating with someone with a disability or chronic medical condition. Keep in mind that a person with a disability is a person first, and is entitled to the dignity, consideration, respect, and rights you expect for yourself.
- Treat adults as adults. Address people with disabilities by their first names only if extending the same familiarity to all others present. Never patronize people by patting them on the head or shoulder.
- Relax. If you do not know what to do, allow the person who has a disability to identify how you may be of assistance and to put you at ease.
- If you offer assistance and the person declines, do not insist. If your offer is accepted, ask how you can best help, and follow directions. Do not take over.
- If someone with a disability is accompanied by another individual, address the person with a disability directly rather than speaking through the accompanying companion.
- Be considerate of the extra time it might take for a person with a disability to get things done or said. Let the person set the pace.
- Do not be embarrassed to use common expressions such as, “See you later,” or “Got to be running,” that seem to relate to the person’s disability.
- Use person-first language: refer to “a person with a disability” rather than “a disabled person,” and avoid referring to people by the disability or disorder they have (eg, “the diabetic”).

Mobility Limitations

- Do not make assumptions about what a person can and cannot do.
- Do not push a person’s wheelchair or grab the arm of someone walking with difficulty without first asking if you can be of assistance and how you can assist. Personal space includes a person’s wheelchair, scooter, crutches, walker, cane, or other mobility aid.
- Never move someone’s wheelchair, scooter, crutches, walker, cane, or other mobility aid without permission.
- When speaking for more than a few minutes to a person who is seated in a wheelchair, try to find a seat for yourself, so that the two of you are at eye level.
- When giving directions to people with mobility limitations, consider distance, weather conditions, and physical obstacles such as stairs, curbs, and steep hills.
- It is appropriate to shake hands when introduced to a person with a disability. People who have limited hand use or who wear an artificial limb do shake hands.

Vision Loss (Low Vision and Blindness)

- Identify yourself when you approach a person who has low vision or blindness. If a new person approaches, introduce him or her.
- It is appropriate to touch the person’s arm lightly when you speak so that he or she knows to whom you are speaking before you begin.
- Face the person and speak directly to him or her. Use a normal tone of voice.
- Do not leave without saying you are leaving.

- If you are offering directions, be as specific as possible, and point out obstacles in the path of travel. Use specifics such as, “Left about twenty feet,” or “Right two yards.” Use clock cues, such as, “The door is at 10 o’clock.”
- When you offer to assist someone with vision loss, allow the person to take your arm. This will help you to guide rather than propel or lead the person. When offering seating, place the person’s hand on the back or arm of the seat.
- Alert people with low vision or blindness to posted information.
- Never pet or otherwise distract a canine companion or service animal unless the owner has given you permission.

Hearing Loss (Hard of Hearing, Deaf, Deaf-Blind)

- Ask the person how he or she prefers to communicate.
- If you are speaking through a sign language interpreter, remember that the interpreter may lag a few words behind—especially if there are names or technical terms to be fingerspelled—so pause occasionally to allow the interpreter time to translate completely and accurately.
- Talk directly to the person who has hearing loss, not to the interpreter. However, although it may seem awkward to you, the person who has hearing loss will look at the interpreter and may not make eye contact with you during the conversation.
- Before you start to speak, make sure you have the attention of the person you are addressing. A wave, a light touch on the arm or shoulder, or other visual or tactile signals are appropriate ways of getting the person’s attention.
- Speak in a clear, expressive manner. Do not overenunciate or exaggerate words. Unless you are specifically requested to do so, do not raise your voice. Speak in a normal tone; do not shout.
- To facilitate lip reading, face the person and keep your hands and other objects away from your mouth. Maintain eye contact. Do not turn your back or walk around while talking. If you look away, the person might assume the conversation is over.
- Avoid talking while you are writing a message for someone with hearing loss, because the person cannot read your note and your lips at the same time.
- Try to eliminate background noise.
- Encourage feedback to assess clear understanding.
- If you do not understand something that is said, ask the person to repeat it or to write it down. The goal is communication; do not pretend to understand if you do not.
- If you know any sign language, try using it. It may help you communicate, and it will at least demonstrate your interest in communicating and your willingness to try.

Speech Disabilities or Speech Difficulties

- Talk to people with speech disabilities as you would talk to anyone else.
- Be friendly; start up a conversation.
- Be patient; it may take the person a while to answer. Allow extra time for communication. Do not speak for the person.
- Give the person your undivided attention.
- Ask the person for help in communicating with him or her. If the person uses a communication device such as a manual or electronic communication board, ask the person how best to use it.
- Speak in your regular tone of voice.

Continued

Chart 10-5 • Interacting and Communicating With People With Disabilities (Continued)

- Tell the person if you do not understand what he or she is trying to say. Ask the person to repeat the message, spell it, tell you in a different way, or write it down. Use hand gestures and notes.
- Repeat what you understand. The person's reactions will clue you in and guide you to understanding.
- To obtain information quickly, ask short questions that require brief answers or a head nod. However, try not to insult the person's intelligence with oversimplification.
- Keep your manner encouraging rather than correcting.

Intellectual/Cognitive Disabilities

- Treat adults with intellectual/cognitive disabilities as adults.
- Try to be alert to the individual's responses so that you can adjust your method of communication as necessary. For example, some people may benefit from simple, direct sentences or from supplementary visual forms of communication, such as gestures, diagrams, or demonstrations.
- Use concrete rather than abstract language. Be specific, without being too simplistic. When possible, use words that relate to things you both can see. Avoid using directional terms such as right, left, east, or west.
- Be prepared to give the person the same information more than once in different ways.
- When asking questions, phrase them to elicit accurate information. People with intellectual/cognitive disabilities may be eager to please and may tell you what they think you want to hear. Verify responses by repeating the question in a different way.
- Give exact instructions. For example, "Be back for lab work at 4:30," not "Be back in 15 minutes."
- Too many directions at one time may be confusing.
- The person may prefer information provided in written or verbal form. Ask the person how you can best relay the information.
- Using humor is fine, but do not interpret a lack of response as rudeness. Some people may not grasp the meaning of sarcasm or other subtleties of language.
- People with brain injuries may have short-term memory deficits and may repeat themselves or require information to be repeated.
- People with auditory perceptual problems may need to have directions repeated and may take notes to help them remember directions or the sequence of tasks. They may benefit from watching a task demonstrated.
- People with perceptual or "sensory overload" problems may become disoriented or confused if there is too much

to absorb at once. Provide information gradually and clearly. Reduce background noise if possible.

- Repeat information using different wording or a different communication approach if necessary. Allow time for the information to be fully understood.
- Do not pretend to understand if you do not. Ask the person to repeat what was said. Be patient, flexible, and supportive.
- Some people who have an intellectual disability are easily distracted. Try not to interpret distraction as rudeness.
- Do not expect all people to be able to read well. Some people may not read at all.

Psychiatric/Mental Health Disabilities

- Speak directly to the person. Use clear, simple communication.
- Offer to shake hands when introduced. Use the same good manners in interacting with a person who has a psychiatric/mental health disability that you would with anyone else.
- Make eye contact and be aware of your own body language. Like others, people with psychiatric/mental health disabilities will sense your discomfort.
- Listen attentively and wait for the person to finish speaking. If needed, clarify what the person has said. Never pretend to understand.
- Treat adults as adults. Do not patronize, condescend, or threaten. Do not make decisions for the person or assume that you know the person's preferences.
- Do not give unsolicited advice or assistance. Do not panic or summon an ambulance or the police if a person appears to be experiencing a mental health crisis. Calmly ask the person how you can help.
- Do not blame the person. A person with a psychiatric disability has a complex, biomedical condition that is sometimes difficult to control. They cannot just "shape up." It is rude, insensitive, and ineffective to tell or expect a person to do so.
- Question the accuracy of media stereotypes of psychiatric/mental health disabilities: movies and media often sensationalize psychiatric/mental health disabilities. Most people never experience symptoms that include violent behavior.
- Relax. Be yourself. Do not be embarrassed if you happen to use common expressions that seem to relate to a psychiatric/mental health disability.
- Recognize that beneath the symptoms and behaviors of psychiatric disabilities is a person who has many of the same wants, needs, dreams, and desires as anyone else. If you are afraid, learn more about psychiatric/mental health disabilities.

This material is adapted and based in part on *Achieving Physical and Communication Accessibility*, a publication of the National Center for Access Unlimited; *Community Access Facts*, an Adaptive Environments Center publication; and *The Ten Commandments of Interacting with People with Mental Health Disabilities*, a publication of The Ability Center of Greater Toledo.

of coping with the disability itself (Institute of Medicine [IOM], 2007; Smeltzer, et al., 2007; USDHHS, 2005a). These issues affect both men and women who have severe disabilities; however, women appear to be at higher risk for receiving a lower level of health care than men. Women with disabilities are significantly less likely to receive pelvic examinations than women without disabilities; the more severe the disability, the less frequent the

examination. In particular, minority women and older women with disabilities are less likely to have regular pelvic examinations and Papanicolaou (Pap) tests. Reasons given by women for not having regular pelvic examinations are difficulty transferring onto the examination table, belief that they do not need pelvic examinations because of their disability, difficulty in accessing the office or clinic, and difficulty finding transportation

Figure 10-2 Alternative communication methods and types of patient education are essential to provision of appropriate health-related information to people with disabilities. © Will & Deni McIntyre/Photo Researchers, Inc.

(Smeltzer, et al., 2007; USDHHS, 2005a). Health care providers may underestimate the effect of disabilities on women's ability to access health care, including health screening and health promotion, and they may focus on women's disabilities while ignoring women's general health issues and concerns. Furthermore, women with disabilities have also reported a lack of knowledge about disability and insensitivity on the part of health care providers (Smeltzer, et al., 2007).

Because of the persistence of these barriers, it is essential that nurses and other health care providers take steps to ensure that clinics, offices, hospitals, and other health care facilities are accessible to people with disabilities. This includes removal of structural barriers by adding ramps, designating accessible parking spaces, and modifying restrooms to make them usable by people with disabilities. Alternative communication methods (eg, sign interpreters, teletypewriter [TTY] devices, assistive listening devices) and types of patient education (eg, audiotapes, large print, Braille) are essential to provision of appropriate health-related information to people with disabilities (Fig. 10-2). These reasonable accommodations are mandated by the ADA, which requires their provision without cost to the patient.

Federal Assistance Programs

Lack of financial resources, including health insurance, is an important barrier to health care for people with chronic illness and disabilities. However, several federal assistance programs provide financial assistance for health-related expenses for people with some chronic illnesses, acquired disabling acute and chronic diseases, and childhood disabilities.

Medicare is a federal health insurance program that is available to most people 65 years of age and older, people with permanent renal failure, and qualified people with disabilities. Title II of the Social Security Disability Insurance program pays benefits to those people who meet medical criteria for disability, who have worked long enough (40 quarters of covered employment) to qualify, and who have paid Social Security taxes. Title II also provides benefits to people disabled since childhood (younger than 22 years of age) who are dependants of a deceased insured parent or a parent entitled to disability or retirement benefits, and disabled widows or widowers, 50 to 60 years of age, if their deceased spouse was insured under Social Security. Title XVI of the Social Security Disability Insurance program provides supplemental security income (SSI) payments to people who are disabled and have limited income and resources.

Medicaid provides home and community-based services to people with disabilities and long-term illnesses to enable them to lead meaningful lives with their families and in their communities (USDHHS, 2005a). (See Resources at the end of the chapter for more information about these benefits.)

Despite the availability of these federal programs, people with disabilities often have health-related costs and other expenses related to their disabilities that result in low income status. Furthermore, people must undergo a disability determination process to establish eligibility for benefits, and the process can be prolonged and cumbersome for those who may need assistance in establishing their eligibility.

Nursing Care of Patients With Disabilities

As active members of society, people with disabilities are no longer an invisible minority. An increased awareness of the needs of people with disabilities will bring about changes to improve their access and accommodate their needs. Modification of the physical environment permits access to public and private facilities and services, including health care, and nurses can serve as advocates for people with disabilities to eliminate discriminatory practices.

Nursing Considerations During Hospitalization

During hospitalization, as well as during periods of acute illness or injury or while recovering from surgery, patients with preexisting disabilities may require assistance with carrying out ADLs that they could otherwise manage at home independently and easily. Patients should be asked preferences about approaches to carrying out their ADLs, and assistive devices they require should be readily available. Careful planning with patients to ensure that the hospital room is arranged with their input enables them to manage as independently as possible. For example, patients who have paraplegia may be able to transfer independently from bed to wheelchair; however, if the bed is left in an elevated position, they may be unable to do so. If patients usually use

service animals to assist them with ADLs, it is necessary to make arrangements for the accommodation of these animals. If patients with hearing loss or communication impairments are hospitalized, it is essential to establish effective communication strategies (Lieu, Sadler, Fullerton, et al., 2007; Wallhagen, Pettengill & Whiteside, 2006). Alternative methods for these patients to communicate with the health care team must be put in place and used, and all staff members must be aware that some patients are not able to respond to the intercom or telephone. If patients have vision impairment, it is necessary to orient them to the environment and to make an effort to talk to them in a normal tone of voice (Rushing, 2007).

Health Promotion and Prevention

Health care providers often neglect health promotion concerns of people with disabilities, who may be unaware of these concerns. For example, people who have had hearing loss since childhood may lack exposure to information about AIDS through radio and television. People with lifelong disabilities may not have received information about general health issues as children, and people with new-onset as well as lifelong disabilities may not receive encouragement to participate in health promotion activities. Therefore, nurses should take every opportunity to emphasize the importance of participation, both in health promotion activities (eg, healthy diet, exercise, social interactions) and in preventive health screening.

The management of some disabilities increases the risk of illness, and in some people, health screening (eg, bone density testing, gynecologic examinations, mammography) may be required earlier in life or more frequently (Smeltzer, 2006; Smeltzer & Sharts-Hopko, 2005). Referrals by nurses to accessible sites for screening may be needed, because many imaging centers are inaccessible. In addition, nursing consultation with physical therapists may be needed to identify creative ways of enabling people with disabilities to exercise safely, because exercise facilities are also often inaccessible for people with disabilities.

General health promotion strategies and health screening recommendations for all men and women also apply to those with disabilities. Although physical limitations, cognitive impairments, and structural and attitudinal barriers that exist in clinical facilities may make it difficult for some men and women to obtain health care and preventive health screening, the presence of a disability should not be used as a reason or excuse to defer recommended screening. Rather, the presence of a disability may increase the risk of **secondary conditions** that require screening and follow-up. Just as people without disabilities should have regular screening tests, such as mammography or testicular and prostate examinations, so should people with disabilities (USDHHS, 2005a, 2005b). Nurses are often in a position to influence decisions about how equipment and procedures can be adapted to meet the special needs of their patients, whether these needs are cognitive, motor, or communicative.

The effect of the disabling condition on health risks should be considered. For example, the risk of osteoporosis may be increased in women and men whose disabilities limit their ability to participate in weight-bearing exercise or who use medications that contribute to bone loss

(Smeltzer, Zimmerman & Capriotti, 2005). Although people with disabilities have an increased risk of osteoporosis at a younger age than people without disabilities, little attention is given to prevention, detection, and treatment of osteoporosis, despite the increased risk for falls associated with many disabling disorders (Smeltzer, 2006).

Nurses can provide expert health promotion education classes that are targeted to people with disabilities and refer them to accessible online resources. Classes on nutrition and weight management are extremely important to people who are wheelchair users and need assistance with transfers. Safer sex classes are needed by adolescents and young adults who have spinal cord injury, traumatic brain injury, or developmental disabilities, because the threats of sexually transmitted infections (STIs) and unplanned pregnancy exist for these populations just as they do for the population in general. Other healthy behaviors about which people with neurologic disabilities need education include avoiding alcohol and nonprescription medications while taking antispasmodic and antiseizure medications.

Significance of “People-First” Language

It is important to all people, both those with and those without disabilities, that they not be equated with their illness or physical condition. Therefore, it is important to refer to all people using “people-first” language. Using “people-first” language means referring to the person first: “the patient with diabetes” rather than “the diabetic” or “the diabetic patient”; “the person with a disability” rather than the “disabled person”; “women with disabilities” rather than “disabled women”; and “people who are wheelchair users” rather than “the wheelchair-bound.” This simple use of language conveys the message that the person, rather than the illness or disability, is of greater importance to the nurse.

Gerontologic Considerations

Stereotypical thinking often leads to the conclusion that disability is associated only with being elderly. However, aging is an important issue that affects people with preexisting disabilities. In addition, the process of aging has been described as accelerated in people with disabilities because they often develop changes associated with aging at a younger age than do those without disabilities (IOM, 2007). Therefore, it is important that the nurse consider the effects of aging on a preexisting disability and in turn the effects of disability on aging. The following examples may be useful.

- People who use crutches for ambulation because of polio often experience muscle problems as they age because of long-time overuse of the upper extremities; symptoms may not occur for many years but may cause discomfort and interfere with the person’s ability to perform ADLs.
- People who experienced respiratory compromise with the onset of polio decades earlier may experience increasing respiratory symptoms with aging (Bartels & Omura, 2005).
- Women with long-standing mobility limitations and lack of weight-bearing exercise may experience bone loss and osteoporosis prior to menopause (Smeltzer, et al., 2005). Therefore, people with a preexisting

disability should be evaluated for early onset of changes related to aging.

Concern about what the future holds is common in people aging with preexisting disabilities who may have questions about what physical, financial, and emotional supports they will have as they age (Nosek, 2000). If their disability becomes more severe in the future, they may be concerned about placement in an assisted living facility or a long-term care facility. The nurse should recognize the concerns of people with disabilities about their future and encourage them to make suitable plans, which may relieve some of their fears and concerns about what will happen to them as they age.

Parents of adult children with developmental disabilities often fear what will happen when they are no longer available and able to care for their children. Limited long-term care resources, increased life expectancy for people with developmental disabilities, changing family patterns, and competition with the elderly population for similar resources increase the fears of these parents (Parish & Lutwick, 2005). Thus, there is a need for the nurse to identify needed community resources and services. Identifying these issues and concerns and assessing arrangements made by aging parents of adult children with disabilities can help reduce some of their fears about their children's futures.

Disability in Medical-Surgical Nursing Practice

Disability is often considered an issue that is specific or confined to rehabilitation nursing or to gerontologic nursing. However, as noted previously, disability can occur across the lifespan, and it is encountered in all settings. Patients with preexisting disabilities due to conditions that have been present from birth or due to illnesses or injuries experienced as an adolescent or young adult often require health care and nursing care in medical-surgical settings. Although in the past many people with lifelong disabilities or adult onset of severe disabilities may have had shortened lifespans, today most can expect to have a normal or near-normal lifespan and to live a productive and meaningful life (Cristian, 2005). They are also at risk for the same acute and chronic illnesses that can affect all people.

Because of unfavorable interactions with health care providers, including negative attitudes, insensitivity, and lack of knowledge, people with disabilities may avoid seeking medical intervention or health care services. For this reason, and because the number of people with disabilities is increasing, nurses must acquire knowledge and skills and be accessible to assist them in maintaining a high level of wellness. Nurses are in key positions to influence the architectural design of health care settings and the selection of equipment that promotes ease of access and health. Padded examination tables that can be raised or lowered make transfers easier for people with disabilities. Birthing chairs benefit women with disability during yearly pelvic examinations and Pap smears and during urologic evaluations. Ramps, grab bars, and raised and padded toilet seats benefit many people who have neurologic or musculoskeletal disabilities and need routine physical examination and monitoring (eg, bone density measurements). When a patient with a disability is admitted to the hospital for any reason,

the patient's needs for these modifications should be assessed and addressed (Smeltzer, 2007b).

Men and women with disabilities may be encountered in hospitals, clinics, offices, and nursing centers when they seek health care to address a problem related to their disabilities. However, they may also be encountered in these settings when they seek care for a health problem that is not related in any way to their disabilities. For example, a woman with spina bifida or polio might seek health care related to a gynecologic issue, such as vaginal bleeding. Although her disability should be considered in the course of assessment and delivery of health and nursing care, it should not become the overriding focus or exclusive focus of the assessment or the care that she receives. Furthermore, neither a severe physical disability that affects a woman's ability to transfer to an examination table for a gynecologic examination nor a cognitive disability should be a reason to defer a complete health assessment and physical examination, including a pelvic examination. Health care, including preventive health screening, is essential to enable people with disabilities to live the highest quality of life within the limitations imposed by their disabling conditions. Men and women with disabilities have the same needs and same rights for health care and preventive health screening as others, although in some cases, the consequences of their disability increase rather than decrease their need for health screening and for participation in health-promoting activities (Smeltzer & Sharts-Hopko, 2005). Therefore, it is essential that medical-surgical nurses be knowledgeable about disability and how it affects people across the lifespan and how to provide sensitive and quality nursing care for patients with preexisting as well as new-onset disability. In an effort to address these issues, specific information on health care of people with disabilities has been included throughout this book.

Home and Community-Based Care

Teaching Patients Self-Care

A major and often overlooked issue in teaching patients about a health problem, a treatment regimen, or health promotion strategies is the need for alternative formats to accommodate people with a variety of disabilities. Patients with disabilities are in need of the same information as other patients; however, they often require large print, Braille, audiotapes, or the assistance of a sign interpreter. Materials may be obtained from a variety of sources for patients who need these teaching strategies and for patients with cognitive impairments due to developmental disabilities or newly acquired disabilities.

Nurses should ensure that all people, whether or not they have disabilities, recognize the warning signs and symptoms of stroke, heart attack, and cancer, as well as how to access help. In addition, nurses should teach all patients who are stroke survivors and those with diabetes how to monitor their own blood pressure or glucose levels.

Continuing Care

When caring for patients with disabilities and helping them plan for discharge and continuing care in the home, it is

important to consider how a particular disability affects a patient's ability to adhere to recommended treatment regimens and to keep follow-up appointments. Furthermore, it is important to consider how the health issue or treatment regimen affects the disability. Although many people with disabilities are independent and able to make decisions, arrangements for transportation, and appointments to accessible facilities, others may have difficulty doing so, particularly if they are experiencing a health problem. The nurse should recognize the effect that the disability has on the patient's ability to follow-up. The nurse should ask the patient whether he or she anticipates having any difficulties arranging for follow-up care. It is important for the nurse to assist the patient with disabilities to identify unmet needs and to find and use resources (community and social resources, financial and transportation services) that enable the patient to obtain needed services while remaining in his or her home, if preferred. The nurse should have a list of accessible sites and services available and share those resources with the patient and family. In collaboration with other health care providers (occupational and physical therapists, speech therapists), the nurse can identify needed home modifications, including those that are simple and inexpensive that will enable the patient to participate in self-care at home.

CRITICAL THINKING EXERCISES

1 A 28-year-old woman with three children younger than 4 years of age has recently been diagnosed with multiple sclerosis (MS) following vision loss secondary to optic neuritis. Her neurologist has recommended that she begin injection therapy with one of the disease-modifying agents to minimize the number and severity of MS exacerbations. She is very active in her community and church and states that she cannot fit learning about MS or injection therapy into her very busy life. Further, she states that she doubts that the diagnosis is correct but is not interested in seeking a second opinion or in talking to anyone knowledgeable about MS. Identify approaches you would use to establish a plan of care with her. Link your teaching to the trajectory onset phase of chronic illness. How would your plan of nursing care change in the acute and crisis stages of chronic illness?

EBP 2 A 28-year-old man with Down syndrome has been diagnosed with asthma and has received a prescribed inhaler. He lives in a group home and has had a job at the post office assisting office personnel for the past 5 years. What approaches will you use to teach the patient and other significant people in his life about asthma management? Identify the evidence base for the asthma treatments that you will teach him and any modifications that may be needed in management and in teaching approaches.

EBP 3 A 41-year-old woman with quadriplegia due to spinal cord injury (SCI) has never had a mammography and has not had a gynecologic examination in more than 15 years, before the SCI. During a recent admission for treatment of a secondary condition due to her disability, you de-

cide to encourage her to undergo preventive health screening, including screening for breast, cervical, and colon cancer, as well as for low bone density. In discussing these issues with her, what evidence will you use to provide recommendations for screening? What is the research evidence about the patterns of women with disabilities undergoing preventive health screening and barriers to screening? How would you help prepare her for the health screening tests?

Principles and Practices of Rehabilitation

LEARNING OBJECTIVES

On completion of this chapter, the learner will be able to:

- 1 Describe the goals of rehabilitation.
- 2 Discuss the interdisciplinary approach to rehabilitation.
- 3 Identify emotional reactions exhibited by patients with disabilities.
- 4 Use the nursing process as a framework for care of patients with self-care deficits, impaired physical mobility, impaired skin integrity, and altered patterns of elimination.
- 5 Describe nursing strategies appropriate for promoting self-care through activities of daily living.
- 6 Describe nursing strategies appropriate for promoting mobility and ambulation and the use of assistive devices.
- 7 Describe risk factors and related nursing measures to prevent development of pressure ulcers.
- 8 Incorporate bladder training and bowel training into the plan of care for patients with bladder and bowel problems.
- 9 Describe the significance of continuity of care and community reentry from the health care facility to the home or extended care facility for patients who need rehabilitative assistance and services.

GLOSSARY

activities of daily living (ADLs): self-care activities including bathing, grooming, dressing, eating, toileting, and bowel and bladder care

adaptive device: a type of assistive technology that is used to change the environment or help the person to modify the environment (eg, a ramp that can be used in place of steps for someone in a wheelchair)

assistive device: a type of assistive technology that helps people with disabilities perform a given task (eg, a lap board with pictures that is used to assist a person who cannot talk to communicate)

assistive technology: any item, piece of equipment, or product system—whether acquired commercially, off the shelf, modified, or customized—that is used to improve the functional capabilities of individuals with disabilities; this term encompasses both assistive devices and adaptive devices

disability: restriction or lack of ability to perform an activity in a normal manner, the consequences of impairment in terms of an individual's functional performance and activity; disabilities represent disturbances at the level of the person (eg, bathing, dressing, communication, walking, grooming)

habilitation: making able; learning new skills and abilities to meet maximum potential

impairment: loss or abnormality of psychological, physiologic, or anatomic structure or function at the organ level (eg, dysphagia, hemiparesis); an abnormality of body structure, appearance, an organ, or system function resulting from any cause

instrumental activities of daily living (IADLs): complex aspects of independence including meal preparation, grocery shopping, household management, finances, and transportation

pressure ulcer: breakdown of the skin due to prolonged pressure and insufficient blood supply, usually at bony prominences

rehabilitation: making able again; relearning skills or abilities or adjusting existing functions

Rehabilitation is a dynamic, health-oriented process that helps people with acute or chronic disorders or people with physical, mental, or emotional **disabilities** (restrictions in performance or function in everyday activities) to achieve the greatest possible level of physical, mental, spiritual, social, and economic functioning. The rehabilitation process also helps patients achieve an acceptable quality of life with dignity, self-respect, and independence. During rehabilitation—sometimes called **habilitation**—patients adjust to disabilities by learning how to use resources and focus on existing abilities. In **habilitation**, abilities, not disabilities, are emphasized.

Rehabilitation is an integral part of nursing because every major illness or injury carries the threat of disability or **impairment**, which involves a loss of function or an abnormality in body structure or function. The principles of rehabilitation are basic to the care of all patients, and rehabilitation efforts should begin during the initial contact with a patient. The goal of rehabilitation is to restore the patient's ability to function independently or at a preillness or preinjury level of functioning as quickly as possible. If this is not possible, the aims of rehabilitation are to maximize independence and prevent secondary disability as well as to promote a quality of life acceptable to the patient.

Rehabilitation services are required by more people than ever before because of advances in technology that save or prolong the lives of seriously ill and injured patients and patients with disabilities. Increasing numbers of patients who are recovering from serious illnesses or injuries are returning to their homes and communities with ongoing needs. Significant disability caused by war and terrorism also increases the demand for rehabilitation services. All patients, regardless of age, gender, ethnic group, socioeconomic status, or diagnosis, have a right to rehabilitation services (Chart 11-1).

CHART
11-1

Ethics and Related Issues

Are All Persons Entitled to Rehabilitation?

Situation

You work in an area where many illegal aliens and uninsured residents live. Community violence often creates life-threatening and disabling conditions in members of the population. After a victim of violence has been saved and stabilized, the health care team identifies rehabilitation needs. You are concerned about your patient's inability to perform self-care and to demonstrate safe mobility skills.

Dilemma

As a health care provider, you are concerned about the community as a whole; costs to the community, and the values of the community. You are also aware of client fiduciary responsibility; you recognize costs to your patient when treatment is provided or not provided.

Discussion

1. Who determines the length of stay and level of care?
2. Who will take care of patients who need rehabilitation but who are unable to pay? Is rehabilitation a basic health care need?

A person is considered to have a disability, such as a restriction in performance or function in everyday activities, if he or she has difficulty talking, hearing, seeing, walking, climbing stairs, lifting or carrying objects, performing activities of daily living, doing schoolwork, or working at a job. The disability is severe if the person cannot perform one or more activities, uses an assistive device for mobility, or needs help from another person to accomplish basic activities. The purpose of **adaptive devices** and **assistive devices** is to maximize independence and thereby promote access. A person is also considered severely disabled if he or she receives federal benefits because of an inability to work.

Approximately 1 in 5 Americans over 5 years of age has some form of disability, and 1 in 10 has a severe disability (U.S. Census Bureau, 2006). Approximately 54 to 60 million people are affected by some form of disability, and this number is expected to increase in the coming decades due to the aging of the population. The results of the 2006 American Community Survey indicated that the prevalence of disability in men and boys was higher than among women and girls. Conversely, reported disability rates were higher for women than men 65 years of age and older (43% for women, 40% for men). In this survey, nearly 10 million people identified a self-care deficit requiring personal assistance with one or more **activities of daily living** (ADLs), defined as activities related to personal care; or **instrumental activities of daily living** (IADLs), defined as activities related to independent living (National Center for Health Statistics, 2007) (Chart 11-2). It is estimated that among the U.S. population 15 years of age and older, 2.7 million people use a wheelchair and 9.1 million use an ambulatory aid such as a cane, crutches, or a walker (U.S. Census Bureau, 2002). Use of these devices and other types of **assistive technology** has increased dramatically due to the aging of the population, technologic advances, public policy initiatives, and changes in the delivery and financing of health care (U.S. Census Bureau, 2006).

Chart 11-2 • Activities of Daily Living and Independent Activities of Daily Living

Activities of Daily Living (ADLs): Activities related to personal care

- Bathing
- Showering
- Dressing
- Getting in or out of bed or a chair
- Using the toilet
- Eating

Independent Activities of Daily Living (IADLs): Skills for independent living

- Cooking
- Cleaning
- Shopping
- Doing laundry
- Managing personal finances
- Developing social and recreational skills
- Handling emergencies

Americans With Disabilities Act

For years, people with disabilities have been discriminated against in employment, public accommodations, and public and private services, including health care. In 1990, the U.S. Congress passed the Americans With Disabilities Act (ADA) (PL 101-336), which is civil rights legislation designed to provide people with disabilities access to job opportunities and to the community. See Chapter 10 for discussion of the ADA, access to health care and health promotion, and special issues that should be addressed in providing health care to people with disabilities.

Patients' Reactions to Disability

Disability can occur at any age and may result from an acute incident, such as stroke, traumatic spinal cord injury, or brain injury, or from the progression of a chronic condition, such as arthritis or multiple sclerosis. Certain factors common to both disability and chronic illness may include some functional limitation, interference with daily activities and life roles, an uncertain prognosis, prolonged medical treatment and rehabilitation, psychosocial stress associated with the trauma or disease process, a negative impact on family and friends, and negative economic implications (Livneh & Antonak, 2005). The interaction of these factors has a profound effect on the lives of individuals with chronic illness and disability.

Patients and families who suddenly experience a physically disabling event or the onset of a chronic illness face several psychosocial adjustments. Their reactions and responses to such life-altering illness events influence immediate and long-term rehabilitation processes and the process of adapting to chronic illness and disability. As suggested by Livneh and Antonak (2005), psychosocial adaptation to chronic illness and disability is generally identi-

fied by “basic concepts,” “chronic illness and disability-triggered reactions,” and “chronic illness and disability-associated coping strategies.” Basic concepts include stress, crisis, loss and grief, body image, self-concept, stigma, uncertainty and unpredictability, and quality of life. The most frequently reported chronic illness and disability-triggered reactions include shock, which is a short-lived reaction experienced at the onset of a traumatic and sudden injury or the onset of a life-threatening or chronic and debilitating disease; anxiety, which is a panic-like state as the nature and magnitude of the event is processed; denial, which is a defense mechanism used to ward off anxiety and other intense emotions; depression, which reflects the realization of the permanence and magnitude of the chronic illness or disability; anger and hostility that are both self-directed and externalized; and adjustment, which is exemplified by self-acceptance as a person with a chronic illness or disability and marked by reintegration into the community. Finally, chronic illness and disability-associated coping strategies are those psychological strategies that are used to decrease, modify, or diffuse the impact of stressful life events. Individuals with chronic illnesses or disabilities may choose to disengage from the recovery process (eg, through denial or substance abuse) or actively engage in activities to meet challenges associated with the chronic illness or disability (eg, information seeking, problem solving, planning).

All professionals involved in health care, including nurses, should recognize the emotional and psychological needs of patients and should be able to intervene by providing effective information, compassionate communication, and general psychological support (Chart 11-3). The nurse should take time to listen to patients talk about their disabilities; be respectful of their values and beliefs; and understand that grief, anger, regret, resentment, and acceptance are all part of the healing process. Chart 11-4 lists concerns unique to older adults.

CHART 11-3 NURSING RESEARCH PROFILE Needs of Patients in Rehabilitation

Sigurgeirsdottir, J. & Halldorsdottir, S. (2007). Existential struggle and self-reported needs of patients in rehabilitation. *Journal of Advanced Nursing*, 61(4), 384–392.

Purpose

Nurses need to be able to recognize individual patient needs to plan effective care. Few studies have explored rehabilitation needs from the patient's perspective. This study intended to increase understanding of patients' experiences of rehabilitation and their self-reported rehabilitation needs.

Design

The purposive sample for this phenomenological study consisted of 16 in-depth interviews with 12 participants between the ages of 26 and 85 years. Each of these participants had experienced rehabilitation therapy to treat an acute or chronic illness within a recent 2-year time frame. Researchers predetermined that each potential participant was capable of tolerating a 60- to 90-minute interview.

Findings

Participants' self-reported needs included individualized caring and emotional support from family, peers, and staff. Patients also expressed a need for a sense of security in a stable and homelike environment, with assistance, help, and presence of supportive others. Finally, participants reported needing goal-oriented and progressive care in which realistic and achievable goals were established. Individualized educational approaches were well received and improved participants' self-esteem.

Nursing Implications

Rehabilitation nursing should focus on assessment of existential well-being of patients. This may be fostered by individualizing plans of nursing care. The findings of this study suggest that patients in rehabilitation experience existential struggles, described as struggling with changes to self-identity while trying to maintain characteristics of the “old life” or “old self.” This struggle makes patients feel vulnerable. Being attuned to each patient's hierarchy of needs and educational needs may enhance the existential well-being of patients who require rehabilitation.

CHART
11-4

Concerns of Adults Aging With Disability

- Loss of independence, which is a source of self-respect and dignity
- Increased potential for discrimination or abuse
- Increased social isolation
- Added burden on spouse, who may also have impaired health
- Less access to community services and health care
- Less access to religious institutions
- Increased vulnerability to declining health secondary to other disorders, reduced physiologic reserve, or preexisting impairments of mobility and balance
- Fears and doubts about ability to learn or relearn self-care activities, exercises, and transfer and independent mobility techniques
- Inadequate support system for successful rehabilitation

The patient's preexisting coping abilities play an important role in the adaptation process. One patient may be particularly independent and determined, whereas another may be dependent and feel powerless. One goal of rehabilitation is to help the patient gain a positive self-image through effective coping. The nurse must recognize differing coping abilities and identify when a patient is not coping well or not adjusting to the disability or chronic illness. The patient and family may benefit from participation in a support group or talking with a mental health professional to achieve this goal, and the nurse may need to refer them to someone who can help them with particular challenges. Refer to Chapter 6 for a detailed discussion of adaptive and maladaptive responses to illness.

The Rehabilitation Team

Rehabilitation is a creative, dynamic process that requires a team of professionals working together with patients and families. The team members represent a variety of disciplines, with each health professional making a unique contribution to the rehabilitation process. In addition to nurses, members of the rehabilitation team may include physicians, nurse practitioners, psychiatrists, physical therapists, occupational therapists, recreational therapists, speech-language therapists, psychologists, psychiatric liaison nurses, spiritual advisors, social workers, vocational counselors, orthotists or prosthetists, and sex counselors.

Nurses assume an equal or, depending on the circumstances of the patient, a more critical role than other members of the health care team in the rehabilitation process. The evidence-based plan of care that nurses develop must be approved by the patient and family and is an integral part of the rehabilitation process. The rehabilitation process is cyclical and includes a comprehensive assessment; establishment of short-term, medium-term, and long-term goals; development of a collaborative plan to work toward achieving the goals; and evaluation of progress toward the goals (Booth & Jester, 2007).

In working toward maximizing independence, nurses affirm the patient as an active participant and recognize the

importance of informal caregivers in the rehabilitation process. The patient is a key member of the rehabilitation team, the focus of the team's effort, and the one who determines the final outcomes of the process. The patient participates in goal setting, in learning to function using his or her remaining abilities, and in adjusting to living with disabilities. The patient's family is also incorporated into the team. Families are dynamic systems; therefore, the disability of one member affects other family members. Only by incorporating the family into the rehabilitation process can the family system adapt to the change in one of its members. The family provides ongoing support, participates in problem solving, and learns to participate in providing ongoing care.

The nurse develops a therapeutic and supportive relationship with the patient and family. The nurse emphasizes the patient's assets and strengths, positively reinforcing the patient's efforts to improve self-concept and self-care abilities. During nurse-patient interactions, the nurse actively listens, encourages, and shares patient and family successes. Using the nursing process, the nurse develops a plan of care designed to facilitate rehabilitation, restore and maintain optimal health, and prevent complications.

Coping with the disability, fostering self-care, identifying mobility limitations, and managing skin care and bowel and bladder training are areas that frequently require nursing care. The nurse acts as a caregiver, teacher, counselor, patient advocate, case manager, and consultant. The nurse is often responsible for coordinating the total rehabilitative plan and collaborating with and coordinating the services provided by all members of the health care team, including home care nurses, who are responsible for directing patient care after the patient returns home.

Areas of Specialty Rehabilitation

Although rehabilitation must be a component of every patient's care, specialty rehabilitation programs have been established in general hospitals, free-standing rehabilitation hospitals, and outpatient facilities. The Commission for the Accreditation of Rehabilitation Facilities (CARF) sets standards for these programs and monitors compliance with the standards.

- *Stroke recovery programs* and *traumatic brain injury rehabilitation* emphasize cognitive remediation, helping patients compensate for memory, perceptual, judgment, and safety deficits as well as teaching self-care and mobility skills. Other goals include helping patients swallow food safely and communicate effectively. Neurologic disorders treated in addition to stroke and brain injury include multiple sclerosis, Parkinson's disease, amyotrophic lateral sclerosis, and nervous system tumors.
- *Spinal cord injury rehabilitation* programs promote understanding of the effects and complications of spinal cord injury; neurogenic bowel and bladder management; sexuality and fertility enhancement; self-care, including prevention of skin breakdown; bed mobility and transfers; and driving with adaptive equipment. The programs also focus on vocational assessment,

training, and reentry into employment and the community. There are 16 federally funded designated spinal cord injury centers in the United States.

- *Orthopedic rehabilitation programs* provide comprehensive services to patients with traumatic or nontraumatic amputation, patients undergoing joint replacements, and patients with arthritis. Independence with a prosthesis or new joint is a major goal of these programs. Other goals include pain management, energy conservation, and joint protection.
- *Cardiac rehabilitation* for patients who have had myocardial infarction begins during the acute hospitalization and continues on an outpatient basis. Emphasis is placed on monitored, progressive exercise; nutritional counseling; stress management; sexuality; and risk reduction.
- *Pulmonary rehabilitation programs* may be appropriate for patients with restrictive or chronic obstructive pulmonary disease or ventilator dependency. Respiratory therapists help patients achieve more effective breathing patterns. The programs also teach energy conservation techniques, self-medication, and home ventilatory management.
- *Comprehensive pain management programs* are available for people with chronic pain, especially low back pain. These programs focus on alternative pain treatment modalities, exercise, supportive counseling, and vocational evaluation.
- *Comprehensive burn rehabilitation programs* may serve as step-down units from intensive care burn units. Although rehabilitation strategies are implemented immediately in acute care, a program focused on progressive joint mobility, self-care, and ongoing counseling is imperative for burn patients.
- *Pediatric rehabilitation programs* meet the needs of children with developmental and acquired disabilities, including cerebral palsy, spina bifida, traumatic brain injuries, and spinal cord injuries.

As in all areas of nursing practice, nurses practicing in the area of rehabilitation must be skilled and knowledgeable about the care of patients with substance abuse. For all people with disabilities, including adolescents, nurses must assess actual or potential substance abuse. Fifty percent of spinal cord injuries are related to substance abuse, and approximately 50% of all patients with traumatic brain injury were intoxicated at the time of injury (U.S. Department of Health and Human Services [DHHS], 2006a).

Substance abuse is a critical issue in rehabilitation, especially for people with disabilities who are attempting to gain employment via vocational rehabilitation. The rates of substance abuse, including alcohol abuse, in people with disabilities are two to four times as high as in the general population, and this increased abuse is associated with a number of risks that may have an adverse impact. These risks include medication and health problems, societal enabling (ie, acceptance and tolerance of substance abuse by key social and cultural groups), a lack of identification of potential problems, and a lack of accessible and appropriate prevention and treatment services. Treatment for alcoholism and drug dependencies includes thorough physical and psychosocial evaluations; detoxification; counseling; medical treatment; psychological

assistance for patients and families; treatment of any coexisting psychiatric illness; and referral to community resources for social, legal, spiritual, or vocational assistance. The length of treatment and the rehabilitation process depends on the patient's needs. Self-help groups are also encouraged, although attendance at meetings of such groups (eg, Alcoholics Anonymous, Narcotics Anonymous) poses various challenges for people who have neurologic disorders, are permanent wheelchair users, or must adapt to encounters with nondisabled attendees who may not understand disability.

Assessment of Functional Ability

Comprehensive assessment of functional capacity is the basis for developing a rehabilitation program. Functional capacity is a person's ability to perform ADLs and IADLs (see Chart 11-2).

The nurse observes the patient performing specific activities (eg, eating, dressing) and notes the degree of independence; the time taken; the patient's mobility, coordination, and endurance; and the amount of assistance required. The nurse also carefully assesses joint motion, muscle strength, cardiovascular reserve, and neurologic function, because functional ability depends on these factors as well. Observations are recorded on a functional assessment tool. These tools provide a way to standardize assessment parameters and include a scale or score against which improvements may be measured. They also clearly communicate the patient's level of functioning to all members of the rehabilitation team. Rehabilitation staff members use these tools to provide an initial assessment of the patient's abilities and to monitor the patient's progress in achieving independence.

One of the most frequently used tools to assess the patient's level of independence is the Functional Independence Measure (FIMTM). The FIMTM is a minimum data set, measuring 18 items. The self-care items measured are eating, bathing, grooming, dressing upper body, dressing lower body, toileting, bladder management, and bowel management. The FIMTM addresses transfers and the ability to ambulate and climb stairs and also includes communication and social cognition items. Scoring is based on a seven-point scale, with items used to assess the patient's level of independence. The Alpha FIMTM is used frequently in acute care settings to measure functional abilities within 72 hours of admission.

Although there are many disease-specific tools used to assess the patient's functional ability, some frequently used generic measures include the following:

- The PULSES profile, which is used to assess physical condition (eg, health/illness status), upper extremity functions (eg, eating, bathing), lower extremity functions (eg, transfer, ambulation), sensory function (eg, vision, hearing, speech), bowel and bladder function (ie, control of bowel or bladder), and situational factors (eg, social and financial support). Each of these areas is rated on a scale from one (independent) to four (greatest dependency).
- The Barthel Index, which is used to measure the patient's level of independence in ADLs, continence,

toileting, transfers, and ambulation (or wheelchair mobility). This scale does not address communicative or cognitive abilities.

- The Patient Evaluation Conference System (PECS), which contains 15 categories, is a comprehensive assessment scale that includes such areas as medications, pain, nutrition, use of assistive devices, psychological status, vocation, and recreation.

A detailed functional evaluation of secondary conditions related to the patient's disability, such as muscle atrophy and deconditioning, skin integrity, bowel and bladder control, and sexual function, together with residual strengths unaffected by disease or disability, is necessary. In addition, the nurse assesses the patient's physical, mental, emotional, spiritual, social, and economic status, and cultural and familial environment. These elements may provide a context to the functional findings and influence the rehabilitation plan. For example, the patient's perception of what it means to have a disability and the implications this might have on familial and social roles can influence the rehabilitation process.

NURSING PROCESS

THE PATIENT WITH SELF-CARE DEFICITS IN ACTIVITIES OF DAILY LIVING

ADLs are those self-care activities that the patient must accomplish each day to meet personal needs; they include personal hygiene/bathing, dressing/grooming, feeding, and toileting. Many patients cannot perform such activities easily. An ADL program is started as soon as the rehabilitation process begins, because the ability to perform ADLs is frequently the key to independence, return to the home, and reentry into the community.

Assessment

The nurse must observe and assess the patient's ability to perform ADLs to determine the level of independence in self-care and the need for nursing intervention. Chart 11-5 depicts indications of potential problems in function or movement. The activity of bathing requires obtaining bath water and items used for bathing (eg, soap, washcloth), washing, and drying the body after bathing. Dressing requires getting clothes from the closet, putting on and taking off clothing, and fastening the clothing. Self-feeding requires using utensils to bring food to the mouth and chewing and swallowing the food. The activity of toileting includes removing clothing to use the toilet, cleansing oneself, and readjusting clothing. Grooming activities include combing hair, brushing one's teeth, shaving or applying makeup, and handwashing. Patients who can sit up and raise their hands to their head can begin self-care activities. Assistive devices are often essential in achieving some level of independence in ADLs.

The nurse should also be aware of the patient's medical conditions or other health problems, the effect that they have on the ability to perform ADLs, and the family's involvement in the patient's ADLs. This information is valuable in setting goals and developing the plan of care to maximize self-care.

Nursing Diagnosis

Based on the assessment data, major nursing diagnoses may include the following:

- Self-care deficit: bathing/hygiene, dressing/grooming, feeding, toileting

Planning and Goals

The major goals include performing the following activities independently or with assistance, using adaptive or assistive devices as appropriate: bathing/hygiene, dressing/grooming, feeding, and toileting. Another goal is patient expression of

CHART
11-5

Assessment of Potential Problems in Function or Movement

Be alert for the following behaviors, which may indicate problems in function or movement:

- Holding onto a handrail to pull the body while going up stairs
- Holding onto a bedside rail or bedcovers to pull to sitting in bed
- Leaning to one side and using both hands on the handrail while going down the stairs or a ramp
- Holding onto furniture or doorways and watching the feet while walking in the house
- Lifting a leg (or arm) by using the other leg (or arm) as support or by lifting with the pants leg (or sleeve)
- Tilting the head to reach the back or side of the hair while grooming
- Pushing up, rocking forward and back, and/or leaning the body over for momentum ("nose over toes") when rising to stand from a chair
- Leaning over from the waist without bending the knees and then using one hand on the thigh, as if it were a prop, to assist in moving to the upright position
- Turning to reach for an object and then using the other arm or an object to support the reaching arm at the elbow or wrist
- Positioning a chair before sitting down by using the front or back of the knees and then using the back of the knees to guide sitting down; using the torso and hips to lean against a table or chair
- Reaching and leaning with the body rather than with an arm
- Walking with a lean to one side, a limp, a waddle, or other variation of a gait
- Scanning (ie, observing or being aware of surroundings) ineffectively while eating or grooming
- Rolling or scooting the body, sliding forward in a seat, or other maneuvers to move off a bed or out of a chair

satisfaction with the extent of independence achieved in self-care activities.

Nursing Interventions

Repetition, practice, and demonstrations help patients achieve maximum independence in personal care activities. The nurse's role is to provide an optimal learning environment that minimizes distractions. The nurse can identify the patient's optimal time to work on activities, encourage concentration, identify endurance issues that may affect safety, and provide cues and reminders to patients with specific disabilities (eg, hemiparesis or hemineglect) (Hoeman, 2008). Patients with impaired mobility, sensation, strength, or dexterity may need to use assistive devices to accomplish self-care.

Fostering Self-Care Abilities

A patient's approach to self-care may be affected by altered or impaired mobility and influenced by family or cultural expectations. The inability to perform self-care as carried out previously may lead to ineffective coping behaviors such as social isolation, dependency on caregivers, or depression. The nurse must motivate the patient to learn and accept responsibility for self-care. It helps to encourage an "I'd rather do it myself" attitude. The nurse must also help the patient identify the safe limits of independent activity; knowing when to ask for assistance is particularly important.

The nurse teaches, guides, and supports the patient who is learning or relearning how to perform self-care activities while maintaining a focus on patient strengths and optimal level of function. Consistency in instructions and assistance given by health care providers facilitates the learning process. Recording the patient's performance provides data for evaluating progress and may be used as a source for motivation and morale building. Guidelines for teaching about ADLs are presented in Chart 11-6.

Often, a simple maneuver requires concentration and the exertion of considerable effort on the part of the patient with a disability; therefore, self-care techniques need to be adapted to accommodate the lifestyle of individual patients. There is usually more than one way to accomplish a self-care activity, and common sense and a little ingenuity may promote increased independence. For example, a person who cannot quite reach his or her head may be able to do so by leaning forward. Encouraging the patient to participate in a support group may also help the patient discover creative solutions to self-care problems.

Preexisting cultural norms may influence the degree of self-care the patient is willing to consider. Cultural and ethnic beliefs about hygiene can vary among individuals and families. It is important for the nurse to recognize these beliefs, work through any issues with the patient and family, and communicate pertinent findings to the rehabilitation team.

Recommending Adaptive and Assistive Devices

If the patient has difficulty performing an ADL, an adaptive or assistive device (self-help device) may be useful. A large variety of adaptive devices are available commercially or can be constructed by the nurse, occupational therapist, patient, or family. These devices may include built-up handles

Chart 11-6 • Teaching About Activities of Daily Living

1. Define the goal of the activity with the patient. Be realistic. Set short-term goals that can be accomplished in the near future.
2. Identify several approaches to accomplish the task (eg, there are several ways to put on a given garment).
3. Select the approach most likely to succeed.
4. Specify the approach on the patient's plan of care and the patient's level of accomplishment on the progress notes.
5. Identify the motions necessary to accomplish the activity (eg, to pick up a glass, extend arm with hand open; place open hand next to glass; flex fingers around glass; move arm and hand holding glass vertically; flex arm toward body).
6. Focus on gross functional movements initially, and gradually include activities that use finer motions (eg, buttoning clothes, eating with a fork).
7. Encourage the patient to perform the activity up to maximal capacity within the limitations of the disability.
8. Monitor the patient's tolerance.
9. Minimize frustration and fatigue.
10. Support the patient by giving appropriate praise for effort put forth and for acts accomplished.
11. Assist the patient to perform and practice the activity in real-life situations and in a safe environment.

on toothbrushes or razors; long, curved handles on mirrors or shoe horns; suction cups to hold items in place; shower chairs; raised toilet seats; and universal cuffs to grip self-care items. Some of these are shown in Figure 11-1. To assist premenopausal women with managing menstruation, clothing adaptations (eg, Velcro crotch flaps for ease of access), mirrors, self-sticking sanitary pads, packaged wipes, and loose underwear may be used.

NURSING ALERT

People who take anticoagulant medication should be encouraged to use an electric razor. Women may wish to consider depilatory creams or electrolysis.

A wide selection of computerized devices is available, or devices can be designed to help individual patients with severe disabilities to function more independently. The ABLEDATA project (see Resources list at the end of this chapter) offers a computerized listing of commercially available aids and equipment for patients with disabilities.

The nurse should be alert to "gadgets" coming on the market and evaluate their potential usefulness. The nurse must exercise professional judgment and caution in recommending devices, because in the past, unscrupulous vendors have marketed unnecessary, overly expensive, or useless items to patients.

Helping Patients Accept Limitations

If the patient has a severe disability, independent self-care may be an unrealistic goal; in this situation, the nurse teaches the patient how to direct his or her own care. The patient

Figure 11-1 Adaptive devices. **A**, Feeding tools. **B**, Raised toilet seat. **C**, Shower chair.

may require a personal attendant to perform ADLs. Family members may not be appropriate for providing bathing/hygiene, dressing/grooming, feeding, and toileting assistance, and spouses may have difficulty providing bowel and bladder care for patients and maintaining the role of sexual partners. If a personal caregiver is necessary, the patient and family members must learn how to manage an employee effectively. The nurse helps the patient accept self-care dependency. Independence in other areas, such as social interaction, should be emphasized to promote a positive self-concept.

Evaluation

Expected Patient Outcomes

Expected patient outcomes may include:

1. Demonstrates independent self-care in bathing/hygiene or with assistance, using adaptive devices as appropriate
 - a. Bathes self at maximal level of independence
 - b. Uses adaptive and assistive devices effectively
 - c. Reports satisfaction with level of independence in bathing/hygiene
2. Demonstrates independent self-care in dressing/grooming or with assistance, using adaptive devices as appropriate
 - a. Dresses/grooms self at maximal level of independence
 - b. Uses adaptive devices effectively
 - c. Reports satisfaction with level of independence in dressing/grooming
 - d. Demonstrates increased interest in appearance
3. Demonstrates independent self-care in feeding or with assistance, using adaptive and assistive devices as appropriate
 - a. Feeds self at maximal level of independence
 - b. Uses adaptive and assistive devices effectively
 - c. Demonstrates increased interest in eating
 - d. Maintains adequate nutritional intake
4. Demonstrates independent self-care in toileting or with assistance, using adaptive and assistive devices as appropriate
 - a. Toilets self at maximal level of independence
 - b. Uses adaptive and assistive devices effectively
 - c. Indicates positive feelings regarding level of toileting independence
 - d. Experiences adequate frequency of bowel and bladder elimination
 - e. Does not experience incontinence, constipation, urinary tract infection, or other complications

NURSING PROCESS

THE PATIENT WITH IMPAIRED PHYSICAL MOBILITY

Problems commonly associated with immobility include weakened muscles, joint contracture, and deformity. Each joint of the body has a normal range of motion; if the range is limited, the functions of the joint and the

muscles that move the joint are impaired, and painful deformities may develop. The nurse must identify patients at risk for such complications. The nurse needs to assess, plan, and intervene to prevent complications of immobility.

Another problem frequently seen in rehabilitation nursing is an altered ambulatory/mobility pattern. Patients with disabilities may be either temporarily or permanently unable to walk independently and unaided. The nurse assesses the mobility of the patient and designs care that promotes independent mobility within the prescribed therapeutic limits. If a patient cannot exercise and move his or her joints through their full range of motion, contractures may develop. A contracture is a shortening of the muscle and tendon that leads to deformity and limits joint mobility. When the contracted joint is moved, the patient experiences pain; in addition, more energy is required to move when joints are contracted.

Assessment

At times, mobility is restricted because of pain, paralysis, loss of muscle strength, systemic disease, an immobilizing device (eg, cast, brace), or prescribed limits to promote healing. Assessment of mobility includes positioning, ability to move, muscle strength and tone, joint function, and the prescribed mobility limits. The nurse must collaborate with physical therapists or other team members to assess mobility.

During position change, transfer, and ambulation activities, the nurse assesses the patient's abilities, the extent of disability, and residual capacity for physiologic adaptation. The nurse observes for orthostatic hypotension, pallor, diaphoresis, nausea, tachycardia, and fatigue.

In addition, the nurse assesses the patient's ability to use various assistive devices that promote mobility. If the patient cannot ambulate without assistance, the nurse assesses the patient's ability to balance, transfer, and use assistive devices (eg, crutches, walker). Crutch walking requires high energy expenditure and produces considerable cardiovascular stress; therefore, people with reduced exercise capacity, decreased arm strength, and problems with balance because of aging or multiple diseases may be unable to use them. A walker is more stable and may be a better choice for such patients. If the patient uses an orthosis (an external appliance that provides support, prevents or corrects joint deformities, and improves function), the nurse monitors the patient for effective use and potential problems associated with its use.

Nursing Diagnosis

Based on the assessment data, major nursing diagnoses may include the following:

- Impaired physical mobility
- Activity intolerance
- Risk for injury
- Risk for disuse syndrome
- Impaired walking
- Impaired wheelchair mobility
- Impaired bed mobility

Planning and Goals

The major goals may include absence of contracture and deformity, maintenance of muscle strength and joint mobility,

independent mobility, increased activity tolerance, and prevention of further disability.

Nursing Interventions

Positioning to Prevent Musculoskeletal Complications

Deformities and contractures can often be prevented by proper positioning. Maintaining correct body alignment when the patient is in bed is essential regardless of the position selected. During each patient contact, the nurse evaluates the patient's position and assists the patient to achieve and maintain proper positioning and alignment. The most common positions that patients assume in bed are supine (dorsal), side-lying (lateral), and prone. The nurse helps the patient assume these positions and uses pillows to support the body in correct alignment. At times, a splint (eg, wrist or hand splint) may be made by the occupational therapist to support a joint and prevent deformity. The nurse must ensure proper use of the splint and provide skin care.

PREVENTING EXTERNAL ROTATION OF THE HIP. The patient who is in bed for an extended period of time may develop external rotation deformity of the hip because the ball-and-socket joint of the hip tends to rotate outward when the patient lies on his or her back. A trochanter roll (ie, a flannel sheet or bath towel folded in thirds lengthwise and rolled toward the patient or a commercially manufactured roll) extending from the crest of the ilium to the midhigh prevents this deformity; with correct placement, it serves as a mechanical wedge under the projection of the greater trochanter.

PREVENTING FOOTDROP. Footdrop is a deformity in which the foot is plantar flexed (the ankle bends in the direction of the sole of the foot). If the condition continues without correction, the patient will not be able to hold the foot in a normal position and will be able to walk only on his or her toes, without touching the ground with the heel of the foot. The deformity is caused by contracture of both the gastrocnemius and soleus muscles. Damage to the peroneal nerve or loss of flexibility of the Achilles tendon may also result in footdrop. To prevent this disabling deformity, the patient is positioned to sit at a 90-degree angle in a wheelchair with his or her feet on the footrests or flat on the floor.

NURSING ALERT

Patients should be encouraged to wear shoes for support and protection to prevent footdrop.

When the patient is supine in bed, padded splints or protective boots are used to keep the patient's feet at right angles to the legs. Frequent skin inspection of the feet must also be performed to determine whether positioning devices have created any unwanted pressure areas.

The patient is encouraged to perform the following ankle exercises several times each hour: dorsiflexion and plantar flexion of the feet, flexion and extension (curl and stretch) of the toes, and eversion and inversion of the feet at the ankles. The nurse provides frequent passive range-of-motion exercises if the patient cannot perform active exercises.

NURSING ALERT

Prolonged bed rest, lack of exercise, incorrect positioning in bed, and the weight of bedding that forces the toes into plantar flexion must be avoided to prevent footdrop.

Maintaining Muscle Strength and Joint Mobility

Optimal function depends on the strength of the muscles and joint motion, and active participation in ADLs promotes maintenance of muscle strength and joint mobility. Range-of-motion exercises and specific therapeutic exercises may be included in the nursing plan of care.

PERFORMING RANGE-OF-MOTION EXERCISES. Range of motion involves moving a joint through its full range in all appropriate planes (Chart 11-7). To maintain or increase the motion of a joint, range-of-motion exercises are initiated as soon as the patient's condition permits. The exercises are planned for individual patients to accommodate the wide variation in the degrees of motion that people of varying body builds and age groups can attain (Chart 11-8).

Range-of-motion exercises may be active (performed by the patient under the supervision of the nurse), assisted

Chart 11-7 • Range-of-Motion Terminology

Abduction: movement away from the midline of the body
Adduction: movement toward the midline of the body
Flexion: bending of a joint so that the angle of the joint diminishes
Extension: the return movement from flexion; the joint angle is increased
Rotation: turning or movement of a part around its axis
Internal: turning inward, toward the center
External: turning outward, away from the center
Dorsiflexion: movement that flexes or bends the hand back toward the body or the foot toward the leg
Palmar flexion: movement that flexes or bends the hand in the direction of the palm
Plantar flexion: movement that flexes or bends the foot in the direction of the sole
Pronation: rotation of the forearm so that the palm of the hand is down
Supination: rotation of the forearm so that the palm of the hand is up
Opposition: touching the thumb to each fingertip on same hand
Inversion: movement that turns the sole of the foot inward
Eversion: movement that turns the sole of the foot outward

Chart 11-8 • Performing Range-of-Motion Exercises

Abduction of shoulder. Move arm from side of body to above the head, then return arm to side of body or neutral position (adduction).

Forward flexion of shoulder. Move arm forward and upward until it is alongside of head.

Flexion of elbow. Bend elbow, bringing forearm and hand toward shoulder, then return forearm and hand to neutral position (arm straight).

Internal rotation of shoulder. With arm at shoulder height, elbow bent at a 90-degree angle, and palm toward feet, turn upper arm until palm and forearm point backward.

Pronation of forearm. With elbow at waist and bent at a 90-degree angle, turn hand so that palm is facing down.

Wrist extension.

Continued on following page

Chart 11-8 • *Performing Range-of-Motion Exercises (Continued)*

External rotation of shoulder. With arm at shoulder height, elbow bent at a 90-degree angle, and palm toward feet, turn upper arm until the palm and forearm point forward.

Supination of forearm. With elbow at waist and arm bent at a 90-degree angle, turn hand so that palm is facing up.

Flexion of wrist. Bend wrist so that palm is toward forearm. Straighten to a neutral position.

Ulnar deviation. Move hand sideways so that the side of hand on which the little finger is located moves toward forearm.

Extension of fingers.

Internal-external rotation of hip. Turn leg in an inward motion so that toes point in. Turn leg in an outward motion so that toes point out.

Radial deviation. Move hand sideways so that side of hand on which thumb is located moves toward forearm.

To perform abduction-adduction of hip, move leg outward from the body as far as possible, as shown. Return leg from abducted position to neutral position and across the other leg as far as possible.

Hyperextension of hip. Place the patient in a prone position, and move leg backward from the body as far as possible.

Thumb opposition. Move thumb out and around to touch little finger.

Flexion of the hip and the knee. Bend hip by moving the leg forward as far as possible. Return leg from the flexed position to the neutral position.

Dorsiflexion of foot. Move foot up and toward the leg. Then move the foot down and away from the leg (plantar flexion).

Chart 11-8 • Performing Range-of-Motion Exercises (Continued)

Inversion and eversion of foot. Move foot so that sole is facing outward (eversion). Then move foot so that sole is facing inward (inversion).

Flexion of toes. Bend the toes toward the ball of foot.

Extension of toes. Straighten toes and pull them toward the leg as far as possible.

(with the nurse helping if the patient cannot do the exercise independently), or passive (performed by the nurse). Unless otherwise prescribed, a joint should be moved through its range of motion three times, at least twice a day. The joint to be exercised is supported, the bones above the joint are stabilized, and the body part distal to the joint is moved through the range of motion of the joint. For example, the humerus must be stabilized while the radius and ulna are moved through their range of motion at the elbow joint.

A joint should not be moved beyond its free range of motion; the joint is moved to the point of resistance and stopped at the point of pain. If muscle spasms are present, the joint is moved slowly to the point of resistance. Gentle, steady pressure is then applied until the muscle relaxes, and the motion is continued to the joint's final point of resistance.

To perform assisted or passive range-of-motion exercises, the patient must be in a comfortable supine position with the arms at the sides and the knees extended. Good body posture is maintained during the exercises. The nurse also uses good body mechanics during the exercise session.

PERFORMING THERAPEUTIC EXERCISES. Therapeutic exercises are prescribed by the physician and performed with the assistance and guidance of the physical therapist or nurse. The patient should have a clear understanding of the goal of the prescribed exercise. Written instructions about the frequency, duration, and number of repetitions, as well as simple line drawings of the exercise, help ensure adherence to the exercise program. Return demonstration of the exercises also helps the patient and family to follow the instructions correctly.

When performed correctly, exercise assists in maintaining and building muscle strength, maintaining joint function, preventing deformity, stimulating circulation, developing endurance, and promoting relaxation. Exercise is also valuable in helping restore motivation and the well-being of the patient. Weight-bearing exercises may slow the bone loss that occurs with disability. There are five types of exercise: passive, active-assistive, active, resistive, and isometric. The description, purpose, and action of each of these exercises are summarized in Table 11-1.

Promoting Independent Mobility

When the patient's condition stabilizes, and the patient is able to stand, the patient is assisted to sit up on the side of the bed and then to stand. Tolerance of this activity is assessed. Orthostatic (postural) hypotension may develop when the patient assumes a vertical position. Because of inadequate vasomotor reflexes, blood pools in the splanchnic (visceral or intestinal) area and in the legs, resulting in inadequate cerebral circulation. If indicators of orthostatic hypotension (eg, drop in blood pressure, pallor, diaphoresis, nausea, tachycardia, dizziness) are present, the activity is stopped, and the patient is assisted to a supine position in bed.

Some disabling conditions, such as spinal cord injury, acute brain injury, and other conditions that require extended periods in the recumbent position, prevent the patient from assuming an upright position at the bedside. Several strategies can be used to help the patient assume a 90-degree sitting position. A reclining wheelchair with elevating leg rests allows a slow and controlled progression from a supine position to a 90-degree sitting position. A tilt table (a board that can be tilted in 5- to 10-degree increments from a horizontal to a vertical position) may also be used. The tilt table promotes vasomotor adjustment to positional changes and helps patients with limited standing balance and limited weight-bearing activities avoid the decalcification of bones and low bone mass associated with disuse syndrome and lack of weight-bearing exercise. Physical therapists may use a tilt table for patients who have not been upright due to illness or disability. Gradual elevation of the head of the bed may help. When getting patients with spinal cord injury out of bed, it is important to gradually raise the head of the bed to a 90-degree angle; this may take approximately 10 to 15 minutes.

Graduated compression stockings are used to prevent venous stasis. For some patients, a compression garment (leotard) or snug-fitting abdominal binder and elastic compression bandaging of the legs are needed to prevent venous stasis and orthostatic hypotension. When the patient is standing, the feet are protected with a pair of properly fitted shoes. Extended periods of standing are avoided because of venous pooling and pressure on the soles of the feet. The nurse monitors the patient's blood pressure and pulse and observes for signs and

	Description	Purposes	Action
<i>Passive</i>	An exercise carried out by the therapist or the nurse without assistance from the patient	To retain as much joint range of motion as possible; to maintain circulation	Stabilize the proximal joint and support the distal part; move the joint smoothly, slowly, and gently through its full range of motion; avoid producing pain.
<i>Active-assistive</i>	An exercise carried out by the patient with the assistance of the therapist or the nurse	To encourage normal muscle function	Support the distal part, and encourage the patient to take the joint actively through its range of motion; give no more assistance than is necessary to accomplish the action; short periods of activity should be followed by adequate rest periods.
<i>Active</i>	An exercise accomplished by the patient without assistance; activities include turning from side to side and from back to abdomen and moving up and down in bed	To increase muscle strength	When possible, active exercise should be performed against gravity; the joint is moved through full range of motion without assistance; make sure that the patient does not substitute another joint movement for the one intended.
<i>Resistive</i>	An active exercise carried out by the patient working against resistance produced by either manual or mechanical means	To provide resistance to increase muscle power	The patient moves the joint through its range of motion while the therapist resists slightly at first and then with progressively increasing resistance; sandbags and weights can be used and are applied at the distal point of the involved joint; the movements should be performed smoothly.
<i>Isometric or muscle setting</i>	Alternately contracting and relaxing a muscle while keeping the part in a fixed position; this exercise is performed by the patient	To maintain strength when a joint is immobilized	Contract or tighten the muscle as much as possible without moving the joint, hold for several seconds, then let go and relax; breathe deeply.

symptoms of orthostatic hypotension and cerebral insufficiency (eg, the patient reports feeling faint and weak), which suggest intolerance of the upright position. If the patient does not tolerate the upright position, the nurse should return the patient to the reclining position and elevate his or her legs.

ASSISTING PATIENTS WITH TRANSFER. A transfer is movement of the patient from one place to another (eg, bed to chair, chair to commode, wheelchair to tub). As soon as the patient is permitted out of bed, transfer activities are started. The nurse assesses the patient's ability to participate actively in the transfer and determines, in conjunction with occupational therapists or physical therapists, the adaptive equipment required to promote independence and safety. A lightweight wheelchair with brake extensions, removable and detachable arm rests, and leg rests minimizes structural obstacles during the transfer. Tub seats or benches make transfers in and out of the tub easier and safer. Raised, padded commode seats may also be warranted for patients who must avoid flexing the hips greater than 90 degrees when transferring to a toilet. It is important that the nurse teach the patient hip precautions (ie, no adduction past the midline, no flexion greater than 90 degrees, and no internal rotation); abduction pillows can be used to keep the hip in correct alignment if precautions are warranted.

It is important that the patient maintain muscle strength and, if possible, perform push-up exercises to strengthen the

arm and shoulder extensor muscles. The push-up exercise requires the patient to sit upright in bed; a book is placed under each of the patient's hands to provide a hard surface, and the patient is instructed to push down on the book, raising the body. The nurse should encourage the patient to raise and move the body in different directions by means of these push-up exercises.

The nurse or physical therapist teaches the patient how to transfer. There are several methods of transferring from the bed to the wheelchair when the patient cannot stand, and the technique chosen should take into account the patient's abilities and disabilities. It is helpful for the nurse to demonstrate the technique. If the physical therapist is involved in teaching the patient to transfer, the nurse and physical therapist must collaborate so that consistent instructions are given to the patient. During transfer, the nurse assists and coaches the patient. Figure 11-2 shows weight-bearing and non-weight-bearing transfer.

If the patient's muscles are not strong enough to overcome the resistance of body weight, a polished lightweight board (transfer board, sliding board) may be used to bridge the gap between the bed and the chair. The patient slides across on the board with or without assistance from a caregiver. This board may also be used to transfer the patient from the chair to the toilet or bathtub bench. It is important to avoid the effects of shear on the patient's skin while

Figure 11-2 Methods of patient transfer from the bed to a wheelchair. The wheelchair is in a locked position. Colored areas indicate non-weight-bearing body parts. **A**, Weight-bearing transfer from bed to chair. The patient stands up, pivots until his back is opposite the new seat, and sits down. **B**, (Left) Non-weight-bearing transfer from chair to bed. (Right) With legs braced. **C**, (Left) Non-weight-bearing transfer, combined method. (Right) Non-weight-bearing transfer, pull-up method. One of the wheelchair arms is removed to make getting in and out of the chair easier.

sliding across the board. The nurse should make sure that the patient's fingers do not curl around the edge of the board during the transfer, because the patient's body weight can crush the fingers as he or she moves across the board. Safety is a primary concern during a transfer, and the following guidelines are recommended:

- Wheelchairs and beds must be locked before transfer begins.
- Detachable arm and foot rests are removed to make getting in and out of the chair easier.
- One end of the transfer board is placed under the buttocks and the other end on the surface to which the transfer is being made (eg, the chair).
- The patient is instructed to lean forward, push up with his or her hands, and then slide across the board to the other surface.

Nurses frequently assist weak and incapacitated patients out of bed. The nurse supports and gently assists the patient during position changes, protecting the patient from injury. The nurse avoids pulling on a weak or paralyzed upper ex-

tremity to prevent dislocation of the shoulder. The patient is assisted to move toward the stronger side.

In the home setting, getting in and out of bed and performing chair, toilet, and tub transfers are difficult for patients with weak muscles and loss of hip, knee, and ankle motion. A rope attached to the headboard of the bed enables a patient to move toward the center of the bed, and the use of a rope attached to the footboard facilitates getting in and out of bed. The height of a chair can be raised with cushions on the seat or with hollowed-out blocks placed under the chair legs. Grab bars can be attached to the wall near the toilet and tub to provide leverage and stability.

PREPARING FOR AMBULATION. Regaining the ability to walk is a prime morale builder. However, to be prepared for ambulation—whether with a brace, walker, cane, or crutches—the patient must strengthen the muscles required. Therefore, exercise is the foundation of preparation. The nurse and physical therapist instruct and supervise the patient in these exercises.

For ambulation, the quadriceps muscles, which stabilize the knee joint, and the gluteal muscles are strengthened. To perform quadriceps-setting exercises, the patient contracts the quadriceps muscle by attempting to push the popliteal area against the mattress and at the same time raising the heel. The patient maintains the muscle contraction for a count of five and relaxes for a count of five. The exercise is repeated 10 to 15 times hourly. Exercising the quadriceps muscles prevents flexion contractures of the knee.

In gluteal setting, the patient contracts or “pinches” the buttocks together for a count of five, relaxes for a count of five; the exercise is repeated 10 to 15 times hourly. If assistive devices (ie, walker, cane, crutches) will be used, the muscles of the upper extremities are exercised and strengthened. Push-up exercises are especially useful. While in a sitting position, the patient raises the body by pushing the hands against the chair seat or mattress. The patient should be encouraged to do push-up exercises while in a prone position also. Pull-up exercises done on a trapeze while lifting the body are also effective for conditioning. The patient is taught to raise the arms above the head and then lower them in a slow, rhythmic manner while holding weights. Gradually, the weight is increased. The hands are strengthened by squeezing a rubber ball.

Typically, the physical therapist designs exercises to help the patient develop sitting and standing balance, stability, and coordination needed for ambulation. After sitting and standing balance is achieved, the patient is able to use parallel bars. Under the supervision of the physical therapist, the patient practices shifting weight from side to side, lifting one leg while supporting weight on the other, and then walking between the parallel bars.

A patient who is ready to begin ambulation must be fitted with the appropriate assistive device, instructed about the prescribed weight-bearing limits (eg, non-weight-bearing, partial weight-bearing ambulation), and taught how to use the device safely. Figure 11-3 illustrates some of the

Figure 11-3 Mechanical aids to walking. **A**, Walker. **B**, Three types of canes.

Figure 11-4 Crutch walking. The tripod position for basic crutch stance.

more common assistive devices used in rehabilitation settings. The nurse continually assesses the patient for stability and adherence to weight-bearing precautions and protects the patient from falling. The nurse provides contact guarding by holding on to a gait belt that the patient wears around the waist. The patient should wear sturdy, well-fitting shoes and be advised of the dangers of wet or highly polished floors and throw rugs. The patient should also learn how to ambulate on inclines, uneven surfaces, and stairs.

Ambulating With an Assistive Device: Crutches, a Walker, or a Cane

Crutches are for partial weight-bearing or non-weight-bearing ambulation. Good balance, adequate cardiovascular reserve, strong upper extremities, and erect posture are essential for crutch walking. Ambulating a functional distance (at least the length of a room or house) or maneuvering stairs on crutches requires significant arm strength, because the arms must bear the patient’s weight (Fig. 11-4). The nurse or physical therapist determines which gait is best (Chart 11-9).

A walker provides more support and stability than a cane or crutches. A pick-up walker is best for patients with poor balance and poor cardiovascular reserve, and a rolling walker, which allows automatic walking, is best for patients who cannot lift. A cane helps the patient walk with balance and support and relieves the pressure on weight-bearing joints by redistributing weight.

Before patients can be considered to be independent in walking with crutches, a walker, or a cane, they should learn to sit, stand from sitting, and go up and down stairs using the device. Table 11-2 describes how patients can ambulate and maneuver using each of the three devices.

Table 11-2 NURSING ACTIONS INVOLVED IN USING ASSISTIVE DEVICES (Continued)

	Crutches	Walker	Cane
Going up stairs	Instruct patient to: Advance unaffected leg first up next step. Advance crutches and affected extremity. Unaffected leg goes up first and comes down first.	n/a	Instruct patient to: Step up on unaffected extremity. Place cane and affected extremity up on step.

*For patients who cannot support their weight through the wrist and hand because of arthritis or fracture, platform crutches that support the forearm and allow the weight to be borne through the elbow are available. If weight is borne on the axilla, the pressure of the crutch can damage the brachial plexus nerves, producing “crutch paralysis.”

**Teach patient two gaits so that he or she can change from one to another to avoid fatigue. Also, a faster gait can be used when walking an uninterrupted distance and a slower gait can be used for short distances or in crowded places.

Assisting Patients With an Orthosis or Prosthesis

Orthoses and prostheses are designed to facilitate mobilization and to maximize the patient’s quality of life. An orthosis is an external appliance that provides support, prevents or corrects deformities, and improves function. Orthoses include braces, splints, collars, corsets, and supports that are designed and fitted by orthotists or prosthetists. Static orthoses (no moving parts) are used to stabilize joints and prevent contractures. Dynamic orthoses are flexible and are used to improve function by assisting weak muscles. A prosthesis is an artificial body part; it may be internal, such as an artificial knee or hip joint, or external, such as an artificial leg or arm.

In addition to learning how to apply and remove the orthosis and maneuver the affected body part correctly, patients must learn how to properly care for the skin that comes in contact with the appliance. Skin problems or pressure ulcers may develop if the device is applied too tightly or too loosely, or if it is adjusted improperly. The nurse instructs the patient to clean and inspect the skin daily, to make sure the brace fits snugly without being too tight, to check that the padding distributes pressure evenly, and to wear a cotton garment without seams between the orthosis and the skin.

If the patient has had an amputation, the nurse promotes tissue healing, uses compression dressings to promote residual limb shaping, and minimizes contracture formation. A permanent prosthetic limb cannot be fitted until the tissue has healed completely and the residual limb shape is stable and free of edema. The nurse also helps the patient cope with the emotional issues surrounding loss of a limb and encourages acceptance of the prosthesis. The prosthetist, nurse, and physician collaborate to provide instructions related to skin care and care of the prosthesis.

Evaluation

Expected Patient Outcomes

Expected patient outcomes may include:

1. Demonstrates improved physical mobility
 - a. Maintains muscle strength and joint mobility
 - b. Does not develop contractures
 - c. Participates in exercise program
2. Transfers safely
 - a. Demonstrates assisted transfers
 - b. Performs independent transfers

3. Ambulates with maximum independence
 - a. Uses ambulatory aid safely
 - b. Adheres to weight-bearing prescription
 - c. Requests assistance as needed
4. Demonstrates increased activity tolerance
 - a. Does not experience episodes of orthostatic hypotension
 - b. Reports absence of fatigue with ambulatory efforts
 - c. Gradually increases distance and speed of ambulation

NURSING PROCESS

THE PATIENT WITH IMPAIRED SKIN INTEGRITY

Pressure ulcers are localized areas of necrotic soft tissue that occur when pressure applied to the skin over time is greater than normal capillary closure pressure, which is about 32 mm Hg. Critically ill patients have a lower capillary closure pressure and a greater risk of pressure ulcers.

Patients who are prone to pressure ulcers include those confined to bed for long periods, those with motor or sensory dysfunction, and those who experience muscular atrophy and reduction of padding between the overlying skin and the underlying bone.

The Healthcare Cost and Utilization Project (HCUP) reported that 455,000 hospitalizations annually in the United States are complicated by pressure ulcers (Russo & Elixhauser, 2006); this represents a 63% increase over a 10-year period. The average length of stay for hospitalizations related to pressure ulcers is 13 days, with an average treatment cost of nearly \$37,800 for each affected patient. All possible efforts to prevent skin breakdown must be made because the treatment of pressure ulcers is costly in terms of health care dollars and quality of life for patients at risk.

The initial sign of pressure is erythema (redness of the skin) caused by reactive hyperemia, which normally resolves in less than 1 hour. Unrelieved pressure results in tissue ischemia or anoxia. The cutaneous tissues become broken or destroyed, leading to progressive destruction and necrosis of underlying soft tissue, and the resulting pressure ulcer is painful and slow to heal.

CHART
11-10

**Risk Factors for Pressure
Ulcers**

- Prolonged pressure on tissue
- Immobility, compromised mobility
- Loss of protective reflexes, sensory deficit/loss
- Poor skin perfusion, edema
- Malnutrition, hypoproteinemia, anemia, vitamin deficiency
- Friction, shearing forces, trauma
- Incontinence of urine or feces
- Altered skin moisture: excessively dry, excessively moist
- Advanced age, debilitation
- Equipment: casts, traction, restraints

Assessment

Immobility, impaired sensory perception or cognition, decreased tissue perfusion, decreased nutritional status, friction and shear forces, increased moisture, and age-related skin changes all contribute to the development of pressure ulcers. Chart 11-10 lists risk factors for pressure ulcers.

Immobility

When a person is immobile and inactive, pressure is exerted on the skin and subcutaneous tissue by objects on which the person rests, such as a mattress, chair seat, or cast. The development of pressure ulcers is directly related to the duration of immobility: If pressure continues long enough, small vessel thrombosis and tissue necrosis occur and a pressure ulcer results. Weight-bearing bony prominences are most susceptible to pressure ulcer development because they are covered only by skin and small amounts of subcutaneous tissue. Susceptible areas include the sacrum and coccygeal areas, ischial tuberosities (especially in people who sit for prolonged periods), greater trochanter, heel, knee, malleolus, medial condyle of the tibia, fibular head, scapula, and elbow (Fig. 11-5).

Impaired Sensory Perception or Cognition

Patients with sensory loss, impaired level of consciousness, or paralysis may not be aware of the discomfort associated with prolonged pressure on the skin and therefore may not change their position themselves to relieve the pressure. This prolonged pressure impedes blood flow, reducing nourishment of the skin and underlying tissues. A pressure ulcer may develop in a short period of time.

Decreased Tissue Perfusion

Any condition that reduces the circulation and nourishment of the skin and subcutaneous tissue (altered peripheral tissue perfusion) increases the risk of pressure ulcer development. Patients with diabetes mellitus have compromised microcirculation. Similarly, patients with edema have impaired circulation and poor nourishment of the skin tissue. Obese patients have large amounts of poorly vascularized adipose tissue, which is susceptible to breakdown.

Decreased Nutritional Status

Nutritional deficiencies, anemias, and metabolic disorders also contribute to development of pressure ulcers. Anemia, regardless of its cause, decreases the blood's oxygen-carrying ability and predisposes the patient to pressure ulcers. Patients who have low protein levels or who are in a negative nitrogen

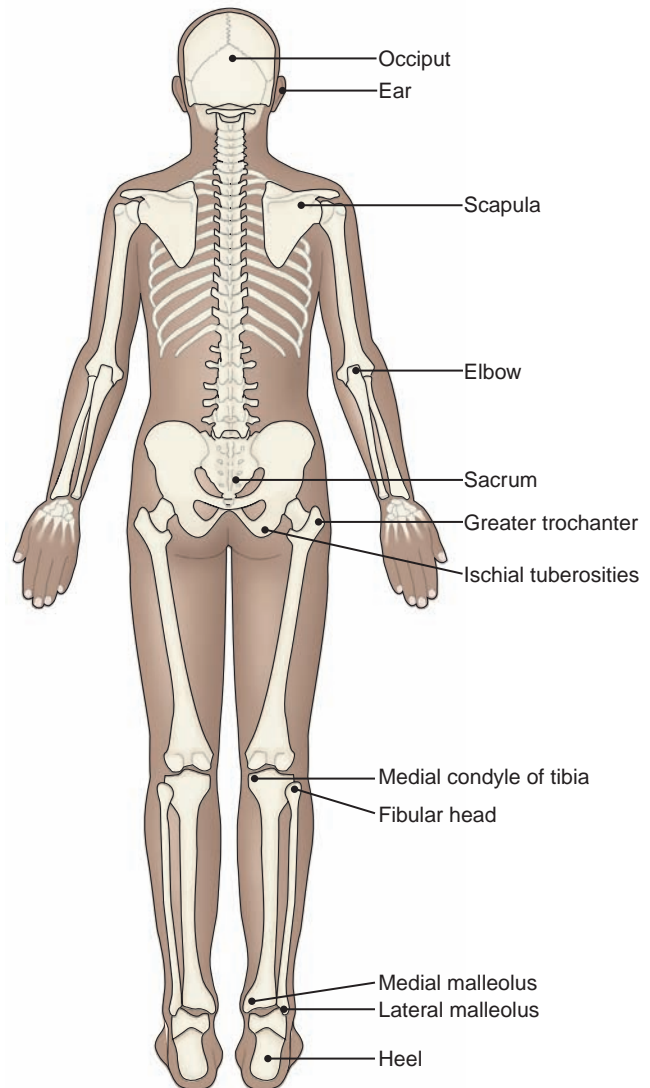

Figure 11-5 Areas susceptible to pressure ulcers.

balance experience tissue wasting and inhibited tissue repair. Serum albumin and prealbumin levels are sensitive indicators of protein deficiency. Serum albumin levels of less than 3 g per mL are associated with hypoalbuminemic tissue edema and increased risk of pressure ulcers. Prealbumin levels are more sensitive indicators of protein status than albumin levels, but they are more costly to assess. The nurse should assess the patient's prealbumin and albumin values and electrolyte panel. Specific nutrients, such as vitamin C and trace minerals, are needed for tissue maintenance and repair.

Friction and Shear

Mechanical forces also contribute to the development of pressure ulcers. Friction is the resistance to movement that occurs when two surfaces are moved across each other. Shear is created by the interplay of gravitational forces (forces that push the body down) and friction. When shear occurs, tissue layers slide over one another, blood vessels stretch and twist, and the microcirculation of the skin and subcutaneous tissue is disrupted. Evidence of deep tissue damage may be slow to develop and may present through the development of a sinus tract. The sacrum and heels are most susceptible to the

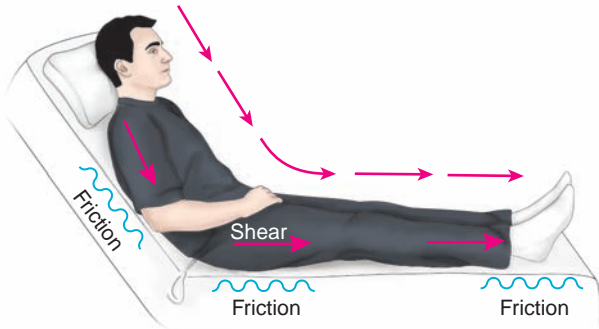

Figure 11-6 Mechanical forces contribute to pressure ulcer development. As the person slides down or is improperly pulled up in bed, *friction* resists this movement. *Shear* occurs when one layer of tissue slides over another, disrupting microcirculation of skin and subcutaneous tissue.

effects of shear. Pressure ulcers from friction and shear occur when the patient slides down in bed (Fig. 11-6) or when the patient is positioned or moved improperly (eg, dragged up in bed). Spastic muscles and paralysis increase the patient's vulnerability to pressure ulcers related to friction and shear.

Increased Moisture

Prolonged contact with moisture from perspiration, urine, feces, or drainage produces maceration (softening) of the skin. The skin reacts to the caustic substances in the excreta or drainage and becomes irritated. Moist, irritated skin is more vulnerable to pressure breakdown. Once the skin breaks, the area is invaded by microorganisms (eg, streptococci, staphylococci, *Pseudomonas aeruginosa*, *Escherichia coli*), and infection occurs. Foul-smelling infectious drainage is present. The lesion may enlarge and allow a continuous loss of serum, which may further deplete the body of essential protein needed for tissue repair and maintenance. The lesion may continue to enlarge and extend deep into the fascia, muscle, and bone, with multiple sinus tracts radiating from the pressure ulcer. With extensive pressure ulcers, life-threatening infections and sepsis may develop, frequently from gram-negative organisms.

Gerontologic Considerations

In older adults, the skin has diminished epidermal thickness, dermal collagen, and tissue elasticity. The skin is drier as a result of diminished sebaceous and sweat gland activity. Cardiovascular changes result in decreased tissue perfusion. Muscles atrophy and bone structures become prominent. Diminished sensory perception and reduced ability to reposition oneself contribute to prolonged pressure on the skin. Therefore, older adults are more susceptible to pressure ulcers, which cause pain, suffering, and reduced quality of life.

Nursing Actions Related to Assessment

In assessing patients for potential risk of pressure ulcer development, the nurse assesses the patient's mobility, sensory perception, cognitive abilities, tissue perfusion, nutritional status, friction and shear forces, sources of moisture on the skin, and age. Nursing actions include:

- Assess total skin condition at least twice a day.
- Inspect each pressure site for erythema.
- Assess areas of erythema for blanching response.
- Palpate the skin for increased warmth.

- Inspect for dry skin, moist skin, and breaks in skin.
- Note drainage and odor.
- Evaluate level of mobility.
- Note safety and assistive devices (eg, restraints, splints).
- Evaluate circulatory status (eg, peripheral pulses, edema).
- Assess neurovascular status.
- Determine presence of incontinence.
- Evaluate nutritional and hydration status.
- Review the results of the patient's laboratory studies, including hematocrit, hemoglobin, electrolytes, albumin, transferrin, and creatinine.
- Note present health problems.
- Review current medications.

Scales such as the Braden scale (Table 11-3) or Norton scale may be used to facilitate systematic assessment and quantification of a patient's risk for pressure ulcer, although the nurse should recognize that the reliability of these scales is not well established for all patient populations. If a pressure area is noted, the nurse notes size and location and uses a grading system to describe severity (Chart 11-11).

The appearance of purulent drainage or foul odor suggests an infection. With an extensive pressure ulcer, deep pockets of infection are often present. Drying and crusting of exudate may be present. Infection of a pressure ulcer may advance to osteomyelitis, pyarthrosis (pus formation within a joint cavity), sepsis, and septic shock.

Nursing Diagnosis

Based on the assessment data, the nursing diagnoses may include the following:

- Risk for impaired skin integrity
- Impaired skin integrity related to immobility, decreased sensory perception, decreased tissue perfusion, decreased nutritional status, friction and shear forces, excessive moisture, or advanced age

Planning and Goals

The major goals may include relief of pressure, improved mobility, improved sensory perception, improved tissue perfusion, improved nutritional status, minimized friction and shear forces, dry surfaces in contact with skin, and healing of pressure ulcer, if present.

Nursing Interventions

Relieving Pressure

Frequent changes of position are needed to relieve and redistribute the pressure on the patient's skin and to promote blood flow to the skin and subcutaneous tissues. This can be accomplished by teaching the patient to change position or by turning and repositioning the patient. The patient's family members should be taught how to position and turn the patient at home to prevent pressure ulcers. Shifting weight allows the blood to flow into the ischemic areas and helps tissues recover from the effects of pressure.

For patients who spend long periods in a wheelchair, pressure can be relieved by:

- Push-ups: The patient pushes down on armrests and raises buttocks off the seat of the chair (Fig. 11-7).
- One half push-up: The patient repeats the push-up on the right side and then the left, pushing up on one side by pushing down on the armrest.

Table 11-3 BRADEN SCALE FOR PREDICTING PRESSURE SORE RISK

Patient's Name _____ Evaluator's Name _____		Date of Assessment _____						
SENSORY PERCEPTION Ability to respond meaningfully to pressure-related discomfort	1. Completely Limited Unresponsive (does not moan, flinch, or grasp) to painful stimuli, due to diminished level of consciousness or sedation OR limited ability to feel pain over most of body.	2. Very Limited Responds only to painful stimuli. Cannot communicate discomfort except by moaning or restlessness OR has a sensory impairment that limits the ability to feel pain or discomfort over ½ of body.	3. Slightly Limited Responds to verbal commands, but cannot always communicate discomfort or the need to be turned. OR has some sensory impairment that limits ability to feel pain or discomfort in 1 or 2 extremities.	4. No Impairment Responds to verbal commands. Has no sensory deficit that would limit ability to feel or voice pain or discomfort.				
MOISTURE Degree to which skin is exposed to moisture	1. Constantly Moist Skin is kept moist almost constantly by perspiration, urine, etc. Dampness is detected every time patient is moved or turned.	2. Very Moist Skin is often, but not always, moist. Linen must be changed at least once a shift.	3. Occasionally Moist: Skin is occasionally moist, requiring an extra linen change approximately once a day.	4. Rarely Moist Skin is usually dry, linen only requires changing at routine intervals.				
ACTIVITY Degree of physical activity	1. Bedfast Confined to bed.	2. Chairfast Ability to walk severely limited or nonexistent. Cannot bear own weight and/or must be assisted into chair or wheelchair.	3. Walks Occasionally Walks occasionally during day, but for very short distances, with or without assistance. Spends majority of each shift in bed or chair.	4. Walks Frequently Walks outside room at least twice a day and inside room at least once every two hours during waking hours.				
MOBILITY Ability to change and control body position	1. Completely Immobile Does not make even slight changes in body or extremity position without assistance.	2. Very Limited Makes occasional slight changes in body or extremity position but unable to make frequent or significant changes independently.	3. Slightly Limited Makes frequent though slight changes in body or extremity position independently.	4. No Limitation Makes major and frequent changes in position without assistance.				
NUTRITION Usual food intake pattern	1. Very Poor Never eats a complete meal. Rarely eats more than a 1/3 of any food offered. Eats 2 servings or less of protein (meat or dairy products) per day. Takes fluids poorly. Does not take a liquid dietary supplement OR is NPO and/or maintained on clear liquids or IVs for more than 5 days.	2. Probably Inadequate Rarely eats a complete meal and generally eats only about 1/2 of any food offered. Protein intake includes only 3 servings of meat or dairy products per day. Occasionally will take a dietary supplement. OR receives less than optimum amount of liquid diet or tube feeding.	3. Adequate Eats over half of most meals. Eats a total of 4 servings of protein (meat, dairy products) per day. Occasionally will refuse a meal, but will usually take a supplement when offered OR is on a tube feeding or TPN regimen, which probably meets most of nutritional needs	4. Excellent Eats most of every meal. Never refuses a meal. Usually eats a total of 4 or more servings of meat and dairy products. Occasionally eats between meals. Does not require supplementation.				
FRICITION AND SHEAR	1. Problem Requires moderate to maximum assistance in moving. Complete lifting without sliding against sheets is impossible.	2. Potential Problem Moves feebly or requires minimum assistance. During a move skin probably slides to some extent against	3. No Apparent Problem Moves in bed and in chair independently and has sufficient muscle strength to lift up completely during move.

Chart 11-11 • Stages in the Development of Pressure Ulcers

Stage I

- Area of erythema
- Erythema does not blanch with pressure
- Skin temperature elevated
- Tissue swollen and congested
- Patient complains of discomfort
- Erythema progresses to dusky blue-gray

Stage II

- Skin breaks
- Abrasion, blister, or shallow crater
- Edema persists
- Ulcer drains
- Infection may develop
- Partial-thickness wound

Stage III

- Ulcer extends into subcutaneous tissue
- Necrosis and drainage continue
- Infection develops
- Full-thickness wound

Stage IV

- Ulcer extends to underlying muscle and bone
- Deep pockets of infection develop
- Necrosis and drainage continue
- Full-thickness wound

From Weber, J. W. & Kelley, J. (2003). *Health assessment in nursing* (2nd ed.). Philadelphia: Lippincott Williams & Wilkins.

Figure 11-7 Wheelchair push-up to prevent ischial pressure ulcers. These push-ups should become an automatic routine (every 15 minutes) for the person with paraplegia. The person should stay up, out of contact with the seat for several seconds. The wheels are kept in the locked position during the exercise.

- Moving side to side: The patient moves from one side to the other while sitting in the chair.
- Shifting: The patient bends forward with the head down between the knees (if able) and constantly shifts in the chair.

Positioning the Patient

The degree of ability to move independently, the comfort, fatigue, loss of sensation, overall physical and mental status, and specific disorder, influences plans for changing position. Patients should be positioned laterally, prone, and dorsally in sequence unless a position is not tolerated or is contraindicated. Generally, those who experience discomfort after 30 to 60 minutes of lying prone need to be repositioned. The recumbent position is preferred to the semi-Fowler's position because of increased supporting body surface area in this position.

Patients able to shift their weight every 15 to 20 minutes and move independently may change total position every 2 to 4 hours. Indications for routine repositioning every 2 hours or more frequently include loss of sensation, paralysis, coma, and edema.

In addition to regular turning, small shifts of body weight, such as repositioning of an ankle, elbow, or shoulder, are necessary. The skin is inspected at each position change and assessed for temperature elevation. If redness or heat is noted or if the patient complains of discomfort, pressure on the area must be relieved.

Another way to relieve pressure over bony prominences is the bridging technique, accomplished through the correct positioning of pillows. Just as a bridge is supported on pillars

to allow traffic to move underneath, the body can be supported by pillows to allow for space between bony prominences and the mattress. A pillow or commercial heel protector may be used to support the heels off the bed when the patient is supine. Placing pillows superior and inferior to the sacrum relieves sacral pressure. Supporting the patient in a 30-degree side-lying position avoids pressure on the trochanter. In elderly patients, frequent small shifts of body weight may be effective. Placing a small rolled towel or sheepskin under a shoulder or hip allows a return of blood flow to the skin in the area on which the patient is sitting or lying. The towel or sheepskin is moved around the patient's pressure points in a clockwise fashion. A turning schedule can help the family keep track of the patient's turns.

Using Pressure-Relieving Devices

At times, special equipment and beds may be needed to help relieve the pressure on the skin. This is particularly important for patients who cannot get out of bed and who have risk factors for pressure ulcer development. These devices are designed to provide support for specific body areas or to distribute pressure evenly.

A patient who sits in a wheelchair for prolonged periods should have wheelchair cushions fitted and adjusted on an individualized basis, using pressure measurement techniques as a guide to selection and fitting. The aim is to redistribute pressure away from areas at risk for ulcers, but no cushion can eliminate excessive pressure completely. The patient should be reminded to shift weight frequently and to rise for a few seconds every 15 minutes while sitting in a chair (see Fig. 11-7).

Static support devices (eg, high-density foam, air, or liquid mattress overlays) distribute pressure evenly by bringing more of the patient's body surface into contact with the supporting surface. Gel-type flotation pads and air-fluidized beds reduce pressure. The weight of a body floating on a fluid system is evenly distributed over the entire supporting surface. Therefore, as the body sinks into the fluid, additional surface becomes available for weight bearing, body weight per unit area is decreased, and there is less pressure on the body parts.

Soft, moisture-absorbing padding is also useful because the softness and resilience of padding provide for more even distribution of pressure and the dissipation and absorption of moisture, along with freedom from wrinkles and friction. Bony prominences may be protected by gel pads, sheepskin padding, or soft foam rubber beneath the sacrum, the trochanters, heels, elbows, scapulae, and back of the head when there is pressure on these sites.

Specialized beds are designed to prevent pressure on the skin. Air-fluidized beds allow the patient to float. Dynamic support surfaces, such as low air-loss pockets, alternately inflate and deflate sections to change support pressure for very high-risk patients who are critically ill and debilitated and cannot be repositioned to relieve pressure. Oscillating or kinetic beds change pressure by means of rocking movements of the bed that redistribute the patient's weight and stimulate circulation. These beds may be used with patients who have injuries due to multiple trauma. A systematic review of 59 randomized controlled trials has suggested that specialized beds, which are more expensive than mattress overlays, are no more effective at preventing pressure ulcers than the overlays (Reddy, Gill & Rochon, 2006).

Improving Mobility

The patient is encouraged to remain active and is ambulated whenever possible. When sitting, the patient is reminded to change positions frequently to redistribute weight. Active and passive exercises increase muscular, skin, and vascular tone. For patients at risk for pressure ulcers, turning and exercise schedules are essential: repositioning must occur around the clock.

Improving Sensory Perception

The nurse helps the patient recognize and compensate for altered sensory perception. Depending on the origin of the alteration (eg, decreased level of consciousness, spinal cord lesion), specific interventions are selected. Strategies to improve cognition and sensory perception may include stimulating the patient to increase awareness of self in the environment, encouraging the patient to participate in self-care, or supporting the patient's efforts toward active compensation for loss of sensation (eg, a patient with paraplegia lifting up from the sitting position every 15 minutes). A patient with quadriplegia should be weight-shifted every 30 minutes while sitting in a wheelchair. When decreased sensory perception exists, the patient and caregivers are taught to inspect potential pressure areas visually every morning and evening, using a mirror if necessary, for evidence of pressure ulcer development.

Improving Tissue Perfusion

Activity, exercise, and repositioning improve tissue perfusion. Massage of erythematous areas is avoided because damage to the capillaries and deep tissue may occur.

NURSING ALERT

The nurse should avoid massaging reddened areas because this may increase the damage to already traumatized skin and tissue.

In patients who have evidence of compromised peripheral circulation (eg, edema), positioning and elevation of the edematous body part to promote venous return and diminish congestion improve tissue perfusion. In addition, the nurse or family must be alert to environmental factors (eg, wrinkles in sheets, pressure of tubes) that may con-

tribute to pressure on the skin and diminished circulation and remove the source of pressure.

Improving Nutritional Status

The patient's nutritional status must be adequate and a positive nitrogen balance must be maintained because pressure ulcers develop more quickly and are more resistant to treatment in patients with nutritional disorders. A high-protein diet with protein supplements may be helpful. Iron preparations may be necessary to raise the hemoglobin concentration so that tissue oxygen levels can be maintained within acceptable limits. Ascorbic acid (vitamin C) is necessary for tissue healing. Other nutrients associated with healthy skin include vitamin A, B vitamins, zinc, and sulfur. With adequate nutrition and hydration, the skin can remain healthy, and damaged tissues can be repaired (Table 11-4).

To assess the patient's nutritional status in response to therapeutic strategies, the nurse monitors the patient's hemoglobin, prealbumin level, and body weight weekly. Nutritional assessment is described in further detail in Chapter 5.

Reducing Friction and Shear

Shear occurs when patients are pulled, allowed to slump, or move by digging heels or elbows into the mattress. Raising the head of the bed by even a few centimeters increases the shearing force over the sacral area; therefore, the semireclining position is avoided in patients at risk. Proper positioning with adequate support is also important when the patient is sitting in a chair.

NURSING ALERT

To avoid shearing forces when repositioning patients, the nurse must lift and avoid dragging patients across a surface. Lift devices should be used to prevent occupational injuries.

Minimizing Irritating Moisture

Continuous moisture on the skin must be prevented by meticulous hygiene measures. It is important to pay special attention to skin folds, including areas under the breasts, arms, and groin, and between the toes. Perspiration, urine, stool, and drainage must be removed from the skin promptly. The soiled skin should be washed immediately

Nutrient	Rationale	Recommended Amount
Protein	Tissue repair	1.25–1.50 g/kg/day
Calories	Spare protein Restore normal weight	30–35 calories/kg/day
Water	Maintain homeostasis	1 mL/calorie fed or 30 mL/kg/day
Multivitamin	Promote collagen formation	1 daily
Vitamin C	Promote collagen synthesis Support integrity of capillary wall	500–1000 mg daily
Zinc sulfate	Cofactor for collagen formation and protein synthesis Normal lymphocyte and phagocyte response	220 mg daily
Vitamin A	Stimulate epithelial cells Stimulate immune response	
<i>Caution:</i> An excess can cause an excessive inflammatory response that could impair healing		

with mild soap and water and blotted dry with a soft towel. The skin may be lubricated with a bland lotion to keep it soft and pliable. Drying agents and powders are avoided. Topical barrier ointments (eg, petroleum jelly) may be helpful in protecting the skin of patients who are incontinent.

Absorbent pads that wick moisture away from the body should be used to absorb drainage. Patients who are incontinent need to be checked regularly and have their wet incontinence pads and linens changed promptly. Their skin needs to be cleansed and dried promptly.

Promoting Pressure Ulcer Healing

Regardless of the stage of the pressure ulcer, the pressure on the area must be eliminated because the ulcer will not heal until all pressure is removed. The patient must not lie or sit on the pressure ulcer, even for a few minutes. Individualized positioning and turning schedules must be written in the plan of nursing care and followed meticulously.

In addition, inadequate nutritional status and fluid and electrolyte abnormalities must be corrected to promote healing. Wounds from which body fluids and protein drain place the patient in a catabolic state and predispose to hypoproteinemia and serious secondary infections. Protein deficiency must be corrected to promote the healing of the pressure ulcer. Carbohydrates are necessary to “spare” the protein and to provide an energy source. Vitamin C and trace elements, especially zinc, are necessary for collagen formation and wound healing.

DEEP TISSUE INJURY. Deep tissue injury (DTI) is a localized area of discolored, purple, intact skin, or blood-filled blister that is due to underlying soft tissue damage from pressure or shear. DTIs may be preceded by reports of localized pain or detection of skin with underlying tissue that feels firm, mushy, boggy, or warmer or colder than adjacent skin. These tissue injuries may evolve rapidly, and immediate pressure relief to the affected area is indicated.

STAGE I PRESSURE ULCERS. To permit healing of stage I pressure ulcers, the pressure is removed to allow increased tissue perfusion, nutritional and fluid and electrolyte balance are maintained, friction and shear are reduced, and moisture to the skin is avoided.

STAGE II PRESSURE ULCERS. Stage II pressure ulcers typically have broken skin and present with a red-pink wound bed. However, intact, serum-filled blisters or ruptured blisters are sometimes apparent. In addition to measures listed for stage I pressure ulcers, a moist environment, in which migration of epidermal cells over the ulcer surface occurs more rapidly, should be provided to aid wound healing. The ulcer is gently cleansed with sterile saline solution. Use of a heat lamp to dry the open wound is avoided, as is use of antiseptic solutions that damage healthy tissues and delay wound healing. Semipermeable occlusive dressings, hydrocolloid wafers, or wet saline dressings are helpful in providing a moist environment for healing and in minimizing the loss of fluids and proteins from the body.

STAGES III AND IV PRESSURE ULCERS. Stages III and IV pressure ulcers are characterized by extensive tissue damage. In addition to the measures listed for stage I, these advanced, draining, necrotic pressure ulcers must be cleaned

(débrided) to create an area that will heal. Necrotic, devitalized tissue favors bacterial growth, delays granulation, and inhibits healing. Wound cleaning and dressing are uncomfortable; therefore, the nurse must prepare the patient for the procedure by explaining what will occur and administering prescribed analgesia.

Débridement may be accomplished by wet-to-damp dressing changes, mechanical flushing of necrotic and infective exudate, application of prescribed enzyme preparations that dissolve necrotic tissue, or surgical dissection. If an eschar (dry scab) covers the ulcer, it is removed surgically to ensure a clean, vitalized wound. Exudate may be absorbed by dressings or special hydrophilic powders, beads, or gels. Cultures of infected pressure ulcers are obtained to guide the selection of antibiotic therapy.

After the pressure ulcer is clean, a topical treatment is prescribed to promote granulation. New granulation tissue must be protected from reinfection, drying, and damage, and care should be taken to prevent pressure and further trauma to the area. Dressings, solutions, and ointments applied to the ulcer should not disrupt the healing process. For chronic, noninfected ulcers that are healing by secondary intention (healing of an open wound from the base upward by laying down new tissue), vacuum-assisted closure (VAC) or hyperbaric oxygen treatment may be used. VAC involves the use of a negative-pressure sponge dressing in the wound to increase blood flow, increasing formation of granulation tissue and nutrient uptake and decreasing bacterial load. Hyperbaric oxygen therapy involves either the application of topical oxygen at increased pressure directly to the wound or placing the patient into a hyperbaric oxygen chamber. Both methods of hyperbaric oxygen therapy promote wound healing by stimulating new vascular growth and aiding in the preservation of damaged tissue (Roedek-Wiedmann, Bennett & Kranke, 2005).

Multiple agents and protocols are used to treat pressure ulcers, but consistency is an important key to success. Objective evaluation of the pressure ulcer (eg, measurement of the size and depth of the pressure ulcer, inspection for granulation tissue) for response to the treatment protocol must be made every 4 to 6 days. Taking photographs at weekly intervals is a reliable strategy for monitoring the healing process, which may take weeks to months.

Surgical intervention is necessary when the ulcer is extensive, when complications (eg, fistula) exist, and when the ulcer does not respond to treatment. Surgical procedures include débridement, incision and drainage, bone resection, and skin grafting. Osteomyelitis is a common complication of wounds of stage IV depth. See Chapter 68 for more information on osteomyelitis.

Preventing Recurrence

Recurrence of pressure ulcers should be anticipated; therefore, active, preventive intervention and frequent continuing assessments are essential. The patient's tolerance for sitting or lying on the healed pressure area is increased gradually by increasing the time that pressure is allowed on the area in 5- to 15-minute increments. The patient is taught to increase mobility and to follow a regimen of turning, weight-shifting, and repositioning. The patient teaching plan includes strategies to reduce the risk of pressure

ulcers and methods to detect, inspect, and minimize pressure areas. Early recognition and intervention are keys to long-term management of potential impaired skin integrity.

Evaluation

Expected Patient Outcomes

Expected patient outcomes may include:

1. Maintains intact skin
 - a. Exhibits no areas of nonblanchable erythema at bony prominences
 - b. Avoids massage of bony prominences
 - c. Exhibits no breaks in skin
2. Limits pressure on bony prominences
 - a. Changes position every 1 to 2 hours
 - b. Uses bridging techniques to reduce pressure
 - c. Uses special equipment as appropriate
 - d. Raises self from seat of wheelchair every 15 minutes
3. Increases mobility
 - a. Performs range-of-motion exercises
 - b. Adheres to turning schedule
 - c. Advances sitting time as tolerated
4. Has improved sensory and cognitive ability
 - a. Demonstrates improved level of consciousness
 - b. Remembers to inspect potential pressure ulcer areas every morning and evening
5. Demonstrates improved tissue perfusion
 - a. Exercises to increase circulation
 - b. Elevates body parts susceptible to edema
6. Attains and maintains adequate nutritional status
 - a. Verbalizes the importance of protein and vitamin C in diet
 - b. Eats diet high in protein and vitamin C
 - c. Exhibits hemoglobin, electrolyte, prealbumin, transferrin, and creatinine levels at acceptable levels
7. Avoids friction and shear
 - a. Avoids semireclining position
 - b. Uses heel protectors when appropriate
 - c. Lifts body instead of sliding across surfaces
8. Maintains clean, dry skin
 - a. Avoids prolonged contact with wet or soiled surfaces
 - b. Keeps skin clean and dry
 - c. Uses lotion to keep skin lubricated

NURSING PROCESS

THE PATIENT WITH ALTERED ELIMINATION PATTERNS

Urinary incontinence and bowel incontinence or constipation and impaction are problems that often occur in patients with disabilities. Incontinence curtails the person's independence, causing embarrassment and isolation. It occurs in as much as 15% of the community-based elderly population, and nearly 50% of nursing home residents have bowel or bladder incontinence or both (Taylor & Kuchel, 2006). In addition, constipation may be

a problem in patients with disabilities. Complete and predictable evacuation of the bowel is the goal. If a bowel routine is not established, the patient may experience abdominal distention; small, frequent oozing of stool; or impaction.

Assessment

Urinary incontinence may result from multiple causes, including urinary tract infection, detrusor instability, bladder outlet obstruction or incompetence, neurologic impairment, bladder spasm or contracture, and inability to reach the toilet in time. Urinary incontinence can be classified as urge, reflex, stress, functional, or total:

- *Urge incontinence*: involuntary elimination of urine associated with a strong perceived need to void
- *Reflex (neurogenic) incontinence*: associated with a spinal cord lesion that interrupts cerebral control, resulting in no sensory awareness of the need to void
- *Stress incontinence*: associated with weakened perineal muscles that permit leakage of urine when intra-abdominal pressure is increased (eg, with coughing or sneezing)
- *Functional incontinence*: incontinence in patients with intact urinary physiology who experience mobility impairment, environmental barriers, or cognitive problems and cannot reach and use the toilet before soiling themselves
- *Total incontinence*: occurs in patients who cannot control excreta because of physiologic or psychological impairment; management of the excreta is an essential focus of nursing care.

The health history is used to explore bladder and bowel function, symptoms associated with dysfunction, physiologic risk factors for elimination problems, perception of micturition (urination, or voiding) and defecation cues, and functional toileting abilities. Previous and current fluid intake and voiding patterns may be helpful in designing the plan of nursing care. A record of times of voiding and amounts voided is kept for at least 48 hours. In addition, episodes of incontinence and associated activity (eg, coughing, sneezing, lifting), fluid intake time and amount, and medications are recorded. This record is analyzed and used to determine patterns and relationships of incontinence to other activities and factors.

The ability to get to the bathroom, manipulate clothing, and use the toilet are important functional factors that may be related to incontinence. Related cognitive functioning (perception of need to void, verbalization of need to void, and ability to learn to control urination) must also be assessed. In addition, the nurse reviews the results of the diagnostic studies (eg, urinalysis, urodynamic tests, postvoiding residual volumes).

Bowel incontinence and constipation may result from multiple causes, such as diminished or absent sphincter control, cognitive or perceptual impairment, neurogenic factors, diet, and immobility. The origin of the bowel problem must be determined. The nurse assesses the patient's normal bowel patterns, nutritional patterns, use of laxatives, gastrointestinal problems (eg, colitis), bowel sounds, anal reflex and tone, and functional abilities. The character and frequency of bowel movements are recorded and analyzed.

Nursing Diagnosis

Based on the assessment data, major nursing diagnoses may include the following:

- Impaired urinary elimination
- Urinary retention
- Bowel incontinence

Planning and Goals

The major goals may include control of urinary incontinence or urinary retention, control of bowel incontinence, and regular elimination patterns.

Nursing Interventions

Promoting Urinary Continence

After the nature of the urinary incontinence has been identified, a plan of nursing care is developed based on analysis of the assessment data. Various approaches to promote urinary continence have been developed. Most approaches attempt to condition the body to control urination or to minimize the occurrence of unscheduled urination. Selection of the approach depends on the cause and type of the incontinence. For the program to be successful, participation by the patient and a desire to avoid incontinence episodes are crucial; an optimistic attitude with positive feedback for even slight gains is essential for success. Accurate recording of intake and output and of the patient's response to selected strategies is essential for evaluation.

At no time should the fluid intake be restricted to decrease the frequency of urination. Sufficient fluid intake (2000 to 3000 mL per day, according to patient needs) must be ensured. To optimize the likelihood of voiding as scheduled, measured amounts of fluids may be administered about 30 minutes before voiding attempts. In addition, most of the fluids should be consumed before evening to minimize the need to void frequently during the night.

NURSING ALERT

Carbonated soft drinks, milk shakes, alcohol, tomato juice, and citrus fruit juices are alkaline-producing drinks that promote bacterial growth in the urine. Patients should be encouraged to drink more acid-producing fluids (eg, cranberry and cranapple juice) to reduce the chance of urinary tract infection. Water is a preferred fluid because it flushes the kidneys and bladder.

The goal of bladder training is to restore the bladder to normal function. Bladder training can be used with cognitively intact patients experiencing urge incontinence. A voiding and toileting schedule is developed based on analysis of the assessment data. The schedule specifies times for the patient to try to empty the bladder using a bedpan, toilet, or commode. Privacy should be provided during voiding efforts. The interval between voiding times in the early phase of the bladder training period is short (90 to 120 minutes). The patient is encouraged not to void until the specified voiding time. Voiding success and episodes of incontinence are recorded. As the patient's bladder capacity and control increase, the interval is lengthened. Usually, there is a tempo-

ral relationship between drinking, eating, exercising, and voiding. Alert patients can participate in recording intake, activity, and voiding and can plan the schedule to achieve maximum continence. Barrier-free access to the toilet and modification of clothing can help patients with functional incontinence achieve self-care in toileting and continence.

Habit training is used to try to keep patients dry by strict adherence to a toileting schedule and may be successful with stress, urge, or functional incontinence. If the patient is confused, caregivers take the patient to the toilet according to the schedule before involuntary voiding occurs. Simple cuing and consistency promote success. Periods of continence and successful voiding are positively reinforced.

Biofeedback is a system through which patients learn to consciously contract urinary sphincters and control voiding cues. Cognitively intact patients who have stress or urge incontinence may gain bladder control through biofeedback.

Pelvic floor exercises (Kegel exercises) strengthen the pubococcygeus muscle. The patient is instructed to tighten the pelvic floor muscles for 4 seconds 10 times, and this is repeated 4 to 6 times a day. Stopping and starting the stream during urination is recommended to increase control. Daily practice is essential. These exercises are helpful for cognitively intact women who experience stress incontinence.

Suprapubic tapping or stroking of the inner thigh may produce voiding by stimulating the voiding reflex arc in patients with reflex incontinence. However, this method is not always effective, due to a lack of detrusor sphincter muscle coordination. As the bladder reflexively contracts to expel urine, the bladder sphincter reflexively closes, producing a high residual urine volume and an increased incidence of urinary tract infection.

Intermittent self-catheterization is an appropriate alternative for managing reflex incontinence, urinary retention, and overflow incontinence due to an overdistended bladder. The nurse emphasizes regular emptying of the bladder rather than sterility. Patients with disabilities may reuse and clean catheters with bleach or hydrogen peroxide solutions or soap and water and may use a microwave oven to sterilize catheters. Aseptic intermittent catheterization technique is required in health care institutions because of the potential for bladder infection from resistant organisms. Intermittent self-catheterization may be difficult for patients with limited mobility, dexterity, or vision; however, family members can be taught the procedure.

Self-catheterization is also particularly pertinent for patients with spinal cord injury, because most of these patients do not have voluntary control of urination. Even those patients with spinal cord injuries who can voluntarily void should measure their residual urine (the amount of urine that remains in the bladder after voluntary or involuntary voiding) by self-catheterization.

Indwelling catheters are avoided if at all possible because of the high incidence of urinary tract infections with their use. Short-term use may be needed during treatment of severe skin breakdown due to continued incontinence. Patients with disabilities who cannot perform intermittent self-catheterization may elect to use suprapubic catheters for long-term bladder management. Suprapubic catheters are easier to maintain than indwelling catheters. A daily fluid intake of 3000 mL is encouraged.

External catheters (condom catheters) and leg bags to collect spontaneous voidings are useful for male patients with reflex or total incontinence. The appropriate design and size must be chosen for maximal success, and the patient or caregiver must be taught how to apply the condom catheter and how to provide daily hygiene, including skin inspection. Instruction on emptying the leg bag must also be provided, and modifications can be made for patients with limited hand dexterity.

Incontinence pads (briefs) may be useful at times for patients with stress or total incontinence to protect clothing, but they should be avoided whenever possible. Incontinence pads only manage, rather than solve, the incontinence problem. Also, they have a negative psychological effect on patients, because many people think of the pads as diapers. Every effort should be made to reduce the incidence of incontinence episodes through the other methods that have been described. When incontinence pads are used, they should wick moisture away from the body to minimize contact of moisture and excreta with the skin. Wet incontinence pads must be changed promptly, the skin cleansed, and a moisture barrier applied to protect the skin. It is important for the patient's self-esteem to avoid use of the term *diapers*.

Promoting Bowel Continence

The goals of a bowel training program are to develop regular bowel habits and to prevent uninhibited bowel elimination. Regular, complete emptying of the lower bowel results in bowel continence. A bowel-training program takes advantage of the patient's natural reflexes. Regularity, timing, nutrition and fluids, exercise, and correct positioning promote predictable defecation.

The nurse records defecation time, character of stool, nutritional intake, cognitive abilities, and functional self-care toileting abilities for 5 to 7 days. Analysis of this record is helpful when designing a bowel program for patients with fecal incontinence.

Consistency in implementing the plan is essential. A regular time for defecation is established, and attempts at evacuation should be made within 15 minutes of the designated time daily. Natural gastrocolic and duodenocolic reflexes occur about 30 minutes after a meal; therefore, after breakfast is one of the best times to plan for bowel evacuation. However, if the patient had a previously established habit pattern at a different time of day, it should be followed.

The anorectal reflex may be stimulated by a rectal suppository (eg, glycerin) or by mechanical stimulation (eg, digital stimulation with a lubricated gloved finger or anal dilator). Mechanical stimulation should be used only in patients with a disability who have no voluntary motor function and no sensation as a result of injuries above the sacral segments of the spinal cord, such as patients with quadriplegia, high paraplegia, or severe brain injuries. The technique is not effective in patients who do not have an intact sacral reflex arc (eg, those with flaccid paralysis). Mechanical stimulation, suppository insertion, or both should be initiated about 30 minutes before the scheduled bowel elimination time, and the interval between stimulation and defecation is noted for subsequent modification of the

bowel program. Once the bowel routine is well established, stimulation with a suppository may not be necessary.

The patient should assume the normal squatting position and be in a private bathroom for defecation if at all possible, although a padded commode chair or bedside toilet is an alternative. An elevated toilet seat is a simple modification that may make use of the toilet easier for the patient with a disability. Seating time is limited in patients who are at risk for skin breakdown. Bedpans should be avoided. A patient with a disability who cannot sit on a toilet should be positioned on the left side with legs flexed and the head of the bed elevated 30 to 45 degrees to increase intra-abdominal pressure. Protective padding is placed behind the buttocks. When possible, the patient is instructed to bear down and to contract the abdominal muscles. Massaging the abdomen from right to left facilitates movement of feces in the lower tract.

Preventing Constipation

The record of bowel elimination, character of stool, food and fluid intake, level of activity, bowel sounds, medications, and other assessment data are reviewed to develop the plan of care. Multiple approaches may be used to prevent constipation. The diet should include adequate intake of high-fiber foods (vegetables, fruits, bran) to prevent hard stools and to stimulate peristalsis. Daily fluid intake should be 2 to 3 L unless contraindicated. Drinking prune juice (120 mL) 30 minutes before a meal once daily is helpful in some cases when constipation is a problem. Physical activity and exercise are encouraged, as is self-care in toileting. Patients are encouraged to respond to the natural urge to defecate. Privacy during toileting is provided. Stool softeners, bulk-forming agents, mild stimulants, and suppositories may be prescribed to stimulate defecation and to prevent constipation.

Evaluation

Expected Patient Outcomes

Expected patient outcomes may include:

1. Demonstrates control of bowel and bladder function
 - a. Experiences no episodes of incontinence
 - b. Avoids constipation
 - c. Achieves independence in toileting
 - d. Expresses satisfaction with level of bowel and bladder control
2. Achieves urinary continence
 - a. Uses therapeutic approach that is appropriate to type of incontinence
 - b. Maintains adequate fluid intake
 - c. Washes and dries skin after episodes of incontinence
3. Achieves bowel continence
 - a. Participates in bowel program
 - b. Verbalizes need for regular time for bowel evacuation
 - c. Modifies diet to promote continence
 - d. Uses bowel stimulants as prescribed and needed
4. Experiences relief of constipation
 - a. Uses high-fiber diet, fluids, and exercise to promote defecation
 - b. Responds to urge to defecate

Disability and Sexuality Issues

An important issue confronting patients with disabilities, and a vital component of self-concept, is sexuality. Sexuality involves not only biologic sexual activity but also one's concept of masculinity or femininity. It affects the way people react to others and are perceived by them, and it is expressed not only by physical intimacy but also by caring and emotional intimacy.

Sexuality problems experienced by patients with disabilities include limited access to information about sexuality, lack of opportunity to form friendships and loving relationships, impaired self-image, and low self-esteem. People with disabilities may have physical and emotional difficulties that interfere with sexual activities. For example, diabetes and spinal cord injury may affect the ability of men to have erections. Patients who have suffered a heart attack or stroke may fear having a life-threatening event (eg, another heart attack or stroke) during sexual activity. Some patients may fear loss of bowel or bladder control during intimate moments. Changes in desire for sex and in the quality of sexual activities can occur for the patient and partner who may be too involved as a caregiver to have the desire and energy for sexual activities. However, a loss of sexual function does not necessarily correspond to a loss of sexual feeling. The physical and emotional aspects of sexuality, despite physical loss of function, continue to be important for people with disabilities.

Unfortunately, society and some health care providers contribute to these problems by ignoring the patient's sexuality and by viewing people with disabilities as asexual. Health care providers' own discomfort and lack of knowledge related to sexuality issues prevent them from providing patients with disabilities and their partners with interventions that promote healthy intimacy. Nurses caring for people with disabilities must recognize and address sexual issues to promote feelings of self-worth. The nurse should give the patient "permission" to discuss sexuality concerns and show a willingness to listen and help the patient overcome these concerns. In the case of a couple coping with disability, this may take the form of a simple comment, such as "Other people in your situation have expressed concern about how this disability may affect their own sexuality, feelings toward each other, and intimate aspects of their relationship. If either of you has these kinds of concerns, I am here to listen." The nurse also plays a key role in providing appropriate patient education about how specific disabilities affect sexual function. For example, arthritis produces fatigue and morning stiffness, making planned afternoon sex a better alternative; spinal cord injury impairs erections and ejaculations; and traumatic brain injury may produce an increased or decreased interest in sexual behavior. Classes, books, movies, and support groups are useful tools to help patients learn about sexuality and disability. When open discussion and education about disability and sexuality do not result in the patient achieving his or her sexuality goals, the nurse should refer the patient for ongoing counseling with a sex counselor or therapist. The patient may need training in communication and in social and assertiveness skills to develop desired relationships. Support and advocacy groups such as the

National Peer Support Network of the National Spinal Cord Injury Association (see Resources list at the end of this chapter) provide excellent information resources that relate to issues such as sexuality for patients, families, and nurses.

Fatigue

People with disabilities frequently experience fatigue, which may impede functional recovery and full reintegration into family and community roles. For example, patients with strokes may experience fatigue and a subsequent lack of endurance that affects their ability to participate in normal daily activities (Scheepers, Visser-Meily, Ketelaar, et al., 2006). Physical and emotional weariness may be caused by discomfort and pain associated with a chronic health problem, deconditioning associated with prolonged periods of bed rest and immobility, impaired motor function requiring excessive expenditure of energy to ambulate, and the frustrations of performing ADLs. Ineffective coping with the disability, unresolved grief, disordered sleep patterns, and depression can also contribute to fatigue, which may interfere with active engagement in the rehabilitation process. The patient is encouraged to use coping strategies to manage the psychological impact of the disability and pain management techniques to control the associated discomforts (see Chapter 13 for a discussion of pain management). In addition, the nurse can teach the patient to manage fatigue through priority setting and energy-conserving techniques (Chart 11-12).

Complementary and Alternative Therapies

People with disabilities may seek a variety of different therapies. For some people, therapeutic horseback riding affects all body systems. Instructors are certified through the North American Riding for the Handicapped Association. Pet therapy and canine companion programs have reduced stress and promoted coping for many people with disabilities. Some animals, including simian monkeys, can pick up the phone, retrieve small assistive devices, assist with drinking beverages, or assist with activating emergency calls. The service animals provide companionship as well as physical assistance for elderly people and people with disabilities who may live alone.

Nurses can encourage people with disabilities to take advantage of community programs. T'ai chi classes improve muscle strength, balance, and coordination and can help prevent falls in the elderly. People with disabilities, including wheelchair users, can participate in T'ai chi classes for improved balance, coordination, muscle strength and control, and a sense of well-being.

Daily journal writing has helped depressed people and their families overcome many emotionally draining reactions to adverse circumstances. Nurses are instrumental in teaching patients and family members this cost-effective technique. Relaxation exercises can also be taught by the nurse and encouraged in all settings, including the hospital, rehabilitation setting, outpatient areas, and the home.

CHART
11-12

PATIENT EDUCATION

Learning to Cope With Disabilities

Take Control of Your Life

- Face the reality of your disability.
- Emphasize areas of strength.
- Remain outward looking.
- Seek inventive ways to tackle problems.
- Share concerns and frustrations.
- Maintain and improve general health.
- Plan for recreation.

Have Well-Defined Goals and Priorities

- Keep priorities in order; eliminate nonessential activities.
- Plan and pace your activities.

Organize Your Life

- Plan each day.
- Organize work.
- Perform tasks in steps.
- Distribute heavy work throughout the day or week.

Conserve Energy

- Rest before undertaking difficult tasks.
- Stop the activity before fatigue occurs.
- Continue with an exercise conditioning program to strengthen muscles.

Control Your Environment

- Try to be well organized.
- Keep possessions in the same place, so that they can be found with a minimum of effort.
- Store equipment (personal care, crafts, work) in a box or basket.
- Use energy-conservation and work-simplification techniques.
- Keep work within easy reach and in front of you.
- Use adaptive equipment, self-help aids, and labor-saving devices.
- Recruit assistance from others; delegate when necessary.
- Take safety precautions.

Promoting Home and Community-Based Care

An important goal of rehabilitation is to assist the patient to return to the home environment after learning to manage the disability. A referral system maintains continuity of care when the patient is transferred to the home or to a long-term care facility. The plan for discharge is formulated when the patient is first admitted to the hospital, and discharge plans are made with the patient's functional potential in mind.

Teaching Patients Self-Care

Significant expenditures of time and resources are necessary to ensure that patients gain the skills and confidence to self-manage their health effectively after discharge from the hospital. Formal programs provide patients with effective strategies for interpreting and managing disease-specific is-

suess and skills needed for problem solving, as well as building and maintaining self-awareness and self-efficacy. Self-care programs often use multifaceted approaches, including didactic teaching, group sessions, individual learning plans, and Web-based resources. When planning the approach to self-care, it is important that the nurse consider the individual patient's knowledge, experience, social and cultural background, level of formal education, and psychological status. The preparation for self-care must also be spread out over the course of the recovery period and it must be monitored and updated regularly as aspects of self-care are mastered by the patient. Preparation for self-care is also highly relevant for informal caregivers of patients in rehabilitation.

When a patient is discharged from acute care or a rehabilitation facility, informal caregivers, typically family members, often assume the care and support of the patient. Although the most obvious care tasks involve physical care (eg, personal hygiene, dressing, meal preparation), other elements of the caregiving role include psychosocial support and a commitment to this supportive role. Thus, it is necessary to assess the patient's support system (family, friends) well in advance of discharge. The attitudes of family and friends toward the patient, his or her disability, and the return home are important in making a successful transition to home. Not all families can carry out the arduous programs of exercise, physical therapy, and personal care that the patient may need. They may not have the resources or stability to care for family members with a severe disability. The physical, emotional, economic, and energy strains of a disabling condition may overwhelm even a stable family. Members of the rehabilitation team must not judge the family but rather should provide supportive interventions that help the family to attain its highest level of function.

The family members need to know as much as possible about the patient's condition and care so that they do not fear the patient's return home. The nurse develops methods to help the patient and family cope with problems that may arise. An ADL checklist individualized for the patient and family can be developed to make certain that the family is proficient in assisting the patient with certain tasks (Chart 11-13).

Continuing Care

A home care nurse may visit the patient in the hospital, interview the patient and the family, and review the ADL sheet to learn which activities the patient can perform. This helps ensure that continuity of care is provided and that the patient does not regress, but instead maintains the independence gained while in the hospital or rehabilitation setting. The family may need to purchase, borrow, or improvise needed equipment, such as safety rails, a raised toilet seat or commode, or a tub bench. Ramps may need to be built or doorways widened to allow full access.

Family members are taught how to use equipment and are given a copy of the equipment manufacturer's instruction booklet, the names of resource people, lists of equipment-related supplies, and locations where they may be obtained. A written summary of the care plan is included in family teaching. The patient and family members are re-

CHART
11-13

HOME CARE CHECKLIST
Managing the Therapeutic Regimen at Home

At the completion of the home care instruction, the patient or caregiver will be able to:	PATIENT	CAREGIVER
• State the impact of disability on physiologic functioning.	✓	✓
• State changes in lifestyle necessary to maintain health.	✓	✓
• State the name, dose, side effects, frequency, and schedule for all medications.	✓	✓
• State how to obtain medical supplies after discharge.	✓	✓
• Identify durable medical equipment needs, proper usage, and maintenance necessary for safe utilization:	✓	✓
<input type="checkbox"/> Wheelchair—manual/power <input type="checkbox"/> Bedside toilet <input type="checkbox"/> Cushion <input type="checkbox"/> Crutches <input type="checkbox"/> Grab bars <input type="checkbox"/> Walker <input type="checkbox"/> Sliding board <input type="checkbox"/> Prosthesis <input type="checkbox"/> Mechanical lift <input type="checkbox"/> Orthosis <input type="checkbox"/> Raised padded commode seat <input type="checkbox"/> Specialty bed <input type="checkbox"/> Padded commode wheelchair		
• Demonstrate usage of adaptive equipment for activities of daily living:	✓	✓
<input type="checkbox"/> Long-handled sponge <input type="checkbox"/> Rocker-knife, spork, weighted utensils <input type="checkbox"/> Reacher <input type="checkbox"/> Special closures for clothing <input type="checkbox"/> Universal cuff <input type="checkbox"/> Other <input type="checkbox"/> Plate mat and guard		
• Demonstrate mobility skills:	✓	✓
<input type="checkbox"/> Transfers: bed to chair; in and out of toilet and tub; in and out of car <input type="checkbox"/> Negotiate ramps, curbs, stairs <input type="checkbox"/> Assume sitting from supine position <input type="checkbox"/> Turn side to side in bed <input type="checkbox"/> Maneuver wheelchair; manage arm and leg rests; lock brakes <input type="checkbox"/> Ambulate safely using assistive devices <input type="checkbox"/> Perform range-of-motion exercises <input type="checkbox"/> Perform muscle-strengthening exercises		
• Demonstrate skin care:	✓	✓
<input type="checkbox"/> Inspect bony prominences every morning and evening <input type="checkbox"/> Identify stage I pressure ulcer and actions to take if present <input type="checkbox"/> Change dressings for stage II to IV pressure ulcers <input type="checkbox"/> State dietary requirements to promote healing of pressure ulcers <input type="checkbox"/> Demonstrate pressure relief at prescribed intervals <input type="checkbox"/> State sitting schedule and demonstrate weight lifts in wheelchair <input type="checkbox"/> Demonstrate adherence to bed turning schedule, bed positioning, and use of bridging techniques <input type="checkbox"/> Apply and wear protective boots at prescribed times <input type="checkbox"/> Demonstrate correct wheelchair sitting posture <input type="checkbox"/> Demonstrate techniques to avoid friction and shear in bed <input type="checkbox"/> Demonstrate proper hygiene to maintain skin integrity		
• Demonstrate bladder care:	✓	✓
<input type="checkbox"/> State schedule for voiding, toileting, and catheterization <input type="checkbox"/> Identify relationship of fluid intake to voiding and catheterization schedule <input type="checkbox"/> State how to perform pelvic floor exercises <input type="checkbox"/> Demonstrate clean self-intermittent catheterization and care of catheterization equipment <input type="checkbox"/> Demonstrate indwelling catheter care <input type="checkbox"/> Demonstrate application of external condom catheter <input type="checkbox"/> Demonstrate application, emptying, and cleaning of urinary drainage bag <input type="checkbox"/> Demonstrate application of incontinence pads and performance of perineal hygiene <input type="checkbox"/> State signs and symptoms of urinary tract infection		
• Demonstrate bowel care:	✓	✓
<input type="checkbox"/> State optimum dietary intake to promote evacuation <input type="checkbox"/> Identify schedule for optimum bowel evacuation <input type="checkbox"/> Demonstrate techniques to increase intra-abdominal pressure; Valsalva maneuver; abdominal massage; leaning forward

HOME CARE CHECKLIST

Managing the Therapeutic Regimen at Home (Continued)

At the completion of the home care instruction, the patient or caregiver will be able to:	PATIENT	CAREGIVER
<input type="checkbox"/> Demonstrate techniques to stimulate bowel movements: ingesting warm liquids; digital stimulation; insertion of suppositories		
<input type="checkbox"/> Demonstrate optimum position for bowel evacuation: on toilet with knees higher than hips; left side in bed with knees flexed and head of bed elevated 30 to 45 degrees		
<input type="checkbox"/> Identify complications and corrective strategies for bowel retraining: constipation, impaction, diarrhea, hemorrhoids, rectal bleeding, anal tears		
• Identify community resources for peer and family support:	✓	✓
<input type="checkbox"/> Identify phone numbers of support groups for people with disabilities		
<input type="checkbox"/> State meeting locations and times		
• Demonstrate how to access transportation:	✓	✓
<input type="checkbox"/> Identify locations of wheelchair accessibility for public buses or trains		
<input type="checkbox"/> Identify phone numbers for private wheelchair van		
<input type="checkbox"/> Contact Division of Motor Vehicles for handicapped parking permit		
<input type="checkbox"/> Contact Division of Motor Vehicles for driving test when appropriate		
<input type="checkbox"/> Identify resources for adapting private vehicle with hand controls or wheelchair lift		
• Identify vocational rehabilitation resources:	✓	✓
<input type="checkbox"/> State name and phone number of vocational rehabilitation counselor		
<input type="checkbox"/> Identify educational opportunities that may lead to future employment		
• Identify community resources for recreation:	✓	✓
<input type="checkbox"/> State local recreation centers that offer programs for people with disabilities		
<input type="checkbox"/> Identify leisure activities that can be pursued in the community		
• Identify the need for health promotion and screening activities:	✓	✓

mindful about the importance of routine health screening and other health promotion strategies.

A network of support services and communication systems may be required to enhance opportunities for independent living. The nurse uses collaborative, administrative skills to coordinate these activities and pull together the network of care. The nurse also provides skilled care, initiates additional referrals when indicated, and serves as a patient advocate and counselor when obstacles are encountered. The nurse continues to reinforce prior teaching and helps the patient to set and achieve attainable goals. The degree to which the patient adapts to the home and community environment depends on the confidence and self-esteem developed during the rehabilitation process and on the acceptance, support, and reactions of family members, employers, and community members.

There is a growing trend toward independent living by people with severe disabilities, either alone or in groups that share resources. Preparation for independent living should include training in managing a household and working with personal care attendants as well as training in mobility. The goal is integration into the community—living and working in the community with accessible housing, employment, public buildings, transportation, and recreation.

State rehabilitation administration agencies provide services to assist people with disabilities in obtaining the help they need to engage in gainful employment. These services include diagnostic, medical, and mental health services. Counseling, training, placement, and follow-up services are available to help people with disabilities select and obtain jobs.

If the patient is transferred to a long-term care facility, the transition is planned to promote continued progress. Independence gained continues to be supported, and progress

is fostered. Adjustment to the facility is promoted through communication. Family members are encouraged to visit, to be involved, and to take the patient home on weekends and holidays if possible.

CRITICAL THINKING EXERCISES

EBP 1 A 40-year-old unmarried man with a 15-year history of multiple sclerosis (MS) is admitted to your rehabilitation nursing unit. He currently has secondary-progressive MS with many disabling symptoms. He is heavily dependent on his family, home nursing staff, a personal assistant, and rehabilitation professionals. His secondary conditions include bladder and bowel dysfunction, visual impairment, impaired mobility caused by spasticity and paralysis of his lower limbs, severe fatigue, tremor, and pain. What is the nursing role in preventing pressure ulcers from developing in this patient? Describe the instructions you would give the patient, family, and home care providers about the prevention of pressure ulcers. What is the evidence that supports the appropriateness of these instructions, and how strong is this evidence? What criteria did you use to determine the strength of the evidence for interventions that assist in the prevention of pressure ulcers?

2 A 45-year-old married woman who is recovering from a spinal epidural abscess has just been admitted to your medical-surgical unit. She has undergone surgical excision of the abscess and continues to be treated with antibiotics via a peripherally inserted central catheter. Her

ongoing problems include pain, impaired physical mobility, urinary retention, and nutritional deficits. How does a functional assessment tool help determine the patient's level of functioning? In discussing the patient's level of functioning with the rehabilitation team, describe the kinds of self-care activities that you would include in your rehabilitation plan for the patient and family. How important would it be to include a psychosocial assessment in the rehabilitation plan and why?

3 A 78-year-old woman who resides in a nursing home is admitted to your medical-surgical unit following surgical treatment for a fractured hip. The overall goal of rehabilitation is to regain prefracture function. What short-term goals of the rehabilitation process would support improvement in functional return? How would you promote early mobilization? What assessments are important to consider when coordinating a rehabilitation plan with the interdisciplinary team?

Health Care of the Older Adult

LEARNING OBJECTIVES

On completion of this chapter, the learner will be able to:

- 1 Describe the aging American population based on demographic trends.
- 2 Describe the significance of preventive health care and health promotion for the elderly.
- 3 Compare and contrast the physiologic aspects of aging in older adults with those of middle-age adults.
- 4 Identify the common physical and mental health problems of aging and their effects on the functioning of older people and their families.
- 5 Identify the role of the nurse in meeting the health care needs of the older patient.
- 6 Specify nursing implications related to medication therapy in older people.
- 7 Examine the concerns of older people and their families in the home and community, in the acute care setting, and in the long-term care facility.
- 8 Discuss the potential economic effect on health care of the large aging population in America.

GLOSSARY

activities of daily living (ADLs): basic personal care activities; bathing, dressing, grooming, eating, toileting, and transferring

advance directive: a formal, legally endorsed document that provides instructions for care ("living will")

ageism: a bias that discriminates, stigmatizes, and disadvantages older people based solely on their chronologic age

comorbidity: having more than one illness at the same time (eg, diabetes mellitus and congestive heart failure)

delirium: an acute, confused state that begins with disorientation that if not immediately evaluated and treated, can progress to changes in level of consciousness, irreversible brain damage, and sometimes death

dementia: broad term for a syndrome characterized by a general decline in higher brain functioning, such as reasoning, with a pattern of eventual decline in ability to perform even basic activities of daily living, such as toileting and eating

depression: the most common affective (mood) disorder of old age; results from changes in reuptake of the neurochemical serotonin in response to chronic illness and emotional stresses related to the physical and social changes associated with the aging process

durable power of attorney: a formal, legally endorsed document that identifies a proxy decision maker who can make decisions if the signer becomes incapacitated

elder abuse: the physical, emotional, or financial harm to an elderly person by one or more of the individual's children, caregivers, or others; includes neglect

instrumental activities of daily living (IADLs): activities that are essential for independent living, such as shopping, cooking, housework, using the telephone, managing medications and finances, and being able to travel by car or public transportation

orientation: a person's ability to recognize who and where he or she is in a time continuum; used to evaluate one's basic cognitive status

polypharmacy: the administration of multiple medications at the same time; common in older persons with several chronic illnesses

presbycusis: the decreased ability to hear high-pitched tones that naturally begins in midlife as a result of irreversible inner ear changes

presbyopia: the decrease in visual accommodation that occurs with advancing age

sundowning: increased confusion at night

Aging, the normal process of time-related change, begins with birth and continues throughout life. Americans are living longer, and thus the number of older Americans is the most rapidly expanding segment of the population. Therefore, whenever nurses work with an adult population, they are likely to encounter a majority of elderly patients. This chapter presents theories of aging, normal age-related changes, health problems associated with aging, and ways nurses can address the health issues of older adults.

Overview of Aging

Demographics of Aging

Life expectancy, the average number of years that a person can be expected to live, has risen dramatically in the past 100 years. The proportion of Americans 65 years of age and older has tripled in the past 100 years (4.1% in 1900 to 12.4% of the population in 2006) (U.S. Census Bureau, 2007). By 2030, it is estimated that 20% of Americans will be 65 years of age or older (Fig. 12-1). In 1900, the average life expectancy was 47 years, but by 2004, that figure had increased to 77.8 years. As the older population increases, the number of people who live to a very old age is dramatically increasing. In 1950, there were 3.8 million elderly people older than 75 years of age; this was 2.6% of the total population. This number is estimated to increase to about 20 million in 2010 (6.8% of total), to 33 million in 2030 (9.2%), and to almost 50 million in 2050 (11.6%) (National Center for Health Statistics [NCHS], 2006).

The older population is becoming more diverse, reflecting changing demographics in the United States. Although the older population will increase in number for all racial and ethnic groups, the rate of growth is projected to be fastest in the Hispanic population, in which it is expected to increase from 6 million in 2004 to an estimated 17.5 million by 2050 (NCHS, 2006). Proportionally, there will be a significant decline in the percentage of the white non-Hispanic population. By 2030, it is estimated that the white non-Hispanic population will decrease to 72% of the elderly population; 11% will be Hispanic, 10% black, and 5% Asian (Centers for Disease Control and Prevention [CDC], 2007a).

Figure 12-1 Profile of Americans age 65 years and older based on data from the U.S. Bureau of the Census. Data from 1900 to the present are used to predict the millions of Americans age 65 years and older in the year 2030. From www.aoa.gov/aoa/stats/profile/default.htm

Although the majority of older adults enjoy good health, in national surveys as many as 20% of adults 65 years of age and older report a chronic disability. Chronic disease is the major cause of disability; heart disease, cancer, and stroke continued to be the three leading causes of death in people 65 years of age and older in the United States (Table 12-1). In 2005, Alzheimer’s disease and diabetes mellitus ranked as the fifth and sixth causes of disease, respectively (NCHS, 2006). See Chapter 10 for a further discussion of chronic illness and disability.

Health Status of the Older Adult

The majority of deaths in the United States occur in people 65 years of age and older, and half of these are caused by heart disease and cancer. However, due to improvements in the prevention and early detection and treatment of diseases, there has been a noticeable impact on the health of people 65 years of age and older. In the past 50 years, there has been a decline in overall deaths and, specifically, deaths from heart disease and more recently cancer. Between 2003 and 2004, there was a significant decline in all of the top 10 leading causes of death; deaths

Table 12-1 DEATH RATES FOR THE 10 LEADING CAUSES OF DEATH IN PEOPLE AGE 65 YEARS AND OLDER IN 2004

Rank	Cause of Death	Rate (per 100,000)
	All causes	4698.8
1	Heart diseases	1898.7
2	Malignant neoplasms	1051.7
3	Cerebrovascular diseases	346.2
4	Chronic obstructive pulmonary diseases and allied conditions	284.3
5	Alzheimer’s disease	170.6
6	Diabetes mellitus	146.0
7	Pneumonia and influenza	139.0
8	Nephritis, nephrotic syndrome, and nephrosis	93.8
9	Accidents (unintentional injuries)	93.7
10	Septicemia	68.6

From National Center for Health Statistics, Health, United States (NCHS), 2006. Available at: www.cdc.gov/nchs/data/hus/06.pdf

from heart disease declined 6.4% and those from cancer declined 2.9% (NCHS, 2006).

In 2006, more than 70% of noninstitutionalized older Americans reported their health to be very good or excellent. Men and women reported comparable levels of health; however, positive health reports declined with advancing age, and a greater number of African American and Hispanic or Latinos were less likely to report good health than their Caucasian or Asian counterparts. But even among people 75 years of age and over, the majority remain functionally independent, and the proportion of older Americans with limitations in activities is declining (CDC, 2007a). These declines in limitations reflect recent trends in health promotion and disease prevention activities, such as improved nutrition, decreased smoking, increased exercise, and early detection and treatment of risk factors such as hypertension and elevated serum cholesterol levels.

Many chronic conditions commonly found among older people can be managed, limited, and even prevented. Older people are more likely to maintain good health and functional independence if encouraged to do so and if appropriate community-based support services are available (King, 2006; Miller, 2009). Nurses are challenged to promote positive lifelong health behaviors among all populations because the impact of unhealthy behaviors and choices can result in chronic disease.

Nursing Care of the Older Adult

Gerontology, the scientific study of the aging process, is a multidisciplinary field that draws from the biologic, psychological, and sociologic sciences. Geriatrics is the practice (medical or nursing) that focuses on the physiology, pathology, diagnosis, and management of the disorders and diseases of older adults. Because aging is a normal process, care for the elderly cannot be limited to one discipline but is best provided through a cooperative effort. An interdisciplinary approach to providing care combines expertise and resources to provide comprehensive geriatric assessment and intervention. Nurses collaborate with the team to obtain appropriate services for patients and provide a holistic approach to care.

Gerontologic or geriatric nursing is the field of nursing that specializes in the care of the elderly. The Standards and Scope of Gerontological Nursing Practice were originally developed in 1969 by the American Nurses Association and revised in 2001. The nurse gerontologist can be either a specialist or a generalist providing comprehensive nursing care to older people by combining the basic nursing process of assessment, diagnosis, planning, implementation, and evaluation with a specialized knowledge of aging. Gerontological nursing is provided in acute care, skilled and assisted living, the community, and home settings. The goals of care include promoting and maintaining functional status and helping older adults identify and use their strengths to achieve optimal independence.

Nurses who are certified in gerontology have specialized knowledge of the acute and chronic changes specific to older people. The use of gerontologic advanced practice nurses in long-term care has proved to be very effective; when they use current scientific knowledge about clinical problems to collaborate with nursing home staff, signifi-

cantly less deterioration in the overall health issues of patients occurs (Krichbaum, 2007; Krichbaum, Pearson, Savik, et al., 2005).

Nurses who work in all areas of adult medical-surgical nursing encounter elderly patients. They must be knowledgeable and skilled in meeting the needs of older patients. It is important that nurses and caregivers who work with patients who are older understand that aging is not synonymous with disease and that the effects of the aging process alone are not the primary contributors to disability and disease. As research and scientific knowledge increase, it is becoming apparent that aging is a highly complex process.

Functional assessment is a common framework for assessing elderly people. Age-related changes, as well as additional risk factors such as disease and the effects of medications, can result in a negative impact on function. Assessing the functional consequences of aging and proposing practical interventions help maintain and improve the health of the elderly. The goal is to help older people maintain maximum functional level and dignity despite physical, social, and psychological losses. Early intervention can prevent complications of many health problems and help maximize the quality of life.

Theories of Aging

Aging has been defined chronologically by the passing of time—subjectively, as in how a person feels, and functionally, as in changes in physical or mental capabilities. The many theories of aging attempt to provide a framework in which to understand aging from different perspectives. Each theory is useful to the clinician because it provides a framework and insight into the differences among elderly patients. In addition to the biologic, developmental, and sociologic theories of aging, Miller (2009) developed the functional consequences theory, which challenges nurses to consider the effects of normal age-related changes as well as the damage incurred through disease or environmental and behavioral risk factors when planning care. Miller suggests that nurses can alter the outcome for patients through nursing interventions that address the consequences of these changes. Age-related changes and risk factors may negatively interfere with patient outcomes and actually impair patient activity and quality of life. For example, normal age-related changes in vision may increase sensitivity to glare. Alterations in the environment that reduce glare may enhance patient comfort and safety. In contrast, the development of cataracts, which is not a normal age-related change, also may increase sensitivity to glare. The nurse must differentiate between normal age-related changes that cannot be reversed and risk factors that can be modified. Doing so is useful in designing appropriate nursing interventions that have a positive impact on patient outcomes for the elderly—most importantly, for quality of life.

Age-Related Changes

The well-being of older people depends on physical, psychosocial, mental, social, economic, and environmental factors. A total assessment includes an evaluation of all major body systems, social and mental status, and the ability of

a person to function independently despite having a chronic illness or disability.

Physical Aspects of Aging

As previously mentioned, intrinsic aging (from within the person) refers to those changes caused by the normal aging process that are genetically programmed and essentially universal within a species. Universality is the major criterion used to distinguish normal aging from pathologic changes associated with illness. However, people age quite differently and at different rates, so chronologic age is often less predictive of obvious aging characteristics than other factors, such as one's genetics and lifestyle. For example, extrinsic aging results from influences outside the person. Air pollution and excessive exposure to sunlight are examples of extrinsic factors that may hasten the aging process and that can be eliminated or reduced.

Cellular and extracellular changes of old age cause a change in physical appearance and a decline in function. Measurable changes in shape and body makeup occur. The body's ability to maintain homeostasis becomes increasingly diminished with cellular aging, and organ systems cannot function at full efficiency because of cellular and tissue deficits. Cells become less able to replace themselves, and they accumulate a pigment known as lipofuscin. A degradation of elastin and collagen causes connective tissue to become stiffer and less elastic. These changes result in diminished capacity for organ function and increased vulnerability to disease and stress.

Table 12-2 summarizes the signs and symptoms of age-related changes in the functioning of body systems. More in-depth information about age-related changes can be found in the chapters pertaining to each organ system. Specifics of diseases, medical and surgical management, as well as nursing interventions are also presented in the related chapters.

Cardiovascular System

Heart disease is the leading cause of death in the elderly. Heart failure is the leading cause of hospitalization among Medicare recipients, and it is also a major cause of morbidity and mortality among the elderly population in the United States. Age-related changes reduce the efficiency of the heart and contribute to decreased compliance of the heart muscle. These changes include myocardial hypertrophy, which changes left ventricular strength and function; fibrosis and stenosis of the valves; and decreased pacemaker cells (Neal-Boylan, 2007). As a result, the heart valves become thicker and stiffer, and the heart muscle and arteries lose their elasticity, resulting in a reduced stroke volume. Calcium and fat deposits accumulate within arterial walls, and veins become increasingly tortuous, increasing arterial resistance; this increases the workload of the heart.

It is difficult to differentiate between age-related and disease-related changes in cardiovascular function because of the significant influence of behavioral factors on cardiovascular health. When cross-cultural studies are conducted, cardiovascular changes that in the past were thought to be age related do not consistently appear. For example, the higher blood pressure found in older adults in Western societies does not occur in less-developed societies and may be

a result of different lifestyle behaviors rather than normal age-related changes (Miller, 2009). Under normal circumstances, the cardiovascular system can adapt to the normal age-related changes, and an older person is unaware of any significant decline in cardiovascular performance. However, when challenged, the cardiovascular system of an older person is less efficient under conditions of stress and exercise and when life-sustaining activities are needed.

Careful assessment of older people is necessary because they often present with different symptoms than those seen in younger patients. Older people are more likely to have dyspnea or neurologic symptoms associated with heart disease, and they may experience mental status changes or report vague symptoms such as fatigue, nausea, and syncope. Rather than the typical substernal chest pain associated with myocardial ischemia, older patients may report burning or sharp pain or discomfort in an area of the upper body. Complicating the assessment is the fact that many elderly patients have more than one underlying disease. When a patient complains about symptoms related to digestion and breathing and upper extremity pain, cardiac disease must be considered. The absence of chest pain in an older patient is not a reliable indicator of the absence of heart disease.

Hypotension may be a concern. The risk of orthostatic and postprandial hypotension increases significantly after 75 years of age (Miller, 2009). A patient experiencing hypotension should be counseled to rise slowly (from a lying, to a sitting, to a standing position), to avoid straining when having a bowel movement, and to consider having five or six small meals each day, rather than three, to minimize the hypotension that can occur after a large meal. Extremes in temperature, including hot showers and whirlpool baths, should be avoided.

Respiratory System

The respiratory system is the one system that seems to be the most able to compensate for the functional changes of aging. In general, healthy, nonsmoking, older adults show very little decline in respiratory function; however, there are substantial individual variations. The age-related changes that do occur are subtle and gradual, and healthy older adults are able to compensate for these changes. Diminished respiratory efficiency as well as reduced maximal inspiratory and expiratory force may occur as a result of calcification and weakening of the muscles of the chest wall. Lung mass decreases, and residual volume increases (Bickley, 2007).

Conditions of stress, such as illness, may increase the demand for oxygen and affect the overall function of other systems. Like cardiovascular diseases, respiratory diseases manifest more subtly in older adults than in younger adults and do not necessarily follow the typical pattern of cough, chills, and fever. Older adults may exhibit headache, weakness, lethargy, anorexia, dehydration, and mental status changes (Miller, 2009).

Smoking is the most significant risk factor for respiratory and other diseases. Therefore, a major focus of health promotion activities should be on smoking cessation and avoidance of environmental smoke. Pneumonia and influenza together are the fifth leading cause of death in people older than 65 years of age (NCHS, 2006). Education to promote the use of recommended vaccines is an essential nursing intervention. A pneumococcal vaccine that

Table 12-2 AGE-RELATED CHANGES IN BODY SYSTEMS AND HEALTH PROMOTION STRATEGIES

Changes	Subjective and Objective Findings	Health Promotion Strategies
Cardiovascular System		
Decreased cardiac output; diminished ability to respond to stress; heart rate and stroke volume do not increase with maximum demand; slower heart recovery rate; increased blood pressure	Complaints of fatigue with increased activity Increased heart rate recovery time Optimal blood pressure $\leq 120/80$ mm Hg Prehypertension $>120\text{--}139/80\text{--}89$ mm Hg Hypertension $\geq 140/90$ mm Hg	Exercise regularly; pace activities; avoid smoking; eat a low-fat, low-salt diet; participate in stress-reduction activities; check blood pressure regularly; medication compliance; weight control
Respiratory System		
Increase in residual lung volume; decrease in muscle strength, endurance, and vital capacity; decreased gas exchange and diffusing capacity; decreased cough efficiency	Fatigue and breathlessness with sustained activity; decreased respiratory excursion and chest/lung expansion with less effective exhalation; difficulty coughing up secretions	Exercise regularly; avoid smoking; take adequate fluids to liquefy secretions; receive yearly influenza immunization and pneumonia vaccine at 65 years of age; avoid exposure to upper respiratory tract infections
Integumentary System		
Decreased subcutaneous fat, interstitial fluid, muscle tone, glandular activity, sensory receptors resulting in decreased protection against trauma and sun exposure, and temperature extremes; diminished secretion of natural oils and perspiration; capillary fragility	Thin, wrinkled, and dry skin; complaints of injuries, bruises, and sunburn; complaints of intolerance to heat; bone structure is prominent	Limit solar exposure to 10–15 minutes daily for vitamin D (use protective clothing and sunscreen); dress appropriately for temperature; maintain a safe indoor temperature; take shower rather than hot tub bath if possible; lubricate skin with lotions that contain petroleum or mineral oil
Reproductive System		
<i>Female:</i> Vaginal narrowing and decreased elasticity; decreased vaginal secretions <i>Male:</i> Less firm testes and decreased sperm production <i>Male and Female:</i> Slower sexual response	<i>Female:</i> Painful intercourse; vaginal bleeding following intercourse; vaginal itching and irritation; delayed orgasm <i>Male:</i> Delayed erection and achievement of orgasm	May require vaginal estrogen replacement; gynecology/urology follow-up; use a lubricant with sexual intercourse
Musculoskeletal System		
Loss of bone density; loss of muscle strength and size; degenerated joint cartilage	Height loss; prone to fractures; kyphosis; back pain; loss of strength, flexibility, and endurance; joint pain	Exercise regularly; eat a high-calcium diet; limit phosphorus intake; take calcium and vitamin D supplements as prescribed
Genitourinary System		
<i>Male:</i> Benign prostatic hyperplasia <i>Female:</i> Relaxed perineal muscles, detrusor instability (urge incontinence), urethral dysfunction (stress urinary incontinence)	Urinary retention; irritative voiding symptoms including frequency, feeling of incomplete bladder emptying, multiple nighttime voidings Urgency/frequency syndrome, decreased “warning time,” drops of urine lost with cough, laugh, position change	<i>Male:</i> Limit drinking in evening (eg, caffeinated beverages, alcohol); do not wait long periods between voiding and empty bladder all the way when passing urine. <i>Female:</i> Wear easily manipulated clothing; drink adequate fluids; avoid bladder irritants (eg, caffeinated beverages, alcohol, artificial sweeteners); pelvic floor muscle exercises, preferably learned via biofeedback; consider urologic workup
Gastrointestinal System		
Decreased sense of thirst, smell and taste; decreased salivation; difficulty swallowing food; delayed esophageal and gastric emptying; reduced gastrointestinal motility	Risk of dehydration, electrolyte imbalances, and poor nutritional intake; complaints of dry mouth; complaints of fullness, heartburn, and indigestion; constipation, flatulence, and abdominal discomfort	Use ice chips, mouthwash; brush, floss, and massage gums daily; receive regular dental care; eat small, frequent meals; sit up and avoid heavy activity after eating; limit antacids; eat a high-fiber, low-fat diet; limit laxatives; toilet regularly; drink adequate fluids
Nervous System		
Reduced speed in nerve conduction; increased confusion with physical illness and loss of environmental cues; reduced cerebral circulation (becomes faint, loses balance)	Slower to respond and react; learning takes longer; becomes confused with hospital admission; faintness; frequent falls	Pace teaching; with hospitalization, encourage visitors; enhance sensory stimulation; with sudden confusion, look for cause; encourage slow rising from a resting position

Continued

Table 12-2  **AGE-RELATED CHANGES IN BODY SYSTEMS AND HEALTH PROMOTION STRATEGIES (Continued)**

Changes	Subjective and Objective Findings	Health Promotion Strategies
Special Senses		
<i>Vision:</i> Diminished ability to focus on close objects; inability to tolerate glare; difficulty adjusting to changes of light intensity; decreased ability to distinguish colors	Holds objects far away from face; complains of glare; poor night vision; confuses colors	Wear eyeglasses, use sunglasses outdoors; avoid abrupt changes from dark to light; use adequate indoor lighting with area lights and nightlights; use large-print books; use magnifier for reading; avoid night driving; use contrasting colors for color coding; avoid glare of shiny surfaces and direct sunlight
<i>Hearing:</i> Decreased ability to hear high-frequency sounds; tympanic membrane thinning and loss of resiliency	Gives inappropriate responses; asks people to repeat words; strains forward to hear	Recommend a hearing examination; reduce background noise; face person; enunciate clearly; speak with a low-pitched voice; use nonverbal cues
<i>Taste and smell:</i> Decreased ability to taste and smell	Uses excessive sugar and salt	Encourage use of lemon, spices, herbs Recommend smoking cessation

prevents 85% to 90% of all cases of pneumonia is available, and it is effective in preventing 75% of cases in people older than 65 years of age. Influenza vaccination is less effective in preventing influenza in the elderly than in the younger population, but it reduces influenza-related deaths, hospitalizations, and other complications (Miller, 2009).

Activities that help elderly people maintain adequate respiratory function include regular exercise, appropriate fluid intake, pneumococcal vaccination, yearly influenza immunizations, and avoidance of people who are ill. Hospitalized older adults should be frequently reminded to cough and take deep breaths, particularly postoperatively, because their decreased lung capacity and decreased cough efficiency predispose them to atelectasis and respiratory infections.

Integumentary System

The functions of the skin include protection, temperature regulation, sensation, and excretion. With aging, changes occur that affect the function and appearance of the skin. There is a decrease of epidermal proliferation, and the dermis becomes thinner. Elastic fibers are reduced in number, and collagen becomes stiffer. Subcutaneous fat diminishes, particularly in the extremities, but gradually increases in other areas, such as the abdomen (men) and thighs (women), leading to an overall increase in body fat in older people (Tabloski, 2006). Decreased numbers of capillaries in the skin result in diminished blood supply. These changes cause a loss of resiliency and wrinkling and sagging of the skin. The skin becomes drier and more susceptible to burns, injury, and infection. Hair pigmentation may change and balding may occur; genetic factors strongly influence these changes. These changes in the integument reduce tolerance to temperature extremes and sun exposure.

Lifestyle practices are likely to have a large impact on skin changes. Therefore, strategies to promote healthy skin function include not smoking, avoiding exposure to the sun, using a sun protection factor (SPF) of 15 or higher, using emollient skin cream containing petrolatum or mineral oil, avoiding hot soaks in the bathtub, and maintaining

optimal nutrition and hydration. Older adults should be encouraged to have any changes in the skin examined, because early detection and treatment of precancerous or cancerous lesions are essential for the best outcome.

Reproductive System

Sexuality is no longer considered pertinent only to the young. However, research about sexuality among the elderly, especially in women, has not been extensive. Ovarian production of estrogen and progesterone ceases with menopause. Changes occurring in the female reproductive system include thinning of the vaginal wall, along with a shortening of the vagina and a loss of elasticity; decreased vaginal secretions, resulting in vaginal dryness, itching, and decreased acidity; involution (atrophy) of the uterus and ovaries; and decreased pubococcygeal muscle tone, resulting in a relaxed vagina and perineum. Without the use of water-soluble lubricants, these changes may contribute to vaginal bleeding and painful intercourse.

In older men, the testes become less firm but men up to 90 years of age continue to produce viable sperm. At about 50 years of age, production of testosterone begins to diminish (Tabloski, 2006). Decreased libido and erectile dysfunction may develop but are more likely to be associated with factors other than age-related changes. These risk factors include cardiovascular disease; neurologic disorders; diabetes; respiratory disease; pain; and medications such as vasodilators, antihypertensive agents, and tricyclic antidepressants.

In both older men and women, it may take longer to become sexually aroused, longer to complete intercourse, and longer before sexual arousal can occur again. Although a less intense response to sexual stimulation and a decline in sexual activity occurs with increasing age, sexual desire does not disappear. Men may experience a decline in sexual function related to health conditions or interference from medications. Women may lose their partner; the absence of a partner is often the primary factor causing lack of sexual activity. Many couples are unaware of the causes of decreased libido or erectile dysfunction and are often reluctant to discuss decreased sexual function. There are many

methods of improving the quality of sexual interactions, but the assessment and communication require sensitivity and expert knowledge in the field of sexual dysfunction. If sexual dysfunction is present, referral to a gynecologist, urologist, or sex therapist may be warranted.

Genitourinary System

The genitourinary system continues to function adequately in older people, although there is a decrease in kidney mass, primarily because of a loss of nephrons. However, the loss of nephrons does not typically become significant until about 90 years of age, and changes in kidney function vary widely; about one third of elderly people show no decrease in renal function (Tabloski, 2006). Changes in renal function may be due to a combination of aging and pathologic conditions such as hypertension. The changes most commonly seen include a decreased filtration rate, diminished tubular function with less efficiency in resorbing and concentrating the urine, and a slower restoration of acid–base balance in response to stress. In addition, older adults who take medications may experience serious consequences due to decline in renal function because of impaired absorption, decreased ability to maintain fluid and electrolyte balance, and decreased ability to concentrate urine.

Certain genitourinary disorders are more common in older adults than in the general population. At least 1 in 10 older adults in the United States suffers from urinary incontinence, and women are more likely than men to have this disorder. Unfortunately, this condition is often mistakenly viewed as a normal consequence of aging. Costly and embarrassing, it should be evaluated, because in many cases it is reversible or can be treated (Specht, 2005). Urinary incontinence is discussed in more detail in Chapter 45. Benign prostatic hyperplasia (enlarged prostate gland), a common finding in older men, causes a gradual increase in urine retention and overflow incontinence.

Changes in the urinary tract increase the susceptibility to urinary tract infections. Adequate consumption of fluids is an important nursing intervention that reduces the risk of bladder infections and also helps decrease urinary incontinence.

Gastrointestinal System

Digestion of food is less influenced by age-related changes than by the risk of poor nutrition. Older people can adjust to the age-related changes but may have difficulty purchasing, preparing, and enjoying their meals. The sense of smell diminishes as a result of neurologic changes and environmental factors such as smoking, medications, and vitamin B₁₂ deficiencies. The ability to recognize sweet, sour, bitter, or salty foods diminishes over time, altering satisfaction with food. Salivary flow does not decrease in healthy adults, but about 30% of older people may experience a dry mouth as a result of medications and diseases (Miller, 2009). Difficulties with chewing and swallowing are generally associated with disease.

Experts disagree on the extent of gastric changes that occur as a result of normal aging. However, there does appear to be a modest slowing of gastric motility, which results in delayed emptying of stomach contents and early satiety (feeling of fullness). Diminished secretion of gastric acid

and pepsin, seemingly the result of pathologic conditions rather than normal aging, reduces the absorption of iron, calcium, and vitamin B₁₂. Absorption of nutrients in the small intestine, particularly calcium and vitamin D, appears to diminish with age. Functions of the liver, gallbladder, and pancreas are generally maintained, although absorption and tolerance to fat may decrease. The incidence of gallstones and common bile duct stones increases progressively with advancing years.

Difficulty in swallowing, or dysphagia, increases with age and is a major health care problem in elderly patients. Normal aging alters some aspects of the swallowing function, and it is a frequent complication of stroke and a significant risk factor for development of pneumonia. This serious condition can be life-threatening. It is caused by interruption or dysfunction of neural pathways, such as can occur with stroke. Dysphagia may also result from dysfunction of the striated and smooth muscles of the gastrointestinal tract in patients with Parkinson's disease and in patients with disorders such as multiple sclerosis, poliomyelitis, and amyotrophic lateral sclerosis (ie, Lou Gehrig's disease). Aspiration of food or fluid is the most serious complication and can occur in the absence of coughing or choking.

Constipation is a common pathologic condition that affects as many as 80% of institutionalized and 45% of community-dwelling elderly people (Miller, 2009). Symptoms of mild constipation are abdominal discomfort and flatulence, and more serious constipation leads to fecal impaction that contributes to diarrhea around the impaction, fecal incontinence, and obstruction. Predisposing factors for constipation include lack of dietary bulk, prolonged use of laxatives, use of some medications, inactivity, insufficient fluid intake, and excessive dietary fat. Ignoring the urge to defecate may also be a contributing factor.

Practices that promote gastrointestinal health include regular tooth brushing and flossing; receiving regular dental care; eating small, frequent meals; avoiding heavy activity after eating; eating a high-fiber, low-fat diet; drinking enough fluids; and avoiding the use of laxatives and antacids. Understanding that there is a direct correlation between loss of smell and taste perception and food intake helps caregivers intervene to maintain elderly patients' nutritional health.

Nutritional Health

The social, psychological, and physiologic functions of eating influence the dietary habits of older people. Increasing age alters nutrient requirements; the elderly require fewer calories and a more nutrient-rich, healthy diet in response to alterations in body mass and a more sedentary lifestyle. Recommendations include reducing fat intake while consuming sufficient protein, vitamins, minerals, and dietary fiber for health and disease prevention. Decreased physical activity and a slower metabolic rate reduce the number of calories needed by older adults to maintain an ideal weight. As previously stated, age-related changes that alter pleasure in eating include a decrease in taste and smell. Older people are likely to maintain a taste for sweetness but require more sugar to achieve a sweet flavor. They also may lose the ability to differentiate sour, salty, and bitter tastes. Apathy, immobility, depression, loneliness, poverty, inadequate

knowledge, and poor oral health also contribute to suboptimal nutrient intake. Budgetary constraints and physical limitations may interfere with food shopping and meal preparation.

Health promotion includes encouraging a varied diet that is low in sodium and saturated fats and high in vegetables, fruits, and fish. Education regarding healthy foods versus foods with inadequate nutrients is helpful. The incidence of obesity in Americans as old as 80 years of age has reached epidemic proportions, and this greatly increases the incidence of chronic disease such as diabetes and cardiovascular diseases.

No more than 30% of dietary calories should be consumed as fat. Protein intake may need to be increased in later adulthood to maintain adequate nitrogen equilibrium (DiMaria-Ghalili & Amella, 2005). Carbohydrates, a major source of energy, should supply 55% to 60% of the daily calories. Simple sugars should be avoided, and complex carbohydrates should be encouraged. Potatoes, whole grains, brown rice, and fruit are sources of minerals, vitamins, and fiber and should be encouraged. Drinking 8 to 10 eight-ounce glasses of water per day is recommended unless contraindicated by a medical condition. A multivitamin each day helps meet daily nutritional needs. Adults older than 50 years of age should have a daily calcium intake to 1200 g, and 600 IU of vitamin D to maintain bone health (Miller, 2009).

Undernutrition may also be a problem for older adults; as many as 40% to 60% of hospitalized and 40% to 85% of nursing home patients are malnourished. A recent unintentional weight loss may be a result of an illness or other factors, such as depression, that may have serious consequences and affect a person's ability to maintain health and fight illness (Martin, Kayser-Jones, Stotts, et al., 2007). Many people are unaware of dietary deficits. Nurses are in an ideal position to identify nutritional problems among their patients and to work within the patient's own framework of knowledge of his or her health status to improve health behaviors. Chapter 5 provides more information on nutritional assessment.

Sleep

Sleep disturbances affect more than 50% of adults 65 years of age or older. The elderly tend to take longer to fall asleep, awaken more easily and frequently, and spend less time in deep sleep. Consequently, they may feel that their sleep is less satisfactory (Miller, 2009). Although older adults require as much sleep as younger people, they may experience variations in their normal sleep-wake cycles, and the lack of quality sleep at night often creates the need for napping during the day. Older people are more likely to awaken because of factors such as noise, pain, or nocturia.

The incidence of sleep apnea (a sleep disorder characterized by brief periods in which respirations are absent) increases with age. Having insomnia symptoms and a sleep-related disorder (snoring, choking, or pauses in breathing) is associated with significantly impaired daytime functioning and longer psychomotor reaction times compared with having either condition (Cole & Richards, 2007; Gooneratne, Gehrman, Nkwuo, et al., 2006). Sleep apnea is discussed in more detail in Chapter 22.

The nurse is the caregiver who observes patients while they are sleeping. The nurse can observe problems and also recommend sleep hygiene behaviors such as avoiding use of the bed for activities other than sleeping (or sex), maintaining a consistent bedtime routine, avoiding or limiting daytime napping, limiting alcohol intake to one or two drinks a day, and avoiding caffeine and nicotine after noon.

Musculoskeletal System

Intact musculoskeletal and neurologic systems are essential for the maintenance of safe mobility, performance of **activities of daily living** (ADLs) (basic personal care activities), and **instrumental activities of daily living** (IADLs) (activities that are essential for independent living), thus allowing older adults to remain safe and live independently in the community. Age-related changes that affect mobility include alterations in bone remodeling, leading to decreased bone density, loss of muscle mass, deterioration of muscle fibers and cell membranes, and degeneration in the function and efficiency of joints. These factors are discussed in detail in Unit 15.

Without exercise, a gradual, progressive decrease in bone mass begins before 40 years of age. The cartilage of joints also progressively deteriorates in middle age. Degenerative joint disease is found in most adults older than 70 years of age, and weight-bearing joint and back pain is a common complaint. Excessive loss of bone density results in osteoporosis, which leads to potentially life-altering hip and vertebral fractures. Osteoporosis is preventable.

The axiom "use it or lose it" is very relevant to the physical capacity of older adults. Nurses play an important role by encouraging older adults to participate in a regular exercise program (Chart 12-1). The benefits of regular exercise cannot be overstated. Aerobic exercises are the foundation of programs of cardiovascular conditioning, but resistance and strength training as well as flexibility exercises are essential components of an exercise program. Even late in life, in adults who are very old and frail, it is generally believed that exercise has the benefits of increasing strength, aerobic capacity, flexibility, and balance (Fahlman, Topp, McNevin, et al., 2007).

Nervous System

Homeostasis is difficult to maintain with aging, but most older people function adequately and retain their cognitive and intellectual abilities in the absence of pathologic changes. However, normal aging changes in the nervous system can affect all parts of the body.

The structure and function of the nervous system change with advanced age, and a reduction in cerebral blood flow accompanies nervous system changes. Reports of the loss of nerve cells are highly varied with variations in neuron loss in different parts of the brain (Mauk, 2006). The loss of nerve cells contributes to a progressive loss of brain mass.

In addition, the synthesis and metabolism of the major neurotransmitters are also reduced. Because nerve impulses are conducted more slowly, older people take longer to respond and react. The autonomic nervous system performs less efficiently, and postural hypotension, which causes people to lose consciousness or feel lightheaded when standing up quickly, may occur. Neurologic changes can affect gait

Structured Exercise

Fahlman, M. M., Topp, R., McNevin, N., et al. (2007). Assessing the benefits of an aerobic plus resistance training program. *Journal of Gerontological Nursing*, 33(6), 33–39.

Purpose

This study examined the effects of a 16-week exercise program designed to increase aerobic capacity, muscular strength, and endurance among community-dwelling older adults. The participants reported and demonstrated limited functional ability, such as being unable to climb 26 steps in less than 12.6 seconds (the average speed for people 65 years of age and older).

Design

The 79 adults, with an average age of 75 years (range 65 to 92 years), had not been in an exercise program previously. They were randomly divided into an exercise group and a control group. The control group was told that the exercise program was delayed, whereas the exercise group participated in a 25-minute group walk and two sets of 12 repetitions of 13 different resistance exercises three times a week for 16 weeks. The distance participants were able to walk in a 6-minute period was used to measure endurance and strength testing was preformed in the legs and the arms.

Findings

The findings demonstrated that a structured 16-week exercise program in older adults with limited functional ability led to an increase of functional ability such as endurance and strength when compared with the control group. Participants in the exercise group increased their 6-minute walk distance by 12%, their leg strength by 9%, and their arm strength by 6% compared to baseline measurements.

Nursing Implications

This study supports the value of exercise in maintaining basic functional ability and demonstrates that older adults can increase their functional ability for muscle strength and for endurance with a regular structured exercise program. Maintaining muscle strength, cardiovascular endurance, and balance enable the older person to maintain independence into old age. Nurses can be proactive by keeping patients out of bed and moving, recommending ongoing exercise to older patients, and identifying patients who are demonstrating a functional decline and referring them to moderate exercise programs geared toward older adults.

and balance, which may interfere with mobility and safety. Nurses must advise elderly people to allow a longer time to respond to a stimulus and to move more deliberately.

This slowed reaction time puts older people at risk for falls and injuries, as well as driving errors. Even though older adults spend less time driving compared with younger people, elderly people are just as likely to be involved in motor vehicle crashes that result in serious injury or death. Elderly people who are driving unsafely should receive a driving fitness evaluation (Miller, 2009). This is often administered by an occupational therapist in conjunction with a neuropsychologist, who conducts more detailed cognitive testing.

Mental function is threatened by physical or emotional stresses. A sudden onset of confusion may be the first symptom of an infection or change in physical condition (eg, pneumonia, urinary tract infection, medication interactions, and dehydration).

Sensory System

People interact with the world through their senses. Sensory losses associated with old age affect all sensory organs, and it can be devastating not to be able to see to read or watch television, hear conversation well enough to communicate, or discriminate taste well enough to enjoy food. Nearly half of older men and one third of older women report difficulty hearing without a hearing aid. Sixteen percent of older men and 19% of older women report difficulty seeing, even with corrective lenses (Federal Interagency Forum on Aging-Related Statistics, 2008). An uncompensated alteration in a sensory loss negatively affects the functional ability and quality of life of the older adult.

Sensory Loss Versus Sensory Deprivation

Sensory loss can often be compensated for by assistive devices such as glasses and hearing aids. In contrast, sensory deprivation is the absence of stimuli in the environment or the inability to interpret existing stimuli (perhaps as a result of a sensory loss). Sensory deprivation can lead to boredom, confusion, irritability, disorientation, and anxiety. A decline in sensory input can mimic a decline in cognition that is in fact not present. Meaningful sensory stimulation provided to the older person is often helpful in correcting this problem. In some situations, one sense can substitute for another in observing and interpreting stimuli. Nurses can enhance sensory stimulation in the environment with colors, pictures, textures, tastes, smells, and sounds. The stimuli are most meaningful if they are interpreted to older people and if the stimuli are changed often. Cognitively impaired people tend to respond well to touch and to familiar music.

Vision

As new cells form on the outside surface of the lens of the eye, the older central cells accumulate and become yellow, rigid, dense, and cloudy, leaving only the outer portion of the lens elastic enough to change shape (accommodate) and focus at near and far distances. As the lens becomes less flexible, the near point of focus gets farther away. This condition, **presbyopia**, usually begins in the fifth decade of life and requires the person to wear reading glasses to magnify objects. In addition, the yellowing, cloudy lens cause light to scatter and make the older person sensitive to glare. The ability to discern blue from green decreases. The pupil dilates slowly and less completely because of increased stiffness of the muscles of the iris, so the older person takes more time to adjust when going to and from

light and dark settings and needs brighter light for close vision. Pathologic visual conditions are not a part of normal aging, but the incidence of eye disease (most commonly cataracts, glaucoma, diabetic retinopathy, and age-related macular degeneration) increases in older people.

Age-related macular degeneration is the primary cause of vision loss in the elderly. More than 25% of people older than 75 years of age have some signs of this disease, and 6% to 8% have advanced disease associated with severe vision loss. Macular degeneration does not affect peripheral vision, which means that it does not cause blindness. However, it affects central vision, color perception, and fine detail, greatly affecting common visual skills such as reading, driving, and seeing faces. Risk factors include sunlight exposure, cigarette smoking, and heredity, and people with fair skin and blue eyes may be at increased risk. Sunglasses and hats with visors provide some protection, and stopping smoking is paramount in preventing the disease. Although there is no definitive treatment and no cure that restores vision, several treatment options are available, depending on factors such as the location of the abnormal blood vessels. Injected medication in conjunction with photodynamic therapy has demonstrated improved outcomes in clinical trials for the wet type of acute macular degeneration (Blick, Keating & Wagstaff, 2007). The earlier this condition is diagnosed, the greater the chances of preserving sight. More information on altered vision can be found in Chapter 58.

Hearing

Auditory changes begin to be noticed at about 40 years of age. Environmental factors, such as exposure to noise, medications, and infections, as well as genetics, may contribute to hearing loss as much as age-related changes. **Presbycusis** is a gradual, sensorineural loss that progresses from the loss of the ability to hear high-frequency tones to a generalized loss of hearing. It is attributed to irreversible inner ear changes. Older people often cannot follow conversation because tones of high-frequency consonants (the sounds *f*, *s*, *th*, *ch*, *sh*, *b*, *t*, *p*) all sound alike. Hearing loss may cause older people to respond inappropriately, misunderstand conversation, and avoid social interaction. This behavior may be erroneously interpreted as confusion. Wax buildup or other correctable problems may also be responsible for hearing difficulties. A properly prescribed and fitted hearing aid may be useful in reducing some types of hearing deficits. Chapter 59 discusses alterations in hearing.

Taste and Smell

Of the four basic tastes (sweet, sour, salty, and bitter), sweet tastes are particularly dulled in older people. Blunted taste may contribute to the preference for salty, highly seasoned foods, but herbs, onions, garlic, and lemon can be used as substitutes for salt to flavor food.

Changes in the sense of smell are related to cell loss in the nasal passages and in the olfactory bulb in the brain. Environmental factors such as long-term exposure to toxins (eg, dust, pollen, and smoke) contribute to the cellular damage.

Psychosocial Aspects of Aging

Successful psychological aging is reflected in the ability of older people to adapt to physical, social, and emotional

losses and to achieve life satisfaction. Because changes in life patterns are inevitable over a lifetime, older people need resiliency and coping skills when confronting stresses and change. A positive self-image enhances risk taking and participation in new, untested roles.

Although attitudes toward older people differ in ethnic subcultures, a subtle theme of **ageism**—prejudice or discrimination against older people—predominates in our society, and many myths surround aging. Ageism is based on stereotypes, simplified and often untrue beliefs that reinforce society's negative image of older people. Although older people make up an extremely heterogeneous and increasingly a racially and ethnically diverse group, negative stereotypes are attributed to all older people.

Fear of aging and the inability of many to confront their own aging process may trigger ageist beliefs. Retirement and perceived nonproductively are also responsible for negative feelings, because a younger working person may falsely see older people as not contributing to society, as draining economic resources, and may actually feel that they are in competition with children for resources. Concern about the large numbers of elderly leaving the workforce (baby boomers begin to turn age 65 in 2011) is fueling this debate.

Many negative images are so common in society that the elderly themselves often believe and perpetuate them. An understanding of the aging process and respect for each person as an individual can dispel the myths of aging. If the elderly are treated with dignity and encouraged to maintain autonomy, the quality of their lives will improve.

Stress and Coping in the Older Adult

Coping patterns and the ability to adapt to stress develop over the course of a lifetime and remain consistent later in life. Experiencing success in younger adulthood helps a person develop a positive self-image that remains solid through old age. A person's abilities to adapt to changes, make decisions, and respond predictably are also determined by past experiences. A flexible, well-functioning person will probably continue as such. However, losses may accumulate within a short period of time and may become overwhelming. The older person often has fewer choices and diminished resources to deal with stressful events. Common stressors of old age include normal aging changes that impair physical function, activities, and appearance; disabilities from injury or chronic illness; social and environmental losses related to loss of income and decreased ability to perform previous roles and activities; and the deaths of significant others. Many older adults rely strongly on their spiritual beliefs for comfort during stressful times.

Living Arrangements

Most older people want to remain in their own homes; in fact, they function best in their own environment. The family home and familiar community may have strong emotional significance for them, and this should not be ignored. However, with advanced age and increasing disability, adjustments to the environment may be required to allow older adults to remain in their own homes or apartments. Additional family support or more formal support such as Meals on Wheels or transportation services may be necessary to compensate for declining function and mobility.

Many elderly people have more than adequate financial resources and good health even until very late in life; therefore, they have many housing options. More than 90% of the elderly live in the community, with a relatively small percentage (4.5%) of elderly residing in nursing homes, and a comparable percentage (5%) living in some type of senior housing. Eighty percent of those older than 65 years of age own their homes. At this time, 30.1% of noninstitutionalized elderly people live alone. Of the elderly people who live alone in the community, widowed women predominate. Seventy-two percent of men older than 65 years of age are married compared with 42% of women in the same age group. Among those 85 years of age or older, about 50% of the men are married compared with 13% of the women. This difference in marital status is a result of several factors: women have a longer life expectancy than men; women tend to marry older men; and women tend to remain widowed, whereas men often remarry (Administration on Aging [AoA], 2006).

Older people tend to relocate in response to changes in their lives such as retirement or widowhood, a significant deterioration in health, or disability. The type of housing they choose depends on their reason for moving (Hooymann & Kiyak, 2005). For example, there has been a significant increase in the elderly population in the “Sun Belt”—in the states of Florida, California, Texas, and Arizona—as relatively young older adults (60 to 74 years of age) and recent retirees move to warmer climates and retirement communities. With increasing disability and illness, elderly people may move to retirement facilities or assisted living communities that provide some support such as meals, transportation, and housekeeping but allow them to live somewhat independently. If they develop a serious illness or disability and can no longer live independently or semi-independently, they may need to move to a setting where additional support is available. Older people may move in with a relative or to a nursing home or an assisted living facility near a child’s home.

Sometimes older adults or couples move in with adult children. This can be a rewarding experience as the children, their parents, and the grandchildren interact and share household responsibilities (Fig. 12-2). It can also be

Figure 12-2 Families are an important source of psychosocial and physical support for elderly people and youngsters alike. Caring interaction among grandchildren, grandparents, and other family members typically contributes to the health of all.

stressful, depending on family dynamics. Adult children and their older parents may choose to pool their financial resources by moving into a house that has an attached “in-law suite.” This arrangement provides security for the older adult and privacy for both families.

Unfortunately, many elderly people and their adult children make housing decisions in times of crisis, such as during a serious illness or after the death of a spouse. Older people and their families often are unaware of all of the ramifications of shared housing and assuming care for an increasingly dependent person. Families can be helped by anticipatory guidance and long-term planning before a crisis occurs. Older adults should participate in decisions that affect them as much as possible.

Continuing Care Retirement Communities

Continuing care retirement communities (CCRCs) provide three levels of living arrangements and care and are becoming more popular. CCRCs consist of independent single-dwelling houses or apartments for people who can manage all of their day-to-day needs; assisted living apartments for those who need limited assistance with their daily living needs; and skilled nursing services when continuous nursing assistance is required. CCRCs usually contract for a large down payment before the resident moves into the community. This payment gives a person or couple the option of residing in the same community from the time of total independence through the need for assisted or skilled nursing care. Decisions about living arrangements and health care can be made before any decline in health status occurs. CCRCs also provide continuity at a time in an older adult’s life when many other factors, such as health status, income, and availability of friends and family members, may be changing.

Assisted Living Facilities

Assisted living facilities are an option when an older person’s physical or cognitive changes necessitate at least minimal supervision or assistance. Assisted living allows for a degree of independence while providing minimal nursing assistance with administration of medication, assistance with ADLs, or other chronic health care needs. Other services, such as laundry, cleaning, and meals, may also be included.

Long-Term Care Facilities

Many types of nursing homes, nursing facilities, or long-term care facilities offer continuous nursing care. Contrary to the myth of family abandonment and the fear of “ending up in a nursing home,” the actual percentage of long-term nursing home residents has declined, from 5.4% in 1985 to 4.5% in 2005 (AoA, 2006). However, the actual number of elderly people who reside in long-term care facilities has risen due to the large increase in the aging population and the use of nursing homes today for short-term rehabilitation.

Short-term nursing home care is often reimbursed by Medicare if the patient is recovering from an acute illness such as a stroke, myocardial infarction, or cancer and requires skilled nursing care or therapy for recuperation. Usually, if an older adult suffers a major health event and is hospitalized and then goes to a nursing facility, Medicare

covers the cost of the first 30 to 90 days in a skilled nursing facility if ongoing therapy is needed. The requirement for continued Medicare coverage during this time is documentation of persistent improvement in the condition that requires therapy, most often physical therapy, occupational therapy, respiratory therapy, and cognitive therapy. Some adults choose to have long-term care insurance as a means of paying, at least in part, for the cost of these services should they become necessary. For elderly people who are living in nursing homes and who are medically stable, even though they may have multiple chronic and debilitating health issues, costs are primarily paid out-of-pocket by the patient. Family members are not responsible for nursing home costs. When a person's financial resources become exhausted as a result of prolonged nursing home care, the patient, the institution, or both may apply for Medicaid reimbursement.

An increasing number of skilled nursing facilities offer subacute care. This area of the facility offers a high level of nursing care that may either avoid the need for a resident to be transferred to a hospital from the nursing home or allow a hospitalized patient to be transferred back to the nursing facility sooner.

The Role of the Family

Planning for care and understanding the psychosocial issues confronting older people must be accomplished within the context of the family. If dependency needs occur, the spouse often assumes the role of primary caregiver. In the absence of a surviving spouse, an adult child usually assumes caregiver responsibilities and may eventually need help in providing or arranging for care and support.

Two common myths in American society are that adult children and their aged parents are socially alienated, and that adult children abandon their parents when health and other dependency problems arise. In reality, the family has been and continues to be an important source of support for older people; similarly, older family members provide a great deal of support to younger family members.

Although adult children are not financially responsible for their older parents, social attitudes and cultural values often dictate that adult children should provide services and assume the burden of care if their aged parents cannot care for themselves. Among the elderly who need assistance, about 11% of Medicare enrollees received assistance from informal (family and friends) or formal sources (service provider agencies). More than 90% of this population received some or all of their care from informal caregivers. Fewer than 10% received services only from the formal network (AoA, 2006).

Caregiving, which may continue for many years, can become a source of family stress. For prolonged periods, it is not uncommon for caregivers to neglect their own emotional and health needs. In addition, because many people tend to have children later in life, they may face the competing demands of caring for their aging parents while caring for their own dependent children. Furthermore, because of smaller family sizes, fewer numbers of siblings are available to help with parental care issues. If community agencies or adult children cannot provide care, elders are at high risk for institutionalization.

Cognitive Aspects of Aging

Cognition can be affected by many variables, including sensory impairment, physiologic health, environment, and psychosocial influences. Older adults may experience temporary changes in cognitive function when hospitalized or admitted to skilled nursing facilities, rehabilitation centers, or long-term care facilities. These changes are related to differences in the environment or in medical therapy or to alteration in role performance. Despite myths to the contrary, smoking does not improve cognition, mood, or decrease stress in older adults (Cataldo, 2007).

Intelligence

When intelligence test scores from people of all ages are compared, test scores for older adults show a progressive decline beginning in midlife. However, research has shown that environment and health have a considerable influence on scores, and that certain types of intelligence (eg, spatial perceptions and retention of nonintellectual information) decline, whereas others (eg, problem-solving ability based on past experiences, verbal comprehension, mathematical ability) do not. Cardiovascular health, a stimulating environment, high levels of education, occupational status, and income all appear to have a positive effect on intelligence scores in later life.

Learning and Memory

According to Hooyman and Kiyak (2005), significant age-related declines in intelligence, learning, and memory are not inevitable. These authors summarized the major studies on cognitive function in later years and provided the following overview.

Many factors affect the ability of older people to learn and remember and to perform well in testing situations. Older adults who have higher levels of education, good sensory function, good nutrition, and jobs that require complex problem-solving skills continue to demonstrate intelligence, memory, and the capacity for learning. Part of the challenge in testing older adults is determining what is actually being tested (eg, speed of response) and whether the test results are indicative of a normal age-related change, a sensory deficit, or poor health. However, age differences continue to emerge even with untimed tests and when the tests are controlled for variations in motor and sensory function. In general, there is a decline in fluid intelligence, the biologically determined intelligence used for flexibility in thinking and problem solving. Crystallized intelligence, that gained through education and lifelong experiences (eg, verbal skills), remains intact. This is termed the *classic aging pattern of intelligence*. Despite these slight declines, many older people continue to learn and participate in varied educational experiences.

Good health and motivation are important influences on learning. Nurses can support the processes by which older adults learn by using the following strategies:

- Supply mnemonics to enhance recall of related data
- Encourage ongoing learning
- Link new information with familiar information
- Use visual, auditory, and other sensory cues
- Encourage learners to wear prescription glasses and hearing aids

- Provide glare-free lighting
- Provide a quiet, nondistracting environment
- Set short-term goals with input from the learner
- Keep teaching periods short
- Pace learning tasks according to the endurance of the learner
- Encourage verbal participation by learners
- Reinforce successful learning in a positive manner

Pharmacologic Aspects of Aging

Because an increasing number of chronic conditions affect older people, they use more medications than any other age group. Older adults constitute only about 13% of the U.S. population, but they use 25% to 30% of all prescription medications and 40% of all nonprescription medications (Fulmer & Conchita, 2005). Although these medications improve health and well-being by relieving pain and discomfort, treating chronic illnesses, and curing infectious processes, adverse drug reactions are common because of medication interactions, multiple medication effects, incorrect dosages, and the use of multiple medications (**polypharmacy**). On average, the elderly, especially those people 85 years of age or older, take between five and eight medications each day (Cefalu, 2006). The potential for drug–drug interactions increases with increased medication use and with multiple coexisting diseases (**comorbidity**) that affect the absorption, distribution, metabolism, and elimination of the medications. Such interactions are responsible for numerous emergency department and physician visits, which cost billions of dollars annually.

Medications such as antipsychotics, anticoagulants, diuretics, and antiepileptics carry high risks for older patients and are often inappropriately prescribed (Cefalu, 2006). In one study of 50 patients 65 years of age or older, one or more potentially inappropriate medications were prescribed for 25% of the patients. The most common drug classes prescribed were psychotropic and anti-inflammatory agents (Maio, Hartman, Poston, et al., 2006). An effective resource for identifying potentially risky drug interactions and adverse effects in older adults is *Beers' Criteria for Potentially Inappropriate Medication Use in the Elderly* (Fick, Cooper, Wade, et al., 2003).

Any medication is capable of altering nutritional status, and the nutritional health of the elderly person may already be compromised by a marginal diet or by chronic disease and its treatment. Medications can affect the appetite, cause nausea and vomiting, irritate the stomach, cause constipation or diarrhea, and decrease absorption of nutrients. In addition, these medications may alter electrolyte balance as well as carbohydrate and fat metabolism. For example, antacids cause thiamine deficiency; laxatives diminish absorption; antibiotics and phenytoin (Dilantin) reduce utilization of folic acid; and phenothiazines, estrogens, and corticosteroids increase food intake and cause weight gain.

Combining multiple medications with alcohol, as well as with over-the-counter and herbal medications, complicates the problem. For example, St. John's wort, a common herbal supplement used for mild depression, decreases the anticoagulant effect of warfarin (Coumadin) and interacts with many other medications metabolized in the liver (Fitzgerald, 2007).

Altered Pharmacokinetics

Alterations in absorption, metabolism, distribution, and excretion occur as a result of normal aging and may also result from drug and food interactions. Absorption may be affected by changes in gastric pH and a decrease in gastrointestinal motility. Drug distribution may be altered as a result of decrease in body water and increase in body fat. Normal age-related changes and diseases that alter blood flow, liver and renal function, or cardiac output may affect distribution and metabolism (Table 12-3).

Nursing Implications

Prescription principles that have been identified as appropriate for older patients include “start low and go slow” and keep the medication regimen as simple as possible (Fulmer & Conchita, 2005). A comprehensive assessment that begins with a thorough medication history, including use of alcohol, recreational drugs, and over-the-counter and herbal medications, is essential. It is best to ask the patient or reliable informants to provide all medications for review. Ascertain the patient's understanding of when and how to take each medication as well as the purpose of each medication allows the nurse to assess the patient's knowledge about and compliance with the medication regimen. The patient's beliefs and concerns about the medications should be identified. It is helpful to ask patients if they believe that a given medication is helpful.

Noncompliance leads to significant morbidity and mortality among the elderly. Among people 60 years of age and older, reports of noncompliance with medication regimens range from 14% to 77% depending on the disease and the measurement method (Chia, 2006). The many contributing factors include the number of medications prescribed, the complexity of the regimen, difficulty opening containers, inadequate patient education, financial cost, and the disease or medication interfering with the patient's life. Furthermore, visual and hearing problems may make it difficult to read or to hear directions.

Multifaceted interventions tailored to the individual patient are the most effective strategies in improving compliance. The following steps can help patients manage their medications and improve compliance:

- Explain the purpose, adverse effects, and dosage of each medication.
- Provide the medication schedule in writing.
- Encourage the use of standard containers without safety lids (if there are no children in the household).
- Suggest the use of a multiple-day, multiple-dose medication dispenser to help the patient adhere to the medication schedule.
- Destroy or remove old, unused medications.
- Encourage the patient to inform the primary health care provider about the use of over-the-counter medications and herbal agents, alcohol, and recreational drugs.
- Encourage the patient to keep a list of all medications, including over-the-counter and herbal medications, in his or her purse or wallet to share with the primary care provider at each visit and in case of an emergency.

Table 12-3 ALTERED DRUG RESPONSES IN OLDER PEOPLE

Age-Related Changes	Effect of Age-Related Change	Applicable Medications
Absorption		
Reduced gastric acid; increased pH (less acid) Reduced gastrointestinal motility; prolonged gastric emptying	Rate of drug absorption—possibly delayed Extent of drug absorption—not affected	Vitamins Calcium
Distribution		
Decreased albumin sites	Serious alterations in drug binding to plasma proteins (the unbound drug gives the pharmacologic response); highly protein-bound medications have fewer binding sites, leading to increased effects and accelerated metabolism and excretion	Selected highly protein-binding medications: Oral anticoagulants (warfarin) Oral hypoglycemic agents (sulfonylureas) Barbiturates Calcium channel blockers Furosemide (Lasix) Nonsteroidal anti-inflammatory drugs (NSAIDs) Sulfonamides Quinidine Phenytoin (Dilantin)
Reduced cardiac output Impaired peripheral blood flow Increased percentage of body fat	Decreased perfusion of many bodily organs Decreased perfusion Proportion of body fat increases with age, resulting in increased ability to store fat-soluble medications; this causes drug accumulation, prolonged storage, and delayed excretion	Selected fat-soluble medications: Barbiturates Diazepam (Valium) Lidocaine Phenothiazines (antipsychotics) Ethanol Morphine
Decreased lean body mass	Decreased body volume allows higher peak levels of medications	
Metabolism		
Decreased cardiac output and decreased perfusion of the liver	Decreased metabolism and delay of breakdown of medications, resulting in prolonged duration of action, accumulation, and drug toxicity	All medications metabolized by the liver
Excretion		
Decreased renal blood flow; loss of functioning nephrons; decreased renal efficiency	Decreased rates of elimination and increased duration of action; danger of accumulation and drug toxicity	Selected medications with prolonged action: Aminoglycoside antibiotics Cimetidine (Tagamet) Chlorpropamide (Diabinese) Digoxin Lithium Procainamide

- Review the medication schedule periodically and update it as necessary.
- Recommend using one supplier for prescriptions; pharmacies frequently track patients and are likely to notice a prescription problem such as duplication or contraindications in the medication regimen.
- If the patient’s competence is doubtful, identify a reliable family member or friend who might monitor the patient for compliance.

Mental Health Problems in the Older Adult

Changes in cognitive ability, excessive forgetfulness, and mood swings are not a part of normal aging. These symptoms should not be dismissed as age-related changes; a thor-

ough assessment may reveal a treatable, reversible physical or mental condition. Changes in mental status may be related to many factors, such as alterations in diet and fluid and electrolyte balance, fever, or low oxygen levels associated with many cardiovascular and pulmonary diseases. Cognitive changes may be reversible when the underlying condition is identified and treated. However, the susceptibility to depression, delirium, and incidence of dementia increases with age. Older adults are less likely than younger people to acknowledge or seek treatment for mental health symptoms. Therefore, health professionals must recognize, assess, refer, collaborate, treat, and support older adults who exhibit noticeable changes in intellect or affect.

Depression

Depression is the most common affective or mood disorder of old age. About 15% of older Americans suffer from

depression, and of those, 3% to 26% are elderly residing in the community. The incidence of depression is higher among the hospitalized elderly (23%) and ranges from 16% to 30% among nursing home residents (Greenberg, 2007).

Depression among the elderly can follow a major precipitating event or loss and is often related to chronic illness or pain. It may also be secondary to a medication interaction or an undiagnosed physical condition. Signs of depression include feelings of sadness, fatigue, diminished memory and concentration, feelings of guilt or worthlessness, sleep disturbances, appetite disturbances with excessive weight loss or gain, restlessness, impaired attention span, and suicidal ideation. Even mild depression with symptoms that do not meet the criteria for a major depression reduces quality of life and function (Evans, 2007). The risk of suicide increases in depressed patients, especially elderly Caucasian and Asian American men. Seventy-five percent of elderly adults who committed suicide had visited their physician 1 month prior to the suicide, and 39% had seen a physician within the week (Salzman, 2006). This supports the need for routine assessment of patients for depression and risk for suicide. Geriatric depression may be confused with dementia. However, the cognitive impairment resulting from depression is a result of apathy rather than decline in brain function. When depression and medical illnesses coexist, as they often do, neglect of the depression can impede physical recovery. Assessing the patient's mental status, including depression, is vital and must not be overlooked. Two commonly used assessment tools are the Mini Mental Status Examination (MMSE) and the Geriatric Depression Scale (GDS) (Charts 12-2 and 12-3).

Depression is highly responsive to treatment but is often not recognized and therefore is undertreated. Initial man-

agement involves evaluation of the patient's medication regimen and eliminating or changing any medications that contribute to depression. Furthermore, treatment of underlying medical conditions that may produce depressive symptoms may alleviate the depression. For mild depression, nonpharmacologic measures such as exercise, bright lighting, increasing interpersonal interactions, cognitive therapy, and reminiscence therapy are effective (Evans, 2007). However for major depression, antidepressants and short-term psychotherapy, particularly in combination, are effective in the elderly. Newer atypical antidepressants, such as bupropion (Wellbutrin), venlafaxine (Effexor), mirtazapine (Remeron), and nefazodone (Serzone), as well as selective serotonin reuptake inhibitors, such as paroxetine (Paxil), may be used (Butcher & McGonigal-Kenney, 2005).

Tricyclic antidepressants can be an effective medication for depression in some patients. However, medications with anticholinergic, cardiac, and orthostatic adverse effects, as well as interactions with other medications, should be used with care to avoid medication toxicity, hypotensive events, and falls. It may take 4 to 6 weeks for symptoms to diminish, and during this period, nurses should offer support and encouragement. In life-threatening cases, electroconvulsive therapy has proved effective.

Alcohol and Drug Abuse

Alcohol and drug abuse may be related to depression, and its incidence is significant in the elderly population. Thirty-six percent of adults 65 years of age and older report that they are current drinkers. Excessive drinking in people 55 to 64 years of age of all ethnic backgrounds has reportedly decreased from 12% to approximately 7% (CDC, 2007a).

Alcohol abuse is especially dangerous in older people because of age-related changes in renal and liver function as well as the high risk of interactions with prescription medications and the resultant adverse effects. Alcohol-related and drug-related problems in older people often remain hidden because many older adults deny their habit when questioned. Assessing for drug and alcohol use with direct questions in a nonaccusatory manner should be part of the routine physical assessment. More information and specific assessment tools can be found in Chapter 5.

Delirium

Delirium, often called acute confusional state, begins with confusion and progresses to disorientation. It is a common and life-threatening complication for the hospitalized elderly and the most frequent complication of hospitalization, occurring in 15% to 53% of older people postoperatively and in 70% to 87% of those in intensive care (Inouye, 2006). Patients may experience an altered level of consciousness, ranging from stupor (hypoalert–hypoactive) to excessive activity (hyperalert–hyperactive); alternatively, they may have a combination of these two types (mixed). Thinking is disorganized, and the attention span is short. Hallucinations, delusions, fear, anxiety, and paranoia may also be evident. Patients who tend to be hyperalert and hyperactive demand more attention from nurses and thus are easier to diagnose, whereas those who are hypoalert or hypoactive tend to be less problematic and pose diagnostic difficulties. Recognition of delirium can also be complicated in

Chart 12-3 • Geriatric Depression Scale

Choose the best answer for how you felt this past week.					
*1. Are you basically satisfied with your life?	YES	NO	17. Do you feel pretty worthless the way you are now?	YES	NO
2. Have you dropped many of your activities and interests?	YES	NO	18. Do you worry a lot about the past?	YES	NO
3. Do you feel that your life is empty?	YES	NO	*19. Do you find life very exciting?	YES	NO
4. Do you often get bored?	YES	NO	20. Is it hard for you to get started on new projects?	YES	NO
*5. Are you hopeful about the future?	YES	NO	*21. Do you feel full of energy?	YES	NO
6. Are you bothered by thoughts you can't get out of your head?	YES	NO	22. Do you feel that your situation is hopeless?	YES	NO
*7. Are you in good spirits most of the time?	YES	NO	23. Do you think that most people are better off than you are?	YES	NO
8. Are you afraid that something bad is going to happen to you?	YES	NO	24. Do you frequently get upset over little things?	YES	NO
*9. Do you feel happy most of the time?	YES	NO	25. Do you frequently feel like crying?	YES	NO
10. Do you often feel helpless?	YES	NO	26. Do you have trouble concentrating?	YES	NO
11. Do you often get restless and fidgety?	YES	NO	*27. Do you enjoy getting up in the morning?	YES	NO
12. Do you prefer to stay at home, rather than going out and doing new things?	YES	NO	28. Do you prefer to avoid social gatherings?	YES	NO
13. Do you frequently worry about the future?	YES	NO	*29. Is it easy for you to make decisions?	YES	NO
14. Do you feel you have more problems with memory than most?	YES	NO	*30. Is your mind as clear as it used to be?	YES	NO
*15. Do you think it is wonderful to be alive now?	YES	NO	Score: _____ (Number of "depressed" answers)		
16. Do you often feel downhearted and blue?	YES	NO	Norms		
			Normal: 5 ± 4		
			Mildly depressed: 15 ± 6		
			Very depressed: 23 ± 5		

* Appropriate (nondepressed) answers = yes; all others = no. Yesavage, J., Brink, T. L., Rose, T. L., et al. (1983). patients with the mixed type of disorders. Patients with the hypoalert–hypoactive type of delirium have higher mortality rates and even poorer outcomes of care because the delirium tends not to be recognized and treated (Forrest, Willis, Holm, et al., 2007).

Attentive clinical assessment is essential because delirium is sometimes mistaken for dementia; Table 12-4 compares dementia and delirium. It helps to know an individual patient's usual mental status and whether the changes noted are long term, which probably represents dementia, or are abrupt in onset, which is more likely delirium.

Delirium occurs secondary to a number of causes, including physical illness, medication or alcohol toxicity, dehydration, fecal impaction, malnutrition, infection, head trauma, lack of environmental cues, and sensory deprivation or overload. Older adults are particularly vulnerable to acute confusion because of their decreased biologic reserve and the large number of medications they may take. Nurses must recognize the implications of the acute symptoms of delirium and report them immediately. Because of the acute

and unexpected onset of symptoms and the unknown underlying cause, delirium is a medical emergency. If the delirium goes unrecognized and the underlying cause is not treated, permanent, irreversible brain damage or death can follow.

The most effective strategy is prevention, which may be achievable in 30% to 40% of cases (Inuoye, 2006). Prevention includes therapeutic activities for cognitive impairment, early mobilization, controlling pain, minimizing the use of psychoactive drugs, preventing sleep deprivation, enhancing communication methods (particularly eye glasses and hearing aids) for vision and hearing impairment, maintaining oxygen levels and fluid and electrolyte balance, and preventing surgical complications (Vance, Webb, Marceaux, et al., 2008).

Once delirium occurs, treatment of the underlying cause is most important. Therapeutic interventions vary depending on the cause. Delirium increases the risk of falls; therefore, management of patient safety and behavioral problems is essential. Because medication interactions and

Table 12-4 SUMMARY OF DIFFERENCES BETWEEN DEMENTIA AND DELIRIUM

	Dementia		Delirium
	Alzheimer's Disease (AD)	Vascular (Multi-Infarct) Dementia	
Etiology	Early onset (familial, genetic [chromosomes 14, 19, 21]) Late onset sporadic	Cardiovascular (CV) disease Cerebrovascular disease Hypertension	Drug toxicity and interactions; acute disease; trauma; chronic disease exacerbation
Risk factors	Advanced age; genetics	Preexisting CV disease	Fluid and electrolyte disorders
Occurrence	50–60% of dementias	20% of dementias	Preexisting cognitive impairment
Onset	Slow	Often abrupt Follows a stroke or transient ischemic attack	6%–56% among hospitalized people. Rapid, acute onset A harbinger of acute medical illness
Age of onset (yr)	Early onset AD: 30s–65 Late onset AD: 65+ Most commonly: 85+	Most commonly 50–70 yr	Any age, but predominantly in older persons
Gender	Males and females equally	Predominantly males	Males and females equally
Course	Chronic, irreversible; progressive, regular, downhill	Chronic, irreversible Fluctuating, stepwise progression	Acute onset Hypoalert–hypoactive Hyperalert–hyperactive Mixed hypo–hyper
Duration	2–20 yr	Variable; years	Lasts 1 day to 1 month
Symptom progress	Onset insidious. <i>Early</i> —mild and subtle <i>Middle and late</i> —intensified Progression to death (infection or malnutrition)	Depends on location of infarct and success of treatment; death due to underlying CV disease	Symptoms are fully reversible with adequate treatment; can progress to chronicity or death if underlying condition is ignored
Mood	Early depression (30%)	Labile: mood swings	Variable
Speech/language	Speech remains intact until late in disease <i>Early</i> —mild anomia (cannot name objects); deficits progress until speech lacks meaning; echoes and repeats words and sounds; mutism <i>Early</i> —no motor deficits	May have speech deficit/aphasia depending on location of lesion	Fluctuating; often cannot concentrate long enough to speak May be somnolent
Physical signs	<i>Middle</i> —apraxia (70%) (cannot perform purposeful movement) <i>Late</i> —Dysarthria (impaired speech) <i>End stage</i> —loss of all voluntary activity; positive neurologic signs	According to location of lesion: focal neurologic signs, seizures Commonly exhibits motor deficits	Signs and symptoms of underlying disease
Orientation	Becomes lost in familiar places (topographic disorientation) Has difficulty drawing three-dimensional objects (visual and spatial disorientation)		May fluctuate between lucidity and complete disorientation to time, place, and person
Memory	Disorientation to time, place, and person—with disease progression Loss is an early sign of dementia; loss of recent memory is soon followed by progressive decline in recent and remote memory		Impaired recent and remote memory; may fluctuate between lucidity and confusion
Personality	Apathy, indifference, irritability <i>Early disease</i> —social behavior intact; hides cognitive deficits <i>Advanced disease</i> —disengages from activity and relationships; suspicious; paranoid delusions caused by memory loss; aggressive; catastrophic reactions		Fluctuating; cannot focus attention to converse; alarmed by symptoms (when lucid); hallucinations; paranoid
Functional status, activities of daily living	Poor judgment in everyday activities; has progressive decline in ability to handle money, use telephone, function in home and workplace		Impaired
Attention span	Distractable; short attention span		Highly impaired; cannot maintain or shift attention
Psychomotor activity	Wandering, hyperactivity, pacing, restlessness, agitation		Variable; alternates between high agitation, hyperactivity, restlessness, and lethargy
Sleep–wake cycle	Often impaired; wandering and agitation at nighttime		Takes brief naps throughout day and night

toxicity are often implicated, nonessential medications should be discontinued. Nutritional and fluid intake should be supervised and monitored. The environment should be quiet and calm. To increase function and comfort, the nurse provides familiar environmental cues and encourages family members or friends to touch and talk to the patient

(Fig. 12-3). Ongoing mental status assessments using prior mental cognitive status as a baseline are helpful in evaluating responses to treatment and upon admission to a hospital or extended-care facility. If the underlying problem is adequately treated, the patient often returns to baseline within several days. Several resources specific to delirium

Figure 12-3 Talking to family members may increase the comfort of patients with delirium.

are included in the Resource section at the end of the chapter.

Dementia

The cognitive, functional, and behavioral changes that characterize **dementia** eventually destroy a person's ability to function. The symptoms are usually subtle in onset and often progress slowly until they are obvious and devastating. The two most common types of dementia are Alzheimer's disease (AD), which accounts for 50% to 60% of cases, and vascular or multi-infarct dementia, which accounts for 10% to 20% of cases. Other non-Alzheimer dementias include Parkinson's disease, acquired immunodeficiency syndrome (AIDS)-related dementia, and Pick's disease; these types of dementia account for fewer than 15% of cases (National Institute of Neurological Disorders and Stroke [NINDS], 2006). Approximately one in seven Americans 71 years of age and older has dementia; 2.4 million people with dementia have AD (Guralnik, Fried, Simonsick, et al., 2007).

Alzheimer's Disease

AD is a progressive, irreversible, degenerative neurologic disease that begins insidiously and is characterized by gradual losses of cognitive function and disturbances in behavior and affect. Although AD can occur in people as young as 40 years of age, it is uncommon before 65 years of age. Although the prevalence of AD increases dramatically with increasing age, affecting as many as half of those 85 years of age and older, it is important to note that AD is not a normal part of aging. Without a cure or any preventive measures, it is estimated that 13.2 million Americans will have this disease by 2050 (NIA, 2007).

There are numerous theories about the cause of age-related cognitive decline. Although the greatest risk factor for AD is increasing age, many environmental, dietary, and inflammatory factors also may determine whether a person suffers from this cognitive disease. AD is a complex brain disorder caused by a combination of various factors that may include genetics, neurotransmitter changes, vascular abnormalities, stress hormones, circadian changes, head trauma, and the presence of seizure disorders.

AD can be classified into two types: familial or early-onset AD and sporadic or late-onset AD. Familial AD is rare, accounting for less than 10% of all cases, and is frequently associated with genetic mutations. It occurs in middle-aged adults. If family members have at least one other relative with AD, then there is a familial component, which nonspecifically includes both environmental triggers and genetic determinants.

Pathophysiology

Specific neuropathologic and biochemical changes are found in patients with AD. These include neurofibrillary tangles (tangled masses of nonfunctioning neurons) and senile or neuritic plaques (deposits of amyloid protein, part of a larger protein called amyloid precursor protein in the brain). The neuronal damage occurs primarily in the cerebral cortex and results in decreased brain size. Similar changes are found in the normal brain tissue of older adults, but to a lesser extent. Cells that use the neurotransmitter acetylcholine are principally affected by AD. At the biochemical level, the enzyme active in producing acetylcholine, which is specifically involved in memory processing, is decreased.

Scientists have been studying complex neurodegenerative diseases such as AD and have focused on two key issues: whether a gene might influence a person's overall risk of developing the disease, and whether a gene might influence some particular aspect of a person's risk, such as the age at which the disease begins (age at onset). There are genetic differences in early-onset and late-onset forms of AD. Researchers are conducting tests to explain what predisposes people to develop the plaques and neurofibrillary tangles that can be seen at autopsy in the brains of patients with AD. Understanding the complex ways in which aging and genetic and nongenetic factors affect brain cells over time, eventually leading to AD, continues to increase. Researchers have discovered how amyloid plaques form and cause neuronal death, the possible relationship between various forms of tau protein and impaired function, the roles of inflammation and oxidative stress, and the contribution of brain infarctions to the disease (NIA, 2007).

Clinical Manifestations

In the early stages of AD, forgetfulness and subtle memory loss occur. Patients may experience small difficulties in work or social activities but have adequate cognitive function to compensate for the loss and continue to function independently. With further progression of AD, the deficits can no longer be concealed. Forgetfulness is manifested in many daily actions; patients may lose their ability to recognize familiar faces, places, and objects, and they may become lost in a familiar environment. They may repeat the same stories because they forget that they have already told them. Trying to reason with people with AD and using reality **orientation** only increase their anxiety without increasing function. Conversation becomes difficult, and word-finding difficulties occur. The ability to formulate concepts and think abstractly disappears; for example, a patient can interpret a proverb only in concrete terms. Patients are often unable to recognize the consequences of their actions and therefore exhibit impulsive behavior. For example, on a hot

day, a patient may decide to wade in the city fountain fully clothed. Patients have difficulty with everyday activities, such as operating simple appliances and handling money.

Personality changes are also usually evident. Patients may become depressed, suspicious, paranoid, hostile, and even combative. Progression of the disease intensifies the symptoms: speaking skills deteriorate to nonsense syllables, agitation and physical activity increase, and patients may wander at night. Eventually, assistance is needed for most ADLs, including eating and toileting, because dysphagia and incontinence develop. The terminal stage, in which patients are usually immobile and require total care, may last months or years. Occasionally, patients may recognize family members or caregivers. Death occurs as a result of complications such as pneumonia, malnutrition, or dehydration.

Assessment and Diagnostic Findings

A definitive diagnosis of AD can be made only at autopsy, but an accurate clinical diagnosis can be made in about 90% of cases. The most important goal is to rule out other causes of dementia or reversible causes of confusion, such as other types of dementia, depression, delirium, alcohol or drug abuse, or inappropriate drug dosage or drug toxicity (NIA, 2007). AD is a diagnosis of exclusion, and a diagnosis of probable AD is made when the medical history, physical examination, and laboratory tests have excluded all known causes of other dementias.

The health history—including medical history, family history, social and cultural history, and medication history—and the physical examination, including functional and mental health status, are essential to the diagnosis of probable AD. Diagnostic tests, including complete blood count, chemistry profile, and vitamin B₁₂ and thyroid hormone levels, as well as screening with electroencephalography, computed tomography (CT), magnetic resonance imaging (MRI), and examination of the cerebrospinal fluid may all refute or support a diagnosis of probable AD.

Depression can closely mimic early-stage AD and coexists in many patients. Therefore, assessing the patient for underlying depression is important to rule this out. Tests such as the MMSE (see Chart 12-2) are useful for screening (Borson, Scanlan, Watanabe, et al., 2005). Both CT and MRI of the brain are useful for excluding hematoma, brain tumor, stroke, normal-pressure hydrocephalus, and atrophy but are not reliable in making a definitive diagnosis of AD. Infections and physiologic disturbances, such as hypothyroidism, Parkinson's disease, and vitamin B₁₂ deficiency, can cause cognitive impairment that may be misdiagnosed as AD. Biochemical abnormalities can be excluded through examination of the blood and cerebrospinal fluid.

Medical Management

The primary goal is to manage the cognitive and behavioral symptoms. There is no cure and no way to slow the progression of the disease. Four U.S. Food and Drug Administration (FDA)-approved medications are available to treat AD symptoms; however, none of these agents stops the progression of the disease. The cholinesterase inhibitors (CEIs) donepezil hydrochloride (Aricept), rivastigmine tartrate (Exelon), galantamine hydrobromide (Razadyne [formerly known as Reminyl]), and tacrine (Cognex) enhance acetyl-

choline uptake in the brain, thus maintaining memory skills for a period of time; these medications are used for mild to moderate symptoms. Donepezil and the newest medication memantine (Namenda), a receptor agonist, can be used for management of moderate to severe symptoms (NIA, 2007). Cognitive ability may improve within 6 to 12 months of therapy, but cessation of the medications results in disease progression and cognitive decline. It is recommended that treatment continue at least through the moderate stage of the illness. Combination of a CEI with memantine may be useful for mild to moderate cognitive symptoms (Evans, 2007).

Behavioral problems such as agitation and psychosis can be managed by behavioral and psychosocial therapies. Associated depression and behavioral problems can also be treated pharmacologically if other interventions fail. Because symptoms change over time, all patients with AD who take medications should be reevaluated routinely, and the nurse should document and report both positive or negative responses to medications (Evans, 2007).

Nursing Management

Nurses play an important role in the recognition of dementia, particularly in hospitalized elderly, by assessing for signs (eg, repeating or asking the same thing over and over, getting lost) during the nursing admission assessment (Maslow & Mezey, 2008). Nursing interventions for dementia are aimed at promoting patient function and independence for as long as possible. Other important goals include promoting the patient's physical safety, promoting independence in self-care activities, reducing anxiety and agitation, improving communication, providing for socialization and intimacy, promoting adequate nutrition, promoting balanced activity and rest, and supporting and educating family caregivers. These nursing interventions apply to all patients with dementia, regardless of cause.

Supporting Cognitive Function. Because dementia of any type is degenerative and progressive, patients display a decline in cognitive function over time. In the early phase of dementia, minimal cuing and guidance may be all that are needed for the patient to function fairly independently for a number of years. However, as the patient's cognitive ability declines, family members must provide more and more assistance and supervision. A calm, predictable environment helps people with dementia interpret their surroundings and activities. Environmental stimuli are limited, and a regular routine is established. A quiet, pleasant manner of speaking, clear and simple explanations, and use of memory aids and cues help minimize confusion and disorientation and give patients a sense of security. Prominently displayed clocks and calendars may enhance orientation to time. Color-coding the doorway may help patients who have difficulty locating their room. Active participation may help patients maintain cognitive, functional, and social interaction abilities for a longer period. Physical activity and communication have also been demonstrated to slow some of the cognitive decline of AD.

Promoting Physical Safety. A safe home and hospital environment allows the patient to move about as freely as possible and relieves the family of constant worry about safety. To prevent falls and other injuries, all obvious hazards are removed and hand rails are installed in the home. A hazard-

free environment allows the patient maximum independence and a sense of autonomy. Adequate lighting, especially in halls, stairs, and bathrooms, is necessary. Nightlights are helpful, particularly if the patient has increased confusion at night (**sundowning**). Driving is prohibited, and smoking is allowed only with supervision. The patient may have a short attention span and be forgetful. Wandering behavior can often be reduced by gentle persuasion or distraction. Restraints should be avoided because they increase agitation. Doors leading from the house must be secured. Outside the home, all activities must be supervised to protect the patient, and the patient should wear an identification bracelet or neck chain in case of separation from the caregiver.

Promoting Independence in Self-Care Activities. Pathophysiologic changes in the brain make it difficult for people with AD to maintain physical independence. Patients should be assisted to remain functionally independent for as long as possible. One way to do this is to simplify daily activities by organizing them into short, achievable steps so that the patient experiences a sense of accomplishment. Frequently, occupational therapists can suggest ways to simplify tasks or recommend adaptive equipment. Direct patient supervision is sometimes necessary, but maintaining personal dignity and autonomy is important for people with AD, who should be encouraged to make choices when appropriate and to participate in self-care activities as much as possible.

Reducing Anxiety and Agitation. Despite profound cognitive losses, patients are sometimes aware of their diminishing abilities. Patients need constant emotional support that reinforces a positive self-image. When loss of skills occurs, goals are adjusted to fit the patient's declining ability.

The environment should be kept familiar and noise-free. Excitement and confusion can be upsetting and may precipitate a combative, agitated state known as a catastrophic reaction (overreaction to excessive stimulation). The patient may respond by screaming, crying, or becoming abusive (physically or verbally); this may be the patient's only way of expressing an inability to cope with the environment. When this occurs, it is important to remain calm and unhurried. Forcing the patient to proceed with the activity only increases the agitation. It is better to postpone the activity until later, even to another day. Frequently, the patient quickly forgets what triggered the reaction. Measures such as moving to a familiar environment, listening to music, stroking, rocking, or distraction may quiet the patient. Structuring activity is also helpful. Becoming familiar with a particular patient's predicted responses to certain stressors helps caregivers avoid similar situations.

Patients with dementia who have progressed to the late stages of the disease often reside in nursing homes and are predominantly cared for by unlicensed assistive personnel (UAP). Dementia education for caregivers is essential to minimize patient agitation and can be effectively taught by geriatric advanced nurse practitioners.

Improving Communication. To promote the patient's interpretation of messages, the nurse should remain unhurried and reduce noises and distractions. Use of clear, easy-to-understand sentences to convey messages is essential

because patients frequently forget the meaning of words or have difficulty organizing and expressing thoughts. In the earlier stages of dementia, lists and simple written instructions that serve as reminders may be helpful. In later stages, the patient may be able to point to an object or use nonverbal language to communicate. Tactile stimuli, such as hugs or hand pats, are usually interpreted as signs of affection, concern, and security.

Providing for Socialization and Intimacy Needs. Because socialization with friends can be comforting, visits, letters, and phone calls are encouraged. Visits should be brief and nonstressful; limiting visitors to one or two at a time helps reduce overstimulation. Recreation is important, and people with dementia are encouraged to participate in simple activities. Realistic goals for activities that provide satisfaction are appropriate. Hobbies and activities such as walking, exercising, and socializing can improve the quality of life. The nonjudgmental friendliness of a pet may provide stimulation, comfort, and contentment. Care of plants or of a pet can also be satisfying and an outlet for energy.

AD does not eliminate the need for intimacy. Patients and their spouses may continue to enjoy sexual activity. Spouses should be encouraged to talk about any sexual concerns, and sexual counseling may be necessary. Simple expressions of love, such as touching and holding, are often meaningful.

Promoting Adequate Nutrition. Mealtime can be a pleasant social occasion or a time of upset and distress, and it should be kept simple and calm, without confrontations. Patients prefer familiar foods that look appetizing and taste good. To avoid any "playing" with food, one dish is offered at a time. Food is cut into small pieces to prevent choking. Liquids may be easier to swallow if they are converted to gelatin. Hot food and beverages are served warm, and the temperature of the foods should be checked to prevent burns.

When lack of coordination interferes with self-feeding, adaptive equipment is helpful. Some patients may do well eating with a spoon or with their fingers. If this is the case, an apron or a smock, rather than a bib, is used to protect clothing. As deficits progress, it may become necessary to feed the patient. Forgetfulness, disinterest, dental problems, lack of coordination, overstimulation, and choking all serve as barriers to good nutrition and hydration.

Promoting Balanced Activity and Rest. Many patients with dementia exhibit sleep disturbances, wandering, and behaviors that may be considered inappropriate. These behaviors are most likely to occur when there are unmet underlying physical or psychological needs. Caregivers must identify the needs of patients who are exhibiting these behaviors because further health decline may occur if the source of the problem is not corrected. Adequate sleep and physical exercise are essential. If sleep is interrupted or the patient cannot fall asleep, music, warm milk, or a back rub may help the patient relax. During the day, patients should be encouraged to participate in exercise because a regular pattern of activity and rest enhances nighttime sleep. Long periods of daytime sleeping are discouraged.

Supporting Home and Community-Based Care. The emotional burden on the families of patients with all types of

dementia is enormous. The physical health of the patient is often very stable, and the mental degeneration is gradual. Family members may cling to the hope that the diagnosis is incorrect and that their relative will improve with greater effort. Family members are faced with numerous difficult decisions (eg, when the patient should stop driving, when to assume responsibility for the patient's financial affairs). Aggression and hostility exhibited by the patient are often misunderstood by families or caregivers, who feel unappreciated, frustrated, and angry. Feelings of guilt, nervousness, and worry contribute to caregiver fatigue, depression, and family dysfunction.

Neglect or abuse of the patient can occur, and this has been documented in home situations as well as in institutions. If neglect or abuse of any kind—including physical, emotional, sexual, or financial abuse—is suspected, the local adult protective services agency must be notified. The role of the nurse is to report the suspected abuse, not to prove it.

The Alzheimer's Association is a coalition of family members and professionals who share the goals of family support and service, education, research, and advocacy. Family support groups, respite (relief) care, and adult day care may be available through different community resources, such as the Area Agency on Aging, in which concerned volunteers are trained to provide structure to caregiver support groups. Respite care is a commonly provided service in which caregivers can get away from the home for short periods while someone else tends to the needs of the patient.

Vascular Dementia

Vascular dementia, formerly known as multi-infarct dementia, affects about 10% to 20% of people with dementia, and the rate is higher in men than women (NIH, 2007). Vascular dementia tends to have a more abrupt onset than AD, and it is characterized by an uneven, stepwise downward decline in mental function associated with a vascular incident such as a subclinical stroke. The clinical course of this type of dementia is unpredictable; as a result, it is sometimes confused with AD, paranoia, or delirium. Diagnosis may be even more difficult if a patient has vascular dementia as well as AD.

Because vascular dementia is associated with hypertension and cardiovascular disease, risk factors (eg, hypercholesterolemia, history of smoking, diabetes mellitus) are similar. Prevention and management are also similar. Therefore, measures to decrease blood pressure and lower cholesterol levels may prevent future mini-infarcts.

Geriatric Syndromes

Elderly people tend to acquire multiple problems and illnesses as they age. The decline of physical function leads to a loss of independence and increasing frailty as well as to susceptibility to both acute and chronic health problems, which generally result from several factors rather than from a single cause. When combined with a decrease in host resistance, these factors can lead to illness or injury. A number of problems commonly experienced by the elderly are becoming recognized as geriatric syndromes. These conditions do not fit into discrete disease categories. Examples include frailty, delirium, falls, urinary incontinence, and pressure

ulcers (Inouye, Studenski, Tinetti, et al., 2007). Although these conditions may develop slowly, the onset of symptoms is often acute. Furthermore, the presenting symptoms may appear in other body systems before becoming apparent in the affected system. For example, an elderly patient may present with confusion, and the underlying disease may be a urinary tract infection, dehydration, or a heart attack.

The term *frail* is used to describe elderly people who are at highest risk for adverse health outcomes. The most widely used criteria include weight loss, weakness, exhaustion or poor endurance, slowness, and low activity (Bergman, Ferrucci, Hogan, et al., 2007). For all geriatric syndromes, older age, functional impairment, cognitive impairment, and impaired mobility are risk factors. Research suggests that frail older adults are at increased risk for falls, hospitalization, disability, and mortality (Inouye, et al., 2007).

Impaired Mobility

The causes of decreased mobility are many and varied. Common causes include strokes, Parkinson's disease, diabetic neuropathy, cardiovascular compromise, osteoarthritis, osteoporosis, and sensory deficits. To avoid the downward spiral of immobility, elderly people should be encouraged to stay as active as possible. During illness, bed rest should be kept to a minimum, even in hospitalized patients, because even brief periods of bed rest quickly lead to deconditioning and, consequently, to a wide range of complications (Wallace & Skelkey, 2008). When bed rest cannot be avoided, patients should perform active range-of-motion and strengthening exercises with the unaffected extremities, and nurses or family caregivers should perform passive range-of-motion exercises on the affected extremities. Frequent position changes help offset the hazards of immobility. Both the health care staff and the patient's family can assist in maintaining the current level of mobility.

Dizziness

Older people frequently seek help for dizziness, which presents a particular challenge because there are numerous possible causes. For many, the problem is complicated by an inability to differentiate between true dizziness (a sensation of disorientation in relation to position) and vertigo (a spinning sensation). Other similar sensations include near-syncope and disequilibrium. The causes for these sensations range in severity from minor (eg, buildup of ear wax) to severe (eg, dysfunction of the cerebral cortex, cerebellum, brainstem, proprioceptive receptors, or vestibular system). Even a minor reversible cause, such as ear wax impaction, can result in a loss of balance and a subsequent fall and injury. Because dizziness has many predisposing factors, nurses should seek to identify any potentially treatable factors related to the condition.

Falls and Falling

Injuries rank ninth as a cause of death for older people, and falls are the leading cause of injury in the elderly, accounting for 34% of emergency department visits for men and 48% for women 65 years of age or older (NCHS, 2006). Between 35% and 40% of community-dwelling elderly people and 60% of nursing home residents fall annually, and about half fall multiple times. The incidence of falls rises with increasing

age. It tends to be highest in people who are 85 years of age and older, and outcomes are worst in these adults. Yet fall prevention strategies, which are estimated to prevent 30% of falls, have largely been neglected in clinical practice; only 37% of primary care providers ask their patients about falls (Inouye, et al., 2007). Some causes of falls are treatable.

Although most falls by elderly adults do not result in injury, between 5% and 10% of elderly people who fall sustain serious injury. The most common fracture occurring from falls is hip fracture, which results from both osteoporosis and the situation that provoked the fall. Many older adults who fall and sustain a hip fracture are unable to regain their prefracture ability. Overall, older women who fall sustain a greater degree of injury than do older men.

Causes of falls are multifactorial. Both extrinsic factors such as changes in the environment or poor lighting and intrinsic factors such as physical illness, neurologic changes, or sensory impairment play a role. Mobility difficulties, medication effects, foot problems or unsafe footwear, postural hypotension, visual problems, and tripping hazards are common, treatable causes. Polypharmacy, medication interactions, and use of alcohol precipitate falls by causing drowsiness, decreased coordination, and postural hypotension. Falls have physical dangers as well as serious psychological and social consequences. It is not uncommon for an older person who has experienced a fall to become fearful and lose self-confidence.

Nurses can encourage older adults and their families to make lifestyle and environmental changes to prevent falls. Adequate lighting with minimal glare and shadow can be achieved through the use of small area lamps, indirect lighting, sheer curtains to diffuse direct sunlight, dull rather than shiny surfaces, and nightlights. Sharply contrasting colors can be used to mark the edges of stairs. Grab bars by the bathtub, shower, and toilet are useful. Loose clothing, improperly fitting shoes, scatter rugs, small objects, and pets create hazards and increase the risk for falls. Older adults function best in familiar settings when the arrangement of furniture and objects remains unchanged.

In institutionalized elderly people, physical restraints (lap belts; geriatric chairs; vest, waist, and jacket restraints) and chemical restraints (medications) precipitate many of the injuries they were meant to prevent. Documented injuries and deaths resulting from these restraints include strangulation, vascular and neurologic damage, pressure ulcers, skin tears, fractures, increased confusion, and significant emotional trauma. The time required to supervise restrained patients adequately is better used addressing the unmet need that provoked the behavior that resulted in the use of restraint. Because of the overwhelming negative consequences of restraint use, accrediting agencies of nursing homes and acute care facilities now maintain stringent guidelines concerning their use.

Urinary Incontinence

Urinary incontinence may be acute, occurring during an illness, or may develop chronically over a period of years. Older patients often do not report this very common problem unless specifically asked. Transient causes may be attributed to **delirium** and **dehydration**; **restricted mobility** and **restraints**; **inflammation**, **infection**, and **impaction**; and

pharmaceuticals and **polyuria** (the acronym *drip* may be used to remember them). Once identified, the causative factor can be eliminated. Incontinence may also be a result of neurologic or structural abnormalities. Urinary incontinence has been associated with depression and low self-esteem and may reduce the patient's quality of life by causing restriction in social activities.

The pelvic floor serves as the supporting mechanism or "hammock" for the bladder, uterus, and rectum. It may have become weakened as a result of pregnancy, labor and delivery, prior pelvic surgeries, or activities that required prolonged standing or lifting. Dysfunction of the pelvic floor can be greatly improved with Kegel exercises. Other measures that help prevent episodes of incontinence include having quick access to toilet facilities and wearing clothing that can be unfastened easily.

Patients with incontinence should be urged to seek help from appropriate health care providers because incontinence can be both emotionally devastating and physically debilitating. Nurses who specialize in behavioral approaches to urinary incontinence management can help patients regain full continence or significantly improve the level of continence. Although medications such as anticholinergics may decrease some of the symptoms of urge incontinence (detrusor instability), the adverse effects of these medications (dry mouth, slowed gastrointestinal motility, and confusion) may make them inappropriate choices for the elderly. Various surgical procedures are also used to manage urinary incontinence, particularly stress urinary incontinence.

Detrusor hyperactivity with impaired contractility is a type of urge incontinence that is seen predominantly in the elderly population. In this variation of urge incontinence, patients have no warning that they are about to urinate. They often void only a small volume of urine or none at all and then experience a large volume of incontinence after leaving the bathroom. The nursing staff should be familiar with this form of incontinence and should not show disapproval when it occurs. Many patients with dementia suffer from this type of incontinence, because both incontinence and dementia are a result of dysfunction in similar areas of the brain. Prompted, timed voiding can be of assistance in these patients, although clean intermittent catheterization may be necessary because of postvoid residual urine (see Chapter 45).

Increased Susceptibility to Infection

Infectious diseases present a significant threat of morbidity and mortality to older people, in part because of the blunted response of host defenses caused by a reduction in both cell-mediated and humoral immunity (see Chapters 50 and 51). Age-related loss of physiologic reserve and chronic illnesses also contribute to increased susceptibility. Pneumonia, urinary tract infections, tuberculosis (TB), gastrointestinal infections, and skin infections are some of the common infections in older people.

The effects of influenza and pneumococcal infections on older people are also significant. An estimated 5% to 20% of Americans have influenza each year; more than 200,000 are hospitalized with influenza-related complications, and more than 35,000 die (CDC, 2007b). An estimated 175,000 hospitalizations for pneumococcal pneumonia oc-

cur in the United States each year, and more than 6000 people die from invasive pneumococcal disease. More than half of the deaths occur in adults who had not received the recommended vaccination against pneumococcal disease (National Foundation for Infectious Disease, 2007).

The influenza and the pneumococcal vaccinations lower the risks of hospitalization and death in elderly people. The influenza vaccine, which is prepared yearly to adjust for the specific immunologic characteristics of the influenza viruses at that time, should be administered annually in autumn. The pneumococcal vaccine, which has 23 type-specific capsular polysaccharides, should be administered every 5 years. Both of these injections can be received at the same time in separate injection sites. Nurses should urge older people to be vaccinated. All health care providers working with older people or high-risk chronically ill people should also be immunized.

TB affects a significant number of older adults. Case rates for TB are highest among those who are 65 or older, with the exception of people with human immunodeficiency virus (HIV) infection. Nursing home residents account for the majority of the cases of TB in older adults. Much of the infection rate is attributed to reactivation of old infection. Pulmonary TB and extrapulmonary TB often have subtle, nonspecific symptoms. This is of particular concern in nursing homes because an active case of TB places patients and staff at risk for infection.

CDC guidelines suggest that all patients newly admitted to nursing homes have a Mantoux (purified protein derivative [PPD]) test unless there is a history of TB or a previous positive response. All patients whose tests are negative (a positive test is indicated by induration of more than 10 mm at 48 to 72 hours) should have a second test in 1 to 2 weeks. The first PPD serves to boost the suppressed immune response that may occur in older people. Chest x-rays and possibly sputum studies should be used to follow-up on PPD-positive responders and converters. For positive converters, a course of preventive therapy for 6 to 9 months with isoniazid (INH) is effective in eliminating active disease. All patients who test negative should be periodically retested (see Chapter 23).

AIDS occurs across the age spectrum. It is increasingly recognized that AIDS does not spare the older segment of society, and many who are living with HIV/AIDS are aging. In the past, male homosexual contact and blood transfusions were the predominant modes of transmission among older patients. Transmission by contaminated blood is now rare and the predominant mode of transmission in older people now is by sexual contact. The most common AIDS-indicator disease in older people is *Pneumocystis pneumonia* (PCP). Wasting syndrome and HIV encephalopathy are also common in older people with HIV infection.

Altered Pain and Febrile Responses

Many altered physical, emotional, and systemic reactions to disease are attributed to age-related changes in older people. Physical indicators of illness that are useful and reliable in young and middle-age people cannot be relied on for the diagnosis of potential life-threatening problems in older adults. The response to pain in older people may be lessened because of reduced acuity of touch, alterations in neural pathways, and diminished processing of sensory data.

Many older adults who are experiencing a myocardial infarction do not have chest pain. Hiatal hernia or upper gastrointestinal distress is often the cause of chest pain. Acute abdominal conditions may go unrecognized in elderly people because of atypical signs and absence of pain.

The baseline body temperature for older people is about 1°F lower than it is for younger people. In the event of illness the body temperature of an older person may not be high enough to qualify as a traditionally defined fever. A temperature of 37.8°C (100°F), in combination with systemic symptoms, may signal infection. A temperature of 38.3°C (101°F) almost certainly indicates a serious infection that needs prompt attention. A blunted fever in the face of an infection often indicates a poor prognosis. Temperatures rarely exceed 39.5°C (103°F). Nurses must be alert to other subtle signs of infection, such as mental confusion, increased respirations, tachycardia, and skin color.

Altered Emotional Impact

The emotional component of illness in older people may differ from that in younger people. Many elderly people equate good health with the absence of old age and believe “you are as old as you feel.” An illness that requires hospitalization or a change in lifestyle is an imminent threat to well-being. Admission to the hospital is often feared and actively avoided. Older people admitted to the hospital are at high risk for disorientation, confusion, change in level of consciousness, and other symptoms of delirium, as well as anxiety and fear. In addition, economic concerns and fear of becoming a burden to families often lead to high anxiety in older people. Nurses must recognize the implications of fear, anxiety, and dependency in elderly patients. They should encourage autonomy, independent decision making, and early mobilization. A positive and confident demeanor in nurses and family members promotes a positive mental outlook in elderly patients.

Altered Systemic Response

In an elderly person, illness has far-reaching repercussions. The decline in organ function that occurs in every system of the aging body eventually depletes the body’s ability to respond at full capacity. Illness places new demands on body systems that have little or no reserve to meet the crisis. Homeostasis, the ability of the body to maintain an internal balance of function and chemical composition, is jeopardized. Older people may be unable to respond effectively to an acute illness or, if a chronic health condition is present, they may be unable to sustain appropriate responses over a long period. Furthermore, their ability to respond to definitive treatment is impaired. The altered responses of older adults reinforce the need for nurses to monitor all body system functions closely, being alert to signs of impending systemic complication.

Other Aspects of Health Care of the Older Adult

Elder Neglect and Abuse

Older adults who live in communities and institutions can be at risk for abuse and neglect. Because of different defini-

tions and terminology and the pattern of underreporting, a clear picture of the incidence and prevalence of abuse among the elderly is lacking. Furthermore, one of the major barriers to fully understanding **elder abuse** is that most professionals in all professions, including law enforcement, are not equipped to recognize and report this type of abuse (Wood, 2006). Both victims and perpetrators are reluctant to report the abuse, and clinicians are unaware of the frequency of the problems.

Neglect is the most common type of abuse. Other forms of abuse include physical, emotional, sexual, and financial abuse. Contributing factors include a family history of violence, mental illness, and drug or alcohol abuse, as well as financial dependency on the older person. In addition, diminished cognitive and physical function or disruptive and abusive behavior on the part of the older person can lead to caregiver strain and emotional exhaustion. Elderly people with disabilities of all types are at increased risk for abuse from family members and paid caregivers.

Nurses should be alert to possible elder abuse and neglect. During the health history, in a private portion of the interview, the elderly person should be asked about abuse. Most states require that care providers, including nurses, report suspected abuse. Preventive action should be taken when caregiver strain is evident, before elder abuse occurs. Early detection and intervention may provide sufficient resources to the family or person at risk to ensure patient safety. Interdisciplinary team members, including the psychologist, social worker, or chaplain, can be enlisted to help the caregiver develop self-awareness, increased insight, and an understanding of the disease or aging process. Community resources such as caregiver support groups, respite services, and local offices of Area Agencies on Aging are useful for both the elderly person and the caregiver.

Social Services

Since the 1960s, many programs have been instituted for older Americans, including Medicare, Medicaid, the Older Americans Act, Supplemental Security Income (SSI), Social Security amendments, Section 202 housing, and Title XX social services legislation. These federal programs have dramatically increased health care options and financial support for elderly Americans. The Older Americans Act mandated creation of a federal aging network, resulting in the establishment of the Area Agencies on Aging (AAAs), a national system of social services and network providing many community services for the elderly. Each state has an advisory network that is charged with overseeing statewide planning and advocacy for the elderly throughout the state. Among the services provided by the AAAs are assessment of need, information and referral, case management, transportation, outreach, homemaker services, day care, nutritional education and congregate meals, legal services, respite care, senior centers, and part-time community work. The AAAs target low-income, ethnic minority, rural-living, and frail elders who are at risk for institutionalization; however, the assessment and information services are available to all elderly people (Hooyman & Kiyak, 2005). Similar services such as homemaker, home health aide, and chore services can be obtained at an hourly rate through these agencies or through local community nursing services

if the family does not meet the low-income criteria. Informal sources of help, such as family, friends, mail carriers, church members, and neighbors, can all keep an informal watch on community-dwelling senior citizens.

Other community support services are available to help older people outside the home. Senior centers have social and health promotion activities, and some provide a nutritious noontime meal. Adult day care facilities offer daily supervision and social opportunities for elderly people who cannot be left alone. Adult day care services, although expensive, provide respite and enable family members to carry on daily activities while the older person is at the day care center.

Health Care Costs of Aging

Health care is a major expenditure for the elderly, especially for those with chronic illness and limited financial resources. The elderly, who make up about 13% of the population, consume more than 30% of health care costs, particularly in the last year of life (Hooyman & Kiyak, 2005).

The two major programs that finance health in the United States are Medicare and Medicaid, both of which are overseen by the Centers for Medicaid and Medicare Services (CMS). Both programs cover acute care needs such as inpatient hospitalization, physician care, outpatient care, home health services, and skilled nursing care in a nursing facility. Medicare is federally funded, whereas Medicaid is administered by states; therefore, eligibility and reimbursements for Medicaid services vary from state to state. For older adults with limited incomes, even with the support of Medicare or Medicaid, paying out-of-pocket expenses can be a hardship. Out-of-pocket health care expenses represents 28% of the income of poor and near-poor elderly people (Federal Interagency Forum on Aging-Related Statistics, 2008). Despite the recent additional Medicare prescription benefit plan, out-of-pocket expenditures and prescription costs are burdensome. As more and more people in the United States become eligible for publicly funded health programs, there are serious concerns about whether sufficient health services will be available.

Home Health Care

Use of home care services and skilled nursing home care increases with age. Because of the rapidly growing elderly population and the availability of Medicare funding for acute care, home health care in the United States has rapidly expanded. In 2003, home care reimbursement represented 3% of the total Medicare budget (Federal Interagency Forum on Aging-Related Statistics, 2008).

Home care involves the individual patient, the family, and caregivers. Home care nurses are generally considered skilled generalists who are holistic in their approach to care. In addition to providing skilled nursing care, home care nurses also consider the needs of the family and the impact of the environment and community on the patient situation, and they identify areas for collaboration and referral. Care is episodic (periodic short visits). Home care agencies generally offer several services, including skilled nursing; hospice care; physical, occupational, and speech therapy; and home health aide and homemaker services. Consultation with specialists in nutrition, cardiac, diabetic, and

wound care is available. As hospital stays have shortened, the acuity level of home care patients has risen dramatically. “High-tech” therapies such as infusion therapy are frequently available. The primary goal is to promote optimal health and independent function in the home for both patients and their families.

Hospice Services

Hospice is a program of supportive and palliative services for terminally ill patients and their families that includes physical, psychological, social, and spiritual care. In most cases, patients are not expected to live longer than 6 months. The goal of hospice is to improve the quality of life by focusing on symptom management, pain control, and emotional support. Under Medicare and Medicaid, medical and nursing services are provided to keep patients as pain free and comfortable as possible. Hospice services may be incorporated into the care of residents in long-term care facilities and include care for end-stage dementia and other chronic diseases such as end-stage congestive heart disease.

Home care and hospice nurses are in a unique position to facilitate discussions about a patient’s wishes and goals at the end of life. Too often, discussion regarding end-of-life care is postponed until a crisis occurs, making it difficult or impossible for the patient to be an active participant in the discussion. Home health nurses can assist patients and families by identifying options and initiating conversation about preparing an end-of-life plan. For an in-depth discussion of hospice care, see Chapter 17.

Aging with a Disability

As the life expectancy of people with all types of physical, cognitive, and mental disabilities has increased, individuals must deal with the normal changes associated with aging in addition to their preexisting disabilities. There are still large gaps in our understanding of the interaction between disabilities and aging, including how this interaction varies depending on the type and degree of disability and other factors such as socioeconomic and gender. For adults without disabilities, the changes associated with aging may be minor inconveniences. For adults with disorders such as polio, multiple sclerosis, and cerebral palsy, aging may lead to greater disability. In addition, many people with disabilities are greatly concerned and fearful about what will happen to them as they age and whether assistance will be available when they need care.

It has been proposed that nurses view people with disabilities as capable, responsible individuals who are able to function effectively despite having a disability. Both the interface and the biopsychosocial models of disability can serve as a basis for the role of nurses as advocates for removal of barriers to health care (Smeltzer, 2007). Use of such models would also encourage public policies that support full participation of all citizens through greater availability of personal assistants and affordable and accessible transportation. Other disability models are discussed in Chapter 10.

Today, children born with intellectual and physical disabilities and those who acquire them early in life are also living into middle and older age. Often, their care has

been provided by the family, primarily by the parents. As parents age and can no longer provide the needed care, they seek additional help with the care or long-term care alternatives for their children. However, few services are available at present to support a smooth transition between caregiving by parents and then by others. Research and public policy must focus on supports and interventions that allow people with disabilities who are aging to increase or maintain function within their personal environment as well as in the outside community. Important questions include who will provide the care and how will it be financed. The National Institute on Aging has identified aging with a disability as a focus and is striving to provide streamlined information and access to those with a disability and their family caregivers (Guralnik, et al., 2007).

Ethical and Legal Issues Affecting the Older Adult

Nurses play an important role in supporting and informing patients and families when making treatment decisions. This nursing role becomes even more important in the care of aging patients who are facing life-altering and possibly end-of-life decisions. There is the potential for loss of rights, victimization, and other serious problems if a patient has not made plans for personal and property management in the event of disability or death. As advocates, nurses should encourage end-of-life discussions and educate older people to prepare advance directives before incapacitation (Bickley, 2007).

An **advance directive** is a formal, legally endorsed document that provides instructions for care (living will) or names a proxy decision maker (**durable power of attorney**). It is to be implemented if the signer becomes incapacitated. This written document must be signed by the person and by two witnesses, and a copy should be given to the physician and placed in the medical record. The person must understand that the advance directive is not meant to be used only when certain (or all) types of medical treatment are withheld; rather, it allows for a detailed description of all health care preferences, including full use of all available medical interventions. The health care proxy may have the authority to interpret the patient’s wishes on the basis of medical circumstances and is not restricted to the decisions or situations stated in the living will, such as whether life-sustaining treatment can be withdrawn or withheld.

When such serious decisions are made, possibilities exist for significant conflict of values among patients, family members, health care providers, and the legal representative. Autonomy and self-determination are Western concepts, and people from different cultures may view advance directives as a method for denial of care. Elderly people from some cultures may be unwilling to consider the future, or they may wish to protect relatives and not want them to be informed about a serious illness. Nurses can facilitate the decision-making process by being sensitive to the complexity of patients’ values and respecting their decisions. Directives must be focused on the wishes

CHART
12-4**Ethics and Related Issues****Should an Elderly Person be Allowed to Refuse Treatment When That Treatment is Likely to Extend the Person's Life?**

The patient is an 88-year-old man with an extensive cardiac history who has been a resident of a skilled nursing facility for the past 3 years. Comorbid conditions include type 2 diabetes (15 years) and severe peripheral vascular disease. For 6 months the patient has suffered from a serious left leg wound that has not responded to treatment and that has become much worse over the past 2 months. At this point, the leg is gangrenous to above the ankle, and the normal course of treatment would be to remove the leg above the circulatory problem. However, the patient is refusing surgery and states that he wants "to die with all of my limbs intact." The patient has been assessed with mild to moderate dementia and has named his daughter as his durable power of attorney. The nurses on the unit, the daughter, and the primary care physician all realize that an amputation is necessary to save the patient's life.

Dilemma

Several ethical issues are relevant to the resolution of the situation. The obligation to respect the patient's autonomy in the decision to refuse an amputation puts his life at risk. However, after hearing about the need for surgery and the likely outcome without the surgery, he continues to state, "I want to die with all of my limbs intact." The daughter and some of the nurses who care for the patient question the his ability to make such a decision.

Discussion

1. What are the ethical issues in this case study?
2. What arguments would you offer *against* the surgery?
3. What arguments would you offer *in favor of* the surgery?
4. What arguments would you offer *against* and *in favor of* supporting the patient in his decision to refuse the surgery?

of the patient, not those of the family or the designated proxy (Chart 12-4).

If no advance arrangement has been made and the older person appears unable to make decisions, the court may be petitioned for a competency hearing. If the court rules that an elderly person is incompetent, the judge appoints a guardian—a third party who is given powers by the court to assume responsibility for making financial or personal decisions for that person.

People with communication difficulties or mild dementia may be viewed as incapable of self-determination. Most people with mild dementia have sufficient cognitive capability to make some, but perhaps not all, decisions. For example, a patient may be able to identify a proxy decision maker yet be unable to select specific treatment options. People with mild dementia may be competent to understand the nature and significance of such decisions.

In 1990, the Patient Self-Determination Act (PSDA), a federal law, was enacted to require patient education about advance directives at the time of hospital admission, as well as documentation of this education. Nursing homes are also

mandated to enhance residents' autonomy by increasing their involvement in health care decision making. A growing body of research indicates that nursing homes implement the PSDA more vigorously than hospitals. However, in both settings, the documentation and placement of advance directives in the medical record and the education of patients about advance directives vary considerably. Periodically it is important to ensure that the directives reflect the current wishes of the patient and that all providers have a copy so they are aware of the patient's wishes.

CRITICAL THINKING EXERCISES

1 You are a new nurse manager on a busy unit where the majority of patients are older than 65 years of age. Summarize the current demographics of aging and theories of aging that are important to include in an educational program for the staff. What will be the aims of the program? Who would you involve in its planning?

EBP 2 You are conducting an admission assessment on a 68-year-old man admitted for a planned knee replacement. His wife reports that he has become confused in the past 3 days. What is the evidence base that indicates the differences between dementia and AD? What is the strength of the evidence? Based on this evidence-based information, what assessment parameters would you evaluate? What information should you provide to the patient's wife? What actions are indicated?

3 As a home care nurse, you are visiting an 88-year-old patient who has a paid caregiver. You have begun to suspect elder abuse. Identify your state requirements for reporting suspected elder abuse. What other team members and community resources could be used to support the patient and the caregiver? What actions are indicated?

Concepts and Challenges in Patient Management

Case Study • Applying Concepts from NANDA, NIC, and NOC

A Patient With Debilitating Pain

Mr. Southers is a 48-year-old man who sustained a back injury in a work-related incident. He reports severe shooting pains in his lower back and both buttocks. Mr. Southers is not a candidate for surgery and has undergone physical therapy with little improvement in his pain. He reports that the pain makes it impossible for him to return to his former job, work around the house, or obtain enjoyment from leisure activities. He has been referred to a pain clinic for management.

Visit thePoint to view a concept map that illustrates the relationships that exist between the nursing diagnoses, interventions, and outcomes for the patient's clinical problems.

Nursing Classifications and Languages

NANDA NURSING DIAGNOSES	NIC NURSING INTERVENTIONS	NOC NURSING OUTCOMES
		Return to functional baseline status, stabilization of, or improvement in:
CHRONIC PAIN —Unpleasant sensory and emotional experience arising from actual or potential tissue damage or described in terms of such damage; sudden or slow onset of any intensity from mild to severe, constant or recurring, without an anticipated or predictable end and a duration of greater than 6 months	PAIN MANAGEMENT —Alleviation of pain or reduction in pain to a level of comfort that is acceptable to the patient	PAIN LEVEL —Severity of observed or reported pain
RISK FOR POWERLESSNESS —At risk for perceived lack of control over a situation and/or one's ability to significantly affect an outcome	MEDICATION MANAGEMENT —Facilitation of safe and effective use of prescribed or over-the-counter medicine	COMFORT LEVEL —Extent of positive perception of physical and psychological ease
	SIMPLE RELAXATION THERAPY —Use of techniques to encourage and elicit relaxation for the purpose of decreasing undesirable signs and symptoms such as pain, muscle tension, or anxiety	PAIN CONTROL —Personal actions to control pain
	SIMPLE GUIDED IMAGERY —Purposeful use of imagination to achieve relaxation and/or direct attention away from undesirable sensations	PAIN: DISRUPTIVE EFFECTS —Severity of observed or reported disruptive effects of chronic pain on daily functioning
	EMOTIONAL SUPPORT —Provision of reassurance, acceptance, and encouragement during times of stress	PAIN: ADVERSE PSYCHOLOGICAL RESPONSE —Severity of observed or reported adverse responses to physical pain
	SELF-ESTEEM ENHANCEMENT —Assisting a patient to increase his or her personal judgment of self-worth

chapter 13

Pain Management

LEARNING OBJECTIVES

On completion of this chapter, the learner will be able to:

- 1 Compare characteristics of acute pain, chronic pain, and cancer pain.
- 2 Describe the negative consequences of pain.
- 3 Describe the pathophysiology of pain.
- 4 Describe factors that can alter the perception of pain.
- 5 Demonstrate appropriate use of pain measurement instruments.
- 6 Explain the physiologic basis of pain relief interventions.
- 7 Explain the impact of aging on pain.
- 8 Discuss when opioid tolerance may be a problem.
- 9 Identify appropriate pain relief interventions for selected groups of patients.
- 10 Compare the various types of neurosurgical procedures used to treat intractable pain.
- 11 Develop a plan to prevent and treat the adverse effects of analgesic agents.
- 12 Use the nursing process as a framework for the care of patients with pain.

GLOSSARY

addiction: a behavioral pattern of substance use characterized by a compulsion to take the substance (drug or alcohol) primarily to experience its psychic effects

agonist: a substance that when combined with the receptor produces the drug effect or desired effect.

Endorphins and morphine are agonists on the opioid receptors

algogenic: causing pain

antagonist: a substance that blocks or reverses the effects of the agonist by occupying the receptor site without producing the drug effect

balanced analgesia: using more than one form of analgesia concurrently to obtain more pain relief with fewer side effects

GLOSSARY (Continued)

breakthrough pain: a sudden and temporary increase in pain occurring in a patient being managed with opioid analgesia

dependence: occurs when a patient who has been taking opioids experiences a withdrawal syndrome when the opioids are discontinued; often occurs with opioid tolerance and does not indicate an addiction

endorphins and enkephalins: morphinelike substances produced by the body. Primarily found in the central nervous system, they have the potential to reduce pain

nociception: activation of sensory transduction in nerves by thermal, mechanical, or chemical energy impinging on specialized nerve endings; the nerves involved convey information about tissue damage to the central nervous system

nociceptor: a receptor preferentially sensitive to a noxious stimulus

non-nociceptor: nerve fiber that usually does not transmit pain

opioid: a morphinelike compound that produces bodily effects including pain relief, sedation, constipation, and respiratory depression

pain: an unpleasant sensory and emotional experience resulting from actual or potential tissue damage

pain threshold: the point at which a stimulus is perceived as painful

pain tolerance: the maximum intensity or duration of pain that a person is able to endure

patient-controlled analgesia (PCA): self-administration of analgesic agents by a patient instructed about the procedure

placebo effect: analgesia that results from the expectation that a substance will work, not from the actual substance itself

prostaglandins: chemical substances that increase the sensitivity of pain receptors by enhancing the pain-provoking effect of bradykinin

referred pain: pain perceived as coming from an area different from that in which the pathology is occurring

sensitization: a heightened response seen after exposure to a noxious stimulus. Response to the same stimulus is to feel more pain

tolerance: occurs when a person who has been taking opioids becomes less sensitive to their analgesic properties (and usually side effects); characterized by the need for increasing doses to maintain the same level of pain relief

Pain is defined as an unpleasant sensory and emotional experience associated with actual or potential tissue damage (Merskey & Bogduk, 1994). It is the most common reason for seeking health care (Shi, Langer, Cohen, et al., 2007). Pain occurs as the result of many disorders, diagnostic tests, and treatments; it disables and distresses more people than any single disease. Because nurses spend more time with patients in pain than other health care providers do, nurses need to understand the pathophysiology of pain, the physiologic and psychological consequences of acute and chronic pain, and the methods used to treat pain. Nurses encounter patients in pain in a variety of settings, including acute care, outpatient, and long-term care settings, as well as in the home. Therefore, they must have the knowledge and skills to assess pain, to implement pain relief strategies, and to evaluate the effectiveness of these strategies, regardless of setting.

Importance of Pain Assessment and Management

Pain management is considered such an important part of care that it is referred to as “the fifth vital sign” to emphasize its significance and to increase the awareness among health care professionals of the importance of effective pain management (American Pain Society, 2003). Identifying pain as the fifth vital sign suggests that the assessment of pain should be as automatic as taking a patient’s blood pressure and pulse. The Joint Commission (2005, p.1) standards state that “pain is assessed in all patients” and that “patients have the right to appropriate assessment and management of pain.”

Documentation of pain assessment is now as important as documentation of the “traditional” vital signs. The American Nurses Association and the American Society for Pain Management Nursing (2005) published standards that indicated that nurses must document assessment of the patient’s pain in the medical record.

The American Pain Foundation developed the Pain Care Bill of Rights, which addresses the importance of pain management (Chart 13-1). To date, California is the only state to have enacted a Pain Patient’s Bill of Rights. In addition, the U.S. Congress identified 2000 to 2010 as the Decade of Pain Control and Research. The National Pain Care Policy Act of 2007 was designed to address the barriers to pain management by improving pain research, education, access, outreach, and care through creating a pain and palliative care research and quality program within the Agency for Healthcare Research and Quality (AHRQ).

Types of Pain

Pain is categorized according to its duration, location, and etiology. Three basic categories of pain are generally recognized: acute pain, chronic (nonmalignant) pain, and cancer-related pain. The International Association for the Study of Pain Web site provides ongoing updates on pain terminology and treatment (see Web site listed under Resources at the end of this chapter).

Chart 13-1 • Pain Care Bill of Rights

Although not always required by law, these are the rights you should expect, and if necessary demand, for your pain care.

As a person with pain, you have the right to:

- Have your report of pain taken seriously and be treated with dignity and respect by doctors, nurses, pharmacists, and other health care professionals.
- Have your pain thoroughly assessed and promptly treated.
- Be informed by your health care provider about what may be causing the pain, possible treatments, and the benefits, risks, and cost of each.
- Participate actively in decisions about how to manage your pain.
- Have your pain reassessed regularly and your treatment adjusted if your pain has not been eased.
- Be referred to a pain specialist if your pain persists.
- Get clear and prompt answers to your questions, take time to make decisions, and refuse a particular type of treatment if you choose.

Classic Categories of Pain

Acute Pain

Usually of recent onset and commonly associated with a specific injury, acute pain indicates that damage or injury has occurred. Pain is significant in that it draws attention to its existence and teaches people to avoid similar potentially painful situations. If no lasting damage occurs and no systemic disease exists, acute pain usually decreases as healing occurs. For definitional purposes, acute pain can last from seconds to 6 months. However, the traditional 6-month time frame is controversial because many acute injuries heal within a few weeks and most heal by 6 weeks. In a situation in which healing is expected within 3 weeks and a patient continues to be in pain, the pain should be considered chronic, and appropriate treatment should be used.

Chronic Pain

Chronic pain is constant or intermittent pain that persists beyond the expected healing time and that can seldom be attributed to a specific cause or injury. It may have a poorly defined onset, and it is often difficult to treat because the cause or origin may be unclear. Although acute pain may be a useful signal that something is wrong, chronic pain usually becomes a problem in its own right.

Chronic pain is pain that lasts for 6 months or longer, although 6 months is an arbitrary period for differentiating between acute and chronic pain, as previously noted. An episode of pain may assume the characteristics of chronic pain before 6 months have elapsed, or some types of pain may remain primarily acute in nature for longer than 6 months. Nevertheless, after 6 months, most pain experiences are accompanied by problems related to the pain itself. Chronic pain serves no useful purpose. If it continues, it may become a patient’s primary disorder.

Nurses may come in contact with patients with chronic pain when these patients are admitted to the hospital for treatment or when they are seen out of the hospital for home care. Frequently, nurses are called on in community-based settings to assist patients in managing pain.

Cancer-Related Pain

Pain associated with cancer may be acute or chronic. Pain resulting from cancer is so ubiquitous that when cancer patients are asked about possible outcomes, pain is reported to be the most feared outcome (Munoz Sastre, Albaret, Maria Raich Escursell, et al., 2006). Pain in patients with cancer can be directly associated with the cancer (eg, bony infiltration with tumor cells or nerve compression), a result of cancer treatment (eg, surgery or radiation), or not associated with the cancer (eg, trauma). However, most pain associated with cancer is a direct result of tumor involvement. Cancer pain management is discussed in Chapter 16.

Pain Classified by Location

Pain can also be categorized according to location (eg, pelvic pain, headache, chest pain). This type of categorization aids in communication about and treatment of the pain. For example, chest pain may suggest acute coronary syndrome (ACS) and indicates the need for diagnostic evaluation and treatment according to cardiac care standards as appropriate.

Pain Classified by Etiology

Pain can also be categorized by etiology (Chart 13-2). Burn pain and postherpetic neuralgia are examples of pain described in terms of their cause. Clinicians often can predict the course of pain and plan effective treatment using this categorization.

Harmful Effects of Pain

Regardless of its nature, pattern, or cause, pain that is inadequately treated has harmful effects beyond the suffering it causes. For example, unrelieved pain is associated with sleep alterations. Sleep deprivation affects the pain experience. Research suggests that patients with sleep deprivation frequently display hyposomnia (ie, little sleep), fatigue, chronic pain, and depression (Gevirtz, 2007). Analgesics may also be less effective if patients experience sleep deprivation.

Effects of Acute Pain

Unrelieved acute pain can affect the pulmonary, cardiovascular, gastrointestinal, endocrine, and immune systems. The stress response (“neuroendocrine response to stress”) that occurs with trauma also occurs with other causes of severe pain. The widespread endocrine, immunologic, and inflammatory changes that occur with stress can have significant negative effects. This is particularly harmful in patients whose health is already compromised by age, illness, or injury.

The stress response generally consists of increased metabolic rate and cardiac output, impaired insulin response, increased production of cortisol, and increased retention of fluids (see Chapter 6 for details about the stress response).

The stress response may increase the risk of physiologic disorders (eg, myocardial infarction, pulmonary infection, venous thromboembolism, prolonged paralytic ileus). Patients with severe pain and associated stress may be unable to take deep breaths and may experience increased fatigue and decreased mobility. Although these effects may be tolerated by young, healthy people, they may hamper recovery in elderly, debilitated, or critically ill people. Effective pain relief may result in faster recovery and improved outcomes.

Effects of Chronic Pain

Like acute pain, chronic pain also has adverse effects. Suppression of the immune function associated with chronic pain may promote tumor growth. In addition, chronic pain often results in depression and disability. Although health care providers may express concern about high dosages of opioid medications required to relieve chronic pain in some patients, it is safe to use gradually increased dosages of these medications to control progressive chronic pain. In fact, failure to administer adequate pain relief may be unsafe because of the consequences of unrelieved pain.

Regardless of how patients cope with chronic pain, pain that lasts for an extended period can result in disability. Patients with a number of chronic pain syndromes report depression, anger, and fatigue (Norelli & Harju, 2008). Patients may be unable to continue the activities and interpersonal relationships they engaged in before the pain began. Disabilities may range from an impaired ability to participate in physical activities to an inability to take care of personal needs, such as dressing or eating. Nurses should understand the effects of chronic pain on patients and families and should be knowledgeable about pain relief strategies and appropriate resources to assist effectively with pain management.

Pathophysiology of Pain

The sensory experience of pain depends on the interaction between the nervous system and the environment. The processing of noxious stimuli and the resulting perception of pain involve the peripheral and central nervous systems.

Nociceptors

Neurologic transmission of pain is also referred to as **nociception**. **Nociceptors** are neuronal receptors involved in the transmission of pain perceptions to and from the brain that respond to biochemical mediators or noxious stimuli. They are free nerve endings in the skin that respond only to intense, potentially damaging stimuli. Such stimuli may be mechanical, thermal, or chemical in nature. The joints, skeletal muscle, fascia, tendons, and cornea also have nociceptors with the potential to transmit stimuli that produce pain. However, the large internal organs (viscera) do not contain nerve endings that respond only to painful stimuli. Pain originating in these organs results from intense stimulation of receptors that have other purposes. For example, inflammation, stretching, ischemia, dilation, and spasm of the internal organs all cause an intense response in these multipurpose fibers and can cause severe pain.

Nociceptors are part of complex multidirectional pathways. These nerve fibers branch very near their origin in the

Chart 13-2 • Pain Syndromes and Unusual Severe Pain Problems**Complex Regional Pain Syndrome**

Complex regional pain syndrome (CRPS) describes a variety of painful conditions that often follow an injury. It refers to a group of conditions previously described as causalgia, reflex sympathetic dystrophy (RSD), and other diagnoses. The magnitude and duration of the pain far exceed the expected duration and often result in significant impairment of motor function. There are two categories of CRPS: type I and type II. CRPS type I, the most common type, is characterized by unexplained diffuse burning pain, usually in the periphery of an extremity. RSD is categorized as CRPS type I and occurs after a relatively minor trauma (Quisel, Gill, & Witherell, 2005). Pain is accompanied by weakness, a change in skin color and temperature relative to the other extremity, limited range of motion, hyperesthesia, hypoesthesia, edema, altered hair growth, and sweating.

Pain, which worsens with movement, cutaneous stimulation, or stress, often occurs after surgery or trauma to the extremity but is not limited to the area of surgery or trauma. CRPS type I is usually managed through a pain clinic. Currently, regional sympathetic blockade and regional intravenous (IV) bretylium offer promise for relief. Tricyclic antidepressants may be tried as well.

CRPS type II refers to causalgia. Type II is more likely to develop after trauma with detectable peripheral nerve lesions (Quisel, et al., 2005). The pain is characterized as burning and hyperpathia in an extremity after partial injury to a nerve or one of its major branches.

Postmastectomy Pain Syndrome

Postmastectomy pain syndrome (PMP) occurs after mastectomy with node dissection but is not necessarily related to the continuation of disease. Characterized by the sensation of constriction accompanied by a burning, prickling, or numbness in the posterior arm, axilla, or chest wall, PMP is often aggravated by movement of the shoulder, resulting in a frozen shoulder from immobilization.

Fibromyalgia (Fibrositis)

Fibromyalgia, a chronic pain syndrome characterized by generalized musculoskeletal pain, trigger points, stiffness, fatigability, and sleep disturbances, is aggravated by stress and overexertion. Treatment consists of nonsteroidal anti-inflammatory drugs (NSAIDs), trigger-point injections with local anesthetic agents, tricyclic antidepressant medications, stress reduction, and regular exercise (Gevirtz, 2007).

Hemiplegia-Associated Shoulder Pain

Hemiplegia-associated shoulder pain is a pain syndrome that affects as many as 80% of stroke patients. It may result from stretching of the shoulder joint due to the uncompensated pull of gravity on the impaired arm. It may be preventable with functional electrical stimulation of involved shoulder muscles.

Sickle Cell Disease and Pain

Pain experienced by patients with sickle cell disease results from venous occlusion caused by the sickle shape of the blood cells, impaired circulation to a muscle or organ, ischemia, and infarction. Acute pain may be managed with IV opioid analgesics administered according to a schedule or by a patient-controlled analgesia (PCA) pump and NSAIDs. Warm soaks and elevating the affected body part may help as well. Meperidine (Demerol) therapy is not recommended in patients with compromised renal function, nor is cold therapy. Patients with sickle cell disease may have a long history of chronic pain. Some issues related to their history include tolerance, possible long-term drug dependence, racial prejudice, and inadequate pain treatment.

Acquired Immunodeficiency Syndrome-Related Pain

As acquired immunodeficiency syndrome (AIDS) progresses, so do problems that produce increasing amounts of pain, such as neuropathy, esophagitis, headaches, postherpetic pain, and abdominal, back, bone, and joint pain (Douaihy, Stowell, Kohnen, et al., 2007). Pain relief interventions are individualized and may consist of NSAIDs; long-lasting opioids, such as fentanyl patches; and topical lidocaine. Tricyclic antidepressant medications may provide comfort in neuropathic and postherpetic pain.

Burn Pain

Possibly the most severe pain, burn pain requires accurate assessment by all health care professionals to effectively manage it. Besides administration of IV opioid analgesic agents, current therapies to relieve or control pain in burn patients include débridement under general anesthesia; anxiety reduction; intervention with PCA devices, such as a handheld nitrous oxide delivery system; and cognitive techniques, particularly hypnosis.

Guillain-Barré Syndrome and Pain

A progressive, inflammatory disorder of the peripheral nervous system, Guillain-Barré syndrome is characterized by flaccid paralysis accompanied by paresthesia and pain—muscle pain and severe, unrelenting, burning pain. Complaints of severe pain may be difficult to accept in the face of the characteristic flaccid facial response; therefore, the nurse must be sensitive and learn to disregard nonverbal cues that contradict the verbal report of pain. Treatment interventions include NSAIDs for muscle pain and opioids if NSAIDs are ineffective. Causalgia and neurogenic pain may be relieved by systemic or epidural opioids or, possibly, antiseizure agents or tricyclic antidepressant medications. To relieve the burning, some patients beg to have windows opened and clothing removed, even in cold weather. This suggests that gentle ice massage may help. Research is needed, however, to test its effectiveness.

skin and send fibers to local blood vessels, mast cells, hair follicles, and sweat glands. When these fibers are stimulated, histamine is released from mast cells, causing vasodilation. Nociceptors respond to high-intensity mechanical, thermal, and chemical stimuli. Some receptors respond to only one type of stimulus, and others, called polymodal nociceptors, respond to all three types. These highly special-

ized neurons transfer the mechanical, thermal, or chemical stimulus into electrical activity or action potentials (Porth & Matfin, 2009).

The cutaneous fibers located more centrally further branch and communicate with the paravertebral sympathetic chain of the nervous system and with large internal organs. As a result of the connections among these nerve

fibers, pain is often accompanied by vasomotor, autonomic, and visceral effects. For example, gastrointestinal peristalsis may decrease or cease in a patient with severe acute pain.

Peripheral Nervous System

A number of **allogenic** (pain-causing) substances that affect the sensitivity of nociceptors are released into the extracellular tissue as a result of tissue damage. Histamine, bradykinin, acetylcholine, serotonin, and substance P are chemicals that increase the transmission of pain. **Prostaglandins** are a group of chemical substances that are believed to increase the sensitivity of pain receptors by enhancing the pain-provoking effect of bradykinin. These chemical mediators also cause vasodilation and increased vascular permeability, resulting in redness, warmth, and swelling of the injured area.

Once nociception is initiated, the nociceptive action potentials are transmitted in the peripheral nervous system. The first-order neurons travel from the periphery (skin, cornea, visceral organs) to the spinal cord via the dorsal horn. There are two main types of fibers involved in the transmission of nociception. Smaller, myelinated A δ (A delta) fibers transmit nociception rapidly, which produces the initial “fast pain.” Type C fibers are larger, unmyelinated fibers that transmit what is called “second pain.” This type of pain has dull, aching, or burning qualities that last longer than the initial fast pain. The type and concentration of nerve fibers to transmit pain vary by tissue type.

If there is repeated C-fiber stimulation, a greater response is noted in dorsal horn neurons, causing the person to perceive more pain. In other words, the same noxious stimulus produces hyperalgesia, and the person reports greater pain than was felt at the first stimulus. For this reason, it is important to treat patients with analgesic agents when they first feel pain. Patients require less medication and experience more effective pain relief if analgesia is administered before they become sensitized to the pain.

Chemicals that reduce or inhibit the transmission or perception of pain include **endorphins** and **enkephalins**. These morphinelike neurotransmitters are endogenous (produced by the body). They are examples of substances that reduce nociceptive transmission when applied to certain nerve fibers. The term *endorphin* is a combination of two words: endogenous and morphine. Endorphins and enkephalins are found in heavy concentrations in the central nervous system (CNS), particularly the spinal and medullary dorsal horn, periaqueductal gray matter, hypothalamus, and amygdala. Morphine and other opioid medications act at receptor sites to suppress the excitation initiated by noxious stimuli. The binding of opioids to receptor sites is responsible for the effects noted after their administration. Each receptor (μ , κ , δ) responds differently when activated (Porth & Matfin, 2009).

Central Nervous System

After tissue injury occurs, nociception to the spinal cord via the A δ and C fibers continues. The fibers enter the dorsal horn, which is divided into laminae based on cell type. The laminae II cell type is commonly referred to as the substantia gelatinosa. In the substantia gelatinosa are projections that relay nociception to other parts of the spinal cord (Fig. 13-1).

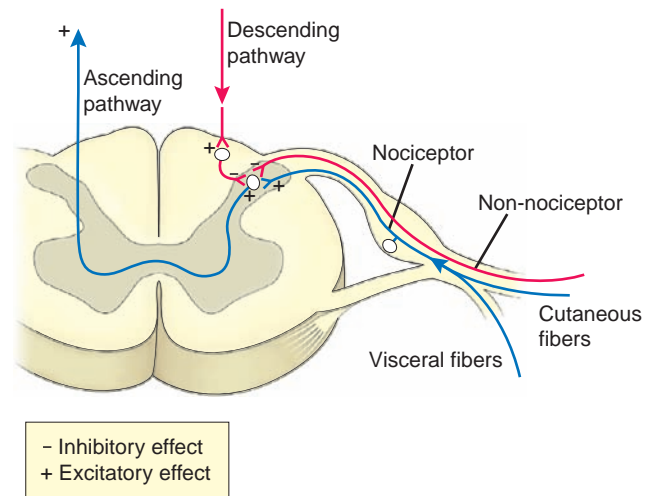

Figure 13-1 Representative nociception system, showing ascending and descending sensory pathways of the dorsal horn.

Nociception continues from the spinal cord to the reticular formation, thalamus, limbic system, and cerebral cortex. Here nociception is localized, and its characteristics become apparent, including the intensity. The involvement of the reticular formation, limbic, and reticular activating systems is responsible for the individual variations in the perception of noxious stimuli. People may report the same stimulus differently based on their anxiety level, past experiences, and expectations. This is a result of the conscious perception of pain.

For pain to be consciously perceived, neurons in the ascending system must be activated. Activation occurs as a result of input from the nociceptors located in the skin and internal organs. Once activated, the inhibitory interneuronal fibers in the dorsal horn inhibit or turn off the transmission of noxious stimulating information in the ascending pathway.

Descending Control System

The descending control system is a system of fibers that originate in the lower and midportion of the brain (specifically, in the periaqueductal gray matter) and terminate on the inhibitory interneuronal fibers in the dorsal horn of the spinal cord. This system is always active; it prevents continuous transmission of painful stimuli, partly through the action of the endorphins. As nociception occurs, the descending control system is activated to inhibit pain.

Cognitive processes may stimulate endorphin production in the descending control system. The effectiveness of this system is illustrated by the effects of distraction. The distractions provided by visitors or a favorite TV show may increase activity in the descending control system. Therefore, patients who have visitors may not report pain, because activation of the descending control system results in less noxious or painful information being transmitted to consciousness. Once the distraction by the visitors ends, activity in the descending control system decreases, resulting in increased transmission of painful stimuli.

The interconnections between the descending neuronal system and the ascending sensory tract are called inhibitory interneuronal fibers. These fibers contain enkephalins and

Figure 13-2 A schematic representation of the gate control system and aspects of the nociceptive system. The nervous system is made up of stimulatory and inhibitory fibers. For example, stimulation of the nociceptor results in the transmission of an impulse that will be interpreted as pain. When it is stimulated, it will stimulate transmission at the next fiber junction (represented as $+>-$). The interneuronal fiber is an inhibitory neuron ($->-$). When it is stimulated, it, in turn, inhibits or shuts off transmission at the next junction. So a placebo has a (+) stimulatory effect on the descending control system, which has a stimulatory effect (+) on the interneuronal fiber, which has an inhibitory effect (-) on the ascending control system. A topical anesthetic has an inhibitory effect (-) on nerve transmission at the nociceptor level, and a spinal anesthetic has the same impact (-) on the ascending nociceptive fibers.

are primarily stimulated through the activity of **non-nociceptor** peripheral fibers (fibers that normally do not transmit painful or noxious stimuli) in the same receptor field as the pain receptor, and descending fibers, grouped together in a system called descending control. The enkephalins and endorphins are thought to inhibit pain impulses by stimulating the inhibitory interneuronal fibers, which in turn reduce the transmission of noxious impulses via the ascending system (Porth & Matfin, 2009).

Gate Control Theory

The classic gate control theory of pain, described by Melzack and Wall in 1965, was the first to clearly articulate the existence of a pain-modulating system (Melzack, 1996). This theory proposed that stimulation of the skin evokes nervous impulses that are then transmitted by three systems located in the spinal cord. The substantia gelatinosa in the dorsal horn, the dorsal column fibers, and the central transmission cells act to influence nociceptive impulses. The noxious impulses are influenced by a “gating mechanism.” Stimulation of the large-diameter fibers inhibits the transmission of pain, thus “closing the gate.” Conversely, when smaller fibers are stimulated, the gate is opened. The gating mechanism is influenced by nerve impulses that descend from the brain. This theory proposes a specialized system of large-diameter fibers that activate selective cognitive processes via the modulating properties of the spinal gate. Figure 13-2 shows a schematic representation of a gate control system and nociceptive pathways.

The gate control theory was the first theory to suggest that psychological factors play a role in the perception of pain. The theory guided research toward identifying cognitive-behavioral approaches to pain management. Therefore, this theory helps explain how interventions such as distraction and music therapy relieve pain.

Melzack (1996) extended the gate control theory after studying phantom limb pain. He proposed that a large, widespread network of neurons exists that consists of loops between the thalamus and cortex and between the cortex and the limbic system. Melzack labeled this network the neuromatrix. As information is processed in the neuromatrix, a characteristic pattern emerges. This pattern, referred to as the neurosignature, is a continuous outflow from the neuromatrix. Melzack (1996) theorized that, in the absence of modulating inputs from the missing limb, the active neuromatrix produces a neurosignature pattern that is perceived as pain. The neuromatrix theory highlights the role of the brain in sustaining the experience of pain.

Factors Influencing Pain Response

Several factors, including past experiences with pain, anxiety, culture, age, gender, genetics, and expectations about pain relief, influence a person’s experience of pain. These factors may increase or decrease perception of pain, increase or decrease tolerance for pain, and affect responses to pain.

Past Experience

It is tempting to expect that people who have had multiple or prolonged experiences with pain will be less anxious and more tolerant of pain than those who have had little experience with pain. However, this is not true for many people. The more experience a person has had with pain, the more frightened he or she is likely to be about subsequent painful events. The person may be less able to tolerate pain; that is, he or she wants relief from pain sooner, before it becomes severe. This reaction is more likely to occur if the person has received inadequate pain relief in the past. A person with repeated pain experiences may have learned to fear the escalation of pain and its inadequate treatment. Once a person experiences severe pain, he or she knows just how severe it can be. Conversely, a person who has never had severe pain may have no fear of such pain.

The way a person responds to pain is a result of many separate painful events during a lifetime. For some, past pain may have been constant and unrelenting, as in chronic pain. Such people may become irritable, withdrawn, and depressed.

The undesirable effects that may result from previous experience point to the need for the nurse to be aware of the patient's past experiences with pain. If pain is relieved promptly and adequately, the person may be less fearful of future pain and better able to tolerate it.

Anxiety and Depression

Although it is commonly believed that anxiety increases pain, this is not necessarily true. Anxiety that is relevant or related to the pain may increase the patient's perception of pain. For example, the patient who was treated 2 years ago for breast cancer and now has hip pain may fear that the pain indicates metastasis. In this case, the anxiety may result in increased pain. Anxiety that is unrelated to the pain may distract the patient and may actually decrease the perception of pain. For example, a mother who is hospitalized with complications from abdominal surgery and is anxious about her children may perceive less pain as her anxiety about her children increases.

The most effective way to relieve pain is by directing the treatment at the pain rather than at the anxiety. The routine use of antianxiety medications to treat anxiety in patients with pain may prevent patients from reporting pain because of sedation and may impair their ability to take deep breaths, get out of bed, and cooperate with the treatment plan.

Just as anxiety is associated with pain because of concerns and fears about the underlying disease, depression is associated with chronic pain and unrelieved cancer pain. In cases of chronic pain, the incidence of depression is increased (Youssef, Atienza, Langseder, et al., 2008). Depression is associated with major life changes caused by the limiting effects of chronic pain, including unemployment, disability, and possibly imminent death. Unrelieved cancer pain drastically interferes with the patient's quality of life, and relieving the pain may also help treat the depression.

Culture

Beliefs about pain and how to respond to it differ from one culture to the next. Early in childhood, people learn from those around them what responses to pain are acceptable or unacceptable. For example, a child may learn that a sports injury is not expected to hurt as much as a comparable in-

jury caused by a motor vehicle crash. The child also learns what stimuli are expected to be painful and what behavioral responses are acceptable. These beliefs vary from one culture to another; therefore, people from different cultures who experience the same intensity of pain may not report it or respond to it in the same ways.

Cultural factors must be taken into account to manage pain effectively. Many studies have examined the cultural aspects of pain. Inconsistent results, methodologic weaknesses or flaws, and failure of many researchers to carefully distinguish ethnicity, culture, and race make it difficult to interpret the findings of many of these studies. Factors that help explain differences between cultural groups include age, gender, education level, and income. In addition, the degree to which patients identify with a culture influences the degree to which they will adopt new health behaviors or rely on traditional health beliefs and practices. Other factors that affect the patients' responses to pain include their interactions with the health care system and their health care providers (Ludwig-Beymer, 2008). Patients from some cultures may feel frustrated and powerless if they feel that their clinicians do not appreciate the magnitude of their pain.

The cultural expectations and values of nurses may differ from those of other cultures and may include avoiding exaggerated expressions of pain, such as excessive crying and moaning; seeking immediate relief from pain; and giving complete descriptions of the pain. Whereas patients of one cultural background may moan and complain about pain, refuse pain relief measures that do not cure the cause of the pain, or use adjectives such as "unbearable" in describing the pain, patients of another cultural background may behave in a quiet, stoic manner rather than express the pain loudly. The nurse must react to the person's perception of pain and not to the person's behavior, because the behavior may differ from the nurse's cultural expectations.

Recognizing the values of one's own culture and learning how these values differ from those of other cultures helps avoid evaluating the patient's behavior on the basis of one's own cultural expectations and values (Mitchell, 2008). The nurse who recognizes cultural differences has a greater understanding of the patient's pain, is more accurate in assessing pain and behavioral responses to pain, and is more effective at relieving pain.

Regardless of the patient's culture, the nurse should learn about that particular culture and be aware of power and communication issues that affect care outcomes. The nurse should avoid stereotyping the patient by culture and provide individualized care rather than assuming that a patient of a specific culture will exhibit more or less pain. In addition to avoiding stereotyping, health care providers should individualize the amount of medications or therapy according to the information provided by the patient (Good & Sukhee, 2008). The nurse should recognize that stereotypes exist and become sensitive to how stereotypes negatively affect care. In turn, patients must be instructed about how and what to communicate about their pain.

Gerontologic Considerations

Aging seems to influence the functional features of the nervous system as evidenced by a loss of myelinated and unmyelinated fibers in the peripheral nervous system. The decrease in myelinated fibers is partly responsible for causing a

decrease in expression of the major myelin proteins. This causes a gradual reduction in endoneural blood flow with increasing age, which may contribute to reduced peripheral nerve function and diminished pain perception. However, McCleane (2008) asserts that if pain perception is diminished in elderly patients, it is most likely secondary to a disease process, such as diabetes, rather than to the effects of normal aging. A lack of sufficiently strong research-based evidence limits making definitive associations between aging and pain perceptions.

Although many elderly people seek health care because of pain, others are reluctant to seek help even when in severe pain because they consider pain to be part of normal aging. Assessment of pain in older adults may be difficult because of the physiologic, psychosocial, and cognitive changes that often accompany aging. Research has revealed that a large number of residents in long-term care facilities reported being in pain daily; this pain is often described as excruciating and is often unrelieved without treatment (Sawyer, Lillis, Bodner, et al., 2007). It contributes to depression, sleep disturbances, delayed rehabilitation, malnutrition, and cognitive dysfunction (McCleane, 2008).

Older people may respond differently to pain than younger people. Because elderly people have a slower metabolism and a greater ratio of body fat to muscle mass compared to younger people, small doses of analgesic agents may be sufficient to relieve pain, and these doses may be effective longer. Elderly patients deal with pain based on their lifestyle, personality, and cultural background. Many elderly people fear addiction and, as a result, do not report that they are in pain or ask for medication to relieve pain. Others fail to seek care because they fear that the pain may indicate serious illness or that pain relief will result in a loss of independence.

Elderly patients must receive adequate pain relief after surgery or trauma. When an elderly person becomes confused after surgery or trauma, the confusion is often attributed to medications, which are then inappropriately discontinued. However, confusion in the elderly may also result from untreated and unrelieved pain. In some cases, postoperative confusion clears once the pain is relieved. Judgments about pain and the adequacy of treatment should be based on the patient's report of pain and pain relief rather than on age.

Gender

The results of studies of gender in regard to pain levels and response to pain have been inconsistent. In some studies, women consistently reported higher pain intensity, pain unpleasantness, frustration, and fear, compared to men (Wise, Price, Myers, et al., 2002). Men and women are thought to be socialized to respond differently and differ in their expectations about pain.

The Nurse's Role in Assessment and Care of Patients with Pain

The highly subjective nature of pain means that pain assessment and management present challenges for all clinicians. Assessment and management of pain require that the nurse has a good rapport with the person in pain.

Assessment

The International Association for the Study of Pain's definition of pain that was identified at the beginning of this chapter encompasses the multidimensional nature of pain (Merskey & Bogduk, 1994). A broad definition of pain is, "whatever the person says it is, existing whenever the experiencing person says it does" (McCaffery & Pasero, 1999, p.17). This definition emphasizes the highly subjective nature of pain and pain management. Patients are the best authority on the existence of their own pain. Therefore, validation of the existence of pain is based on the patient's report that it exists.

Although it is important to believe patients who report pain, it is equally important to be alert to patients who deny pain in situations where pain would be expected. A nurse who suspects pain in a patient who denies it should explore with the patient the reason for suspecting pain, such as the fact that the disorder or procedure is usually painful or that the patient grimaces when moving or avoids movement. For example, it is not uncommon for a patient recovering from a total joint replacement to deny feeling "pain," but on further questioning he or she will readily admit to having a "terrible ache or pressure, but I wouldn't call it pain." From then on, when evaluating this person's pain, the nurse would use the patient's words rather than the word "pain."

It may also be helpful to explore why the patient may be denying that he or she is in pain. Some people deny pain because they fear the treatment that may result if they report or admit pain. Others deny pain for fear of becoming addicted to opioids if these medications are prescribed.

In assessing a patient with pain, the nurse reviews the patient's description of the pain and other factors that may influence pain (see previous discussion), as well as the patient's response to pain relief strategies. Documentation of the pain level as rated on a pain scale becomes part of the patient's medical record, as does the record of the pain relief obtained from interventions.

Pain assessment includes determining what level of pain relief the acutely ill patient believes is needed to recover quickly or improve function, or what level of relief the chronically or terminally ill patient requires to maintain comfort. Part of a thorough pain assessment includes assessing the patient's expectations and misconceptions about pain (Chart 13-3). People who understand that pain relief not only contributes to comfort but also hastens recovery are more likely to request or self-administer treatment appropriately.

Characteristics of Pain

Pain assessment begins by careful patient observation, noting overall posture and presence or absence of overt pain behaviors. In addition, it is essential to ask the patient to describe, in his or her own words, the specifics of the pain. The words used to describe the pain may point toward the cause. For example, the classic description of chest pain that results from a myocardial infarction includes pressure or squeezing on the chest. A detailed history should follow the initial description of pain. The factors to consider in a complete pain assessment are the intensity, timing, location, quality, personal meaning of pain; aggravating and alleviating factors; and pain behaviors.

Chart 13-3 • Common Concerns and Misconceptions About Pain and Analgesia

- Complaining about pain will distract my doctor from his primary responsibility—curing my illness.
- Pain is a natural part of aging.
- I don't want to bother the nurse—he/she is busy with other patients.
- Pain medicine can't really control pain.
- People get addicted to pain medicine easily.
- It is easier to put up with pain than with the side effects that come from pain medicine.
- Good patients avoid talking about pain.
- Pain medicine should be saved in case the pain gets worse.
- Pain builds character. It's good for you.
- Patients should expect to have pain; it's part of almost every hospitalization.

Intensity

The intensity of pain ranges from none to mild discomfort to excruciating. There is no correlation between reported intensity and the stimulus that produced it. The reported intensity is influenced by the person's **pain threshold**, the smallest stimulus for which a person reports pain, and **pain tolerance**, the maximum amount of pain a person can tolerate. To understand variations, the nurse can ask about the present pain intensity as well as the least and the worst pain intensity. Various scales and surveys are helpful to patients trying to describe pain intensity (see later discussion of instruments for assessing pain).

Timing

Sometimes the cause of pain can be determined when time aspects are known. Therefore, the nurse inquires about the onset, duration, relationship between time and intensity (eg, at what time the pain is the worst), and changes in rhythmic patterns. The nurse asks the patient if the pain began suddenly or increased gradually. Sudden pain that rapidly reaches maximum intensity is indicative of tissue injury, and immediate intervention is necessary. Pain from ischemia gradually increases and becomes intense over a longer time. The chronic pain of rheumatoid arthritis illustrates the usefulness of determining the relationship between time and intensity because people with rheumatoid arthritis usually report that pain is worse during the night.

Location

Having the patient point to the area of the body involved best determines the location of pain. Some general assessment forms include drawings of human figures, on which the patient is asked to shade in the area involved. This is especially helpful if the pain radiates (**referred pain**). The shaded figures are helpful in determining the effectiveness of treatment or change in the location of pain over time.

Quality

The nurse asks the patient to describe the pain in his or her own words without offering clues. For example, the nurse asks the patient to describe what the pain feels like. The nurse must give the patient sufficient time to describe the pain, and the nurse must record all words in the answer. If the patient cannot describe the quality of the pain, the nurse can suggest words such as burning, aching, throbbing, or stabbing. It is important to document the exact words used by the patient to describe the pain and which words were suggested by the nurse conducting the assessment.

Personal Meaning

Pain means different things to different people; as a result, patients experience pain differently. The meaning of the pain experience helps the clinician understand how the patient is affected and assists in planning treatment. It is important to ask how the pain affects the person's daily life. Some people with pain can continue to work or study, whereas others may be disabled by their pain, thus affecting their financial situation. For some patients, the recurrence of pain may mean worsening of disease, such as the spread of cancer.

Aggravating and Alleviating Factors

The nurse asks the patient what, if anything, makes the pain worse and what makes it better and asks specifically about the relationship between activity and pain. This helps detect factors associated with pain. For example, in a patient with advanced metastatic cancer, pain with coughing may signal spinal cord compression. The nurse ascertains whether environmental factors influence pain because they may easily be changed to help the patient. For example, making the room warmer may help a patient relax and may decrease the person's pain. Finally, the nurse asks the patient whether the pain is influenced by or affects the quality of sleep or anxiety. Both can significantly affect pain intensity and the quality of life.

Knowledge of alleviating factors assists the nurse in developing a treatment plan. Therefore, it is important to ask about the patient's use of medications (prescribed and over-the-counter [OTC]), including amount and frequency. In addition, the nurse asks if herbal remedies, nonpharmacologic interventions, or alternative therapies have been used and whether or not they were successful. This information assists the nurse in determining teaching needs.

Pain Behaviors

When experiencing pain, people express pain through many different behaviors. Nonverbal and behavioral expressions of pain are not consistent or reliable indicators of the quality or intensity of pain, and they should not be used to determine the presence of or the severity of pain experienced. A patient may grimace, cry, rub the affected area, guard the affected area, or immobilize it. Others may moan, groan, grunt, or sigh. Not all patients exhibit the same behaviors, and there may be different meanings associated with the same behavior.

Sometimes in nonverbal patients, pain behaviors are used as a proxy to assess pain. It is unwise to make judgments and formulate treatment plans based on behaviors that may or may not indicate pain. In unconscious patients, pain should be assumed to be present and treated (Robinson, Vollmer,

Jirka, et al., 2008). All patients have a right to adequate pain management.

Physiologic responses to pain, such as tachycardia, hypertension, tachypnea, pallor, diaphoresis, mydriasis, hypervigilance, and increased muscle tone, are related to stimulation of the autonomic nervous system. These responses are short-lived as the body adapts to the stress. These physiologic signs could be the result of a change in the patient's condition, such as the onset of hypovolemia. Use of physiologic signs to indicate pain is unreliable. Although it is important to observe for any and all pain behaviors, the absence of these behaviors does not indicate an absence of pain.

Instruments for Assessing the Perception of Pain

Only the patient can accurately describe and assess his or her pain. Clinicians consistently underestimate patients' levels of pain. Therefore, a number of pain assessment tools have been developed to assist in the assessment of the patient's perception of pain. Such tools may be used to document the need for intervention, to evaluate the effectiveness of the intervention, and to identify the need for alternative or additional interventions if the initial intervention is ineffective in relieving the pain. For a pain assessment tool to be useful, it must require little effort on the part of the patient, be easy to understand and use, be easily scored, and be sensitive to small changes in the characteristic being measured.

Visual Analogue Scales and Other Intensity Scales

Visual analogue scales (VASs) are useful in assessing the intensity of pain (Fig. 13-3). One version of the scale includes a horizontal 10-cm line with anchors (ends) indicating the extremes of pain. The patient is asked to place a mark indicating where the current pain lies on the line. The left anchor usually represents "none" or "no pain," whereas the right anchor usually represents "severe" or "worst possible pain." To score the results, a ruler is placed along the line, and the distance the patient marked from the left or low end is measured and reported in millimeters or centimeters.

Some patients (eg, children, elderly patients, visually or cognitively impaired patients) may find it difficult to use an unmarked VAS. In those circumstances, ordinal scales, such as a simple descriptive pain intensity scale or a 0-to-10 numeric pain intensity scale, may be used (see Fig. 13-3).

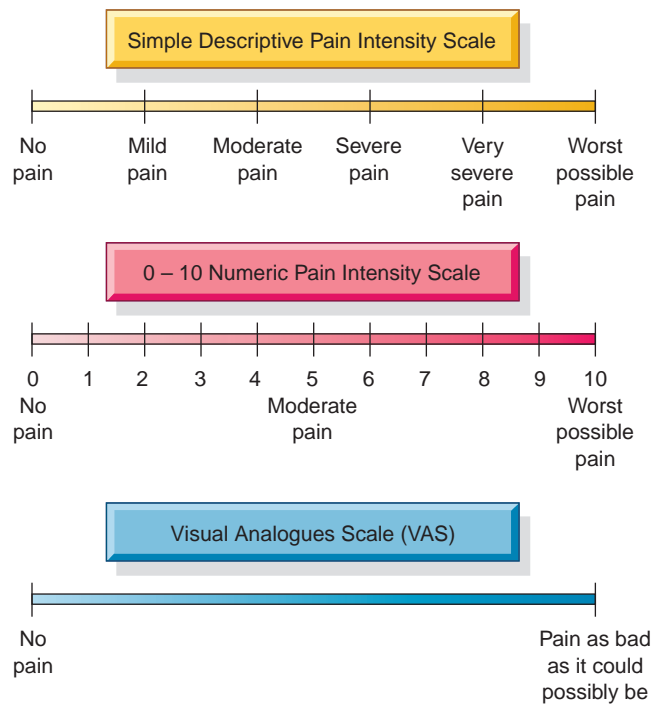

Figure 13-3 Examples of pain intensity scales.

Faces Pain Scale–Revised

This instrument has six faces depicting expressions that range from contented to obvious distress (Fig. 13-4). The patient is asked to point to the face that most closely resembles the intensity of his or her pain.

Using Pain Assessment Scales

Using a written scale to assess pain may not be possible if a person is seriously ill, is in severe pain, or has just returned from surgery. In these cases, the nurse can ask the patient, "On a scale of 0 to 10, 0 being no pain and 10 being pain as bad as it can be, how bad is your pain now?" For patients who have difficulty with a 0-to-10 scale, a 0-to-5 scale may be tried. Whichever scale is used, it should be used consistently. Ideally, the nurse teaches the patient how to use the pain scale before the pain occurs (eg, before surgery). The

Figure 13-4 Faces Pain Scale–Revised. This pain scale is especially suited for helping children describe pain. Instructions for using this scale follow: "These faces show how much something can hurt. This face (point to left-most face) shows no pain. The faces show more and more pain (point to each from left to right) up to this one (point to right-most face). It shows very much pain. Point to the face that shows how much you hurt (right now)." Score the chosen face 0, 2, 4, 6, 8, or 10, counting left to right, so 0 = no pain and 10 = very much pain. Do not use words like "happy" or "sad." This scale is intended to measure how children feel inside, not how their face looks. (From the *Pediatric Pain Sourcebook*. Original Copyright © 2001. Used with permission of the International Association for the Study of Pain and the Pain Research Unit, Sydney Children's Hospital, Randwick NSW 2031, Australia.)

patient's numerical rating is documented and used to assess the effectiveness of pain relief interventions.

If a patient does not speak English or cannot clearly communicate information needed to manage pain, an interpreter or translator should be consulted and a method established for pain assessment. Often a chart can be constructed with English words on one side and the foreign language on the other. The patient can then point to the corresponding word to tell the nurse about the pain.

When people with pain are cared for at home by family caregivers or home care nurses, a pain scale may help assess the effectiveness of the interventions if the scale is used before and after the interventions are implemented. The patient and family caregivers can be taught to use a pain scale to assess and manage the patient's pain. Scales that address the location and pattern of pain may be useful in identifying new sources or sites of pain in chronically or terminally ill patients and in monitoring changes in the patient's level of pain. For example, a home care nurse who sees a patient only periodically may benefit from consulting the patient's or family's written record of the pain scores to evaluate how effective the pain management strategies have been over time.

Guidelines for Assessing Pain in Patients With Disabilities

Alternative forms of communication may be necessary for people with sensory impairments or other disabilities. For people who are blind and who know how to read Braille, pain assessment instruments can be obtained in Braille. In addition, there is now computer software that allows written documents to be scanned and converted into Braille. If these programs are not available, agencies that provide services for people who are blind may be able to assist in developing Braille versions.

For people who are deaf or hard of hearing, outside interpreters (ie, not family members) should be used. Other useful communication strategies may include sign language, written notes, or pictures. When writing notes on a "magic slate" or making written notes, it is necessary to make every effort to guard the patient's privacy and confidentiality. For people with disabilities that result in communication impairment, computer-generated speech may be useful.

Nursing Care

The role of the nurse in pain management is to perform pain assessment, identify goals for pain management, provide patient teaching, perform physical care, help relieve pain by administering pain-relieving interventions (including both pharmacologic and nonpharmacologic approaches), assess the effectiveness of those interventions, monitor for adverse effects, and serve as an advocate for the patient when the prescribed intervention is ineffective in relieving pain. Figure 13-5 depicts a pathway that can be used at the time of assessment to direct clinical decisions for pain management. Specific pain management strategies are discussed later in the chapter.

Identifying Goals for Pain Management

The information the nurse obtains from the pain assessment is used to identify goals for managing pain. These goals are shared and validated with the patient. For a few patients, the

goal may be complete elimination of the pain. However, this expectation may be unrealistic. Other goals may include a decrease in the intensity, duration, or frequency of pain and a decrease in the negative effects of the pain. For example, pain may have a negative effect by interfering with sleep and thereby hamper recovery from an acute illness or decrease appetite. In such instances, the goals might be to sleep soundly and to take adequate nutrition. Chronic pain may affect the patient's quality of life by interfering with work, interpersonal relationships, or sleep. Therefore, a goal might be to decrease time lost from work, to increase the quality of interpersonal relationships, or to improve the quality of sleep.

To determine the goal, a number of factors are considered. The first factor is the severity of the pain as judged by the patient. The second factor is the anticipated harmful effects of pain. Patients with other serious health issues are at much greater risk for harmful effects of pain than are young, healthy patients. The third factor is the anticipated duration of the pain. In patients with pain from a disease such as cancer, the pain may be prolonged, possibly for the remainder of the patient's life. Therefore, interventions will be needed for some time and should not detract from the patient's quality of life. A different set of interventions is required if the pain is likely to last for only a few days or weeks.

In patients receiving palliative care who had pain when they were conscious, it should be assumed that the pain persists even if the patient cannot communicate. Often family members can be taught what behaviors to look for to assess for pain (eg, a furrowed brow, stiffening of a part of the body, or moaning).

The goals for the patient may be accomplished by pharmacologic or nonpharmacologic means, but most success is achieved with a combination of these methods. In the acute stages of illness, the patient may be unable to participate actively in relief measures, but when sufficient mental and physical energy is present, the patient may learn self-management techniques to relieve the pain. Therefore, as the patient progresses through the stages of recovery, increased patient use of self-management pain relief measures may be a goal.

Establishing the Nurse–Patient Relationship and Teaching

A positive nurse–patient relationship and teaching are key to caring for patients with pain, because open communication and patient cooperation are essential to success. A positive nurse–patient relationship characterized by trust is essential. By acknowledging that the patient has pain, the nurse often helps reduce the patient's anxiety. Occasionally, a patient who fears that no one believes that he or she has pain feels relieved to know that the nurse can be trusted to believe that the pain exists.

Teaching is equally important, because the patient or family may be responsible for managing the pain at home and preventing or managing side effects. Teaching the patient about pain and strategies to relieve it may reduce pain in the absence of other pain relief measures and may enhance the effectiveness of the pain relief measures used.

The nurse also provides information by explaining how pain can be controlled. For example, the patient should be informed that pain should be reported in the early stages.

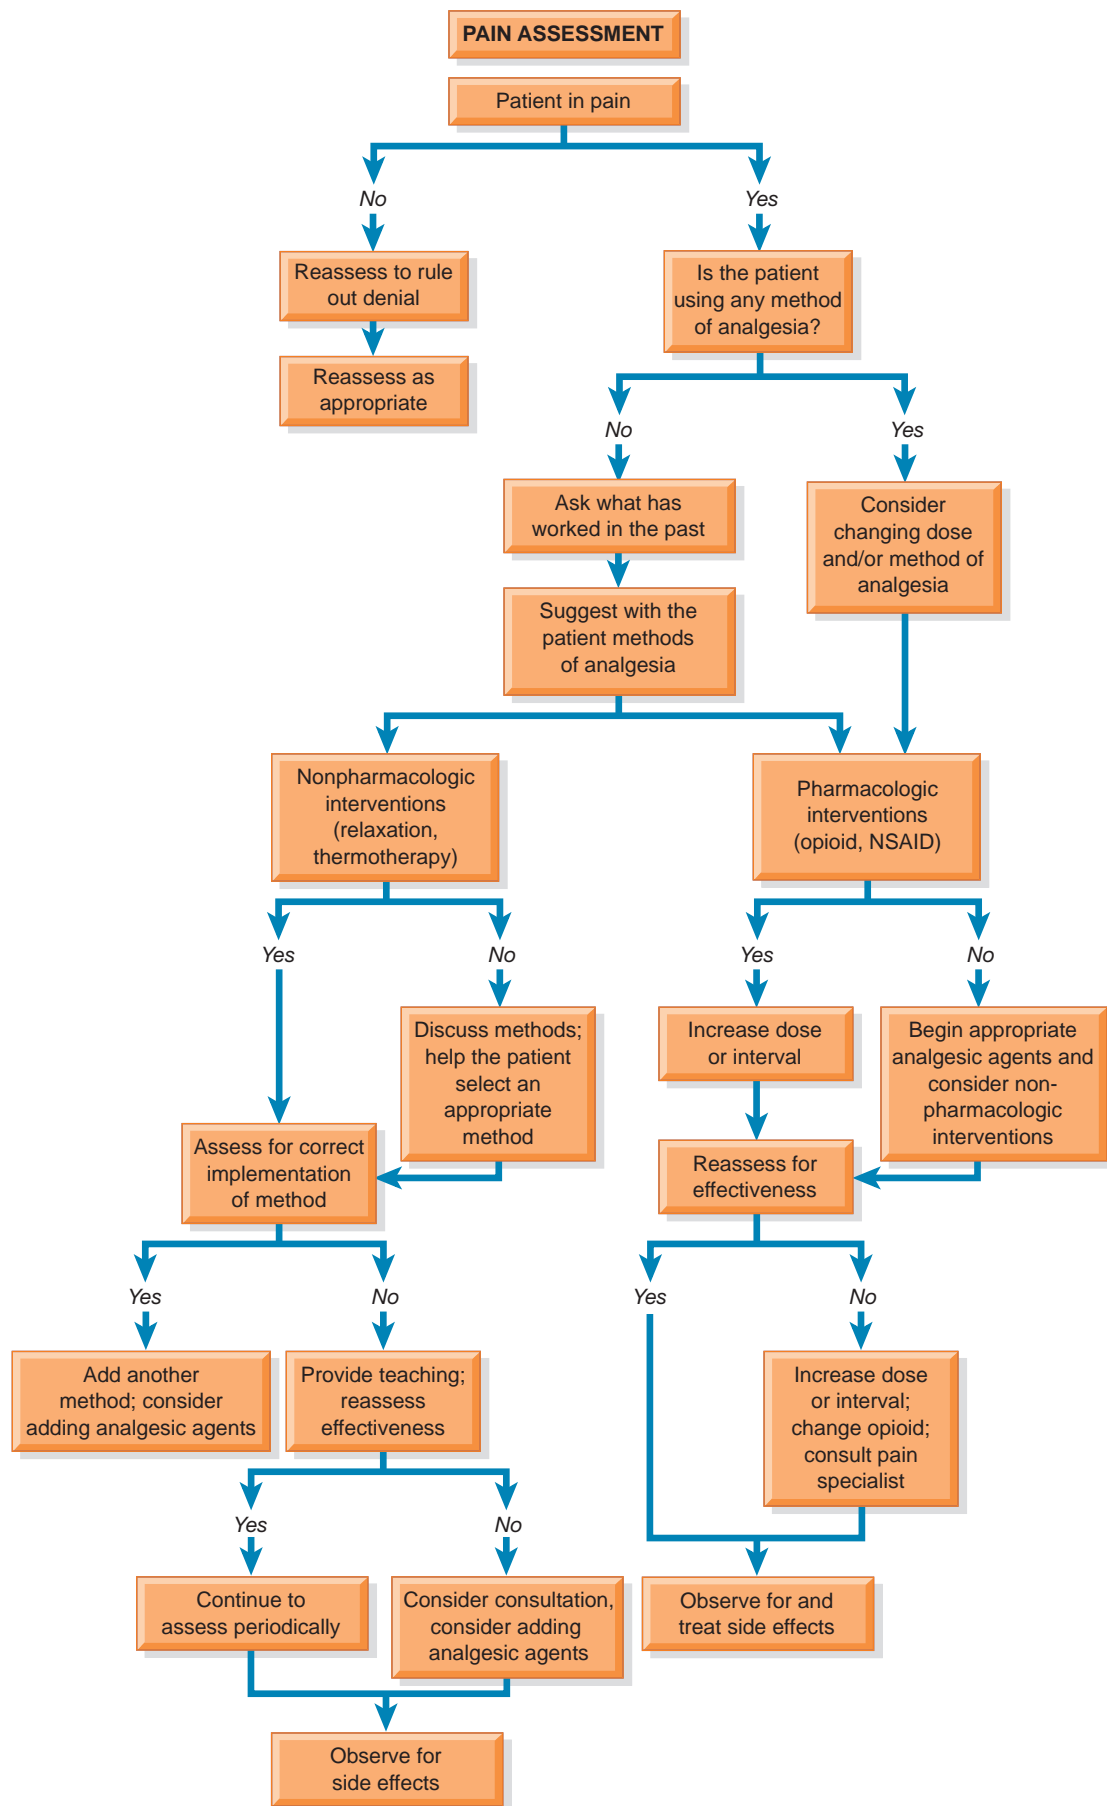

Figure 13-5 Pain assessment pathway. NSAID, nonsteroidal anti-inflammatory drug.

When the patient waits too long to report pain, **sensitization** may occur, and the pain may be so intense that it is difficult to relieve. The phenomenon of sensitization is important in effective pain management. A heightened response is seen after exposure to a noxious stimulus; as a result, the response to that stimulus is greater, causing the person to feel more pain. When health care providers assess and treat pain before it becomes severe, sensitization is diminished or avoided, and less medication is needed.

Providing Physical Care

Patients in pain may be unable to participate in the usual activities of daily living or to perform usual self-care and may need assistance to carry out these activities. Patients are usually more comfortable when physical and self-care needs have been met and efforts have been made to ensure as comfortable a position as possible. A fresh gown and change of bed linens, along with efforts to make the person feel refreshed (eg, brushing teeth, combing hair), often increase the level of comfort and improve the effectiveness of the pain relief measures.

In acute, long-term, and home settings, the nurse who provides physical care to patients also has the opportunity to perform complete assessments and to identify problems that may contribute to the patient's discomfort and pain. Appropriate and gentle physical touch during care may be reassuring and comforting. If topical treatments such as fentanyl (an opioid analgesic) patches or intravenous (IV) or intraspinal catheters are used, the skin around the patch or catheter should be assessed for integrity during physical care.

Managing Anxiety Related to Pain

Anxiety may affect the patient's response to pain. A patient who anticipates pain may become increasingly anxious. Teaching the patient about the nature of the impending painful experience and the ways to reduce pain often decreases anxiety; people who experience pain use previously learned strategies to reduce anxiety and pain. Learning about measures to relieve pain may lessen the threat of pain and give the patient a sense of control. The patient's anxiety may be reduced by explanations that point out the degree of pain relief that can be expected from each measure. For example, a patient who is informed that an intervention may not eliminate pain completely is less likely to become anxious when a certain amount of pain persists.

A patient who is anxious about pain may be less tolerant of the pain, which in turn may increase his or her anxiety level. To prevent the pain and anxiety from escalating, the anxiety-producing cycle must be interrupted. Pain relief measures should be used before pain becomes severe. Many patients believe that they should not request pain relief measures until they cannot tolerate the pain, making it difficult for medications to provide relief. It is important to explain to all patients that pain relief or control is more successful if such measures begin before the pain becomes unbearable.

Pain Management Strategies

Reducing pain to a "tolerable" level was once considered the goal of pain management. However, even patients who have

described pain relief as adequate often report disturbed sleep and marked distress because of pain. In view of the harmful effects of pain and inadequate pain management, the goal of tolerable pain has been replaced by the goal of relieving the pain. Pain management strategies include both pharmacologic and nonpharmacologic approaches. These approaches are selected on the basis of the requirements and goals of particular patients. Chart 13-4 provides a discussion of pain management for patients at the end of life. Appropriate analgesic medications are used as prescribed. They are not considered a last resort to be used only when other pain relief measures fail. As previously discussed, any intervention is most successful if it is initiated before pain sensitization occurs, and the greatest success is usually achieved if several interventions are applied simultaneously.

PHARMACOLOGIC INTERVENTIONS

Pharmacologic management of pain is accomplished in collaboration with physicians, patients, and often families. A physician or nurse practitioner prescribes specific medications for pain or may insert an IV line for administration of analgesic medications. Alternatively, an anesthesiologist or nurse anesthetist may insert an epidural catheter for administration of such analgesic agents. However, it is the nurse who maintains the analgesia, assesses its effectiveness, and reports whether the intervention is ineffective or produces side effects.

Close collaboration and effective communication among health care providers are necessary. In the home setting, the family often manages the patient's pain and assesses the effectiveness of pharmacologic interventions, and the home care nurse evaluates the adequacy of pain relief strategies and the ability of the family to manage the pain. Home care nurses reinforce teaching and ensure communication among patients, family care providers, physicians, pharmacists, and other health care providers involved in the care of patients.

Premedication Assessment

Before administering any medication, the nurse should ask the patient about allergies to medications and the nature of any previous allergic responses. True allergic or anaphylactic responses to opioids are rare, but it is not uncommon for patients to report an allergy to one of the opioids. On further questioning, the nurse often learns that the extent of the allergy is "itching" or "nausea and vomiting." These responses are not allergies; rather, they are side effects that can be managed while the patient's pain is relieved. The patient's description of responses or reactions should be documented and reported before medication is administered.

The nurse obtains the patient's medication history (eg, current, usual, or recent use of prescription or OTC medications or herbal agents), along with a history of health disorders. Certain medications, herbal agents, or conditions may affect the analgesic medication's effectiveness or its metabolism and excretion or may produce adverse interactions (Table 13-1). Before administering analgesic agents, the nurse should assess the patient's pain status, including the intensity of current pain, changes in pain intensity after the previous dose of medication, and side effects of the medication.

It is also critical to assess the patient's ethnic and racial background, because there appears to be a higher frequency

Chart 13-4 • Pain at the End of Life

Pain is one of the most feared symptoms at the end of life. Many patients experience pain as a terminal illness progresses. The inadequate treatment of cancer pain has been well documented. In the classic Study to Understand Prognoses and Preferences for Outcomes and Risks of Treatments (SUPPORT) (1995), investigators noted that nearly 40% of severely chronically ill and older patients who died in hospitals suffered moderate to severe pain in the last 3 days of life. The suffering caused by unrelieved pain touches all aspects of quality of life (activity, appetite, sleep) and can weaken an already fatigued person. Unrelieved pain can create anxiety and depression, negatively affect relationships, and promote thoughts of suicide.

The Joint Commission's pain standards issued in January 2001 present a unique opportunity to improve care for hospitalized patients. Even though hospices and palliative care agencies are not subject to review by the Joint Commission, many patients with chronic illness who are receiving palliative care may be hospitalized at various times. The standards emphasize pain assessment, patient and family education, continuity of care for symptom management, and evaluation of interventions.

Barriers to Pain Management

Current barriers to pain management include lack of education, lack of access to opioids, fear of addiction, and legal issues.

Lack of Education

Strategies to increase health care professionals' knowledge about pain, pain assessment, and pain management in general and at the end of life are needed to ensure that a patient's pain is effectively addressed. Many studies have increased what is known about pain and pain management. However, the information from these studies must be disseminated to health care providers to be translated into evidence-based practice. Health care professionals, including nurses, must remain current about the pharmacokinetics and pharmacodynamics of analgesic agents and about new technologies to deliver analgesic medications. Continuing education (CE) can be obtained through conferences, journal articles, and online programs. Studies are needed to evaluate the effect that educational interventions have on health care providers' knowledge about pain and their ability to manage pain effectively (Gunnarsdottir, Donovan & Ward, 2003).

Accessibility of Opioids

The lack of access to opioids is another barrier to adequate pain relief. Patients may have difficulty affording medications. Some pharmacists, fearing crime, paperwork, and regulatory oversight, may not stock opioids or may keep limited quantities on hand. Some insurance companies limit the types of medications they will reimburse and the amount and frequency of renewal of analgesics.

Addiction Fears

The fear of addiction plays a role even at the end of life. Family members may be hesitant to assist the patient in pain management for fear of the social stigma of addiction. This causes needless pain and suffering. Some health care

providers continue to have unfounded fears of contributing to a patient's risk for addiction when administering opioids.

Legal Barriers

Legislative issues play a role in the inadequate management of pain. Many states are enacting intractable pain statutes to reduce physicians' fear of civil or criminal liability or disciplinary action for aggressively managing pain. The tracking system by the Drug Enforcement Agency, however, acts as a deterrent since opioids prescribed by physicians can be tracked. Some physicians fear that prescribing "too many" opioids could be interpreted as treating an addicted patient.

Other Issues Related to Pain Management

Pain management at the end of life requires comprehensive pain assessment and pain management, even though assessment may be hampered by confusion, delirium, or unconsciousness. Caregivers are taught to observe for signs of restlessness or facial expressions as a "proxy" indicator of pain.

Analgesic agents should be titrated to find the most effective dose and the best-tolerated route. The nurse and family members should assess the effectiveness of the current pain therapy. If the pain is not relieved, a larger dose of medication may be necessary. If the pain continues, another medication may be needed or the patient should be given a different analgesic agent. This process requires frequent assessment to effectively manage pain. The analgesic agent or treatment should be appropriate for the type of pain. For example, neuropathic pain, usually described as burning, tingling, numbness, shooting, stabbing, or electric, requires a different treatment approach than acute pain.

Nonpharmacologic approaches, such as guided imagery and relaxation, can be used to decrease pain and help the patient cope. Careful patient positioning and environmental control are other methods to increase patient comfort.

Respiratory depression should be assessed because, over time, the patient's risk for this side effect increases. The rate, depth, and level of consciousness should be monitored to determine whether respiratory depression is occurring and requires treatment. A respiratory rate of 6/min or greater is usually adequate. If respiratory depression occurs, a decrease in the opioid dose may be indicated. Frequent stimulation to encourage deep breathing may be required until the opioid is metabolized. In the last few days of life, the patient may become restless, which is an indicator of pain. The need to increase the opioid to provide pain relief and the respiratory effects of opioids are considered in decision making. However, comfort should be a priority in the case of a person who clearly is at the end of life.

Side effects from analgesics must be managed. A careful bowel regimen involving diet, bowel stimulants, stool softeners, and/or osmotic agents must be instituted to prevent constipation. Vigilance in the assessment, management, and treatment of other side effects is similar to that included in previous discussions.

Careful assessment and management of pain at the end of life can make a "good" death possible by helping patients realize the goal of adequate pain relief throughout the dying process.

Analgesic Agent	Herb or Food	Effect
NSAIDs	Ginkgo, garlic, ginger, bilberry, dongquai, feverfew, ginseng, turmeric, meadowsweet, willow	Enhanced risk for bleeding
Acetaminophen	Ginkgo and possibly some of the above-mentioned herbs Echinacea, kava, willow, meadowsweet	Enhanced risk for bleeding Increased potential for hepatotoxicity and nephrotoxicity
Opioids	Valerian, kava, chamomile Ginseng	Increased central nervous system depression Inhibits analgesic effects
Alfentanil, fentanyl, sufentanil	Grapefruit juice	Inhibits the cytochrome P450 3A4 enzyme in the liver, blocking metabolism of the drug

NSAID, nonsteroidal anti-inflammatory drugs.

From Abebe, W. (2002). Herbal medication: Potential for adverse interactions with analgesic drugs. *Journal of Clinical Pharmacologic Therapies*, 27(6), 391–401; and Karch, A. (2004). The grapefruit challenge. *American Journal of Nursing*, 104(12), 33–35.

of poor drug metabolizers among Caucasian people compared with Asian American and African American people. Genetic factors play a role in the varied responses to nonsteroidal anti-inflammatory drugs (NSAIDs) and opioids seen in patients (Desmeules, Pigué, Ehret, et al., 2004). The most extensively studied genetic variation in humans is in the metabolism of codeine. Drug metabolism involves genetically controlled enzyme activity for absorption, distribution, inactivation, and excretion. In both experimental and clinical pain, a polymorphism (deoxyribonucleic acid [DNA] proteins with variant alleles) in CYP2D6 (encoding cytochrome P450) results both in poor metabolism and poor analgesic efficacy. People who are “poor metabolizers” do not demethylate codeine to morphine; therefore, they do not experience its analgesic effects. See Chapter 9 for further discussion of genetics.

Agents Used to Treat Pain

The three general categories of analgesic agents are **opioids**, NSAIDs, and local anesthetics. These agents work by different mechanisms. Other adjunctive agents such as antidepressant and anticonvulsant medications may also be used.

Opioid Analgesic Agents

The goal of administering opioids is to relieve pain and improve quality of life; therefore, the route, dose, and frequency of administration are determined on an individual basis. Factors that are considered in determining the route, dose, and frequency of medication include the characteristics of the pain (eg, its expected duration and severity), the overall status of the patient, the patient’s response to analgesic medications, and the patient’s report of pain. Opioids can be administered by various routes—oral, IV, subcutaneous, intraspinal, intranasal, rectal, and transdermal. Although the oral route is usually preferred for opioid administration, oral opioids must be given frequently enough and in large enough doses to be effective. Opioid analgesic agents given orally may provide a more consistent serum level than those given intramuscularly.

Adverse Effects

With the administration of opioids by any route, side effects must be considered and anticipated. Clinicians who take

steps to minimize the side effects increase the likelihood that the patient will receive adequate pain relief without interrupting therapy to treat the effects.

Respiratory Depression and Sedation. Respiratory depression is the most serious adverse effect of opioid analgesic agents administered by IV, subcutaneous, or epidural routes. However, it is relatively rare because doses administered through these routes are small, and tolerance to respiratory depressant effects increases if the dose is increased slowly. The risk of respiratory depression increases with age and with the concomitant use of other opioids or other CNS depressant medications. The risk of respiratory depression also increases when the epidural catheter is placed in the thoracic area and when the intra-abdominal or intrathoracic pressure is increased.

A patient who receives opioids by any route must be assessed frequently for changes in respiratory status. Specific notable changes are shallow respirations and decreasing respiratory rate. Despite the risks associated with their use, IV and epidural opioids are considered safe, with the risks related to epidural administration no greater than those related to IV or other systemic routes of administration. Sedation, which may occur with any method of administering opioids, is likely to occur when opioid doses are increased. However, patients often develop tolerance quickly, so that in a short time they are no longer sedated by the dose that initially caused sedation. Increasing the time between doses or reducing the dose temporarily, as prescribed, usually prevents deep sedation from occurring. Patients at risk for sedation must be monitored closely for changes in respiratory status. Patients are also at risk for problems associated with sedation and immobility. The nurse must initiate strategies to prevent complications such as pressure ulcers.

Nausea and Vomiting. Nausea and vomiting may occur with opioid use. Usually these effects occur some hours after the initial injection. Patients, especially postoperative patients, may not think to tell the nurse that they are nauseated, particularly if the nausea is mild. However, a patient receiving opioids should be assessed for nausea and vomiting, which may be triggered by a position change and may be prevented by having the patient change positions slowly. Adequate hydration and the administration of antiemetic agents may also decrease the incidence of nausea. Opioid-induced nausea and vomiting often subside within a few days.

Constipation. Constipation, a common side effect of opioid use, may become so severe that the patient is forced to choose between relief of pain and relief of constipation. This situation can occur in patients after surgery and in patients receiving large doses of opioids to treat cancer-related pain. Preventing constipation must be a high priority in all patients receiving opioids. Whenever a patient receives opioids, a bowel regimen should begin at the same time. Tolerance to this side effect does not occur; rather, constipation persists even with long-term use of opioids.

Several strategies may help prevent and treat opioid-related constipation. Mild laxatives and a high intake of fluid and fiber may be effective in managing mild constipation. Unless contraindicated, a mild laxative and a stool softener should be administered on a regular schedule. However, continued severe constipation often requires the use of a stimulating cathartic agent, such as senna derivatives (Senokot) or bisacodyl (Dulcolax). If oral agents fail, rectal suppositories may be used. Two new agents, alvimopan (Entereg) and methylnaltrexone (Relistor), appear promising for patients with severe opioid-induced constipation because they work as antagonistic agents on the peripheral opioid receptors in the bowel to counteract opioid-induced delays in gastrointestinal motility. These medications do not reverse the analgesic effects of the opioids (Thomas, 2008).

Pruritus. When asked about drug allergies, patients with previous hospital experience (especially for surgery) may report that they are “allergic” to morphine. This report should be thoroughly investigated. Commonly, this “allergy” is described as itching only. Pruritus (itching) is a frequent side effect of opioids administered by any route, but it is not an allergic reaction. It can be relieved by administering prescribed antihistamines. Epidurally administered opioids may also cause urinary retention. The patient should be monitored and may require urinary catheterization. Small doses of naloxone (Narcan) may be prescribed to relieve these problems in patients who are receiving epidural opioids for the relief of acute postoperative pain.

Opioid Use With Selected Conditions and Medications

A number of factors may influence the safety and effectiveness of opioid administration. Opioid analgesic agents are primarily metabolized by the liver and excreted by the kidney. Therefore, metabolism and excretion of analgesic medications are impaired in patients with liver or kidney disease, increasing the risk of cumulative or toxic effects. In addition, normeperidine, a metabolite of meperidine (Demerol), may rapidly or unexpectedly accumulate to toxic levels. This is more likely to occur in patients with impaired kidney function and may result in seizures in susceptible patients. Many institutions no longer stock meperidine because of the risks associated with the metabolite normeperidine and because many physicians do not prescribe a high enough dose for it to be effective.

Patients with untreated hypothyroidism are more susceptible to the analgesic effects and side effects of opioids. In contrast, patients with hyperthyroidism may require larger doses for pain relief. Patients with a decreased respiratory reserve from disease or aging may be more susceptible to the depressant effects of opioids and must be carefully monitored for respiratory depression.

Patients who are dehydrated are at increased risk for the hypotensive effects of opioids. Patients who become hypotensive after the administration of an opioid should be kept recumbent and rehydrated unless fluids are contraindicated. Patients who are dehydrated are also more likely to experience nausea and vomiting with opioid use. Rehydration usually relieves these symptoms.

Patients receiving certain other medications, such as monoamine oxidase inhibitors, phenothiazines, or tricyclic antidepressants, may have an exaggerated response to the depressant effects of opioids. Patients taking these medications should receive small doses of opioids and must be monitored closely. Continued pain in these patients indicates that a therapeutic level of the analgesic has not been achieved. Patients must be monitored for sedation even if an analgesic effect has not been obtained.

Inadequate Pain Relief

One factor commonly associated with ineffective pain relief is an inadequate dose of opioid. This is most likely to occur when the caregiver underestimates the patient’s pain or fails to consider differences in absorption and action after a change in the route of administration. Consequently, the patient receives doses that are too small to be effective and, possibly, too infrequent to relieve pain. For example, if opioid delivery is changed from the IV route to the oral route, the oral dose must be approximately three times greater than that given parenterally to provide relief. Because of differences in absorption of orally administered opioids among individuals, patients must be assessed carefully to ensure that the pain is relieved (Chart 13-5).

Effects of opioid analgesic medications must be monitored, especially when the first dose is given or when the

Ethics and Related Issues

Inadequate Pain Management

Situation

When taking over the care of ethnic minority patients at the change of shift from a particular colleague, you usually find these patients to be in a great deal of postoperative pain. Your nonsystematic observations have led you to conclude that these patients receive only a small portion of the analgesia prescribed for them. You have heard a nurse colleague state a belief that people of certain ethnic groups have “no pain tolerance” and are “just looking for drugs.”

Dilemma

Racial biases are difficult to deal with and change. To confront this nurse may not alter the behavior but will certainly disrupt the working relationships on the unit. It would be easier to look the other way. On the other hand, you believe that the nurse is giving inadequate and unethical care to selected patients and placing them at greater risk for postoperative complications.

Discussion

- What information would you need to collect before acting?
- From whom could you seek counsel?
- Are the two aspects of the dilemma equally important?

dose is changed or given more frequently. The time, date, patient's pain rating (scale of 0 to 10), analgesic agent, other pain relief measures, side effects, and patient activity are recorded. For example, when the first dose of an analgesic is administered, the nurse should record a pain rating score, blood pressure, and respiratory and pulse rates (all of which are considered "vital signs"). If the pain has not decreased in 30 minutes (sooner if an IV route is used) and the patient is reasonably alert and has a satisfactory respiratory

status, blood pressure, and pulse rate, then some change in analgesia is indicated. Although the dose of analgesic medication is safe for this patient, it is ineffective in relieving the pain. Therefore, another dose of medication may be indicated. In such instances, the nurse consults with the physician to determine what further action is warranted.

Table 13-2 lists opioids and dosages that are equivalent to morphine. It serves only as a guide; the doses listed are not necessarily the most appropriate doses for all patients.

Table 13-2  **SELECTED OPIOID ANALGESIC AGENTS COMMONLY USED FOR MODERATE AND SEVERE PAIN IN ADULTS**

Name	Starting Dose (milligrams)		Comments	Precautions and Contraindications
	Moderate Pain	Severe Pain		
Morphine	—	30–60 (oral) 10 (parenteral)	Acts as an agonist at specific opioid receptors in the CNS to produce analgesia, euphoria, and sedation.	Use with caution, especially in elderly patients, very ill patients, and those with respiratory impairment. Major risks include respiratory depression, apnea, circulatory depression, and respiratory arrest, shock, and cardiac arrest. Obtain history of hypersensitivity to opioids. Monitor patient closely. If prescribed in correct dose, oral preparations (MS Contin) are effective in treating moderate and severe pain.
Codeine	15–30 (oral)	60 (oral) up to 360/24 h	Acts as an agonist at specific opioid receptors in the CNS to produce analgesia, euphoria, and sedation. Is also an antitussive. 10% of people lack the enzyme needed to make codeine active. Codeine may cause more nausea and constipation per unit of analgesia than other mu agonist opioids.	Many preparations of codeine and the other opioids in this table are combinations with nonopioid analgesic agents. Caution must be used in patients with impaired ventilation, bronchial asthma, increased intracranial pressure, or impaired liver function and in elderly and very ill patients.
Oxycodone (OxyContin)	5 (oral)	10–20 (oral)	Acts as an agonist at specific opioid receptors in the CNS to produce analgesia, euphoria, and sedation.	Caution must be used in patients with impaired ventilation, bronchial asthma, increased intracranial pressure, or impaired liver function and in elderly and very ill patients.
Meperidine (Demerol)	50 (oral)	300 (oral) 75 (parenteral)	Acts as an agonist at specific opioid receptors in the CNS to produce analgesia, euphoria, and sedation. Shorter acting than morphine. Meperidine is biotransformed to normeperidine, a toxic metabolite.	Normeperidine, a toxic metabolic of meperidine, accumulates with repetitive dosing, causing CNS excitation. High risk for seizures. Should be avoided in patients with impaired renal function who are receiving MAO inhibitors. Is irritating to tissues with repeated intramuscular injections. Chronic use should be avoided. Should not be used for more than 1 or 2 days.
Propoxyphene (Darvon)	65–130 (oral)	—	Weak analgesic; acts as an agonist at specific opioid receptors in the CNS to produce analgesia, euphoria, and sedation. Many preparations include nonopioid analgesic agents; biotransformed to potentially toxic metabolite (norpropoxyphene).	Accumulation of propoxyphene and toxic metabolites occurs with repetitive dosing. Overdose is complicated by seizures. Propoxyphene is not recommended for older adults or patients with renal impairment.
Hydrocodone (Vicodin)	5–10 (oral)	—	—	Most preparations are combined with nonopioid analgesic agents.
Tramadol (Ultram)	50–100 (oral)	—	Unique mechanism; analgesia results from the synergy of two mechanisms. Maximum dose is 400 mg/day.	Most common side effects are dizziness, nausea, constipation, and somnolence. Lowers seizure threshold.

CNS, central nervous system; MAO, monoamine oxidase.

Adapted from American Pain Society. (2003). *Principles of analgesic use in the treatment of acute pain and cancer pain* (5th ed.). Glenview, IL: American Pain Society; and Karch, A. M. (2005). *Lippincott's nursing drug guide*. Philadelphia: Lippincott Williams & Wilkins.

However, the table does give clinicians some idea of equivalency between two different opioids. After administering the first dose of an opioid, clinicians should conduct a complete pain assessment to determine the efficacy of that dose. In general, no recalculation needs to be done when changing from one brand of an agent to another brand of the same medication, with the exception of extended-release oral morphine. Currently, four brands of extended-release morphine (Avinza, MS Contin, Oramorph, and Kadian) are commonly used by patients with cancer. Although these agents come in the same dosage form and contain the same drug, they are not therapeutically equivalent because they use different release mechanisms. Patients who need to change brands should be monitored carefully both for overdose and for inadequate pain relief.

Tolerance and Addiction

There is no maximum safe dosage of opioids, nor is there any easily identifiable therapeutic serum level. Both the maximal safe dosage and the therapeutic serum level are relative and individual. **Tolerance** (the need for increasing doses of opioids to achieve the same therapeutic effect) develops in almost all patients taking opioids for extended periods. Patients requiring opioids over a long term, especially patients with cancer, need increasing doses to relieve pain. After the first few weeks of therapy, their dosing requirements usually level off. Patients who become tolerant to the analgesic effects of large doses of morphine may obtain pain relief by changing to a different opioid. Symptoms of physical dependence may occur when the opioids are discontinued; dependence often occurs with opioid tolerance and does not indicate an addiction.

NURSING ALERT

Although patients may need increasing levels of opioids, they are not addicted. Physical tolerance usually occurs in the absence of addiction. Tolerance to opioids is common and becomes a problem primarily in terms of delivering or administering the medication (eg, how to administer very large doses of morphine to a patient). On the other hand, addiction is rare and should not be the primary concern of nurses caring for patients in pain.

Addiction is a behavioral pattern of substance use characterized by a compulsion to take the substance (drug or alcohol) primarily to experience its psychic effects. Fear that patients will become addicted or dependent on opioids has contributed to inadequate treatment of pain. This fear may be expressed by health care providers as well as patients and their families and results from lack of knowledge about the low risk of addiction.

Addiction after therapeutic opioid administration is so negligible that it should not be a consideration when caring for patients in pain. Therefore, patients and health care providers should be dissuaded from withholding opioid analgesics because of concerns about addiction.

When caring for people with a known history of addiction, nurses should consider that each individual person has the right to be treated for pain. The American Society for

Pain Management Nursing (2005) developed a position paper on pain management of patients with addictive disease. It stressed education, communication about methods for pain management, and methods to safely discontinue opioids in this patient population. The opioids should be tapered slowly to prevent withdrawal symptoms.

Nonsteroidal Anti-inflammatory Drugs

NSAIDs are thought to decrease pain by inhibiting cyclooxygenase (COX), the enzyme involved in the production of prostaglandin from traumatized or inflamed tissues. There are two types of COX, COX-1, and COX-2.

COX-1 mediates prostaglandin formation involved in the maintenance of physiologic functions, such as gastric mucosal blood flow and platelet aggregation. Inhibition of COX-1 results in gastric ulceration, bleeding, and renal damage.

COX-2 mediates prostaglandin formation that results in symptoms of pain, inflammation, and fever. Therefore, inhibition of COX-2 is desirable. Celecoxib (Celebrex) is the only COX-2 inhibitor that is currently approved by the U.S. Food and Drug Administration (FDA). Several COX-2 inhibitors (rofecoxib [Vioxx], valdecoxib [Bextra]) are no longer available because of their cardiovascular effects.

Ibuprofen (Advil, Motrin), another NSAID, blocks both COX-1 and COX-2, is effective in relieving mild to moderate pain, and has a low incidence of adverse effects. Aspirin, the oldest NSAID, also blocks COX-1 as well as COX-2; however, because it causes frequent and severe side effects, aspirin is infrequently used to treat significant acute or chronic pain.

NSAIDs are very helpful in treating arthritic diseases and may be especially powerful in treating cancer-related bone pain. They have been effectively combined with opioids to treat postoperative and other severe pain. The use of NSAIDs in combination with opioids relieves pain more effectively than opioids alone. In such cases, patients may obtain pain relief with decreased doses of opioid and with fewer side effects. In addition, intraoperative administration of NSAIDs reportedly improves postoperative pain control after abdominal hysterectomy surgery (Krenzischek, Dunwoody, Polomano, et al., 2008). A regimen of a fixed-dose, periodically dosed NSAID (eg, every 4 hours) and a separately administered fluctuating dose of opioid may be effective in managing moderate to severe cancer pain. In more severe pain, the opioid dose is also fixed, with an additional fluctuating dose as needed for **breakthrough pain** (a sudden increase in pain despite the administration of pain-relieving medications). These regimens result in better pain relief with fewer opioid-related side effects (Krenzischek, et al., 2008).

Most patients tolerate NSAIDs well. However, those with impaired kidney function may require a smaller dose and must be monitored closely for side effects. Likewise, these medications should be administered with caution in dehydrated and elderly patients. Patients taking NSAIDs bruise easily because these agents have some anticoagulant effects. Furthermore, NSAIDs may displace other medications, such as warfarin (Coumadin), from receptor sites on plasma proteins and increase their effects. Because, high doses or prolonged use can irritate the stomach and result in

gastrointestinal bleeding, monitoring for gastrointestinal bleeding is indicated (Krenzischek, et al., 2008).

Local Anesthetic Agents

Local anesthetics work by blocking nerve conduction when applied directly to the nerve fibers. They can be applied directly to the site of injury (eg, a topical anesthetic spray for sunburn) or directly to nerve fibers by injection or at the time of surgery. They can also be administered through an epidural catheter.

Local anesthetic agents have been successful in reducing the pain associated with thoracic or upper abdominal surgery when injected by the surgeon intercostally. Local anesthetic agents are rapidly absorbed into the bloodstream, resulting in decreased availability at the surgical or injury site and an increased anesthetic level in the blood, increasing the risk of toxicity. Therefore, a vasoconstrictive agent (eg, epinephrine or phenylephrine) is added to the anesthetic agent to decrease its systemic absorption and maintain its concentration at the surgical or injury site.

Topical Application

A topical anesthetic agent known as eutectic mixture or emulsion of local anesthetics, or EMLA cream, has been effective in preventing the pain associated with invasive procedures such as lumbar puncture or the insertion of IV lines. To be effective, EMLA must be applied to the site 60 to 90 minutes before the procedure.

A lidocaine 5% (Lidoderm) patch can be effective in treating the pain associated with postherpetic neuralgia (Meier, Wasner, Kuntzer, et al., 2003). Currently, this is its only use approved by the FDA. The patch acts locally by targeting damaged nerves responsible for discharging pain impulses. Because the lidocaine 5% patch does not cause sensory block in the area of application, it has a wide margin of safety. The recommended dose is one to three patches at a time applied for 12 hours daily.

Intraspinal Administration

Intermittent or continuous administration of local anesthetic agents through an epidural catheter has been used for years to produce anesthesia during surgery. Although the administration of local anesthetic agents in the spinal canal is still largely confined to acute pain, such as postoperative pain and pain associated with labor and delivery, the epidural administration of local anesthetic agents for pain management is increasing.

A local anesthetic agent administered through an epidural catheter is applied directly to the nerve root. The anesthetic agent can be administered continuously in low doses, intermittently on a schedule, or on demand as the patient requires it, and it is often combined with the epidural administration of opioids. Surgical patients treated with this combination experience fewer complications after surgery, ambulate sooner, and have shorter hospital stays than patients who receive standard therapy (Polomano, Rathmell, Krenzischek, et al., 2008).

Tricyclic Antidepressant Agents and Antiseizure Medications

Pain of neurologic origin (eg, causalgia, tumor impingement on a nerve, postherpetic neuralgia) is difficult to treat and

in general is not responsive to opioid therapy. If these pain syndromes are accompanied by dysesthesia (burning or cutting pain), they may be responsive to a tricyclic antidepressant or an antiseizure agent. When indicated, tricyclic antidepressant agents, such as amitriptyline (Elavil) or imipramine (Tofranil), are prescribed in doses considerably smaller than those generally used for depression. Patients need to know that a therapeutic effect may not occur until they have taken the medication for 3 weeks. Antiseizure medications such as phenytoin (Dilantin) or carbamazepine (Tegretol) also are used in doses lower than those prescribed for seizure disorders. Because a variety of medications can be tried, nurses should be familiar with the possible side effects and should teach patients and families how to recognize these effects.

Approaches for Using Analgesic Agents

Medications are most effective when the dose and interval between doses are individualized to meet the needs of a particular patient. The only safe and effective way to administer analgesic medications is by asking the patient to rate the pain and by observing the response to medications.

Balanced Analgesia

Pharmacologic interventions are most effective when a multimodal or balanced analgesia approach is used. **Balanced analgesia** refers to the use of more than one form of analgesia concurrently to obtain more pain relief with fewer side effects. These agents work by different mechanisms. Using two or three types of agents simultaneously can maximize pain relief while minimizing the potentially toxic effects of any one agent. When one agent is used alone, it usually must be used in a higher dose to be effective. In other words, although it might require 15 mg of morphine to relieve a certain pain, it may take only 8 mg of morphine plus 30 mg of ketorolac (Toradol, an NSAID) to relieve the same pain.

Pro Re Nata

In the past, analgesic agents were prescribed *pro re nata* (PRN), or “as needed.” The standard practice was for the nurse to wait for the patient to complain of pain and then administer analgesia. As a result, many patients remained in pain because they did not know they needed to ask for medication or waited until the pain became intolerable.

By its very nature, the PRN approach to analgesia leaves patients sedated or in severe pain much of the time. To receive pain relief from an opioid analgesic, the serum level of that opioid must be maintained at a minimum therapeutic level (Fig. 13-6). By the time the patient complains of pain, the serum opioid concentration is below the therapeutic level. From the time the patient requests pain medication until the nurse administers it, the patient’s serum levels continue to decrease. The lower the serum opioid level, the more difficult it is to achieve the therapeutic level with the next dose. Using this outdated method, the only way to ensure significant periods of analgesia is to give doses large enough to produce periodic sedation.

Preventive Approach

The preventive approach to relieving pain by administering analgesic agents is most effective because a therapeutic serum level of medication is maintained. With the preventive

Figure 13-6 Relationship of mode of delivery of analgesia to serum analgesic level. *Top:* intramuscular (IM) and intravenous patient-controlled analgesia (PCA). *Bottom:* transdermal (TD) and transmucosal (*) delivery.

approach, analgesic agents are administered at set intervals so that the medication acts before the pain becomes severe and before the serum opioid level decreases to a subtherapeutic level.

Administering analgesic medication on a timed basis, rather than on the basis of a patient's report of pain, prevents the serum drug level from falling to subtherapeutic levels. For example, a patient takes prescribed morphine or a prescribed NSAID (eg, ibuprofen) every 4 hours rather than waiting until the pain is severe. If the pain is likely to occur around the clock or for a substantial portion of a 24-hour period, a regular around-the-clock schedule of administering analgesia may be indicated. Even if the analgesic agent is prescribed PRN, it can be administered on a preventive basis before the patient is in severe pain, as long as the prescribed interval between doses is observed. The preventive approach reduces the peaks and troughs in the serum level and provides more pain relief with fewer adverse effects (Chart 13-6).

Smaller doses of medication are needed with the preventive approach, because the pain does not escalate to a level of severe intensity. Therefore, a preventive approach may result in the administration of less medication over a 24-hour period, helping prevent tolerance to analgesic agents and decreasing the severity of side effects (eg, sedation, constipation). Better pain control can be achieved with a preventive approach, reducing the amount of time patients are in pain.

In using the preventive approach, the nurse assesses the patient for sedation before administering the next dose. The goal is to provide analgesia before the pain becomes severe. It is not safe to medicate the patient with opioids repeatedly if the patient is sedated or not in pain. It may be necessary

to decrease the dosage of the opioid analgesic medication so that the patient receives pain relief with less sedation.

Patient-Controlled Analgesia

Used to manage postoperative pain as well as persistent pain, **patient-controlled analgesia (PCA)** allows patients to control the administration of their own medication within predetermined safety limits. This approach can be used with oral analgesic agents as well as with continuous infusions of opioid analgesic agents by IV, subcutaneous, or epidural routes. PCA can be used in hospitals or in home settings (Pasero & McCaffery, 2005).

The PCA pump permits the patient to self-administer continuous infusions of medication (basal rates) safely and to administer extra medication (bolus doses) with episodes of increased pain or painful activities. A patient experiencing pain can administer small amounts of medication directly into his or her IV, subcutaneous, or epidural catheter by pressing a button. The pump then delivers a preset amount of medication.

A PCA pump is electronically controlled by a timing device. The timer can be programmed to prevent additional doses from being administered until a specified time period has elapsed (lock-out time) and until the first dose has had time to exert its maximal effect. Even if the patient pushes the button multiple times in rapid succession, no additional doses are released. If another dose is required at the end of the delay period, the button must be pushed again to receive the dose. Patients who are controlling their own opioid administration usually become sedated and stop pushing the button before any significant respiratory depression occurs. Nevertheless, assessment of respiratory status remains a major nursing role.

CHART
13-6 **NURSING RESEARCH PROFILE**
PRN Range Opioid Analgesic Orders

Gordon, D., Pellino, T. A., Higgins, A. G., et al. (2008). Nurses' opinions on appropriate administration of PRN range opioid analgesic orders for acute pain. *Pain Management Nursing*, 9(3), 131–140.

Purpose

Opioids are commonly used to treat moderate to severe pain. A common clinical practice is the use of “as-needed” or “PRN” range orders. This type of prescription can cause two sources of confusion, namely, which dose to give within the ordered range and the total time interval in which the maximum dose can be administered. The purpose of this study was to:

1. Determine how much agreement exists among nurses about the timing and dosing of analgesic agents ordered with a PRN range order.
2. Identify respondent characteristics, such as education, years of nursing experience, and attendance at a pain education event, that affect the knowledge and comfort of the nurse in titrating these opioids.
3. Identify factors nurses consider when selecting a dose to administer from a range order.

Design

An Internet survey was conducted in one midwestern medical center and a multihospital system. The survey contained 15 questions and took 10 to 15 minutes to complete. It contained four vignettes whereby the respondent was asked what dose of analgesic agent would be chosen and the timing between the doses. E-mail notifications of the survey were sent to the midwestern medical center. The multihospital system did not have individual e-mail accounts for nurses so the researchers posted a message about the survey on the institution's home Web page.

Findings

A sample of 602 nurses participated. Forty-one percent of the nurses ($n = 247$) reported no knowledge about an existing policy concerning PRN range orders that could direct their practice. Forty-three percent ($n = 259$) of the respondents had some form of pain education and 2% ($n = 12$) were certified in pain management.

An increase in nurses' comfort level with opioid titration was positively associated with increased experience. Attendance at a pain course was positively associated with higher titration to comfort levels.

The factors nurses considered in opioid administration, in decreasing order of frequency, were sedation level, pain intensity, respiratory rate, and the patient's response to prior dosing. The sedation level of monitoring was chosen first by 56% ($n = 337$) of the respondents. Thus, 44% ($n = 265$) considered sedation levels as of less importance. One quarter of the nurses ($n = 150$) consistently chose responses that would delay or underdose patients. Twenty-one percent of the nurses ($n = 126$) replied that they would give a dose that was less than the prescribed minimum. Because the Internet was used, there is possible bias among the respondents and one cannot generalize the findings to all nurses.

Nursing Implications

The authors recommended that nurses closely examine the pharmacokinetics of opioids to understand when they peak and trough. Clearer understanding and communication about range orders between nurses and other health care professionals are needed. Clear, evidence-based guidelines should be established to guide nurses in the titration of PRN doses of opioids.

To initiate PCA or any analgesia used at home or in the hospital, it is important to avoid playing “catch-up.” Pain should be brought under control before PCA starts, often by the use of an initial, larger bolus dose or loading dose or by administering repeated bolus doses of an IV opioid over short periods until the pain is relieved. Then, after pain control is achieved, the pump is programmed to deliver small doses of medication at preset intervals. The goal is to achieve a minimum therapeutic level of analgesia and to allow the patient to maintain that level by using the PCA pump. The patient is instructed not to wait until the pain is severe before pushing the button to obtain a bolus dose. The patient is also reminded not to become so distracted by an activity or visitor that he or she forgets to self-administer a prescribed dose of medication. One potential drawback to distraction is that the patient who is using a PCA pump may not self-administer any analgesia during the time of effective distraction. When distraction ends suddenly (eg, a movie ends, visitors leave), the patient may be left without a therapeutic serum opioid level. When intermittent distraction is used for pain relief, a continuous low-level basal infusion of opioid through the PCA pump may be prescribed so that, after the distraction ends, it will not be necessary to try to “catch up.”

A continuous infusion plus bolus doses may be effective with patients who have cancer and require large doses of

analgesia and with postsurgical patients. Although this allows more uninterrupted sleep, the risk of sedation increases, especially when the patient has minimal or decreasing pain.

Patients who use PCA achieve better pain relief and often require less pain medication than those who are treated in the PRN fashion (Costa & Coleman, 2008). Because the patient can maintain a near-constant level of medication, the periods of severe pain and sedation that occur with the PRN regimen are avoided. If PCA is to be used in the patient's home, the patient and family are taught about the operation of the pump as well as the side effects of the medication and strategies to manage them (Pasero & McCaffery, 2005).

Patients might not be able to activate their PCA pumps and other people may administer their analgesia by PCA pumps, a situation known as “PCA by proxy.” The American Society for Pain Management Nursing supports the safe practice of authorized agent-controlled analgesia (AACA), in which the analgesic agent is administered by a proxy who is specially trained. The American Society for Pain Management Nursing does not condone unauthorized dosing by proxy, which increases the risk for potential harm to the patient (Wuhrman, Cooney, Dunwoody, et al., 2007). AACA involves selecting and educating an appropriate person, typically a family member. Health care agencies and

hospitals that promote AACA usually develop policies that stipulate the roles and responsibilities of the prescriber, the nurse, and the caregiver who provides the analgesia via the PCA. The medical order in the chart should note the name of the authorized proxy.

NURSING ALERT

Family members who are not authorized agents are cautioned not to push the button for a patient, especially if the patient is asleep, because this overrides some of the safety features of the PCA system. The nurses retain the responsibility for monitoring the patient.

Routes of Administration

The route selected for administration of an analgesic agent depends on the condition of the individual patient and the desired effect of the medication. Analgesic agents can be administered by parenteral, oral, rectal, transdermal, transmucosal, intraspinal, or epidural routes. Each method of administration has advantages and disadvantages. The route chosen should be based on patient need.

Parenteral Route

Parenteral administration (intramuscular, IV, or subcutaneous) of the analgesic medication produces effects more rapidly than oral administration, but these effects are of shorter duration. Parenteral administration may be indicated if the patient is not permitted oral intake or is vomiting. Medication administered by the intramuscular route enters the bloodstream more slowly than medication given IV and is metabolized slowly. The rate of absorption may be erratic, depending on the site selected and the amount of body fat.

The IV route is the preferred parenteral route in most acute care situations because it is much more comfortable for patients. In addition, peak serum levels and pain relief occur more rapidly and more reliably. Because most analgesic medications peak rapidly (usually within minutes) and are metabolized quickly, an appropriate IV dose is smaller and is prescribed at shorter intervals than an intramuscular dose.

Many commonly prescribed analgesics, including opioids, may be administered by IV push or slow push (eg, over a 5- to 10-minute period) or by continuous infusion with a pump. Continuous infusion provides a steady level of analgesia and is indicated when pain occurs over a 24-hour period, such as after surgery for the first day or two, or in a patient with prolonged pain who cannot tolerate medication by other routes. The dose of analgesic agent is calculated carefully to relieve pain without producing respiratory depression and other side effects.

The subcutaneous route for infusion of opioid analgesic agents is used for patients with severe pain such as cancer pain. In addition, it is particularly useful for patients with limited IV access who cannot take oral medications and for patients who are managing their pain at home. The subcutaneous route is often an effective and convenient way to manage pain, but the dose of opioid that can be infused through this route is limited because of the small volume that can be administered at one time into the subcutaneous tissue.

Oral Route

Oral administration is preferred over parenteral administration if the patient can tolerate medication by mouth, because it is easy and noninvasive. Severe pain can be relieved with oral opioids if the doses are high enough (see Table 13-2). In terminally ill patients with prolonged pain, doses may be gradually increased as the disease progresses and causes more pain or as the patient develops a tolerance to the medication. If higher doses are increased gradually, they usually provide additional pain relief without producing respiratory depression or sedation. If the route of administration is changed from a parenteral route to the oral route at a dose that is not equivalent in strength (equianalgesic), the smaller oral dose may result in a withdrawal reaction and recurrence of pain.

Rectal Route

The rectal route may be indicated in patients who cannot take medications by any other route. The rectal route may also be indicated for patients with bleeding problems, such as hemophilia. The onset of action of opioids administered rectally is unclear but is delayed compared with other routes of administration. Similarly, the duration of action is prolonged.

Transdermal Route

The transdermal route is used to achieve a consistent opioid serum level through absorption of the medication via the skin. It is most often used in the home or hospice care settings for patients with cancer. Transdermal opioids include fentanyl (Duragesic) and buprenorphine (Buprenex), which are marketed as patches consisting of a reservoir containing the medication and a porous membrane.

Fentanyl was the first commercially available transdermal opioid (Chart 13-7). When the fentanyl transdermal system

Chart 13-7 • Safe Use of Transdermal Fentanyl

The U.S. Food and Drug Administration issued a public health advisory in 2005 about the use of fentanyl skin patches and warned patients and health care providers about the need for the patches to be used as intended. The advisory also included precautions about safe storage and disposal of fentanyl skin patches:

- Fentanyl skin patches are very strong opioids and should always be prescribed at the lowest dose needed for pain relief. They should be used only for patients with chronic pain that is not well controlled with shorter-acting opioids.
- Patients should be cautioned that a sudden and possibly dangerous rise in the level of fentanyl in their blood can occur with use of alcohol or other medications that affect brain function; an increase in body temperature or exposure to heat; or use of other medicines that affect the metabolism of fentanyl.
- Patients should be informed about signs and symptoms of fentanyl overdose (ie, shallow or difficult breathing; fatigue, extreme sleepiness, or sedation; inability to think, talk, or walk normally; and feeling faint, dizzy, or confused).

is first applied to the skin, fentanyl, which is fat soluble, binds to the skin and fat layers. Then it is slowly and systemically absorbed. Therefore, there is a delay in effect while the dermal layer is being saturated. A drug reservoir actually forms in the upper layer of skin. This results in a slowly rising serum level and a slow tapering of the serum level once the patch is removed (see Fig. 13-6). Because it takes 12 to 24 hours for the fentanyl levels to gradually increase after application of the first patch, the last dose of sustained-release morphine should be administered at the same time the first patch is applied (D'Arcy, 2005a, 2005b; Pasero, 2005). Transdermal fentanyl is associated with slightly less constipation than oral opioids. Absorption is increased in febrile patients. A heating pad should never be applied to the area where the patch is applied. Transdermal fentanyl is much more expensive than sustained-release morphine, but it is less costly than methods that deliver parenteral opioids.

Buprenorphine, another transdermal system, is available in three strengths. It has many of the same advantages as fentanyl and has been shown in limited clinical studies to be associated with a high level of patient adherence and improved quality of life (Poulain, Denier, Douma, et al., 2008).

Once it is determined that switching from other routes of morphine administration to a transdermal system is appropriate, the correct dosage or strength for the patch must be calculated. If the patient uses an opioid other than morphine, conversion to milligrams of oral morphine is the first step. After determining how many milligrams of morphine (or morphine equivalents) the patient has been using over 24 hours, an initial dose of transdermal fentanyl or buprenorphine is calculated (Johnson, Fudala & Payne, 2005). Patients switched from morphine to transdermal patches of either fentanyl or buprenorphine should be assessed not only for pain and potential side effects but also for dependence, reflected by withdrawal symptoms, which may consist of shivering, a feeling of coldness, sweating, headache, and paresthesia (Johnson, et al., 2005). Patients may require short-acting opioids for breakthrough pain before the systemic opioid delivered through the transdermal system reaches a therapeutic level.

NURSING ALERT

Conversion tables available for the transdermal systems should be used only to establish the initial dose of the transdermal fentanyl or buprenorphine when patients switch from oral morphine to the transdermal route of delivery (and not vice versa). If these tables are inappropriately used to determine the dosages of oral morphine for patients who have been receiving transdermal fentanyl or buprenorphine, many patients will not achieve satisfactory analgesia and will require an increase in their opioid dose to treat breakthrough pain.

NURSING ALERT

If the conversion table or equation is used incorrectly to calculate a morphine dose, there is a risk of overdose. If a patient requires a change from transdermal fentanyl or buprenorphine back to oral or IV morphine (as in the case of surgery), the patch should be removed and IV morphine administered on an as-needed basis. Before a new patch is applied, the patient should be carefully checked for any older, forgotten patches, which should be removed and discarded. Patches should be replaced every 72 hours.

Transmucosal Route

Patients with cancer pain who are being cared for at home may be receiving continuous opioids using sustained-release morphine, hydromorphone, oxycodone, transdermal fentanyl or buprenorphine, or other medications. These patients often experience short episodes of severe pain (eg, after coughing or moving), or they may experience sudden increases in their baseline pain resulting from a change in their condition. These periods, called breakthrough pain, can be well managed with an oral dose of a short-acting transmucosal opioid that has a rapid onset of action. Available transmucosal opioids are fentanyl, buprenorphine, sufentanil, and methadone.

Currently, butorphanol (Stadol), fentanyl (Duragesic, Sublimaze), sufentanil (Sufenta), and morphine are the only approved transmucosal opioid analgesic agents commercially available in the form of nasal sprays. Butorphanol is a complex medication that simultaneously acts to induce or promote (**agonist**) and inhibit or reverse (**antagonist**) opioid effects. It works like an opioid agonist and an opioid antagonist at the same time. Butorphanol in any form cannot be combined with other opioids (eg, for cancer breakthrough pain), because the antagonist component blocks the action of the opioids the patient is already receiving. The principal use of this agent is for brief, moderate to severe pain, such as migraine headaches.

Intranasal morphine is useful in cancer-related breakthrough pain. When it is given in this form, analgesia is achieved within 5 to 10 minutes, resulting in significant decreases in pain intensity and high patient satisfaction (Fitzgibbon, Morgan, Dockter, et al., 2003).

Intraspinal and Epidural Routes

Infusion of opioids or local anesthetic agents into the subarachnoid space (intrathecal space or spinal canal) or epidural space has been used for effective control of pain in postoperative patients and those with chronic pain unrelieved by other methods. A catheter is inserted into the subarachnoid or the epidural space at the thoracic or lumbar level for administration of opioid or anesthetic agents (Fig. 13-7). With intrathecal administration, medication infuses directly into the subarachnoid space and cerebrospinal fluid, which surrounds the spinal cord. With epidural administration, medication is deposited in the dura of the spinal canal and diffuses into the subarachnoid space. It is believed that

A

B

Figure 13-7 Placement of intraspinal catheters for administration of analgesic medications: **A**, intrathecal route; **B**, epidural route.

pain relief from intraspinal administration of opioids is based on the existence of opioid receptors in the spinal cord.

Infusion of opioids and local anesthetic agents through an intrathecal or epidural catheter results in pain relief with fewer side effects, including sedation, than with systemic analgesia. Adverse effects associated with intraspinal administration include spinal headache resulting from loss of spinal fluid when the dura is punctured. This is more likely to occur in younger patients (less than 40 years of age). The dura must be punctured with the intrathecal route, and dural puncture may occur inadvertently with the epidural route. If dural puncture inadvertently occurs, spinal fluid seeps out of the spinal canal. The resultant headache is likely to be more severe with an epidural needle because it is larger than a spinal needle, and therefore more spinal fluid escapes.

Respiratory depression generally peaks 6 to 12 hours after epidural opioids are administered, but it can occur earlier or up to 24 hours after the first injection. Depending on the lipophilicity (affinity for body fat) of the opioid injected, the time frame for respiratory depression can be short or long. Morphine is hydrophilic, and the time for peak effect is longer than that of fentanyl, which is lipophilic. The patient should be monitored closely for at least 24 hours after the first injection and longer if changes in respiratory status or level of consciousness occur. Opioid antagonist agents such as naloxone (Narcan) must be available for IV use if respiratory depression occurs.

The patient is also observed for urinary retention, pruritus, nausea, vomiting, and dizziness. Precautions must be taken to avoid infection at the catheter site and catheter displacement. Only medications without preservatives should be administered into the subarachnoid or epidural space because of the potential neurotoxic effects of preservatives.

For patients who have persistent, severe pain that fails to respond to other treatments, or who obtain pain relief only with the risk of serious side effects, medication administered by a long-term intrathecal or epidural catheter may be effective. After the physician tunnels the catheter through the subcutaneous tissue and places the inlet (or port) under the skin, the medication is injected through the skin into the inlet and catheter, which delivers the medication directly into the epidural space. It may be necessary to inject the medication several times a day to maintain an adequate level of pain relief.

For patients who require more frequent doses or continuous infusions of opioid analgesic agents to relieve pain, an implantable infusion device or pump may be used to administer the medication continuously. The medication is administered at a small, constant dose at a preset rate into the epidural or subarachnoid space. The reservoir of the infusion device stores the medication for slow release and needs to be refilled every 1 or 2 months, depending on the patient's needs. This eliminates the need for repeated injections through the skin.

Another delivery method of epidural morphine provides effective analgesia for patients who have undergone major surgical procedures. A single-dose extended-release epidural morphine (DepoDur) is administered into the epidural space at the lumbar level immediately prior to surgery. The morphine is released slowly from microvesicular liposomes. One dose of 5 to 15 mg is absorbed around the epidural space and systemically. DepoDur has been shown to provide up to 48 hours of postoperative analgesia. Although supplemental analgesic agents may be needed, patients who have received DepoDur tend to report less intense pain and greater satisfaction with pain relief (Gambling, Hughes, Martin, et al., 2005). Side effects are similar to those of other epidural opioids (ie, nausea, vomiting, pruritus, and hypotension); its use is contraindicated in patients with allergy to morphine, respiratory depression, severe asthma or upper airway obstruction, and circulatory shock.

NURSING ALERT

Epidural catheters inserted for pain control are usually managed by nurses. Baseline information necessary to provide safe and effective pain control includes the level or site of catheter insertion, the medications (eg, local anesthetic agents, opioids) that have been administered, and the medications anticipated in the future. The infusion rate is increased with caution when anesthetic agents are combined with opioids. Sensory deficits can occur, and patients must be assessed frequently. An infusion with a lower concentration of anesthetic agent allows for administration of a greater concentration of opioid with a lower risk of sensory deficits.

Nursing Management

Headache resulting from spinal fluid loss may be delayed. Therefore, the nurse needs to assess regularly for headache after either type of catheter is placed. If headache develops, the patient should remain flat in bed and should be given large amounts of fluids (provided the medical condition allows), and the physician should be notified. An epidural blood patch may be performed to reduce leakage of spinal fluid.

Cardiovascular effects (hypotension and decreased heart rate) may result from dilation of the vasculature in the lower extremities. Therefore, the nurse should assess frequently for decreases in blood pressure, pulse rate, and urine output.

Urinary retention and pruritus may develop, and the physician may prescribe small doses of naloxone to combat these effects. The nurse administers these doses in continuous IV infusions that are small enough to reverse the side effects of the opioids without reversing the analgesic effects. Diphenhydramine (Benadryl) may also be used to relieve opioid-related pruritus. Patients who receive epidural analgesic agents at home and their families must be taught how to administer the prescribed medication using sterile technique and how to assess for infection. Patients and families also need to learn how to recognize side effects and what to do about them. Respiratory depression is uncommon, but urinary retention may be a problem, and patients and families must be prepared to deal with it if it occurs. Implanted analgesic delivery systems can be safely and confidently used at home if health care personnel are available for consultation and, possibly, intervention on short notice.

Placebo Effect

A **placebo effect** occurs when a person responds to the medication or other treatment because of an expectation that the treatment will work rather than because it should work. Simply receiving a medication or treatment may produce positive effects. The placebo effect results from natural (endogenous) production of endorphins in the descending control system. It is a true physiologic response that can be reversed by naloxone, an opioid antagonist (Kaptchuk, Kelly, Deykin, et al., 2008).

A patient's positive expectations about treatment may increase the effectiveness of a medication or other intervention. Often, the more cues the patient receives about the intervention's effectiveness, the more effective it is. Patients who are told that a medication is expected to relieve pain are more likely to experience pain relief than those who are told that a medication is unlikely to have any effect.

Hrobjartsson and Gotzsche (2006) reviewed the methods used in over 50 studies whose aim was to examine the placebo effect. They concluded that what is commonly called a placebo effect may be an actual analgesic effect.

The American Society for Pain Management Nursing (2005) contends that placebos (tablets or injections with no active ingredients) should not be used to assess or manage pain in any patient, regardless of age or diagnosis. Furthermore, this group recommends that all health care institutions have policies in place prohibiting the use of placebos

Chart 13-8 • Administration of Placebos

Because of misperceptions about placebos and the placebo effect, it is important to keep in mind some specific principles and guidelines:

- A placebo effect is *not* an indication that the person does not have pain; rather, it is a true physiologic response.
- Placebos (tablets or injections with no active ingredients) should *never* be used to test the person's truthfulness about pain or as the first line of treatment.
- A positive response to a placebo (eg, reduction in pain) should *never* be interpreted as an indication that the person's pain is not real.
- A patient should *never* be given a placebo as a substitute for an analgesic medication. Although a placebo can produce analgesia, patients receiving a placebo may report that their pain is relieved or that they feel better simply to avoid disappointing the nurse.

for this purpose. Nurses and other health care providers should be taught about effective pain management and these policies should be disseminated (Chart 13-8).

Gerontologic Considerations

Physiologic changes in older adults require that analgesic agents be administered with caution. Drug interactions are more likely to occur in older adults because of the higher incidence of chronic illness and the increased use of prescription and OTC medications. Although the elderly population is an extremely heterogeneous group, differences in response to pain or medications by patients over this 40-year span (approximately 60 to 100 years) are more likely to be due to chronic illness or other individual factors than to age. Before administering opioid and nonopioid analgesic agents to elderly patients, the nurse should obtain a careful medication history to identify potential drug interactions (see Table 13-1).

Elderly patients are more sensitive to medications and at an increased risk for drug toxicity (McCleane, 2008). Liver, renal, and gastrointestinal functions are decreased in elderly patients, resulting in changes in the absorption and metabolism of medications. In addition, changes in body weight, protein stores, and distribution of body fluid alter the distribution of medications in the body. Consequently, medications are not metabolized as quickly, and blood levels of the medications remain higher for a longer period.

Opioid and nonopioid analgesic medications can be administered to elderly patients but must be used cautiously because of the increased susceptibility to depression of both the nervous and the respiratory systems. Although there is no reason to avoid opioids in patients simply because they are elderly, meperidine (Demerol) should be avoided because its active and neurotoxic metabolite, normeperidine, is more likely to accumulate and cause CNS excitation and seizures. In addition, because of decreased binding of meperidine by plasma proteins, blood concentrations of the medication twice those found in younger patients may occur.

In many cases, the initial dose of analgesic medication prescribed for elderly patients is the same as that for younger patients, or slightly smaller than the normal dose, but because

of slowed metabolism and excretion related to aging, the safe interval for subsequent doses may be longer (or prolonged). The American Geriatrics Society (AGS) (2002) has published clinical practice guidelines for managing persistent pain in elderly patients. As always, the best guide to pain management and administration of analgesic agents in all patients, regardless of age, is what the individual patient says. Elderly patients may obtain more pain relief for a longer time than younger patients do from the same dose. As a result, smaller and less frequent doses of analgesics may be required.

Promoting Home and Community-Based Care

In preparing the patient and family to manage pain at home, the patient and family should be taught and guided about what type of pain or discomfort to expect, how long the pain is expected to last, and when the pain indicates a problem that should be reported. People who have experi-

enced pain as a result of injury, illness, a medical procedure, or surgery will probably receive one or more prescriptions for analgesic medication for use at home.

Teaching Patients Self-Care

The patient and family must understand the purpose of each medication, the appropriate time to use it, the associated side effects, and the strategies that can be used to prevent these problems. The patient and family often need reassurance that pain can be successfully managed at home.

Inadequate control of pain at home is a common reason people seek health care or are readmitted to the hospital. When persistent pain exists, anxiety and fear are often intensified at the time the patient is about to return home. The patient and family are instructed about the techniques for assessing pain, using pain assessment tools, and administering medications to relieve pain. These instructions are given verbally and in writing (Chart 13-9).

CHART
13-9

PATIENT EDUCATION

At-Home Pain Management Plan

Pain control plan for _____

At home, I will take the following medicines for pain control:

Medicine	How to take	How many	How often	Comments
_____	_____	_____	_____	_____
_____	_____	_____	_____	_____
_____	_____	_____	_____	_____

Medicines that I may take to help treat side effects:

Side effect	Medicine	How to take	How many	How often	Comments
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____

Constipation is a very common problem when taking opioid medications. Activities aimed at prevention include:

- Increase fluid intake (8 to 10 glasses of fluid).
- Exercise regularly.
- Increase fiber in the diet (bran, fresh fruits, vegetables).
- Use a mild laxative, such as milk of magnesia, if no bowel movement in 3 days.
- Take _____ every day at _____ (time) with a full glass of water.
- Use a glycerin suppository every morning (this may help make a bowel movement less painful).

Nondrug pain control methods:

Additional instructions:

Important phone numbers:

Your doctor _____ Your nurse _____

Your pharmacy _____ Emergencies _____

Call your doctor or nurse immediately if your pain increases or if you have a new pain. Also call your doctor early for refill of pain medicines. Do not let your medicines get below 3 or 4 days' supply.

From Agency for Health Care Policy and Research. (1994). *Management of cancer pain*. Clinical Practice Guidelines. Rockville, MD: Agency for Health Care Policy and Research, Public Health Service, U.S. Department of Health and Human Services.

Opportunities are provided for the patient and family members to practice administering the medication until they are comfortable and confident with the procedure. They are instructed about the risks of respiratory and CNS depression associated with opioids and ways to assess for these complications. If the medications cause other predictable effects, such as constipation, the instructions include measures for preventing and treating the problem, as previously described. Steps are taken to ensure that the needed medications are available from the local pharmacy so that the patient receives the medication when required. If the patient is expected to require opioid analgesic agents at home, during discharge planning the nurse should consider the ability of the patient and family to administer opioids as prescribed and should take steps to ensure that the required medications will be available to the patient. Many pharmacies, especially those in smaller rural areas or inner cities, may not stock large amounts of opioids. Therefore, arrangements for obtaining these prescription medications must be made ahead of time.

Education for patients and families must stress the need for keeping analgesic agents away from children, who might mistake them for candy. Elderly patients may become lax about this because no children live in the home, but visiting children can be placed at risk. In addition, analgesic medications should be stored safely in their original containers and clearly labeled. They should be stored out of sight to prevent others from taking them for their own use or diverting them to others.

Continuing Care

If parenteral or intraspinal analgesia will be administered at home, the patient should be referred to a home care nurse. This nurse will make a home visit to assess the patient and to determine whether the pain management program is being implemented and the technique for injecting or infusing the analgesic agent is being carried out safely and effectively. If the patient has an implanted infusion pump in place, the nurse examines the condition of the pump or injection site and may refill the reservoir with medication as prescribed or may supervise family members in this procedure. The nurse assesses for any change in the patient's need for analgesic medications, and, in collaboration with the physician, the nurse may assist the patient and family in modifying the medication dose. These efforts enable the patient to obtain adequate pain relief while remaining at home and with family.

NONPHARMACOLOGIC INTERVENTIONS

Activities to Promote Comfort

Analgesic medication is the most powerful tool for pain relief that is available, but it is not the only one. Nonpharmacologic nursing activities can assist in pain relief, usually with low risk to the patient. Although such measures are not a substitute for medication, they may be appropriate to relieve episodes of pain lasting only seconds or minutes. In instances of severe pain that lasts for hours or days, combining nonpharmacologic interventions with medications may be the most effective way to relieve pain.

Massage

The gate control theory of pain proposes that stimulation of fibers that transmit nonpainful sensations can block or decrease the transmission of pain impulses. Several nonpharmacologic pain relief strategies, including rubbing the skin and using heat and cold, are based on this theory.

Massage, which is generalized cutaneous stimulation of the body, often concentrates on the back and shoulders. A massage does not specifically stimulate the nonpain receptors in the same receptor field as the pain receptors, but it may have an impact through the descending control system (see previous discussion). Massage also promotes comfort because it produces muscle relaxation (Adams & Arminio, 2008).

Thermal Therapies

Ice and heat therapies may be effective pain relief strategies in some circumstances; however, their effectiveness and mechanisms of action need further study. Proponents believe that ice and heat stimulate the nonpain receptors in the same receptor field as the injury.

For greatest effect, ice should be placed on the injury site immediately after injury or surgery. Ice therapy after joint surgery can significantly reduce the amount of analgesic medication required. Ice therapy may also relieve pain if applied later. Care must be taken to assess the skin before treatment and to protect the skin from direct application of the ice. Ice should be applied to an area for no longer than 15 to 20 minutes at a time and should be avoided in patients with compromised circulation (Adams & Arminio, 2008). Long applications of ice may result in frostbite or nerve injury.

Application of heat increases blood flow to an area and contributes to pain reduction by speeding healing. Both dry and moist heat may provide some analgesia, but their mechanisms of action are not well understood. Both ice and heat therapy must be applied carefully and monitored closely to avoid injuring the skin. Neither therapy should be applied to areas with impaired circulation or used in patients with impaired sensation.

NURSING ALERT

Heat should not be applied to a painful area that is the site of acute untreated infection (eg, mastitis, tooth abscess), because it may cause increased pain with increased blood flow to the site.

Transcutaneous Electrical Nerve Stimulation

Transcutaneous electrical nerve stimulation (TENS) uses a battery-operated unit with electrodes applied to the skin to produce a tingling, vibrating, or buzzing sensation in the area of pain. It has been used in both acute and chronic pain relief and is thought to decrease pain by stimulating the nonpain receptors in the same area as the fibers that transmit the pain. This mechanism is consistent with the gate control theory of pain and explains the effectiveness of cutaneous stimulation when applied in the same area as an injury. For example, when TENS is used in a postoperative patient, the electrodes are placed around the surgical wound. Other possible explanations for the effectiveness of TENS are the placebo effect (the

patient expects it to be effective) and release of endorphins and enkephalins (Adams & Arminio, 2008).

Distraction

Distraction helps relieve both acute and chronic pain (Porth & Matfin, 2009). Distraction, which involves focusing the patient's attention on something other than the pain, may be the mechanism responsible for other effective cognitive techniques. Distraction is thought to reduce the perception of pain by stimulating the descending control system, resulting in fewer painful stimuli being transmitted to the brain. The effectiveness of distraction depends on the patient's ability to receive and create sensory input other than pain. Distraction techniques may range from simple activities, such as watching TV or listening to music, to highly complex physical and mental exercises. Pain relief generally increases in direct proportion to the patient's active participation, the number of sensory modalities used, and interest in the stimuli. Therefore, the stimulation of sight, sound, and touch is likely to be more effective in reducing pain than is the stimulation of a single sense.

Visits from family and friends can be effective in relieving pain. Watching an action-packed movie on a large screen through headphones may be effective (provided the patient finds it acceptable). Others may benefit from games and activities (eg, chess, crossword puzzles) that require concentration. Not all patients obtain pain relief with distraction, especially those in severe pain. Severe pain may prevent patients from concentrating well enough to participate in complex physical or mental activities.

Relaxation Techniques

Skeletal muscle relaxation is believed to reduce pain by relaxing tense muscles that contribute to the pain. Research findings support the use of relaxation in relieving postoperative pain. Kwekkeboom, Wanta, and Bumpus (2008) reported greater pain control and less pain intensity among patients with cancer who used relaxation techniques compared to those who did not use these techniques.

A simple relaxation technique consists of abdominal breathing at a slow, rhythmic rate. The patient may close both eyes and breathe slowly and comfortably. A constant rhythm can be maintained by counting silently and slowly with each inhalation ("in, two, three") and exhalation ("out, two, three"). When teaching this technique, the nurse may count out loud with the patient at first. Slow, rhythmic breathing may also be used as a distraction technique. Relaxation techniques, as well as other noninvasive pain relief measures, may require practice before the patient becomes skilled in using them. Patients who already know a relaxation technique may need to be reminded to use it to reduce or prevent increased pain.

Almost all people with chronic pain benefit from some method of relaxation. Regular relaxation periods may help combat the fatigue and muscle tension that occur with and increase chronic pain.

Guided Imagery

Guided imagery is using one's imagination to achieve a specific positive effect. Guided imagery for relaxation and pain relief may consist of combining slow, rhythmic breathing

with a mental image of relaxation and comfort (Kwekkeboom, et al., 2008). The nurse instructs the patient to close both eyes and breathe slowly in and out. With each slowly exhaled breath, the patient imagines muscle tension and discomfort being breathed out, carrying away pain and tension and leaving behind a relaxed and comfortable body. With each inhaled breath, the patient imagines healing energy flowing to the area of discomfort.

If guided imagery is to be effective, it requires a considerable amount of time to explain the technique and time for the patient to practice it. Usually, the patient is asked to practice guided imagery for about 5 minutes, three times a day. Several days of practice may be needed before the intensity of pain is reduced. Many patients experience the relaxing effects of guided imagery the first time they try it. Pain relief can continue for hours after the imagery is used. Patients should be informed that guided imagery may work only for some people; it should be used only in combination with other forms of treatment that have demonstrated effectiveness.

Hypnosis

Hypnosis, which has been effective in relieving pain or decreasing the amount of analgesic agents required in patients with acute and chronic pain, may promote pain relief in particularly difficult situations (eg, burns). The mechanism by which hypnosis acts is unclear. Its effectiveness depends on the hypnotic susceptibility of the individual (DePascalis, Bellusci, Gallo, et al., 2004). In some cases, hypnosis may be effective in the first session, with effectiveness increasing in additional sessions. In other cases, hypnosis does not work at all. Usually, hypnosis must be induced by specially skilled people (a psychologist or a nurse with specialized training in hypnosis). Some patients may learn to perform self-hypnosis.

Music Therapy

Music therapy is an inexpensive and effective therapy for the reduction of pain and anxiety. Research among elderly Korean and American women who had gynecologic surgery demonstrated decreased pain among those patients who received a music therapy intervention (Good & Sukhee, 2008).

Alternative Therapies

People suffering chronic, debilitating pain are often desperate. They may try anything, recommended by anyone, at any price. Information about an array of potential therapies can be found on the Internet and in the self-help section of many bookstores. Therapies recommended for pain from these sources include, but are not limited to, chelation, therapeutic touch, herbal therapy, reflexology, magnetic therapy, electrotherapy, polarity therapy, acupressure, emu oil, pectin therapy, aromatherapy, homeopathy, and macrobiotic dieting. Many of these "therapies" (with the exception of macrobiotic dieting) are probably not harmful. However, they have yet to be proved effective by the standards used to evaluate the effectiveness of medical and nursing interventions. The National Institutes of Health has established an office to examine the effectiveness of complementary and alternative therapies.

Despite the lack of scientific evidence that these alternative therapies are effective, patients may find any one of them helpful via the placebo response. Problems arise when

patients do not obtain relief but are deprived of conventional therapy because the alternative therapy “should be helping,” or when patients abandon conventional therapy for alternative therapy. In addition, few alternative therapies are free. Desperate patients may risk financial ruin seeking alternative therapies that are ineffective.

It is important when caring for patients who are using or considering using untested therapies (often referred to as alternative therapies) not to diminish the patient’s hope and the potential placebo response. This must be weighed against the nurse’s responsibility to protect the patient from costly and potentially harmful and dangerous therapies that the patient is not in a position to evaluate scientifically.

Nurses should help patients and families understand scientific research and how it differs from anecdotal evidence. Without diminishing the placebo effects that may occur, the nurse encourages the patient to assess the effectiveness of the therapy, continually using standard pain assessment techniques. In addition, patients are encouraged to combine alternative therapies with conventional therapies.

Neurologic and Neurosurgical Approaches to Pain Management

In some situations, especially with long-term and severe intractable pain, usual pharmacologic and comfort methods of pain relief are ineffective. In those situations, neurologic and neurosurgical approaches to pain management may be considered. Intractable pain refers to pain that cannot be relieved satisfactorily by the usual approaches, including medications. Such pain often is the result of malignancy (especially of the cervix, bladder, prostate, and lower bowel), but it may occur in other conditions, such as postherpetic neuralgia, trigeminal neuralgia, spinal cord arachnoiditis, and uncontrollable ischemia and other forms of tissue destruction.

Neurologic and neurosurgical methods available for pain relief include (1) stimulation procedures (intermittent electrical stimulation of a tract or center to inhibit the transmission of pain impulses), (2) administration of intraspinal opioids (see previous discussion), and (3) interruption of the tracts conducting the pain impulse from the periphery to cerebral integration centers. Stimulation of nerves with minute amounts of electricity is used if other pharmacologic and nonpharmacologic treatments fail to provide adequate relief. These treatments are reversible. If they need to be discontinued, the nervous system continues to function. However, methods that involve interruption of the tracts are destructive procedures. They are used only after other methods of pain relief have failed, because their effects are permanent.

Stimulation Procedures

Electrical stimulation, or neuromodulation, is a method of suppressing pain by applying controlled low-voltage electrical pulses to the different parts of the nervous system. Electrical stimulation is thought to block painful stimuli (the gate control theory). This pain-modulating technique is administered by many modes. TENS (discussed earlier) and dorsal spinal cord stimulation are the most common types of electrical stimulation used. There are also brain-stimulating techniques, in which electrodes are implanted in the

periventricular area of the posterior third ventricle, allowing the patient to stimulate this area to produce analgesia.

Spinal cord stimulation is a technique used for the relief of chronic, intractable pain; ischemic pain; and pain from angina. A surgically implanted device allows the patient to apply pulsed electrical stimulation to the dorsal aspect of the spinal cord to block pain impulses (Varma, 2005). (The largest accumulation of afferent fibers is found in the dorsal column of the spinal cord.) The dorsal column stimulation unit consists of a radiofrequency stimulation transmitter, a transmitter antenna, a radiofrequency receiver, and a stimulation electrode. The battery-powered transmitter and antenna are worn externally; the receiver and electrode are implanted. A laminectomy, which is the surgical removal of a posterior portion of the vertebra, is performed above the highest level of pain input, and the electrode is placed in the epidural space over the posterior column of the spinal cord. (The placement of the stimulating systems varies.) A subcutaneous pocket is created over the clavicular area or at some other site for placement of the receiver. The two are connected through a subcutaneous tunnel. Careful patient selection is necessary, and not all patients receive total pain relief.

Deep brain stimulation is performed for special pain problems if there is no response to the usual techniques of pain control. Under local anesthesia, electrodes are introduced through a burr hole in the skull and inserted into a selected site in the brain, depending on the location or type of pain. After the effectiveness of stimulation is confirmed, the implanted electrode is connected to a radiofrequency device or pulse-generator system operated by external telemetry (Varma, 2005). It is used for patients with neuropathic pain that may be caused by damage or injury from a stroke, brain or spinal cord injuries, or phantom limb pain. Use of deep brain stimulation is effective for chronic cluster headaches (Magis, Allena, DePasqua, et al., 2007).

Interruption of Pain Pathways

Pain-conducting fibers can be interrupted at any point from their origin to the cerebral cortex. Some part of the nervous system is destroyed, resulting in varying amounts of neurologic deficit and incapacity. In time, pain usually returns due to either regeneration of axonal fibers or the development of alternative pain pathways. Destructive procedures used to interrupt the transmission of pain include cordotomy and rhizotomy. These procedures are offered if it is thought that the patient is near the end of life and the procedure will result in an improved quality of life (Varma, 2005). Often these procedures can provide pain relief for the duration of the patient’s life. The use of other methods to interrupt pain transmission is decreasing, because intraspinal therapies and newer pain management treatments are available.

Cordotomy

Cordotomy is the division of certain tracts of the spinal cord (Fig. 13-8). It may be performed percutaneously, by the open method after laminectomy, or by other techniques. Cordotomy is performed to interrupt the transmission of pain. Care is taken to destroy only the sensation of pain, leaving motor functions intact.

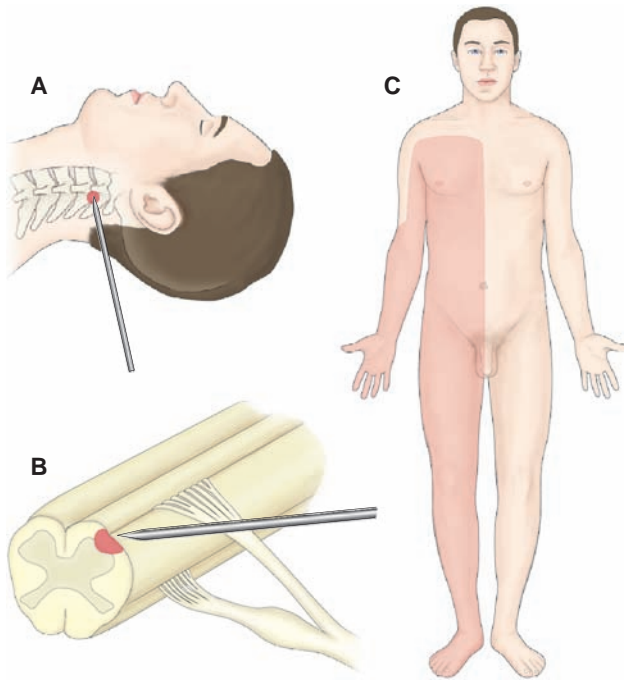

Figure 13-8 A, Site of percutaneous C1-C2 cordotomy. B, Lesion produced by percutaneous C1-C2 cordotomy. C, Extent of analgesia produced by left C1-C2 percutaneous cordotomy.

Rhizotomy

Sensory nerve roots are destroyed where they enter the spinal cord. A lesion is made in the dorsal root to destroy neuronal dysfunction and reduce nociceptive input. With the advent of microsurgical techniques, the complications are few, with mild sensory deficits and mild weakness (Fig. 13-9).

Nursing Interventions

With each of these procedures, the patient is provided with written and verbal instructions about the intervention's expected effect on pain and on possible untoward consequences. The patient is monitored for specific effects of each method of pain intervention, both positive and negative. The specific nursing care of patients who undergo neurologic and neurosurgical procedures for the relief of chronic pain depends on the type of procedure performed, its effectiveness in relieving the pain, and the changes in neurologic function that accompany the procedure. After the procedure, the patient's pain level and neurologic function are assessed. Other nursing interventions that may be indicated include positioning, turning and skin care, bowel and bladder management, and interventions to promote patient safety. Pain management remains an important aspect of nursing care with each of these procedures.

Evaluating Pain Management Strategies

An important aspect of caring for patients in pain is reassessing the pain after the intervention has been implemented. Its effectiveness is based on the patient's assess-

ment of pain, using pain assessment tools. If the intervention was ineffective, the nurse should consider other measures. If these are ineffective, pain relief goals need to be reassessed in collaboration with the physician. The nurse serves as the patient's advocate in obtaining additional pain relief.

After interventions have had a chance to work, the nurse asks the patient to rate the intensity of pain. The nurse repeats this assessment at appropriate intervals after the intervention and compares the result with the previous rating. These assessments indicate the effectiveness of the pain relief measures and provide a basis for continuing or modifying the plan of care. A plan of nursing care for a patient with pain is given in Chart 13-10. Expected patient outcomes include the following:

Relief of pain, evidenced when the patient

- Rates pain at a lower intensity (on a scale of 0 to 10) after intervention
- Rates pain at a lower intensity for longer periods

Correct administration of prescribed analgesic medications, evidenced when the patient or family

- States correct dose of medication
- Administers correct dose using correct procedure
- Identifies side effects of medication

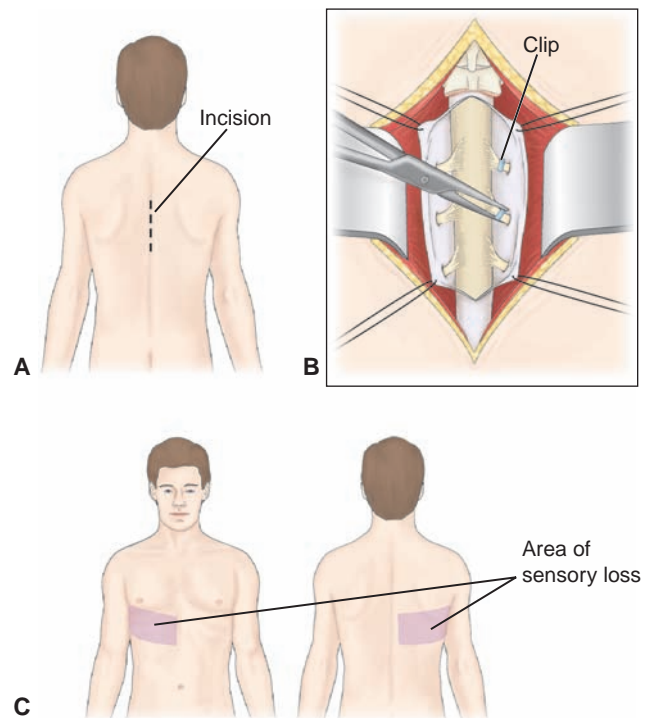

Figure 13-9 A rhizotomy may be performed surgically, percutaneously, or chemically, depending on a patient's condition and needs. The procedure is usually performed to relieve severe chest pain, for example, from lung cancer. In a surgical rhizotomy (A), the spinal roots (B) are divided and banded with a clip to form a lesion and produce subsequent loss of sensation (C). Adapted with permission from Loeser, J. D. (Ed.) (2000). *Bonica's management of pain* (3rd ed.). Philadelphia: Lippincott Williams & Wilkins.

 CHART
13-10

PLAN OF NURSING CARE
Care of the Patient With Pain
NURSING DIAGNOSIS: Pain**GOAL:** Relief of pain or decrease in intensity of pain

Nursing Interventions	Rationale	Expected Outcomes
<ol style="list-style-type: none"> 1. Reassure patient that you know pain is real and will assist him or her in dealing with it. 2. Use pain assessment scale to identify intensity of pain. 3. Assess and record pain and its characteristics: intensity, location, quality, frequency, and duration. 4. Administer balanced analgesic agents as prescribed to promote optimal pain relief. 5. Readminister pain assessment scale. 6. Document severity of patient's pain on chart. 7. Obtain additional prescriptions as needed. 8. Identify and encourage patient to use strategies that have been successful with previous pain. 9. Teach patient additional strategies to relieve pain and discomfort: distraction, relaxation, cutaneous stimulation, etc. 10. Instruct patient and family about potential side effects of analgesic agents and their prevention and management. 	<ol style="list-style-type: none"> 1. Fear that pain will not be accepted as real increases tension and anxiety and decreases pain tolerance. 2. A pain assessment scale provides baseline for assessing changes in pain level and evaluating interventions. 3. Data assist in evaluating pain and pain relief and identifying multiple sources and types of pain. 4. Analgesic agents are more effective if administered early in the pain cycle. Simultaneous use of analgesic agents that work on different portions of the nociceptive system will provide greater pain relief with fewer side effects. 5. This permits assessment of effectiveness of analgesia and identifies need for further action if ineffective. 6. This assists in demonstrating the need for additional analgesic agents or alternative approach to pain management. 7. Inadequate pain relief results in an increased stress response, suffering, and prolonged hospitalizations. 8. This encourages use of pain relief strategies familiar to and accepted by patient. 9. Use of these strategies along with analgesia may produce more effective pain relief. 10. Anticipating and preventing side effects enable the patient to continue analgesia without interruption because of side effects. 	<ul style="list-style-type: none"> • Reports relief that pain is accepted as real and that he or she will receive assistance in pain relief • Reports lower intensity of pain and discomfort after interventions implemented • Reports less disruption from pain and discomfort after use of intervention • Uses pain medication as prescribed • Identifies effective pain relief strategies • Demonstrates use of new strategies to relieve pain and reports their effectiveness • Experiences minimal side effects of analgesia without interruption to treat side effects • Increases interactions with family and friends

- Describes actions taken to prevent or correct side effects

Use of nonpharmacologic pain strategies as recommended, evidenced when the patient:

- Reports practice of nonpharmacologic strategies
- Describes expected outcomes of nonpharmacologic strategies

Minimal effects of pain and minimal side effects of interventions, evidenced when the patient:

- Participates in activities important to recovery (eg, drinking fluids, coughing, ambulating)
- Participates in activities important to self and to family (eg, family activities, interpersonal relationships, parenting, social interaction, recreation, work)
- Reports adequate sleep and absence of fatigue and constipation

CRITICAL THINKING EXERCISES

EBP 1 A 44-year-old man is admitted to a university hospital with a traumatic amputation of his left lower leg as a result of a motor vehicle crash. He is transferred to an orthopedic unit postoperatively after emergent débridement and revision of his stump. He received 2 mg of morphine IV prior to leaving the postanesthesia care unit 45 minutes ago. After assessing his vital signs and incisional dressing, the nurse notes that the patient rates his pain intensity as an 8 on a 0-to-10 scale (0 = no pain and 10 = pain as bad as could be). His analgesia orders include IV morphine delivered by PCA pump with a basal rate of 1 mg/h and additional 1 to 2 mg that may be delivered on demand (ie, self-administered) with a lock-out set so that

no more than 4 mg may be administered per hour. Identify the evidence base and strength of the evidence that would guide the nurse to decide how much morphine to administer to this patient.

2 An 85-year-old woman is admitted to a medical-surgical unit complaining of a sudden onset of very sharp and severe pain in her left flank. A computed tomography scan revealed renal calculi in her left ureter. Upon the initial nursing assessment, the patient is noted to be grimacing and gently rocking side to side on the bed. She does not respond to questions about whether or not she is experiencing pain. Rather, she reaches for her IV catheter and attempts to pull it out. Attempts to orient the patient fail. What methods would you recommend to assess this patient's pain? Describe how you would address pain relief for this patient and give the rationale for your actions. Who would you consult to help with this patient's pain management?

EBP 3 A 22-year-old man is admitted to the hospital after a motor vehicle crash. He has a Glasgow Coma Scale score of 7. He is intubated and placed on a ventilator to provide adequate oxygenation. He has multiple lacerations and contusions on his arms and legs. A computed tomography scan shows large hematomas to the front and back of his skull. Discuss how pain can be assessed and managed for this patient. The resident physician tells you not to administer any analgesic medications to this patient because it might hamper performing a neurologic examination. What is the strength of the evidence that either supports or refutes withholding analgesic medications from patients with these types of injuries?

Fluid and Electrolytes: Balance and Disturbance

LEARNING OBJECTIVES

On completion of this chapter, the learner will be able to:

- 1 Differentiate between osmosis, diffusion, filtration, and active transport.
- 2 Describe the role of the kidneys, lungs, and endocrine glands in regulating the body's fluid composition and volume.
- 3 Identify the effects of aging on fluid and electrolyte regulation.
- 4 Plan effective care of patients with the following imbalances: fluid volume deficit and fluid volume excess; sodium deficit (hyponatremia) and sodium excess (hypernatremia); potassium deficit (hypokalemia) and potassium excess (hyperkalemia).
- 5 Describe the cause, clinical manifestations, management, and nursing interventions for the following imbalances: calcium deficit (hypocalcemia) and calcium excess (hypercalcemia); magnesium deficit (hypomagnesemia) and magnesium excess (hypermagnesemia); phosphorus deficit (hypophosphatemia) and phosphorus excess (hyperphosphatemia); chloride deficit (hypochloremia) and chloride excess (hyperchloremia).
- 6 Explain the roles of the lungs, kidneys, and chemical buffers in maintaining acid–base balance.
- 7 Compare metabolic acidosis and alkalosis with regard to causes, clinical manifestations, diagnosis, and management.
- 8 Compare respiratory acidosis and alkalosis with regard to causes, clinical manifestations, diagnosis, and management.
- 9 Interpret arterial blood gas measurements.
- 10 Identify a safe and effective procedure of venipuncture.
- 11 Describe measures used for preventing complications of intravenous therapy.

GLOSSARY

- acidosis:** an acid–base imbalance characterized by an increase in H^+ concentration (decreased blood pH). A low arterial pH due to reduced bicarbonate concentration is called metabolic acidosis; a low arterial pH due to increased PCO_2 is respiratory acidosis
- active transport:** physiologic pump that moves fluid from an area of lower concentration to one of higher concentration; active transport requires adenosine triphosphate for energy
- alkalosis:** an acid–base imbalance characterized by a reduction in H^+ concentration (increased blood pH). A high arterial pH with increased bicarbonate concentration is called metabolic alkalosis; a high arterial pH due to reduced PCO_2 is respiratory alkalosis
- diffusion:** the process by which solutes move from an area of higher concentration to one of lower concentration; does not require expenditure of energy
- homeostasis:** maintenance of a constant internal equilibrium in a biologic system that involves positive and negative feedback mechanisms
- hydrostatic pressure:** the pressure created by the weight of fluid against the wall that contains it. In the body, hydrostatic pressure in blood vessels results from the weight of fluid itself and the force resulting from cardiac contraction
- hypertonic solution:** a solution with an osmolality higher than that of serum
- hypotonic solution:** a solution with an osmolality lower than that of serum
- isotonic solution:** a solution with the same osmolality as serum and other body fluids. Osmolality falls within normal range for serum (280 to 300 mOsm/kg)
- osmolality:** the number of osmoles (the standard unit of osmotic pressure) per kilogram of solution. Expressed as mOsm/kg, osmolality is used more often than the term *osmolarity* to evaluate serum and urine
- osmolarity:** the number of osmoles (the standard unit of osmotic pressure) per liter of solution. It is expressed as milliosmoles per liter (mOsm/L); describes the concentration of solutes or dissolved particles
- osmosis:** the process by which fluid moves across a semipermeable membrane from an area of low solute concentration to an area of high solute concentration; the process continues until the solute concentrations are equal on both sides of the membrane
- tonicity:** fluid tension within the extracellular fluid or intracellular fluid that describes the relationship between the solutes and water, primarily determined by fluid osmolality

Fluid and electrolyte balance is a dynamic process that is crucial for life and **homeostasis**. Potential and actual disorders of fluid and electrolyte balance occur in every setting, with every disorder, and with a variety of changes that affect healthy people (eg, increased fluid and sodium loss with strenuous exercise and high environmental temperature, inadequate intake of fluid and electrolytes) as well as those who are ill.

Fundamental Concepts

Nurses need an understanding of the physiology of fluid and electrolyte balance and acid–base balance to anticipate, identify, and respond to possible imbalances. Nurses also must use effective teaching and communication skills to help prevent and treat various fluid and electrolyte disturbances.

Amount and Composition of Body Fluids

Approximately 60% of the weight of a typical adult consists of fluid (water and electrolytes). Factors that influence the amount of body fluid are age, gender, and body fat. In general, younger people have a higher percentage of body fluid than older people, and men have proportionately more body fluid than women. People who are obese have less fluid than those who are thin, because fat cells contain little water. The skeleton also has a low water content. Muscle, skin, and blood have the highest amount of water.

Body fluid is located in two fluid compartments: the intracellular space (fluid in the cells) and the extracellular space (fluid outside the cells). Approximately two thirds of body fluid is in the intracellular fluid (ICF) compartment and is located primarily in the skeletal muscle mass. Approximately one third is in the extracellular fluid (ECF) compartment.

The ECF compartment is further divided into the intravascular, interstitial, and transcellular fluid spaces. Circulatory and neurologic symptoms, physical examination findings, and laboratory test results can be used to identify the compartment from which fluid is lost (McPhee, Papadakis & Tierney, 2007). The intravascular space (the fluid within the blood vessels) contains plasma, the effective circulating volume. Approximately 3 L of the average 6 L of blood volume is made up of plasma. The remaining 3 L is made up of erythrocytes, leukocytes, and thrombocytes. The interstitial space contains the fluid that surrounds the cell and totals about 11 to 12 L in an adult. Lymph is an interstitial fluid. The transcellular space is the smallest division of the ECF compartment and contains approximately 1 L. Examples of transcellular fluids include cerebrospinal, pericardial, synovial, intraocular, and pleural fluids; sweat; and digestive secretions. As the next section describes, the ECF transports electrolytes; it also carries other substances, such as enzymes and hormones.

Body fluid normally moves between the two major compartments or spaces in an effort to maintain an equilibrium between the spaces. Loss of fluid from the body can disrupt this equilibrium. Sometimes fluid is not lost from the body but is unavailable for use by either the ICF or ECF. Loss of ECF into a space that does not contribute to equilibrium

between the ICF and the ECF is referred to as a third-space fluid shift, or “third spacing” for short (Holcomb, 2008).

Early evidence of a third-space fluid shift is a decrease in urine output despite adequate fluid intake. Urine output decreases because fluid shifts out of the intravascular space; the kidneys then receive less blood and attempt to compensate by decreasing urine output. Other signs and symptoms of third spacing that indicate an intravascular fluid volume deficit include increased heart rate, decreased blood pressure, decreased central venous pressure, edema, increased body weight, and imbalances in fluid intake and output (I&O). Third-space shifts occur in patients who have hypocalcemia, decreased iron intake, severe liver diseases, alcoholism, hypothyroidism, malabsorption, immobility, burns, and cancer (Holcomb, 2008).

Electrolytes

Electrolytes in body fluids are active chemicals (cations that carry positive charges and anions that carry negative charges). The major cations in body fluid are sodium, potassium, calcium, magnesium, and hydrogen ions. The major anions are chloride, bicarbonate, phosphate, sulfate, and proteinate ions.

These chemicals unite in varying combinations. Therefore, electrolyte concentration in the body is expressed in terms of milliequivalents (mEq) per liter, a measure of chemical activity, rather than in terms of milligrams (mg), a unit of weight. More specifically, a milliequivalent is defined as being equivalent to the electrochemical activity of 1 mg of hydrogen. In a solution, cations and anions are equal in milliequivalents per liter.

Electrolyte concentrations in the ICF differ from those in the ECF, as reflected in Table 14-1. Because special tech-

Table 14-1 APPROXIMATE MAJOR ELECTROLYTE CONTENT IN BODY FLUID

niques are required to measure electrolyte concentrations in the ICF, it is customary to measure the electrolytes in the most accessible portion of the ECF, namely, the plasma.

Sodium ions, which are positively charged, far outnumber the other cations in the ECF. Because sodium concentration affects the overall concentration of the ECF, sodium is important in regulating the volume of body fluid. Retention of sodium is associated with fluid retention, and excessive loss of sodium is usually associated with decreased volume of body fluid.

As shown in Table 14-1, the major electrolytes in the ICF are potassium and phosphate. The ECF has a low concentration of potassium and can tolerate only small changes in potassium concentrations. Therefore, release of large stores of intracellular potassium, typically caused by trauma to the cells and tissues, can be extremely dangerous.

The body expends a great deal of energy maintaining the high extracellular concentration of sodium and the high intracellular concentration of potassium. It does so by means of cell membrane pumps that exchange sodium and potassium ions. Normal movement of fluids through the capillary wall into the tissues depends on **hydrostatic pressure** (the pressure exerted by the fluid on the walls of the blood vessel) at both the arterial and the venous ends of the vessel and the osmotic pressure exerted by the protein of plasma. The direction of fluid movement depends on the differences in these two opposing forces (hydrostatic versus osmotic pressure).

Regulation of Body Fluid Compartments

Osmosis and Osmolality

When two different solutions are separated by a membrane that is impermeable to the dissolved substances, fluid shifts through the membrane from the region of low solute concentration to the region of high solute concentration until the solutions are of equal concentration. This diffusion of water caused by a fluid concentration gradient is known as **osmosis** (Fig. 14-1A). The magnitude of this force depends on the number of particles dissolved in the solutions, not on their weights. The number of dissolved particles contained in a unit of fluid determines the osmolality of a solution, which influences the movement of fluid between the fluid compartments (Goertz, 2006). **Tonicity** is the ability of all the solutes to cause an osmotic driving force that promotes water movement from one compartment to another. The control of tonicity determines the normal state of cellular hydration and cell size. Sodium, mannitol, glucose, and sorbitol are effective osmoles (capable of affecting water movement). Three other terms are associated with osmosis: osmotic pressure, oncotic pressure, and osmotic diuresis.

- Osmotic pressure is the amount of hydrostatic pressure needed to stop the flow of water by osmosis. It is

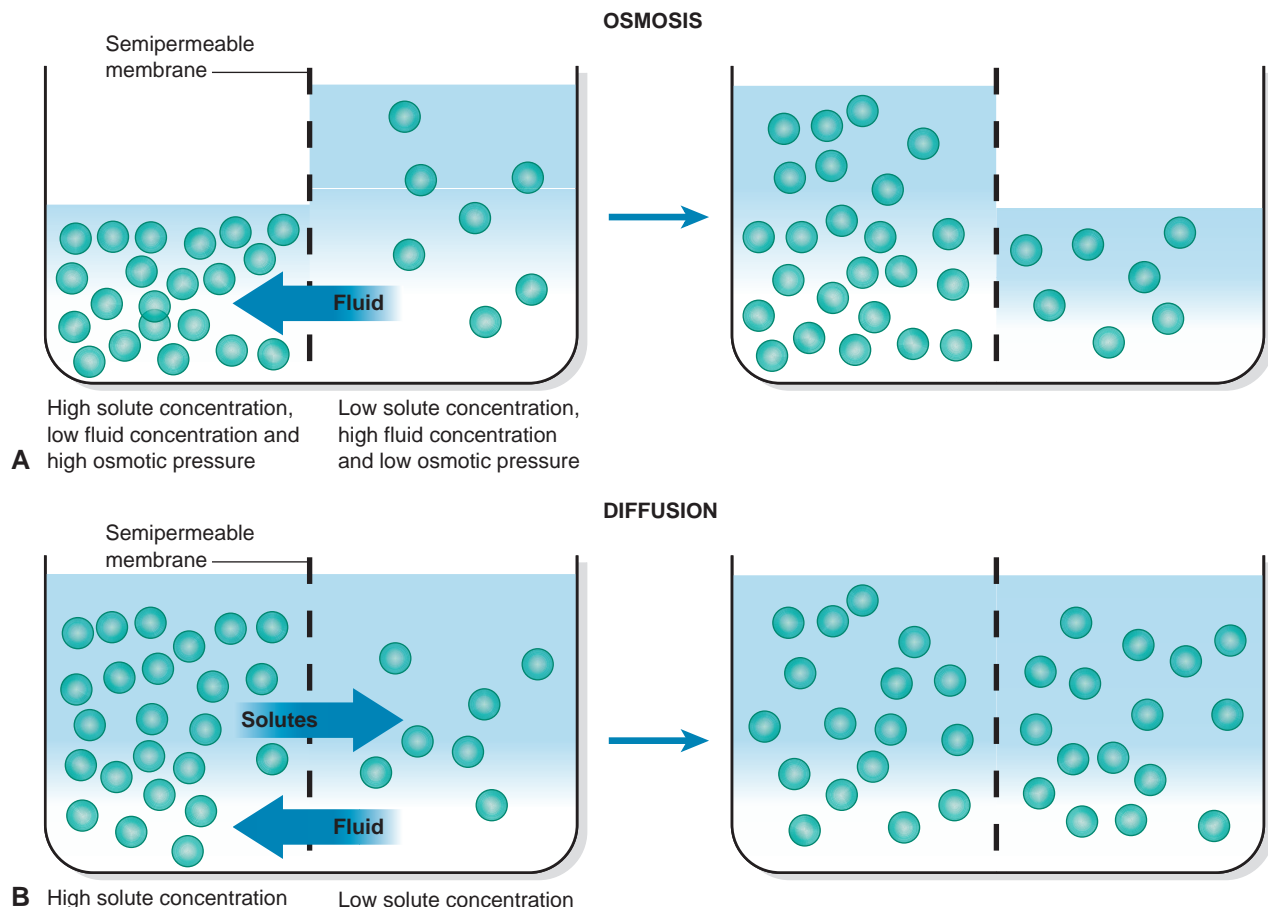

Figure 14-1 **A**, Osmosis: movement of fluid from an area of lower solute concentration to an area of higher solute concentration with eventual equalization of the solute concentrations. **B**, Diffusion: movement of solutes from an area of greater concentration to an area of lesser concentration, leading ultimately to equalization of the solute concentrations.

primarily determined by the concentration of solutes.

- Oncotic pressure is the osmotic pressure exerted by proteins (eg, albumin).
- Osmotic diuresis is the increase in urine output caused by the excretion of substances such as glucose, mannitol, or contrast agents in the urine.

Diffusion

Diffusion is the natural tendency of a substance to move from an area of higher concentration to one of lower concentration (see Fig. 14-1B). It occurs through the random movement of ions and molecules (Porth & Matfin, 2009). Examples of diffusion are the exchange of oxygen and carbon dioxide between the pulmonary capillaries and alveoli and the tendency of sodium to move from the ECF compartment, where the sodium concentration is high, to the ICF, where its concentration is low.

Filtration

Hydrostatic pressure in the capillaries tends to filter fluid out of the intravascular compartment into the interstitial fluid. Movement of water and solutes occurs from an area of high hydrostatic pressure to an area of low hydrostatic pressure. The kidneys filter approximately 180 L of plasma per day. Another example of filtration is the passage of water and electrolytes from the arterial capillary bed to the interstitial fluid; in this instance, the hydrostatic pressure results from the pumping action of the heart.

Sodium–Potassium Pump

As previously stated, the sodium concentration is greater in the ECF than in the ICF, and because of this, sodium tends to enter the cell by diffusion. This tendency is offset by the sodium–potassium pump that is maintained by the cell membrane and actively moves sodium from the cell into the ECF. Conversely, the high intracellular potassium concentration is maintained by pumping potassium into the cell. By definition, **active transport** implies that energy must be expended for the movement to occur against a concentration gradient.

Systemic Routes of Gains and Losses

Water and electrolytes are gained in various ways. Healthy people gain fluids by drinking and eating, and their daily average intake and output of water are approximately equal (Table 14-2).

Table 14-2 AVERAGE DAILY INTAKE AND OUTPUT IN AN ADULT

Intake (mL)		Output (mL)	
Oral liquids	1300	Urine	1500
Water in food	1000	Stool	200
Water produced by metabolism	300	Insensible	
		Lungs	300
		Skin	600
Total gain*	2600	Total loss*	2600

*Approximate volumes.

NURSING ALERT

When fluid balance is critical, all routes of systemic gain and loss must be recorded and all volumes compared. Organs of fluid loss include the kidneys, skin, lungs, and gastrointestinal (GI) tract.

Kidneys

The usual daily urine volume in the adult is 1 to 2 L. A general rule is that the output is approximately 1 mL of urine per kilogram of body weight per hour (1 mL/kg/h) in all age groups.

Skin

Sensible perspiration refers to visible water and electrolyte loss through the skin (sweating). The chief solutes in sweat are sodium, chloride, and potassium. Actual sweat losses can vary from 0 to 1000 mL or more every hour, depending on factors such as the environmental temperature. Continuous water loss by evaporation (approximately 600 mL/day) occurs through the skin as insensible perspiration, a nonvisible form of water loss. Fever greatly increases insensible water loss through the lungs and the skin, as does loss of the natural skin barrier (eg, through major burns).

Lungs

The lungs normally eliminate water vapor (insensible loss) at a rate of approximately 300 mL every day. The loss is much greater with increased respiratory rate or depth, or in a dry climate.

Gastrointestinal Tract

The usual loss through the GI tract is 100 to 200 mL daily, even though approximately 8 L of fluid circulates through the GI system every 24 hours. Because the bulk of fluid is normally reabsorbed in the small intestine, diarrhea and fistulas cause large losses.

Laboratory Tests for Evaluating Fluid Status

Osmolality is the concentration of fluid that affects the movement of water between fluid compartments by osmosis. Osmolality measures the solute concentration per kilogram in blood and urine. It is also a measure of a solution's ability to create osmotic pressure and affect the movement of water. Serum osmolality primarily reflects the concentration of sodium, although blood urea nitrogen (BUN) and glucose also play a major role in determining serum osmolality. Urine osmolality is determined by urea, creatinine, and uric acid. When measured with serum osmolality, urine osmolality is the most reliable indicator of urine concentration. Osmolality is reported as milliosmoles per kilogram of water (mOsm/kg) (Goertz, 2006).

In healthy adults, serum osmolality is 280 to 300 mOsm/kg, and normal urine osmolality is 200 to 800 mOsm/kg (Goertz, 2006). Sodium predominates in ECF osmolality and holds water in this compartment. Factors that increase and decrease serum and urine osmolality are identified in Chart 14-1. Serum osmolality may be measured directly through laboratory tests or estimated at the

Chart 14-1 • Factors Affecting Serum and Urine Osmolality

Fluid	Factors Increasing Osmolality	Factors Decreasing Osmolality
Serum (280–300 mOsm/kg water)	<ul style="list-style-type: none"> • Severe dehydration • Free water loss • Diabetes insipidus • Hypernatremia • Hyperglycemia • Stroke or head injury • Renal tubular necrosis • Consumption of methanol or ethylene glycol (antifreeze) 	<ul style="list-style-type: none"> • Fluid volume excess • Syndrome of inappropriate antidiuretic hormone (SIADH) • Renal failure • Diuretic use • Adrenal insufficiency • Hyponatremia • Overhydration • Paraneoplastic syndrome associated with lung cancer
Urine (200–800 mOsm/kg water)	<ul style="list-style-type: none"> • Fluid volume deficit • SIADH • Congestive heart failure • Acidosis • Prerenal failure 	<ul style="list-style-type: none"> • Fluid volume excess • Diabetes insipidus • Hyponatremia • Aldosteronism • Pyelonephritis • Acute tubular necrosis

bedside by doubling the serum sodium level or by using the following formula:

$$\text{Na}^+ \times 2 = \frac{\text{Glucose}}{18} + \frac{\text{BUN}}{3}$$

= Approximate value of serum osmolality

Osmolarity, another term that describes the concentration of solutions, is measured in milliosmoles per liter (mOsm/L). However, the term osmolality is used more often in clinical practice. The calculated value usually is within 10 mOsm of the measured osmolality.

Urine specific gravity measures the kidneys' ability to excrete or conserve water. The specific gravity of urine is compared to the weight of distilled water, which has a specific gravity of 1.000. The normal range of urine specific gravity is 1.010 to 1.025. Urine specific gravity can be measured at the bedside by placing a calibrated hydrometer or urinometer in a cylinder of approximately 20 mL of urine. Specific gravity can also be assessed with a refractometer or dipstick with a reagent for this purpose. Specific gravity varies inversely with urine volume; normally, the larger the volume of urine, the lower the specific gravity is. Specific gravity is a less reliable indicator of concentration than urine osmolality; increased glucose or protein in urine can cause a falsely elevated specific gravity. Factors that increase or decrease urine osmolality are the same as those for urine specific gravity.

BUN is made up of urea, which is an end product of the metabolism of protein (from both muscle and dietary intake) by the liver. Amino acid breakdown produces large amounts of ammonia molecules, which are absorbed into the bloodstream. Ammonia molecules are converted to urea and excreted in the urine. The normal BUN is 10 to 20 mg/dL (3.6 to 7.2 mmol/L). The BUN level varies with urine output. Factors that increase BUN include decreased renal function, GI bleeding, dehydration, increased protein intake, fever, and sepsis. Those that decrease BUN include end-stage liver disease, a low-protein diet, starvation, and any condition that results in expanded fluid volume (eg, pregnancy).

Creatinine is the end product of muscle metabolism. It is a better indicator of renal function than BUN because it does not vary with protein intake and metabolic state. The normal serum creatinine is approximately 0.7 to 1.4 mg/dL (62 to 124 mmol/L); however, its concentration depends on lean body mass and varies from person to person. Serum creatinine levels increase when renal function decreases.

Hematocrit measures the volume percentage of red blood cells (erythrocytes) in whole blood and normally ranges from 42% to 52% for males and 35% to 47% for females. Conditions that increase the hematocrit value are dehydration and polycythemia, and those that decrease hematocrit are overhydration and anemia.

Urine sodium values change with sodium intake and the status of fluid volume: As sodium intake increases, excretion increases; as the circulating fluid volume decreases, sodium is conserved. Normal urine sodium levels range from 75 to 200 mEq/24 hours (75 to 200 mmol/24 hours). A random specimen usually contains more than 40 mEq/L of sodium. Urine sodium levels are used to assess volume status and are useful in the diagnosis of hyponatremia and acute renal failure.

Homeostatic Mechanisms

The body is equipped with remarkable homeostatic mechanisms to keep the composition and volume of body fluid within narrow limits of normal. Organs involved in homeostasis include the kidneys, lungs, heart, adrenal glands, parathyroid glands, and pituitary gland (Porth & Matfin, 2009).

Kidney Functions

Vital to the regulation of fluid and electrolyte balance, the kidneys normally filter 180 L of plasma every day in the adult and excrete 1 to 2 L of urine. They act both autonomously and in response to bloodborne messengers, such as aldosterone and antidiuretic hormone (ADH) (Porth & Matfin, 2009). Major functions of the kidneys in maintaining normal fluid balance include the following:

- Regulation of ECF volume and osmolality by selective retention and excretion of body fluids

- Regulation of normal electrolyte levels in the ECF by selective electrolyte retention and excretion
- Regulation of pH of the ECF by retention of hydrogen ions
- Excretion of metabolic wastes and toxic substances

Given these functions, failure of the kidneys results in multiple fluid and electrolyte abnormalities.

Heart and Blood Vessel Functions

The pumping action of the heart circulates blood through the kidneys under sufficient pressure to allow for urine formation. Failure of this pumping action interferes with renal perfusion and thus with water and electrolyte regulation.

Lung Functions

The lungs are also vital in maintaining homeostasis. Through exhalation, the lungs remove approximately 300 mL of water daily in the normal adult. Abnormal conditions, such as hyperpnea (abnormally deep respiration) or continuous coughing, increase this loss; mechanical ventilation with excessive moisture decreases it. The lungs also play a major role in maintaining acid–base balance.

Pituitary Functions

The hypothalamus manufactures ADH, which is stored in the posterior pituitary gland and released as needed to conserve water. Functions of ADH include maintaining the osmotic pressure of the cells by controlling the retention or excretion of water by the kidneys and by regulating blood volume (Fig. 14-2).

Adrenal Functions

Aldosterone, a mineralocorticoid secreted by the zona glomerulosa (outer zone) of the adrenal cortex, has a profound effect on fluid balance. Increased secretion of aldosterone causes sodium retention (and thus water retention) and potassium loss. Conversely, decreased secretion of aldosterone causes sodium and water loss and potassium retention.

Cortisol, another adrenocortical hormone, has less mineralocorticoid action. However, when secreted in large quantities (or administered as corticosteroid therapy), it can also produce sodium and fluid retention.

Parathyroid Functions

The parathyroid glands, embedded in the thyroid gland, regulate calcium and phosphate balance by means of parathyroid hormone (PTH). PTH influences bone resorption, calcium absorption from the intestines, and calcium reabsorption from the renal tubules.

Other Mechanisms

Changes in the volume of the interstitial compartment within the ECF can occur without affecting body function. However, the vascular compartment cannot tolerate change as readily and must be carefully maintained to ensure that tissues receive adequate nutrients.

Baroreceptors

The baroreceptors are located in the left atrium and the carotid and aortic arches. These receptors respond to changes in the circulating blood volume and regulate sym-

pathetic and parasympathetic neural activity as well as endocrine activities (Rottmann, 2007).

As arterial pressure decreases, baroreceptors transmit fewer impulses from the carotid and the aortic arches to the vasomotor center. A decrease in impulses stimulates the sympathetic nervous system and inhibits the parasympathetic nervous system. The outcome is an increase in cardiac rate, conduction, and contractility and an increase in circulating blood volume. Sympathetic stimulation constricts renal arterioles; this increases the release of aldosterone, decreases glomerular filtration, and increases sodium and water reabsorption.

Renin–Angiotensin–Aldosterone System

Renin is an enzyme that converts angiotensinogen, a substance formed by the liver, into angiotensin I (Porth & Matfin, 2009). Renin is released by the juxtaglomerular cells of the kidneys in response to decreased renal perfusion. Angiotensin-converting enzyme (ACE) converts angiotensin I to angiotensin II. Angiotensin II, with its vasoconstrictor properties, increases arterial perfusion pressure and stimulates thirst. As the sympathetic nervous system is stimulated, aldosterone is released in response to an increased release of renin. Aldosterone is a volume regulator and is also released as serum potassium increases, serum sodium decreases, or adrenocorticotrophic hormone (ACTH) increases.

Antidiuretic Hormone and Thirst

ADH and the thirst mechanism have important roles in maintaining sodium concentration and oral intake of fluids. Oral intake is controlled by the thirst center located in the hypothalamus (Porth & Matfin, 2009). As serum concentration or osmolality increases or blood volume decreases, neurons in the hypothalamus are stimulated by intracellular dehydration; thirst then occurs, and the person increases his or her intake of oral fluids. Water excretion is controlled by ADH, aldosterone, and baroreceptors, as mentioned previously. The presence or absence of ADH is the most significant factor in determining whether the urine that is excreted is concentrated or dilute.

Osmoreceptors

Located on the surface of the hypothalamus, osmoreceptors sense changes in sodium concentration. As osmotic pressure increases, the neurons become dehydrated and quickly release impulses to the posterior pituitary, which increases the release of ADH, which then travels in the blood to the kidneys, where it alters permeability to water, causing increased reabsorption of water and decreased urine output. The retained water dilutes the ECF and returns its concentration to normal. Restoration of normal osmotic pressure provides feedback to the osmoreceptors to inhibit further ADH release (see Fig. 14-2).

Release of Atrial Natriuretic Peptide

Atrial natriuretic peptide (ANP), also called atrial natriuretic factor, is a peptide that is synthesized, stored, and released by muscle cells of the atria of the heart in response to several factors. These factors include increased atrial pressure, angiotensin II stimulation, endothelin (a powerful vasoconstrictor of vascular smooth muscle peptide released from damaged endothelial cells in the kidneys or other tissues), and

Physiology ■ ■ Pathophysiology

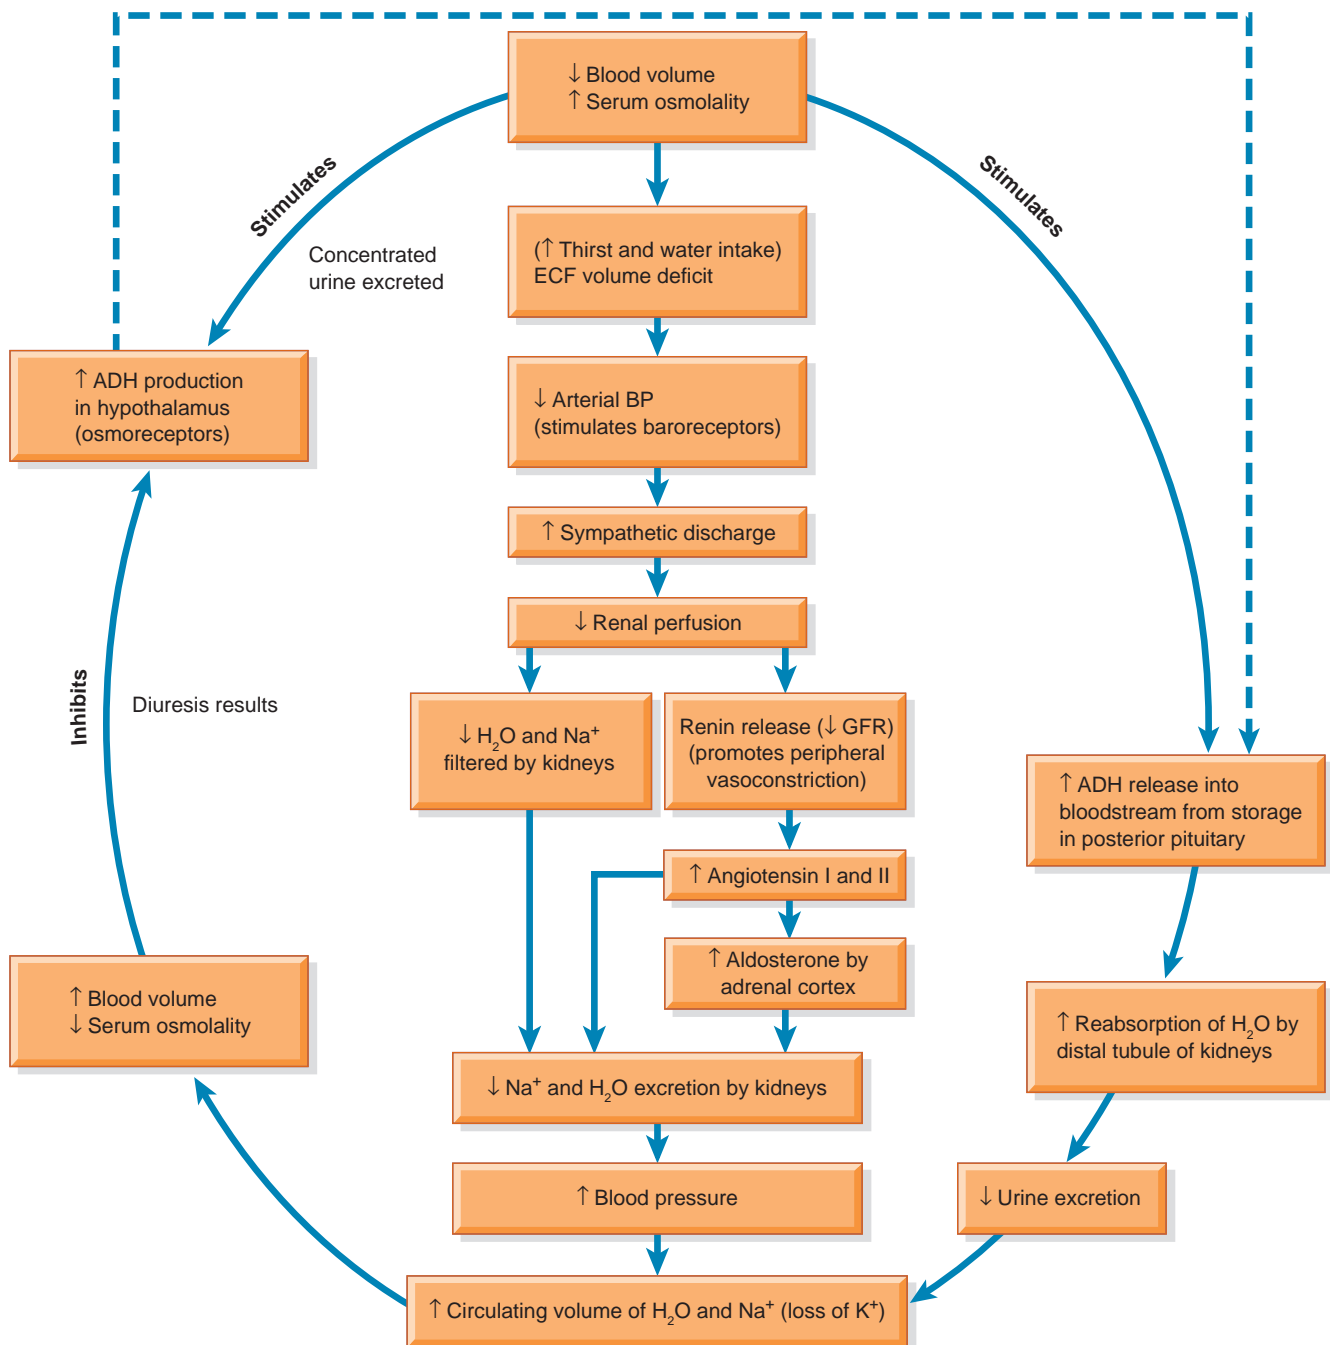

Figure 14-2 Fluid regulation cycle. ADH, antidiuretic hormone; BP, blood pressure; ECF, extracellular fluid; GFR, glomerular filtration rate.

sympathetic stimulation (Porth & Matfin, 2009). In addition, any condition that results in volume expansion (exercise, pregnancy), hypoxia, or increased cardiac filling pressures (eg, high sodium intake, heart failure, chronic renal failure, atrial tachycardia, or use of vasoconstrictor agents such as epinephrine) increases the release of ANP. The action of ANP is the direct opposite of the renin-angiotensin-aldosterone system; ANP decreases blood pressure and volume (Fig. 14-3). The ANP measured in plasma is normally 20 to 77 pg/mL (20 to 77 ng/L). This level in-

creases in acute heart failure, paroxysmal supraventricular tachycardia, hyperthyroidism, subarachnoid hemorrhage, and small cell lung cancer. The level decreases in chronic heart failure and with the use of medications such as urea (Ureaphil) and prazosin (Minipress).

Gerontologic Considerations

Normal physiologic changes of aging, including reduced cardiac, renal, and respiratory function and reserve and alterations in the ratio of body fluids to muscle mass, may

Physiology ■ Pathophysiology

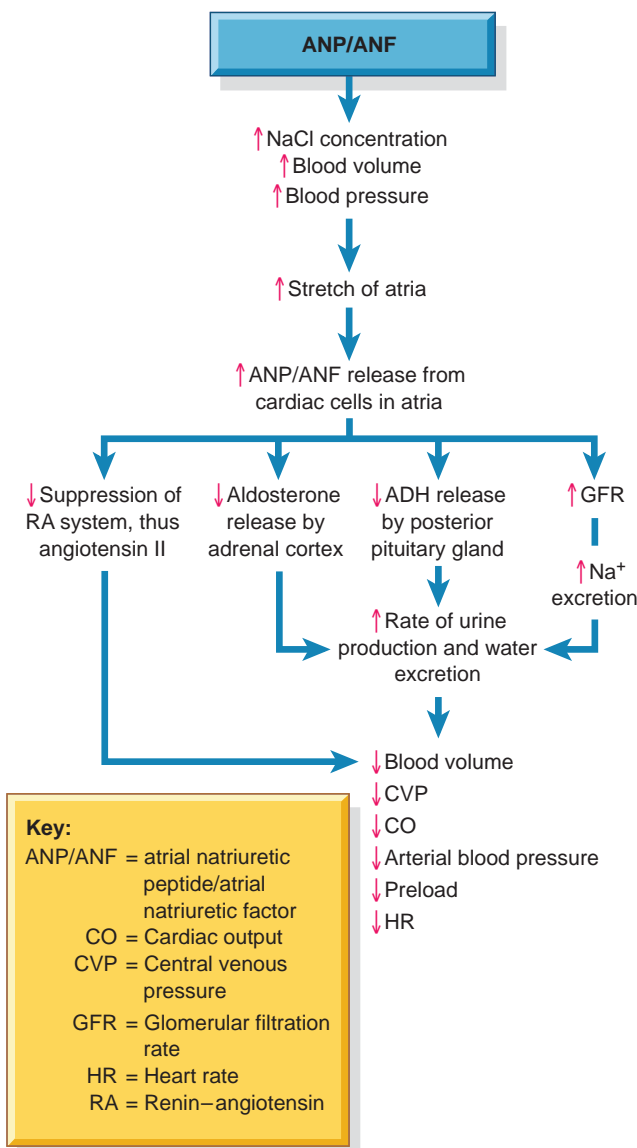

Figure 14-3 Role of ANP in maintenance of fluid balance.

alter the responses of elderly people to fluid and electrolyte changes and acid-base disturbances. Decreased respiratory function can cause impaired pH regulation in older adults with major illness or trauma. Renal function declines with age, as do muscle mass and daily exogenous creatinine production. Therefore, high-normal and minimally elevated serum creatinine values may indicate substantially reduced renal function in older adults.

In addition, the use of multiple medications by older adults can affect renal and cardiac function, thereby increasing the likelihood of fluid and electrolyte disturbances. Routine procedures, such as the vigorous administration of laxatives or enemas before colon x-ray studies, may produce a serious fluid volume deficit, necessitating the use of intra-

venous (IV) fluids to prevent hypotension and other effects of hypovolemia.

Alterations in fluid and electrolyte balance that may produce minor changes in young and middle-aged adults may produce profound changes in older adults. In many elderly patients, the clinical manifestations of fluid and electrolyte disturbances may be subtle or atypical. For example, fluid deficit may cause delirium in the elderly person (see Chapter 12), whereas in the young or middle-aged person the first sign commonly is increased thirst. Rapid infusion of an excessive volume of IV fluids may produce fluid overload and cardiac failure in elderly patients. These reactions are likely to occur more quickly and with the administration of smaller volumes of fluid than in healthy young and middle-aged adults because of the decreased cardiac reserve and reduced renal function that accompany aging. Dehydration in the elderly is common as a result of decreased kidney mass, decreased glomerular filtration rate, decreased renal blood flow, decreased ability to concentrate urine, inability to conserve sodium, decreased excretion of potassium, and a decrease of total body water (Powers & Daly, 2007).

FLUID VOLUME DISTURBANCES

Hypovolemia

Fluid volume deficit (FVD), or hypovolemia, occurs when loss of ECF volume exceeds the intake of fluid. It occurs when water and electrolytes are lost in the same proportion as they exist in normal body fluids, so that the ratio of serum electrolytes to water remains the same. FVD (hypovolemia) should not be confused with dehydration, which refers to loss of water alone, with increased serum sodium levels. FVD may occur alone or in combination with other imbalances. Unless other imbalances are present concurrently, serum electrolyte concentrations remain essentially unchanged.

Pathophysiology

FVD results from loss of body fluids and occurs more rapidly when coupled with decreased fluid intake. FVD can also develop with a prolonged period of inadequate intake. Causes of FVD include abnormal fluid losses, such as those resulting from vomiting, diarrhea, GI suctioning, and sweating; decreased intake, as in nausea or lack of access to fluids (Heitz & Horne, 2005); and third-space fluid shifts, or the movement of fluid from the vascular system to other body spaces (eg, with edema formation in burns, ascites with liver dysfunction). Additional causes include diabetes insipidus, adrenal insufficiency, osmotic diuresis, hemorrhage, and coma.

Clinical Manifestations

FVD can develop rapidly, and its severity depends on the degree of fluid loss. Clinical signs and symptoms include acute weight loss; decreased skin turgor; oliguria; concentrated urine; orthostatic hypotension due to volume depletion; a weak, rapid heart rate; flattened neck veins; increased temperature; thirst; decreased or delayed capillary refill; decreased central venous pressure; cool, clammy, pale skin related to peripheral vasoconstriction; anorexia; nausea; lassitude; muscle weakness; and cramps.

Assessment and Diagnostic Findings

Laboratory data useful in evaluating fluid volume status include BUN and its relation to serum creatinine concentration. A volume-depleted patient has a BUN elevated out of proportion to the serum creatinine (ratio greater than 20:1). The BUN can be elevated because of dehydration or decreased renal perfusion and function. The cause of hypovolemia may be determined through the health history and physical examination. Also, the hematocrit level is greater than normal because there is a decreased plasma volume (Powers & Daly, 2007).

Serum electrolyte changes may also exist. Potassium and sodium levels can be reduced (hypokalemia, hyponatremia) or elevated (hyperkalemia, hypernatremia).

- Hypokalemia occurs with GI and renal losses.
- Hyperkalemia occurs with adrenal insufficiency.
- Hyponatremia occurs with increased thirst and ADH release.
- Hypernatremia results from increased insensible losses and diabetes insipidus.

Urine specific gravity is increased in relation to the kidneys' attempt to conserve water and is decreased with diabetes insipidus. Aldosterone is secreted when fluid volume is low causing reabsorption of sodium and chloride, resulting in decreased urinary sodium and chloride. Urine osmolality can be greater than 450 mOsm/kg, because the kidneys try to compensate by conserving water. Normal values for laboratory data are listed in Appendix A.

Gerontologic Considerations

Increased sensitivity to fluid and electrolyte changes in elderly patients requires careful assessment of intake and output of fluids from all sources, assessment of changes in daily weight, careful monitoring of side effects and interactions of medications, and prompt reporting and management of disturbances. It is necessary to monitor skin turgor serially to detect subtle changes. However, assessment of skin turgor is not as valid in the elderly because the skin has lost some of its elasticity; therefore, other assessment measures (eg, slowness in filling of veins of the hands and feet) become more useful in detecting FVD. Skin turgor is best tested over the forehead or the sternum in elderly patients, because alterations in skin elasticity are less marked in these areas.

The nurse also performs a functional assessment of the ability of the elderly patient to determine fluid and food needs and to obtain adequate intake in addition to other assessments discussed earlier in this chapter. For example, is the patient cognitively intact, able to ambulate and to use both arms and hands to reach fluids and foods, and able to swallow? Results of this assessment have a direct bearing on how the patient will be able to meet his or her own need for fluids and foods. During an elderly patient's hospital stay, the nurse provides fluids if the patient is unable to carry out self-care activities.

The nurse should also recognize that some elderly patients deliberately restrict their fluid intake to avoid embarrassing episodes of incontinence. In this situation, the nurse identifies interventions to deal with the incontinence, such as encouraging the patient to wear protective clothing or devices, to carry a urinal in the car, or to pace fluid intake

to allow access to toilet facilities during the day. Elderly people without cardiovascular or renal dysfunction should be reminded to drink adequate fluids, particularly in very warm or humid weather.

Medical Management

When planning the correction of fluid loss for the patient with FVD, the primary health care provider considers the maintenance requirements of the patient and other factors (eg, fever) that can influence fluid needs. If the deficit is not severe, the oral route is preferred, provided the patient can drink. However, if fluid losses are acute or severe, the IV route is required. Isotonic electrolyte solutions (eg, lactated Ringer's solution, 0.9% sodium chloride) are frequently used to treat the hypotensive patient with FVD because they expand plasma volume. As soon as the patient becomes normotensive, a hypotonic electrolyte solution (eg, 0.45% sodium chloride) is often used to provide both electrolytes and water for renal excretion of metabolic wastes. These and additional fluids are listed in Table 14-3.

Accurate and frequent assessments of I&O, weight, vital signs, central venous pressure, level of consciousness, breath sounds, and skin color should be performed to determine when therapy should be slowed to avoid volume overload. The rate of fluid administration is based on the severity of loss and the patient's hemodynamic response to volume replacement (Porth & Matfin, 2009).

If the patient with severe FVD is not excreting enough urine and is therefore oliguric, the primary health care provider needs to determine whether the depressed renal function is caused by reduced renal blood flow secondary to FVD (prerenal azotemia) or, more seriously, by acute tubular necrosis from prolonged FVD. The test used in this situation is referred to as a fluid challenge test. During a fluid challenge test, volumes of fluid are administered at specific rates and intervals while the patient's hemodynamic response to this treatment is monitored (ie, vital signs, breath sounds, sensorium, central venous pressure, urine output).

An example of a typical fluid challenge involves administering 100 to 200 mL of normal saline solution over 15 minutes. The goal is to provide fluids rapidly enough to attain adequate tissue perfusion without compromising the cardiovascular system. The response by a patient with FVD but normal renal function is increased urine output and an increase in blood pressure and central venous pressure.

Shock can occur when the volume of fluid lost exceeds 25% of the intravascular volume, or when fluid loss is rapid. Shock and its causes and treatment are discussed in detail in Chapter 15.

Nursing Management

To assess for FVD, the nurse monitors and measures fluid I&O at least every 8 hours, and sometimes hourly. As FVD develops, body fluid losses exceed fluid intake through excessive urination (polyuria), diarrhea, vomiting, or other mechanisms. Once FVD has developed, the kidneys attempt to conserve body fluids, leading to a urine output of less than 30 mL/h in an adult. Urine in this instance is concentrated and represents a healthy renal response. Daily body weights are monitored; an acute loss of 0.5 kg (1 lb)

Table 14-3 SELECTED WATER AND ELECTROLYTE SOLUTIONS

Solution	Comments
<p>Isotonic Solutions 0.9% NaCl (isotonic, also called normal saline [NS]) Na⁺ 154 mEq/L Cl⁻ 154 mEq/L (308 mOsm/L) Also available with varying concentrations of dextrose (the most frequently used is a 5% dextrose concentration)</p>	<ul style="list-style-type: none"> • An isotonic solution that expands the extracellular fluid (ECF) volume, used in hypovolemic states, resuscitative efforts, shock, diabetic ketoacidosis, metabolic alkalosis, hypercalcemia, mild Na⁺ deficit • Supplies an excess of Na⁺ and Cl⁻; can cause fluid volume excess and hyperchloremic acidosis if used in excessive volumes, particularly in patients with compromised renal function, heart failure, or edema • Not desirable as a routine maintenance solution, as it provides only Na⁺ and Cl⁻ (and these are provided in excessive amounts) • When mixed with 5% dextrose, the resulting solution becomes hypertonic in relation to plasma and, in addition to the above described electrolytes, provides 170 cal/L • Only solution that may be administered with blood products • Tonicity similar to plasma
<p>Lactated Ringer's solution (Hartmann's solution) Na⁺ 130 mEq/L K⁺ 4 mEq/L Ca⁺⁺ 3 mEq/L Cl⁻ 109 mEq/L Lactate (metabolized to bicarbonate) 28 mEq/L (274 mOsm/L) Also available with varying concentrations of dextrose (the most common is 5% dextrose)</p>	<ul style="list-style-type: none"> • An isotonic solution that contains multiple electrolytes in roughly the same concentration as found in plasma (note that solution is lacking in Mg⁺⁺): provides 9 cal/L • Used in the treatment of hypovolemia, burns, fluid lost as bile or diarrhea, and for acute blood loss replacement • Lactate is rapidly metabolized into HCO₃⁻ in the body. Lactated Ringer's solution should not be used in lactic acidosis because the ability to convert lactate into HCO₃⁻ is impaired in this disorder. • Not to be given with a pH > 7.5 because bicarbonate is formed as lactate breaks down, causing alkalosis • Should not be used in renal failure because it contains potassium and can cause hyperkalemia • Tonicity similar to plasma
<p>5% dextrose in water (D₅W) No electrolytes 50 g of dextrose</p>	<ul style="list-style-type: none"> • An isotonic solution that supplies 170 cal/L and free water to aid in renal excretion of solutes • Used in treatment of hypernatremia, fluid loss, and dehydration • Should not be used in excessive volumes in the early postoperative period (when antidiuretic hormone secretion is increased due to stress reaction) • Should not be used solely in treatment of fluid volume deficit, because it dilutes plasma electrolyte concentrations • Contraindicated in head injury because it may cause increased intracranial pressure • Should not be used for fluid resuscitation because it can cause hyperglycemia • Should be used with caution in patients with renal or cardiac disease because of risk of fluid overload • Electrolyte-free solutions may cause peripheral circulatory collapse, anuria in patients with sodium deficiency, and increased body fluid loss. • Converts to hypotonic solution as dextrose is metabolized by body. Over time, D₅W without NaCl can cause water intoxication (intracellular fluid volume excess [FVE]) because the solution is hypotonic. • Fluid therapy for an extended period of time without electrolytes may result in hypokalemia
<p>Hypotonic Solutions 0.45% NaCl (half-strength saline) Na⁺ 77 mEq/L Cl⁻ 77 mEq/L (154 mOsm/L) Also available with varying concentrations of dextrose (the most common is a 5% concentration)</p>	<ul style="list-style-type: none"> • Provides Na⁺, Cl⁻, and free water • Free water is desirable to aid the kidneys in elimination of solute. • Lacking in electrolytes other than Na⁺ and Cl⁻ • When mixed with 5% dextrose, the solution becomes slightly hypertonic to plasma and in addition to the above-described electrolytes provides 170 cal/L. • Used to treat hypertonic dehydration, Na⁺ and Cl⁻ depletion, and gastric fluid loss • Not indicated for third-space fluid shifts or increased intracranial pressure • Administer cautiously, because it can cause fluid shifts from vascular system into cells, resulting in cardiovascular collapse and increased intracranial pressure.
<p>Hypertonic Solutions 3% NaCl (hypertonic saline) Na⁺ 513 mEq/L Cl⁻ 513 mEq/L (1026 mOsm/L)</p>	<ul style="list-style-type: none"> • Used to increase ECF volume, decrease cellular swelling • Highly hypertonic solution used only in critical situations to treat hyponatremia • Must be administered slowly and cautiously, because it can cause intravascular volume overload and pulmonary edema • Supplies no calories • Assists in removing intracellular fluid excess
<p>5% NaCl (hypertonic solution) Na⁺ 855 mEq/L Cl⁻ 855 mEq/L (1710 mOsm/L)</p>	<ul style="list-style-type: none"> • Highly hypertonic solution used to treat symptomatic hyponatremia • Administer slowly and cautiously, because it can cause intravascular volume overload and pulmonary edema. • Supplies no calories
<p>Colloid Solutions Dextran in NS or 5% D₅W Available in low-molecular-weight (Dextran 40) and high-molecular-weight (Dextran 70) forms</p>	<ul style="list-style-type: none"> • Colloid solution used as volume/plasma expander for intravascular part of ECF • Affects clotting by coating platelets and decreasing ability to clot • Remains in circulatory system up to 24 h • Used to treat hypovolemia in early shock to increase pulse pressure, cardiac output, and arterial blood pressure • Improves microcirculation by decreasing red blood cell aggregation • Contraindicated in hemorrhage, thrombocytopenia, renal disease, and severe dehydration • Not a substitute for blood or blood products

represents a fluid loss of approximately 500 mL. (One liter of fluid weighs approximately 1 kg, or 2.2 lb.)

Vital signs are closely monitored. The nurse observes for a weak, rapid pulse and orthostatic hypotension (ie, a decrease in systolic pressure exceeding 15 mm Hg when the patient moves from a lying to a sitting position). A decrease in body temperature often accompanies FVD, unless there is a concurrent infection.

Skin and tongue turgor are monitored on a regular basis. In a healthy person, pinched skin immediately returns to its normal position when released. This elastic property, referred to as turgor, is partially dependent on interstitial fluid volume. In a person with FVD, the skin flattens more slowly after the pinch is released. In a person with severe FVD, the skin may remain elevated for many seconds. Tissue turgor is best measured by pinching the skin over the sternum, inner aspects of the thighs, or forehead. Tongue turgor is not affected by age (see previous Gerontologic Considerations), and evaluating this may be more valid than evaluating skin turgor. In a normal person, the tongue has one longitudinal furrow. In the person with FVD, there are additional longitudinal furrows and the tongue is smaller, because of fluid loss. The degree of oral mucous membrane moisture is also assessed; a dry mouth may indicate either FVD or mouth breathing.

Urine concentration is monitored by measuring the urine specific gravity. In a volume-depleted patient, the urine specific gravity should be greater than 1.020, indicating healthy renal conservation of fluid.

Mental function is eventually affected in severe FVD as a result of decreasing cerebral perfusion. Decreased peripheral perfusion can result in cold extremities. In patients with relatively normal cardiopulmonary function, a low central venous pressure is indicative of hypovolemia. Patients with acute cardiopulmonary decompensation require more extensive hemodynamic monitoring of pressures in both sides of the heart to determine if hypovolemia exists.

Preventing Hypovolemia

To prevent FVD, the nurse identifies patients at risk and takes measures to minimize fluid losses. For example, if the patient has diarrhea, measures should be implemented to control diarrhea and replacement fluids administered. This includes administering antidiarrheal medications and small volumes of oral fluids at frequent intervals.

Correcting Hypovolemia

When possible, oral fluids are administered to help correct FVD, with consideration given to the patient's likes and dislikes. The type of fluid the patient has lost is also considered and fluids most likely to replace the lost electrolytes are appropriate. If the patient is reluctant to drink because of oral discomfort, the nurse assists with frequent mouth care and provides nonirritating fluids. The patient may be offered small volumes of oral rehydration solutions (eg, Rehydralyte, Elete, Cytomax). These solutions provide fluid, glucose, and electrolytes in concentrations that are easily absorbed. If nausea is present, antiemetics may be needed before oral fluid replacement can be tolerated.

If the deficit cannot be corrected by oral fluids, therapy may need to be initiated by an alternative route (enteral or parenteral) until adequate circulating blood volume and renal perfusion are achieved. Isotonic fluids are prescribed to increase ECF volume.

Hypervolemia

Fluid volume excess (FVE), or hypervolemia, refers to an isotonic expansion of the ECF caused by the abnormal retention of water and sodium in approximately the same proportions in which they normally exist in the ECF. It is always secondary to an increase in the total body sodium content, which, in turn, leads to an increase in total body water. Because there is isotonic retention of body substances, the serum sodium concentration remains essentially normal.

Pathophysiology

FVE may be related to simple fluid overload or diminished function of the homeostatic mechanisms responsible for regulating fluid balance. Contributing factors can include heart failure, renal failure, and cirrhosis of the liver. Another contributing factor is consumption of excessive amounts of table or other sodium salts. Excessive administration of sodium-containing fluids in a patient with impaired regulatory mechanisms may predispose him or her to a serious FVE as well (Heitz & Horne, 2005).

Clinical Manifestations

Clinical manifestations of FVE result from expansion of the ECF and include edema, distended neck veins, and crackles (abnormal lung sounds). Other manifestations include tachycardia; increased blood pressure, pulse pressure, and central venous pressure; increased weight; increased urine output; and shortness of breath and wheezing.

Assessment and Diagnostic Findings

Laboratory data useful in diagnosing FVE include BUN and hematocrit levels. In FVE, both of these values may be decreased because of plasma dilution. Other causes of abnormalities in these values include low protein intake and anemia. In chronic renal failure, both serum osmolality and the sodium level are decreased due to excessive retention of water. The urine sodium level is increased if the kidneys are attempting to excrete excess volume. A chest x-ray may reveal pulmonary congestion. Hypervolemia occurs when aldosterone is chronically stimulated (ie, cirrhosis, heart failure, and nephrotic syndrome). Therefore, the urine sodium level does not increase in these conditions.

Medical Management

Management of FVE is directed at the causes, and if related to excessive administration of sodium-containing fluids, discontinuing the infusion may be all that is needed. Symptomatic treatment consists of administering diuretics and restricting fluids and sodium.

Pharmacologic Therapy

Diuretics are prescribed when dietary restriction of sodium alone is insufficient to reduce edema by inhibiting the reabsorption of sodium and water by the kidneys. The choice of diuretic is based on the severity of the hypervolemic state, the degree of impairment of renal function, and the potency of the diuretic. Thiazide diuretics block sodium reabsorption in the distal tubule, where only 5% to 10% of filtered sodium is reabsorbed. Loop diuretics, such as furosemide (Lasix), bumetanide (Bumex), or torsemide (Demadex), can cause a greater loss of both sodium and water because they block sodium reabsorption in the ascending limb of the loop of Henle, where 20% to 30% of filtered sodium is normally reabsorbed. Generally, thiazide diuretics, such as hydrochlorothiazide (HydroDIURIL) or metolazone (Mykrox, Zaroxolyn), are prescribed for mild to moderate hypervolemia and loop diuretics for severe hypervolemia.

Electrolyte imbalances may result from the effect of the diuretic. Hypokalemia can occur with all diuretics except those that work in the last distal tubule of the nephrons. Potassium supplements can be prescribed to avoid this complication. Hyperkalemia can occur with diuretics that work in the last distal tubule (eg, spironolactone [Aldactone]), especially in patients with decreased renal function. Hyponatremia occurs with diuresis due to increased release of ADH secondary to reduction in circulating volume. Decreased magnesium levels occur with administration of loop and thiazide diuretics due to decreased reabsorption and increased excretion of magnesium by the kidney.

Azotemia (increased nitrogen levels in the blood) can occur with FVE when urea and creatinine are not excreted due to decreased perfusion by the kidneys and decreased excretion of wastes. High uric acid levels (hyperuricemia) can also occur from increased reabsorption and decreased excretion of uric acid by the kidneys.

Dialysis

If renal function is so severely impaired that pharmacologic agents cannot act efficiently, other modalities are considered to remove sodium and fluid from the body. Hemodialysis or peritoneal dialysis may be used to remove nitrogenous wastes and control potassium and acid-base balance, and to remove sodium and fluid. Continuous renal replacement therapy may also be required. See Chapter 44 for a discussion of these treatment modalities.

Nutritional Therapy

Treatment of FVE usually involves dietary restriction of sodium. An average daily diet not restricted in sodium contains 6 to 15 g of salt, whereas low-sodium diets can range from a mild restriction to as little as 250 mg of sodium per day, depending on the patient's needs. A mild sodium-restricted diet allows only light salting of food (about half the usual amount) in cooking and at the table, and no addition of salt to commercially prepared foods that are already seasoned. Of course, foods high in sodium must be avoided. It is the sodium salt, sodium chloride,

rather than sodium itself that contributes to edema. Therefore, patients are instructed to read food labels carefully to determine salt content.

Because about half of ingested sodium is in the form of seasoning, seasoning substitutes can play a major role in decreasing sodium intake. Lemon juice, onions, and garlic are excellent substitute flavorings, although some patients prefer salt substitutes. Most salt substitutes contain potassium and must therefore be used cautiously by patients taking potassium-sparing diuretics (eg, spironolactone, triamterene [Dyrenium], amiloride [Midamor]). They should not be used at all in conditions associated with potassium retention, such as advanced renal disease. Salt substitutes containing ammonium chloride can be harmful to patients with liver damage.

In some communities, the drinking water may contain too much sodium for a sodium-restricted diet. Depending on its source, water may contain as little as 1 mg or more than 1500 mg of sodium per quart. Patients may need to use distilled water if the local water supply is very high in sodium. Bottled water can have a sodium content that ranges from 0 to 1200 mg/L; therefore, if sodium is restricted, the label must be carefully examined for sodium content before purchasing and drinking bottled water. Also, patients on sodium-restricted diets should be cautioned to avoid water softeners that add sodium to water in exchange for other ions, such as calcium. Protein intake may be increased in patients who are malnourished or who have low serum protein levels in an effort to increase capillary oncotic pressure and pull fluid out of the tissues into vessels for excretion by the kidneys.

Nursing Management

To assess for FVE, the nurse measures I&O at regular intervals to identify excessive fluid retention. The patient is weighed daily, and rapid weight gain is noted. An acute weight gain of 2.2 lb (1 kg) is equivalent to a gain of approximately 1 L of fluid. Breath sounds are assessed at regular intervals in at-risk patients, particularly if parenteral fluids are being administered. The nurse monitors the degree of edema in the most dependent parts of the body, such as the feet and ankles in ambulatory patients and the sacral region in patients confined to bed. Pitting edema is assessed by pressing a finger into the affected part, creating a pit or indentation that is evaluated on a scale of 1+ (minimal) to 4+ (severe). Peripheral edema is monitored by measuring the circumference of the extremity with a tape marked in millimeters (Weber & Kelley, 2007).

Preventing Hypervolemia

Specific interventions vary with the underlying condition and the degree of FVE. However, most patients require sodium-restricted diets in some form, and adherence to the prescribed diet is encouraged. Patients are instructed to avoid over-the-counter medications without first checking with a health care provider, because these substances may contain sodium. If fluid retention persists despite adherence to a prescribed diet, hidden sources of

sodium, such as the water supply or use of water softeners, should be considered.

Detecting and Controlling Hypervolemia

It is important to detect FVE before the condition becomes severe. Interventions include promoting rest, restricting sodium intake, monitoring parenteral fluid therapy, and administering appropriate medications.

Regular rest periods may be beneficial, because bed rest favors diuresis of edema fluid. The mechanism is probably related to diminished venous pooling and the subsequent increase in effective circulating blood volume and renal perfusion. Sodium and fluid restriction should be instituted as indicated. Because most patients with FVE require diuretics, the patient's response to these agents is monitored. The rate of parenteral fluids and the patient's response to these fluids are also closely monitored. If dyspnea or orthopnea is present, the patient is placed in a semi-Fowler's position to promote lung expansion. The patient is turned and repositioned at regular intervals because edematous tissue is more prone to skin breakdown than normal tissue. Because conditions predisposing to FVE are likely to be chronic, patients are taught to monitor their response to therapy by documenting fluid I&O and body weight changes. The importance of adhering to the treatment regimen is emphasized.

Teaching Patients About Edema

Because edema is a common manifestation of FVE, patients need to recognize its symptoms and understand its importance. The nurse gives special attention to edema when teaching the patient with FVE. Edema can occur as a result of increased capillary fluid pressure, decreased capillary oncotic pressure, or increased interstitial oncotic pressure, causing expansion of the interstitial fluid compartment (Porth & Matfin, 2009). Edema can be localized (eg, in the ankle, as in rheumatoid arthritis) or generalized (as in cardiac and renal failure). Severe generalized edema is called *anasarca*.

Edema occurs when there is a change in the capillary membrane, increasing the formation of interstitial fluid or decreasing the removal of interstitial fluid. Sodium retention is a frequent cause of the increased ECF volume. Burns and infection are examples of conditions associated with increased interstitial fluid volume. Obstruction to lymphatic outflow, a plasma albumin level less than 1.5 to 2 g/dL, or a decrease in plasma oncotic pressure contributes to increased interstitial fluid volume. The kidneys retain sodium and water when there is decreased ECF volume as a result of decreased cardiac output from heart failure. A thorough medication history is necessary to identify any medications that could cause edema, such as nonsteroidal anti-inflammatory drugs (NSAIDs), estrogens, corticosteroids, and antihypertensive agents.

Ascites is a form of edema in which fluid accumulates in the peritoneal cavity; it results from nephrotic syndrome, cirrhosis, and some malignant tumors. The patient commonly reports shortness of breath and a sense of pressure because of pressure on the diaphragm.

The goal of treatment is to preserve or restore the circulating intravascular fluid volume. Thus, in addition to treating the cause of the edema, other treatments may include diuretic therapy, restriction of fluids and sodium, elevation of the extremities, application of anti-embolism stockings, paracentesis, dialysis, and continuous renal replacement therapy in cases of renal failure or life-threatening fluid volume overload (see Chapter 44).

ELECTROLYTE IMBALANCES

Disturbances in electrolyte balances are common in clinical practice and must be corrected (Table 14-4).

Sodium Imbalances

Sodium is the most abundant electrolyte in the ECF; its concentration ranges from 135 to 145 mEq/L (135 to 145 mmol/L) and it is the primary determinant of ECF volume and osmolality. Sodium has a major role in controlling water distribution throughout the body, because it does not easily cross the cell wall membrane and because of its abundance and high concentration in the body. Sodium is regulated by ADH, thirst, and the renin-angiotensin-aldosterone system. A loss or gain of sodium is usually accompanied by a loss or gain of water. Sodium also functions in establishing the electrochemical state necessary for muscle contraction and the transmission of nerve impulses (Criddle, 2006; Hayes, 2007a).

The syndrome of inappropriate secretion of antidiuretic hormone (SIADH) may be associated with sodium imbalance. When there is a decrease in the circulating plasma osmolality, blood volume, or blood pressure, arginine vasopressin (AVP) is released from the posterior pituitary. Oversecretion of AVP can cause SIADH. Patients who are at risk are the elderly, those with acquired immunodeficiency syndrome (AIDS), those on mechanical ventilation, and people taking selective serotonin reuptake inhibitors (SSRIs) (Haskal, 2007; Rottmann, 2007).

Sodium imbalance can develop under simple or complex circumstances. The two most common sodium imbalances are sodium deficit and sodium excess.

SODIUM DEFICIT (HYPONATREMIA)

Hyponatremia refers to a serum sodium level that is less than 135 mEq/L (135 mmol/L) (Criddle, 2006). Plasma sodium concentration represents the ratio of total body sodium to total body water. A decrease in this ratio can occur because of a low total body sodium with a lesser reduction in total body water, a normal total body sodium content with excess total body water, or an excess of total body sodium with an even greater excess of total body water. A hyponatremic state can be superimposed on an existing FVD or FVE.

Table 14-4 MAJOR FLUID AND ELECTROLYTE IMBALANCES		
Imbalance	Contributing Factors	Signs/Symptoms and Laboratory Findings
Fluid volume deficit (hypovolemia)	Loss of water and electrolytes, as in vomiting, diarrhea, fistulas, fever, excess sweating, burns, blood loss, gastrointestinal suction, and third-space fluid shifts; and decreased intake, as in anorexia, nausea, and inability to gain access to fluid. Diabetes insipidus and uncontrolled diabetes mellitus also contribute to a depletion of extracellular fluid volume.	Acute weight loss, ↓ skin turgor, oliguria, concentrated urine, weak rapid pulse, capillary filling time prolonged, low CVP, ↓ blood pressure, flattened neck veins, dizziness, weakness, thirst and confusion, ↑ pulse, muscle cramps, sunken eyes <i>Labs indicate:</i> ↑ hemoglobin and hematocrit, ↑ serum and urine osmolality and specific gravity, ↓ urine sodium, ↑ BUN and creatinine, ↑ urine specific gravity and osmolality
Fluid volume excess (hypervolemia)	Compromised regulatory mechanisms, such as renal failure, heart failure, and cirrhosis; overzealous administration of sodium-containing fluids; and fluid shifts (ie, treatment of burns). Prolonged corticosteroid therapy, severe stress, and hyperaldosteronism augment fluid volume excess.	Acute weight gain, peripheral edema and ascites, distended jugular veins, crackles, elevated CVP, shortness of breath, ↑ blood pressure, bounding pulse and cough, ↑ respiratory rate <i>Labs indicate:</i> ↓ hemoglobin and hematocrit, ↓ serum and urine osmolality, ↓ urine sodium and specific gravity
Sodium deficit (hyponatremia) Serum sodium <135 mEq/L	Loss of sodium, as in use of diuretics, loss of GI fluids, renal disease, and adrenal insufficiency. Gain of water, as in excessive administration of D ₅ W and water supplements for patients receiving hypotonic tube feedings; disease states associated with SIADH such as head trauma and oat-cell lung tumor; medications associated with water retention (oxytocin and certain tranquilizers); and psychogenic polydipsia. Hyperglycemia and heart failure cause a loss of sodium.	Anorexia, nausea and vomiting, headache, lethargy, dizziness, confusion, muscle cramps and weakness, muscular twitching, seizures, papilledema, dry skin, ↑ pulse, ↓ BP, weight gain, edema <i>Labs indicate:</i> ↓ serum and urine sodium, ↓ urine specific gravity and osmolality
Sodium excess (hypernatremia) Serum sodium >145 mEq/L	Water deprivation in patients unable to drink at will, hypertonic tube feedings without adequate water supplements, diabetes insipidus, heatstroke, hyperventilation, watery diarrhea, burns, and diaphoresis. Excess corticosteroid, sodium bicarbonate, and sodium chloride administration, and salt water near-drowning victims	Thirst, elevated body temperature, swollen dry tongue and sticky mucous membranes, hallucinations, lethargy, restlessness, irritability, focal or grand mal seizures, pulmonary edema, hyperreflexia, twitching, nausea, vomiting, anorexia, ↑ pulse, and ↑ BP <i>Labs indicate:</i> ↑ serum sodium, ↓ urine sodium, ↑ urine specific gravity and osmolality, ↓ CVP
Potassium deficit (hypokalemia) Serum potassium <3.5 mEq/L	Diarrhea, vomiting, gastric suction, corticosteroid administration, hyperaldosteronism, carbenicillin, amphotericin B, bulimia, osmotic diuresis, alkalosis, starvation, diuretics, and digoxin toxicity	Fatigue, anorexia, nausea and vomiting, muscle weakness, polyuria, decreased bowel motility, ventricular asystole or fibrillation, paresthesias, leg cramps, ↓ BP, ileus, abdominal distention, hypoaortic reflexes. ECG: flattened T waves, prominent U waves, ST depression, prolonged PR interval
Potassium excess (hyperkalemia) Serum potassium >5.0 mEq/L	Pseudohyperkalemia, oliguric renal failure, use of potassium-conserving diuretics in patients with renal insufficiency, metabolic acidosis, Addison's disease, crush injury, burns, stored bank blood transfusions, rapid IV administration of potassium, and certain medications such as ACE inhibitors, NSAIDs, cyclosporine	Muscle weakness, tachycardia → bradycardia, dysrhythmias, flaccid paralysis, paresthesias, intestinal colic, cramps, abdominal distention, irritability, anxiety. ECG: tall tented T waves, prolonged PR interval and QRS duration, absent P waves, ST depression
Calcium deficit (hypocalcemia) Serum calcium <8.5 mg/dL	Hypoparathyroidism (may follow thyroid surgery or radical neck dissection), malabsorption, pancreatitis, alkalosis, vitamin D deficiency, massive subcutaneous infection, generalized peritonitis, massive transfusion of citrated blood, chronic diarrhea, decreased parathyroid hormone, diuretic phase of renal failure, ↑ PO ₄ , fistulas, burns, alcoholism	Numbness, tingling of fingers, toes, and circumoral region; positive Trousseau's sign and Chvostek's sign; seizures, carpopedal spasms, hyperactive deep tendon reflexes, irritability, bronchospasm, anxiety, impaired clotting time, ↓ prothrombin, diarrhea, ↓ BP. ECG: prolonged QT interval and lengthened ST <i>Labs indicate:</i> ↓ Mg ⁺⁺
Calcium excess (hypercalcemia) Serum calcium >10.5 mg/dL	Hyperparathyroidism, malignant neoplastic disease, prolonged immobilization, overuse of calcium supplements, vitamin D excess, oliguric phase of renal failure, acidosis, corticosteroid therapy, thiazide diuretic use, increased parathyroid hormone, and digoxin toxicity	Muscular weakness, constipation, anorexia, nausea and vomiting, polyuria and polydipsia, dehydration, hypoaortic deep tendon reflexes, lethargy, deep bone pain, pathologic fractures, flank pain, calcium stones, hypertension. ECG: shortened ST segment and QT interval, bradycardia, heart blocks
Magnesium deficit (hypomagnesemia) Serum magnesium <1.8 mg/dL	Chronic alcoholism, hyperparathyroidism, hyperaldosteronism, diuretic phase of renal failure, malabsorptive disorders, diabetic ketoacidosis, refeeding after starvation, parenteral nutrition, chronic laxative use, diarrhea, acute myocardial infarction, heart failure, decreased serum K ⁺ and Ca ⁺⁺ and certain pharmacologic agents (such as gentamicin, cisplatin, and cyclosporine)	Neuromuscular irritability, positive Trousseau's and Chvostek's signs, insomnia, mood changes, anorexia, vomiting, increased tendon reflexes, and ↑ BP. ECG: PVCs, flat or inverted T waves, depressed ST segment, prolonged PR interval, and widened QRS

Continued

Table 14-4 MAJOR FLUID AND ELECTROLYTE IMBALANCES (Continued)

Imbalance	Contributing Factors	Signs/Symptoms and Laboratory Findings
Magnesium excess (hypermagnesemia) Serum magnesium >2.7 mg/dL	Oliguric phase of renal failure (particularly when magnesium-containing medications are administered), adrenal insufficiency, excessive IV magnesium administration, diabetic ketoacidosis, and hypothyroidism	Flushing, hypotension, muscle weakness, drowsiness, hypoactive reflexes, depressed respirations, cardiac arrest and coma, diaphoresis. ECG: tachycardia → bradycardia, prolonged PR interval and QRS, peaked T waves
Phosphorus deficit (hypophosphatemia) Serum phosphorus <2.5 mg/dL	Refeeding after starvation, alcohol withdrawal, diabetic ketoacidosis, respiratory and metabolic alkalosis, ↓ magnesium, ↓ potassium, hyperparathyroidism, vomiting, diarrhea, hyperventilation, vitamin D deficiency associated with malabsorptive disorders, burns, acid-base disorders, parenteral nutrition, and diuretic and antacid use	Paresthesias, muscle weakness, bone pain and tenderness, chest pain, confusion, cardiomyopathy, respiratory failure, seizures, tissue hypoxia, and increased susceptibility to infection, nystagmus
Phosphorus excess (hyperphosphatemia) Serum phosphorus >4.5 mg/dL	Acute and chronic renal failure, excessive intake of phosphorus, vitamin D excess, respiratory and metabolic acidosis, hypoparathyroidism, volume depletion, leukemia/lymphoma treated with cytotoxic agents, increased tissue breakdown, rhabdomyolysis	Tetany, tachycardia, anorexia, nausea and vomiting, muscle weakness, signs and symptoms of hypocalcemia; hyperactive reflexes; soft tissue calcifications in lungs, heart, kidneys, and cornea
Chloride deficit (hypochloremia) Serum chloride <96 mEq/L	Addison's disease, reduced chloride intake or absorption, untreated diabetic ketoacidosis, chronic respiratory acidosis, excessive sweating, vomiting, gastric suction, diarrhea, sodium and potassium deficiency, metabolic alkalosis; loop, osmotic, or thiazide diuretic use; overuse of bicarbonate, rapid removal of ascitic fluid with a high sodium content, intravenous fluids that lack chloride (dextrose and water), draining fistulas and ileostomies, heart failure, cystic fibrosis	Agitation, irritability, tremors, muscle cramps, hyperactive deep tendon reflexes, hypertonicity, tetany, slow shallow respirations, seizures, dysrhythmias, coma <i>Labs indicate:</i> ↓ serum chloride, ↓ serum sodium, ↑ pH, ↑ serum bicarbonate, ↑ total carbon dioxide content, ↓ urine chloride level, ↓ serum potassium
Chloride excess (hyperchloremia) Serum chloride >108 mEq/L	Excessive sodium chloride infusions with water loss, head injury (sodium retention), hypernatremia, renal failure, corticosteroid use, dehydration, severe diarrhea (loss of bicarbonate), respiratory alkalosis, administration of diuretics, overdose of salicylates, Kayexalate, acetazolamide, phenylbutazone and ammonium chloride use, hyperparathyroidism, metabolic acidosis	Tachypnea, lethargy, weakness, deep rapid respirations, decline in cognitive status, ↓ cardiac output, dyspnea, tachycardia, pitting edema, dysrhythmias, coma <i>Labs indicate:</i> ↑ serum chloride, ↑ serum potassium and sodium, ↓ serum pH, ↓ serum bicarbonate, normal anion gap, ↑ urinary chloride level

↑ increased; ↓ decreased; ACE, angiotensin-converting enzyme; BP, blood pressure; BUN, blood urea nitrogen; CVP, central venous pressure; D₅W, dextrose 5% in water; GI, gastrointestinal; IV, intravenous; NSAIDs, nonsteroidal anti-inflammatory drugs; PVCs, premature ventricular contractions; SIADH, syndrome of inappropriate secretion of antidiuretic hormone.

Pathophysiology

Hyponatremia primarily occurs due to an imbalance of water rather than sodium. The urine sodium assists in differentiating renal from nonrenal causes of hyponatremia. Low urine sodium occurs as the kidney retains sodium to compensate for nonrenal fluid loss (ie, vomiting, diarrhea, sweating). High urine sodium concentration is associated with renal salt wasting (ie, diuretic use). In dilutional hyponatremia, the ECF volume is increased without any edema.

A deficiency of aldosterone, as occurs in adrenal insufficiency, also predisposes to sodium deficiency. In addition, the use of certain medications, such as anticonvulsants (ie, carbamazepine [Tegretol], levetiracetam [Keppra]) and SSRIs (fluoxetine [Sarafem], sertraline [Zoloft], paroxetine [Paxil]), increases the risk of hyponatremia (McPhee, et al., 2007; Rottmann, 2007).

SIADH is seen in hyponatremia as well as hypernatremia. The physiologic disturbances include excessive ADH activity, with water retention and dilutional hypona-

tremia, and inappropriate urinary excretion of sodium in the presence of hyponatremia. SIADH can be the result of either sustained secretion of ADH by the hypothalamus or production of an ADH-like substance from a tumor (aberrant ADH production). Conditions affecting the central nervous system are associated with SIADH. SIADH is discussed in more detail in Chapter 42.

Clinical Manifestations

Clinical manifestations of hyponatremia depend on the cause, magnitude, and speed with which the deficit occurs. Poor skin turgor, dry mucosa, headache, decreased saliva production, orthostatic fall in blood pressure, nausea, vomiting, and abdominal cramping occur. Neurologic changes, including altered mental status, status epilepticus, and coma, are probably related to the cellular swelling and cerebral edema associated with hyponatremia. As the extracellular sodium level decreases, the cellular fluid becomes relatively more concentrated and pulls water into the cells (Fig. 14-4). In general, patients with an acute

Figure 14-4 Effect of extracellular sodium level on cell size.

decrease in serum sodium levels have more cerebral edema and higher mortality rates than do those with more slowly developing hyponatremia. Acute decreases in sodium, developing in less than 48 hours, may be associated with brain herniation and compression of midbrain structures. Chronic decreases in sodium, developing over 48 hours or more, can occur in status epilepticus and cerebral pontine myelinolysis.

Features of hyponatremia associated with sodium loss and water gain include anorexia, muscle cramps, and a feeling of exhaustion. The severity of symptoms increases with the degree of hyponatremia and the speed with which it develops. When the serum sodium level decreases to less than 115 mEq/L (115 mmol/L), signs of increasing intracranial pressure, such as lethargy, confusion, muscle twitching, focal weakness, hemiparesis, papilledema, seizures, and death, may occur.

Assessment and Diagnostic Findings

Assessment includes the history and physical examination, including a focused neurologic examination; evaluation of signs and symptoms as well as laboratory test results; identification of current IV fluids, if applicable; and a review of all medications the patient is taking. Regardless of the cause of hyponatremia, the serum sodium level is less than 135 mEq/L; in SIADH, it may be lower than 100 mEq/L (100 mmol/L). Serum osmolality is also decreased, except in azotemia with the accumulation of toxins. When hyponatremia is due primarily to sodium loss, the urinary sodium content is less than 20 mEq/L (20 mmol/L), suggesting increased proximal reabsorption of sodium secondary to ECF volume depletion, and the specific gravity is low (1.002 to 1.004). However, when hyponatremia is due to SIADH, the urinary sodium content is greater than 20 mEq/L, and the urine specific gravity is

usually greater than 1.012. Although the patient with SIADH retains water abnormally and therefore gains body weight, there is no peripheral edema; instead, fluid accumulates inside the cells. This phenomenon sometimes manifests as pitting edema.

Medical Management

The key to treating hyponatremia is assessment including identifying patients who are at risk and recognizing that the rapidity of the onset of hyponatremia is of primary importance (Haskal, 2007).

Sodium Replacement

The most common treatment for hyponatremia is careful administration of sodium by mouth, nasogastric tube, or a parenteral route. For patients who can eat and drink, sodium is easily replaced, because sodium is consumed abundantly in a normal diet. For those who cannot consume sodium, lactated Ringer's solution or isotonic saline (0.9% sodium chloride) solution may be prescribed. Serum sodium must not be increased by more than 12 mEq/L in 24 hours to avoid neurologic damage due to osmotic demyelination. This condition may occur when the serum sodium concentration is overcorrected (exceeding 140 mEq/L) too rapidly or in the presence of hypoxia or anoxia. It may produce lesions that show symmetric myelin destruction affecting all the fiber tracts that cause paraparesis, dysarthria, dysphagia, and coma (Abbott, Silber, Felber, et al., 2005). The usual daily sodium requirement in adults is approximately 100 mEq, provided there are not excessive losses. Selected water and electrolyte solutions are described in Table 14-3.

In SIADH, the administration of hypertonic saline solution alone cannot change the plasma sodium concentration. Excess sodium would be excreted rapidly in highly concentrated urine. With the addition of the diuretic furosemide (Lasix), urine is not concentrated and isotonic urine is excreted to effect a change in water balance. In patients with SIADH, in whom water restriction is difficult, lithium (Eskalith) or demeclocycline (Declomycin) can antagonize the osmotic effect of ADH on the medullary collecting tubule.

Water Restriction

In a patient with normal or excess fluid volume, hyponatremia is treated by restricting fluid to a total of 800 mL in 24 hours. This is far safer than sodium administration and is usually an effective treatment. However, if neurologic symptoms are severe (eg, seizures, delirium, coma), as well as in traumatic brain injury, it may be necessary to administer small volumes of a hypertonic sodium solution (see Chapter 61) (Mortimer & Jancik, 2006). Incorrect use of these fluids is extremely dangerous, because 1 L of 3% sodium chloride solution contains 513 mEq of sodium and 1 L of 5% sodium chloride solution contains 855 mEq of sodium. The prescribed volume of hypertonic saline administered depends on the patient's weight and on current and desired serum sodium levels (Mortimer & Jancik, 2006). If edema exists alone, sodium is restricted; if edema and hyponatremia occur together, both sodium and water are restricted.

 **NURSING ALERT**

Highly hypertonic sodium solutions (2% to 23% sodium chloride) should be administered only in intensive care settings under close observation, because only small volumes are needed to elevate the serum sodium concentration from a dangerously low level. These fluids are administered slowly and in small volumes, and the patient is monitored closely.

Pharmacologic Therapy

AVP receptor antagonists are new pharmacologic agents that treat hyponatremia by stimulating free water excretion (Haskal, 2007). IV conivaptan hydrochloride (Vaprisol) use is limited to the treatment of hospitalized patients. It may be a useful therapy for those patients with moderate to severe symptomatic hyponatremia, but is contraindicated in patients with seizures, delirium, or coma, which warrant the use of hypertonic saline (Ellison & Berl, 2007; Hayes, 2007a).

Nursing Management

The nurse needs to identify and monitor patients at risk of hyponatremia. Early detection and treatment of this disorder are necessary to prevent serious consequences. For patients at risk, the nurse monitors fluid I&O as well as daily body weight. It is also necessary to note abnormal losses of sodium or gains of water, as well as GI manifestations such as anorexia, nausea, vomiting, and abdominal cramping. The nurse must be alert for central nervous system changes, such as lethargy, confusion, muscle twitching, and seizures. Neurologic signs are associated with very low sodium levels that have fallen rapidly because of fluid overloading. Serum sodium is monitored very closely in patients who are at risk for hyponatremia; when indicated, urine sodium and specific gravity are also monitored.

Hyponatremia is a frequently overlooked cause of confusion in elderly patients, who have an increased risk of hyponatremia because of decreased renal function and thus inability to excrete excess fluids. Administration of prescribed and over-the-counter (OTC) medications that cause sodium loss or water retention are predisposing factors. A diminished sense of thirst or loss of access to food or fluids may also contribute to the problem.

Detecting and Controlling Hyponatremia

For a patient with abnormal losses of sodium who can consume a general diet, the nurse encourages foods and fluids with high sodium content. For example, broth made with one beef cube contains approximately 900 mg of sodium; 8 oz of tomato juice contains approximately 700 mg of sodium. The nurse also needs to be familiar with the sodium content of parenteral fluids (see Table 14-3).

If the primary problem is water retention, it is safer to restrict fluid intake than to administer sodium. In normovolemia or hypervolemia, administration of sodium predisposes a patient to fluid volume overload. In severe hyponatremia, the aim of therapy is to elevate the serum sodium level only enough to alleviate neurologic signs and symptoms. It is generally recommended that the serum

sodium concentration be increased to no greater than 125 mEq/L (125 mmol/L) with a hypertonic saline solution.

 **NURSING ALERT**

When administering fluids to patients with cardiovascular disease, the nurse assesses for signs of circulatory overload (eg, cough, dyspnea, puffy eyelids, dependent edema, weight gain in 24 hours). The lungs are auscultated for crackles.

For the patient taking lithium, the nurse observes for lithium toxicity, particularly when sodium is lost by an abnormal route. In such instances, supplemental salt and fluid are administered. Because diuretics promote sodium loss, the patient taking lithium is instructed not to use diuretics without close medical supervision. For all patients on lithium therapy, adequate salt intake should be ensured.

Excess water supplements are avoided in patients receiving isotonic or hypotonic enteral feedings, particularly if abnormal sodium loss occurs or water is being abnormally retained (as in SIADH). Actual fluid needs are determined by evaluating fluid I&O, urine specific gravity, and serum sodium levels.

SODIUM EXCESS (HYPERNATREMIA)

Hypernatremia is a serum sodium level higher than 145 mEq/L (145 mmol/L). It can be caused by a gain of sodium in excess of water or by a loss of water in excess of sodium. It can occur in patients with normal fluid volume or in those with FVD or FVE. With a water loss, the patient loses more water than sodium; as a result, the serum sodium concentration increases and the increased concentration pulls fluid out of the cell. This is both an extracellular and an intracellular FVD. In sodium excess, the patient ingests or retains more sodium than water.

Pathophysiology

A common cause of hypernatremia is fluid deprivation in unconscious patients who cannot perceive, respond to, or communicate their thirst (Porth & Matfin, 2009). Most often affected are very old, very young, and cognitively impaired patients. Administration of hypertonic enteral feedings without adequate water supplements leads to hypernatremia, as does watery diarrhea and greatly increased insensible water loss (eg, hyperventilation, denuding effects of burns). In addition, both central and nephrogenic diabetes insipidus, which is a decreased ability to concentrate urine due to a defect in the kidney tubules that interferes with water reabsorption, result in hypernatremia if the patient does not experience or cannot respond to thirst, or if fluids are excessively restricted.

Less common causes of hypernatremia are heat stroke, near drowning in sea water (which contains a sodium concentration of approximately 500 mEq/L), and malfunction of hemodialysis or peritoneal dialysis systems. IV administration of hypertonic saline or excessive use of sodium bicarbonate also causes hypernatremia (Porth & Matfin, 2009).

Clinical Manifestations

The clinical manifestations of hypernatremia are primarily neurologic and are due to increased plasma osmolality caused by an increase in plasma sodium concentration. Water moves out of the cell into the ECF, resulting in cellular dehydration and a more concentrated ECF (see Fig. 14-4). Clinically, these changes may be manifested by restlessness and weakness in moderate hypernatremia and by disorientation, delusions, and hallucinations in severe hypernatremia. Dehydration (resulting in hypernatremia) is often overlooked as the primary reason for behavioral changes in elderly patients. If hypernatremia is severe, permanent brain damage can occur (especially in children). Brain damage is due to hemorrhages that result from brain contraction.

A primary characteristic of hypernatremia is thirst. Thirst is such a strong defender of serum sodium levels in healthy people that hypernatremia never occurs unless the person is unconscious or does not have access to water. However, ill people may have an impaired thirst mechanism. Other signs include a dry, swollen tongue and sticky mucous membranes; flushed skin; peripheral and pulmonary edema; postural hypotension; oliguria; and increased muscle tone and deep tendon reflexes (DTRs). Body temperature may increase mildly, but it returns to normal after the hypernatremia is corrected.

Assessment and Diagnostic Findings

In hypernatremia, the serum sodium level exceeds 145 mEq/L (145 mmol/L) and the serum osmolality exceeds 300 mOsm/kg (300 mmol/L). The urine specific gravity and urine osmolality are increased as the kidneys attempt to conserve water (provided the water loss is from a route other than the kidneys). Patients with nephrogenic or central diabetes insipidus have hypernatremia and produce a dilute urine with a urine osmolality less than 250 mOsm/kg.

Medical Management

Treatment of hypernatremia consists of a gradual lowering of the serum sodium level by the infusion of a hypotonic electrolyte solution (eg, 0.3% sodium chloride) or an isotonic nonsaline solution (eg, dextrose 5% in water [D₅W]). D₅W is indicated when water needs to be replaced without sodium. Clinicians consider a hypotonic sodium solution to be safer than D₅W because it allows a gradual reduction in the serum sodium level, thereby decreasing the risk of cerebral edema. It is the solution of choice in severe hyperglycemia with hypernatremia. A rapid reduction in the serum sodium level temporarily decreases the plasma osmolality below that of the fluid in the brain tissue, causing dangerous cerebral edema. Diuretics also may be prescribed to treat the sodium gain.

There is no consensus about the exact rate at which serum sodium levels should be reduced. As a general rule, the serum sodium level is reduced at a rate no faster than 0.5 to 1 mEq/L/h to allow sufficient time for readjustment through diffusion across fluid compartments. Desmopressin acetate (DDAVP), a synthetic antidiuretic hormone, may be prescribed to treat diabetes insipidus if it is the cause of hypernatremia (Porth & Matfin, 2009).

Nursing Management

As in hyponatremia, fluid losses and gains are carefully monitored in patients who are at risk for hypernatremia. The nurse should assess for abnormal losses of water or low water intake and for large gains of sodium, as might occur with ingestion of OTC medications that have a high sodium content (eg, Alka-Seltzer). In addition, the nurse obtains a medication history, because some prescription medications have a high sodium content. The nurse also notes the patient's thirst or elevated body temperature and evaluates it in relation to other clinical signs. The nurse monitors for changes in behavior, such as restlessness, disorientation, and lethargy.

Preventing Hypernatremia

The nurse attempts to prevent hypernatremia by providing fluids at regular intervals, particularly in debilitated or unconscious patients who are unable to perceive or respond to thirst. If fluid intake remains inadequate, the nurse consults with the physician to plan an alternative route for intake, either by enteral feedings or by the parenteral route. If enteral feedings are used, sufficient water should be administered to keep the serum sodium and BUN within normal limits. As a rule, the higher the osmolality of the enteral feeding, the greater is the need for water supplementation.

For patients with diabetes insipidus, adequate water intake must be ensured. If the patient is alert and has an intact thirst mechanism, merely providing access to water may be sufficient. If the patient has a decreased level of consciousness or other disability interfering with adequate fluid intake, parenteral fluid replacement may be prescribed. This therapy can be anticipated in patients with neurologic disorders, particularly in the early postoperative period.

Correcting Hypernatremia

When parenteral fluids are necessary for managing hypernatremia, the nurse monitors the patient's response to the fluids by reviewing serial serum sodium levels and by observing for changes in neurologic signs. With a gradual decrease in the serum sodium level, the neurologic signs should improve. Too-rapid reduction in the serum sodium level renders the plasma temporarily hypo-osmotic to the fluid in the brain tissue, causing movement of fluid into brain cells and dangerous cerebral edema.

Potassium Imbalances

Potassium is the major intracellular electrolyte; in fact, 98% of the body's potassium is inside the cells. The remaining 2% is in the ECF and is important in neuromuscular function. Potassium influences both skeletal and cardiac muscle activity. For example, alterations in its concentration change myocardial irritability and rhythm. Under the influence of the sodium-potassium pump, potassium is constantly moving in and out of cells. The normal serum potassium concentration ranges from 3.5 to 5.0 mEq/L (3.5 to 5 mmol/L), and even minor variations are significant. Potassium imbalances are commonly associated with various diseases, injuries, medications (eg, NSAIDs and ACE

inhibitors), and acid–base imbalances (Hayes, 2007b; McPhee, et al., 2007).

To maintain potassium balance, the renal system must function, because 80% of the potassium excreted daily leaves the body by way of the kidneys; the other 20% is lost through the bowel and in sweat. The kidneys regulate potassium balance by adjusting the amount of potassium that is excreted in the urine. As serum potassium levels increase, so does the potassium level in the renal tubular cell. A concentration gradient occurs, favoring the movement of potassium into the renal tubule and excretion of potassium in the urine. Aldosterone also increases the excretion of potassium by the kidney. Because the kidneys do not conserve potassium as well as they conserve sodium, potassium may still be lost in urine in the presence of a potassium deficit.

POTASSIUM DEFICIT (HYPOKALEMIA)

Hypokalemia (below 3.5 mEq/L [3.5 mmol/L]) usually indicates a deficit in total potassium stores. However, it may occur in patients with normal potassium stores: When **alkalosis** is present, a temporary shift of serum potassium into the cells occurs (see later discussion).

Pathophysiology

Potassium-losing diuretics, such as the thiazides and loop diuretics, can induce hypokalemia (Baumberger-Henry, 2008). Other medications that can lead to hypokalemia include corticosteroids, sodium penicillin, carbenicillin, and amphotericin B. GI loss of potassium is another common cause of potassium depletion. Vomiting and gastric suction frequently lead to hypokalemia, partly because potassium is actually lost when gastric fluid is lost and because potassium is lost through the kidneys in response to metabolic alkalosis. Because relatively large amounts of potassium are contained in intestinal fluids, potassium deficit occurs frequently with diarrhea, which may contain as much potassium as 30 mEq/L. Potassium deficit also occurs from prolonged intestinal suctioning, recent ileostomy, and villous adenoma (a tumor of the intestinal tract characterized by excretion of potassium-rich mucus).

Alterations in acid–base balance have a significant effect on potassium distribution due to shifts of hydrogen and potassium ions between the cells and the ECF. Respiratory or metabolic alkalosis promotes the transcellular shift of potassium and can have a variable and unpredictable effect on serum potassium (O'Neill, 2007). For example, hydrogen ions move out of the cells in alkalotic states to help correct the high pH, and potassium ions move in to maintain an electrically neutral state (see later discussion of acid–base balance).

Hyperaldosteronism increases renal potassium wasting and can lead to severe potassium depletion. Primary hyperaldosteronism is seen in patients with adrenal adenomas. Secondary hyperaldosteronism occurs in patients with cirrhosis, nephrotic syndrome, heart failure, or malignant hypertension (Heitz & Horne, 2005).

Because insulin promotes the entry of potassium into skeletal muscle and hepatic cells, patients with persistent insulin hypersecretion may experience hypokalemia, which is often the case in patients receiving high-carbohydrate parenteral nutrition.

Patients who do not eat a normal diet for a prolonged period are at risk for hypokalemia. This may occur in debilitated elderly people, patients with alcoholism, and patients with anorexia nervosa. In addition to poor intake, people with bulimia frequently suffer increased potassium loss through self-induced vomiting, misuse of laxatives, diuretics, and enemas. Magnesium depletion causes renal potassium loss and must be corrected first; otherwise, urine loss of potassium will continue.

Clinical Manifestations

Potassium deficiency can result in widespread derangements in physiologic function. Severe hypokalemia can cause death through cardiac or respiratory arrest. Clinical signs rarely develop before the serum potassium level has decreased to less than 3 mEq/L (3 mmol/L) unless the rate of decline has been rapid. Manifestations of hypokalemia include fatigue, anorexia, nausea, vomiting, muscle weakness, leg cramps, decreased bowel motility, paresthesias (numbness and tingling), and dysrhythmias. If prolonged, hypokalemia can lead to an inability of the kidneys to concentrate urine, causing dilute urine (resulting in polyuria, nocturia) and excessive thirst. Potassium depletion suppresses the release of insulin and results in glucose intolerance. Decreased muscle strength and DTRs can be found on physical assessment.

Assessment and Diagnostic Findings

In hypokalemia, the serum potassium concentration is less than the lower limit of normal. Electrocardiographic (ECG) changes can include flat T waves or inverted T waves or both, suggesting ischemia, and depressed ST segments (Fig. 14-5). An elevated U wave is specific to hypokalemia. Hypokalemia increases sensitivity to digitalis, predisposing the patient to digitalis toxicity at lower digitalis levels. Metabolic alkalosis is commonly associated with hypokalemia (Her, 2007). This is discussed further in the section on acid–base disturbances in this chapter.

The source of the potassium loss is usually evident from a careful history. However, if the cause of the loss is unclear, a 24-hour urinary potassium excretion test can be performed to distinguish between renal and extrarenal loss. Urinary potassium excretion exceeding 20 mEq/day with hypokalemia suggests that renal potassium loss is the cause.

Medical Management

If hypokalemia cannot be prevented by conventional measures such as increased intake in the daily diet or by oral potassium supplements for deficiencies, then it is treated cautiously with IV replacement therapy (Hayes, 2007b). Potassium loss must be corrected daily; administration of 40 to 80 mEq/day of potassium is adequate in the adult if there are no abnormal losses of potassium.

For patients who are at risk for hypokalemia, a diet containing sufficient potassium should be provided. Dietary intake of potassium in the average adult is 50 to 100 mEq/day. Foods high in potassium include most fruits and vegetables, legumes, whole grains, milk, and meat.

If dietary intake is inadequate for any reason, the physician may prescribe oral or IV potassium supplements (Muller & Bell, 2008). Many salt substitutes contain 50 to 60 mEq of potassium per teaspoon and may be sufficient to prevent hypokalemia.

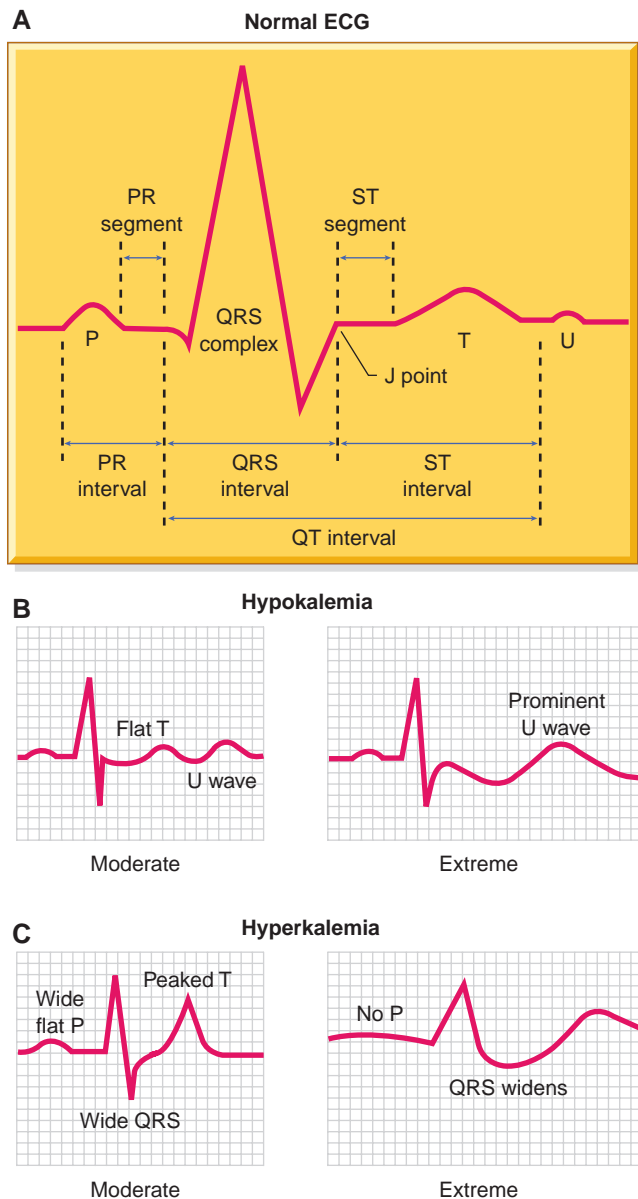

Figure 14-5 Effect of potassium on the electrocardiogram (ECG). **A**, Normal tracing. **B**, Hypokalemia: serum potassium level below normal. *Left*: Flattening of the T wave and the appearance of a U wave. *Right*: Further flattening with prominent U wave. **C**, Hyperkalemia: serum potassium level above normal. *Left*: Moderate elevation with wide, flat P wave; wide QRS complex; and peaked T wave. *Right*: ECG changes seen with extreme potassium elevation: widening of QRS complex and absence of P wave.

If oral administration of potassium is not feasible, the IV route is indicated. The IV route is mandatory for patients with severe hypokalemia (eg, serum level of 2 mEq/L). Although potassium chloride is usually used to correct potassium deficits, potassium acetate or potassium phosphate may be prescribed.

Nursing Management

Because hypokalemia can be life-threatening, the nurse needs to monitor for its early presence in patients who are at risk. Fatigue, anorexia, muscle weakness, decreased bowel

motility, paresthesias, and dysrhythmias are signals that warrant assessing the serum potassium concentration. When available, the ECG may provide useful information. For example, patients receiving digitalis who are at risk for potassium deficiency should be monitored closely for signs of digitalis toxicity, because hypokalemia potentiates the action of digitalis.

Preventing Hypokalemia

Prevention may involve encouraging the patient at risk to eat foods rich in potassium (when the diet allows). Sources of potassium include fruit juices and bananas, melon, citrus fruits, fresh and frozen vegetables, fresh meats, milk, and processed foods. If the hypokalemia is caused by abuse of laxatives or diuretics, patient education may help alleviate the problem. Part of the health history and assessment should be directed at identifying problems that are amenable to prevention through education. Careful monitoring of fluid I&O is necessary, because 40 mEq of potassium is lost for every liter of urine output. The ECG is monitored for changes, and arterial blood gas values are checked for elevated bicarbonate and pH levels.

Correcting Hypokalemia

The oral route is ideal to treat a mild to moderate hypokalemia because oral potassium supplements are absorbed well. Care should be exercised when administering potassium, particularly in older adults, who have lower lean body mass and total body potassium levels and therefore lower potassium requirements. In addition, because of the physiologic loss of renal function with advancing years, potassium may be retained more readily in older than in younger people.

NURSING ALERT

Oral potassium supplements can produce small-bowel lesions; therefore, the patient must be assessed for and cautioned about abdominal distention, pain, or GI bleeding.

Administering Intravenous Potassium

Potassium should be administered only after adequate urine flow has been established. A decrease in urine volume to less than 20 mL/h for 2 consecutive hours is an indication to stop the potassium infusion until the situation is evaluated. Potassium is primarily excreted by the kidneys; when oliguria occurs, potassium administration can cause the serum potassium concentration to rise dangerously (Hayes, 2007b).

NURSING ALERT

Potassium is *never* administered by IV push or intramuscularly to avoid replacing potassium too quickly. IV potassium must be administered using an infusion pump.

Each health care facility has its own standard of care for the administration of potassium, which should be consulted; however, the maximum concentration of potassium that should be administered on a medical-surgical unit through a

peripheral IV line is 20 mEq/100 mL and the rate no faster than 10 to 20 mEq/h. Concentrations of potassium greater than 20 mEq/100 mL should be administered through a central IV catheter using an infusion pump with the patient monitored by ECG. Caution must be used when selecting the correct premixed solution of IV fluid containing potassium chloride as the concentrations range from 10 to 40 mEq/100 mL. Renal function should be monitored through BUN and creatinine levels and urine output if the patient is receiving potassium replacement. During potassium replacement, smooth muscle hyperactivity can lead to hyperactive bowel sounds, a sign of hyperkalemia (Hayes, 2007b).

POTASSIUM EXCESS (HYPERKALEMIA)

Hyperkalemia (greater than 5.0 mEq/L [5 mmol/L]) seldom occurs in patients with normal renal function (Vacca, 2008). Like hypokalemia, hyperkalemia is often caused by iatrogenic (treatment-induced) causes. Although hyperkalemia is less common than hypokalemia, it is usually more dangerous, because cardiac arrest is more frequently associated with high serum potassium levels.

Pathophysiology

The three major causes of hyperkalemia are decreased renal excretion of potassium, rapid administration of potassium, and movement of potassium from the ICF compartment to the ECF compartment. Hyperkalemia is commonly seen in patients with untreated renal failure, particularly those in whom potassium levels increase as a result of infection or excessive intake of potassium in food or medications. Patients with hypoaldosteronism or Addison's disease are at risk for hyperkalemia, because deficient adrenal hormones lead to sodium loss and potassium retention.

Medications have been identified as a probable contributing factor in more than 60% of hyperkalemic episodes. Medications commonly implicated are potassium chloride, heparin, ACE inhibitors, NSAIDs, beta-blockers, and potassium-sparing diuretics (Muller & Bell, 2008). Potassium regulation is compromised in acute and chronic renal failure, with a glomerular filtration rate less than 10% to 20% of normal.

Improper use of potassium supplements predisposes all patients to hyperkalemia, especially if salt substitutes are used. Not all patients receiving potassium-losing diuretics require potassium supplements, and patients receiving potassium-conserving diuretics should not receive supplements.

NURSING ALERT

Potassium supplements are extremely dangerous for patients who have impaired renal function and thus decreased ability to excrete potassium. Even more dangerous is the IV administration of potassium to such patients, because serum levels can rise very quickly. Aged (stored) blood should not be administered to patients with impaired renal function, because the serum potassium concentration of stored blood increases due to red blood cell deterioration. It is possible to exceed the renal tolerance of any patient with rapid IV potassium administration, as well as when large amounts of oral potassium supplements are ingested.

In **acidosis**, potassium moves out of the cells and into the ECF. This occurs as hydrogen ions enter the cells to buffer the pH of the ECF (see later discussion). An elevated ECF potassium level should be anticipated when extensive tissue trauma has occurred, as in burns, crushing injuries, or severe infections. Similarly, it can occur with lysis of malignant cells after chemotherapy (ie, tumor lysis syndrome).

Pseudohyperkalemia (a variation of hyperkalemia) has a number of causes, the most common being the use of a tight tourniquet around an exercising extremity while drawing a blood sample, producing hemolysis of the sample before analysis. Other causes include marked leukocytosis (white blood cell count exceeding 200,000/mm³) and thrombocytosis (platelet count exceeding 1 million/mm³); drawing blood above a site where potassium is infusing; and familial pseudohyperkalemia, in which potassium leaks out of the red blood cells while the blood is awaiting analysis. Lack of awareness of these causes of pseudohyperkalemia can lead to aggressive treatment of a nonexistent hyperkalemia, resulting in serious lowering of serum potassium levels. Therefore, measurements of grossly elevated levels should be verified by retesting.

Clinical Manifestations

The most important consequence of hyperkalemia is its effect on the myocardium. Cardiac effects of elevated serum potassium are usually not significant when the level is less than 7 mEq/L (7 mmol/L), but they are almost always present when the level is 8 mEq/L (8 mmol/L) or greater. As the plasma potassium level rises, disturbances in cardiac conduction occur. The earliest changes, often occurring at a serum potassium level greater than 6 mEq/L (6 mmol/L), are peaked, narrow T waves; ST-segment depression; and a shortened QT interval. If the serum potassium level continues to increase, the PR interval becomes prolonged and is followed by disappearance of the P waves. Finally, there is decomposition and widening of the QRS complex (see Fig. 14-5). Ventricular dysrhythmias and cardiac arrest may occur at any point in this progression.

Severe hyperkalemia causes skeletal muscle weakness and even paralysis, related to a depolarization block in muscle. Similarly, ventricular conduction is slowed. Although hyperkalemia has marked effects on the peripheral nervous system, it has little effect on the central nervous system. Rapidly ascending muscular weakness leading to flaccid quadriplegia has been reported in patients with very high serum potassium levels. Paralysis of respiratory and speech muscles can also occur. In addition, GI manifestations, such as nausea, intermittent intestinal colic, and diarrhea, may be evident.

Assessment and Diagnostic Findings

Serum potassium levels and ECG changes are crucial to the diagnosis of hyperkalemia, as discussed previously. Arterial blood gas analysis may reveal both a metabolic and respiratory acidosis. Correcting the acidosis helps correct the hyperkalemia.

Medical Management

An ECG should be obtained immediately to detect changes. Shortened repolarization and peaked T waves are seen initially. To verify results, a repeat serum potassium

level should be obtained from a vein without an IV infusing a potassium-containing solution.

In nonacute situations, restriction of dietary potassium and potassium-containing medications may correct the imbalance. For example, eliminating the use of potassium-containing salt substitutes in a patient who is taking a potassium-conserving diuretic may be all that is needed to deal with mild hyperkalemia.

Prevention of serious hyperkalemia by the administration, either orally or by retention enema, of cation exchange resins (eg, sodium polystyrene sulfonate [Kayexalate]) may be necessary in patients with renal impairment. Cation exchange resins cannot be used if the patient has a paralytic ileus, because intestinal perforation can occur. Kayexalate binds with other cations in the GI tract and contributes to the development of hypomagnesemia and hypocalcemia; it may also cause sodium retention and fluid overload, and should be used with caution in patients with heart failure.

Emergency Pharmacologic Therapy

If serum potassium levels are dangerously elevated, it may be necessary to administer IV calcium gluconate. Within minutes after administration, calcium antagonizes the action of hyperkalemia on the heart, but it does not reduce the serum potassium concentration. Calcium chloride and calcium gluconate are not interchangeable; calcium gluconate contains 4.5 mEq of calcium and calcium chloride contains 13.6 mEq of calcium. Therefore, caution is required.

Monitoring the blood pressure is essential to detect hypotension, which may result from the rapid IV administration of calcium gluconate. The ECG should be continuously monitored during administration; the appearance of bradycardia is an indication to stop the infusion. The myocardial protective effects of calcium last about 30 minutes. Extra caution is required if the patient has been “digitalized” (ie, has received accelerated dosages of a digitalis-based cardiac glycoside to reach a desired serum digitalis level rapidly); parenteral administration of calcium sensitizes the heart to digitalis and may precipitate digitalis toxicity.

IV administration of sodium bicarbonate may be necessary to alkalinize the plasma, cause a temporary shift of potassium into the cells, and furnish sodium to antagonize the cardiac effects of potassium (Vacca, 2008). Effects of this therapy begin within 30 to 60 minutes and may persist for hours; however, they are temporary.

IV administration of regular insulin and a hypertonic dextrose solution causes a temporary shift of potassium into the cells. Glucose and insulin therapy has an onset of action within 30 minutes and lasts for several hours. Loop diuretics, such as furosemide (Lasix), increase excretion of water by inhibiting sodium, potassium, and chloride reabsorption in the ascending loop of Henle and distal renal tubule.

Beta-2 agonists, such as albuterol (Proventil, Ventolin), are highly effective in decreasing potassium, but their use remains controversial, because they can cause tachycardia and chest discomfort (Porth & Matfin, 2009). Beta-2 agonists move potassium into the cells and may be used in the absence of ischemic cardiac disease. Their use

is a stopgap measure that only temporarily protects the patient from hyperkalemia. If the hyperkalemic condition is not transient, actual removal of potassium from the body is required through cation exchange resins, peritoneal dialysis, hemodialysis, or other forms of renal replacement therapy.

Nursing Management

Patients at risk for potassium excess (eg, those with renal failure) need to be identified and closely monitored for signs of hyperkalemia. The nurse observes for signs of muscle weakness and dysrhythmias. The presence of paresthesias and GI symptoms such as nausea and intestinal colic are noted. Serum potassium levels, as well as BUN, creatinine, glucose, and arterial blood gas values, are monitored for patients at risk for developing hyperkalemia (Heitz & Horne, 2005).

Preventing Hyperkalemia

Measures are taken to prevent hyperkalemia in patients at risk, when possible, by encouraging the patient to adhere to the prescribed potassium restriction. Potassium-rich foods to be avoided include many fruits and vegetables, legumes, whole-grain breads, meat, milk, eggs, coffee, tea, and cocoa (Dudek, 2006). Conversely, foods with minimal potassium content include butter, margarine, cranberry juice or sauce, ginger ale, gumdrops or jellybeans, hard candy, root beer, sugar, and honey. Labels of cola beverages must be checked carefully because some are high in potassium and some are not.

Correcting Hyperkalemia

It is possible to exceed the tolerance for potassium if administered rapidly by the IV route. Therefore, care is taken to administer and monitor potassium solutions closely. Particular attention is paid to the solution's concentration and rate of administration. Potassium is not added to parenteral solutions on the nursing units but in the pharmacy. IV administration is via a volumetric infusion pump (Hayes, 2007b).

It is important to caution patients to use salt substitutes sparingly if they are taking other supplementary forms of potassium or potassium-conserving diuretics (O'Neill, 2007). Also, potassium-conserving diuretics, such as spironolactone (Aldactone), triamterene (Dyrenium), and amiloride (Midamor); potassium supplements; and salt substitutes should not be administered to patients with renal dysfunction. Most salt substitutes contain approximately 50 to 60 mEq of potassium per teaspoon.

Calcium Imbalances

More than 99% of the body's calcium is located in the skeletal system; it is a major component of bones and teeth. About 1% of skeletal calcium is rapidly exchangeable with blood calcium, and the rest is more stable and only slowly exchanged. The small amount of calcium located outside the bone circulates in the serum, partly bound to protein and partly ionized. Calcium plays a major role in transmitting nerve impulses and helps regulate muscle contraction

and relaxation, including cardiac muscle. Calcium is instrumental in activating enzymes that stimulate many essential chemical reactions in the body, and it also plays a role in blood coagulation. Because many factors affect calcium regulation, both hypocalcemia and hypercalcemia are relatively common disturbances.

The normal total serum calcium level is 8.6 to 10.2 mg/dL (2.2 to 2.6 mmol/L). Calcium exists in plasma in three forms: ionized, bound, and complexed. About 50% of the serum calcium exists in a physiologically active ionized form that is important for neuromuscular activity and blood coagulation; this is the only physiologically and clinically significant form. The normal ionized serum calcium level is 4.5 to 5.1 mg/dL (1.1 to 1.3 mmol/L). Less than half of the plasma calcium is bound to serum proteins, primarily albumin. The remainder is combined with nonprotein anions: phosphate, citrate, and carbonate.

Calcium is absorbed from foods in the presence of normal gastric acidity and vitamin D. It is excreted primarily in the feces, with the remainder excreted in the urine. The serum calcium level is controlled by PTH and calcitonin. As ionized serum calcium decreases, the parathyroid glands secrete PTH. This, in turn, increases calcium absorption from the GI tract, increases calcium reabsorption from the renal tubule, and releases calcium from the bone. The increase in calcium ion concentration suppresses PTH secretion. When calcium increases excessively, the thyroid gland secretes calcitonin, which inhibits calcium reabsorption from bone and decreases the serum calcium concentration.

CALCIUM DEFICIT (HYPOCALCEMIA)

Hypocalcemia (serum values lower than 8.6 mg/dL [2.15 mmol/L]) occurs in a variety of clinical situations. A patient may have a total body calcium deficit (as in osteoporosis) but a normal serum calcium level. Elderly people and those with disabilities, who spend an increased amount of time in bed, have an increased risk of hypocalcemia, because bed rest increases bone resorption.

Pathophysiology

Several factors can cause hypocalcemia, including primary hypoparathyroidism and surgical hypoparathyroidism. The latter is far more common. Not only is hypocalcemia associated with thyroid and parathyroid surgery, but it can also occur after radical neck dissection and is most likely in the first 24 to 48 hours after surgery. Transient hypocalcemia can occur with massive administration of citrated blood (ie, massive hemorrhage and shock), because citrate can combine with ionized calcium and temporarily remove it from the circulation.

Inflammation of the pancreas causes the breakdown of proteins and lipids. It is thought that calcium ions combine with the fatty acids released by lipolysis, forming soaps. As a result of this process, hypocalcemia occurs and is common in pancreatitis. Hypocalcemia may be related to excessive secretion of glucagon from the inflamed pancreas, which results in increased secretion of calcitonin.

Hypocalcemia is common in patients with renal failure, because these patients frequently have elevated serum phosphate levels. Hyperphosphatemia usually causes a reciprocal

drop in the serum calcium level. Other causes of hypocalcemia include inadequate vitamin D consumption, magnesium deficiency, medullary thyroid carcinoma, low serum albumin levels, alkalosis, and alcohol abuse. Medications predisposing to hypocalcemia include aluminum-containing antacids, aminoglycosides, caffeine, cisplatin, corticosteroids, mithramycin, phosphates, isoniazid, and loop diuretics.

Clinical Manifestations

Tetany, the most characteristic manifestation of hypocalcemia and hypomagnesemia, refers to the entire symptom complex induced by increased neural excitability. These symptoms are caused by spontaneous discharges of both sensory and motor fibers in peripheral nerves. Sensations of tingling may occur in the tips of the fingers, around the mouth, and, less commonly, in the feet. Spasms of the muscles of the extremities and face may occur. Pain may develop as a result of these spasms. Hyperactive DTRs are another clinical sign associated with tetany.

Trousseau's sign (Fig. 14-6) can be elicited by inflating a blood pressure cuff on the upper arm to about 20 mm Hg above systolic pressure; within 2 to 5 minutes, carpal spasm (an adducted thumb, flexed wrist and metacarpophalangeal joints, extended interphalangeal joints with fingers together) will occur as ischemia of the ulnar nerve develops. Chvostek's sign consists of twitching of muscles innervated by the facial nerve when the region that is about 2 cm anterior to the earlobe, just below the zygomatic arch, is tapped.

Seizures may occur because hypocalcemia increases irritability of the central nervous system as well as of the peripheral nerves (Tocco, 2007). Other changes associated with hypocalcemia include mental changes such as depression, impaired memory, confusion, delirium, and hallucinations. A prolonged QT interval is seen on the ECG due to prolongation of the ST segment, and torsades de pointes, a type of ventricular tachycardia, may occur. Respiratory effects with decreasing calcium include dyspnea and laryngospasm. Signs and symptoms of chronic hypocalcemia include hyperactive bowel sounds, dry and brittle hair and nails, and abnormal clotting.

Figure 14-6 Trousseau's sign. Ischemia-induced carpal spasm can occur with hypocalcemia or hypomagnesemia. Occluding the brachial artery with a blood pressure cuff for 3 minutes can produce carpal spasm (contraction of the fingers and hand), which mimics the spasm that occurs with hypocalcemia or hypomagnesemia.

Osteoporosis is associated with prolonged low intake of calcium and represents a total body calcium deficit, even though serum calcium levels are usually normal. This disorder occurs in millions of Americans and is most common in postmenopausal women. It is characterized by loss of bone mass, which causes bones to become porous and brittle and therefore susceptible to fracture. See Chapter 68 for further discussion of osteoporosis.

Assessment and Diagnostic Findings

When evaluating serum calcium levels, the serum albumin level and the arterial pH must also be considered. Because abnormalities in serum albumin levels may affect interpretation of the serum calcium level, it may be necessary to calculate the corrected serum calcium if the serum albumin level is abnormal. For every decrease in serum albumin of 1 g/dL below 4 g/dL, the total serum calcium level is underestimated by approximately 0.8 mg/dL. The following is a quick method to calculate the corrected serum calcium level:

$$\begin{aligned} & \text{Measured total serum Ca}^{++} \text{ level (mg/dL)} + 0.8 \\ & \times (4.0 - \text{Measured albumin level [g/dL]}) \\ & = \text{Corrected total calcium concentration (mg/dL)} \end{aligned}$$

An example of the calculations needed to obtain the corrected total serum calcium level is as follows:

A patient's reported serum albumin level is 2.5 g/dL; the reported serum calcium level is 10.5 mg/dL. First, the decrease in serum albumin level from normal (ie, the difference from the normal albumin concentration of 4 g/dL) is calculated: 4 g/dL - 2.5 g/dL = 1.5 g/dL. Next, the following ratio is calculated:

$$\begin{aligned} 0.8 \text{ mg/dL} : 1 \text{ g/dL} &= X \text{ mg/dL} : 1.5 \text{ mg/dL} \\ X &= 0.8 \times 1.5 \text{ mg/dL} \\ X &= 1.2 \text{ mg/dL calcium} \end{aligned}$$

Finally, 1.2 mg/dL is added to 10.5 mg/dL (the reported serum calcium level) to obtain the corrected total serum calcium level: 1.2 mg/dL + 10.5 mg/dL = 11.7 mg/dL.

Clinicians often discount a low serum calcium level in the presence of a similarly low serum albumin level. The ionized calcium level is usually normal in patients with reduced total serum calcium levels and concomitant hypoalbuminemia. When the arterial pH increases (alkalosis), more calcium becomes bound to protein. As a result, the ionized portion decreases. Symptoms of hypocalcemia may occur with alkalosis. Acidosis (low pH) has the opposite effect; that is, less calcium is bound to protein and therefore more exists in the ionized form. However, relatively small changes in serum calcium levels occur in these acid-base abnormalities.

Ideally, the ionized level of calcium should be measured in the laboratory. However, in many laboratories, only the total calcium level is reported; therefore, the concentration of the ionized fraction must be estimated by simultaneous measurement of the serum albumin level. PTH levels are decreased in hypoparathyroidism. Magnesium and phosphorus levels need to be assessed to identify possible causes of decreased calcium.

Medical Management

Acute symptomatic hypocalcemia is life-threatening and requires prompt treatment with IV administration of a calcium salt (Avent, 2007). Parenteral calcium salts include

calcium gluconate, calcium chloride, and calcium gluceptate. Although calcium chloride produces a significantly higher ionized calcium level than calcium gluconate does, it is not used as often because it is more irritating and can cause sloughing of tissue if it infiltrates. Too-rapid IV administration of calcium can cause cardiac arrest, preceded by bradycardia. IV administration of calcium is particularly dangerous in patients receiving digitalis-derived medications, because calcium ions exert an effect similar to that of digitalis and can cause digitalis toxicity, with adverse cardiac effects. Therefore, calcium should be diluted in D₅W and administered as a slow IV bolus or a slow IV infusion using a volumetric infusion pump. The IV site must be observed often for any evidence of infiltration because of the risk of extravasation and resultant cellulitis or necrosis. A 0.9% sodium chloride solution should not be used with calcium because it increases renal calcium loss. Solutions containing phosphates or bicarbonate should not be used with calcium because they cause precipitation when calcium is added. The nurse must clarify with the physician and pharmacist which calcium salt to administer, because calcium gluconate yields 4.5 mEq of calcium and calcium chloride provides 13.6 mEq of calcium. Calcium replacement can cause postural hypotension; therefore, the patient is kept in bed during IV infusion, and blood pressure is monitored.

Vitamin D therapy may be instituted to increase calcium absorption from the GI tract; otherwise, the amount of calcium absorbed may not satisfy the body's calcium requirement. In addition, aluminum hydroxide, calcium acetate, or calcium carbonate antacids may be prescribed to decrease elevated phosphorus levels before treating hypocalcemia in the patient with chronic renal failure. Increasing the dietary intake of calcium to at least 1000 to 1500 mg/day in the adult is recommended. Calcium-containing foods include milk products; green, leafy vegetables; canned salmon; sardines; and fresh oysters. Hypomagnesemia can also cause tetany; if the tetany responds to IV calcium, then a low magnesium level is considered as a possible cause in chronic renal failure.

Nursing Management

It is important to observe for hypocalcemia in at-risk patients. Seizure precautions are initiated if hypocalcemia is severe. The status of the airway is closely monitored, because laryngeal stridor can occur. Safety precautions are taken, as indicated, if confusion is present.

It is important to teach the patient with hypocalcemia what foods are rich in calcium. The nurse must also advise the patient to consider calcium supplements if sufficient calcium is not consumed in the diet. Such supplements should be taken in divided doses with meals. Alcohol and caffeine in high doses inhibit calcium absorption, and moderate cigarette smoking increases urinary calcium excretion. The patient is also cautioned to avoid the overuse of laxatives and antacids that contain phosphorus, because their use decreases calcium absorption.

CALCIUM EXCESS (HYPERCALCEMIA)

Hypercalcemia (greater than 10.2 mg/dL [2.6 mmol/L]) is a dangerous imbalance when severe; in fact, hypercalcemic crisis has a mortality rate as high as 50% if not treated promptly.

Pathophysiology

The most common causes of hypercalcemia are malignancies and hyperparathyroidism. Malignant tumors can produce hypercalcemia by a variety of mechanisms (Stewart, 2005). The excessive PTH secretion associated with hyperparathyroidism causes increased release of calcium from the bones and increased intestinal and renal absorption of calcium. Calcifications of soft tissue occur when the calcium–phosphorus product (serum calcium \times serum phosphorus) exceeds 70 mg/dL.

Bone mineral is lost during immobilization, and sometimes this causes elevation of total (and especially ionized) calcium in the bloodstream. However, symptomatic hypercalcemia from immobilization is rare; when it does occur, it is virtually limited to people with high calcium turnover rates (eg, adolescents during a growth spurt). Most cases of hypercalcemia secondary to immobility occur after severe or multiple fractures or spinal cord injury.

Thiazide diuretics can cause a slight elevation in serum calcium levels because they potentiate the action of PTH on the kidneys, reducing urinary calcium excretion. The milk-alkali syndrome has occurred in patients with peptic ulcer treated previously for a prolonged period with milk and alkaline antacids, particularly calcium carbonate. Vitamin A and D intoxication, as well as chronic lithium use and theophylline toxicity, can cause calcium excess. Calcium levels are inversely related to phosphorus levels.

Hypercalcemia reduces neuromuscular excitability because it suppresses activity at the myoneural junction. Decreased tone in smooth and striated muscle may cause symptoms such as muscle weakness, incoordination, anorexia, and constipation. Cardiac standstill can occur when the serum calcium level is about 18 mg/dL (4.5 mmol/L). Calcium enhances the inotropic effect of digitalis; therefore, hypercalcemia aggravates digitalis toxicity.

Clinical Manifestations

The symptoms of hypercalcemia are proportional to the degree of elevation of the serum calcium level. Anorexia, nausea, vomiting, and constipation are common symptoms of hypercalcemia. Dehydration occurs with nausea, vomiting, anorexia, and calcium reabsorption at the proximal renal tubule. Abdominal and bone pain may also be present. Abdominal distention and paralytic ileus may complicate severe hypercalcemic crisis. Excessive urination due to disturbed renal tubular function produced by hypercalcemia may occur. Severe thirst may occur with polyuria secondary to high solute (calcium) load. Patients with chronic hypercalcemia may develop symptoms similar to peptic ulcer disease because hypercalcemia increases the secretion of acid and pepsin in the stomach.

Confusion, impaired memory, slurred speech, lethargy, acute psychotic behavior, or coma may occur (Stewart, 2005). The more severe symptoms tend to appear when the serum calcium level is approximately 16 mg/dL (4 mmol/L) or higher. However, some patients become profoundly disturbed with serum calcium levels of only 12 mg/dL (3 mmol/L). These symptoms resolve as serum calcium levels return to normal after treatment.

Hypercalcemic crisis refers to an acute rise in the serum calcium level to 17 mg/dL (4.3 mmol/L) or higher. Severe thirst and polyuria are often present. Other findings may include muscle weakness, intractable nausea, abdominal cramps, severe constipation, diarrhea, peptic ulcer symptoms, and bone pain. Lethargy, confusion, and coma may also occur. This condition is dangerous and may result in cardiac arrest.

Assessment and Diagnostic Findings

The serum calcium level is greater than 10.2 mg/dL (2.6 mmol/L). Cardiovascular changes may include a variety of dysrhythmias (ie, heart blocks) and shortening of the QT interval and ST segment. The PR interval is sometimes prolonged. The double-antibody PTH test may be used to differentiate between primary hyperparathyroidism and malignancy as a cause of hypercalcemia: PTH levels are increased in primary or secondary hyperparathyroidism and suppressed in malignancy. X-rays may reveal bone changes if the patient has hypercalcemia secondary to a malignancy, bone cavitation, or urinary calculi. The Sulkowitch urine test analyzes the amount of calcium in the urine; in hypercalcemia, dense precipitation is observed due to hypercalciuria.

Medical Management

Therapeutic aims in hypercalcemia include decreasing the serum calcium level and reversing the process causing hypercalcemia. Treating the underlying cause (eg, chemotherapy for a malignancy, partial parathyroidectomy for hyperparathyroidism) is essential.

Pharmacologic Therapy

Measures include administering fluids to dilute serum calcium and promote its excretion by the kidneys, mobilizing the patient, and restricting dietary calcium intake. IV administration of 0.9% sodium chloride solution temporarily dilutes the serum calcium level and increases urinary calcium excretion by inhibiting tubular reabsorption of calcium. Administering IV phosphate can cause a reciprocal drop in serum calcium. Furosemide (Lasix) is often used in conjunction with administration of a saline solution; in addition to causing diuresis, furosemide increases calcium excretion. Although often overlooked, fluids and medications that contain calcium and dietary sources of calcium should be halted (Stewart, 2005).

Calcitonin can be used to lower the serum calcium level and is particularly useful for patients with heart disease or renal failure who cannot tolerate large sodium loads. Calcitonin reduces bone resorption, increases the deposition of calcium and phosphorus in the bones, and increases urinary excretion of calcium and phosphorus (Karch, 2008). Although several forms are available, calcitonin derived from salmon is commonly used. Skin testing for allergy to salmon calcitonin is necessary before the hormone is administered. Systemic allergic reactions are possible because this hormone is a protein; resistance to the medication may develop later because of antibody formation. Calcitonin is administered by intramuscular injection rather than subcutaneously, because patients with hypercalcemia have poor perfusion of subcutaneous tissue.

For patients with cancer, treatment is directed at controlling the condition by surgery, chemotherapy, or radiation therapy. Corticosteroids may be used to decrease bone turnover and tubular reabsorption for patients with sarcoidosis, myelomas, lymphomas, and leukemias; patients with solid tumors are less responsive. Some bisphosphonates (eg, etidronate disodium [Didronel], pamidronate disodium [Aredia], and ibandronate sodium [Boniva]) inhibit osteoclast activity. IV forms can cause fever, transient leukopenia, eye inflammation, nephrotic syndrome, and jaw osteonecrosis (Karch, 2008). Mithramycin, a cytotoxic antibiotic, inhibits bone resorption and thus lowers the serum calcium level. This agent must be used cautiously because it has significant side effects, including thrombocytopenia, nephrotoxicity, rebound hypercalcemia when discontinued, and hepatotoxicity. Inorganic phosphate salts can be administered orally or by nasogastric tube (in the form of Phospho-Soda or Neutra-Phos), rectally (as retention enemas), or intravenously. IV phosphate therapy is used with extreme caution in the treatment of hypercalcemia, because it can cause severe calcification in various tissues, hypotension, tetany, and acute renal failure.

Nursing Management

It is important to monitor for hypercalcemia in at-risk patients. Interventions such as increasing patient mobility and encouraging fluids can help prevent hypercalcemia, or at least minimize its severity. Hospitalized patients at risk for hypercalcemia should be encouraged to ambulate as soon as possible. Those who are outpatients and receive home care are instructed about the importance of frequent ambulation.

When encouraging oral fluids, the nurse considers the patient's likes and dislikes. Fluids containing sodium should be administered unless contraindicated, because sodium assists with calcium excretion. Patients are encouraged to drink 3 to 4 quarts of fluid daily. Adequate fiber in the diet is encouraged to offset the tendency for constipation. Safety precautions are implemented, as necessary, when mental symptoms of hypercalcemia are present. The patient and family are informed that these mental changes are reversible with treatment. Increased calcium increases the effects of digitalis; therefore, the patient is assessed for signs and symptoms of digitalis toxicity. Because ECG changes (premature ventricular contractions, paroxysmal atrial tachycardia, and heart block) can occur, the cardiac rate and rhythm are monitored for any abnormalities.

Magnesium Imbalances

Magnesium is the most abundant intracellular cation after potassium. It acts as an activator for many intracellular enzyme systems and plays a role in both carbohydrate and protein metabolism. The normal serum magnesium level is 1.3 to 2.3 mg/dL (0.62 to 0.95 mmol/L). Approximately one third of serum magnesium is bound to protein; the remaining two thirds exists as free cations—the active component (Mg^{++}). Magnesium balance is important in neuromuscular function. Because magnesium acts directly on the myoneural junction, variations in the serum level affect neuro-

muscular irritability and contractility. For example, an excess of magnesium diminishes the excitability of the muscle cells, whereas a deficit increases neuromuscular irritability and contractility. Magnesium produces its sedative effect at the neuromuscular junction, probably by inhibiting the release of the neurotransmitter acetylcholine. It also increases the stimulus threshold in nerve fibers.

Magnesium also affects the cardiovascular system, acting peripherally to produce vasodilation and decreased peripheral resistance. Magnesium is predominantly found in bone and soft tissues and eliminated by the kidneys.

MAGNESIUM DEFICIT (HYPOMAGNESEMIA)

Hypomagnesemia refers to a below-normal serum magnesium concentration (1.3 mg/dL [0.62 mmol/L]) and is frequently associated with hypokalemia and hypocalcemia. Magnesium is similar to calcium in two aspects: (1) it is the ionized fraction of magnesium that is primarily involved in neuromuscular activity and other physiologic processes, and (2) magnesium levels should be evaluated in combination with albumin levels. About 30% of magnesium is protein bound, principally to albumin. A decreased serum albumin level can, therefore, reduce the measured total magnesium concentration; however, it does not reduce the ionized plasma magnesium concentration.

Pathophysiology

An important route of magnesium loss is the GI tract. Loss of magnesium from the GI tract may occur with nasogastric suction, diarrhea, or fistulas. Because fluid from the lower GI tract has a higher concentration of magnesium (10 to 14 mEq/L) than fluid from the upper tract (1 to 2 mEq/L), losses from diarrhea and intestinal fistulas are more likely to induce magnesium deficit than are those from gastric suction. Although magnesium losses are relatively small in nasogastric suction, hypomagnesemia occurs if losses are prolonged and magnesium is not replaced through IV infusion. Because the distal small bowel is the major site of magnesium absorption, any disruption in small-bowel function (eg, intestinal resection or inflammatory bowel disease) can lead to hypomagnesemia. Hypomagnesemia is a common yet often overlooked imbalance in acutely and critically ill patients. It may occur with withdrawal from alcohol and administration of tube feedings or parenteral nutrition.

Alcoholism is currently the most common cause of symptomatic hypomagnesemia in the United States. The serum magnesium level should be measured at least every 2 or 3 days in patients undergoing withdrawal from alcohol. The serum magnesium level may be normal on admission but may decrease as a result of metabolic changes, such as the intracellular shift of magnesium associated with IV glucose administration.

During nutritional replacement, the major cellular electrolytes move from the serum to newly synthesized cells. Therefore, if the enteral or parenteral feeding formula is deficient in magnesium content, serious hypomagnesemia will occur. Because of this, serum magnesium levels should be measured at regular intervals in patients who are receiving parenteral or enteral feedings, especially those who have

undergone a period of starvation. Other causes of hypomagnesemia include the administration of aminoglycosides, cyclosporine, cisplatin, diuretics, digitalis, and amphotericin, as well as the rapid administration of citrated blood, especially to patients with renal or hepatic disease. Magnesium deficiency often occurs in diabetic ketoacidosis, secondary to increased renal excretion during osmotic diuresis and shifting of magnesium into the cells with insulin therapy. Other contributing causes are pregnancy, lactation, sepsis, burns, and hypothermia.

Clinical Manifestations

Clinical manifestations of hypomagnesemia are largely confined to the neuromuscular system. Some are due directly to the low serum magnesium level; others are due to secondary changes in potassium and calcium metabolism. Symptoms do not usually occur until the serum magnesium level has dropped to less than 1 mEq/L (0.5 mmol/L).

Among the neuromuscular changes are hyperexcitability with muscle weakness, tremors, and athetoid movements (slow, involuntary twisting and writhing). Others include tetany, nystagmus, vertigo, generalized tonic-clonic or focal seizures, laryngeal stridor, and positive Chvostek's and Trousseau's signs (see earlier discussion), which occur, in part, because of accompanying hypocalcemia.

Hypomagnesemia may be accompanied by marked alterations in mood. Apathy, depression, apprehension, and extreme agitation have been noted, as well as ataxia, dizziness, insomnia, and confusion. At times, delirium, auditory or visual hallucinations, and frank psychoses may occur.

Magnesium deficiency can disturb the ECG by prolonging the QRS, depressing the ST segment, and predisposing to cardiac dysrhythmias, such as premature ventricular contractions, supraventricular tachycardia, torsades de pointes (a form of ventricular tachycardia), and ventricular fibrillation. Increased susceptibility to digitalis toxicity is associated with low serum magnesium levels. This is important, because patients receiving digoxin are also likely to be receiving diuretic therapy, predisposing them to renal loss of magnesium. Hypercalcemia and hypokalemia may be refractory to correction until the magnesium level is corrected.

Assessment and Diagnostic Findings

On laboratory analysis, the serum magnesium level is less than 1.3 mg/dL (0.62 mmol/L). Urine magnesium may help identify the cause of magnesium depletion, and levels are measured after a loading dose of magnesium sulfate is administered. Two newer diagnostic techniques (nuclear magnetic resonance spectroscopy and the ion-selective electrode) are sensitive and direct means of measuring ionized serum magnesium levels.

Medical Management

Mild magnesium deficiency can be corrected by diet alone. Principal dietary sources of magnesium include green leafy vegetables, nuts, seeds, legumes, whole grains, seafood, peanut butter, and cocoa.

If necessary, magnesium salts can be administered orally in an oxide or gluconate form to replace continuous losses but can produce diarrhea. Patients receiving parenteral nu-

trition require magnesium in the IV solution to prevent hypomagnesemia. IV magnesium sulfate must be administered by an infusion pump and at a rate not to exceed 150 mg/min, or 67 mEq over 8 hours. Overt symptoms of hypomagnesemia are treated with parenteral administration of magnesium. A bolus dose of magnesium sulfate given too rapidly can produce alterations in cardiac conduction leading to heart block or asystole. Vital signs must be assessed frequently during magnesium administration to detect changes in cardiac rate or rhythm, hypotension, and respiratory distress. Monitoring urine output is essential before, during, and after magnesium administration; the physician is notified if urine volume decreases to less than 100 mL over 4 hours. Calcium gluconate must be readily available to treat hypocalcemic tetany or hypermagnesemia.

Nursing Management

The nurse should be aware of patients at risk for hypomagnesemia and observe them for its signs and symptoms. Patients receiving digitalis are monitored closely, because a deficit of magnesium can predispose them to digitalis toxicity. If hypomagnesemia is severe, seizure precautions are implemented (Tocco, 2007). Other safety precautions are instituted, as indicated, if confusion is observed. Because difficulty in swallowing (dysphagia) may occur in those with magnesium depletion, these patients should be screened for dysphagia.

Teaching plays a major role in treating magnesium deficit, particularly a deficit resulting from abuse of diuretic or laxative medications. In such cases, the nurse instructs the patient about the need to consume magnesium-rich foods. For patients experiencing hypomagnesemia from abuse of alcohol, the nurse provides teaching, counseling, support, and possible referral to alcohol abstinence programs or other professional help.

MAGNESIUM EXCESS (HYPERMAGNESEMIA)

Hypermagnesemia (serum levels over 2.3 mg/dL [0.95 mmol/L]) is a rare electrolyte abnormality, because the kidneys efficiently excrete magnesium. A serum magnesium level can appear falsely elevated if blood specimens are allowed to hemolyze or are drawn from an extremity with a tourniquet that was applied too tightly.

Pathophysiology

By far the most common cause of hypermagnesemia is renal failure. In fact, most patients with advanced renal failure have at least a slight elevation in serum magnesium levels. This condition is aggravated when such patients receive magnesium to control seizures.

Hypermagnesemia can occur in patients with untreated diabetic ketoacidosis when catabolism causes the release of cellular magnesium that cannot be excreted because of profound fluid volume depletion and resulting oliguria. A surplus of magnesium can also result from excessive magnesium administered to treat hypertension of pregnancy or to treat low hypomagnesemia. Increased serum magnesium levels can also occur in adrenocortical insufficiency, Addison's disease, or hypothermia. Excessive use of magnesium-

based antacids (eg, Maalox, Riopan, Mylanta) or laxatives (Milk of Magnesia) and medications that decrease GI motility, including opioids and anticholinergics, can also increase serum magnesium levels. Decreased elimination of magnesium or its increased absorption due to intestinal hypomotility from any cause can contribute to hypermagnesemia. Lithium intoxication can also cause an increase in serum magnesium levels. Extensive soft-tissue injury or necrosis as with trauma, shock, sepsis, cardiac arrest, or severe burns can also result in hypermagnesemia (Muller & Bell, 2008).

Clinical Manifestations

Acute elevation of the serum magnesium level depresses the central nervous system as well as the peripheral neuromuscular junction. At mildly increased levels, there is a tendency for lowered blood pressure because of peripheral vasodilation. Nausea, vomiting, weakness, soft-tissue calcifications, facial flushing, and sensations of warmth may also occur. At higher magnesium concentrations, lethargy, difficulty speaking (dysarthria), and drowsiness can occur. DTRs are lost, and muscle weakness and paralysis may develop. The respiratory center is depressed when serum magnesium levels exceed 10 mEq/L (5 mmol/L). Coma, atrioventricular heart block, and cardiac arrest can occur when the serum magnesium level is greatly elevated and not treated. High levels of magnesium also result in platelet clumping and delayed thrombin formation (Chernecky & Berger, 2007).

Assessment and Diagnostic Findings

On laboratory analysis, the serum magnesium level is greater than 2.3 mg/dL (0.95 mmol/L). Increased potassium and calcium are present concurrently. As creatinine clearance decreases to less than 3.0 mL/min, the serum magnesium levels increase. ECG findings may include a prolonged PR interval, tall T waves, a widened QRS, and a prolonged QT interval, as well as an atrioventricular block.

Medical Management

Hypermagnesemia can be prevented by avoiding the administration of magnesium to patients with renal failure and by carefully monitoring seriously ill patients who are receiving magnesium salts. In patients with severe hypermagnesemia, all parenteral and oral magnesium salts are discontinued. In emergencies, such as respiratory depression or defective cardiac conduction, ventilatory support and IV calcium gluconate are indicated. In addition, hemodialysis with a magnesium-free dialysate can reduce the serum magnesium to a safe level within hours. Administration of loop diuretics (Lasix) and sodium chloride or lactated Ringer's IV solution enhances magnesium excretion in patients with adequate renal function. IV calcium gluconate antagonizes the cardiovascular and neuromuscular effects of magnesium.

Nursing Management

Patients at risk for hypermagnesemia are identified and assessed. If hypermagnesemia is suspected, the nurse monitors the vital signs, noting hypotension and shallow respirations. The nurse also observes for decreased DTRs and changes in the level of consciousness. Medications that contain mag-

nesium are not administered to patients with renal failure or compromised renal function, and patients with renal failure are cautioned to check with their health care providers before taking OTC medications. Caution is essential when preparing and administering magnesium-containing fluids parenterally, because available parenteral magnesium solutions (eg, 2-mL ampules, 50-mL vials) differ in concentration.

Phosphorus Imbalances

Phosphorus is a critical constituent of all the body's tissues. It is essential to the function of muscle and red blood cells; the formation of adenosine triphosphate (ATP) and of 2,3-diphosphoglycerate, which facilitates release of oxygen from hemoglobin; and the maintenance of acid-base balance, as well as the nervous system and the intermediary metabolism of carbohydrate, protein, and fat. It provides structural support to bones and teeth. Phosphorus is the primary anion of the ICF. About 85% of phosphorus is located in bones and teeth, 14% in soft tissue, and less than 1% in the ECF. The normal serum phosphorus level is 2.5 to 4.5 mg/dL (0.8 to 1.45 mmol/L) in adults.

PHOSPHORUS DEFICIT (HYPOPHOSPHATEMIA)

Hypophosphatemia is indicated by a value below 2.5 mg/dL (0.8 mmol/L). Although it often indicates phosphorus deficiency, hypophosphatemia may occur under a variety of circumstances in which total body phosphorus stores are normal. Conversely, phosphorus deficiency is an abnormally low content of phosphorus in lean tissues that may exist in the absence of hypophosphatemia. It can be caused by an intracellular shift of potassium from serum into cells, by increased urinary excretion of potassium, or by decreased intestinal absorption of potassium.

Pathophysiology

Hypophosphatemia may occur during the administration of calories to patients with severe protein-calorie malnutrition. It is most likely to result from overzealous intake or administration of simple carbohydrates. This syndrome can be induced in any person with severe protein-calorie malnutrition (eg, patients with anorexia nervosa or alcoholism, elderly debilitated patients who are unable to eat). As many as 50% of patients hospitalized because of chronic alcoholism have hypophosphatemia.

Marked hypophosphatemia may develop in malnourished patients who receive parenteral nutrition if the phosphorus loss is not corrected. Other causes of hypophosphatemia include heat stroke, prolonged intense hyperventilation, alcohol withdrawal, poor dietary intake, diabetic ketoacidosis, respiratory alkalosis, hepatic encephalopathy, and major thermal burns. Low magnesium levels, low potassium levels, and hyperparathyroidism related to increased urinary losses of phosphorus contribute to hypophosphatemia. Loss of phosphorus through the kidneys also occurs with acute volume expansion, osmotic diuresis, use of carbonic anhydrase inhibitors (acetazolamide

[Diamox]), and some malignancies. Respiratory alkalosis can cause a decrease in phosphorus because of an intracellular shift of phosphorus.

Excess phosphorus binding by antacids may decrease the phosphorus available from the diet to an amount lower than required to maintain serum phosphorus balance. The degree of hypophosphatemia depends on the amount of phosphorus in the diet compared to the dose of antacid. Phosphate can occur with chronic diarrhea or through severe potassium restriction. Vitamin D regulates intestinal ion absorption; therefore, a deficiency of vitamin D may cause decreased calcium and phosphorus levels, which may lead to osteomalacia (softened, brittle bones).

Clinical Manifestations

Most of the signs and symptoms of phosphorus deficiency appear to result from a deficiency of ATP, 2,3-diphosphoglycerate, or both. ATP deficiency impairs cellular energy resources; diphosphoglycerate deficiency impairs oxygen delivery to tissues, resulting in a wide range of neurologic manifestations, such as irritability, fatigue, apprehension, weakness, numbness, paresthesias, dysarthria, dysphagia, diplopia, confusion, seizures, and coma. Hypoxia leads to an increase in respiratory rate and respiratory alkalosis, causing phosphorus to move into the cells and potentiating hypophosphatemia. Hypophosphatemia may predispose a person to infection. In laboratory animals, hypophosphatemia is associated with depression of the chemotactic, phagocytic, and bacterial activity of granulocytes.

Muscle damage may develop as the ATP level in the muscle tissue declines. Clinical manifestations are muscle weakness, which may be subtle or profound and may affect any muscle group; muscle pain; and at times acute rhabdomyolysis (breakdown of skeletal muscle) (Spradling, 2007). Weakness of respiratory muscles may greatly impair ventilation. Hypophosphatemia also may predispose a person to insulin resistance and thus hyperglycemia. Chronic loss of phosphorus can cause bruising and bleeding from platelet dysfunction.

Assessment and Diagnostic Findings

On laboratory analysis, the serum phosphorus level is less than 2.5 mg/dL (0.80 mmol/L) in adults. When reviewing laboratory results, the nurse should keep in mind that glucose or insulin administration causes a slight decrease in the serum phosphorus level. PTH levels are increased in hyperparathyroidism. Serum magnesium may decrease due to increased urinary excretion of magnesium. Alkaline phosphatase is increased with osteoblastic activity. X-rays may show skeletal changes of osteomalacia or rickets.

Medical Management

Prevention of hypophosphatemia is the goal. In patients at risk for hypophosphatemia, serum phosphate levels should be closely monitored and correction initiated before deficits become severe. Adequate amounts of phosphorus should be added to parenteral solutions, and attention should be paid to the phosphorus levels in enteral feeding solutions.

Severe hypophosphatemia is dangerous and requires prompt attention. Aggressive IV phosphorus correction is usually limited to the patient whose serum phosphorus lev-

els decrease to less than 1 mg/dL (0.3 mmol/L) and whose GI tract is not functioning. Possible dangers of IV administration of phosphorus include tetany from hypocalcemia and calcifications in tissues (blood vessels, heart, lung, kidney, eyes) from hyperphosphatemia. IV preparations of phosphorus are available as sodium or potassium phosphate. The rate of phosphorus administration should not exceed 10 mEq/h, and the site should be carefully monitored because tissue sloughing and necrosis can occur with infiltration. In less acute situations, oral phosphorus replacement is usually adequate.

Nursing Management

The nurse identifies patients who are at risk for hypophosphatemia and monitors them. Because malnourished patients receiving parenteral nutrition are at risk when calories are introduced too aggressively, preventive measures involve gradually introducing the solution to avoid rapid shifts of phosphorus into the cells.

For patients with documented hypophosphatemia, careful attention is given to preventing infection, because hypophosphatemia may alter the granulocytes. In patients requiring correction of phosphorus losses, the nurse frequently monitors serum phosphorus levels and documents and reports early signs of hypophosphatemia (apprehension, confusion, change in level of consciousness). If the patient experiences mild hypophosphatemia, foods such as milk and milk products, organ meats, nuts, fish, poultry, and whole grains should be encouraged. With moderate hypophosphatemia, supplements such as Neutra-Phos capsules (250 mg phosphorus/capsule; 7 mEq sodium and potassium), K-Phos (250 mg phosphorus/tablet; 14 mEq potassium), and Fleet's Phospho-Soda (815 mg phosphorus/5 mL) may be prescribed.

PHOSPHORUS EXCESS (HYPERPHOSPHATEMIA)

Hyperphosphatemia is a serum phosphorus level that exceeds 4.5 mg/dL (1.45 mmol/L) in adults.

Pathophysiology

Various conditions can lead to hyperphosphatemia, but the most common is renal failure. Other causes include increased intake, decreased output, or a shift from the intracellular to extracellular space. Conditions such as excessive vitamin D intake, administration of total parenteral nutrition, chemotherapy for neoplastic disease, hypoparathyroidism, metabolic or respiratory acidosis, diabetic ketoacidosis, acute hemolysis, high phosphate intake, profound muscle necrosis, and increased phosphorus absorption may also lead to this phosphorus imbalance. The primary complication of increased phosphorus is metastatic calcification (soft tissue, joints, and arteries), which occurs when the calcium–magnesium product (calcium \times magnesium) exceeds 70 mg/dL.

Clinical Manifestations

An increased serum phosphorus level causes few symptoms. Symptoms that do occur usually result from decreased calcium levels and soft-tissue calcifications. The most important short-term consequence is tetany. Because of the recip-

rocal relationship between phosphorus and calcium, a high serum phosphorus level tends to cause a low serum calcium concentration. Tetany can result, causing tingling sensations in the fingertips and around the mouth. Anorexia, nausea, vomiting, bone and joint pain, muscle weakness, hyperreflexia, and tachycardia may occur.

The major long-term consequence is soft-tissue calcification, which occurs mainly in patients with a reduced glomerular filtration rate. High serum levels of inorganic phosphorus promote precipitation of calcium phosphate in nonosseous sites, decreasing urine output, impairing vision, and producing palpitations.

Assessment and Diagnostic Findings

On laboratory analysis, the serum phosphorus level exceeds 4.5 mg/dL (1.5 mmol/L) in adults. The serum calcium level is useful also for diagnosing the primary disorder and assessing the effects of treatments. X-rays may show skeletal changes with abnormal bone development. PTH levels are decreased in hypoparathyroidism. BUN and creatinine levels are used to assess renal function.

Medical Management

When possible, treatment is directed at the underlying disorder. For example, hyperphosphatemia may be related to volume depletion or respiratory or metabolic acidosis. In renal failure, elevated PTH production contributes to a high phosphorus level and bone disease. Measures to decrease the serum phosphate level and bind phosphorus in the GI tract of these patients include vitamin D preparations, such as calcitriol, which is available in both oral (Rocaltrol) and parenteral (Calcijex, paricalcitol [Zemlar]) forms. IV administration of calcitriol does not increase the serum calcium unless its dose is excessive, thus permitting more aggressive treatment of hyperphosphatemia with calcium-binding antacids (calcium carbonate or calcium citrate). Administration of Amphojel with meals is effective but can cause bone and central nervous system toxicity with long-term use. Restriction of dietary phosphate, forced diuresis with a loop diuretic, volume replacement with saline, and dialysis may also lower phosphorus. Surgery may be indicated for removal of large calcium and phosphorus deposits.

Nursing Management

The nurse monitors patients at risk for hyperphosphatemia. If a low-phosphorus diet is prescribed, the patient is instructed to avoid phosphorus-rich foods such as hard cheeses, cream, nuts, meats, whole-grain cereals, dried fruits, dried vegetables, kidneys, sardines, sweetbreads, and foods made with milk. When appropriate, the nurse instructs the patient to avoid phosphate-containing substances such as laxatives and enemas. The nurse also teaches the patient to recognize the signs of impending hypocalcemia and to monitor for changes in urine output.

Chloride Imbalances

Chloride, the major anion of the ECF, is found more in interstitial and lymph fluid compartments than in blood. Chloride is also contained in gastric and pancreatic juices,

sweat, bile, and saliva. Sodium and chloride make up the largest electrolyte composition of the ECF and assist in determining osmotic pressure. Chloride is produced in the stomach, where it combines with hydrogen to form hydrochloric acid. Chloride control depends on the intake of chloride and the excretion and reabsorption of its ions in the kidneys. A small amount of chloride is lost in the feces.

The normal serum chloride level is 97 to 107 mEq/L (97 to 107 mmol/L). Inside the cell, the chloride level is 4 mEq/L. The serum level of chloride reflects a change in dilution or concentration of the ECF and does so in direct proportion to the sodium concentration. Serum osmolality parallels chloride levels as well. Aldosterone secretion increases sodium reabsorption, thereby increasing chloride reabsorption. The choroid plexus, which secretes cerebrospinal fluid in the brain, depends on sodium and chloride to attract water to form the fluid portion of the cerebrospinal fluid. Bicarbonate has an inverse relationship with chloride. As chloride moves from plasma into the red blood cells (called the chloride shift), bicarbonate moves back into the plasma. Hydrogen ions are formed, which then help release oxygen from hemoglobin. When the level of one of these three electrolytes (sodium, bicarbonate, or chloride) is disturbed, the other two are also affected. Chloride assists in maintaining acid–base balance and works as a buffer in the exchange of oxygen and carbon dioxide in red blood cells. Chloride is primarily obtained from the diet as table salt.

CHLORIDE DEFICIT (HYPOCHLOREMIA)

Hypochloremia is a serum chloride level below 97 mEq/L (97 mmol/L).

Pathophysiology

Hypochloremia can occur with GI tube drainage, gastric suctioning, gastric surgery, and severe vomiting and diarrhea. Administration of chloride-deficient IV solutions, low sodium intake, decreased serum sodium levels, metabolic alkalosis, massive blood transfusions, diuretic therapy, burns, and fever may cause hypochloremia. Administration of aldosterone, ACTH, corticosteroids, bicarbonate, or laxatives decreases serum chloride levels as well. As chloride decreases (usually because of volume depletion), sodium and bicarbonate ions are retained by the kidney to balance the loss. Bicarbonate accumulates in the ECF, which raises the pH and leads to hypochloremic metabolic alkalosis.

Clinical Manifestations

The signs and symptoms of hypochloremia are those of acid–base and electrolyte imbalances. The signs and symptoms of hyponatremia, hypokalemia, and metabolic alkalosis may also be present. Metabolic alkalosis is a disorder that results in a high pH and a high serum bicarbonate level as a result of excess alkali intake or loss of hydrogen ions. With compensation, the partial pressure of carbon dioxide in arterial blood (PaCO_2) increases to 50 mm Hg. Hyperexcitability of muscles, tetany, hyperactive DTRs, weakness, twitching, and muscle cramps may result. Hypokalemia can cause hypochloremia, resulting in cardiac dysrhythmias. In

addition, because low chloride levels parallel low sodium levels, a water excess may occur. Hyponatremia can cause seizures and coma.

Assessment and Diagnostic Findings

In addition to the chloride level, sodium and potassium levels are also evaluated, because these electrolytes are lost along with chloride. Arterial blood gas analysis identifies the acid–base imbalance, which is usually metabolic alkalosis. The urine chloride level, which is also measured, decreases in hypochloremia.

Medical Management

Treatment involves correcting the cause of hypochloremia and the contributing electrolyte and acid–base imbalances. Normal saline (0.9% sodium chloride) or half-strength saline (0.45% sodium chloride) solution is administered by IV to replace the chloride. If the patient is receiving a diuretic (loop, osmotic, or thiazide), it may be discontinued or another diuretic prescribed.

Ammonium chloride, an acidifying agent, may be prescribed to treat metabolic alkalosis; the dosage depends on the patient's weight and serum chloride level. This agent is metabolized by the liver, and its effects last for about 3 days. Its use should be avoided in patients with impaired liver or renal function.

Nursing Management

The nurse monitors the patient's I&O, arterial blood gas values, and serum electrolyte levels. Changes in the patient's level of consciousness and muscle strength and movement are reported to the physician promptly. Vital signs are monitored, and respiratory assessment is carried out frequently. The nurse provides and teaches the patient about foods with high chloride content. Foods high in chloride include tomato juice, bananas, dates, eggs, cheese, milk, salty broth, canned vegetables, and processed meats. A person who drinks free water (water without electrolytes) or bottled water and excretes large amounts of chloride needs instruction to avoid drinking this kind of water.

CHLORIDE EXCESS (HYPERCHLOREMIA)

Hyperchloremia exists when the serum level of chloride exceeds 107 mEq/L (107 mmol/L). Hyponatremia, bicarbonate loss, and metabolic acidosis can occur with high chloride levels.

Pathophysiology

High serum chloride levels are almost exclusively a result of iatrogenically induced hyperchloremic metabolic acidosis, stemming from excessive administration of chloride relative to sodium, most commonly as 0.9% normal saline solution, 0.45% normal saline solution, or lactated Ringer's solution (Muller & Bell, 2008). This condition can also be caused by the loss of bicarbonate ions via the kidney or the GI tract with a corresponding increase in chloride ions. Chloride ions in the form of acidifying salts accumulate, and acidosis occurs with a decrease in bicarbonate ions. Head trauma, increased perspiration, excess adrenocortical hormone production, and decreased glomerular filtration can lead to a high serum chloride level.

Clinical Manifestations

The signs and symptoms of hyperchloremia are the same as those of metabolic acidosis: hypervolemia and hypernatremia. Tachypnea; weakness; lethargy; deep, rapid respirations; diminished cognitive ability; and hypertension occur. If untreated, hyperchloremia can lead to a decrease in cardiac output, dysrhythmias, and coma. A high chloride level is accompanied by a high sodium level and fluid retention.

Assessment and Diagnostic Findings

The serum chloride level is 108 mEq/L (108 mmol/L) or greater, the serum sodium level is greater than 145 mEq/L (145 mmol/L), the serum pH is less than 7.35, and the serum bicarbonate level is less than 22 mEq/L (22 mmol/L). Urine chloride excretion increases.

Calculation of the serum anion gap is important in analyzing acid–base disorders. The sum of all negatively charged electrolytes (anions) equals the sum of all positively charged electrolytes (cations), with several anions that are not routinely measured leading to an anion gap. It is based primarily on three electrolytes: sodium, chloride, and bicarbonate or serum carbon dioxide (CO₂). A normal anion gap is 8 to 12 mEq/L (8 to 12 mmol/L). A low anion gap may be attributed to hypoproteinemia, whereas an elevated anion gap can be due to metabolic acidosis.

Medical Management

Correcting the underlying cause of hyperchloremia and restoring electrolyte, fluid, and acid–base balance are essential. Hypotonic IV solutions may be administered to restore balance. Lactated Ringer's solution may be prescribed to convert lactate to bicarbonate in the liver, which increases the bicarbonate level and corrects the acidosis. IV sodium bicarbonate may be administered to increase bicarbonate levels, which leads to the renal excretion of chloride ions because bicarbonate and chloride compete for combination with sodium. Diuretics may be administered to eliminate chloride as well. Sodium, chloride, and fluids are restricted.

Nursing Management

Monitoring vital signs, arterial blood gas values, and I&O is important to assess the patient's status and the effectiveness of treatment. Assessment findings related to respiratory, neurologic, and cardiac systems are documented, and changes are discussed with the physician. The nurse teaches the patient about the diet that should be followed to manage hyperchloremia and maintain adequate hydration.

ACID–BASE DISTURBANCES

Acid–base disturbances are commonly encountered in clinical practice. Identification of the specific acid–base imbalance is important in identifying the underlying cause of the disorder and determining appropriate treatment.

Plasma pH is an indicator of hydrogen ion (H⁺) concentration. Homeostatic mechanisms keep pH within a normal range (7.35 to 7.45) (Ruholl, 2006; Swiderski & Byrum, 2007). These mechanisms consist of buffer systems, the kidneys, and the lungs. The H⁺ concentration is extremely im-

portant: The greater the concentration, the more acidic the solution and the lower the pH. The lower the H^+ concentration, the more alkaline the solution and the higher the pH. The pH range compatible with life (6.8 to 7.8) represents a 10-fold difference in H^+ concentration in plasma.

Buffer systems prevent major changes in the pH of body fluids by removing or releasing H^+ ; they can act quickly to prevent excessive changes in H^+ concentration. Hydrogen ions are buffered by both intracellular and extracellular buffers. The body's major extracellular buffer system is the bicarbonate-carbonic acid buffer system, which is assessed when arterial blood gases are measured. Normally, there are 20 parts of bicarbonate (HCO_3^-) to one part of carbonic acid (H_2CO_3). If this ratio is altered, the pH will change. It is the ratio of HCO_3^- to H_2CO_3 that is important in maintaining pH, not absolute values. CO_2 is a potential acid; when dissolved in water, it becomes carbonic acid ($CO_2 + H_2O = H_2CO_3$). Therefore, when CO_2 is increased, the carbonic acid content is also increased, and vice versa. If either bicarbonate or carbonic acid is increased or decreased so that the 20:1 ratio is no longer maintained, acid-base imbalance results.

Less important buffer systems in the ECF include the inorganic phosphates and the plasma proteins. Intracellular buffers include proteins, organic and inorganic phosphates, and, in red blood cells, hemoglobin.

The kidneys regulate the bicarbonate level in the ECF; they can regenerate bicarbonate ions as well as reabsorb them from the renal tubular cells. In respiratory acidosis and most cases of metabolic acidosis, the kidneys excrete hydrogen ions and conserve bicarbonate ions to help restore balance. In respiratory and metabolic alkalosis, the kidneys retain hydrogen ions and excrete bicarbonate ions to help restore balance. The kidneys obviously cannot compensate for the metabolic acidosis created by renal failure. Renal compensation for imbalances is relatively slow (a matter of hours or days).

The lungs, under the control of the medulla, control the CO_2 and thus the carbonic acid content of the ECF. They do so by adjusting ventilation in response to the amount of CO_2 in the blood. A rise in the partial pressure of CO_2 in arterial blood ($PaCO_2$) is a powerful stimulant to respiration. Of course, the partial pressure of oxygen in arterial blood (PaO_2) also influences respiration. However, its effect is not as marked as that produced by the $PaCO_2$.

In metabolic acidosis, the respiratory rate increases, causing greater elimination of CO_2 (to reduce the acid load). In metabolic alkalosis, the respiratory rate decreases, causing CO_2 to be retained (to increase the acid load) (Swiderski & Byrum, 2007).

Acute and Chronic Metabolic Acidosis (Base Bicarbonate Deficit)

Metabolic acidosis is a common clinical disturbance characterized by a low pH (increased H^+ concentration) and a low plasma bicarbonate concentration. It can be produced by a gain of hydrogen ion or a loss of bicarbonate (Ruhoff, 2006; Swiderski & Byrum, 2007). It can be divided clinically

into two forms, according to the values of the serum anion gap: high anion gap acidosis and normal anion gap acidosis. The anion gap reflects normally unmeasured anions (phosphates, sulfates, and proteins) in plasma. Measuring the anion gap is essential in analyzing acid-base disorders correctly. The anion gap can be calculated by either one of the following equations:

$$\begin{aligned}\text{Anion gap} &= Na^+ + K^+ - (Cl^- + HCO_3^-) \\ \text{Anion gap} &= Na^+ - (Cl^- + HCO_3^-)\end{aligned}$$

Potassium is often omitted from the equation because of its low level in the plasma; therefore, the second equation is used more often than the first.

The normal value for an anion gap is 8 to 12 mEq/L (8 to 12 mmol/L) without potassium in the equation. If potassium is included in the equation, the normal value for the anion gap is 12 to 16 mEq/L (12 to 16 mmol/L). The unmeasured anions in the serum normally account for less than 16 mEq/L of the anion production. An anion gap greater than 16 mEq (16 mmol/L) suggests excessive accumulation of unmeasured anions. An anion gap occurs because not all electrolytes are measured. More anions are left unmeasured than cations.

Pathophysiology

Normal anion gap acidosis results from the direct loss of bicarbonate, as in diarrhea, lower intestinal fistulas, ureterostomies, and use of diuretics; early renal insufficiency; excessive administration of chloride; and the administration of parenteral nutrition without bicarbonate or bicarbonate-producing solutes (eg, lactate). Normal anion gap acidosis is also referred to as hyperchloremic acidosis. A reduced or negative anion gap is primarily caused by hypoproteinemia. Disorders that cause a decreased or negative anion gap are rare compared to those related to an increased or high anion gap.

High anion gap acidosis results from excessive accumulation of fixed acid. If increased to 30 mEq/L (30 mmol/L) or more, then a high anion gap metabolic acidosis is present regardless of the values of pH and HCO_3^- . High ion gap occurs in ketoacidosis, lactic acidosis, the late phase of salicylate poisoning, uremia, methanol or ethylene glycol toxicity, and ketoacidosis with starvation. The hydrogen is buffered by HCO_3^- , causing the bicarbonate concentration to fall. In all of these instances, abnormally high levels of anions flood the system, increasing the anion gap above normal limits.

Clinical Manifestations

Signs and symptoms of metabolic acidosis vary with the severity of the acidosis but include headache, confusion, drowsiness, increased respiratory rate and depth, nausea, and vomiting. Peripheral vasodilation and decreased cardiac output occur when the pH drops to less than 7. Additional physical assessment findings include decreased blood pressure, cold and clammy skin, dysrhythmias, and shock. Chronic metabolic acidosis is usually seen with chronic renal failure.

Assessment and Diagnostic Findings

Arterial blood gas measurements are valuable in diagnosing metabolic acidosis. Expected blood gas changes include a low bicarbonate level (less than 22 mEq/L) and a low pH (less than 7.35) (Swiderski & Byrum, 2007). The cardinal

feature of metabolic acidosis is a decrease in the serum bicarbonate level. Hyperkalemia may accompany metabolic acidosis as a result of the shift of potassium out of the cells. Later, as the acidosis is corrected, potassium moves back into the cells and hypokalemia may occur. Hyperventilation decreases the CO_2 level as a compensatory action. Calculation of the anion gap is helpful in determining the cause of metabolic acidosis. An ECG detects dysrhythmias caused by the increased potassium.

Medical Management

Treatment is directed at correcting the metabolic imbalance (Ruholl, 2006). If the problem results from excessive intake of chloride, treatment is aimed at eliminating the source of the chloride. When necessary, bicarbonate is administered. Although hyperkalemia occurs with acidosis, hypokalemia may occur with reversal of the acidosis and subsequent movement of potassium back into the cells. Therefore, the serum potassium level is monitored closely, and hypokalemia is corrected as acidosis is reversed.

In chronic metabolic acidosis, low serum calcium levels are treated before the chronic metabolic acidosis is treated, to avoid tetany resulting from an increase in pH and a decrease in ionized calcium. Alkalinizing agents may be administered. Treatment modalities may also include hemodialysis or peritoneal dialysis.

Acute and Chronic Metabolic Alkalosis (Base Bicarbonate Excess)

Metabolic alkalosis is a clinical disturbance characterized by a high pH (decreased H^+ concentration) and a high plasma bicarbonate concentration. It can be produced by a gain of bicarbonate or a loss of H^+ (Porth & Matfin, 2009).

Pathophysiology

Probably the most common cause of metabolic alkalosis is vomiting or gastric suction with loss of hydrogen and chloride ions. The disorder also occurs in pyloric stenosis, in which only gastric fluid is lost. Gastric fluid has an acid pH (usually 1 to 3), and loss of this highly acidic fluid increases the alkalinity of body fluids. Other situations predisposing to metabolic alkalosis include those associated with loss of potassium, such as diuretic therapy that promotes excretion of potassium (eg, thiazides, furosemide), and excessive adrenocorticoid hormones (as in hyperaldosteronism and Cushing's syndrome).

Hypokalemia produces alkalosis in two ways: (1) the kidneys conserve potassium, and therefore H^+ excretion increases; and (2) cellular potassium moves out of the cells into the ECF in an attempt to maintain near-normal serum levels (as potassium ions leave the cells, hydrogen ions must enter to maintain electroneutrality). Excessive alkali ingestion from antacids containing bicarbonate or from use of sodium bicarbonate during cardiopulmonary resuscitation can also cause metabolic alkalosis.

Chronic metabolic alkalosis can occur with long-term diuretic therapy (thiazides or furosemide), villous adenoma, external drainage of gastric fluids, significant potassium depletion, cystic fibrosis, and the chronic ingestion of milk and calcium carbonate.

Clinical Manifestations

Alkalosis is primarily manifested by symptoms related to decreased calcium ionization, such as tingling of the fingers and toes, dizziness, and hypertonic muscles. The ionized fraction of serum calcium decreases in alkalosis as more calcium combines with serum proteins. Because it is the ionized fraction of calcium that influences neuromuscular activity, symptoms of hypocalcemia are often the predominant symptoms of alkalosis. Respirations are depressed as a compensatory action by the lungs. Atrial tachycardia may occur. As the pH increases and hypokalemia develops, ventricular disturbances may occur. Decreased motility and paralytic ileus may also be evident.

Symptoms of chronic metabolic alkalosis are the same as for acute metabolic alkalosis, and as potassium decreases, frequent premature ventricular contractions or U waves are seen on the ECG.

Assessment and Diagnostic Findings

Evaluation of arterial blood gases reveals a pH greater than 7.45 and a serum bicarbonate concentration greater than 26 mEq/L. The PaCO_2 increases as the lungs attempt to compensate for the excess bicarbonate by retaining CO_2 . This hypoventilation is more pronounced in semiconscious, unconscious, or debilitated patients than in alert patients. The former may develop marked hypoxemia as a result of hypoventilation. Hypokalemia may accompany metabolic alkalosis.

Urine chloride levels may help identify the cause of metabolic alkalosis if the patient's history provides inadequate information. Metabolic alkalosis is the setting in which urine chloride concentration may be a more accurate estimate of fluid volume than the urine sodium concentration. Urine chloride concentrations help to differentiate between vomiting, diuretic therapy, and excessive adrenocorticosteroid secretion as the cause of the metabolic alkalosis. In patients with vomiting or cystic fibrosis, those receiving nutritional repletion, and those receiving diuretic therapy, hypovolemia and hypochloremia produce urine chloride concentrations lower than 25 mEq/L. Signs of hypovolemia are not present, and the urine chloride concentration exceeds 40 mEq/L in patients with mineralocorticoid excess or alkali loading; these patients usually have expanded fluid volume. The urine chloride concentration should be less than 15 mEq/L when decreased chloride levels and hypovolemia occur.

Medical Management

Treatment of both acute and chronic metabolic alkalosis is aimed at correcting the underlying acid-base disorder (Gennari, 2005; Ruholl, 2006). Because of volume depletion from GI loss, the patient's fluid I&O must be monitored carefully.

Sufficient chloride must be supplied for the kidney to absorb sodium with chloride (allowing the excretion of excess bicarbonate). Treatment also includes restoring normal fluid volume by administering sodium chloride fluids (because continued volume depletion perpetuates the alkalosis). In patients with hypokalemia, potassium is adminis-

tered as KCl to replace both K^+ and Cl^- losses. H_2 receptor antagonists, such as cimetidine (Tagamet), reduce the production of gastric HCl, thereby decreasing the metabolic alkalosis associated with gastric suction. Carbonic anhydrase inhibitors are useful in treating metabolic alkalosis in patients who cannot tolerate rapid volume expansion (eg, patients with heart failure).

Acute and Chronic Respiratory Acidosis (Carbonic Acid Excess)

Respiratory acidosis is a clinical disorder in which the pH is less than 7.35 and the $PaCO_2$ is greater than 42 mm Hg. It may be either acute or chronic.

Pathophysiology

Respiratory acidosis is always due to inadequate excretion of CO_2 with inadequate ventilation, resulting in elevated plasma CO_2 concentrations and, consequently, increased levels of carbonic acid. In addition to an elevated $PaCO_2$, hypoventilation usually causes a decrease in PaO_2 . Acute respiratory acidosis occurs in emergency situations, such as acute pulmonary edema, aspiration of a foreign object, atelectasis, pneumothorax, overdose of sedatives, sleep apnea, administration of oxygen to a patient with chronic hypercapnia (excessive CO_2 in the blood), severe pneumonia, and acute respiratory distress syndrome. Respiratory acidosis can also occur in diseases that impair respiratory muscles, such as muscular dystrophy, myasthenia gravis, and Guillain-Barré syndrome. Mechanical ventilation may be associated with hypercapnia if the rate of ventilation is inadequate and CO_2 retained.

Clinical Manifestations

Clinical signs in acute and chronic respiratory acidosis vary. Sudden hypercapnia (elevated $PaCO_2$) can cause increased pulse and respiratory rate, increased blood pressure, mental cloudiness, and a feeling of fullness in the head. An elevated $PaCO_2$, greater than 60 mm Hg, causes cerebrovascular vasodilation and increased cerebral blood flow. Ventricular fibrillation may be the first sign of respiratory acidosis in anesthetized patients.

If respiratory acidosis is severe, intracranial pressure may increase, resulting in papilledema and dilated conjunctival blood vessels. Hyperkalemia may result as the hydrogen concentration overwhelms the compensatory mechanisms and H^+ moves into cells, causing a shift of potassium out of the cell.

Chronic respiratory acidosis occurs with pulmonary diseases such as chronic emphysema and bronchitis, obstructive sleep apnea, and obesity. As long as the $PaCO_2$ does not exceed the body's ability to compensate, the patient will be asymptomatic. However, if the $PaCO_2$ increases rapidly, cerebral vasodilation will increase the intracranial pressure, and cyanosis and tachypnea will develop. Patients with chronic obstructive pulmonary disease (COPD) who gradually accumulate CO_2 over a prolonged period (days to months) may not develop symptoms of hypercapnia because compensatory renal changes have had time to occur.

NURSING ALERT

If the $PaCO_2$ is chronically higher than 50 mm Hg, the respiratory center becomes relatively insensitive to CO_2 as a respiratory stimulant, leaving hypoxemia as the major drive for respiration. Oxygen administration may remove the stimulus of hypoxemia, and the patient develops "carbon dioxide narcosis" unless the situation is quickly reversed. Therefore, oxygen is administered only with extreme caution.

Assessment and Diagnostic Findings

Arterial blood gas analysis reveals a pH lower than 7.35, a $PaCO_2$ greater than 42 mm Hg, and a variation in the bicarbonate level, depending on the duration of the acute respiratory acidosis. When compensation (renal retention of bicarbonate) has fully occurred, the arterial pH is within the lower limits of normal. Depending on the cause of respiratory acidosis, other diagnostic measures include monitoring of serum electrolyte levels, chest x-ray for determining any respiratory disease, and a drug screen if an overdose is suspected. An ECG to identify any cardiac involvement as a result of COPD may be indicated as well.

Medical Management

Treatment is directed at improving ventilation; exact measures vary with the cause of inadequate ventilation (Gennari, 2005). Pharmacologic agents are used as indicated. For example, bronchodilators help reduce bronchial spasm, antibiotics are used for respiratory infections, and thrombolytics or anticoagulants are used for pulmonary emboli (see Chapter 25).

Pulmonary hygiene measures are initiated, when necessary, to clear the respiratory tract of mucus and purulent drainage. Adequate hydration (2 to 3 L/day) is indicated to keep the mucous membranes moist and thereby facilitate the removal of secretions. Supplemental oxygen is administered as necessary.

Mechanical ventilation, used appropriately, may improve pulmonary ventilation. Inappropriate mechanical ventilation (eg, increased dead space, insufficient rate or volume settings, high fraction of inspired oxygen [FiO_2] with excessive CO_2 production) may cause such rapid excretion of CO_2 that the kidneys are unable to eliminate excess bicarbonate quickly enough to prevent alkalosis and seizures. For this reason, the elevated $PaCO_2$ must be decreased slowly. Placing the patient in a semi-Fowler's position facilitates expansion of the chest wall.

Treatment of chronic respiratory acidosis is the same as for acute respiratory acidosis.

Acute and Chronic Respiratory Alkalosis (Carbonic Acid Deficit)

Respiratory alkalosis is a clinical condition in which the arterial pH is greater than 7.45 and the $PaCO_2$ is less than 38 mm Hg. As with respiratory acidosis, acute and chronic conditions can occur.

Pathophysiology

Respiratory alkalosis is always caused by hyperventilation, which causes excessive “blowing off” of CO_2 and, hence, a decrease in the plasma carbonic acid concentration. Causes include extreme anxiety, hypoxemia, early phase of salicylate intoxication, gram-negative bacteremia, and inappropriate ventilator settings that do not match the patient’s requirements.

Chronic respiratory alkalosis results from chronic hypocapnia, and decreased serum bicarbonate levels are the consequence. Chronic hepatic insufficiency and cerebral tumors are predisposing factors.

Clinical Manifestations

Clinical signs consist of lightheadedness due to vasoconstriction and decreased cerebral blood flow, inability to concentrate, numbness and tingling from decreased calcium ionization, tinnitus, and sometimes loss of consciousness. Cardiac effects of respiratory alkalosis include tachycardia and ventricular and atrial dysrhythmias (Heitz & Horne, 2005).

Assessment and Diagnostic Findings

Analysis of arterial blood gases assists in the diagnosis of respiratory alkalosis. In the acute state, the pH is elevated above normal as a result of a low PaCO_2 and a normal bicarbonate level. (The kidneys cannot alter the bicarbonate level quickly.) In the compensated state, the kidneys have had sufficient time to lower the bicarbonate level to a near-normal level. Evaluation of serum electrolytes is indicated to identify any decrease in potassium, as hydrogen is pulled out of the cells in exchange for potassium; decreased calcium, as severe alkalosis inhibits calcium ionization, resulting in carpopedal spasms and tetany; or decreased phosphate due to alkalosis, causing an increased uptake of phosphate by the cells. A toxicology screen should be performed to rule out salicylate intoxication.

Patients with chronic respiratory alkalosis are usually asymptomatic, and the diagnostic evaluation and plan of care are the same as for acute respiratory alkalosis.

Medical Management

Treatment depends on the underlying cause of respiratory alkalosis. If the cause is anxiety, the patient is instructed to breathe more slowly to allow CO_2 to accumulate or to breathe into a closed system (such as a paper bag). A sedative may be required to relieve hyperventilation in very anxious patients. Treatment of other causes of respiratory alkalosis is directed at correcting the underlying problem.

Mixed Acid–Base Disorders

Patients can simultaneously experience two or more independent acid–base disorders. A normal pH in the presence of changes in the PaCO_2 and plasma HCO_3^- concentration immediately suggests a mixed disorder. An example of a mixed disorder is the simultaneous occurrence of metabolic acidosis and respiratory acidosis during respiratory and cardiac arrest. The only mixed disorder that cannot occur is a mixed respiratory acidosis and alkalosis, because it is impossible to have alveolar hypoventilation and hyperventilation at the same time.

Compensation

Generally, the pulmonary and renal systems compensate for each other to return the pH to normal. In a single acid–base disorder, the system not causing the problem tries to compensate by returning the ratio of bicarbonate to carbonic acid to the normal 20:1. The lungs compensate for metabolic disturbances by changing CO_2 excretion. The kidneys compensate for respiratory disturbances by altering bicarbonate retention and H^+ secretion.

In respiratory acidosis, excess hydrogen is excreted in the urine in exchange for bicarbonate ions. In respiratory alkalosis, the renal excretion of bicarbonate increases, and hydrogen ions are retained. In metabolic acidosis, the compensatory mechanisms increase the ventilation rate and the renal retention of bicarbonate. In metabolic alkalosis, the respiratory system compensates by decreasing ventilation to conserve CO_2 and increase the PaCO_2 . Because the lungs respond to acid–base disorders within minutes, compensation for metabolic imbalances occurs faster than compensation for respiratory imbalances. Table 14-5 summarizes compensation effects.

Blood Gas Analysis

Blood gas analysis is often used to identify the specific acid–base disturbance and the degree of compensation that has occurred. The analysis is usually based on an arterial blood sample, but if an arterial sample cannot be obtained, a mixed venous sample may be used. Results of arterial blood gas analysis provide information about alveolar ventilation, oxygenation, and acid–base balance. It is necessary to evaluate the concentrations of serum electrolytes (sodium, potassium, and chloride) and carbon dioxide along with arterial blood gas data, because they are often the first sign of an acid–base disorder. The health history, physical examination, previous blood gas results, and serum electrolytes should always be part of the assessment used to determine the cause of the acid–base disorder (Porth & Matfin, 2009). Responding to isolated sets of blood gas results without these data can lead to serious errors in interpretation. Treatment

Table 14-5 ACID–BASE DISORDERS AND COMPENSATION

Disorder	Initial Event	Compensation
Respiratory acidosis	↓ pH, ↑ or normal HCO_3^- , ↑ PaCO_2	↑ Renal acid excretion and ↑ serum HCO_3^-
Respiratory alkalosis	↑ pH, ↓ or normal HCO_3^- , ↓ PaCO_2	↓ Renal acid excretion and ↓ serum HCO_3^-
Metabolic acidosis	↓ pH, ↓ HCO_3^- , ↓ or normal PaCO_2	Hyperventilation with resulting ↓ PaCO_2 (conserves HCO_3^-)
Metabolic alkalosis	↑ pH, ↑ HCO_3^- , ↑ or normal PaCO_2	Hypoventilation with resulting ↑ PaCO_2

Table 14-6 NORMAL VALUES FOR ARTERIAL AND MIXED VENOUS BLOOD

Parameter	Arterial Blood	Mixed Venous Blood
pH	7.35–7.45	7.32–7.42
PaCO ₂	35–45 mm Hg	38–52 mm Hg
PaO ₂ *	70–100 mm Hg	24–48 mm Hg
HCO ₃ ⁻	19–25 mEq/L	19–25 mEq/L
Base excess/deficit	±5 mEq/L	±5 mEq/L
Oxygen saturation	>90–95%	40–70%

*At altitudes of 3000 feet and higher, the values for oxygen are decreased.

of the underlying condition usually corrects most acid–base disorders. Table 14-6 compares normal ranges of venous and arterial blood gas values. See also Chart 14-2.

Parenteral Fluid Therapy

When no other route of administration is available, fluids are administered by IV in hospitals, outpatient diagnostic

and surgical settings, clinics, and homes to replace fluids, administer medications, and provide nutrients.

Purpose

The choice of an IV solution depends on the purpose of its administration. Generally, IV fluids are administered to achieve one or more of the following goals:

- To provide water, electrolytes, and nutrients to meet daily requirements
- To replace water and correct electrolyte deficits
- To administer medications and blood products

IV solutions contain dextrose or electrolytes mixed in various proportions with water. Pure, electrolyte-free water can never be administered by IV because it rapidly enters red blood cells and causes them to rupture.

Types of Intravenous Solutions

Solutions are often categorized as **isotonic**, **hypotonic**, or **hypertonic**, according to whether their total osmolality is the same as, less than, or greater than that of blood, respec-

CHART 14-2

Assessing for Arterial Blood Gases

The following steps are recommended to evaluate arterial blood gas values. They are based on the assumption that the average values are:

$$\begin{aligned} \text{pH} &= 7.4 \\ \text{PaCO}_2 &= 40 \text{ mm Hg} \\ \text{HCO}_3^- &= 24 \text{ mEq/L} \end{aligned}$$

1. First, note the pH. It can be high, low, or normal, as follows:

$$\begin{aligned} \text{pH} &> 7.4 \text{ (alkalosis)} \\ \text{pH} &< 7.4 \text{ (acidosis)} \\ \text{pH} &= 7.4 \text{ (normal)} \end{aligned}$$

A normal pH may indicate perfectly normal blood gases, or it may be an indication of a *compensated* imbalance. A compensated imbalance is one in which the body has been able to correct the pH by either respiratory or metabolic changes (depending on the primary problem). For example, a patient with primary metabolic acidosis starts out with a low bicarbonate level but a normal CO₂ level. Soon afterward, the lungs try to compensate for the imbalance by exhaling large amounts of CO₂ (hyperventilation). As another example, a patient with primary respiratory acidosis starts out with a high CO₂ level; soon afterward, the kidneys attempt to compensate by retaining bicarbonate. If the compensatory mechanism is able to restore the bicarbonate-to-carbonic acid ratio back to 20:1, full compensation (and thus normal pH) will be achieved.

2. The next step is to determine the primary cause of the disturbance. This is done by evaluating the PaCO₂ and HCO₃⁻ in relation to the pH.

Example: pH >7.4 (alkalosis)

- a. If the PaCO₂ is <40 mm Hg, the primary disturbance is respiratory alkalosis. (This situation occurs when a patient hyperventilates and “blows off” too much CO₂. Recall that CO₂ dissolved in water becomes carbonic acid, the acid side of the “carbonic acid–bicarbonate buffer system.”)
- b. If the HCO₃⁻ is >24 mEq/L, the primary disturbance is metabolic alkalosis. (This situation occurs when the

body gains too much bicarbonate, an alkaline substance. Bicarbonate is the basic or alkaline side of the “carbonic acid–bicarbonate buffer system.”)

Example: pH <7.4 (acidosis)

- a. If the PaCO₂ is >40 mm Hg, the primary disturbance is respiratory acidosis. (This situation occurs when a patient hypoventilates and thus retains too much CO₂, an acidic substance.)
 - b. If the HCO₃⁻ is <24 mEq/L, the primary disturbance is metabolic acidosis. (This situation occurs when the body’s bicarbonate level drops, either because of direct bicarbonate loss or because of gains of acids such as lactic acid or ketones.)
3. The next step involves determining if compensation has begun. This is done by looking at the value other than the primary disorder. If it is moving in the same direction as the primary value, compensation is under way. Consider the following gases:

	pH	PaCO ₂	HCO ₃ ⁻
(1)	7.2	60 mm Hg	24 mEq/L
(2)	7.4	60 mm Hg	37 mEq/L

The first set (1) indicates acute respiratory acidosis without compensation (the PaCO₂ is high, the HCO₃⁻ is normal). The second set (2) indicates chronic respiratory acidosis. Note that compensation has taken place; that is, the HCO₃⁻ has elevated to an appropriate level to balance the high PaCO₂ and produce a normal pH.

4. Two distinct acid–base disturbances may occur simultaneously. These can be identified when the pH does not explain one of the changes.

Example: Metabolic and respiratory acidosis

- | | | | |
|----|-------------------------------|-----|----------------|
| a. | pH | 7.2 | decreased acid |
| b. | PaCO ₂ | 52 | increased acid |
| c. | HCO ₃ ⁻ | 13 | decreased acid |
5. Evaluate the patient to determine if the clinical signs and symptoms are compatible with acid–base analysis.

tively (see earlier discussion of osmolality). Electrolyte solutions are considered isotonic if the total electrolyte content (anions + cations) is approximately 310 mEq/L, hypotonic if the total electrolyte content is less than 250 mEq/L, and hypertonic if the total electrolyte content is greater than 375 mEq/L. The nurse must also consider a solution's osmolality, keeping in mind that the osmolality of plasma is approximately 300 mOsm/L (300 mmol/L). For example, a 10% dextrose solution has an osmolality of approximately 505 mOsm/L.

Isotonic Fluids

Fluids that are classified as isotonic have a total osmolality close to that of the ECF and do not cause red blood cells to shrink or swell. The composition of these fluids may or may not approximate that of the ECF. Isotonic fluids expand the ECF volume. One liter of isotonic fluid expands the ECF by 1 L; however, it expands the plasma by only 0.25 L because it is a crystalloid fluid and diffuses quickly into the ECF compartment. For the same reason, 3 L of isotonic fluid is needed to replace 1 L of blood loss. Because these fluids expand the intravascular space, patients with hypertension and heart failure should be carefully monitored for signs of fluid overload.

D₅W

A solution of D₅W has a serum osmolality of 252 mOsm/L. Once administered, the glucose is rapidly metabolized, and this initially isotonic solution then disperses as a hypotonic fluid, one-third extracellular and two-thirds intracellular. It is essential to consider this action of D₅W, especially if the patient is at risk for increased intracranial pressure. During fluid resuscitation, this solution should not be used, because hyperglycemia can result. Therefore, D₅W is used mainly to supply water and to correct an increased serum osmolality. About 1 L of D₅W provides fewer than 200 kcal and is a minor source of the body's daily caloric requirements.

Normal Saline Solution

Normal saline (0.9% sodium chloride) solution has a total osmolality of 308 mOsm/L. Because the osmolality is entirely contributed by electrolytes, the solution remains within the ECF. For this reason, normal saline solution is often used to correct an extracellular volume deficit. Although referred to as "normal," it contains only sodium and chloride and is not identical to ECF. It is used with administration of blood transfusions and to replace large sodium losses, such as in burn injuries. It is not used for heart failure, pulmonary edema, renal impairment, or sodium retention. Normal saline does not supply calories.

Other Isotonic Solutions

Several other solutions contain ions in addition to sodium and chloride and are somewhat similar to the ECF in composition. Lactated Ringer's solution contains potassium and calcium in addition to sodium chloride. It is used to correct dehydration and sodium depletion and replace GI losses. Lactated Ringer's solution contains bicarbonate precursors as well. These solutions are marketed, with slight variations, under various trade names.

Hypotonic Fluids

One purpose of hypotonic solutions is to replace cellular fluid, because it is hypotonic compared with plasma. Another is to provide free water for excretion of body wastes. At times, hypotonic sodium solutions are used to treat hyponatremia and other hyperosmolar conditions. Half-strength saline (0.45% sodium chloride) solution, with an osmolality of 154 mOsm/L, is frequently used. Multiple-electrolyte solutions are also available. Excessive infusions of hypotonic solutions can lead to intravascular fluid depletion, decreased blood pressure, cellular edema, and cell damage. These solutions exert less osmotic pressure than the ECF.

Hypertonic Fluids

When normal saline solution or lactated Ringer's solution contains 5% dextrose, the total osmolality exceeds that of the ECF. However, the dextrose is quickly metabolized, and only the isotonic solution remains. Therefore, any effect on the intracellular compartment is temporary. Similarly, with hypotonic multiple-electrolyte solutions containing 5% dextrose, once the dextrose is metabolized, these solutions disperse as hypotonic fluids. Higher concentrations of dextrose, such as 50% dextrose in water, are strongly hypertonic and must be administered into central veins so that they can be diluted by rapid blood flow.

Saline solutions are also available in osmolar concentrations greater than that of the ECF. These solutions draw water from the ICF to the ECF and cause cells to shrink. If administered rapidly or in large quantity, they may cause an extracellular volume excess and precipitate circulatory overload and dehydration. As a result, these solutions must be administered cautiously and usually only when the serum osmolality has decreased to dangerously low levels. Hypertonic solutions exert an osmotic pressure greater than that of the ECF.

Other Intravenous Substances

When the patient is unable to tolerate food, nutritional requirements are often met using the IV route. Solutions may include high concentrations of glucose (such as 50% dextrose in water), protein, or fat to meet nutritional requirements (see Chapter 36). The IV route may also be used to administer colloids, plasma expanders, and blood products. Examples of blood products include whole blood, packed red blood cells, albumin, and cryoprecipitate; these are discussed in more detail in Chapter 33.

Many medications are also delivered by the IV route, either by continuous infusion or intermittent bolus directly into the vein. Because IV medications enter the circulation rapidly, administration by this route is potentially very hazardous. All medications can produce adverse reactions; however, medications administered by the IV route can cause these reactions within seconds to minutes after administration, because the medications are delivered directly into the bloodstream. Administration rates and recommended dilutions for individual medications are available in specialized texts pertaining to IV medications and in manufacturers' package inserts; these should be consulted to ensure safe IV administration of medications.

NURSING ALERT

The nurse must assess the patient for a history of allergic reactions to medications. Although this is important when any medication is to be administered, it is even more important with IV administration, because the medication is delivered directly into the bloodstream.

Nursing Management of the Patient Receiving Intravenous Therapy

The ability to perform venipuncture to gain access to the venous system for administering fluids and medication is an expected nursing skill in many settings. This responsibility includes selecting the appropriate venipuncture site and type of cannula and being proficient in the technique of vein entry. The nurse should demonstrate competency in and knowledge of catheter placement according to the Nurse Practice Act applicable in his or her state and should follow the rules and regulations, organizational policies and procedures, and practice guidelines of that state's board of nursing (Alexander, 2006).

Infusion therapy is initiated by a health care provider who prescribes the type and amount of solution, additives (if any), and rate of flow. When administering parenteral fluids, the nurse monitors the patient's response to the fluids, considering the fluid volume, the fluid content, and the patient's clinical status.

Preparing to Administer Intravenous Therapy

Before performing venipuncture, the nurse carries out hand hygiene, applies gloves, and informs the patient about the procedure. The nurse selects the most appropriate insertion site and type of cannula for a particular patient.

Choosing an Intravenous Site

Many sites can be used for IV therapy, but ease of access and potential hazards vary. Veins of the extremities are designated as peripheral locations and are ordinarily the only sites used by nurses. Because they are relatively safe and easy to enter, arm veins are most commonly used (Fig. 14-7). The metacarpal, cephalic, basilic, and median veins and their branches are recommended sites because of their size and ease of access. Leg veins should rarely, if ever, be used because of the high risk of thromboembolism. Additional sites to avoid include veins distal to a previous IV infiltration or phlebotic area, sclerosed or thrombosed veins, an arm with an arteriovenous shunt or fistula, and an arm affected by edema, infection, blood clot, deformity, severe scarring, or skin breakdown. The arm on the side of a mastectomy is avoided because of impaired lymphatic flow.

Central veins commonly used by physicians include the subclavian and internal jugular veins. It is possible to gain access to (or cannulate) these larger vessels even when peripheral sites have collapsed, and they allow for the administration of hyperosmolar solutions. However, the potential hazards are much greater and include inadvertent entry into an artery or the pleural space.

Ideally, both arms and hands are carefully inspected before a specific venipuncture site that does not interfere with mo-

Figure 14-7 Site selection for peripheral cannulation of veins: anterior (palmar) veins at left, posterior (dorsal) veins at right. Adapted from Agur, A. M. R., Lee, M. J. & Boileau Grant, M. J. (1999). *Grant's atlas of anatomy* (10th ed.). Philadelphia: Lippincott Williams & Wilkins.

bility is chosen. For this reason, the antecubital fossa is avoided, except as a last resort. The most distal site of the arm or hand is generally used first, so that subsequent IV access sites can be moved progressively upward. The following factors should be considered when selecting a site for venipuncture:

- Condition of the vein
- Type of fluid or medication to be infused
- Duration of therapy
- Patient's age and size
- Whether the patient is right- or left-handed
- Patient's medical history and current health status
- Skill of the person performing the venipuncture

After applying a tourniquet, the nurse palpates and inspects the vein. The vein should feel firm, elastic, engorged, and round—not hard, flat, or bumpy. Because arteries lie close to veins in the antecubital fossa, the vessel should be palpated for arterial pulsation (even with a tourniquet on), and cannulation of pulsating vessels should be avoided. General guidelines for selecting a cannula include the following:

- Length: 0.75 to 1.25 inches long
- Diameter: narrow diameter of the cannula to occupy minimal space within the vein
- Gauge:
 - 20 to 22 gauge for most IV fluids; a larger gauge for caustic or viscous solutions
 - 14 to 18 gauge for blood administration and for trauma patients and those undergoing surgery
 - 22 to 24 gauge for elderly patients

Hand veins are easiest to cannulate. Cannula tips should not rest in a flexion area (eg, the antecubital fossa), because this could inhibit the IV flow (Hadaway & Millam, 2007).

Selecting Venipuncture Devices

Equipment used to gain access to the vasculature includes cannulas, needleless IV delivery systems, and peripherally inserted central catheter (PICC) or midline catheter vascular access devices.

Cannulas

Most peripheral access devices are cannulas. They have an obturator inside a tube that is later removed. *Catheter* and *cannula* are terms that are used interchangeably. The main types of cannula devices available are those referred to as winged infusion sets (butterfly) with a steel needle or as over-the-needle catheters with wings; indwelling plastic cannulas that are inserted over a steel needle; and indwelling plastic cannulas that are inserted through a steel needle. Scalp vein or butterfly needles are short steel needles with plastic wing handles. These are easy to insert, but because they are small and nonpliable, infiltration occurs easily. The use of these needles should be limited to obtaining blood specimens or administering bolus injections or infusions lasting only a few hours, because they increase the risk of vein injury and infiltration. Insertion of an over-the-needle catheter requires the additional step of advancing the catheter into the vein after venipuncture. Because these devices are less likely to cause infiltration, they are frequently preferred over winged infusion sets.

Plastic cannulas inserted through a hollow needle are usually called intracatheters. They are available in long lengths and are well suited for placement in central locations. Because insertion requires threading the cannula through the vein for a relatively long distance, these can be difficult to insert. The most commonly used infusion device is the over-the-needle catheter. A hollow metal stylet is preinserted into the catheter and extends through the distal tip of the catheter to allow puncture of the vessel, in an effort to guide the catheter as the venipuncture is performed. The vein is punctured and a flashback of blood appears in the closed chamber behind the catheter hub. The catheter is threaded through the stylet into the vein and the stylet is then removed.

To select the ideal product for use, consideration should be given to which product provides the greatest patient satisfaction and offers quality, cost-effective infusion care. All devices should be radiopaque to determine catheter location by x-ray, if necessary. All catheters increase the risk of thrombus formation to varying degrees. Biocompatibility, another characteristic of a catheter, ensures that inflammation and irritation do not occur. Silicone catheters are the most bioinert catheters available today.

Needleless Intravenous Delivery Systems. In an effort to decrease needlestick injuries and exposure to bloodborne pathogens, the federal government has legislated and agencies have implemented needleless IV delivery systems. These systems have built-in protection against needlestick injuries and provide a safe means of using and disposing of an IV administration set (which consists of

tubing, an area for inserting the tubing into the container of IV fluid, and an adapter for connecting the tubing to the needle). Numerous companies produce needleless components. IV line connectors allow the simultaneous infusion of IV medications and other intermittent medications (known as a piggyback delivery) without the use of needles; this method is being used more frequently, moving away from use of the traditional stylet. An example is a self-sheathing stylet that is recessed into a rigid chamber at the hub of the catheter when its insertion is complete. Other designs have placed the stylet at the end of a flexible wire to avoid needlesticks.

Many types of these devices are on the market. Each institution must evaluate products to determine its own needs based on Occupational Safety and Health Administration (OSHA) guidelines and the institution's policies and procedures.

Peripherally Inserted Central Catheter or Midline Catheter Access Lines. Patients who need moderate- to long-term parenteral therapy often receive a PICC or a midline catheter. These catheters are also used for patients with limited peripheral access (eg, obese or emaciated patients, IV/injection drug users) who require IV antibiotics, blood, and parenteral nutrition. For these devices to be used, the veins must be pliable (not sclerosed or hardened) and not subject to repeated puncture. If these veins are damaged, then central venous access via the subclavian or internal jugular vein, or surgical placement of an implanted port or a vascular access device, must be considered as an alternative (Anderson, 2005; Ludeman, 2007). Table 14-7 compares PICC and midline catheters. Both PICC and midline catheters have the advantages of reducing cost, avoiding repeated venipunctures, and decreasing the incidence of catheter-related infections when compared with centrally placed catheters.

The principles for inserting these lines are much the same as those for inserting peripheral catheters; however, their insertion should be undertaken only by practitioners who are experienced and specially skilled in inserting IV lines.

The physician prescribes the line and the solution to be infused. Insertion of either catheter requires sterile technique. The size of the catheter lumen chosen is based on the type of solution, the patient's body size, and the vein to be used. The patient's consent is obtained before use of these catheters. Use of the dominant arm is recommended as the site for inserting the cannula into the superior vena cava to ensure adequate arm movement, which encourages blood flow and reduces the risk of dependent edema.

Teaching the Patient

Except in emergency situations, the patient should be prepared in advance for an IV infusion. The venipuncture, the expected length of infusion, and activity restrictions are explained. If the patient requires alternative formats (eg, interpreter, large-print written materials) to understand the procedure, these should be provided. Then the patient should have an opportunity to ask questions and express concerns. For example, some patients believe that they will die if small bubbles in the tubing enter their veins.

Table 14-7 COMPARISON OF PERIPHERALLY INSERTED CENTRAL AND MIDLINE CATHETERS

	Peripherally Inserted Central Catheter (PICC)	Midline Catheter
Indications	Parenteral nutrition; IV fluid replacement; administration of chemotherapy agents, analgesics, and antibiotics; removal of blood specimens; administration of blood products	Parenteral nutrition; IV fluid replacement; administration of analgesics and antibiotics (no solution or medications with a pH <5 or >9 or osmolality >500 mOsm/L); removal of blood specimens
Features	Single-, double-, and triple-lumen catheters available (16–24 gauge) 50–70-cm in length; sizes range from 2–7 Fr	Single- and double-lumen catheters available (16–24 gauge) 7.5–20-cm in length; catheter can increase two gauges in size as it softens
Material	Radiopaque, polymer (polyurethane), silastic materials; flexible	Silicone, polyurethane, and their derivatives; available impregnated with heparin to ↓ thrombogenicity (radiopaque or clear, with radiopaque strip)
Insertion sites	Venipuncture performed in the antecubital fossa, above or below it into the basilic, cephalic, or axillary veins of the dominant arm. Median basilic is ideal insertion site.	Venipuncture performed 112 inches above or below antecubital fossa through brachial cephalic, basilic, or median cubital vein.
Catheter placement	Tip of catheter lies in lower third of superior vena cava. Catheter is placed via median basilic, median cubital, or median cephalic vein at antecubital fossa.	Catheter lies between antecubital area and head of clavicle (tip in axilla region). Tip terminates in the proximal portion of extremity below axilla and proximal to central veins and is advanced 3–10 inches.
Insertion method	Sedation and NPO not required. Through-the-needle technique, with or without a guidewire, breakaway needle with introducer or cannula with introducer (peel-away sheath). (A peripherally inserted central catheter can also be used as midline catheter.) Insertion can be accomplished at bedside using sterile technique. Right arm placement is a more direct route to vena cava. Arm to be used should be positioned in abduction to 90-degree angle. Consent is required. Ultrasound-guided placement can allow access to difficult veins at bedside or in x-ray department with fluoroscopy. Catheter may stay in place for up to 12 months.	No separate guidewire or introducer needed. Stiff catheter is passed using catheter advancement tab. Insertion can be accomplished at bedside using sterile technique. Arm to be used should be positioned in abduction to 45-degree angle. Consent is required. The catheter should never be reused. Catheter may stay in place for 2–4 weeks.
Potential complications	Malposition, pneumothorax, hemothorax, hydrothorax, dysrhythmias, nerve or tendon damage, respiratory distress, catheter embolism, thrombophlebitis, or catheter occlusion. Compared with centrally placed catheters, venipuncture in antecubital space reduces risk of insertion complications.	Thrombosis, phlebitis, air embolism, infection, vascular perforation, bleeding, catheter transection, occlusion
Contraindications	Dermatitis, cellulitis, lymphedema, compromised anatomy, burns, high fluid volume infusions, rapid bolus injections, hemodialysis, and venous thrombosis. No clamping of this catheter or splinting of arm permitted. No blood pressure or tourniquets to be used on extremity where peripherally inserted central catheter is inserted.	Dermatitis, cellulitis, burns, high fluid volume infusions, rapid bolus injection, hemodialysis, and venous thrombosis. No blood pressure or tourniquet to be used on extremity where catheter is placed. Patient should avoid heavy lifting with arm that has catheter.
Catheter maintenance	Sterile dressing types and changes are according to agency protocol, training, and competency requirements. Catheter is secured with stabilization device.	Sterile dressing types and changes are according to agency protocol, training, and competency requirements. Catheter must be anchored securely to prevent its dislodgment and can be secured with stabilization device.
Postplacement	Chest x-ray needed to confirm placement of catheter tip	Chest x-ray to assess placement may be obtained if unable to flush catheter, if no free flow blood return, if difficulty with catheter advancement, if guidewire is difficult to remove or bent on removal, or catheter migration is suspected.
Assessment	Daily measurement of arm circumference (4 inches above insertion site) and length of exposed catheter	Daily measurement of arm circumference (4 inches above insertion site) and length of exposed catheter
Removal	Catheter should be removed when no longer indicated for use, if contaminated, or if complications occur. Arm is abducted during removal. Patient should be in dorsal recumbent position with head of bed flat and should perform Valsalva maneuver while catheter is withdrawn. Pressure is applied on removal with sterile dressing and antiseptic ointment to site. Dressing is changed every 24–48 h until epithelialization occurs.	Catheter should be removed when no longer indicated for use, if contaminated, or if complications occur. Arm is abducted during removal. Pull gently from insertion site no more than 1/4–1/2 inch at a time to prevent vasospasm. Pressure is applied on removal with a sterile dressing and antiseptic ointment to site. Dressing is changed every 24–48 h until epithelialization occurs.

After acknowledging this fear, the nurse can explain that usually only relatively large volumes of air administered rapidly are dangerous.

Preparing the Intravenous Site

Before preparing the skin, the nurse should ask the patient if he or she is allergic to latex or iodine, products commonly used in preparing the skin for IV therapy. Excessive hair at the selected site may be removed by clipping to increase the visibility of the veins and to facilitate insertion of the cannula and adherence of dressings to the IV insertion site. Because infection can be a major complication of IV therapy, the IV device, the fluid, the container, and the tubing must be sterile. The nurse must perform hand hygiene and put on gloves. Gloves (nonsterile, disposable) must be worn during the venipuncture procedure because of the likelihood of coming into contact with bloodborne pathogens. The insertion site is prepared according to institutional policy (Rosenthal, 2007; Todd, 2006).

Performing Venipuncture

Guidelines and a suggested sequence for venipuncture are presented in Chart 14-3. For veins that are very small or particularly fragile, modifications in the technique may be necessary. Alternative methods can be found in journal articles or in specialized textbooks on IV therapy. Institutional policies and procedures determine whether all nurses must be certified to perform venipuncture. A nurse certified in IV therapy or an IV team can be consulted to assist with initiating IV therapy. To avoid multiple unsuccessful attempts, causing unnecessary trauma to the patient and limiting future vascular access, no more than two attempts at cannulation by any one nurse should be made (Alexander, 2006).

Maintaining Therapy

Maintaining an existing IV infusion is a nursing responsibility that demands knowledge of the solutions being administered and the principles of flow. In addition, patients must be assessed carefully for both local and systemic complications.

Factors Affecting Flow

The flow of an IV infusion is governed by the same principles that govern fluid movement in general:

- Flow is directly proportional to the height of the liquid column. Raising the height of the infusion container may improve a sluggish flow.
- Flow is directly proportional to the diameter of the tubing. The clamp on IV tubing regulates the flow by changing the tubing diameter. In addition, the flow is faster through large-gauge rather than small-gauge cannulas.
- Flow is inversely proportional to the length of the tubing. Adding extension tubing to an IV line decreases the flow.
- Flow is inversely proportional to the viscosity of a fluid. Viscous IV solutions, such as blood, require a larger cannula than do water or saline solutions.

Monitoring Flow

Because so many factors influence an IV set to gravity flow, a solution does not necessarily continue to run at the speed

originally set. Therefore, the nurse monitors IV infusions frequently to make sure that the fluid is flowing at the intended rate. The IV container should be marked to indicate at a glance whether the correct amount has infused. The flow rate is calculated when the solution is originally started and then monitored at least hourly. To calculate the flow rate, the nurse determines the number of drops delivered per milliliter; this varies with equipment and is usually printed on the administration set packaging. A formula that can be used to calculate the drop rate is

$$\begin{aligned} & \text{gtt/mL of infusion set}/60 \text{ (min in 1 hr)} \\ & \times \text{total hourly volume} = \text{gtt/min} \end{aligned}$$

Flushing of a vascular device is performed to ensure patency and to prevent the mixing of incompatible medications or solutions. This procedure should be carried out at established intervals, according to hospital policy and procedure, especially for intermittently used catheters. Most manufacturers and researchers suggest the use of preservative-free 0.9% sodium chloride for flushing (Alexander, 2006). The volume of the flush solution should be at least twice the volume capacity of the catheter. The catheter should be clamped before the syringe is completely empty and withdrawn to prevent reflux of blood into the lumen, which could cause catheter clotting.

A variety of electronic infusion devices are available to assist in IV fluid delivery. These devices allow more accurate administration of fluids and medications than is possible with routine gravity-flow setups. A pump is a positive-pressure device that uses pressure to infuse fluid at a pressure of 10 psi; newer models use a pressure of 5 psi. The pressure exerted by the pump overrides vascular resistance (increased tubing length, low height of the IV container).

Volumetric pumps calculate the volume delivered by measuring the volume in a reservoir that is part of the set and is calibrated in milliliters per hour (mL/h). A controller is an infusion assist device that relies on gravity for infusion; the volume is calibrated in drops (gtt) per minute. A controller uses a drop sensor to monitor the flow. Factors essential for the safe use of pumps include alarms to signify the presence of air in the IV line or an occlusion. The standard for the accurate delivery of fluid or medication via an electronic IV infusion pump is plus or minus 5%. The manufacturer's directions must be read carefully before use of any infusion pump or controller, because there are many variations in available models. Use of these devices does not eliminate the need for the nurse to monitor the infusion and the patient frequently. The nurse must be knowledgeable about flow control devices and competent regarding their use.

Discontinuing an Infusion

IV therapy should be discontinued as prescribed by an appropriate health care provider or on assessment by the nurse that contamination, phlebitis, or infiltration has occurred. The removal of an IV catheter is associated with two possible dangers: bleeding and catheter embolism. To prevent excessive bleeding, a dry, sterile pressure dressing should be held over the site as the catheter is removed. Firm pressure is applied until bleeding stops.

If a plastic IV catheter is severed, the loose fragment can travel to the right ventricle and block blood flow. To detect

 CHART
14-3

Guidelines for Starting an Intravenous Infusion

Equipment

- Tourniquet
- Tape
- IV solution, tubing and catheter
- Chlorhexidine gluconate, povidone–iodine, or alcohol swabs
- Nonlatex gloves
- Transparent dressing, bandage, or sterile gauze
- Padded, appropriate-length arm board

Implementation

Nursing Action

1. Verify prescription for IV therapy, check solution label, and identify patient. Check for allergies (ie, latex, iodine).
2. Explain procedure to patient.
3. Perform hand hygiene and put on disposable nonlatex gloves.
4. Apply a tourniquet 4 to 6 inches above the site and identify a suitable vein.
5. Choose site. Use distal veins of hands and arms first.
6. Choose IV cannula or catheter.
7. Prepare equipment by connecting infusion bag and tubing, run solution through tubing to displace air, and cover end of tubing.
8. Raise bed to comfortable working height and position for patient; adjust lighting. Position patient's arm below heart level to encourage capillary filling. Place protective pad on bed under patient's arm.
9. Depending on agency policy and procedure, lidocaine 1% (without epinephrine) 0.1–0.2 mL may be injected locally to the IV site or a transdermal analgesic cream (EMLA) may be applied to the site prior to IV placement or blood withdrawal. Alternatively, topical application of lidocaine (Numby Stuff) or an intradermal injection of bacteriostatic 0.9% sodium chloride may be used to produce a local anesthetic effect.
10. Palpate for a pulse distal to the tourniquet. Ask patient to open and close fist several times or position patient's arm in a dependent position to distend a vein.

Rationale

1. Serious errors can be avoided by careful checking. Checking for allergies reduces risk of allergic reaction.
2. Knowledge increases patient comfort and cooperation.
3. Asepsis is essential to prevent infection. Use of nonlatex gloves prevents exposure of nurse to patient's blood and of patient and nurse to latex.
4. This will distend the veins and allow them to be visualized.
5. Careful site selection will increase likelihood of successful venipuncture and preservation of vein. Using distal sites first preserves sites proximal to the previously cannulated site for subsequent venipunctures. Veins of feet and lower extremity should be avoided due to risk of thrombophlebitis. (In consultation with the physician, the saphenous vein of the ankle or dorsum of the foot may occasionally be used.)
6. Length and gauge of cannula should be appropriate for both site and purpose of infusion. The shortest gauge and length needed to deliver prescribed therapy should be used. Inspect the needle or cannula to make sure there are no imperfections.
7. This prevents delay; equipment must be ready to connect immediately after successful venipuncture to prevent clotting.
8. Proper positioning will increase likelihood of success and provide comfort for patient.
9. This reduces pain locally from procedure and decreases anxiety about pain.
10. The tourniquet should never be tight enough to occlude arterial flow. If a radial pulse cannot be palpated distal to the tourniquet, it is too tight. A new tourniquet should be used for each patient to prevent the transmission of microorganisms. A blood pressure cuff may be used for elderly patients to avoid rupture of the veins. A clenched fist encourages the vein to become round and turgid. Positioning the arm below the level of the patient's heart promotes capillary filling. Warm packs applied for 10 to 20 minutes prior to venipuncture can promote vasodilation. Bedside ultrasound-guided visualization of vein location and assessment of venous pathway and flow using ultrasonic waves may also be used.

Continued

 CHART
14-3

Guidelines for Starting an Intravenous Infusion (Continued)

Nursing Action

11. Prepare site by scrubbing with chlorhexidine gluconate or povidone-iodine swabs for 2 to 3 minutes in circular motion, moving outward from injection site. Allow to dry.
 - a. If the site selected is excessively hairy, clip hair. (Check agency's policy and procedure about this practice.)
 - b. Isopropyl alcohol 70% is an alternative solution that may be used.
12. With hand not holding the venous access device, steady patient's arm and use finger or thumb to pull skin taut over vessel.
13. Holding needle bevel up and at 5- to 25-degree angle, depending on the depth of the vein, pierce skin to reach but not penetrate vein.
14. Decrease angle of needle further until nearly parallel with skin, then enter vein either directly above or from the side in one quick motion.
15. If backflow of blood is visible, straighten angle and advance needle. Additional steps for catheter inserted over needle:
 - a. Advance needle 0.6 cm (1/4 to 1/2 inch) after successful venipuncture.
 - b. Hold needle hub, and slide catheter over the needle into the vein. Never reinsert needle into a plastic catheter or pull the catheter back into the needle.
 - c. Remove needle while pressing lightly on the skin over the catheter tip; hold catheter hub in place.
 - d. Never reinsert a stylet back into a catheter.
 - e. Never reuse the same catheter.
16. Release tourniquet and attach infusion tubing; open clamp enough to allow drip.
17. Cover the insertion site with a transparent dressing, bandage, or sterile gauze according to hospital policy and procedure. Tape in place with nonallergenic tape but do not encircle extremity. Tape a small loop of IV tubing onto dressing.
18. Label with type and length of cannula, date, time, and initials.
19. A padded, appropriate-length arm board may be applied to an area of flexion (neurovascular checks should be performed frequently).
20. Calculate infusion rate and regulate flow of infusion. For hourly IV rate use the following formula: $\text{gtt/mL of infusion set}/60 \text{ (min in h)} \times \text{total hourly vol} = \text{gtt/min}$
21. Document date and time therapy initiated; type and amount of solution; additives and dosages; flow rate; gauge, length, and type of vascular access device; catheter insertion site; type of dressing applied; patient response to procedure; patient teaching and name and title of the health care provider who inserted the catheter.
22. Discard needles, stylets, or guidewires into a puncture-resistant needle container that meets OSHA guidelines. Remove gloves and perform hand hygiene.

Rationale

11. Strict asepsis and careful site preparation are essential to prevent infection.
 - a. Hair removal should be performed with scissors or electric clippers. Shaving should not be done with a razor because of the potential for microabrasions that increase the risk of infection. Depilatories should not be used due to the potential for dermal allergic reactions and/or irritation.
12. Applying traction to the vein helps to stabilize it.
13. Bevel-down technique is necessary for small veins to prevent extravasation. One-step method of catheter insertion directly into vein with immediate thrust through the skin is excellent for large veins but may cause a hematoma if used in small veins.
14. Two-stage procedure decreases chance of thrusting needle through posterior wall of vein as skin is entered. No attempt should be made to reinsert the stylet because of risk of severing or puncturing the catheter.
15. Backflow may not occur if vein is small; this position decreases chance of puncturing posterior wall of vein.
 - a. Advancing the needle slightly makes certain the plastic catheter has entered the vein.
 - b. Reinsertion of the needle or pulling the catheter back can sever the catheter, causing catheter embolism.
 - c. Slight pressure prevents bleeding before tubing is attached.
 - d. The stylet can shear off a piece of the plastic if reinserted.
 - e. Reusing the same catheter can cause infection.
16. Releasing the tourniquet restores blood flow and avoids potential ischemic damage to the area distal to the IV insertion site.
17. Transparent dressings allow assessment of the insertion site for phlebitis, infiltration, and infection without removing the dressing. Tape applied around extremity can act as a tourniquet and impede blood flow and infusion of fluid. The loop decreases the chance of inadvertent cannula removal if the tubing is pulled.
18. Labeling facilitates assessment and safe discontinuation.
19. This secures cannula placement and allows correct flow rate (neurovascular checks assess nerve, muscle, and vascular function to be sure function is not affected by immobilization).
20. Infusion must be regulated carefully to prevent overinfusion or underinfusion. Calculation of the IV rate is essential for the safe delivery of fluids. Safe administration requires knowledge of the volume of fluid to be infused, total infusion time, and calibration of the administration set (found on the IV tubing package; 10, 12, 15, or 60 drops to deliver 1 mL of fluid).
21. Documentation is essential to promote continuity of care.
22. Proper disposal of sharps decreases risk of needlesticks.

this complication when the catheter is removed, the nurse compares the expected length of the catheter with its actual length. Plastic catheters should be withdrawn carefully and their length measured to detect a fragment that has broken off in the vein. Both of these actions must be documented in the patient's medical record.

Great care must be exercised when using scissors around the dressing site. If the catheter clearly has been severed, the nurse can attempt to occlude the vein above the site by applying a tourniquet to prevent the catheter from entering the central circulation (until surgical removal is possible). The physician must be notified immediately. It is better to prevent a potentially fatal problem than to deal with it after it has occurred. Catheter embolism can be prevented easily by following simple rules:

- Avoid using scissors near the catheter.
- Avoid withdrawing the catheter through the insertion needle.
- Follow the manufacturer's guidelines carefully (eg, cover the needle point with the bevel shield to prevent severing the catheter).

Managing Systemic Complications

IV therapy predisposes the patient to numerous hazards, including both local and systemic complications. Systemic complications occur less frequently but are usually more serious than local complications. They include circulatory overload, air embolism, febrile reaction, and infection.

Fluid Overload

Overloading the circulatory system with excessive IV fluids causes increased blood pressure and central venous pressure. Signs and symptoms of fluid overload include moist crackles on auscultation of the lungs, edema, weight gain, dyspnea, and rapid, shallow respirations. Possible causes include rapid infusion of an IV solution or hepatic, cardiac, or renal disease. The risk of fluid overload and subsequent pulmonary edema is especially increased in elderly patients with cardiac disease; this is referred to as circulatory overload. Its treatment includes decreasing the IV rate, monitoring vital signs frequently, assessing breath sounds, and placing the patient in a high Fowler's position. The physician is contacted immediately. This complication can be avoided by using an infusion pump and by carefully monitoring all infusions. Complications of circulatory overload include heart failure and pulmonary edema.

Air Embolism

The risk of air embolism is rare but ever-present. It is most often associated with cannulation of central veins. Manifestations of air embolism include palpitations, dyspnea, and cyanosis; hypotension; weak, rapid pulse; loss of consciousness; and chest, shoulder, and low back pain. Treatment calls for immediately clamping the cannula and replacing a leaking or open infusion system, placing the patient on the left side in the Trendelenburg position, assessing vital signs and breath sounds, and administering oxygen. Air embolism can be prevented by using locking adapters on all lines, filling all tubing completely with solution, and using an air detection alarm on an IV infusion pump. Complications of air embolism include shock and death. The amount

of air necessary to induce death in humans is not known; however, the rate of entry is probably as important as the actual volume of air.

Infection

Pyrogenic substances in either the infusion solution or the IV administration set can cause bloodstream infections (Todd, 2006). Signs and symptoms include an abrupt temperature elevation shortly after the infusion is started, backache, headache, increased pulse and respiratory rate, nausea and vomiting, diarrhea, chills and shaking, and general malaise. In severe sepsis, vascular collapse and septic shock may occur. See Chapter 15 for a discussion of septic shock.

Infection ranges in severity from local involvement of the insertion site to systemic dissemination of organisms through the bloodstream, as in sepsis. Measures to prevent infection are essential at the time the IV line is inserted and throughout the entire infusion. Prevention includes the following:

- Careful hand hygiene before every contact with any part of the infusion system or the patient
- Examining the IV containers for cracks, leaks, or cloudiness, which may indicate a contaminated solution
- Using strict aseptic technique
- Firmly anchoring the IV cannula to prevent to-and-fro motion (eg, a catheter stabilization device will help)
- Inspecting the IV site daily and replacing a soiled or wet dressing with a dry sterile dressing (antimicrobial agents that should be used for site care include 2% tincture of iodine, 10% povidone-iodine, alcohol, or chlorhexidine gluconate, used alone or in combination)
- Disinfecting injection/access ports with antimicrobial solution before and after each use
- Removing the IV cannula at the first sign of local inflammation, contamination, or complication
- Replacing the peripheral IV cannula every 72 to 96 hours, or as indicated (Chart 14-4)
- Replacing the IV cannula inserted during emergency conditions (with questionable asepsis) as soon as possible
- Using a 0.2- μm air-eliminating and bacteria/particulate retentive filter with non-lipid-containing solutions that require filtration. The filter can be added to the proximal or distal end of the administration set. If added to the proximal end between the fluid container and the tubing spike, the filter ensures sterility and particulate removal from the infusate container and prevents inadvertent infusion of air. If added to the distal end of the administration set, it filters air particles and contaminants introduced from add-on devices, secondary administration sets, or interruptions to the primary system. Filters should be located as close to the catheter insertion site as possible (Alexander, 2006)
- Replacing the solution bag and administration set in accordance with agency policy and procedure
- Infusing or discarding medication or solution within 24 hours of its addition to an administration set
- Changing primary and secondary continuous administration sets every 72 hours, intermittent administra-

CHART

NURSING RESEARCH PROFILE

14-4

When Should a Peripheral IV Catheter Be Changed?

Gallant, P. & Schultz, A. (2006). Evaluation of a visual infusion phlebitis scale for determining appropriate discontinuation of peripheral intravenous catheters. *Journal of Infusion Nursing*, 29(6), 333–345.

Purpose

Phlebitis is a common occurrence at peripheral IV sites. It is known that phlebitis is related to certain types of medication, infusates the patient is receiving, and length of time the catheter remains in the vein. Therefore, it has been recommended that peripheral IV sites be rotated at prescribed intervals (eg, 48 to 72 hours) to reduce the rate of phlebitis. This study evaluated the use of a visual infusion phlebitis scale for determining appropriate discontinuation of peripheral IV catheters.

Design

A descriptive correlation design was used to compare phlebitis rates between peripheral IV sites that had been indwelling for up to 96 hours with those that had been indwelling for longer than 96 hours. Researchers monitored 851 IV sites in 513 patients in a cardiac surgery critical care unit and in a cardiothoracic stepdown unit. Skin preparation, IV insertion, and dressing site care were according to hospital policy, with insertions initiated using 18-gauge or smaller needles in the antecubital area, forearm, hand, or wrist. Researchers used the Visual Infusion Phlebitis (VIP) scale to rate phlebitis using a range of scores from 0 (no symptoms) to 5 (purulent drainage, redness, and a palpable cord greater than 3 inches). All scores of 2 (pain, redness, warmth, and/or edema extending from 1

to 2 inches above the site) resulted in a change in catheters. The researchers evaluated each IV site daily and documented reasons for removal of catheters, time of catheter removal, and any medications administered through the IV route.

Findings

Chi-square analysis demonstrated no statistically significant difference between the two groups in age, gender, or the type of surgery for the patients who had peripheral IV catheters indwelling for less than 96 hours compared with those who had catheters for more than 96 hours. There was a significant increase in the rate of phlebitis in patients who needed IV restarts (13.4%) as compared with a phlebitis rate of 2.7% in patients who had only one IV inserted (no restarts). There was a significant increase in phlebitis rates when certain medications (antibiotics, diltiazem, potassium chloride, and amiodarone) were infused compared with those in which none of these medications was infused. The VIP scale was found to be a reliable and valid method for determining when a peripheral catheter should be removed.

Nursing Implications

In the sample studied, the peripheral IV catheters in place for longer than 96 hours did not result in significantly increased rates of phlebitis or greater risk of bacteremia compared to IV lines removed at 96 hours. Routine restarting of IV lines and administration of certain medications increased the risk of phlebitis. The VIP scale was useful for determining when catheters should be removed. Clinical assessment remains essential for safe patient care.

tion sets every 24 hours, or immediately if contamination is suspected (Alexander, 2006)

- Using administration sets with a twist-lock design (Rosenthal, 2007)

Managing Local Complications

Local complications of IV therapy include infiltration and extravasation, phlebitis, thrombophlebitis, hematoma, and clotting of the needle.

Infiltration and Extravasation

Infiltration is the unintentional administration of a non-vesicant solution or medication into surrounding tissue. This can occur when the IV cannula dislodges or perforates the wall of the vein. Infiltration is characterized by edema around the insertion site, leakage of IV fluid from the insertion site, discomfort and coolness in the area of infiltration, and a significant decrease in the flow rate. When the solution is particularly irritating, sloughing of tissue may result. Close monitoring of the insertion site is necessary to detect infiltration before it becomes severe.

Infiltration is usually easily recognized if the insertion area is larger than the same site of the opposite extremity; however, it is not always so obvious. A common misconception is that a backflow of blood into the tubing proves that the catheter is properly placed within the vein. However, if the catheter tip has pierced the wall of the vessel, IV

fluid will seep into tissues as well as flow into the vein. Although blood return occurs, infiltration may have occurred as well. A more reliable means of confirming infiltration is to apply a tourniquet above (or proximal to) the infusion site and tighten it enough to restrict venous flow. If the infusion continues to drip despite the venous obstruction, infiltration is present.

As soon as the nurse detects infiltration, the infusion should be stopped, the IV catheter discontinued, and a sterile dressing applied to the site after careful inspection to determine the extent of infiltration. The infiltration of any amount of blood product, irritant, or vesicant is considered the most severe.

The IV infusion should be started in a new site or proximal to the infiltration if the same extremity must be used again. A warm compress may be applied to the site if small volumes of noncaustic solutions have infiltrated over a long period, or if the solution was isotonic with a normal pH; the affected extremity should be elevated to promote the absorption of fluid. If the infiltration is recent and the solution was hypertonic or had an increased pH, a cold compress may be applied to the area. Infiltration can be detected and treated early by inspecting the site every hour for redness, pain, edema, blood return, coolness at the site, and IV fluid leaking from the IV site. Using the appropriate size and type of cannula for the vein prevents this complication. The Infusion Nursing Standards of Practice state that a standard-

CHART 14-5	
Assessing for Infiltration	
Grade	Clinical Criteria
0	No clinical symptoms
1	Skin blanched, edema less than 1 inch in any direction, cool to touch, with or without pain
2	Skin blanched, edema 1 to 6 inches in any direction, cool to touch, with or without pain
3	Skin blanched, translucent, gross edema greater than 6 inches in any direction, cool to touch, mild to moderate pain, possible numbness
4	Skin blanched, translucent, skin tight, leaking, skin discolored, bruised, swollen, gross edema greater than 6 inches in any direction, deep pitting tissue edema, circulatory impairment, moderate to severe pain, infiltration of any amount of blood products, irritant, or vesicant

Adapted from Alexander, M. (2006). Infusion nursing standards of practice. *Journal of Infusion Nursing*, 29(1S), S1–S92.

ized infiltration scale should be used to document the infiltration (Alexander, 2006) (Chart 14-5).

Extravasation is similar to infiltration, with an inadvertent administration of vesicant or irritant solution or medication into the surrounding tissue. Medications such as dopamine, calcium preparations, and chemotherapeutic agents can cause pain, burning, and redness at the site. Blistering, inflammation, and necrosis of tissues can occur. The extent of tissue damage is determined by the concentration of the medication, the quantity that extravasated, the location of the infusion site, the tissue response, and the duration of the process of extravasation.

The infusion must be stopped and the physician notified promptly. The agency's protocol to treat extravasation is initiated; the protocol may specify specific treatments, including antidotes specific to the medication that extravasated, and may indicate whether the IV line should remain in place or be removed before treatment. The protocol often specifies infiltration of the infusion site with an antidote prescribed after assessment by the physician, removal of the cannula, and application of warm compresses to sites of extravasation from vinca alkaloids or cold compresses to sites of extravasation from alkylating and antibiotic vesicants. The affected extremity should not be used for further cannula placement. Thorough neurovascular assessments of the affected extremity must be performed frequently (Hadaway, 2007).

Reviewing the institution's IV policy and procedures and incompatibility charts and checking with the pharmacist before administering any IV medication, whether peripherally or centrally, are recommended to determine incompatibilities and vesicant potential to prevent extravasation. Careful, frequent monitoring of the IV site, avoiding insertion of IV devices in areas of flexion, securing the IV line,

and using the smallest catheter possible that accommodates the vein help minimize the incidence and severity of this complication. In addition, when vesicant medication is administered by IV push, it should be given through a side port of an infusing IV solution to dilute the medication and decrease the severity of tissue damage if extravasation occurs. Extravasation is rated as grade 4 on the infiltration scale.

Phlebitis

Phlebitis is defined as inflammation of a vein, which can be categorized as chemical, mechanical, or bacterial; however, two or more of these types of irritation often occur simultaneously. Chemical phlebitis can be caused by an irritating medication or solution (increased pH or high osmolality of a solution), rapid infusion rates, and medication incompatibilities. Mechanical phlebitis results from long periods of cannulation, catheters in flexed areas, catheter gauges larger than the vein lumen, and poorly secured catheters. Bacterial phlebitis can develop from poor hand hygiene, lack of aseptic technique, failure to check all equipment before use, and failure to recognize early signs and symptoms of phlebitis. Other factors include poor venipuncture technique, catheter in place for a prolonged period, and failure to adequately secure the catheter. Phlebitis is characterized by a reddened, warm area around the insertion site or along the path of the vein, pain or tenderness at the site or along the vein, and swelling. The incidence of phlebitis increases with the length of time the IV line is in place (see Chart 14-4), the composition of the fluid or medication infused (especially its pH and tonicity), the size and site of the cannula inserted, ineffective filtration, inadequate anchoring of the line, and the introduction of microorganisms at the time of insertion. The Infusion Nursing Society has identified specific standards for assessing phlebitis (Alexander, 2006); these appear in Chart 14-6. Phlebitis is graded according to the most severe presenting indication.

CHART 14-6	
Assessing for Phlebitis	
Grade	Clinical Criteria
0	No clinical symptoms
1	Erythema at access site with or without pain
2	Pain at access site Erythema, edema, or both
3	Pain at access site Erythema, edema, or both Streak formation
4	Palpable venous cord (1 inch or shorter) Pain at access site with erythema Streak formation Palpable venous cord (longer than 1 inch) Purulent drainage

Note: If this scale is not being used in an institution, then the description associated with the number can be used to describe the assessment.

Adapted from Alexander, M. (2006). Infusion nursing standards of practice. *Journal of Infusion Nursing*, 29(1S), S1–S92.

Treatment consists of discontinuing the IV line and restarting it in another site, and applying a warm, moist compress to the affected site. Phlebitis can be prevented by using aseptic technique during insertion, using the appropriate-size cannula or needle for the vein, considering the composition of fluids and medications when selecting a site, observing the site hourly for any complications, anchoring the cannula or needle well, and changing the IV site according to agency policy and procedures.

Thrombophlebitis

Thrombophlebitis refers to the presence of a clot plus inflammation in the vein. It is evidenced by localized pain, redness, warmth, and swelling around the insertion site or along the path of the vein, immobility of the extremity because of discomfort and swelling, sluggish flow rate, fever, malaise, and leukocytosis.

Treatment includes discontinuing the IV infusion; applying a cold compress first, to decrease the flow of blood and increase platelet aggregation, followed by a warm compress; elevating the extremity; and restarting the line in the opposite extremity (see Chart 14-4). If the patient has signs and symptoms of thrombophlebitis, the IV line should not be flushed (although flushing may be indicated in the absence of phlebitis to ensure cannula patency and to prevent mixing of incompatible medications and solutions). The catheter should be cultured after the skin around the catheter is cleaned with alcohol. If purulent drainage exists, the site is cultured before the skin is cleaned.

Thrombophlebitis can be prevented by avoiding trauma to the vein at the time the IV line is inserted, observing the site every hour, and checking medication additives for compatibility.

Hematoma

Hematoma results when blood leaks into tissues surrounding the IV insertion site. Leakage can result if the opposite vein wall is perforated during venipuncture, the needle slips out of the vein, or insufficient pressure is applied to the site after removal of the needle or cannula. The signs of a hematoma include ecchymosis, immediate swelling at the site, and leakage of blood at the insertion site.

Treatment includes removing the needle or cannula and applying light pressure with a sterile, dry dressing; applying ice for 24 hours to the site to avoid extension of the hematoma; elevating the extremity; assessing the extremity for any circulatory, neurologic, or motor dysfunction; and restarting the line in the other extremity if indicated (see Chart 14-4). A hematoma can be prevented by carefully inserting the needle and by using diligent care with patients who have a bleeding disorder, are taking anticoagulant medication, or have advanced liver disease.

Clotting and Obstruction

Blood clots may form in the IV line as a result of kinked IV tubing, a very slow infusion rate, an empty IV bag, or failure to flush the IV line after intermittent medication or solution administrations. The signs are decreased flow rate and blood backflow into the IV tubing.

If blood clots in the IV line, the infusion must be discontinued and restarted in another site with a new cannula

and administration set. The tubing should not be irrigated or milked. Neither the infusion rate nor the solution container should be raised, and the clot should not be aspirated from the tubing. Clotting of the needle or cannula may be prevented by not allowing the IV solution bag to run dry, taping the tubing to prevent kinking and maintain patency, maintaining an adequate flow rate, and flushing the line after intermittent medication or other solution administration. In some cases, a specially trained nurse or physician may inject a thrombolytic agent into the catheter to clear an occlusion resulting from fibrin or clotted blood.

Promoting Home and Community-Based Care

Teaching Patients Self-Care

At times, IV therapy must be administered in the home setting, in which case much of the daily management rests with the patient and family. Teaching becomes essential to ensure that the patient and family can manage the IV fluid and infusion correctly and avoid complications. Written instructions as well as demonstration and return demonstration help reinforce the key points for all these functions.

Continuing Care

Home infusion therapies cover a wide range of treatments, including antibiotic, analgesic, and antineoplastic medications; blood or blood component therapy; and parenteral nutrition. When direct nursing care is necessary, arrangements are made to have an infusion nurse visit the home and administer the IV therapy as prescribed. In addition to implementing and monitoring the IV therapy, the nurse carries out a comprehensive assessment of the patient's condition and continues to teach the patient and family about the skills involved in overseeing the IV therapy setup. Any dietary changes that may be necessary because of fluid or electrolyte imbalances are explained or reinforced during such sessions.

Periodic laboratory testing may be necessary to assess the effects of IV therapy and the patient's progress. Blood specimens may be obtained by a laboratory near the patient's home, or a home visit may be arranged to obtain blood specimens for analysis.

The nurse collaborates with the case manager in assessing the patient, family, and home environment; developing a plan of care in accordance with the patient's treatment plan and level of ability; and arranging for appropriate referral and follow-up if necessary. Any necessary equipment may be provided by the agency or purchased by the patient, depending on the terms of the home care arrangements. Appropriate documentation is necessary to assist in obtaining third-party payment for the service provided.

CRITICAL THINKING EXERCISES

- 1 A 38-year-old woman is admitted with a chief complaint of shortness of breath and polyuria for the past 6 weeks. She is hypotensive. Her pulse rate is 110 bpm, and her lungs are clear to auscultation. Her laboratory test results are as follows: pH 7.32; sodium 131 mEq/L; glucose 600 mg/dL; PaCO₂ 28 mm Hg; potassium 4.5 mEq/L; cre-

atinine 1.4 mg/dL; HCO_3^- 14 mEq/L; chloride 95 mEq/L; BUN 30 mg/dL. What fluid and electrolyte or acid–base disorder is the patient experiencing? What IV fluids would you anticipate being prescribed? Give the rationale for their use. What treatments would address the patient’s fluid and electrolyte or acid–base disorders?

2 A 54-year-old obese man who has smoked one pack per day for the past 25 years has had a productive cough for the last 3 months and shortness of breath with little exertion. His wife complains of his loud snoring. His blood pressure is 130/90 mm Hg and pulse rate 126 bpm. His arterial blood gas results are as follows: pH 7.29; PaCO_2 72 mm Hg; HCO_3^- 34 mEq/L; PaO_2 50 mm Hg. How do you interpret the patient’s blood gas values? What treatment would you anticipate?

3 An 85-year-old woman is brought to the hospital with a decreased fluid intake for the past 4 days and weakness. She is not in respiratory distress. Her laboratory test results are as follows: sodium 145 mEq/L; potassium 1.9 mEq/L; chloride 86 mEq/L; pH 7.58; PaCO_2 49 mm Hg; HCO_3^- 44 mEq/L. What fluid and electrolyte or acid–base disorders is the patient experiencing? Outline the nursing plan of care to address the patient’s fluid and electrolyte or acid–base disorders. Give the rationale for the nursing interventions for this patient.

4 A 58-year-old man on the surgical unit is scheduled for an appendectomy and needs an IV for hydration and administration of preoperative medications. What aspects of the patient history must be assessed prior to administration of IV fluids and medications? Describe the site selection process and the factors that affect the choice of an IV site. What factors need to be considered in preparing to administer IV therapy to this patient?

EBP 5 A 35-year-old obese woman has been receiving IV therapy for the past 72 hours. The nurse plans to change the IV site today. A nurse on the IV team has suggested the use of clinical assessment criteria to assess the need for the IV change. What is the evidence for use of clinical criteria in this case? What criteria would you use to assess the strength of the evidence for the use of clinical criteria? Which criteria would you use in this patient’s case?

chapter 15

Shock and Multiple Organ Dysfunction Syndrome

LEARNING OBJECTIVES

On completion of this chapter, the learner will be able to:

- 1 Describe shock and its underlying pathophysiology.
- 2 Compare clinical findings of the compensatory, progressive, and irreversible stages of shock.
- 3 Describe organ dysfunction that may occur with shock.
- 4 Describe similarities and differences in shock due to hypovolemic, cardiogenic, neurogenic, anaphylactic, and septic shock states.
- 5 Identify medical and nursing management priorities in treating patients in shock.
- 6 Identify vasoactive medications used in treating shock, and describe nursing implications associated with their use.
- 7 Discuss the importance of nutritional support in all forms of shock.
- 8 Discuss the role of nurses in psychosocial support of patients experiencing shock and their families.
- 9 Discuss multiple organ dysfunction syndrome.

GLOSSARY

anaphylactic shock: circulatory shock state resulting from a severe allergic reaction producing an overwhelming systemic vasodilation and relative hypovolemia

biochemical mediators: messenger substances that may be released by a cell to create an action at that site or be carried by the bloodstream to a distant site before being activated; also called cytokines

cardiogenic shock: shock state resulting from impairment or failure of the myocardium

circulatory shock: shock state resulting from displacement of blood volume creating a relative hypovolemia and inadequate delivery of oxygen to the cells; also called distributive shock

colloids: intravenous solutions that contain molecules that are too large to pass through capillary membranes

crystalloids: intravenous electrolyte solutions that move freely between the intravascular compartment and interstitial spaces

hypovolemic shock: shock state resulting from decreased intravascular volume due to fluid loss

multiple organ dysfunction syndrome: presence of altered function of two or more organs in an acutely ill patient such that interventions are necessary to support continued organ function

neurogenic shock: shock state resulting from loss of sympathetic tone causing relative hypovolemia

septic shock: circulatory shock state resulting from overwhelming infection causing relative hypovolemia

shock: physiologic state in which there is inadequate blood flow to tissues and cells of the body

systemic inflammatory response syndrome: overwhelming inflammatory response in the absence of infection causing relative hypovolemia and decreased tissue perfusion

Shock is a life-threatening condition with a variety of underlying causes. It is characterized by inadequate perfusion that, if untreated, results in cell death. The progression of shock is neither linear nor predictable, and shock states, especially septic shock, comprise a current area of aggressive clinical research. Nurses caring for patients with shock and for those at risk for shock must understand the underlying mechanisms of shock and recognize its subtle as well as more obvious signs. Rapid assessment with early recognition and response to shock states is essential to the patient's recovery.

Overview of Shock

Shock can best be defined as a condition in which widespread perfusion to the cells is inadequate to deliver oxygen and nutrients to support vital organs and cellular function (VonRueden, Bolton & Vary, 2008). Adequate blood flow to the tissues and cells requires an adequate cardiac pump, effective vasculature or circulatory system, and sufficient blood volume. If one of these components is impaired, perfusion to the tissues is threatened or compromised. Without treatment, inadequate blood flow to the cells results in poor delivery of oxygen and nutrients, cellular hypoxia, and cell death that progresses to organ dysfunction and eventually death.

Shock affects all body systems. It may develop rapidly or slowly, depending on the underlying cause. During shock, the body struggles to survive, calling on all its homeostatic mechanisms to restore blood flow. Any insult to the body can create a cascade of events resulting in poor tissue perfusion. Therefore, almost any patient with any disease state may be at risk for developing shock. Conventionally, the primary underlying pathophysiologic process and underlying disorder are used to classify the shock state (eg, hypovolemic shock, cardiogenic shock, and circulatory shock [all discussed later in the chapter]).

Regardless of the initial cause of shock, certain physiologic responses are common to all types of shock. These physiologic responses include hypoperfusion of tissues, hypermetabolism, and activation of the inflammatory response. The body responds to shock states by activating the sympathetic nervous system and mounting a hypermetabolic and inflammatory response. Once shock develops, the patient's survival may have more to do with the body's ability to effectively respond to it than with the initial cause of shock. Failure of compensatory mechanisms to effectively restore physiologic balance is the final pathway of all shock states and results in end-organ dysfunction and death (Cocchi, Kimlin, Walsh, et al., 2007; Dellinger, Levy, Carlet, et al., 2008; King, 2007; VonRueden, et al., 2008).

Nursing care of patients with shock requires ongoing systematic assessment. Many of the interventions required in caring for patients with shock call for close collaboration with other members of the health care team and rapid implementation of prescribed therapies. Nurses must anticipate these therapies because they need to be implemented with speed and accuracy.

Normal Cellular Function

Energy metabolism occurs within the cell, where nutrients are chemically broken down and stored in the form of adenosine triphosphate (ATP). Cells use this stored energy

to perform necessary functions, such as active transport, muscle contraction, and biochemical synthesis, as well as specialized cellular functions, such as the conduction of electrical impulses. ATP can be synthesized aerobically (in the presence of oxygen) or anaerobically (in the absence of oxygen). Aerobic metabolism yields far greater amounts of ATP per mole of glucose than does anaerobic metabolism; therefore, it is a more efficient and effective means of producing energy. In addition, anaerobic metabolism results in the accumulation of the toxic end product, lactic acid, which must be removed from the cell and transported to the liver for conversion into glucose and glycogen.

Pathophysiology

Cellular Changes

In shock, the cells lack an adequate blood supply and are deprived of oxygen and nutrients; therefore, they must produce energy through anaerobic metabolism. This results in low energy yields from nutrients and an acidotic intracellular environment. Because of these changes, normal cell function ceases (Fig. 15-1). The cell swells and the cell membrane becomes more permeable, allowing electrolytes and fluids to seep out of and into the cell. The sodium–potassium pump becomes impaired; cell structures, primarily the mitochondria, are damaged; and death of the cell results.

Glucose is the primary substrate required for the production of cellular energy in the form of ATP. In stress states, catecholamines, cortisol, glucagons, and inflammatory cytokines and mediators are released, causing hyperglycemia and insulin resistance to mobilize glucose for cellular metabolism. Activation of these substances promotes gluconeogenesis, which is the formation of glucose from noncarbohydrate sources such as proteins and fats. Glycogen that has been stored in the liver is converted to glucose through glycogenolysis to meet metabolic needs, increasing the blood glucose concentration (ie, hyperglycemia).

Continued activation of the stress response by shock states causes a depletion of glycogen stores, resulting in increased proteolysis and eventual organ failure (Vincent, 2007). The inability of the body to have enough nutrients and oxygen for normal cellular metabolism causes a buildup of metabolic end products in the cells and interstitial spaces. Cellular metabolism is impaired, and a negative feedback loop is initiated.

Vascular Responses

Local regulatory mechanisms, referred to as autoregulation, stimulate vasodilation or vasoconstriction in response to **biochemical mediators** (ie, cytokines) released by the cell, communicating the need for oxygen and nutrients (King, 2007). A biochemical mediator is a substance released by a cell or immune cells such as macrophages; the substance triggers an action at a cell site or travels in the bloodstream to a distant site, where it triggers action. Researchers are learning more every day about the physiologic actions of more than 100 known cytokines (VonRueden, et al., 2008).

Blood Pressure Regulation

Three major components of the circulatory system—blood volume, the cardiac pump, and the vasculature—must respond effectively to complex neural, chemical, and

Figure 15-1 Cellular effects of shock. The cell swells and the cell membrane becomes more permeable; fluids and electrolytes seep from and into the cell. Mitochondria and lysosomes are damaged, and the cell dies.

hormonal feedback systems to maintain an adequate blood pressure (BP) and perfuse body tissues. BP is regulated through a complex interaction of neural, chemical, and hormonal feedback systems affecting both cardiac output and peripheral resistance. This relationship is expressed in the following equation:

$$\text{Mean arterial BP} = \text{Cardiac output} \times \text{Peripheral resistance}$$

Cardiac output is a product of the stroke volume (the amount of blood ejected from the left ventricle during systole) and heart rate. Peripheral resistance is determined by the diameter of the arterioles.

Tissue perfusion and organ perfusion depend on mean arterial pressure (MAP), or the average pressure at which blood moves through the vasculature. MAP must exceed 65 mm Hg for cells to receive the oxygen and nutrients needed to metabolize energy in amounts sufficient to sustain life (Dellinger, et al., 2008). True MAP can be calculated only by complex methods. Frequently, MAP is calculated by automatic blood pressure machines, however, the nurse must ensure accurate blood pressure measurement is obtained before interpreting data from automated vital sign equipment.

BP is regulated by baroreceptors (pressure receptors) located in the carotid sinus and aortic arch. These pressure receptors are responsible for monitoring the circulatory volume and regulating neural and endocrine activities (see Chapter 14 for further description). When BP drops, catecholamines (epinephrine and norepinephrine) are released from the adrenal medulla. These increase heart rate and cause vasoconstriction, thus restoring BP. Chemoreceptors, also located in the aortic arch and carotid arteries, regulate BP and respiratory rate using much the same mechanism in

response to changes in oxygen and carbon dioxide concentrations in the blood. These primary regulatory mechanisms can respond to changes in BP on a moment-to-moment basis.

The kidneys regulate BP by releasing renin, an enzyme needed for the conversion of angiotensin I to angiotensin II, a potent vasoconstrictor. This stimulation of the renin-angiotensin mechanism and the resulting vasoconstriction indirectly lead to the release of aldosterone from the adrenal cortex, which promotes the retention of sodium and water. The increased concentration of sodium in the blood stimulates the release of antidiuretic hormone (ADH) by the pituitary gland. ADH causes the kidneys to retain water further in an effort to raise blood volume and BP. These secondary regulatory mechanisms may take hours or days to respond to changes in BP. The relationship between the initiation of shock and the responsiveness of primary and secondary regulatory mechanisms that compensate for deficits in blood volume, the pumping effectiveness of the heart, or vascular tone, which may result because of the shock state, is noted in Figure 15-2.

Stages of Shock

Shock is believed to progress along a continuum of stages. Shock can be identified as early or late, depending on the signs and symptoms and the overall severity of organ dysfunction. A convenient way to understand the physiologic responses and subsequent clinical signs and symptoms of shock is to divide the continuum into separate stages: compensatory (stage 1), progressive (stage 2), and irreversible (stage 3). The earlier that medical and nursing

Physiology ■ ■ ■ Pathophysiology

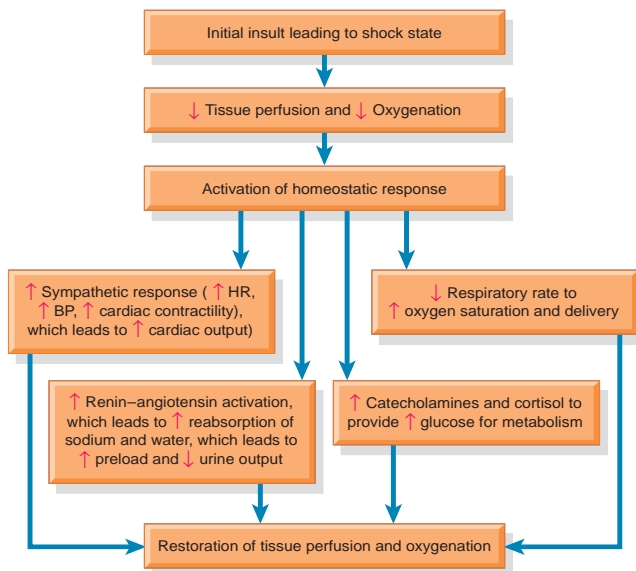

Figure 15-2 Compensatory mechanisms in shock.

interventions are initiated along this continuum, the greater the patient's chance of survival. Current research is focusing on assessing patients at greatest risk for shock and implementing early and aggressive interventions to reverse tissue hypoxia (King, 2007; Otero, Nguyen, Huang, et al., 2006). Studies suggest that the window of opportunity that increases the likelihood of patient survival occurs when aggressive therapy begins within 6 hours of identifying a shock state, especially septic shock (Otero, et al., 2006; Rivers, McIntyre, Morro, et al., 2005).

COMPENSATORY STAGE

In the compensatory stage of shock, the BP remains within normal limits. Vasoconstriction, increased heart rate, and increased contractility of the heart contribute to maintaining adequate cardiac output. This results from stimulation

of the sympathetic nervous system and subsequent release of catecholamines (epinephrine and norepinephrine). Patients display the often-described “fight or flight” response. The body shunts blood from organs such as the skin, kidneys, and gastrointestinal tract to the brain, heart, and lungs to ensure adequate blood supply to these vital organs. As a result, the skin is cool and clammy, bowel sounds are hypoactive, and urine output decreases in response to the release of aldosterone and ADH.

Clinical Manifestations

Despite a normal BP, the patient shows numerous clinical signs indicating inadequate organ perfusion (Table 15-1). The result of inadequate perfusion is anaerobic metabolism and a buildup of lactic acid, producing metabolic acidosis. The respiratory rate increases in response to metabolic acidosis. This rapid respiratory rate facilitates removal of excess carbon dioxide but raises the blood pH and often causes a compensatory respiratory alkalosis. The alkalotic state causes mental status changes, such as confusion or combativeness, as well as arteriolar dilation. If treatment begins in this stage of shock, the prognosis for the patient is better than in later stages.

Medical Management

Medical treatment is directed toward identifying the cause of the shock, correcting the underlying disorder so that shock does not progress, and supporting those physiologic processes that thus far have responded successfully to the threat. Because compensation cannot be maintained indefinitely, measures such as fluid replacement and medication therapy must be initiated to maintain an adequate BP and reestablish and maintain adequate tissue perfusion (Otero, et al., 2006).

Nursing Management

As stated earlier, intervention as soon as possible along the continuum of shock is the key to improving the patient's prognosis. The nurse must systematically assess the patient at risk for shock to recognize the subtle clinical signs of the compensatory stage before the patient's BP drops. Special considerations related to recognizing early signs of shock in the elderly patient are given in Chart 15-1.

Table 15-1 CLINICAL FINDINGS IN STAGES OF SHOCK

Finding	Stage		
	Compensatory	Progressive	Irreversible
Blood pressure	Normal	Systolic <80–90 mm Hg Requires fluids resuscitation to support blood pressure	Requires mechanical or pharmacologic support
Heart rate	>100 bpm	>150 bpm	Erratic or asystole
Respiratory status	>20 breaths/min PaCO ₂ <32 mm Hg	Rapid, shallow respirations; crackles PaO ₂ <80 mm Hg PaCO ₂ >45 mm Hg	Requires intubation and mechanical ventilation and oxygenation
Skin	Cold, clammy	Mottled, petechiae	Jaundice
Urinary output	Decreased	0.5 mL/kg/h	Anuric, requires dialysis
Mentation	Confusion	Lethargy	Unconscious
Acid–base balance	Respiratory alkalosis	Metabolic acidosis	Profound acidosis

CHART
15-1

Recognizing Shock in Older Patients

The physiologic changes associated with aging, coupled with pathologic and chronic disease states, place older people at increased risk for developing a state of shock and possibly multiple organ dysfunction syndrome (MODS). Elderly people can recover from shock if it is detected and treated early with aggressive and supportive therapies. Nurses play an essential role in assessing and interpreting subtle changes in older patients' responses to illness.

- Medications such as beta-blocking agents (metoprolol [Lopressor]) used to treat hypertension may mask tachycardia, a primary compensatory mechanism to increase cardiac output, during hypovolemic states.
- The aging immune system may not mount a truly febrile response (temperature more than 38°C [100.4°F]), but an increasing trend in body temperature should be addressed.

The patient may also report increased fatigue and malaise in the absence of a febrile response.

- The heart does not function well in hypoxemic states, and the aging heart may respond to decreased myocardial oxygenation with dysrhythmias that may be misinterpreted as a normal part of the aging process.
- There is a progressive decline in respiratory muscle strength, maximal ventilation, and response to hypoxia. Older patients have a decreased respiratory reserve and decompensate more quickly.
- Changes in mentation may be inappropriately misinterpreted as dementia. Older people with a sudden change in mentation should be aggressively treated for the presence of infection and organ hypoperfusion.

Monitoring Tissue Perfusion

In assessing tissue perfusion, the nurse observes for changes in level of consciousness, vital signs (including pulse pressure), urinary output, skin, and laboratory values (eg, base deficit and lactic acid levels). In the compensatory stage of shock, serum sodium and blood glucose levels are elevated in response to the release of aldosterone and catecholamines.

The nurse should monitor the patient's hemodynamic status and promptly report deviations to the physician, assist in identifying and treating the underlying disorder by continuous in-depth assessment of the patient, administer prescribed fluids and medications, and promote patient safety. Vital signs are key indicators of hemodynamic status and BP is an indirect measure of tissue hypoxia. The nurse should report a systolic BP lower than 90 mm Hg or a drop in systolic BP of 40 mm Hg from baseline.

Pulse pressure correlates well with stroke volume. Pulse pressure is calculated by subtracting the diastolic measurement from the systolic measurement; the difference is the pulse pressure (Cottingham, 2006). Normally, the pulse pressure is 30 to 40 mm Hg. Narrowing or decreased pulse pressure is an earlier indicator of shock than a drop in systolic BP. Decreased or narrowing pulse pressure, an early indication of decreased stroke volume, is illustrated in the following example:

$$\text{Systolic BP} - \text{Diastolic BP} = \text{Pulse pressure}$$

Normal pulse pressure:

$$120 \text{ mm Hg} - 80 \text{ mm Hg} = 40 \text{ mm Hg}$$

Narrowing of pulse pressure:

$$90 \text{ mm Hg} - 70 \text{ mm Hg} = 20 \text{ mm Hg}$$

Elevation of the diastolic BP with release of catecholamines and attempts to increase venous return through vasoconstriction is an early compensatory mechanism in response to decreased stroke volume, BP, and overall cardiac output.

NURSING ALERT

By the time BP drops, damage has already been occurring at the cellular and tissue levels. Therefore, the patient at risk for shock must be assessed and monitored closely before the BP falls.

Continuous central venous oximetry (ScvO_2) monitoring may be used to evaluate mixed venous blood oxygen saturation and the severity of tissue hypoperfusion states. A central catheter is introduced into the superior vena cava (SVC), and a sensor on the catheter measures the oxygen saturation of the blood in the SVC as blood returns to the heart and pulmonary system for reoxygenation. A normal ScvO_2 value is 70% (Goodrich, 2006; Rivers, et al., 2005). Body tissues use approximately 25% of the oxygen delivered to them during normal metabolism. During states of stress, such as shock, more oxygen is consumed and the ScvO_2 saturation is lower, indicating that the tissues are consuming more oxygen.

Interventions focus on decreasing tissue oxygen requirements and increasing perfusion to deliver more oxygen to the tissues. For instance, sedating agents may be administered to lower metabolic demands, the patient's pain may be treated with intravenous (IV) opioid agents, or measures to prevent shivering, decrease metabolic demands for oxygen. Supplemental oxygen and mechanical ventilation may be required to increase the delivery of oxygen in the blood. Administration of IV fluids and medications supports blood pressure and cardiac output, and the transfusion of packed red blood cells enhances oxygen transport. Monitoring tissue oxygen consumption with ScvO_2 is a minimally invasive measure to more accurately assess tissue oxygenation in the compensatory stage of shock before changes in vital signs detect altered tissue perfusion (Dellinger, et al., 2008; Goodrich, 2006; Otero, et al., 2006).

New technologies allow clinicians to detect changes in tissue perfusion before changes in classic signs (BP, heart rate, and urine output) indicative of hypoperfusion occur.

Two of these technologies include sublingual capnometry and near-infrared spectroscopy. Sublingual capnometry, a noninvasive technology, provides information about the degree of hypoperfusion based on the sublingual partial pressure of carbon dioxide (PCO₂) (Goodrich, 2006). A probe is placed under the patient's tongue, and PCO₂ levels are derived from the blood flow found in the mucosal bed. During shock, an elevated PCO₂ indicates poor tissue perfusion. Near-infrared spectroscopy (NIRS), a continuous noninvasive technology, uses light transmission to measure skeletal muscle oxygenation as an indicator of shock. The NIRS probe is applied to the thenar muscle that is located on the palm of the hand near the thumb, and it measures the oxygen saturation of tissue by determining the amount of infrared light absorption. Low values of tissue oxygenation (eg, less than 80%) indicate severity of shock; the lower the value, the more severe the tissue hypoxia.

Although treatments are prescribed and initiated by the physician, the nurse usually implements them, operates and troubleshoots equipment used in treatment, monitors the patient's status during treatment, and evaluates the immediate effects of treatment. In addition, the nurse assesses the response of the patient and family to the crisis and its treatment.

Reducing Anxiety

Patients and their families often become anxious and apprehensive when they face a major threat to health and well-being and are the focus of attention of many health care providers. Providing brief explanations about the diagnostic and treatment procedures, supporting the patient during these procedures, and providing information about their outcomes are usually effective in reducing stress and anxiety and thus promoting the patient's physical and mental well-being. Speaking in a calm reassuring voice and using gentle touch also help ease the patient's concerns. These actions may provide comfort for critically ill, frightened patients (Benner, 2004; Duran, Oman, Abel, et al., 2007). Research has repeatedly shown that family members have certain needs during a health-related crisis, including needing honest, consistent, and thorough communication with health care providers; needing physical and emotional closeness to the patient; sensing that health care providers care about their patients; seeing the patient frequently; and knowing exactly what has been done for the patient (Duran, et al., 2007).

The nurse should advocate that family members be present during procedures and while patient care is provided. The presence of family provides a necessary connection and support for the patient during a time of crisis.

Promoting Safety

The nurse must be vigilant for potential threats to the patient's safety, because a high anxiety level and altered mental status impair judgment. In this stage of shock, patients who were previously cooperative and followed instructions may now disrupt IV lines and catheters and complicate their condition. Therefore, close monitoring and frequent reorientation interventions are essential.

PROGRESSIVE STAGE

In the second stage of shock, the mechanisms that regulate BP can no longer compensate, and the MAP falls below normal limits. Patients are clinically hypotensive; this is defined as a systolic BP of less than 90 mm Hg or a decrease in systolic BP of 40 mm Hg from baseline (Dellinger, et al., 2008; VonRueden, et al., 2008).

Pathophysiology

Although all organ systems suffer from hypoperfusion at this stage, several events perpetuate the shock syndrome. First, the overworked heart becomes dysfunctional, the body's inability to meet increased oxygen requirements produces ischemia, and biochemical mediators cause myocardial depression (Dellinger, et al., 2008; Otero, et al., 2006; VonRueden, et al., 2008). This leads to failure of the cardiac pump, even if the underlying cause of the shock is not of cardiac origin. Second, the autoregulatory function of the microcirculation fails in response to the numerous biochemical mediators released by the cells, resulting in increased capillary permeability, with areas of arteriolar and venous constriction further compromising cellular perfusion (King, 2007; VonRueden, et al., 2008). At this stage, the prognosis worsens. The relaxation of precapillary sphincters causes fluid to leak from the capillaries, creating interstitial edema and return of less fluid to the heart. In addition, the inflammatory response to injury is activated, and proinflammatory and anti-inflammatory mediators are released, which activate the coagulation system in an effort to reestablish homeostasis (King, 2007). The body mobilizes energy stores and increases oxygen consumption to meet the increased metabolic needs of the underperfused tissues and cells.

Even if the underlying cause of the shock is reversed, the sequence of compensatory responses to the decrease in tissue perfusion perpetuates the shock state, and a vicious circle ensues. The cellular reactions that occur during the progressive stage of shock are an active area of clinical research. It is believed that the body's response to shock or lack of response in this stage of shock may be the primary factor determining the patient's survival.

Clinical Manifestations

Chances of survival depend on the patient's general health before the shock state as well as the amount of time it takes to restore tissue perfusion. As shock progresses, organ systems decompensate.

Respiratory Effects

The lungs, which become compromised early in shock, are affected at this stage. Subsequent decompensation of the lungs increases the likelihood that mechanical ventilation will be needed. Respirations are rapid and shallow. Crackles are heard over the lung fields. Decreased pulmonary blood flow causes arterial oxygen levels to decrease and carbon dioxide levels to increase. Hypoxemia and biochemical mediators cause an intense inflammatory response and pulmonary vasoconstriction, perpetuating pulmonary capillary hypoperfusion and hypoxemia. The hypoperfused alveoli

stop producing surfactant and subsequently collapse. Pulmonary capillaries begin to leak, causing pulmonary edema, diffusion abnormalities (shunting), and additional alveolar collapse. This condition is called acute lung injury (ALI); as ALI continues, interstitial inflammation and fibrosis are common consequences, leading to acute respiratory distress syndrome (ARDS) (Cocci, et al., 2007; Girard, Kess, Fuchs, et al., 2008; Villar, Perez-Mendez, Lopez, et al., 2007). Further explanation of ALI and ARDS, as well as their nursing management, can be found in Chapter 23.

Cardiovascular Effects

A lack of adequate blood supply leads to dysrhythmias and ischemia. The heart rate is rapid, sometimes exceeding 150 bpm. The patient may complain of chest pain and even suffer a myocardial infarction. Levels of cardiac enzymes (eg, myocardial creatine kinase [CK-MB] and cardiac troponin I [cTn-I]) increase. In addition, myocardial depression and ventricular dilation may further impair the heart's ability to pump enough blood to the tissues to meet oxygen requirements.

New laboratory markers can be used to assess the function of the heart. B-type natriuretic peptide (BNP) is one of these markers. BNP is increased when the ventricle is overdistended; therefore, elevations in BNP can be used to assess ventricular function of patients in shock states (Wilson Tang & Francis, 2005).

Neurologic Effects

As blood flow to the brain becomes impaired, mental status deteriorates. Changes in mental status occur with decreased cerebral perfusion and hypoxia. Initially, the patient may exhibit subtle changes in behavior or agitation and confusion. Subsequently, lethargy increases, and the patient begins to lose consciousness.

Renal Effects

When the MAP falls below 70 mm Hg (Cottingham, 2006; Dellinger, et al., 2008; King, 2007; Pinsky, 2007), the glomerular filtration rate of the kidneys cannot be maintained, and drastic changes in renal function occur. Acute renal failure (ARF) may develop. ARF is characterized by an increase in blood urea nitrogen (BUN) and serum creatinine levels, fluid and electrolyte shifts, acid–base imbalances, and a loss of the renal-hormonal regulation of BP. Urinary output usually decreases to less than 0.5 mL/kg/h (or less than 30 mL/h) but may vary depending on the phase of ARF. For further information about ARF, see Chapter 44.

Hepatic Effects

Decreased blood flow to the liver impairs the ability of liver cells to perform metabolic and phagocytic functions. Consequently, the patient is less able to metabolize medications and metabolic waste products, such as ammonia and lactic acid. Metabolic activities of the liver, including gluconeogenesis and glycogenolysis, are impaired. The patient becomes more susceptible to infection as the liver fails to filter bacteria from the blood. Liver enzymes (aspartate aminotransferase [AST], alanine aminotransferase [ALT], lactate dehydrogenase [LDH]) and bilirubin levels are elevated, and the patient appears jaundiced.

Gastrointestinal Effects

Gastrointestinal (GI) ischemia can cause stress ulcers in the stomach, putting the patient at risk for GI bleeding. In the small intestine, the mucosa can become necrotic and slough off, causing bloody diarrhea. Beyond the local effects of impaired perfusion, GI ischemia leads to bacterial toxin translocation, in which bacterial toxins enter the bloodstream through the lymphatic system. In addition to causing infection, bacterial toxins can cause cardiac depression, vasodilation, increased capillary permeability, and an intense inflammatory response with activation of additional biochemical mediators. The net result is interference with healthy cellular functioning and their ability to metabolize nutrients (Stapleton, Jones & Heyland, 2007).

Hematologic Effects

The combination of hypotension, sluggish blood flow, metabolic acidosis, coagulation system imbalance, and generalized hypoxemia can interfere with normal hemostatic mechanisms. In shock states, the inflammatory cytokines activate the clotting cascade, causing deposition of microthrombi in multiple areas of the body and consumption of clotting factors. The alterations of the hematologic system, including imbalance of the clotting cascade, are linked to the overactivation of the inflammatory response of injury (Remick, 2007a; VonRueden, et al., 2008). Disseminated intravascular coagulation (DIC) may occur either as a cause or as a complication of shock. In this condition, widespread clotting and bleeding occur simultaneously. Bruises (ecchymoses) and bleeding (petechiae) may appear in the skin. Coagulation times (eg, prothrombin time [PT], activated partial thromboplastin time [aPTT]) are prolonged. Clotting factors and platelets are consumed and require replacement therapy to achieve hemostasis. Further discussion of DIC appears in Chapter 33.

Medical Management

Specific medical management in the progressive stage of shock depends on the type of shock and its underlying cause. It is also based on the degree of decompensation in the organ systems. Medical management specific to each type of shock is discussed later in this chapter. Although there are several differences in medical management by type of shock, some medical interventions are common to all types. These include the use of appropriate IV fluids and medications to restore tissue perfusion by the following methods:

- Supporting the respiratory system
- Optimizing intravascular volume
- Supporting the pumping action of the heart
- Improving the competence of the vascular system

Other aspects of management may include early enteral nutritional support, aggressive hyperglycemic control with IV insulin (Hafidh, Reuter, Chassels, et al., 2007; Vanhorebeek, Langouche & Van den Berghe, 2007), and use of antacids, histamine-2 (H₂) blockers, or anti-peptic agents to reduce the risk of GI ulceration and bleeding.

 **NURSING ALERT**

Tight glycemic control (blood glucose, 80 to 110 mg/dL) has been shown to reduce morbidity and mortality of acutely ill patients.

**Nursing Management**

Nursing care of patients in the progressive stage of shock requires expertise in assessing and understanding shock and the significance of changes in assessment data. Early interventions are essential to the survival of patients; therefore, suspecting that a patient may be in shock and reporting subtle changes in assessment are imperative. Patients in the progressive stage of shock are cared for in the intensive care setting to facilitate close monitoring (hemodynamic monitoring, electrocardiographic [ECG] monitoring, arterial blood gases, serum electrolyte levels, physical and mental status changes); rapid and frequent administration of various prescribed medications and fluids; and possibly interventions with supportive technologies, such as mechanical ventilation, dialysis, and intra-aortic balloon pump.

Working closely with other members of the health care team, the nurse carefully documents treatments, medications, and fluids that are administered, recording the time, dosage or volume, and patient response. In addition, the nurse coordinates both the scheduling of diagnostic procedures that may be carried out at the bedside and the flow of health care personnel involved in the care of patients.

Preventing Complications

The nurse helps reduce the risk of related complications and monitors the patient for early signs of complications. Monitoring includes evaluating blood levels of medications, observing invasive vascular lines for signs of infection, and checking neurovascular status if arterial lines are inserted, especially in the lower extremities. Simultaneously, the nurse promotes the patient's safety and comfort by ensuring that all procedures, including invasive procedures and arterial and venous punctures, are carried out using correct aseptic techniques and that venous and arterial puncture and infusion sites are maintained with the goal of preventing infection. Nursing interventions that reduce the incidence of ventilator-associated pneumonias must also be implemented. These include frequent oral care, aseptic suction technique, turning, and elevating the head of the bed at least 30 degrees to prevent aspiration (Carson, Tyner, Sanders, et al., 2007; Dellinger, et al., 2008). Positioning and repositioning of the patient to promote comfort and maintain skin integrity are essential.

Promoting Rest and Comfort

Efforts are made to minimize the cardiac workload by reducing the patient's physical activity and treating pain and anxiety. Promoting patient rest and comfort is a priority. To ensure that the patient obtains as much uninterrupted rest as possible, the nurse performs only essential nursing activities. To conserve the patient's energy, the nurse should protect the patient from temperature extremes (eg, exces-

sive warmth or cold, and shivering), which can increase the metabolic rate and oxygen consumption and thus the cardiac workload. The patient should not be warmed too quickly, and warming blankets should not be applied, because they can cause vasodilation and a subsequent drop in BP.

Supporting Family Members

Because patients in shock receive intense attention by the health care team, families may be overwhelmed and frightened. Family members may be reluctant to ask questions or seek information for fear that they will be in the way or will interfere with the attention given to the patient. The nurse should make sure that the family is comfortably situated and kept informed about the patient's status. Often, families need advice from the health care team to get some rest; family members are more likely to take this advice if they feel that the patient is being well cared for and that they will be notified of any significant changes in the patient's status. A visit from the hospital chaplain may be comforting and provides some attention to the family while the nurse concentrates on the patient.

IRREVERSIBLE STAGE

The irreversible (or refractory) stage of shock represents the point along the shock continuum at which organ damage is so severe that the patient does not respond to treatment and cannot survive. Despite treatment, BP remains low. Renal and liver failure, compounded by the release of necrotic tissue toxins, creates an overwhelming metabolic acidosis. Anaerobic metabolism contributes to a worsening lactic acidosis. Reserves of ATP are almost totally depleted, and mechanisms for storing new supplies of energy have been destroyed. Respiratory system failure prevents adequate oxygenation and ventilation despite mechanical ventilatory support, and the cardiovascular system is ineffective in maintaining an adequate MAP for perfusion. Multiple organ dysfunction progressing to complete organ failure has occurred, and death is imminent. Multiple organ dysfunction can occur as a progression along the shock continuum or as a syndrome unto itself and is described in more detail later in this chapter.

**Medical Management**

Medical management during the irreversible stage of shock is usually the same as for the progressive stage. Although the patient may have progressed to the irreversible stage, the judgment that the shock is irreversible can be made only retrospectively on the basis of the patient's failure to respond to treatment. Strategies that may be experimental (eg, investigational medications, such as antibiotic agents and immunomodulation therapy) may be tried to reduce or reverse the severity of shock.

**Nursing Management**

As in the progressive stage of shock, the nurse focuses on carrying out prescribed treatments, monitoring the patient, preventing complications, protecting the patient from injury, and providing comfort. Offering brief explanations to the patient

about what is happening is essential even if there is no certainty that the patient hears or understands what is being said. Simple comfort measures, including reassuring touches, should continue to be provided despite the patient's nonresponsiveness to verbal stimuli (Benner, 2004, Duran, et al., 2007).

As it becomes obvious that the patient is unlikely to survive, the family must be informed about the prognosis and likely outcome. Opportunities should be provided throughout the patient's care for the family to see, touch, and talk to the patient. Close family friends or spiritual advisors may be of comfort to the family members in dealing with the inevitable death of their loved one. Whenever possible and appropriate, the patient's family should be approached regarding any living wills, advance directives, or other written or verbal wishes the patient may have shared in the event that he or she became unable to participate in end-of-life decisions. In some cases, ethics committees may assist families and health care teams in making difficult decisions.

During this stage of shock, the family may misinterpret the actions of the health care team. They have been told that nothing has been effective in reversing the shock and that the patient's survival is very unlikely, yet they find physicians and nurses continuing to work feverishly on the patient. Distraught, grieving families may interpret this as a chance for recovery when none exists, and family members may become angry when the patient dies. Conferences with all members of the health care team and the family promote better understanding by the family of the patient's prognosis and the purpose for management measures. During these conferences, it is essential to explain that the equipment and treatments being provided are intended for patient comfort and do not suggest that the patient will recover. Family members should be encouraged to express their wishes concerning the use of life-support measures.

General Management Strategies in Shock

As described previously and in the discussion of types of shock to follow, management in all types and all phases of shock includes the following:

- Support of the respiratory system with supplemental oxygen and/or mechanical ventilation to provide optimal oxygenation (see Chapter 25)
- Fluid replacement to restore intravascular volume
- Vasoactive medications to restore vasomotor tone and improve cardiac function
- Nutritional support to address the metabolic requirements that are often dramatically increased in shock

Therapies described in this section require collaboration among all members of the health care team to ensure that the manifestations of shock are quickly identified and that adequate and timely treatment is instituted to achieve the best outcome possible.

Fluid Replacement

Fluid replacement, also referred to as fluid resuscitation, is administered in all types of shock. The type of fluids administered and the speed of delivery vary, but fluids are ad-

ministered to improve cardiac and tissue oxygenation, which in part depends on flow. The fluids administered may include **crystalloids** (electrolyte solutions that move freely between intravascular and interstitial spaces), **colloids** (large-molecule IV solutions), and blood components (packed red blood cells, fresh frozen plasma, and platelets).

Crystalloid and Colloid Solutions

The best fluid to treat shock remains controversial. In emergencies, the "best" fluid is often the fluid that is readily available. Fluid resuscitation should be initiated early in shock to maximize intravascular volume. There is no consensus regarding whether crystalloids or colloids should be used; however, with crystalloids, more fluid is necessary to restore intravascular volume (Roberts, Alderson, Bunn, et al., 2007).

Crystalloids are electrolyte solutions that move freely between the intravascular compartment and the interstitial spaces. Isotonic crystalloid solutions are often selected because they contain the same concentration of electrolytes as the extracellular fluid and therefore can be given without altering the concentrations of electrolytes in the plasma. IV crystalloids commonly used for resuscitation in hypovolemic shock include 0.9% sodium chloride solution (normal saline) and lactated Ringer's solution (Boswell & Scalea, 2008; Cottingham, 2006). Ringer's lactate is an electrolyte solution containing the lactate ion, which should not be confused with lactic acid. The lactate ion is converted to bicarbonate, which helps buffer the overall acidosis that occurs in shock. A disadvantage of using isotonic crystalloid solutions is that some of the volume administered is lost to the interstitial compartment and some remains in the intravascular compartment. This occurs as a consequence of cellular permeability that occurs during shock. Diffusion of crystalloids into the interstitial space means that more fluid must be administered than the amount lost (Cottingham, 2006; Roberts, et al., 2007).

Care must be taken when rapidly administering isotonic crystalloids to avoid both underresuscitating and overresuscitating the patient in shock. Insufficient fluid replacement is associated with a higher incidence of morbidity and mortality from lack of tissue perfusion, whereas excessive fluid administration can cause systemic and pulmonary edema that progresses to ARDS, abdominal compartment syndrome, and multiple organ dysfunction syndrome (MODS).

Depending on the cause of the hypovolemia, a hypertonic crystalloid solution, such as 3% sodium chloride, is sometimes administered in hypovolemic shock. These solutions exert a large osmotic force that pulls fluid from the intracellular space to the extracellular space to achieve a fluid balance (Cottingham, 2006). This osmotic effect results in fewer fluids being administered to restore intravascular volume. Complications associated with use of hypertonic solutions include excessive serum osmolality, which can cause rapid fluid shifts overwhelming the heart, and hypernatremia.

Generally, IV colloidal solutions are similar to plasma proteins, in that they contain molecules that are too large to pass through capillary membranes. Colloids expand intravascular volume by exerting oncotic pressure, thereby pulling fluid into the intravascular space. Colloidal solutions

have the same effect as hypertonic solutions in increasing intravascular volume, but less volume of fluid is required than with crystalloids. In addition, colloids have a longer duration of action than crystalloids, because the molecules remain within the intravascular compartment longer.

Typically, if colloids are used to treat tissue hypoperfusion, albumin is the agent prescribed. Albumin is a plasma protein; an albumin solution is prepared from human plasma and is heated during production to reduce its potential to transmit disease. The disadvantage of albumin is its high cost compared to crystalloid solutions. Synthetic colloid preparations, such as hetastarch and dextran solution, may also be used for colloid infusions; however, dextran may interfere with platelet aggregation and, therefore, is not indicated if hemorrhage is the cause of the hypovolemic shock or if the patient has a coagulation disorder.

NURSING ALERT

With all colloidal solutions, side effects include the rare occurrence of anaphylactic reactions. Nurses must monitor patients closely.

Complications of Fluid Administration

Close monitoring of the patient during fluid replacement is necessary to identify side effects and complications. The most common and serious side effects of fluid replacement are cardiovascular overload and pulmonary edema. The patient receiving fluid replacement must be monitored frequently for adequate urinary output, changes in mental status, skin perfusion, and changes in vital signs. Lung sounds are auscultated frequently to detect signs of fluid accumulation. Adventitious lung sounds, such as crackles, may indicate pulmonary edema.

Abdominal compartment syndrome (ACS) is a serious complication that may occur when large volumes of fluid are administered. It may also occur after trauma, abdominal surgery, severe pancreatitis, or sepsis (Brush, 2007). In ACS, fluid leaks into the intra-abdominal cavity, increasing pressure that is displaced onto surrounding vessels and organs. Venous return, preload, and cardiac output are compromised. The pressure also elevates the diaphragm, making it difficult to breathe effectively. The renal system and GI systems also begin to show signs of dysfunction (eg, decreased urine output, absent bowel sounds, intolerance of tube feeding). Abdominal compartment pressure can be measured. Normally, it is 0 to 5 mm Hg, and a pressure of 12 mm Hg is considered to be indicative of intra-abdominal hypertension (Brush, 2007). If ACS is present, interventions that usually include surgical decompression are necessary to relieve the pressure.

NURSING ALERT

When administering large volumes of crystalloid solutions, monitor the lungs for adventitious sounds and signs and symptoms of interstitial edema (eg, abdominal compartment syndrome).

Often a right atrial pressure line (also known as a central venous pressure [CVP] line) is inserted. In addition to physical assessment, the right atrial pressure value helps in monitoring the patient's response to fluid replacement. A normal right atrial pressure value or CVP is 4 to 12 mm Hg or cm H₂O. Several readings are obtained to determine a range, and fluid replacement is continued to achieve a CVP of at least 8 mm Hg (Dellinger, et al., 2008). With newer technologies, right atrial catheters can be placed that allow the monitoring of intravascular pressures and venous oxygen levels. Assessment of venous oxygenation (venous oxygen saturation ([SvO₂], or ScvO₂ with a CVP line) is helpful in evaluating the adequacy of intravascular volume (Goodrich, 2006; Rivers, et al., 2005). Hemodynamic monitoring with arterial and pulmonary artery lines may be implemented to allow close monitoring of the patient's perfusion and cardiac status as well as response to therapy. For additional information about hemodynamic monitoring, see Chapter 26.

Vasoactive Medication Therapy

Vasoactive medications are administered in all forms of shock to improve the patient's hemodynamic stability when fluid therapy alone cannot maintain adequate MAP. Specific medications are selected to correct the particular hemodynamic alteration that is impeding cardiac output. These medications help increase the strength of myocardial contractility, regulate the heart rate, reduce myocardial resistance, and initiate vasoconstriction.

Vasoactive medications are selected for their action on receptors of the sympathetic nervous system. These receptors are known as alpha-adrenergic and beta-adrenergic receptors. Beta-adrenergic receptors are further classified as beta-1 and beta-2 adrenergic receptors. When alpha-adrenergic receptors are stimulated, blood vessels constrict in the cardiorespiratory and GI systems, skin, and kidneys. When beta-1 adrenergic receptors are stimulated, heart rate and myocardial contraction increase. When beta-2 adrenergic receptors are stimulated, vasodilation occurs in the heart and skeletal muscles, and the bronchioles relax. The medications used in treating shock consist of various combinations of vasoactive medications to maximize tissue perfusion by stimulating or blocking the alpha- and beta-adrenergic receptors.

When vasoactive medications are administered, vital signs must be monitored frequently (at least every 15 minutes until stable, or more often if indicated). Vasoactive medications should be administered through a central venous line, because infiltration and extravasation of some vasoactive medications can cause tissue necrosis and sloughing. An IV pump or controller should be used to ensure that the medications are delivered safely and accurately.

Individual medication dosages are usually titrated by the nurse, who adjusts drip rates based on the prescribed dose and the patient's response. Dosages are changed to maintain the MAP at a physiologic level that ensures adequate tissue perfusion (usually greater than 65 mm Hg).

NURSING ALERT

Vasoactive medications should never be stopped abruptly, because this could cause severe hemodynamic instability, perpetuating the shock state.

Dosages of vasoactive medications should be tapered, and the patient should be weaned from medication with frequent monitoring of BP (every 15 minutes). Table 15-2 presents some of the commonly prescribed vasoactive medications used in the treatment of shock. Occasionally, the patient does not respond as expected to vasoactive medications. A current topic of active research is evaluation of patients' adrenal function. Recent studies suggest that critically ill patients should be evaluated for corticosteroid insufficiency, and if this condition is present, corticosteroid replacement (eg, hydrocortisone) should be initiated (Dellinger, et al., 2008).

Nutritional Support

Nutritional support is an important aspect of care for patients with shock. Increased metabolic rates during shock increase energy requirements and therefore caloric requirements. Patients in shock may require more than 3000 calories daily. The release of catecholamines early in the shock continuum causes depletion of glycogen stores in about 8 to 10 hours. Nutritional energy requirements are then met by breaking down lean body mass. In this catabolic process, skeletal muscle mass is broken down even when the patient has large stores of fat or adipose tissue. Loss of skeletal muscle greatly prolongs the patient's recovery time.

Parenteral or enteral nutritional support should be initiated as soon as possible. Enteral nutrition is preferred, promoting GI function through direct exposure to nutrients and limiting infectious complications associated with parenteral feeding (Vincent, 2007). In addition, glutamine (an essential amino acid during stress), which may be administered in enteral formulas, is important in the immunologic function of the GI tract, providing a fuel source for lymphocytes and macrophages (Stapleton, et al., 2007).

Stress ulcers occur frequently in acutely ill patients because of the compromised blood supply to the GI tract. Therefore, antacids, H₂ blockers (eg, famotidine [Pepcid], ranitidine [Zantac]), and proton pump inhibitors (eg, lansoprazole [Prevacid]) are prescribed to prevent ulcer formation by inhibiting gastric acid secretion or increasing gastric pH.

Hypovolemic Shock

Nurses who care for patients in the different stages of shock must tailor interventions to the type of shock, whether hypovolemic, cardiogenic, or circulatory shock. **Hypovolemic shock**, the most common type of shock, is characterized by decreased intravascular volume. Body fluid is contained in the intracellular and extracellular compartments. Intracellular fluid accounts for about two thirds of the total body water. The extracellular body fluid is found in one of two compartments: intravascular (inside blood vessels) or interstitial (surrounding tissues). The volume of interstitial fluid is about three to four times that of intravascular fluid. Hypovolemic shock occurs when there is a reduction in intravascular volume by 15% to 30%, which represents a loss of 750 to 1500 mL of blood in a 70-kg (154-lb) person (American College of Surgeons, 2006).

Pathophysiology

Hypovolemic shock can be caused by external fluid losses, as in traumatic blood loss, or by internal fluid shifts, as in severe dehydration, severe edema, or ascites (Chart 15-2). Intravascular volume can be reduced both by fluid loss and by fluid shifting between the intravascular and interstitial compartments.

The sequence of events in hypovolemic shock begins with a decrease in the intravascular volume. This results in decreased venous return of blood to the heart and subsequent decreased ventricular filling. Decreased ventricular filling results in decreased stroke volume (amount of blood ejected from the heart) and decreased cardiac output. When cardiac output drops, BP drops and tissues cannot be adequately perfused (Fig. 15-3).

Table 15-2 VASOACTIVE AGENTS USED IN TREATING SHOCK

Medication	Desired Action in Shock	Disadvantages
Inotropic Agents		
Dobutamine (Dobutrex)	Improve contractility, increase stroke volume, increase cardiac output	Increase oxygen demand of the heart
Dopamine (Intropin)		
Epinephrine (Adrenalin)		
Milrinone (Primacor)		
Vasodilators		
Nitroglycerin (Tridil)	Reduce preload and afterload, reduce oxygen demand of heart	Cause hypotension
Nitroprusside (Nipride)		
Vasopressor Agents		
Norepinephrine (Levophed)	Increase blood pressure by vasoconstriction	Increase afterload, thereby increasing cardiac workload; compromise perfusion to skin, kidneys, lungs, gastrointestinal tract
Dopamine (Intropin)		
Phenylephrine (Neo-Synephrine)		
Vasopressin (Pitressin)		

CHART
15-2

Risk Factors for Hypovolemic Shock

External: Fluid Losses

- Trauma
- Surgery
- Vomiting
- Diarrhea
- Diuresis
- Diabetes insipidus

Internal: Fluid Shifts

- Hemorrhage
- Burns
- Ascites
- Peritonitis
- Dehydration

Medical Management

Major goals in the treatment of hypovolemic shock are to restore intravascular volume to reverse the sequence of events leading to inadequate tissue perfusion, to redistribute fluid volume, and to correct the underlying cause of the fluid loss as quickly as possible. Depending on the severity of shock and the patient's condition, it is likely that efforts will be made to address all three goals simultaneously.

Treatment of the Underlying Cause

If the patient is hemorrhaging, efforts are made to stop the bleeding. This may involve applying pressure to the bleeding site or surgical interventions to stop internal bleeding. If the cause of the hypovolemia is diarrhea or vomiting, medications to treat diarrhea and vomiting are administered while efforts are made to identify and treat the cause.

Physiology ■■■ Pathophysiology

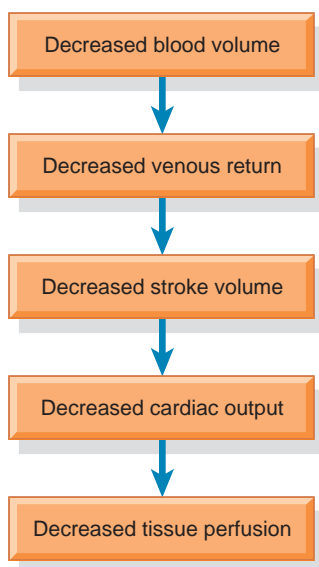

Figure 15-3 Pathophysiologic sequence of events in hypovolemic shock.

In elderly patients, dehydration may be the cause of hypovolemic shock.

Fluid and Blood Replacement

Beyond reversing the primary cause of the decreased intravascular volume, fluid replacement is of primary concern. At least two large-gauge IV lines are inserted to establish access for fluid administration. Two IV lines allow simultaneous administration of fluid, medications, and blood component therapy if required. Because the goal of the fluid replacement is to restore intravascular volume, it is necessary to administer fluids that will remain in the intravascular compartment to avoid fluid shifts from the intravascular compartment into the intracellular compartment. Table 15-3 summarizes the fluids commonly used in the treatment of shock.

As discussed earlier, crystalloid solutions such as lactated Ringer's solution or 0.9% sodium chloride solution are commonly used to treat hypovolemic shock as large amounts of fluid must be administered to restore intravascular volume. If hypovolemia is primarily due to blood loss, the American College of Surgeons recommends administration of 3 mL of crystalloid solution for each milliliter of estimated blood loss. This is referred to as the 3:1 rule (American College of Surgeons, 2006). Colloid solutions (eg, albumin, hetastarch) may also be used. Dextran is not indicated if the cause of the hypovolemic shock is hemorrhage, because it interferes with platelet aggregation.

Blood products, which are also colloids, may need to be administered, particularly if the cause of the hypovolemic shock is hemorrhage. The decision to give blood is based on the patient's lack of response to only crystalloid resuscitation, the volume of blood lost, the need for hemoglobin to assist with oxygen transport, and the necessity to correct the patient's coagulopathy. It should be noted that research indicates that patients who receive massive blood transfusions to achieve near-normal hemoglobin levels tend to have poorer outcomes than those with low hemoglobin levels (eg, less than 7.0 g/dL) (Dellinger, et al., 2008; Holcomb & Hess, 2006). Packed red blood cells are administered to replenish the patient's oxygen-carrying capacity in conjunction with other fluids that will expand volume. Currently, the need for transfusions is based on the patient's oxygenation needs, which are determined by vital signs, blood gas values, and clinical appearance rather than an arbitrary laboratory value. An area of active research is the development of synthetic forms of blood (ie, compounds capable of carrying oxygen in the same way that blood does) as potential alternatives to blood component therapy.

Redistribution of Fluid

In addition to administering fluids to restore intravascular volume, positioning the patient properly assists fluid redistribution. A modified Trendelenburg position (Fig. 15-4) is recommended in hypovolemic shock. Elevation of the legs promotes the return of venous blood. A full Trendelenburg position makes breathing difficult and does not increase BP or cardiac output (Bridges & Jarquin-Valdivia, 2005).

Table 15-3 FLUID REPLACEMENT IN SHOCK

Deliver a minimum of 20 mL/kg of crystalloid (or colloid equivalent).		
Fluids	Advantages	Disadvantages
Crystalloids		
0.9% sodium chloride (normal saline solution)	Widely available, inexpensive	Requires large volume of infusion; can cause hypernatremia, pulmonary edema, abdominal compartment syndrome
Lactated Ringer's	Lactate ion helps buffer metabolic acidosis	Requires large volume of infusion; can cause metabolic acidosis, pulmonary edema, abdominal compartment syndrome
Hypertonic saline (3%)	Small volume needed to restore intravascular volume	Danger of hypernatremia and cardiovascular compromise from rapid fluid shifts
Colloids		
Albumin (5%, 25%)	Rapidly expands plasma volume	Expensive; requires human donors; limited supply; can cause heart failure
Dextran	Synthetic plasma expander	Interferes with platelet aggregation; not recommended for hemorrhagic shock
Hetastarch	Synthetic plasma expander	Prolongs bleeding and clotting times

Pharmacologic Therapy

If fluid administration fails to reverse hypovolemic shock, then vasoactive medications that prevent cardiac failure are given. Medications are also administered to reverse the cause of the dehydration. For example, insulin is administered if dehydration is secondary to hyperglycemia, desmopressin (DDAVP) is administered for diabetes insipidus, anti-diarrheal agents for diarrhea, and antiemetic medications for vomiting.

Nursing Management

Primary prevention of shock is an essential focus of nursing care. Hypovolemic shock can be prevented in some instances by closely monitoring patients who are at risk for fluid deficits and assisting with fluid replacement before intravascular volume is depleted. In other circumstances, nursing care focuses on assisting with treatment

Figure 15-4 Proper positioning (modified Trendelenburg) for the patient who shows signs of shock. The lower extremities are elevated to an angle of about 20 degrees; the knees are straight, the trunk is horizontal, and the head is slightly elevated.

targeted at the cause of the shock and restoring intravascular volume.

General nursing measures include ensuring safe administration of prescribed fluids and medications and documenting their administration and effects. Another important nursing role is monitoring for complications and side effects of treatment and reporting them promptly.

Administering Blood and Fluids Safely

Administering blood transfusions safely is a vital nursing role. In emergency situations, it is important to acquire blood specimens quickly, to obtain a baseline complete blood count, and to type and cross-match the blood in anticipation of blood transfusions. A patient who receives a transfusion of blood products must be monitored closely for adverse effects (see Chapter 33).

Fluid replacement complications can occur, often when large volumes are administered rapidly. Therefore, the nurse monitors the patient closely for cardiovascular overload, signs of difficulty breathing, and pulmonary edema. The risk of these complications is increased in the elderly and in patients with preexisting cardiac disease. Hemodynamic pressures, vital signs, arterial blood gases, serum lactate levels, hemoglobin and hematocrit levels, and fluid intake and output (I&O) are among the parameters monitored. Temperature should also be monitored closely to ensure that rapid fluid resuscitation does not cause hypothermia. IV fluids may need to be warmed during the administration of large volumes. Physical assessment focuses on observing the jugular veins for distention and monitoring jugular venous pressure. Jugular venous pressure is low in hypovolemic shock; it increases with effective treatment and is significantly increased with fluid overload and heart failure. The nurse must monitor cardiac and respiratory status closely and report changes in BP, pulse pressure, CVP, heart rate and rhythm, and lung sounds to the physician.

Implementing Other Measures

Oxygen is administered to increase the amount of oxygen carried by available hemoglobin in the blood. A patient who is confused may feel apprehensive with an oxygen mask or cannula in place, and frequent explanations about the need for the mask may reduce some of the patient's fear and anxiety. Simultaneously, the nurse must direct efforts to the safety and comfort of the patient.

Cardiogenic Shock

Cardiogenic shock occurs when the heart's ability to contract and to pump blood is impaired and the supply of oxygen is inadequate for the heart and tissues. The causes of cardiogenic shock are known as either coronary or non-coronary. Coronary cardiogenic shock is more common than noncoronary cardiogenic shock and is seen most often in patients with acute myocardial infarction (MI) resulting in damage to a significant portion of the left ventricular myocardium (Aymong, Ramanathan & Buller, 2007). Patients who experience an anterior wall MI are at greatest risk for cardiogenic shock because of the potentially extensive damage to the left ventricle caused by occlusion of the left anterior descending coronary artery. Noncoronary causes of cardiogenic shock are related to conditions that stress the myocardium (eg, severe hypoxemia, acidosis, hypoglycemia, hypocalcemia, and tension pneumothorax) as well as conditions that result in ineffective myocardial function (eg, cardiomyopathies, valvular damage, cardiac tamponade, dysrhythmias).

Pathophysiology

In cardiogenic shock, cardiac output, which is a function of both stroke volume and heart rate, is compromised. When stroke volume and heart rate decrease or become erratic, BP falls and tissue perfusion is reduced. Blood supply for tissues and organs and for the heart muscle itself is inadequate, resulting in impaired tissue perfusion. Because impaired tissue perfusion weakens the heart and impairs its ability to pump, the ventricle does not fully eject its volume of blood at systole. As a result, fluid accumulates in the lungs. This sequence of events can occur rapidly or over a period of days (Fig. 15-5).

Clinical Manifestations

Patients in cardiogenic shock may experience the pain of angina, develop dysrhythmias, complain of fatigue, express feelings of doom, and show signs of hemodynamic instability.

Medical Management

The goals of medical management in cardiogenic shock are to limit further myocardial damage and preserve the healthy myocardium and to improve the cardiac function by increasing cardiac contractility, decreasing ventricular afterload, or both (Aymong, et al., 2007; Iakobishvili & Hasdai, 2007; Mann & Nolan, 2006). In general, these goals are achieved by increasing oxygen supply to the heart muscle while reducing oxygen demands.

Physiology ■■■ Pathophysiology

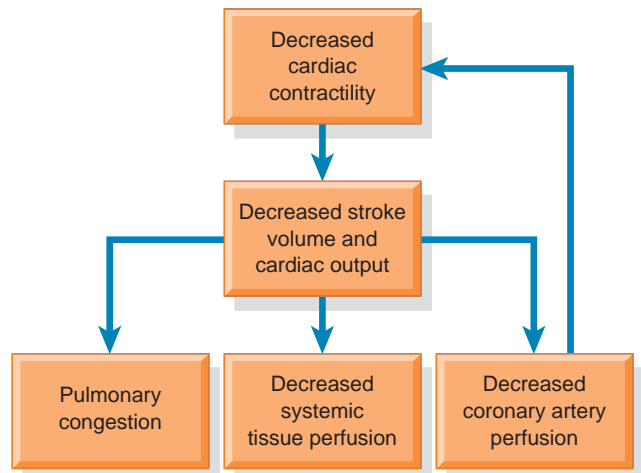

Figure 15-5 Pathophysiologic sequence of events in cardiogenic shock.

Correction of Underlying Causes

As with all forms of shock, the underlying cause of cardiogenic shock must be corrected. It is necessary first to treat the oxygenation needs of the heart muscle to ensure its continued ability to pump blood to other organs. In the case of coronary cardiogenic shock, the patient may require thrombolytic therapy, a percutaneous coronary intervention (PCI), coronary artery bypass graft (CABG) surgery, intra-aortic balloon pump therapy, or some combination of these treatments. In the case of noncoronary cardiogenic shock, interventions focus on correcting the underlying cause, such as replacement of a faulty cardiac valve, correction of a dysrhythmia, correction of acidosis and electrolyte disturbances, or treatment of the tension pneumothorax.

Initiation of First-Line Treatment

Oxygenation

In the early stages of shock, supplemental oxygen is administered by nasal cannula at a rate of 2 to 6 L/min to achieve an oxygen saturation exceeding 90%. Monitoring of arterial blood gas values and pulse oximetry values helps determine whether the patient requires a more aggressive method of oxygen delivery.

Pain Control

If a patient experiences chest pain, IV morphine is administered for pain relief. In addition to relieving pain, morphine dilates the blood vessels. This reduces the workload of the heart by both decreasing the cardiac filling pressure (preload) and reducing the pressure against which the heart muscle has to eject blood (afterload). Morphine also decreases the patient's anxiety.

Hemodynamic Monitoring

Hemodynamic monitoring is initiated to assess the patient's response to treatment. In many institutions, this is performed in the intensive care unit (ICU), where an arterial line can be inserted. The arterial line enables accurate and

continuous monitoring of BP and provides a port from which to obtain frequent arterial blood samples without having to perform repeated arterial punctures. A multilumen pulmonary artery catheter is inserted to allow measurement of the pulmonary artery pressures, myocardial filling pressures, cardiac output, and pulmonary and systemic resistance. For more information, see Chapter 30.

Laboratory Marker Monitoring

Laboratory markers for ventricular dysfunction (eg, BNP) and cardiac enzyme levels (CK-MB and cTn-I) are measured, and serial 12-lead ECGs are obtained to assess the degree of myocardial damage. Continuous ECG and ST-segment monitoring is also used to closely monitor the patient for ischemic changes.

Fluid Therapy

Appropriate fluid administration is also necessary in the treatment of cardiogenic shock. Administration of fluids must be monitored closely to detect signs of fluid overload. Incremental IV fluid boluses are cautiously administered to determine optimal filling pressures for improving cardiac output.

NURSING ALERT

A fluid bolus should never be given rapidly, because rapid fluid administration in patients with cardiac failure may result in acute pulmonary edema.

Pharmacologic Therapy

Vasoactive medication therapy consists of multiple pharmacologic strategies to restore and maintain adequate cardiac output. In coronary cardiogenic shock, the aims of vasoactive medication therapy are improved cardiac contractility, decreased preload and afterload, and stabilized heart rate and rhythm.

Because improving contractility and decreasing cardiac workload are opposing pharmacologic actions, two types of medications may be administered in combination: inotropic agents and vasodilators. Inotropic medications increase cardiac output by mimicking the action of the sympathetic nervous system, activating myocardial receptors to increase myocardial contractility (inotropic action) or increasing the heart rate (chronotropic action). These agents may also enhance vascular tone, increasing preload. Vasodilators are used primarily to decrease afterload, reducing the workload of the heart and the oxygen demand. Vasodilators also decrease preload. Medications commonly combined to treat cardiogenic shock include dobutamine, nitroglycerin, and dopamine (see Table 15-2).

Dobutamine. Dobutamine produces inotropic effects by stimulating myocardial beta-receptors, increasing the strength of myocardial activity and improving cardiac output. Myocardial alpha-adrenergic receptors are also stimulated, resulting in decreased pulmonary and systemic vascular resistance (decreased afterload). Dobutamine enhances the strength of cardiac contraction, improving stroke volume ejection and overall cardiac output (Iakobishvili & Hasdai, 2007; Mann & Nolan, 2006).

Nitroglycerin. IV nitroglycerin in low doses acts as a venous vasodilator and therefore reduces preload. At higher doses, nitroglycerin causes arterial vasodilation and therefore reduces afterload as well. These actions, in combination with dobutamine, increase cardiac output while minimizing cardiac workload. In addition, vasodilation enhances blood flow to the myocardium, improving oxygen delivery to the weakened heart muscle (Iakobishvili & Hasdai, 2007).

Dopamine. Dopamine is a sympathomimetic agent that has varying vasoactive effects depending on the dosage. It may be used with dobutamine and nitroglycerin to improve tissue perfusion. Doses of 2 to 8 $\mu\text{g}/\text{kg}/\text{min}$ improve contractility (inotropic action), slightly increase the heart rate (chronotropic action), and may increase cardiac output. Doses that are higher than 8 $\mu\text{g}/\text{kg}/\text{min}$ predominantly cause vasoconstriction, which increases afterload and thus increases cardiac workload. Because this effect is undesirable in patients with cardiogenic shock, dopamine doses must be carefully titrated.

Low-dose dopamine (ie, 0.5 to 3.0 $\mu\text{g}/\text{kg}/\text{min}$) neither improves renal flow, changes the need for renal support, nor reduces mortality (Friedrich, Adhikari, Herridge, et al., 2005; Iakobishvili & Hasdai, 2007). Thus, low-dose dopamine is no longer recommended. However, some patients respond to lower dosages of dopamine for its inotropic effects (Friedrich, et al., 2005).

In severe metabolic acidosis, which occurs in the later stages of shock, the effectiveness of dopamine is diminished. To maximize the effectiveness of any vasoactive agent, metabolic acidosis must first be corrected (Dellinger, et al., 2008).

Other Vasoactive Medications. Additional vasoactive agents that may be used in managing cardiogenic shock include norepinephrine, epinephrine, milrinone, vasopressin, and phenylephrine. Each of these medications stimulates different receptors of the sympathetic nervous system. A combination of these medications may be prescribed, depending on the patient's response to treatment. All vasoactive medications have adverse effects, making specific medications more useful than others at different stages of shock. Diuretics such as furosemide may be administered to reduce the workload of the heart by reducing fluid accumulation (see Table 15-2).

Antiarrhythmic Medications. Multiple factors, such as hypoxemia, electrolyte imbalances, and acid-base imbalances, contribute to serious cardiac dysrhythmias in all patients with shock. In addition, as a compensatory response to decreased cardiac output and BP, the heart rate increases beyond normal limits. This impedes cardiac output further by shortening diastole and thereby decreasing the time for ventricular filling. Consequently, antiarrhythmic medications are required to stabilize the heart rate. For a full discussion of cardiac dysrhythmias as well as commonly prescribed medications, see Chapter 27. General principles regarding the administration of vasoactive medications are discussed later in this chapter.

Mechanical Assistive Devices

If cardiac output does not improve despite supplemental oxygen, vasoactive medications, and fluid boluses, mechanical assistive devices are used temporarily to improve the heart's ability to pump. Intra-aortic balloon counterpulsation is one means of providing temporary circulatory

assistance (see Chapter 30). Other means of mechanical assistance include left and right ventricular assist devices (VADs) and total temporary artificial hearts (see Chapters 29 and 30). VADs are utilized frequently as bridge therapy to either recovery or heart transplantation. Another short-term means of providing cardiac or pulmonary support to the patient in cardiogenic shock is through an extracorporeal device similar to the cardiopulmonary bypass (CPB) system used in open-heart surgery (see Chapter 28). CPB is used only in emergency situations until definitive treatment, such as heart transplantation, can be initiated.

Nursing Management

Preventing Cardiogenic Shock

Identifying at-risk patients early, promoting adequate oxygenation of the heart muscle, and decreasing cardiac workload can prevent cardiogenic shock. This can be accomplished by conserving the patient's energy, promptly relieving angina, and administering supplemental oxygen. Often, however, cardiogenic shock cannot be prevented. In such instances, nursing management includes working with other members of the health care team to prevent shock from progressing and to restore adequate cardiac function and tissue perfusion.

Monitoring Hemodynamic Status

A major role of the nurse is monitoring the patient's hemodynamic and cardiac status. Arterial lines and ECG monitoring equipment must be well maintained and functioning properly. The nurse anticipates the medications, IV fluids, and equipment that might be used and is ready to assist in implementing these measures. Changes in hemodynamic, cardiac, and pulmonary status and laboratory values are documented and reported promptly. In addition, adventitious breath sounds, changes in cardiac rhythm, and other abnormal physical assessment findings are reported immediately.

Administering Medications and Intravenous Fluids

The nurse plays a critical role in the safe and accurate administration of IV fluids and medications. Fluid overload and pulmonary edema are risks because of ineffective cardiac function and accumulation of blood and fluid in the pulmonary tissues. The nurse documents and records medications and treatments that are administered as well as the patient's response to treatment.

The nurse must be knowledgeable about the desired effects as well as the side effects of medications. For example, it is important to monitor the patient for decreased BP after administering morphine or nitroglycerin. Patients receiving thrombolytic therapy must be monitored for bleeding. Arterial and venous puncture sites must be observed for bleeding, and pressure must be applied at the sites if bleeding occurs. Neurologic assessment is essential after the administration of thrombolytic therapy to assess for the potential complication of cerebral hemorrhage associated with this therapy. IV infusions must be observed closely because tissue necrosis and sloughing may occur if vasopressor medications infiltrate the tissues. It is necessary to monitor urine output, BUN, and serum creatinine levels to detect de-

creased renal function secondary to the effects of cardiogenic shock or its treatment.

Maintaining Intra-Aortic Balloon Counterpulsation

The nurse plays a critical role in caring for the patient receiving intra-aortic balloon counterpulsation (see Chapter 30). The nurse makes ongoing timing adjustments of the balloon pump to maximize its effectiveness by synchronizing it with the cardiac cycle. The patient is at risk for circulatory compromise to the leg on the side where the catheter for the balloon has been inserted; therefore, the nurse must check the neurovascular status of the lower extremities frequently.

Enhancing Safety and Comfort

Throughout care, the nurse must take an active role in safeguarding the patient, enhancing comfort, and reducing anxiety. This includes administering medication to relieve chest pain, preventing infection at the multiple arterial and venous line insertion sites, protecting the skin, and monitoring respiratory and renal function. Proper positioning of the patient promotes effective breathing without decreasing BP and may also increase patient comfort while reducing anxiety.

Brief explanations about procedures that are being performed and the use of comforting touch often provide reassurance to the patient and family. The family is usually anxious and benefits from opportunities to see and talk to the patient. Explanations of treatments and the patient's responses are often comforting to family members.

Circulatory Shock

Circulatory shock occurs when blood volume pools in peripheral blood vessels. This abnormal displacement of blood volume causes a relative hypovolemia because not enough blood returns to the heart, which leads to inadequate tissue perfusion. The ability of the blood vessels to constrict helps return the blood to the heart. The vascular tone is determined both by central regulatory mechanisms, as in BP regulation, and by local regulatory mechanisms, as in tissue demands for oxygen and nutrients. Therefore, circulatory shock can be caused either by a loss of sympathetic tone or by release of biochemical mediators from cells.

The varied mechanisms leading to the initial vasodilation in circulatory shock provide the basis for the further subclassification of shock into three types: septic shock, neurogenic shock, and anaphylactic shock. These types of circulatory shock cause variations in the pathophysiologic chain of events and are explained here separately. In all types of circulatory shock, massive arterial and venous dilation promotes peripheral pooling of blood. Arterial dilation reduces systemic vascular resistance. Initially, cardiac output can be high, both from the reduction in afterload (systemic vascular resistance) and from the heart muscle's increased effort to maintain perfusion despite the incompetent vasculature. Pooling of blood in the periphery results in decreased venous return. Decreased venous return results in decreased stroke volume and decreased cardiac output. Decreased cardiac output, in turn, causes decreased BP and ultimately decreased tissue perfusion. Figure 15-6 presents the pathophysiologic sequence of events in circulatory shock.

Physiology ■■■ Pathophysiology

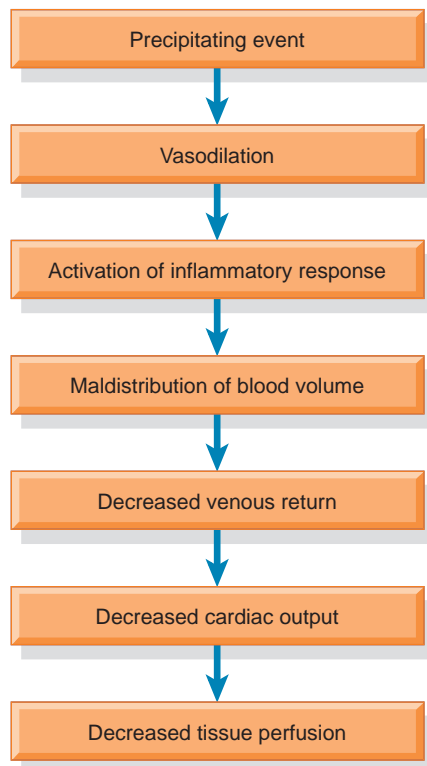

Figure 15-6 Pathophysiologic sequence of events in circulatory shock.

SEPTIC SHOCK

Septic shock, the most common type of circulatory shock, is caused by widespread infection (Chart 15-3). Despite the increased sophistication of antibiotic therapy, the incidence of septic shock has continued to rise during the past 60 years. It is the most common cause of death in noncoronary ICUs in the United States. Each year, severe sepsis affects an estimated 750,000 people in the United States. As the popula-

tion ages, the rate is expected to rise to 1 million cases a year by 2010 (Surviving Sepsis Campaign, 2007). Finding and aggressively treating the source of infection and quickly restoring tissue perfusion are important interventions that may positively influence the clinical outcome.

Health care–associated infections (infections not incubating at the time of admission to the health care setting) in critically ill patients that may progress to septic shock most frequently originate (in decreasing order of frequency) in the bloodstream (bacteremia), lungs, and urinary tract (urosepsis) (Aragon & Sole, 2006). Other infections include intra-abdominal infections and wound infections. Of increasing concern are bacteremias associated with intravascular catheters and indwelling urinary catheters (Aragon & Sole, 2006; Institute for Healthcare Improvement [IHI], 2007).

Additional risk factors that contribute to the growing incidence of septic shock are the increased use of invasive procedures and indwelling medical devices; the increased number of antibiotic-resistant microorganisms; and the increasingly older population (Aragon & Sole, 2006; King, 2007). Elderly patients are at particular risk for sepsis because of decreased physiologic reserves and an aging immune system (Marik, 2006). Other patients at risk are those undergoing surgical and other invasive procedures; those with malnutrition or immunosuppression; and those with chronic illness such as diabetes mellitus, hepatitis, chronic renal failure, and immunodeficiency disorders (Aragon & Sole, 2006; King, 2007).

The incidence of septic shock can be reduced by using strict infection control practices, beginning with thorough hand-hygiene techniques (Aragon & Sole, 2006). Other interventions include implementing programs to prevent central line infection; early débriding of wounds to remove necrotic tissue; carrying out standard precautions and adhering to infection control practices, including the use of meticulous aseptic technique; and properly cleaning and maintaining equipment.

A significant body of research has been conducted in the past decade in an effort aimed at reducing the morbidity and mortality caused by septic shock and at clarifying the understanding of sepsis and related disorders (Chart 15-4). In 1991, 2003, and again in early 2008, critical care experts and infectious disease experts systematically reevaluated the body of research and provided evidence-based recommendations for the acute management of patients with sepsis and septic shock (Dellinger, et al., 2008; Vincent & Abraham, 2006).

Pathophysiology

Gram-negative bacteria traditionally have been the most commonly implicated microorganisms in septic shock. However, there is also an increased incidence of gram-positive bacterial infections, and gram-positive bacteria currently account for 50% of cases of septic shock (Smith & McInnis, 2007). Other infectious agents, such as viruses and fungi, also can cause septic shock. However, it is estimated that 20% to 30% of patients with severe sepsis may never have an identifiable site of infection (King, 2007).

When microorganisms invade body tissues, patients exhibit an immune response. This immune response provokes the activation of biochemical cytokines and mediators associated with an inflammatory response and produces a

CHART 15-3 Risk Factors for Circulatory Shock

Septic Shock

- Immunosuppression
- Extremes of age (<1 yr and >65 yr)
- Malnourishment
- Chronic illness
- Invasive procedures

Anaphylactic Shock

- Penicillin sensitivity
- Transfusion reaction
- Bee sting allergy
- Latex sensitivity
- Severe allergy to some foods or medications

Neurogenic Shock

- Spinal cord injury
- Spinal anesthesia
- Depressant action of medications
- Glucose deficiency

Chart 15-4 • Definitions to Promote Recognition and Earlier Treatment of Patients With Sepsis

Bacteremia: the presence of bacteria in the blood

Infection: the presence of microorganisms that trigger an inflammatory response

Hypotension: a systolic blood pressure <90 mm Hg or a drop in systolic blood pressure of ≥ 40 mm Hg from the patient's baseline blood pressure

Systemic inflammatory response syndrome (SIRS): a syndrome resulting from a *severe clinical insult* that initiates an overwhelming inflammatory response by the body; clinical signs and symptoms may include

- Temperature $>38^{\circ}\text{C}$ or $<36^{\circ}\text{C}$ ($>100.4^{\circ}\text{F}$ or $<96.8^{\circ}\text{F}$)
- Heart rate >90 bpm
- Respiratory rate >20 breaths/min or $\text{PaCO}_2 <32$ mm Hg
- WBC count $>12,000$ cells/ mm^3 , <4000 cells/ mm^3 , or $>10\%$ immature WBC (bands)

Sepsis: a systemic response to *infection*; manifested by two or more of the SIRS criteria as a consequence of documented or presumed infection

Severe sepsis: the presence of signs and symptoms of sepsis associated with organ dysfunction, hypotension, or hypoperfusion; clinical signs and symptoms include those of sepsis as well as

- Lactic acidosis
- Oliguria

- Altered level of consciousness
- Thrombocytopenia and coagulation disorders
- Altered hepatic function

Septic shock: shock associated with sepsis; characterized by symptoms of sepsis plus hypotension and hypoperfusion despite adequate fluid volume replacement

Multiple organ dysfunction syndrome (MODS): the presence of altered function of one or more organs in an acutely ill patient requiring intervention and support of the organs to achieve physiologic functioning required for homeostasis; clinical signs and symptoms may be

- Cardiovascular: hypotension and hypoperfusion
- Respiratory: hypoxemia, hypercarbia, adventitious breath sounds
- Renal: increased creatinine, decreased urine output
- Hematologic: thrombocytopenia, coagulation abnormalities
- Metabolic: lactic acidemia, metabolic acidosis
- Neurologic: altered level of consciousness
- Hepatic: elevated liver function tests, hyperbilirubinemia

From Levy, M. M., Fink, M. P., Marshall, J. C., et al. (2003). 2001 SCCM/ESICM/ACCP/ATS/SIS International Sepsis Definitions Conference. *Critical Care Medicine*, 31(4), 1250–1256; and Dellinger, R. P., Levy, M. M., Carlet, J. M., et al. (2008). Surviving sepsis campaign: International guidelines for management of severe sepsis and septic shock: 2008. *Critical Care Medicine*, 36(1), 296–327.

complex cascade of physiologic events that leads to poor tissue perfusion. Increased capillary permeability, which leads to fluid seeping from the capillaries, and vasodilation are two such effects that interrupt the ability of the body to provide adequate perfusion, oxygen, and nutrients to the tissues and cells. In addition, proinflammatory and anti-inflammatory cytokines released during the inflammatory response activate the coagulation system, which begins to form clots whether or not bleeding is present. The imbalance of the inflammatory response and the clotting and fibrinolysis cascades are considered critical elements of the devastating physiologic progression that occurs in patients with severe sepsis.

Sepsis is an evolving process, with neither clearly definable clinical signs and symptoms nor predictable progression. Initial physiologic changes are subtle. In the early stage of septic shock, BP may remain within normal limits, or the patient may be hypotensive but responsive to fluids. The heart rate increases, progressing to tachycardia. Hyperthermia and fever, with warm, flushed skin and bounding pulses, is evident. The respiratory rate is elevated. Urinary output may remain at normal levels or decrease. GI status may be compromised, as evidenced by nausea, vomiting, diarrhea, or decreased bowel sounds. Signs of hypermetabolism include increased serum glucose and insulin resistance. Subtle changes in mental status, such as confusion or agitation, may be present. The lactate level is elevated because of the maldistribution of blood. Inflammatory markers such as white blood cell counts and C-reactive protein are also elevated (King, 2007).

As sepsis progresses, tissues become less perfused and acidotic, compensation begins to fail, and the patient begins to show signs of organ dysfunction. The cardiovascular system also begins to fail, the BP does not respond to fluid resusci-

tation and vasoactive agents, and signs of end-organ damage are evident (eg, renal failure, pulmonary failure, hepatic failure). As sepsis progresses to septic shock, the BP drops, and the skin becomes cool, pale, and mottled. Temperature may be normal or below normal. Heart and respiratory rates remain rapid. Urine production ceases, and multiple organ dysfunction progressing to death occurs.

Systemic inflammatory response syndrome (SIRS) presents clinically like sepsis and is part of the initial continuum of sepsis. The physiologic presentation of SIRS is similar to sepsis, except there is no identifiable source of infection (Dellinger, et al., 2008; King, 2007). SIRS stimulates an overwhelming inflammatory immunologic and hormonal response similar to that seen in septic patients. Any overwhelming insult stimulates SIRS and may progress to sepsis. Therefore, despite an absence of infection, antibiotic agents may still be administered because of the possibility of unrecognized infection. Additional therapies directed to support patients with SIRS are similar to those for sepsis. If the inflammatory process progresses, septic shock may develop.

Medical Management

Current treatment of sepsis and septic shock involves identification and elimination of the cause of infection. Current goals are to identify and treat patients in early sepsis within 6 hours to optimize patient outcome (Otero, et al., 2006; Rivers, et al., 2005). Several screening tools can be used to help identify patients with severe sepsis. Chart 15-5 provides key elements that may help identify patients with sepsis and guide interventions in the treatment of severe sepsis and

Chart 15-5 • Early Identification and Treatment of Patients with Sepsis and Severe Sepsis

Questions to ask:

Does the patient meet criteria for systemic inflammatory response syndrome (SIRS) (see Chart 15-4)?

Does the patient have signs or symptoms of infection?

- Positive blood cultures
- Currently receiving antibiotic or antifungal therapy
- Examination or chest x-ray suggestive of pneumonia
- Suspected infected wound, abdomen, urine, or other source of infection

Does the patient have signs of acute organ dysfunction?

- Cardiovascular: systolic BP <90 mm Hg or mean arterial pressure (MAP) <65 mm Hg, or drop in systolic BP >40 mm Hg from baseline BP
 - Is hypotension responsive to fluid resuscitation, or is vasopressor support needed?
 - Is the serum lactate >4 mmol/L?
- Respiratory: respiratory rate >20 breaths/min or PaCO₂ <32 mm Hg
 - Is increasing oxygen or mechanical ventilator support needed?
- Renal: urine output <0.5 mL/kg/h
- Hematologic: laboratory analysis and signs and symptoms of coagulopathies
- Metabolic: insulin resistance, metabolic acidosis, or serum lactate >4 mmol/L
- Hepatic: elevated liver function tests or hyperbilirubinemia
- Central nervous system: changes in level of consciousness ranging from agitation to coma

Early interventions:

- Aggressive fluid resuscitation with 20 mL/kg/h of crystalloid (or colloid equivalent)
 - Give fluids to achieve a target central venous pressure of 8 to 12 mm Hg, MAP >65 mm Hg, urine output >0.5 mL/kg/h, and an ScvO₂ >70%
 - Vasopressor agents are used if fluid resuscitation does not restore an effective blood pressure and cardiac output
- Obtain blood, sputum, urine, and wound cultures and administer broad-spectrum antibiotics
- Support the respiratory system with mechanical ventilation
- Transfuse with packed red blood cells when hemoglobin is <7 g/dL
- Provide adequate IV sedation; avoid the use of neuromuscular blockade agents when possible
- Control serum glucose <150 mg/dL with IV insulin therapy
- Implement interventions and medications to prevent deep vein thrombosis and stress ulcer prophylaxis
- Consider IV steroid therapy if the patient is not responding to fluid resuscitation and vasopressor therapy
- Consider administration of recombinant human activated protein C (drotrecogin alfa) in adult patients with sepsis-induced organ dysfunction with clinical assessment of high risk of death

From Dellinger, R. P., Levy, M. M., Carlet, J. M., et al. (2008). Surviving sepsis campaign: International guidelines for management of severe sepsis and septic shock: 2008. *Critical Care Medicine*, 36(1), 296–327; and Rivers, E. P., McIntyre, L., Morro, D. C., et al. (2005). Early and innovative interventions for severe sepsis and septic shock: Taking advantage of a window of opportunity. *Canadian Medical Association Journal*, 173(9), 1054–1065.

septic shock (Dellinger, et al., 2008; King, 2007; Otero, et al., 2006; Surviving Sepsis Campaign, 2007).

Rapid identification of the infectious source is also a critical element in management. Specimens of blood, sputum, urine, wound drainage, and tips of invasive catheters are collected for culture using aseptic technique. Any potential routes of infection must be identified and treated. IV lines are removed and reinserted at alternate sites. Antibiotic-coated IV central lines may be inserted to decrease the risk of invasive line-related bacteremia in high-risk patients (King, 2007). If possible, urinary catheters are removed. Any abscesses are drained, and necrotic areas are debrided.

Research efforts are focusing on better identification and early aggressive treatment of patients with sepsis, rapid and effective restoration of tissue perfusion, evaluation and treatment of the patient's immune response, and treatment of dysregulation of the coagulation system that seems to occur with severe sepsis (Remick, 2007a).

Fluid Replacement Therapy

Fluid replacement must be instituted to correct the tissue hypoperfusion that results from the incompetent vasculature and the inflammatory response. Reestablishing tissue perfusion through aggressive fluid resuscitation is the key to management of severe sepsis and septic shock (Dellinger, et al., 2008; Otero, et al., 2006). See Chart 15-5 for a list of the treatment endpoints of fluid resuscitation.

Pharmacologic Therapy

If the identity of the infecting organism is unknown, broad-spectrum antibiotic agents are started until culture and sensitivity reports are received (Dellinger, et al., 2008; Smith & McInnis, 2007), at which time the antibiotic agents may be changed to agents that are more specific to the infecting organism and less toxic to the patient.

Treatment of the dysregulation of the coagulation system that occurs in patients with severe sepsis and septic shock remains controversial. Nonetheless, current guidelines recommend the administration of recombinant human activated protein C (rhAPC; drotrecogin alfa [Xigris]) to patients with end-organ dysfunction and high risk of death (Dellinger, et al., 2008). In sepsis, an imbalance in proinflammatory mediators activates the coagulation cascade and deposits microthrombi that alter tissue perfusion. Drotrecogin alfa (Xigris) acts as an antithrombotic, anti-inflammatory, and profibrinolytic agent. Drotrecogin alfa acts as an anti-inflammatory cytokine, it stimulates fibrinolysis, restoring balance in the coagulation–anticoagulation homeostatic process of the body's inflammatory response to injury and infection.

Drotrecogin alfa has provided a significant breakthrough in the successful pharmacologic treatment of patients with sepsis. The medication should be administered as early as possible in the sequence of pathophysiologic events of sepsis. It is not without side effects, bleeding being the most common serious effect. Stopping the medication reduces

the risk of bleeding. The patient should be evaluated with regard to the relative risk of bleeding versus the potential benefit from the medication. Drotrecogin alfa is contraindicated in patients with active internal bleeding, recent hemorrhagic stroke, intracranial surgery, or head injury.

Nutritional Therapy

Aggressive nutritional supplementation is critical in the management of septic shock, because malnutrition further impairs the patient's resistance to infection. Nutritional supplementation should be initiated within the first 24 hours after ICU admission (Stapleton, et al., 2007), and continuous infusions of insulin are used to control hyperglycemia (Dellinger, et al., 2008; Vanhorebeek, et al., 2007). Enteral feedings are preferred to the parenteral route because of the increased risk of iatrogenic infection associated with IV catheters; however, enteral feedings may not be possible if decreased perfusion to the GI tract reduces peristalsis and impairs absorption.

Nursing Management

Nurses caring for patients in any setting must keep in mind the risks of sepsis and the high mortality rate associated with sepsis, severe sepsis, and septic shock. All invasive procedures must be carried out with aseptic technique after careful hand hygiene. In addition, IV lines, arterial and venous puncture sites, surgical incisions, traumatic wounds, urinary catheters, and pressure ulcers must be monitored for signs of infection. Nurses need to identify patients who are at particular risk for sepsis and septic shock (ie, elderly and immunosuppressed patients and those with extensive trauma, burns, or diabetes), keeping in mind that these high-risk patients may not develop typical or classic signs of infection and sepsis. For example, confusion may be the first sign of infection and sepsis in elderly patients.

When caring for a patient with septic shock, the nurse collaborates with other members of the health care team to identify the site and source of sepsis and the specific organisms involved. The nurse often obtains appropriate specimens for culture and sensitivity.

Elevated body temperature (hyperthermia) is common with sepsis and raises the patient's metabolic rate and oxygen consumption. Fever is one of the body's natural mechanisms for fighting infections. Therefore, elevated temperatures may not be treated unless they reach dangerous levels (more than 40°C [104°F]) or unless the patient is uncomfortable. Efforts may be made to reduce the temperature by administering acetaminophen or applying a hypothermia blanket. During these therapies, the nurse monitors the patient closely for shivering, which increases oxygen consumption. Efforts to increase comfort are important if the patient experiences fever, chills, or shivering.

The nurse administers prescribed IV fluids and medications, including antibiotic agents and vasoactive medications, to restore vascular volume. Because of decreased perfusion, serum concentrations of antibiotic agents that are normally cleared by the kidneys and liver may increase and produce toxic effects. Therefore, the nurse monitors blood levels (antibiotic agents, BUN, creatinine, white blood cell count, hemoglobin, hematocrit, platelet levels, coagulation studies) and reports changes to the physician. As with other types of

shock, the nurse monitors the patient's hemodynamic status, fluid intake and output, and nutritional status. Daily weights and close monitoring of serum albumin and prealbumin levels help determine the patient's protein requirements.

NEUROGENIC SHOCK

In **neurogenic shock**, vasodilation occurs as a result of a loss of balance between parasympathetic and sympathetic stimulation. Sympathetic stimulation causes vascular smooth muscle to constrict, and parasympathetic stimulation causes vascular smooth muscle to relax or dilate. The patient experiences a predominant parasympathetic stimulation that causes vasodilation lasting for an extended period, leading to a relative hypovolemic state. However, blood volume is adequate, because the vasculature is dilated; the blood volume is displaced, producing a hypotensive (low BP) state. The overriding parasympathetic stimulation that occurs with neurogenic shock causes a drastic decrease in the patient's systemic vascular resistance and bradycardia. Inadequate BP results in the insufficient perfusion of tissues and cells that is common to all shock states.

Neurogenic shock can be caused by spinal cord injury, spinal anesthesia, or other nervous system damage (see Chart 15-3). It may also result from the depressant action of medications or from lack of glucose (eg, insulin reaction or shock). Neurogenic shock may have a prolonged course (spinal cord injury) or a short one (syncope or fainting). Normally, during states of stress, the sympathetic stimulation causes the BP and heart rate to increase. In neurogenic shock, the sympathetic system is not able to respond to body stressors. Therefore, the clinical characteristics of neurogenic shock are signs of parasympathetic stimulation. It is characterized by dry, warm skin rather than the cool, moist skin seen in hypovolemic shock. Another characteristic is hypotension with bradycardia, rather than the tachycardia that characterizes other forms of shock.

Medical Management

Treatment of neurogenic shock involves restoring sympathetic tone, either through the stabilization of a spinal cord injury or, in the instance of spinal anesthesia, by positioning the patient properly. Specific treatment depends on the cause of the shock. Further discussion of management of patients with a spinal cord injury is presented in Chapter 63. If hypoglycemia (insulin shock) is the cause, glucose is rapidly administered (see Chapter 41).

Nursing Management

It is important to elevate and maintain the head of the bed at least 30 degrees to prevent neurogenic shock when a patient receives spinal or epidural anesthesia. Elevation of the head helps prevent the spread of the anesthetic agent up the spinal cord. In suspected spinal cord injury, neurogenic shock may be prevented by carefully immobilizing the patient to prevent further damage to the spinal cord.

Nursing interventions are directed toward supporting cardiovascular and neurologic function until the usually transient episode of neurogenic shock resolves. Applying

anti-embolism stockings and elevating the foot of the bed may minimize pooling of blood in the legs. Pooled blood increases the risk of thrombus formation. Therefore, the nurse must check the patient daily for any lower extremity pain, redness, tenderness, and warmth. If the patient complains of pain and objective assessment of the calf is suspicious, the patient should be evaluated for deep vein thrombosis. Administration of heparin or low-molecular-weight heparin (Lovenox) as prescribed, application of anti-embolism stockings, or use of pneumatic compression of the legs may prevent thrombus formation. Passive range of motion of the immobile extremities helps promote circulation.

A patient who has experienced a spinal cord injury may not report pain caused by internal injuries. Therefore, in the immediate postinjury period, the nurse must monitor the patient closely for signs of internal bleeding that could lead to hypovolemic shock.

ANAPHYLACTIC SHOCK

Anaphylactic shock occurs rapidly and is life-threatening. Because anaphylactic shock occurs in patients already exposed to an antigen and who have developed antibodies to it, it can often be prevented. Patients with known allergies should understand the consequences of subsequent exposure to the antigen and should wear medical identification that lists their sensitivities. This could prevent inadvertent administration of a medication that would lead to anaphylactic shock. In addition, patients and families need instruction about emergency use of medications for treatment of anaphylaxis.

Anaphylactic shock is caused by a severe allergic reaction when patients who have already produced antibodies to a foreign substance (antigen) develop a systemic antigen–antibody reaction (see Chart 15-3). This process requires that the patient has previously been exposed to the substance. An antigen–antibody reaction provokes mast cells to release potent vasoactive substances, such as histamine or bradykinin, causing widespread vasodilation and capillary permeability. Characteristics of severe anaphylaxis usually include rapid onset of hypotension, neurologic compromise, respiratory distress, and cardiac arrest (Brown, 2007).

Medical Management

Treatment of anaphylactic shock requires removing the causative antigen (eg, discontinuing an antibiotic agent), administering medications that restore vascular tone, and providing emergency support of basic life functions. Epinephrine is given for its vasoconstrictive action. Diphenhydramine (Benadryl) is administered to reverse the effects of histamine, thereby reducing capillary permeability. These medications are given intravenously. Nebulized medications, such as albuterol (Proventil), may be given to reverse histamine-induced bronchospasm.

If cardiac arrest and respiratory arrest are imminent or have occurred, cardiopulmonary resuscitation is performed. Endotracheal intubation or tracheotomy may be necessary to establish an airway. IV lines are inserted to provide access for administering fluids and medications. Anaphylaxis and specific chemical mediators are discussed further in Chapter 53.

Nursing Management

The nurse has an important role in preventing anaphylactic shock. The nurse must assess all patients for allergies or previous reactions to antigens (eg, medications, blood products, foods, contrast agents, latex) and communicate the existence of these allergies or reactions to others. In addition, the nurse assesses the patient's understanding of previous reactions and steps taken by the patient and family to prevent further exposure to antigens. When new allergies are identified, the nurse advises the patient to wear or carry identification that names the specific allergen or antigen.

When administering any new medication, the nurse observes all patients for allergic reactions. This is especially important with IV medications, including antibiotics. Previous adverse drug reactions increase the risk that the patient will develop an undesirable reaction to a new medication. If the patient reports an allergy to a medication, the nurse must be aware of the risks involved in the administration of similar medications.

At hospital and outpatient diagnostic testing sites, the nurse must identify patients who are at risk for anaphylactic reactions to contrast agents (radiopaque, dyelike substances that may contain iodine) used for diagnostic tests. Patients with a known allergy to iodine or fish and those who have had previous allergic reactions to contrast agents are at high risk. This information must be communicated to the staff at the diagnostic testing site, including x-ray personnel. The nurse must be knowledgeable about the clinical signs of anaphylaxis, must take immediate action if signs and symptoms occur, and must be prepared to begin cardiopulmonary resuscitation if cardiorespiratory arrest occurs.

Community health and home care nurses who administer medications, including antibiotic agents, in the patient's home or other settings must be prepared to administer epinephrine subcutaneously or intramuscularly in the event of an anaphylactic reaction.

After recovery from anaphylaxis, the patient and family require an explanation of the event. Furthermore, the nurse provides instruction about avoiding future exposure to antigens and administering emergency medications to treat anaphylaxis (see Chapter 53).

Multiple Organ Dysfunction Syndrome

Multiple organ dysfunction syndrome (MODS) is altered organ function in acutely ill patients that requires medical intervention to support continued organ function. It is another phase in the progression of shock states. The actual incidence of MODS is difficult to determine, because it develops with acute illnesses that compromise tissue perfusion. Dysfunction of one organ system is associated with 20% mortality, and if more than four organs fail, the mortality may reach 70% (VonRueden, et al., 2008).

Pathophysiology

MODS may be a complication of any form of shock caused by inadequate tissue perfusion. The precise mechanism by which MODS occurs remains unknown. However, MODS

frequently occurs toward the end of the continuum of septic shock when tissue perfusion cannot be effectively restored. It is not possible to predict which patients who experience shock will develop MODS, partly because much of the organ damage occurs at the cellular level and therefore cannot be directly observed or measured. However, a pattern of progressive organ dysfunction and failure typically occurs; organ failure usually begins in the lungs, and cardiovascular instability as well as failure of the hepatic, GI, renal, immunologic, and central nervous systems follow (Abraham & Singer, 2007; VonRueden, et al., 2008). Advanced age, malnutrition, and coexisting disease appear to increase the risk of MODS in acutely ill patients.

Clinical Manifestations

The clinical presentation of MODS is insidious; tissues become hypoperfused at both a microcellular and macrocellular level, eventually causing organ dysfunction that requires intervention to support organ function.

In MODS, the sequence of organ dysfunction varies depending on the patient's primary illness and comorbidities prior to experiencing shock. For simplicity of presentation, the classic pattern is described. Typically, the lungs are the first organs to show signs of dysfunction. The patient experiences progressive dyspnea and respiratory failure requiring intubation and mechanical ventilation (see Chapters 23 and 25). The patient usually remains hemodynamically stable but may require increasing amounts of IV fluids and vasoactive agents to support the BP and cardiac output. Signs of a hypermetabolic state, characterized by hyperglycemia (elevated blood glucose level), hyperlactic acidemia (excess lactic acid in the blood), and increased BUN, are present. The metabolic rate may be 1.5 to 2 times the basal metabolic rate. At this time, there is a severe loss of skeletal muscle mass (autocatabolism) to meet the high energy demands of the body.

After approximately 7 to 10 days, signs of hepatic dysfunction (eg, elevated bilirubin and liver function tests) and renal dysfunction (eg, elevated creatinine and anuria) are evident. As the lack of tissue perfusion continues, the hematologic system becomes dysfunctional, with worsening immunocompromise and increasing risk of bleeding. The cardiovascular system becomes unstable and unresponsive to vasoactive agents, and the patient's neurologic response progresses to a state of unresponsiveness or coma.

The goal of all shock states is to reverse the tissue hypoperfusion and hypoxia. If effective tissue perfusion is restored before organs become dysfunctional, the patient's condition stabilizes. Along the septic shock continuum, the onset of organ dysfunction is an ominous prognostic sign; the more organs that fail, the worse the outcome.

Medical Management

Prevention remains the top priority in managing MODS. Elderly patients are at increased risk for MODS because of the lack of physiologic reserve and the natural degenerative process, especially immune compromise (Marik, 2006). Early detection and documentation of initial signs of infection are essential in managing MODS in elderly patients. Subtle changes in mentation and a gradual rise in tempera-

ture are early warning signs. Other patients at risk for MODS are those with chronic illness, malnutrition, immunosuppression, or surgical or traumatic wounds.

If preventive measures fail, treatment measures to reverse MODS are aimed at (1) controlling the initiating event, (2) promoting adequate organ perfusion, and (3) providing nutritional support.

Nursing Management

The general plan of nursing care for patients with MODS is the same as that for patients with septic shock. Primary nursing interventions are aimed at supporting the patient and monitoring organ perfusion until primary organ insults are halted. Providing information and support to family members is a critical role of the nurse. It is important that the health care team address end-of-life decisions to ensure that supportive therapies are congruent with the patient's wishes (see Chapter 17).

Promoting Communication

Nurses should encourage frequent and open communication about treatment modalities and options to ensure that the patient's wishes regarding medical management are met. For patients who survive MODS, it is essential that they be informed about the goals of rehabilitation and expectations for progress toward these goals, because massive loss of skeletal muscle mass makes rehabilitation a long, slow process. A strong nurse-patient relationship built on effective communication provides needed encouragement during this phase of recovery.

Promoting Home and Community-Based Care

Teaching Patients Self-Care

Patients who experience and survive shock may have been unable to get out of bed for an extended period of time and are likely to have a slow, prolonged recovery. The patient and family are instructed about strategies to prevent further episodes of shock by identifying the factors implicated in the initial episode. In addition, the patient and family require instruction about assessments needed to identify the complications that may occur after the patient is discharged from the hospital. Depending on the type of shock and its management, the patient or family may require instruction about treatment modalities such as emergency administration of medications, IV therapy, parenteral or enteral nutrition, skin care, exercise, and ambulation. The patient and family are also instructed about the need for gradual increases in ambulation and other activity. The need for adequate nutrition is another crucial aspect of teaching.

Continuing Care

Because of the physical toll associated with recovery from shock, patients may be cared for in a long-term care facility or rehabilitation setting after hospital discharge. Alternatively, a referral may be made for home care. The home care nurse assesses the patient's physical status and monitors

recovery. The nurse also assesses the adequacy of treatments that are continued at home and the ability of the patient and family to cope with these treatments. The patient is likely to require close medical supervision until complete recovery occurs. The home care nurse reinforces the importance of continuing medical care and helps the patient and family identify and mobilize community resources.

CRITICAL THINKING EXERCISES

1 A patient with a history of severe osteoarthritis is prescribed glucosamine and chondroitin supplements. The patient's chart states that he has no known drug allergies, but he does have food allergies that include shell fish and avocados. Fifteen minutes after the first dose of the medication is administered, the patient complains of anxiety, shortness of breath, and chest discomfort. He is flushed and visibly uncomfortable. What are your nursing priorities in providing care to this patient? What assessment data do you need to obtain to determine if this patient is experiencing cardiogenic or anaphylactic shock? What nursing interventions and medical treatments would you anticipate for cardiogenic shock? What risks did the patient have that may have increased his likelihood of experiencing anaphylactic shock? In terms of anaphylactic shock, what nursing interventions and medical treatments would you anticipate?

EBP 2 An elderly man with a 16-year history of Parkinson's disease is admitted with sudden, increasing confusion and combative behavior. You know that changes in mental status may be an early sign of sepsis in the elderly. How would you assess this patient for the possibility of sepsis? What risk factors place an older patient at higher risk for sepsis? How would you ensure the accuracy of vital signs and interpretation of vital signs in the older patient experiencing sepsis? What is the evidence base for these risk factors? How would the management of the elderly patient differ from that of a younger patient?

3 A 32-year-old man is admitted with severe pancreatitis. He has a long history of addiction to alcohol and was recently on a "drinking binge." The patient is agitated and exhibiting nervous behavior. His BP is 106/88 mm Hg, heart rate is 126 bpm, respiratory rate is 32 breaths/min, and he has not voided for the past 3 hours. Is the patient most likely experiencing withdrawal from alcohol or a type of shock? Describe the type of shock that poses the greatest risk for this patient. What interventions should you anticipate to prevent the progression of shock or development of MODS? Given the patient's history, what organ(s) is least likely to tolerate prolonged tissue hypoperfusion? What assessment data would you look at to monitor organ dysfunction in this patient?

4 A 23-year-old patient underwent surgical repair of her shoulder. She had spinal anesthesia for the surgery and currently has a patent epidural catheter for pain management. What types of shock are possible in this patient?

What therapy directed at prevention or treatment of shock would you anticipate? Describe the rationale for the therapies that you have identified. How would you use the patient's history and symptom presentation to help you identify shock states? Describe likely symptoms and the underlying pathophysiology of the shock state.

chapter 16

Oncology: Nursing Management in Cancer Care

LEARNING OBJECTIVES

On completion of this chapter, the learner will be able to:

- 1 Compare the structure and function of the normal cell and the cancer cell.
- 2 Differentiate between benign and malignant tumors.
- 3 Identify agents and factors that have been found to be carcinogenic.
- 4 Describe the significance of health education and preventive care in decreasing the incidence of cancer.
- 5 Differentiate among the purposes of surgical procedures used in cancer treatment, diagnosis, prophylaxis, palliation, and reconstruction.
- 6 Describe the roles of surgery, radiation therapy, chemotherapy, targeted therapy, hematopoietic stem cell transplantation, and other therapies in treating cancer.
- 7 Describe the special nursing needs of patients receiving chemotherapy.
- 8 Describe nursing care related to common nursing diagnoses associated with cancer: impaired skin integrity, alopecia, nutritional problems, and altered body image.
- 9 Identify potential complications for the patient with cancer and discuss associated nursing care.
- 10 Describe the concept of hospice in providing care for patients with advanced cancer.
- 11 Identify assessment parameters and nursing management of patients with oncologic emergencies.

GLOSSARY

alopecia: hair loss
anaplasia: cells that lack normal cellular characteristics and differ in shape and organization with respect to their cells of origin; usually, anaplastic cells are malignant
apoptosis: programmed cell death
benign: not cancerous; benign tumors may grow but are unable to spread to other areas
biologic response modifier (BRM) therapy: use of agents or treatment methods that can alter the immunologic relationship between the tumor and the host to provide a therapeutic benefit
biopsy: a diagnostic procedure to remove a small sample of tissue to be examined microscopically to detect malignant cells
brachytherapy: delivery of radiation therapy through internal implants
cancer: a disease process whereby cells proliferate abnormally, ignoring growth-regulating signals in the environment surrounding the cells
carcinogenesis: process of transforming normal cells into malignant cells
chemotherapy: use of medications to kill tumor cells by interfering with cellular functions and reproduction
control: containment of the growth of cancer cells

GLOSSARY (Continued)

cure: prolonged survival and disappearance of all evidence of disease so that the patient has the same life expectancy as anyone else in his or her age group
cytokines: substances produced by cells of the immune system to enhance production and functioning of components of the immune system
dysplasia: bizarre cell growth resulting in cells that differ in size, shape, or arrangement from other cells of the same type of tissue
extravasation: leakage of medication from the veins into the subcutaneous tissues
grading: identification of the type of tissue from which the tumor originated and the degree to which the tumor cells retain the functional and structural characteristics of the tissue of origin
graft-versus-host disease (GVHD): an immune response initiated by T lymphocytes of donor tissue against the recipient's tissues (skin, gastrointestinal tract, liver); an undesirable response
graft-versus-tumor effect: the donor cell response against the malignancy; a desirable response
hyperplasia: increase in the number of cells of a tissue; most often associated with periods of rapid body growth
malignant: having cells or processes that are characteristic of cancer
metaplasia: conversion of one type of mature cell into another type of cell
metastasis: spread of cancer cells from the primary tumor to distant sites
myelosuppression: suppression of the blood cell-producing function of the bone marrow
nadir: lowest point of white blood cell depression after therapy that has toxic effects on the bone marrow
neoplasia: uncontrolled cell growth that follows no physiologic demand
neutropenia: abnormally low absolute neutrophil count
oncology: field or study of cancer
palliation: relief of symptoms and promotion of comfort and quality of life
radiation therapy: use of ionizing radiation to interrupt the growth of malignant cells
staging: process of determining the extent of disease, including tumor size and spread or metastasis to distant sites
stomatitis: inflammation of the oral tissues, often associated with some chemotherapeutic agents and radiation therapy to the head and neck region
targeted therapies: cancer treatments that seek to minimize the negative effects on healthy tissues by disrupting specific cancer cell functions, such as malignant transformation, communication pathways, processes for growth and metastasis, and genetic coding
thrombocytopenia: decrease in the number of circulating platelets; associated with the potential for bleeding
tumor-specific antigen (TSA): protein on the membrane of cancer cells that distinguishes the malignant cell from a benign cell of the same tissue type
vesicant: substance that can cause tissue necrosis and damage, particularly when extravasated
xerostomia: dry oral cavity resulting from decreased function of salivary glands

Cancer is not a single disease with a single cause; rather, it is a group of distinct diseases with different causes, manifestations, treatments, and prognoses. Cancer nursing practice covers all age groups and nursing specialties and is carried out in a variety of health care settings, including the home, community, acute care institutions, outpatient centers, rehabilitation, and long-term care facilities. The scope, responsibilities, and goals of cancer nursing, also called **oncology** nursing, are as diverse and complex as those of any nursing specialty. Because many people associate cancer with pain and death, nurses need to identify their own reactions to cancer and set realistic goals to meet the challenges inherent in caring for patients with cancer. In addition, cancer nurses must be prepared to support patients and families through a wide range of physical, emotional, social, cultural, and spiritual crises.

Epidemiology of Cancer

Although cancer affects people of all ages, most cancers occur in people older than 65 years of age. Overall, the

incidence of cancer is higher in men than in women and higher in industrialized sectors and nations.

More than 1.4 million Americans are diagnosed each year with cancer, affecting one of various body sites (Fig. 16-1). Cancer is second only to cardiovascular disease as a leading cause of death in the United States. Although the numbers of cancer deaths have decreased slightly, more than 560,000 Americans were expected to die from a malignant process in 2008. The leading causes of cancer death in the United States, in order of frequency, are lung, prostate, and colorectal cancer in men and lung, breast, and colorectal cancer in women (Jemal, Siegel, Ward, et al., 2007).

For all cancer sites combined, African American men have a 15% higher incidence rate and a 38% higher death rate than Caucasian men. African American women have a 9% lower incidence rate, but an 18% higher death rate than Caucasian women for all cancer sites combined. Factors contributing to disparities in cancer morbidity and mortality in this group vary by site and are related to exposure, economics, education, access to health care, and other issues that are not clearly understood (Jemal, et al., 2007).

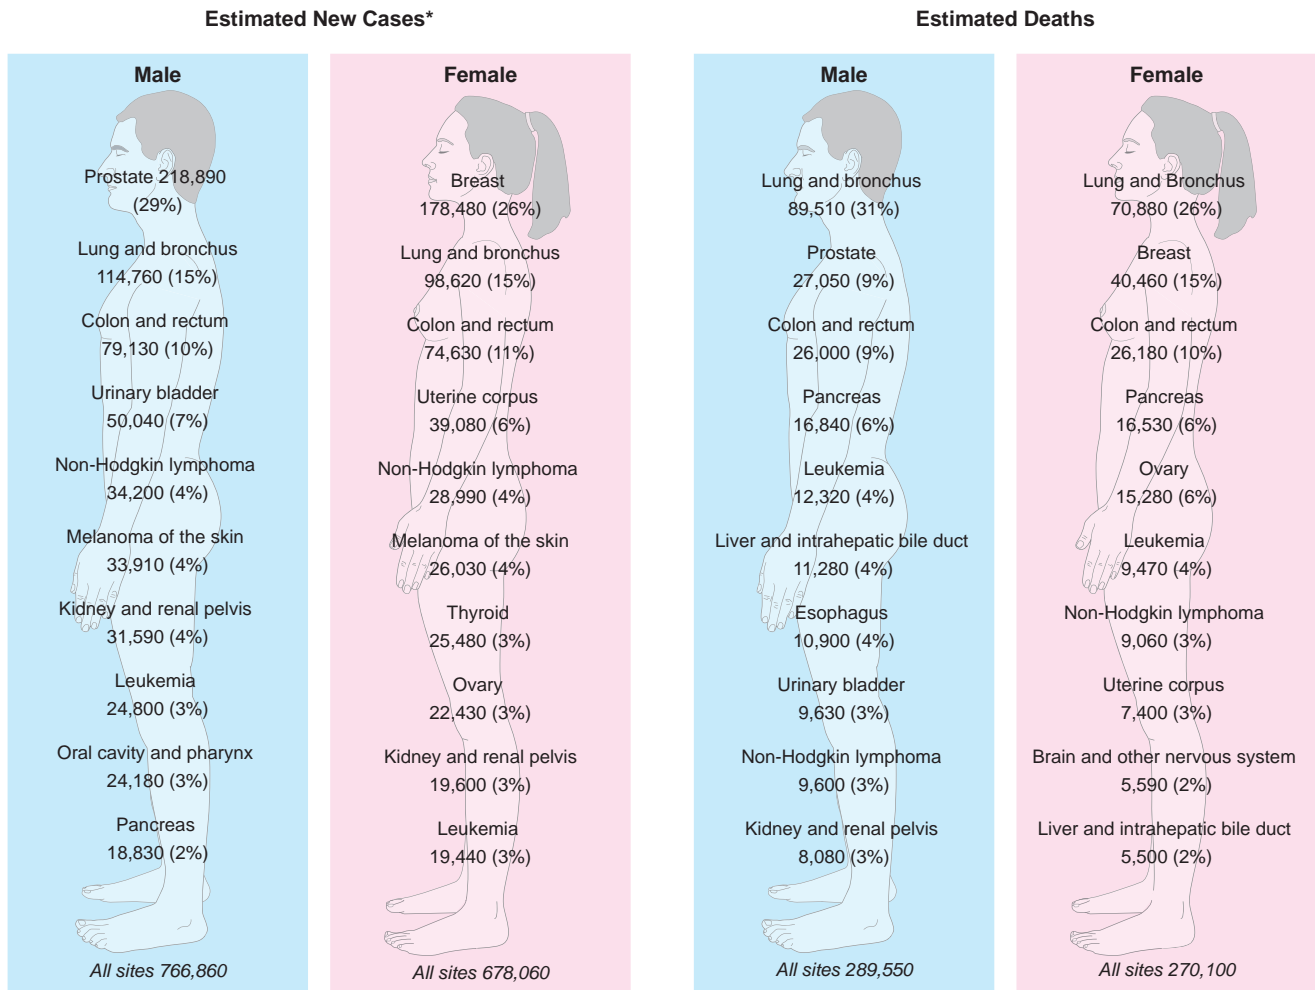

Figure 16-1 Ten leading types of cancer by gender determined on the basis of estimated new cancer cases and deaths in the United States in 2007.
 *Excludes basal and squamous cell skin cancers and in situ cancers except urinary bladder. Note: Percentages may not total 100% because of rounding. Redrawn from Jemal, A., Siegel, R., Ward, E., et al. (2007). Cancer statistics. *CA Cancer Journal for Clinicians*, 57(1), 43–66.

Pathophysiology of the Malignant Process

Cancer is a disease process that begins when an abnormal cell is transformed by the genetic mutation of the cellular DNA. This abnormal cell forms a clone and begins to proliferate abnormally, ignoring growth-regulating signals in the environment surrounding the cell. The cells acquire invasive characteristics, and changes occur in surrounding tissues. The cells infiltrate these tissues and gain access to lymph and blood vessels, which carry the cells to other areas of the body.

Proliferative Patterns

During the lifespan, various body tissues normally undergo periods of rapid or proliferative growth that must be distinguished from malignant growth activity. Several patterns of cell growth exist: **hyperplasia**, **metaplasia**, **dysplasia**, **anaplasia**, and **neoplasia**. Cancerous cells are described as **malignant** neoplasms. They demonstrate uncontrolled cell growth that follows no physiologic demand (neoplasia). **Benign** (noncancerous) and malignant growths are classified and named by tissue of origin (eg, benign tumors of the meninges are called meningioma and malignant tumors of the meninges are called meningeal sarcoma).

Benign and malignant cells differ in many cellular growth characteristics, including the method and rate of growth, ability to metastasize or spread, general effects, destruction of tissue, and ability to cause death. These differences are summarized in Table 16-1. The degree of anaplasia (cells that lack normal cellular characteristics and differ in shape and organization with respect to their cells of origin) ultimately determines the malignant potential.

Characteristics of Malignant Cells

Despite their individual differences, all cancer cells share some common cellular characteristics related to the cell membrane, special proteins, the nuclei, chromosomal abnormalities, and the rate of mitosis and growth. The cell membranes are altered in cancer cells, which affect fluid movement in and out of the cell. The cell membrane of malignant cells also contains proteins called **tumor-specific antigens** (eg, carcinoembryonic antigen [CEA] and prostate-specific antigen [PSA]), which develop over time as the cells become less differentiated (mature). These proteins distinguish malignant cells from benign cells of the same tissue type. They may be useful in measuring the extent of disease in a person and in tracking the course of illness during treatment or relapse. Malignant cellular membranes also contain less fibronectin, a cellular cement. They are therefore less cohesive and do not adhere to adjacent cells readily.

Typically, nuclei of cancer cells are large and irregularly shaped (pleomorphism). Nucleoli, structures within the nucleus that house ribonucleic acid (RNA), are larger and more numerous in malignant cells, perhaps because of increased RNA synthesis. Chromosomal abnormalities (translocations, deletions, additions) and fragility of chromosomes are commonly found when cancer cells are analyzed.

Mitosis (cell division) occurs more frequently in malignant cells than in normal cells. As the cells grow and divide, more glucose and oxygen are needed. If glucose and oxygen are unavailable, malignant cells use anaerobic metabolic channels to produce energy, which makes the cells less dependent on the availability of a constant oxygen supply.

Invasion and Metastasis

Malignant disease processes have the ability to allow the spread or transfer of cancerous cells from one organ or body part to another by invasion and metastasis.

Table 16-1 CHARACTERISTICS OF BENIGN AND MALIGNANT NEOPLASMS

Characteristics	Benign	Malignant
Cell characteristics	Well-differentiated cells that resemble normal cells of the tissue from which the tumor originated	Cells are undifferentiated and often bear little resemblance to the normal cells of the tissue from which they arose
Mode of growth	Tumor grows by expansion and does not infiltrate the surrounding tissues; usually encapsulated	Grows at the periphery and sends out processes that infiltrate and destroy the surrounding tissues
Rate of growth	Rate of growth is usually slow	Rate of growth is variable and depends on level of differentiation; the more anaplastic the tumor, the faster its growth
Metastasis	Does not spread by metastasis	Gains access to the blood and lymphatic channels and metastasizes to other areas of the body
General effects	Is usually a localized phenomenon that does not cause generalized effects unless its location interferes with vital functions	Often causes generalized effects, such as anemia, weakness, and weight loss
Tissue destruction	Does not usually cause tissue damage unless its location interferes with blood flow	Often causes extensive tissue damage as the tumor outgrows its blood supply or encroaches on blood flow to the area; may also produce substances that cause cell damage
Ability to cause death	Does not usually cause death unless its location interferes with vital functions	Usually causes death unless growth can be controlled

Invasion, which refers to the growth of the primary tumor into the surrounding host tissues, occurs in several ways. Mechanical pressure exerted by rapidly proliferating neoplasms may force fingerlike projections of tumor cells into surrounding tissue and interstitial spaces. Malignant cells are less adherent and may break off from the primary tumor and invade adjacent structures. Malignant cells are thought to possess or produce specific destructive enzymes (proteinases), such as collagenases (specific to collagen), plasminogen activators (specific to plasma), and lysosomal hydrolyses. These enzymes are thought to destroy surrounding tissue, including the structural tissues of the vascular basement membrane, facilitating invasion of malignant cells. The mechanical pressure of a rapidly growing tumor may enhance this process.

Metastasis is the dissemination or spread of malignant cells from the primary tumor to distant sites by direct spread of tumor cells to body cavities or through lymphatic and blood circulation. Tumors growing in or penetrating body cavities may shed cells or emboli that travel within the body cavity and seed the surfaces of other organs. This can occur in ovarian cancer when malignant cells enter the peritoneal cavity and seed the peritoneal surfaces of such abdominal organs as the liver or pancreas. Patterns of metastasis can be partially explained by circulatory patterns and by specific affinity for certain malignant cells to bind to molecules in specific body tissue.

Lymphatic and Hematogenous Spread

Lymph and blood are key mechanisms by which cancer cells spread. Lymphatic spread (the transport of tumor cells through the lymphatic circulation) is the most common mechanism of metastasis. Tumor emboli enter the lymph channels by way of the interstitial fluid, which communicates with lymphatic fluid. Malignant cells also may penetrate lymphatic vessels by invasion. After entering the lymphatic circulation, malignant cells either lodge in the lymph nodes or pass between the lymphatic and venous circulations. Tumors arising in areas of the body with rapid and extensive lymphatic circulation are at high risk for metastasis through lymphatic channels. Breast tumors frequently metastasize in this manner through axillary, clavicular, and thoracic lymph channels.

Hematogenous spread is the dissemination of malignant cells via the bloodstream and is directly related to the vascularity of the tumor. Few malignant cells can survive the turbulence of arterial circulation, insufficient oxygenation, or destruction by the body's immune system. In addition, the structure of most arteries and arterioles is far too secure to permit malignant invasion. Those malignant cells that do survive are able to attach to endothelium and attract fibrin, platelets, and clotting factors to seal themselves from immune system surveillance. The endothelium retracts, allowing the malignant cells to enter the basement membrane and secrete lysosomal enzymes. These enzymes destroy surrounding body tissues, allowing implantation.

Angiogenesis

Angiogenesis is the growth of new capillaries from the host tissue by the release of growth factors and enzymes such as vascular endothelial growth factor (VEGF). These proteins rapidly stimulate formation of new blood vessels, which helps

malignant cells obtain the necessary nutrients and oxygen. It is also through this vascular network that tumor emboli can enter the systemic circulation and travel to distant sites. Large tumor emboli that become trapped in the microcirculation of distant sites may further metastasize to other sites. Therapies that target VEGF or its receptors are being used to treat many cancers effectively (see Targeted Therapies).

Carcinogenesis

Molecular Process

Malignant transformation, or **carcinogenesis**, is thought to be at least a three-step cellular process, involving initiation, promotion, and progression. During *initiation*, initiators (carcinogens), such as chemicals, physical factors, and biologic agents, escape normal enzymatic mechanisms and alter the genetic structure of the cellular DNA. Normally, these alterations are reversed by DNA repair mechanisms or the changes initiate programmed cellular death. Occasionally, cells escape these protective mechanisms, and permanent cellular mutations occur. These mutations usually are not significant to cells until the second step of carcinogenesis.

During *promotion*, repeated exposure to promoting agents (cocarcinogens) causes the expression of abnormal or mutant genetics information even after long latency periods. Latency periods for the promotion of cellular mutations vary with the type of agent and the dosage of the promoter as well as the innate characteristics of the target cell.

Cellular oncogenes are responsible for the vital cellular functions of growth and differentiation. Cellular proto-oncogenes act as an “on switch” for cellular growth. Proto-oncogenes are influenced by multiple growth factors that stimulate cell proliferation, such as epidermal growth factor (EGF) and transforming growth factor alpha. Another proto-oncogene that plays an important role in cancer development is the *k-ras* (*KRAS2*) oncogene located on chromosome 12.

Just as proto-oncogenes “turn on” cellular growth, cancer suppressor genes “turn off,” or regulate, unneeded cellular proliferation. When suppressor genes mutate or lose their regulatory capabilities, malignant cells are allowed to reproduce. The *p53* (*TP53*) gene is a tumor suppressor gene that is frequently implicated in many human cancers. This gene determines whether cells will live or die after their DNA is damaged. **Apoptosis** is the innate cellular process of programmed cell death. Alterations in *TP53* may decrease apoptotic signals, thus giving rise to a survival advantage for mutant cell populations. Mutant *TP53* is associated with a poor prognosis and may be associated with determining response to treatment. Once this genetic expression occurs in cells, the cells begin to produce mutant cell populations that are different from their original cellular ancestors.

During *progression*, the altered cells exhibit increased malignant behavior. These cells have a propensity to invade adjacent tissues and to metastasize. Agents that initiate or promote cellular transformation are referred to as carcinogens.

Etiology

Categories of agents or factors implicated in carcinogenesis include viruses and bacteria, physical agents, chemical agents, genetic or familial factors, dietary factors, and hormonal agents.

Viruses and Bacteria

Viruses are difficult to evaluate as a cause of human cancers because they are difficult to isolate. However, infectious causes are considered or suspected when specific cancers appear in clusters. Viruses are thought to incorporate themselves in the genetic structure of cells, thus altering future generations of that cell population, perhaps leading to cancer. For example, the Epstein-Barr virus is highly suspect as a cause in Burkitt lymphoma, nasopharyngeal cancers, and some types of non-Hodgkin and Hodgkin lymphoma.

Bacteria have been evaluated as a cause of cancer over the years but with little evidence to support the link of bacteria to cancer. Chronic inflammatory reactions to bacteria and the production of carcinogenic metabolites are possible mechanisms under investigation. In the early 1990s, the International Agency for Research on Cancer (IARC) identified *Helicobacter pylori* (*H. pylori*) as the first bacterium to be termed a definite cause of cancer in humans. *H. pylori* has been associated with an increased incidence of gastric malignancy related to chronic superficial gastritis, with resultant atrophic and metaplastic changes to the gastric mucosa (Schottenfeld & Bebb-Dimmer, 2006).

Physical Agents

Physical factors associated with carcinogenesis include exposure to sunlight or radiation, chronic irritation or inflammation, and tobacco use.

Excessive exposure to the ultraviolet rays of the sun, especially in fair-skinned, blue- or green-eyed people, increases the risk of skin cancers. Factors such as clothing styles (sleeveless shirts or shorts); use of sunscreens; occupation; recreational habits; and environmental variables, including humidity, altitude, and latitude, all play a role in the amount of exposure to ultraviolet light.

Exposure to ionizing radiation can occur with repeated diagnostic x-ray procedures or with radiation therapy used to treat disease. Fortunately, improved x-ray equipment minimizes the risk of extensive radiation exposure. Radiation therapy used in disease treatment and exposure to radioactive materials at nuclear weapon manufacturing sites or nuclear power plants are associated with a higher incidence of leukemias, multiple myeloma, and cancers of the lung, bone, breast, thyroid, and other tissues. Background radiation from the natural decay processes that produce radon has also been associated with lung cancer. Homes with high levels of trapped radon should be ventilated to allow the gas to disperse into the atmosphere.

Chemical Agents

About 75% of all cancers are thought to be related to the environment. Most hazardous chemicals produce their toxic effects by altering DNA structure in body sites distant from chemical exposure. The liver, lungs, and kidneys are the organ systems most often affected, presumably because of their roles in detoxifying chemicals.

Tobacco smoke, thought to be the single most lethal chemical carcinogen, accounts for at least 30% of cancer deaths. Smoking is strongly associated with cancers of the lung, head and neck, esophagus, stomach, pancreas, cervix, kidney, and bladder and with acute myeloblastic leukemia.

More than 4,000 individual chemicals have been identified in tobacco and tobacco smoke, including more than 60 chemicals that are known carcinogens. Tobacco may also act synergistically with other substances, such as alcohol, asbestos, uranium, and viruses, to promote cancer development. Chewing tobacco is associated with cancers of the oral cavity, which primarily occurs in men younger than 40 years of age. Considerable research has also substantiated the effect of secondhand cigarette smoke as an environmental risk factor for both smokers and nonsmokers (American Cancer Society [ACS], 2008c;2008d).

Many chemical substances found in the workplace have proved to be carcinogens or cocarcinogens. In the United States, carcinogens are classified by two federal agencies: the National Toxicology Program of the Department of Health and Human Services and the Environmental Protection Agency's Integrated Risk Information System (IRIS). The Centers for Disease Control and Prevention established the National Institute for Occupational Safety and Health to provide occupational exposure limits and guidelines for protection of the workforce as regulated by the Occupational Safety and Health Act of 1970. The extensive list of suspected chemical substances continues to grow and includes aromatic amines and aniline dyes; pesticides and formaldehydes; arsenic, soot, and tars; asbestos; benzene; betel nut and lime; cadmium; chromium compounds; nickel and zinc ores; wood dust; beryllium compounds; and polyvinyl chloride.

Genetics and Familial Factors

Almost every cancer type has been shown to run in families. This may be due to genetics, shared environments, cultural or lifestyle factors, or chance alone. Genetic factors play a role in cancer cell development. Abnormal chromosomal patterns and cancer have been associated with extra chromosomes, too few chromosomes, or translocated chromosomes. Specific cancers with underlying genetic abnormalities include Burkitt lymphoma, chronic myelogenous leukemia, meningiomas, acute leukemias, retinoblastomas, Wilms tumor, and skin cancers, including malignant melanoma. Additionally, there are syndromes that represent a cluster of cancers that are identified by a specific genetic alteration that is inherited across generations of a family. In these families, the associated genetic mutation is found in all cells and represents an inherited susceptibility to cancer for all family members who carry the mutation.

Approximately 5% of cancers in adults display a pattern of cancers suggestive of a familial predisposition. The hallmarks of families with a hereditary cancer syndrome include cancer in two or more first-degree or second-degree relatives, early onset of cancer in family members younger than 50 years of age, the same type of cancer in several family members, individual family members with more than one type of cancer, and a rare cancer in one or more family members. There is also evidence of an autosomal dominant inheritance pattern of cancers affecting several generations of the family.

Since the early 1990s, there have been considerable advances in the recognition of inherited cancer susceptibility syndromes and in the ability to isolate and identify the inherited genetic mutation responsible for the cancer patterns. Discoveries of mutations in genes related to critical

CHART
16-1

GENETICS IN NURSING PRACTICE

Concepts and Challenges in Management of the Patient with Cancer

Cancer is a genetic disease. Every phase of carcinogenesis is affected by multiple gene mutations. Some of these mutations are inherited (present in germ-line cells), but most (90%) are somatic mutations that are acquired mutations in specific cells. Examples of cancers influenced by genetics include:

- Cowden syndrome
- Familial adenomatous polyposis
- Familial melanoma syndrome
- Hereditary breast and ovarian cancer
- Hereditary nonpolyposis colon cancer
- Neurofibromatosis type 1
- Retinoblastoma

Nursing Assessments

Family History Assessment

- Obtain information about both maternal and paternal sides of family.
- Obtain cancer history of at least three generations.
- Look for clustering of cancers that occur at young ages, multiple primary cancers in one individual, cancer in paired organs, and two or more close relatives with the same type of cancer suggestive of hereditary cancer syndromes

Patient Assessment

- Physical findings that may predispose the patient to cancer, such as multiple colon polyps, suggestive of a polyposis syndrome
- Skin findings, such as atypical moles, that may be related to familial melanoma syndrome
- Multiple *café au lait* spots, axillary freckling, and two or more neurofibromas associated with neurofibromatosis type 1
- Facial trichilemmomas, mucosal papillomatosis, multinodular thyroid goiter or thyroid adenomas, macrocephaly, fibrocystic breasts and other fibromas or lipomas related to Cowden syndrome

Management Issues Specific to Genetics

- Assess patient's understanding of genetics factors related to his or her cancer
- Refer for cancer risk assessment when a hereditary cancer syndrome is suspected so that patient and family can discuss inheritance risk with other family members and availability of genetic testing
- Offer appropriate genetics information and resources
- Assess patient's understanding of genetics information
- Provide support to patients and families with known genetic test results for hereditary cancer syndromes
- Participate in the management and coordination of risk-reduction measures for those with known gene mutations

Genetics Resources

American Cancer Society—offers general information about cancer and support resources for families, www.cancer.org

Gene Clinics—a listing of common genetic disorders with up-to-date clinical summaries, genetic counseling, and testing information, www.geneclinics.org

Genetic Alliance—a directory of support groups for patients and families with genetic conditions, www.geneticalliance.org

National Cancer Institute—a listing of cancers with clinical summaries and treatment reviews, information on genetic risks for cancer, listing of cancer centers providing genetic cancer risk assessment services, www.cancernet.nci.nih.gov

National Organization of Rare Disorders—a directory of support groups and information for patients and families with rare genetic disorders, www.rarediseases.org

OMIM: Online Mendelian Inheritance in Man—a complete listing of known inherited genetic conditions, www.ncbi.nlm.nih.gov/Omim/mimstats.html

cell control functions, such as tumor suppression, DNA repair mechanisms, and oncogenes, have enabled the appropriate identification of families at risk for these syndromes. Examples of these syndromes include hereditary breast and ovarian cancer syndrome (*BRCA1* and *BRCA2*) and multiple endocrine neoplasia syndrome (*MEN1* and *MEN2*) (Chart 16-1). Cancers associated with familial inheritance syndromes include neuroblastomas, pheochromocytomas, and breast, ovarian, colorectal, stomach, thyroid, renal, prostate, and lung cancers (Nussbaum, McInnes & Willard, 2007).

Dietary Factors

Dietary factors are also linked to environmental cancers. Dietary substances can be proactive (protective), carcinogenic, or cocarcinogenic. The risk of cancer increases with long-term ingestion of carcinogens or cocarcinogens or chronic absence of protective substances in the diet.

Dietary substances that appear to increase the risk of cancer include fats, alcohol, salt-cured or smoked meats, nitrate-containing and nitrite-containing foods, and red and processed meats. Alcohol increases the risk of cancers of the mouth, pharynx, larynx, esophagus, liver, colorectum, and

breast. Alcohol intake should be limited to no more than two drinks per day for men and one drink per day for women. Greater consumption of vegetables and fruits is associated with a decreased risk of lung, esophageal, stomach, and colorectal cancers (Kushi, Byers, Doyle, et al., 2006).

A high caloric dietary intake is also associated with an increased cancer risk. Obesity is clearly associated with endometrial cancer, postmenopausal breast cancers, and colon, esophagus, and kidney cancers. There is evidence that obesity also increases the risk for cancers of the pancreas, gallbladder, thyroid, ovary, cervix, prostate, and for multiple myeloma and Hodgkin lymphoma (Kushi, et al., 2006).

Hormonal Agents

Tumor growth may be promoted by disturbances in hormonal balance, either by the body's own (endogenous) hormone production or by administration of exogenous hormones. Cancers of the breast, prostate, and uterus are thought to depend on endogenous hormonal levels for growth. Diethylstilbestrol (DES) has long been recognized as a cause of vaginal carcinomas. Oral contraceptives and prolonged estrogen therapy are associated with an increased

incidence of hepatocellular, endometrial, and breast cancers, but they decrease the risk of ovarian cancer. The combination of estrogen and progesterone appears safer than estrogen alone in decreasing the risk of endometrial cancers; however, studies support discontinuing hormonal therapy containing both estrogen and progestin because of the increased risk of breast cancer, coronary heart disease, stroke, and blood clots (Chlebowski, Anderson, Pettinger, et al., 2008).

Hormonal changes related to the female reproductive cycle are also associated with cancer incidence. Early onset of menses under age 12 and delayed onset of menopause after age 55, nulliparity (never giving birth), and delayed childbirth after age 30 are all associated with an increased risk of breast cancer. Increased numbers of pregnancies are associated with a decreased incidence of breast, endometrial, and ovarian cancers.

Role of the Immune System

In humans, malignant cells are capable of developing on a regular basis. However, some evidence indicates that the immune system can detect the development of malignant cells and destroy them before cell growth becomes uncontrolled. When the immune system fails to identify and stop the growth of malignant cells, clinical cancer develops.

Patients who are immunocompromised have an increased incidence of cancer. Organ transplant recipients who receive immunosuppressive therapy to prevent rejection of the transplanted organ have an increased incidence of lymphoma, Kaposi's sarcoma, squamous cell cancer of the skin, and cervical and anogenital cancers (Herman, Rogers & Ratner, 2007). Patients with immunodeficiency diseases, such as acquired immunodeficiency syndrome (AIDS), have an increased incidence of Kaposi's sarcoma, lymphoma, rectal cancer, and head and neck cancers (Grulich, Vajdic & Cozen, 2007). Some patients who have received alkylating chemotherapeutic agents to treat cancer have an increased incidence of secondary malignancies (Tward, Glenn, Pulsipher, et al., 2007). Autoimmune diseases, such as rheumatoid arthritis and Sjögren syndrome, are associated with increased cancer development (Wolf & Michaud, 2007). Finally, age-related changes, such as declining organ function, increased incidence of chronic diseases, and diminished immunocompetence, may contribute to an increased incidence of cancer in older people.

Normal Immune Responses

Normally, an intact immune system has the ability to combat cancer cells in several ways. Usually, the immune system recognizes as foreign certain antigens on the cell membranes of many cancer cells. These antigens, known as tumor-associated antigens (also called tumor cell antigens), are capable of stimulating both cellular and humoral immune responses.

Along with the macrophages, T lymphocytes, the soldiers of the cellular immune response, are responsible for recognizing tumor-associated antigens. When T lymphocytes recognize tumor antigens, other T lymphocytes that are toxic to the tumor cells are stimulated. These lymphocytes proliferate and are released into the circulation. In addition to possessing cytotoxic (cell-killing) properties, T

lymphocytes can stimulate other components of the immune system to rid the body of malignant cells.

Certain lymphokines, which are substances produced by lymphocytes, are capable of killing or damaging various types of malignant cells. Other lymphokines can mobilize other immune system cells, such as macrophages, that disrupt cancer cells. Interferon, a substance produced by the body in response to viral infection, also possesses some antitumor properties. Antibodies produced by B lymphocytes, associated with the humoral immune response, also defend the body against malignant cells. These antibodies act either alone or in combination with the complement system or the cellular immune system.

Natural killer (NK) cells are a major component of the body's defense against cancer. NK cells are a subpopulation of lymphocytes that act by directly destroying cancer cells or by producing lymphokines and enzymes that assist in cell destruction.

Immune System Failure

Several theories explain how malignant cells can survive and proliferate despite the elaborate immune system defense mechanisms. If the body fails to recognize the malignant cell as different from "self" (ie, as nonself or foreign), the immune response may not be stimulated. When tumors do not possess tumor-associated antigens that label them as foreign, the immune response is not alerted. This allows the tumor to grow too large to be managed by normal immune mechanisms.

Tumor antigens may combine with the antibodies produced by the immune system and hide or disguise themselves from normal immune defense mechanisms. These tumor antigen-antibody complexes can suppress further production of antibodies. Tumors can also alter their appearance or produce substances that impair usual immune responses. These substances promote tumor growth and increase the patient's susceptibility to infection. After prolonged contact with a tumor antigen, the body may be depleted of the specific lymphocytes and no longer be able to mount an appropriate immune response.

Abnormal concentrations of host suppressor T lymphocytes may play a role in cancer development. Suppressor T lymphocytes normally assist in regulating antibody production and diminishing immune responses when they are no longer required. Low levels of antibodies and high levels of suppressor cells have been found in patients with multiple myeloma, a cancer associated with hypogammaglobulinemia (low amounts of serum antibodies). Carcinogens, such as viruses and certain chemicals, including chemotherapeutic agents, may weaken the immune system and ultimately enhance tumor growth.

Detection and Prevention of Cancer

Nurses and physicians have traditionally been involved with tertiary prevention, the care, and rehabilitation of patients after cancer diagnosis and treatment. However, the American Cancer Society, the National Cancer Institute, clinicians, and researchers also place emphasis on primary

CHART
16-2

HEALTH PROMOTION

American Cancer Society (ACS) Guidelines on Nutrition and Physical Activity for Cancer Prevention**ACS Recommendations for Individual Choices**

- Maintain a healthy weight throughout life
 - Balance caloric intake with physical activity
 - Avoid excessive weight gain throughout the life cycle
 - Achieve and maintain a healthy weight if currently overweight or obese
- Adopt a physically active lifestyle
 - Adults: engage in at least 30 minutes of moderate to vigorous physical activity, above usual activities, on 5 or more days of the week; 45 to 60 minutes of intentional physical activity are preferable
 - Children and adolescents: engage in at least 60 minutes per day of moderate to vigorous physical activity at least 5 days per week
- Consume a healthy diet, with an emphasis on plant sources
 - Choose foods and beverages in amounts that help achieve and maintain a healthy weight
 - Eat five or more servings of a variety of vegetables and fruits each day

- Choose whole grains in preference to processed (refined) grains

- Limit consumption of processed and red meats

If you drink alcoholic beverages, limit consumption. Drink no more than one drink per day for women or two per day for men.

ACS Recommendations for Community Action

- Public, private, and community organizations should work to create social and physical environments that support the adoption and maintenance of healthful nutrition and physical activity behaviors
- Increase access to healthful foods in schools, worksites, and communities
- Provide safe, enjoyable, and accessible environments for physical activity in schools, and for transportation and recreation in communities

From Kushi, L. H., Byers, T., Doyle, C., et al. (2006). American Cancer Society guidelines on nutrition and physical activity for cancer prevention: Reducing the risk of cancer with healthy food choices and physical activity. *CA Cancer Journal for Clinicians*, 56(5), 254–281, with permission.

and secondary prevention of cancer. Nurses must be aware of factors such as race, cultural influences, access to care, patient–physician and patient–nurse relationships, level of education, income, and age that influence the knowledge, attitudes, and beliefs individuals have about cancer. These factors also may affect the health-promoting behaviors that people practice.

Primary Prevention

Primary prevention is concerned with reducing the risks of disease through health promotion strategies. It is estimated that almost one third of all cancers worldwide could be prevented through primary prevention efforts (Williams-Brown & Singh, 2005). By acquiring the knowledge and skills necessary to educate the community about cancer risk, nurses in all settings play a key role in cancer prevention. One way to reduce the risk of cancer is to help patients avoid known carcinogens. Another strategy involves encouraging patients to make dietary and lifestyle changes (smoking cessation, decreased caloric intake, increased physical activity) that studies show influence the risk for cancer. Nurses use their teaching and counseling skills to provide patient education and support public education campaigns through organizations, such as the ACS, that guide patients and families in taking steps to reduce cancer risks through health promotion behaviors (Chart 16-2).

Several clinical trials have been conducted to identify medications or supplements that may help reduce the incidence of certain types of cancer. For example, large-scale breast cancer prevention studies supported by the National Cancer Institute (NCI) indicated that chemoprevention

with the medication tamoxifen (Nolvadex) can reduce the incidence of breast cancer by 50% in women at high risk for breast cancer (Fisher, Constantino, Wickerham, et al., 2005). Currently, the NCI (2008) lists 110 ongoing clinical trials exploring chemoprevention strategies.

Secondary Prevention

Secondary prevention programs promote screening and early detection activities such as breast and testicular self-examination and Papanicolaou (Pap) tests. Many organizations conduct cancer screening events that focus on cancers with the highest incidence rates or those that have improved survival rates if diagnosed early, such as breast or prostate cancer. These events offer education and examinations such as mammograms, digital rectal examinations, and PSA blood tests for minimal or no cost. These programs often target people who lack access to health care insurance or who cannot afford to participate on their own.

The evolving understanding of the role of genetics in cancer cell development has contributed to prevention and screening efforts. Many centers across the country are offering innovative cancer risk evaluation programs that provide in-depth screening and follow-up screening for people who are found to be at high risk for cancer. Nurses in all settings can develop programs that identify risks for patients and families and that incorporate teaching and counseling into all educational efforts, particularly for patients and families with a high incidence of cancer. Nurses and physicians can encourage people to comply with detection efforts as suggested by the ACS (Table 16-2).

Table 16-2 AMERICAN CANCER SOCIETY (ACS) RECOMMENDATIONS FOR THE EARLY DETECTION OF CANCER IN AVERAGE-RISK ASYMPTOMATIC PEOPLE

Cancer Site	Population	Test or Procedure	Frequency
Breast	Women, aged ≥ 20 years	Breast self-examination (BSE) Clinical breast examination (CBE)	Beginning in their early 20s, women should be told about the benefits and limitations of BSE. The importance of prompt reporting of any new breast symptoms to a health professional should be emphasized. Women who choose to do BSE should receive instruction and have their technique reviewed on the occasion of a periodic health examination. It is acceptable for women to choose not to do BSE or to do BSE irregularly. For women in their 20s and 30s, it is recommended that CBE be part of a periodic health examination, preferably at least every 3 years. Asymptomatic women aged ≥ 40 years should continue to receive a clinical breast examination as part of a periodic health examination, preferably annually.
Colorectal	Men and women, aged ≥ 50 years	Mammography Fecal occult blood test (FOBT) [†] or fecal immunochemical test (FIT), or Flexible sigmoidoscopy, or Fecal occult blood test (FOBT) [†] and flexible sigmoidoscopy, [‡] or contrast barium enema (DCBE), or	Begin annual mammography at age 40 years.* Annual, starting at age 50 years Every 5 years, starting at age 50 years Annual FOBT (or FIT) and flexible sigmoidoscopy every 5 years, starting at age 50 years DCBE every 5 years, starting at age 50 years Colonoscopy every 10 years, starting at age 50 years
Prostate	Men, aged ≥ 50 years	Digital rectal examination (DRE) and prostate-specific antigen (PSA) test	The PSA test and the DRE should be offered annually, starting at age 50 years, for men who have a life expectancy of at least 10 years. [§]
Cervix	Women, aged ≥ 18 years	Pap test	Cervical cancer screening should begin approximately 3 years after a woman begins having vaginal intercourse, but no later than age 21 years. Screening should be done every year with conventional Pap tests or every 2 years using liquid-based Pap tests. At or after age 30 years, women who have had normal test results in a row may get screened every 2 to 3 years with cervical cytology (either conventional or liquid-based Pap test) alone, or every 3 years with a human papillomavirus DNA test, plus cervical cytology. Women aged ≥ 70 years who have had or more normal Pap tests and no abnormal Pap tests in the 10 years and women who have had a total hysterectomy may choose to stop cervical cancer screening.
Endometrial	Women, at menopause	At the time of menopause, women at average risk should be informed about risks and symptoms of endometrial cancer and strongly encouraged to report any unexpected bleeding or spotting to their physicians.	
Cancer-related checkup	Men and women, aged ≥ 20 years	On the occasion of a periodic health examination, the cancer-related check-up should include examination for cancers of the thyroid, testicles, ovaries, lymph nodes, oral cavity, and skin, as well as health counseling about tobacco, sun exposure, diet and nutrition, risk factors, sexual practices, and environmental and occupational exposures.	

*Beginning at age 40 years, annual clinical breast examination should be performed prior to mammography.

[†]FOBT, as it is sometimes done in physicians' offices with the single stool sample collected on a fingertip during a DRE, is not an adequate substitute for the recommended at-home procedure of collecting two samples from three consecutive specimens, and is not recommended. Toilet bowl FOBT tests also are not recommended. In comparison with guaiac-based tests for the detection of occult blood, immunochemical tests are more patient-friendly and are likely to be equal or better in sensitivity and specificity. There is no justification for repeating FOBT in response to an initial positive finding. Patients with a positive screening FOBT should undergo colonoscopy.

[‡]Flexible sigmoidoscopy together with FOBT is preferred compared with FOBT or flexible sigmoidoscopy alone.

[§]Information should be provided to men about the benefits and limitations of testing so that an informed decision about testing can be made with the clinician's assistance.

From Smith, R. A., Cokkinides, V. & Eyre, H. J. (2007). Cancer screening in the United States, 2007: A review of current guidelines, practices and prospects. *CA Cancer Journal for Clinicians*, 57(2), 90–104, with permission.

Diagnosis of Cancer

A cancer diagnosis is based on assessment of physiologic and functional changes and results of the diagnostic evaluation. Patients with suspected cancer undergo extensive testing to (1) determine the presence and extent of tumor, (2) identify possible spread (metastasis) of disease or invasion of other body tissues, (3) evaluate the function of involved and uninvolved body systems and organs, and (4) obtain tissue and cells for analysis, including evaluation of tumor stage and grade. The diagnostic evaluation includes a review of systems, physical examination, imaging studies, laboratory tests of blood, urine and other body fluids, and surgical and pathology reports. Knowledge of suspicious symptoms and of the behavior of particular types of cancer assists in determining relevant diagnostic tests (Table 16-3).

Patients undergoing extensive testing may be fearful of the procedures and anxious about the possible test results. Nurses help relieve the patient's fear and anxiety by explaining the tests to be performed, the sensations likely to be experienced, and the patient's role in the test procedures. The nurse encourages the patient and family to voice their fears about the test results, supports the patient and family throughout the test period, and reinforces and clarifies information conveyed

by the physician. The nurse also encourages the patient and family to communicate and share their concerns and to discuss their questions and concerns with one another.

Tumor Staging and Grading

A complete diagnostic evaluation includes identifying the stage and grade of the tumor. This is accomplished prior to treatment to provide baseline data for evaluating outcomes of therapy and to maintain a systematic and consistent approach to ongoing diagnosis and treatment. Treatment options and prognosis are based on staging and grading.

Staging determines the size of the tumor and the existence of local invasion and distant metastasis. Several systems exist for classifying the anatomic extent of disease. The tumor, nodes, and metastasis (TNM) system is frequently used (American Joint Committee on Cancer, 2006) (Chart 16-3). A variety of other staging systems are also used to describe the extent of cancers, such as central nervous system (CNS) cancers, hematologic cancers, and malignant melanoma, which are not well described by the TNM system. Staging systems also provide a convenient shorthand notation that condenses lengthy descriptions into manageable terms for comparisons of treatments and prognoses.

Table 16-3 DIAGNOSTIC AIDS USED TO DETECT CANCER

Test	Description	Examples of Diagnostic Uses
Tumor marker identification	Analysis of substances found in body—tissues, blood, or other body fluids that are made by the tumor or by the body in response to the tumor	Breast, colon, lung, ovarian, testicular, prostate cancers
Genetic profiling	Analysis for the presence of mutations (alterations) in genes found in tumors or body tissues. Assists in diagnosis, selection of treatment, prediction of response to therapy, and risk of progression or recurrence	Breast, lung, kidney, ovarian, brain cancers, leukemia, and lymphoma (many uses of genetic profiling are considered investigational)
Mammography	Use of x-ray images of the breast	Breast cancer
Magnetic resonance imaging (MRI)	Use of magnetic fields and radiofrequency signals to create sectioned images of various body structures	Neurologic, pelvic, abdominal, thoracic, breast cancers
Computed tomography (CT)	Use of narrow-beam x-ray to scan successive layers of tissue for a cross-sectional view	Neurologic, pelvic, skeletal, abdominal, thoracic cancers
Fluoroscopy	Use of x-rays that identify contrasts in body tissue densities; may involve the use of contrast agents	Skeletal, lung, gastrointestinal cancers
Ultrasonography (ultrasound)	High-frequency sound waves echoing off body tissues are converted electronically into images; used to assess tissues deep within the body	Abdominal and pelvic cancers
Endoscopy	Direct visualization of a body cavity or passageway by insertion of an endoscope into a body cavity or opening; allows tissue biopsy, fluid aspiration, and excision of small tumors. Used for diagnostic and therapeutic purposes	Bronchial, gastrointestinal cancers
Nuclear medicine imaging	Uses intravenous injection or ingestion of radioisotope substances followed by imaging of tissues that have concentrated the radioisotopes	Bone, liver, kidney, spleen, brain, thyroid cancers
Positron emission tomography (PET)	Through the use of a tracer, provides black and white or color-coded images of the biologic activity of a particular area, rather than its structure. Used in detection of cancer or its response to treatment	Lung, colon, liver, pancreatic, head and neck cancers; Hodgkin and non-Hodgkin lymphoma and melanoma
PET fusion	Use of a PET scanner and a CT scanner in one machine to provide an image combining anatomic detail, spatial resolution, and functional metabolic abnormalities	See PET
Radioimmunoconjugates	Monoclonal antibodies are labeled with a radioisotope and injected intravenously into the patient; the antibodies that aggregate at the tumor site are visualized with scanners	Colorectal, breast, ovarian, head and neck cancers; lymphoma and melanoma

Chart 16-3 • TNM Classification System

T The extent of the primary tumor
 N The absence or presence and extent of regional lymph node metastasis
 M The absence or presence of distant metastasis

The use of numerical subsets of the TNM components indicates the progressive extent of the malignant disease.

Primary Tumor (T)

Tx Primary tumor cannot be assessed
 T0 No evidence of primary tumor
 Tis Carcinoma in situ
 T1, T2, T3, T4 Increasing size and/or local extent of the primary tumor

Regional Lymph Nodes (N)

Nx Regional lymph nodes cannot be assessed
 N0 No regional lymph node metastasis
 N1, N2, N3 Increasing involvement of regional lymph nodes

Distant Metastasis (M)

Mx Distant metastasis cannot be assessed
 M0 No distant metastasis
 M1 Distant metastasis

From American Joint Committee on Cancer. (2006). *AJCC cancer staging atlas*. Chicago: Springer Science and Business Media, Inc.

Grading refers to the classification of the tumor cells. Grading systems seek to define the type of tissue from which the tumor originated and the degree to which the tumor cells retain the functional and histologic characteristics of the tissue of origin (differentiation). Samples of cells used to establish the grade of a tumor may be obtained from tissue scrapings, body fluids, secretions, or washings, biopsy, or surgical excision. This information helps the health care team predict the behavior and prognosis of various tumors. The tumor is assigned a numeric value ranging from I to IV. Grade I tumors, also known as well-differentiated tumors, closely resemble the tissue of origin in structure and function. Tumors that do not clearly resemble the tissue of origin in structure or function are described as poorly differentiated or undifferentiated and are assigned grade IV. These tumors tend to be more aggressive and less responsive to treatment than well-differentiated tumors.

Management of Cancer

Treatment options offered to cancer patients should be based on treatment goals for each specific type of cancer. The range of possible treatment goals may include complete eradication of malignant disease (**cure**), prolonged survival and containment of cancer cell growth (**control**), or relief of symptoms associated with the disease (**palliation**).

The health care team, the patient, and the patient's family must have a clear understanding of the treatment options and goals. Open communication and support are vital as the patient and family periodically reassess treatment plans and goals when complications of therapy develop or disease progresses.

Multiple modalities are commonly used in cancer treatment. A variety of approaches, including surgery, radiation therapy, chemotherapy, and targeted therapies, may be used at various times throughout treatment. Understanding the principles of each and how they interrelate is important in understanding the rationale and goals of treatment.

Surgery

Surgical removal of the entire cancer remains the ideal and most frequently used treatment method. However, the specific surgical approach may vary for several reasons. Diagnostic surgery is the definitive method of identifying the cellular characteristics that influence all treatment decisions. Surgery may be the primary method of treatment, or it may be prophylactic, palliative, or reconstructive.

Diagnostic Surgery

Diagnostic surgery, such as a **biopsy**, is usually performed to obtain a tissue sample for analysis of cells suspected to be malignant. In most instances, the biopsy is taken from the actual tumor, but in some situations, it is necessary to biopsy lymph nodes near the suspicious tumor. Many cancers can metastasize from the primary site to other areas of the body through the lymphatic circulation. Knowing whether adjacent lymph nodes contain tumor cells helps physicians plan for systemic therapies instead of or in addition to surgery or radiation, to combat tumor cells that have gone beyond the primary tumor site. The use of injectable dyes and nuclear medicine imaging can help the surgeon identify the sentinel lymph node or the initial lymph node to which the primary tumor and surrounding tissue drains. Sentinel lymph node biopsy (SLNB), also known as sentinel lymph node mapping, is a minimally invasive surgical approach that in some instances has replaced more invasive lymph node dissections (lymphadenectomy) and their associated complications such as lymphedema and delayed healing. SLNB has been widely adopted for regional lymph node staging in selected cases of melanoma and breast cancer (Chen, Iddings, Scheri, et al., 2006).

Biopsy Types

The three most common biopsy methods are the excisional, incisional, and needle methods (Szopa, 2005). The choice of biopsy is determined by the size and location of the tumor, the type of treatment anticipated if the cancer diagnosis is confirmed, and the need for surgery and general anesthesia. The biopsy method that allows for the least invasive approach while permitting the most representative tissue sample is chosen. Occasionally diagnostic imaging techniques are used to assist in locating the suspicious lesion and to facilitate accurate tissue sampling. The patient and family are given the opportunity and time to discuss the options before definitive plans are made. The nurse serves as the patient's advocate and liaison between the patient and physician to facilitate this process.

Excisional biopsy is most frequently used for easily accessible tumors of the skin, breast, and upper or lower gastrointestinal and upper respiratory tracts. In many cases, the surgeon can remove the entire tumor as well as the surrounding marginal tissues. The removal of normal tissue beyond the tumor area decreases the possibility that residual microscopic disease cells may lead to a recurrence of the tumor. This approach not only provides the pathologist, who

stages and grades the cells, with the entire tissue specimen but also decreases the chance of seeding the tumor (disseminating cancer cells throughout surrounding tissues).

Incisional biopsy is performed if the tumor mass is too large to be removed. In this case, a wedge of tissue from the tumor is removed for analysis. The cells of the tissue wedge must be representative of the tumor mass so that the pathologist can provide an accurate diagnosis. If the specimen does not contain representative tissue and cells, negative biopsy results do not guarantee the absence of cancer.

Excisional and incisional approaches are often performed through endoscopy. However, surgical incision may be required to determine the anatomic extent or stage of the tumor. For example, a diagnostic or staging laparotomy (the surgical opening of the abdomen to assess malignant abdominal disease) may be necessary to assess malignancies such as gastric cancer.

Needle biopsies are performed to sample suspicious masses that are easily accessible, such as some growths in the breasts, thyroid, lung, liver, and kidney. Needle biopsies are most often performed on an outpatient basis. They are fast, relatively inexpensive, easy to perform, and usually require only local anesthesia. In general, the patient experiences slight and temporary physical discomfort. In addition, the surrounding tissues are disturbed only minimally, thus decreasing the likelihood of seeding cancer cells. Needle aspiration biopsy involves aspirating tissue fragments through a needle guided into an area suspected of bearing disease. Occasionally, x-ray, computed tomography (CT) scanning, ultrasonography, or magnetic resonance imaging (MRI) is used to help locate the suspicious area and guide the placement of the needle. In some instances, the aspiration biopsy does not yield enough tissue to permit accurate diagnosis. A needle core biopsy uses a specially designed needle to obtain a small core of tissue. Most often, this specimen is sufficient to permit accurate diagnosis.

Surgery as Primary Treatment

When surgery is the primary approach in treating cancer, the goal is to remove the entire tumor or as much as is feasible (a procedure sometimes called debulking) and any involved surrounding tissue, including regional lymph nodes.

Two common surgical approaches used for treating primary tumors are local and wide excisions. Local excision,

often performed on an outpatient basis, is warranted when the mass is small. It includes removal of the mass and a small margin of normal tissue that is easily accessible. Wide or radical excisions (en bloc dissections) include removal of the primary tumor, lymph nodes, adjacent involved structures, and surrounding tissues that may be at high risk for tumor spread (Szopa, 2005). This surgical method can result in disfigurement and altered functioning, necessitating rehabilitation or reconstructive procedures. However, wide excisions are considered if the tumor can be removed completely and the chances of cure or control are good.

Video-assisted endoscopic surgery is increasingly replacing surgery associated with long incisions and extended recovery periods to minimize surgical trauma and shorten patient recovery time without compromising surgical outcomes (Swanson, Herndon, D’Amico, et al., 2007). In this minimally invasive procedure, an endoscope with intense lighting and an attached multichip mini-camera is inserted into the body through a small incision. The surgical instruments are inserted into the surgical field through one or two additional small incisions, each about 3 cm in length. The camera transmits the image of the involved area to a monitor so the surgeon can manipulate the instruments to perform the necessary procedure. Such surgery is now being used for many thoracic and abdominal surgeries.

Salvage surgery is an additional treatment option that uses an extensive surgical approach to treat the local recurrence of a cancer after the use of a less extensive primary approach. A mastectomy to treat recurrent breast cancer after primary lumpectomy and radiation is an example of salvage surgery.

In addition to surgery that uses surgical blades or scalpels to excise the mass and surrounding tissues, several other types of surgical techniques are available. Table 16-4 identifies these techniques and provides examples of their use in the patient with cancer. A multidisciplinary approach to patient care is essential for the patient undergoing cancer-related surgery. The effects of surgery on the patient’s body image, self-esteem, and functional abilities are addressed. If necessary, a plan for postoperative rehabilitation is made before the surgery is performed.

The growth and dissemination of cancer cells may have produced distant micrometastases by the time the patient

Table 16-4 SELECTED TECHNIQUES USED TO REMOVE OR DESTROY TUMORS

Type of Procedure	Description	Examples of Use
Electrosurgery	Use of an electric current to destroy tumor cells	Basal and squamous cell skin cancers
Cryosurgery	Use of liquid nitrogen or a very cold probe to freeze tissue and cause cell destruction	Cervical and prostate cancers
Chemosurgery	Use of chemicals or chemotherapy applied directly to tissue to cause destruction	Intraperitoneal chemotherapy for ovarian cancer involving the abdomen and peritoneum
Laser surgery	Use of light and energy aimed at an exact tissue location and depth to vaporize cancer cells (also referred to as photocoagulation or photoablation)	Dyspnea associated with endobronchial obstructions
Photodynamic therapy	Intravenous administration of a light-sensitizing agent (hematoporphyrin derivative [HPD]) that is taken up by cancer cells, followed by exposure to laser light within 24–48 hours; causes cancer cell death	Palliative treatment of dysphagia associated with esophageal and dyspnea associated with endobronchial obstructions
Radiofrequency ablation (RFA)	Uses localized application of thermal energy that destroys cancer cells through heat: temperatures exceed 50°C (122°F)	Nonresectable liver tumors, pain control with bone metastasis

Table 16-5 INDICATIONS FOR PALLIATIVE SURGERY

Procedure	Indications
Pleural drainage tube placement	Pleural effusion
Peritoneal drainage tube placement (Tenckhoff catheter)	Ascites
Abdominal shunt placement (Levine shunt)	Ascites
Pericardial drainage tube placement	Pericardial effusion
Colostomy or ileostomy	Bowel obstruction
Gastrostomy, jejunostomy tube placement	Upper gastrointestinal tract obstruction
Biliary stent placement	Biliary obstruction
Bone stabilization	Displaced bone fracture related to metastatic disease
Excision of solitary metastatic lesion	Metastatic lung, liver or brain lesion
Ureteral stent placement	Ureteral obstruction
Nerve block	Pain
Cordotomy	Pain
Venous access device placement (for administering parenteral analgesics)	Pain
Epidural catheter placement (for administering epidural analgesics)	Pain
Hormone manipulation (removal of ovaries, testes, adrenals, pituitary)	Tumors that depend on hormones for growth

seeks treatment. Therefore, attempting to remove wide margins of tissue in the hope of “getting all the cancer” may not be feasible. This reality substantiates the need for a coordinated multidisciplinary approach to cancer therapy.

Once the surgery has been completed, one or more additional (or adjuvant) modalities may be chosen to increase the likelihood of destroying the remaining cancer cells. However, some cancers that are treated surgically in the very early stages (eg, skin and testicular cancers) are considered to be curable without additional therapies.

Prophylactic Surgery

Prophylactic surgery involves removing nonvital tissues or organs that are at increased risk to develop cancer. The following factors are considered when physicians, nurses, patients, and families discuss possible prophylactic surgery:

- Family history and genetic predisposition
- Presence or absence of symptoms
- Potential risks and benefits
- Ability to detect cancer at an early stage
- The patient’s acceptance of the postoperative outcome

Colectomy, mastectomy, and oophorectomy are examples of prophylactic surgeries. Identification of genetic markers indicative of a predisposition to develop some types of cancer plays a role in decisions concerning prophylactic surgeries. However, what is adequate justification for prophylactic surgery remains controversial. For example, several factors are considered when deciding to proceed with a prophylactic mastectomy, including a strong family history of breast cancer; positive *BRCA1* or *BRCA2* findings; an abnormal physical finding on breast examination, such as progressive nodularity and cystic disease; a proven history of breast cancer in the opposite breast; abnormal mammography findings; and abnormal biopsy results (Calhoun & Anderson, 2006). Prophylactic surgery is offered selectively to patients and discussed thoroughly with patients and families. Preoperative teaching and counseling, as well as long-term follow-up, are provided.

Palliative Surgery

When cure is not possible, the goals of treatment are to make the patient as comfortable as possible and to promote quality of life as defined by the patient and his or her family. Palliative surgery is performed in an attempt to relieve complications of cancer, such as ulceration, obstruction, hemorrhage, pain, and malignant effusion (Table 16-5). Honest and informative communication with the patient and family about the goal of surgery is essential to avoid false hope and disappointment.

Reconstructive Surgery

Reconstructive surgery may follow curative or radical surgery in an attempt to improve function or obtain a more desirable cosmetic effect. It may be performed in one operation or in stages. The surgeon who will perform the surgery discusses possible reconstructive surgical options with the patient before the primary surgery is performed. Reconstructive surgery may be indicated for breast, head and neck, and skin cancers.

The nurse recognizes the patient’s needs and the impact that altered functioning and body image may have on quality of life. The nurse provides the patient and family with opportunities to discuss these issues. The individual needs of the patient undergoing reconstructive surgery must be accurately assessed and addressed.

Nursing Management in Cancer Surgery

Patients undergoing surgery for cancer require general perioperative nursing care, as described in Unit 4 of this text, along with specific care related to age, organ impairment, nutritional deficits, disorders of coagulation, and altered immunity that may increase the risk of postoperative complications. Combining other treatment methods, such as radiation and chemotherapy, with surgery also contributes to postoperative complications, such as infection, impaired wound healing, altered pulmonary or renal function, and the development of deep vein thrombosis. In these situations, the nurse completes a thorough preoperative assessment for

factors that may affect the patient undergoing the surgical procedure.

Patients who are undergoing surgery for the diagnosis or treatment of cancer may be anxious about the surgical procedure, possible findings, postoperative limitations, changes in normal body functions, and prognosis. The patient and family require time and assistance to deal with the possible changes and outcomes resulting from the surgery.

The nurse provides education and emotional support by assessing the needs of the patient and family and by discussing their fears and coping mechanisms. The nurse encourages the patient and family to take an active role in decision making when possible. If the patient or family asks about the results of diagnostic testing and surgical procedures, the nurse's response is guided by the information the physician has previously conveyed to the patient and family. The patient and family may ask the nurse to explain and clarify information that the physician initially provided but that they did not grasp because they were anxious and overwhelmed at the time. It is important that the nurse communicate frequently with the physician and other members of the health care team to be certain that the information provided is consistent.

Postoperatively, the nurse assesses the patient's responses to the surgery and monitors the patient for possible complications, such as infection, bleeding, thrombophlebitis, wound dehiscence, fluid and electrolyte imbalance, and organ dysfunction. The nurse also provides for the patient's comfort. Postoperative teaching addresses wound care, activity, nutrition, and medication information.

Plans for discharge, follow-up, home care, and treatment are initiated as early as possible to ensure continuity of care from hospital to home or from a cancer referral center to the patient's local hospital and health care provider. Patients and families are encouraged to use community resources such as the American Cancer Society for support and information.

Radiation Therapy

More than half of patients with cancer receive a form of **radiation therapy** at some point during treatment. Radiation may be used to cure cancer, as in thyroid carcinomas, localized cancers of the head and neck, and cancers of the uterine cervix. Radiation therapy may also be used to control malignant disease when a tumor cannot be removed surgically or when local nodal metastasis is present, or it can be used neoadjuvantly (prior to local definitive treatment) with or without chemotherapy to reduce the size of a tumor to enable surgical resection. Radiation therapy may be used prophylactically to prevent the spread of a primary cancer to a distant area (eg, irradiating the brain to prevent leukemic infiltration or metastatic lung cancer). Palliative radiation therapy is used to relieve the symptoms of metastatic disease, especially when the cancer has spread to the brain, bone, or soft tissue, or to treat oncologic emergencies, such as superior vena cava syndrome, bronchial airway obstruction, or spinal cord compression.

Two types of ionizing radiation—electromagnetic radiation (x-rays and gamma rays) and particulate radiation (electrons, beta particles, protons, neutrons, and alpha particles)—can lead to tissue disruption. The most harmful tis-

sue disruption is the direct alteration of the DNA molecule within the cells of the tissue. Ionizing radiation breaks the strands of the DNA helix, leading to cell death. It can also lead to the formation of free radicals and irreversibly damage DNA. If the DNA is incapable of repair, the cell may die immediately, or it may initiate cellular suicide, a genetically programmed cell death (Bruner, Haas & Gosselin-Acomb, 2006; Yarbrow, Hansen-Frogge & Goodman, 2005).

Cells are most vulnerable to the disruptive effects of radiation during DNA synthesis and mitosis (early S, G₂, and M phases of the cell cycle). Therefore, those body tissues that undergo frequent cell division are most sensitive to radiation therapy. These tissues include bone marrow, lymphatic tissue, epithelium of the gastrointestinal tract, hair cells, and gonads. Slower-growing tissues and tissues at rest (eg, muscle, cartilage, and connective tissues) are relatively radioreistant (less sensitive to the effects of radiation). However, it is important to remember that radiation therapy is localized treatment, and only the tissues that are within the treatment field will be affected by the radiation therapy.

A radiosensitive tumor is one that can be destroyed by a dose of radiation that still allows for cell regeneration in the normal tissue. Tumors that are well oxygenated also appear to be more sensitive to radiation. In theory, therefore, radiation therapy may be enhanced if more oxygen can be delivered to tumors. In addition, if the radiation is delivered when most tumor cells are cycling through the cell cycle, the number of cancer cells destroyed (cell kill) is maximal. Radiation sensitivity is also enhanced in tumors that are smaller in size and that contain cells that are rapidly dividing (highly proliferative) and poorly differentiated (no longer resembling the tissue of origin) (Bruner, et al., 2006).

Certain chemicals, including chemotherapy agents, act as radiosensitizers and sensitize hypoxic (oxygen-poor) tumors to the effects of radiation therapy. Combinations of chemotherapy and radiation therapy are typically used to take advantage of the radiosensitizing effects of chemotherapy and achieve an improved survival benefit while minimizing side effects of such therapy.

Radiation Dosage

The radiation dosage depends on the sensitivity of the target tissues to radiation, the size of the tumor, tissue tolerance of the surrounding normal tissues, and critical structures adjacent to the tumor target. The lethal tumor dose is defined as that dose that will eradicate 95% of the tumor yet preserve normal tissue. In external beam radiation, the total radiation dose is delivered over several weeks in daily doses called fractions. This allows healthy tissue to repair and to achieve greater cell kill by exposing more cells to the radiation as they begin active cell division. Repeated radiation treatments over time (fractionated doses) also allow for the periphery of the tumor to be reoxygenated repeatedly, because tumors shrink from the outside inward. This increases the radiosensitivity of the tumor, thereby increasing tumor cell death (Bruner, et al., 2006; Yarbrow, et al., 2005).

Administration of Radiation

Radiation therapy can be administered in a variety of ways depending on the source of radiation used, the location of the tumor, and the type of cancer targeted. The primary

applications include teletherapy (external beam radiation), **brachytherapy** (internal radiation), systemic (radioisotopes), and contact or surface molds.

External Radiation

External beam radiation therapy (EBRT) is the most commonly used form of radiation therapy. The energy utilized in EBRT is either generated from a linear accelerator or from a unit that generates energy directly from a core source of radioactive material such as a GammaKnife™ unit. Through computerized software programs, both approaches are able to shape an invisible beam of highly charged electrons to penetrate the body and target a tumor with pinpoint accuracy. Depending on the size, shape, and location of the tumor, different energy levels are generated to produce a carefully shaped beam that will destroy the targeted tumor, yet spare the surrounding healthy tissue and vital organs in an effort to reduce the treatment toxicities for the patient. With advances in computer technology, these beams can be shaped to a two-dimensional or three-dimensional shape to conform to the exact shape of the tumor as measured by imaging studies such as positron emission tomography (PET), CT, or MRI scans. Recent treatment enhancements in EBRT include the ability to direct different energy levels at different angles directed at the tumor, called intensity modulated radiation therapy (IMRT), which enables higher doses to be delivered to the tumor while sparing the important healthy structures surrounding the tumor. IMRT can be administered as standard daily fractions or as “hyperfractionated” twice daily fractions, which shortens the duration of the patient’s treatment schedule. Image-guided radiation therapy (IGRT) uses continuous monitoring of the tumor with ultrasound or CT scans during the treatment to allow for automatic adjustment of the target as the tumor changes shape or position, again in an effort to spare the healthy surrounding tissue and reduce side effects (Sharpe, Craig & Moseley, 2007). The most recent treatment enhancements now include respiratory-gating, where the treatment delivery is actually synchronized with the patient’s respiratory cycle, enabling the beam to be adjusted as the tumor moves (Dawson & Jaffray, 2007).

Gamma rays generated from the spontaneous decay of naturally occurring solid source of radioactivity, such as cobalt-60, is one of the oldest forms of EBRT. With the advent of modern linear accelerators, the use of solid radioactive elements are confined primarily to the GammaKnife™ stereotactic radiosurgery unit, which is used as a one-time, high-dose delivery of EBRT for treatment of benign and malignant intracranial lesions.

Stereotactic body radiotherapy (SBRT) is another form of EBRT using higher doses of radiation to penetrate very deeply into the body to control deep-seated tumors that cannot be treated by other approaches such as surgery. SBRT is delivered with considerably higher treatment fraction doses over a short span of time, usually 1 to 5 treatment days, in contrast to 6 to 8 weeks for conventional EBRT (Timmerman, Kavanagh, Cho, et al., 2007). Specialized linear accelerators with the capability of robotically moving around the patient are used to deliver SBRT, such as the CyberKnife™, Trilogy™, and TomoTherapy™ delivery sys-

tems, which are being utilized more commonly in community hospital settings.

Proton therapy is another very different approach to EBRT. Proton therapy utilizes high-linear energy transfer (LET) in the form of charged protons generated by a large magnetic unit called a cyclotron. The advantage of proton therapy is that it is capable of delivering its high-energy dose to a deep-seated tumor, with no energy exiting through the patient’s healthy tissue behind the tumor, allowing for treatment of deep tumors in close proximity to critical structures such as the heart or major blood vessels (Thornton, Fitzek, Klein, et al., 2007). Due to the limited number of proton units in the United States, most treatment has been investigational in the area of localized prostate cancer, inoperable early stage lung cancer, uveal melanoma, and head and neck tumors. With recent expansion in the number of proton therapy centers, investigation of treatment advantages utilizing proton therapy will be a research priority in the future (Schulz-Ertner & Tsujii, 2007).

Internal Radiation

Internal radiation implantation, or brachytherapy, delivers a high dose of radiation to a localized area. The specific radioisotope for implantation is selected on the basis of its half-life, which is the time it takes for half of its radioactivity to decay. Internal radiation can be implanted by means of needles, seeds, beads, or catheters into body cavities (vagina, abdomen, pleura) or interstitial compartments (breast, prostate). Patients may have many fears or concerns about internal radiation and the nurse must be prepared to explain the various approaches and safety precautions that will be used to protect both the patient and the staff.

Brachytherapy may be delivered as a temporary or a permanent implant. Temporary applications may be delivered as high-dose radiation (HDR) for short periods of time or low-dose radiation (LDR) for a more extended period of time. The primary advantage of HDR sources of brachytherapy is that treatment time is shorter, there is reduced exposure to personnel, and the procedure can typically be performed as an outpatient procedure over several days. HDR brachytherapy can be used for intraluminal, interstitial, intracavitary, and surface lesions.

Intraluminal brachytherapy involves the insertion of catheters or hollow tubes into the lumens of organs so that the radioisotope can be delivered as close to the tumor bed as possible. Obstructive lesions in the bronchus, esophagus, or bile duct can be treated with this approach. Contact or surface application is used for treatment of tumors of the eye such as retinoblastoma in children or ocular melanoma in adults.

Intracavitary radioisotopes are frequently used to treat gynecologic cancers. In these malignancies, the radioisotopes are inserted into specially positioned applicators after their placement is verified by x-ray. Treatment can be achieved with either HDR or LDR brachytherapy sources depending on the extent of disease. LDR therapy requires hospitalization as the patient is treated over several days. Nursing care of the hospitalized LDR patient is essential to maximize effective safe delivery of the therapy and prevention of complications. The patient is maintained on bed rest in a specially prepared private room typically for 72 hours and log-rolled to prevent displacement of the intracavitary

delivery device. An indwelling urinary catheter is inserted to ensure that the bladder remains empty. Low-residue diets and antidiarrheal agents are provided to prevent bowel movements during therapy, which would displace the radioisotopes. Visitors and personnel must limit their time and proximity to the patient due to the risk of radiation exposure. HDR intracavitary brachytherapy is typically delivered as an outpatient procedure in the radiation therapy department over several days.

Interstitial implants, used in treating such malignancies as prostate, pancreatic, or breast cancer, may be temporary or permanent, depending on the radioisotopes used. These implants usually consist of seeds, needles, wires, or small catheters positioned to provide a local radiation source and are infrequently dislodged. With internal radiation therapy, the farther the tissue is from the radiation source, the lower the dosage delivered to the tissue. This spares the non-cancerous tissue from the radiation dose. Prostate seed therapy is probably the most frequently used type of interstitial brachytherapy, where small radioactive seeds are placed directly into the prostate gland under ultrasound guidance. These seeds are permanently placed and appropriate safety precautions must be employed for several days due to the risk of radiation exposure to others. Recently, partial breast irradiation utilizing a technique for interstitial isotope employing the MammoSite™ device has shown benefit in certain localized breast cancers. MammoSite™ involves the placement of an inflatable balloon within the cavity created after surgical resection of the breast tumor. HDR brachytherapy fractions are delivered via a radioactive seed inserted into the balloon over the course of 5 days. Studies have shown comparable 5-year outcomes for selected patients, with minimal toxicities and excellent cosmesis, when compared with outcomes with whole breast EBRT for postlumpectomy patients. The advantages for patients are reduced treatment time (5 days versus 6 to 8 weeks), less radiation exposure to healthy tissues and adjacent organs (heart and lungs), less skin reaction, and improved cosmesis of the breast. Nursing care for these patients must include instruction in rigorous catheter care and wound management, as the patient is treated as an outpatient with a double-lumen catheter projecting from the breast (Benitez, Keisch, Vicini, et al., 2007).

Systemic brachytherapy involves the IV administration of a therapeutic radioactive isotope targeted to a specific tumor. Radioactive iodine (I^{131}) is a widely used form of systemic brachytherapy and is the primary treatment for thyroid cancer. Strontium 89 is utilized for bone metastases, samarium 153 is used for metastatic bone lesions, and phosphorus 32 is used for treatment of malignant ascites associated with ovarian cancer. Radioisotopes are now also being used as radioimmunotherapy for the treatment of refractory non-Hodgkin lymphoma (NHL). Radioimmunotherapy involves the administration of a radionuclide chemically conjugated (bound) to a monoclonal antibody (discussed later in this chapter) that specifically targets NHL tumor cells, delivering the radionuclide directly to the tumor and sparing the surrounding healthy tissue. There are currently two radioimmunotherapy agents available for treatment of NHL: ibritumomab tiuxetan (Zevalin), which utilizes yttrium 90 as the radioactive beta emitting nucleotide, and

iodine 131 tositumomab (Bexxar), which utilizes I^{131} as the beta and gamma emitting radionuclide.

Toxicity

Toxicity of radiation therapy is localized to the region being irradiated. Toxicity may be increased if concomitant chemotherapy is administered. Acute local reactions occur when normal cells in the treatment area are also destroyed and cellular death exceeds cellular regeneration. Body tissues most affected are those that normally proliferate rapidly, such as the skin; the epithelial lining of the gastrointestinal tract, including the oral cavity; and the bone marrow. Altered skin integrity is a common effect and can include **alopecia** (hair loss). Skin reactions are identified and graded by severity along a continuum ranging from erythema and dry desquamation (flaking of skin), to moist desquamation (dermis exposed, skin oozing serous fluid), and potentially, ulceration. Re-epithelialization occurs after treatments have been completed (McQuestion, 2006).

Alterations in oral mucosa secondary to radiation therapy include **stomatitis** (inflammation of the oral tissues), **xerostomia** (dryness of the mouth), change and loss of taste, and decreased salivation. The entire gastrointestinal mucosa may be involved, and esophageal irritation with chest pain and dysphagia may result. Anorexia, nausea, vomiting, and diarrhea may occur if the stomach or colon is in the irradiated field. Symptoms subside and gastrointestinal re-epithelialization occurs after treatments have been completed.

Bone marrow cells proliferate rapidly, and if sites containing bone marrow (eg, the iliac crest, sternum) are included in the radiation field, anemia, leukopenia (decreased white blood cells [WBCs]), and **thrombocytopenia** (a decrease in platelets) may result. The patient is then at increased risk for infection and bleeding until blood cell counts return to normal. Chronic anemia may occur (Bruner, et al., 2006; Yarbro, et al., 2005).

Research to develop cytoprotective agents that can protect normal tissue from radiation damage continues. The most commonly used cytoprotectant is amifostine (Ethyol), which is utilized in head and neck cancer patients to reduce acute and chronic xerostomia while preserving antitumor efficacy (Bruner, et al., 2006; Hogle, 2007).

Certain systemic side effects are also commonly experienced by patients receiving radiation therapy. These side effects include fatigue, malaise, and anorexia and may be secondary to substances released when tumor cells break down. The effects are temporary and most often subside with the cessation of treatment.

Late effects (months to years after treatment) of radiation therapy may also occur in various body tissues. These effects are chronic, usually produce fibrotic changes secondary to a decreased vascular supply, and are irreversible. Severe late effects may affect the lungs, heart, central nervous system, and bladder. Toxicities may intensify when radiation is combined with other treatment modalities.

Nursing Management in Radiation Therapy

The nurse assesses the patient's skin and oropharyngeal mucosa regularly when radiation therapy is directed to these areas. In addition, nutritional status and general feeling of

well-being are assessed throughout the course of treatment. Evidence-based treatment protocols for nursing management of the toxicities associated with radiation therapy are the focus of nursing research. Assessment and management of these problems are discussed in more detail in the Plan of Nursing Care: The Patient With Cancer (Chart 16-7).

If systemic symptoms, such as weakness and fatigue, occur, the nurse explains that these symptoms are a result of the treatment and do not represent deterioration or progression of the disease. The assessment and nursing management of fatigue is discussed in more detail in the Nursing Care of Patients With Cancer: Fatigue (p. 380).

Protecting Caregivers

When the patient has a radioactive implant in place, the nurse and other health care providers need to protect themselves as well as the patient from the effects of radiation. Patients receiving internal radiation emit radiation while the implant is in place; therefore, contact with the health care team is guided by principles of time, distance, and shielding to minimize exposure of personnel to radiation. Specific instructions are usually provided by the radiation safety officer from the x-ray department and specify the maximum time that can be spent safely in the patient's room, the shielding equipment to be used, and special precautions and actions to be taken if the implant is dislodged. Safety precautions used in caring for a patient receiving brachytherapy include assigning the patient to a private room, posting appropriate notices about radiation safety precautions, having staff members wear dosimeter badges, making sure that pregnant staff members are not assigned to the patient's care, prohibiting visits by children or pregnant visitors, limiting visits from others to 30 minutes daily, and seeing that visitors maintain a 6-foot distance from the radiation source.

Patients with seed implants typically are able to return home; radiation exposure to others is minimal. Information about any precautions, if needed, is provided to the patient and family members to ensure safety. Depending on the dose and energy emitted by a systemic radionuclide, patients may or may not require special precautions or hospitalization (Bruner, et al., 2006). The nurse should explain the rationale for these precautions to keep the patient from feeling unduly isolated.

Chemotherapy

In **chemotherapy**, antineoplastic agents are used in an attempt to destroy tumor cells by interfering with cellular functions, including replication. Chemotherapy is used primarily to treat systemic disease rather than localized lesions that are amenable to surgery or radiation. Chemotherapy may be combined with surgery, radiation therapy, or both to reduce tumor size preoperatively (neoadjuvant), to destroy any remaining tumor cells postoperatively (adjuvant), or to treat some forms of leukemia or lymphoma (primary). The goals of chemotherapy (cure, control, palliation) must be realistic because they will determine the medications that are used and the aggressiveness of the treatment plan.

Cell Kill and the Cell Cycle

Each time a tumor is exposed to a chemotherapy agent, a percentage of the tumor cells (20% to 99%, depending on dosage) is destroyed. Repeated doses of chemotherapy

are necessary over a prolonged period to achieve regression of the tumor. Eradication of 100% of the tumor is almost impossible. Instead, the goal of treatment is eradication of enough of the tumor so that the remaining tumor cells can be destroyed by the body's immune system.

Actively proliferating cells within a tumor are the most sensitive to chemotherapeutic agents (the ratio of dividing cells to resting cells is referred to as the growth fraction). Nondividing cells capable of future proliferation are the least sensitive to antineoplastic medications and consequently are potentially dangerous. However, the nondividing cells must be destroyed to eradicate a cancer. Repeated cycles of chemotherapy or sequencing of multiple chemotherapeutic agents are used to kill more tumor cells by destroying these nondividing cells as they begin active cell division.

Reproduction of both healthy and malignant cells follows the cell cycle pattern (Fig. 16-2). The cell cycle time is the time required for one tissue cell to divide and reproduce two identical daughter cells. The cell cycle of any cell has four distinct phases, each with a vital underlying function:

1. G₁ phase—RNA and protein synthesis occur
2. S phase—DNA synthesis occurs

Figure 16-2 Phases of the cell cycle extend over the interval between the midpoint of mitosis and the subsequent end point in mitosis in a daughter cell. G₁ is the postmitotic phase during which ribonucleic acid (RNA) and protein syntheses are increased and cell growth occurs. G₀ is the resting, or dormant, phase of the cell cycle. In the S phase, nucleic acids are synthesized and chromosomes are replicated in preparation for cell mitosis. During G₂, RNA and protein synthesis occur as in G₁. P, prophase; M, metaphase; A, anaphase; T, telophase. Redrawn from Porth, C. M. & Matfin, G. (2009). *Pathophysiology: Concepts of altered health states* (8th ed.). Philadelphia: Lippincott Williams & Wilkins.

3. G₂ phase—premitotic phase; DNA synthesis is complete, mitotic spindle forms
4. Mitosis—cell division occurs

The G₀ phase, the resting or dormant phase of cells, can occur after mitosis and during the G₁ phase. Within the G₀ phase are those dangerous cells that are not actively dividing but have the potential for replicating. The administration of certain chemotherapeutic agents (as well as some other forms of therapy) is coordinated with the cell cycle.

Classification of Chemotherapeutic Agents

Chemotherapeutic agents may be classified by their relationship to the cell cycle. Certain chemotherapeutic agents that are specific to certain phases of the cell cycle are termed cell cycle–specific agents. These agents destroy cells that are actively reproducing by means of the cell cycle; most affect cells in the S phase by interfering with DNA and RNA synthesis. Other agents, such as the vinca or plant alkaloids, are specific to the M phase, where they halt mitotic spindle formation. Chemotherapeutic agents that act independently of the cell cycle phases are termed cell cycle–nonspecific agents. These agents usually have a prolonged effect on cells, leading to cellular damage or death. Many treatment plans combine cell cycle–specific and cell cycle–nonspecific agents to increase the number of vulnerable tumor cells killed during a treatment period (Polovich, White & Kelleher, 2005).

Chemotherapeutic agents are also classified by chemical group, each with a different mechanism of action. These include the alkylating agents, nitrosoureas, antimetabolites, anti-tumor antibiotics, plant alkaloids, hormonal agents, and miscellaneous agents. The classification, mechanism of action, common drugs, cell cycle specificity, and common side effects of selected antineoplastic agents are listed in Table 16-6.

Chemotherapeutic agents from every category may be used to enhance tumor cell kill during therapy by creating multiple cellular lesions. Combined medication therapy relies on agents of differing toxicities and with synergistic actions. Use of combination therapy also prevents the development of drug-resistant mechanisms.

Combining older medications with other agents, such as levamisole (Ergamisole*), leucovorin (Wellcovorin), hormones, or interferons, has shown some benefit in combating resistance of cells to chemotherapeutic agents. Newer investigational agents are being studied for effectiveness in resistant tumor lines.

Administration of Chemotherapeutic Agents

Chemotherapeutic agents may be administered in the hospital, outpatient center, or home setting by topical, oral, intravenous, intramuscular, subcutaneous, arterial, intracavitary, and intrathecal routes. The route of administration depends on the type of agent; the required dose; and the type, location, and extent of tumor being treated. Guidelines for the safe administration of chemotherapy have been developed by the Oncology Nursing Society (Polovich, et al., 2005). Patient education is essential to maximize safety if chemotherapy is administered in the home (Chart 16-4).

*Ergamisol (without an “e” at end) is not available in U.S.

Dosage

Dosage of antineoplastic agents is based primarily on the patient’s total body surface area, previous response to chemotherapy or radiation therapy, and function of major organ systems. Dosages are determined to maximize cell kill while minimizing impact on healthy tissues and subsequent toxicities. The therapeutic effect may be compromised if inadequate dosing is required due to toxicities. Modification of dosage is often required if critical laboratory values or the patient’s symptoms indicate unacceptable or dangerous toxicities. Various laboratory tests are performed prior to, during, and after chemotherapy to determine optimal treatment options, evaluate the patient’s response, and monitor toxicity. Laboratory and physical assessments of the hematologic, hepatic, renal, cardiovascular, and pulmonary systems are critical in evaluating the response to chemotherapy (Duong & Loh, 2006; Nirenburg, Bush, Davis, et al., 2006).

Chemotherapy treatment regimens include standard dosage therapy, dose-dense regimens, and myeloablative regimens with bone marrow or peripheral stem cell transplant. For certain chemotherapeutic agents, there is a maximum lifetime dose limit that must be adhered to because of the danger of long-term irreversible organ complications (eg, because of the risk of cardiomyopathy, doxorubicin [Adriamycin] has a cumulative lifetime dose limit of 550 mg/m²).

Extravasation

Antineoplastic chemotherapeutic agents are additionally classified by their potential to damage soft tissue if they inadvertently leak from a vein (**extravasation**). The consequences of extravasation range from mild discomfort to severe tissue destruction, depending on whether the agent is classified as a nonvesicant, irritant, or vesicant. Irritant agents induce inflammatory reactions but usually cause no permanent tissue damage. **Vesicants** are those agents that, if deposited into the subcutaneous tissue (extravasation), cause tissue necrosis and damage to underlying tendons, nerves, and blood vessels. Although the complete mechanism of tissue destruction is unclear, it is known that the pH of many antineoplastic agents is responsible for the severe inflammatory reaction as well as the ability of these agents to bind to tissue DNA. Sloughing and ulceration of the tissue progresses to tissue necrosis and may be so severe that skin grafting may be necessary. The full extent of tissue damage may take several weeks to become apparent. Medications classified as vesicants include many of the commonly used agents: cisplatin (Platinol-AQ), dactinomycin (Cosmegen), daunorubicin (DaunoXome), doxorubicin, nitrogen mustard (Mustargen), mitomycin (Mutamycin), paclitaxel (Taxol), vinblastine (Velban), vincristine (Oncovin), vindesine (Eldisine), and vinorelbine (Navelbine) (Sauerland, Engelking, Wickham, et al., 2006).

Only specially trained physicians and nurses should administer vesicants. Careful selection of peripheral veins, skilled venipuncture, and careful administration of medications are essential. Indications of extravasation during administration of vesicant agents include the following:

- Absence of blood return from the intravenous (IV) catheter
- Resistance to flow of IV fluid
- Burning or pain, swelling or redness at the site

 Table 16-6 ANTINEOPLASTIC AGENTS			
Drug Class and Examples	Mechanism of Action	Cell Cycle Specificity	Common Side Effects
Alkylating Agents			
Busulfan (Busulfex, Myleran), carboplatin (Paraplatin), chlorambucil (Leukeran), cisplatin (Platinol-AQ), cyclophosphamide (Cytoxan), dacarbazine (DTIC-Dome), hexamethylene amine or altretamine (Hexalen), ifosfamide (Ifex), melphalan (Alkeran), nitrogen mustard (Mustargen), oxaliplatin (Eloxatin), thiotepa (Thioplex)	Alter DNA structure by misreading DNA code, initiating breaks in the DNA molecule, cross-linking DNA strands	Cell cycle–nonspecific	Bone marrow suppression, nausea, vomiting, cystitis (cyclophosphamide, ifosfamide), stomatitis, alopecia, gonadal suppression, renal toxicity (cisplatin)
Nitrosoureas			
Carmustine (BCNU [BiCNU, Gliadel]), lomustine or CCNU (CeeNU), semustine (methyl CCNU [MeCCNU]), streptozocin (Zanosar)	Similar to the alkylating agents; cross the blood–brain barrier	Cell cycle–nonspecific	Delayed and cumulative myelosuppression, especially thrombocytopenia; nausea, vomiting
Topoisomerase I Inhibitors			
Irinotecan (Camptosar) Topotecan (Hycamtin)	Induce breaks in the DNA strand by binding to enzyme topoisomerase I, preventing cells from dividing	Cell cycle–specific (S phase)	Bone marrow suppression, diarrhea, nausea, vomiting, hepatotoxicity
Antimetabolites			
5-Azacytadine, capecitabine (Xeloda), cytarabine (DepoCyt, Tarabine) edatrexate fludarabine (Fludara), 5-fluorouracil (5-FU), gemcitabine (Gemzar), hydroxyurea (Droxia, Hydrea), cladribine (Leustatin), 6-mercaptopurine (Purinethol), methotrexate (Trexall, Rheumatrex), pentostatin (Nipent), 6-thioguanine (Tabloid)	Interferes with the biosynthesis of metabolites or nucleic acids necessary for RNA and DNA synthesis	Cell cycle–specific (S phase)	Nausea, vomiting, diarrhea, bone marrow suppression, proctitis, stomatitis, renal toxicity (methotrexate), hepatotoxicity
Antitumor Antibiotics			
Bleomycin (BLM, Blenoxane), dactinomycin (Cosmegen), daunorubicin (DaunoXome), doxorubicin (Adriamycin), idarubicin (Idamycin), mitomycin (Mutamycin), mitoxantrone (Novantrone), plicamycin (Mithracin)	Interfere with DNA synthesis by binding DNA; prevent RNA synthesis	Cell cycle–nonspecific	Bone marrow suppression, nausea, vomiting, alopecia, anorexia, cardiac toxicity (daunorubicin, doxorubicin)
Mitotic Spindle Poisons			
<i>Plant alkaloids:</i> etoposide (Toposar), teniposide (Vumon) vinblastine (Velban), vincristine (VCR [Oncovin]), vindesine (Eldisine), vinorelbine (Navelbine) <i>Taxanes:</i> paclitaxel (Taxol), docetaxel (Taxotere)	Arrest metaphase by inhibiting mitotic tubular formation (spindle); inhibit DNA and protein synthesis Arrest metaphase by inhibiting tubulin depolymerization	Cell cycle–specific (M phase) Cell cycle–specific (M phase)	Bone marrow suppression (mild with VCR), neuropathies (VCR), stomatitis Bradycardia, hypersensitivity reactions, bone marrow suppression, alopecia, neuropathies
Hormonal Agents			
Androgens and antiandrogens, estrogens and antiestrogens, progestins and anti-progestins, aromatase inhibitors, luteinizing hormone–releasing hormone analogues, steroids	Bind to hormone receptor sites that alter cellular growth; block binding of estrogens to receptor sites (antiestrogens); inhibit RNA synthesis; suppress aromatase of P450 system, which decreases level	Cell cycle–nonspecific	Hypercalcemia, jaundice, increased appetite, masculinization, feminization, sodium and fluid retention, nausea, vomiting, hot flashes, vaginal estrogen dryness
Miscellaneous Agents			
Asparaginase (Elspar), procarbazine (Matulane)	Unknown or too complex to categorize	Varies	Anorexia, nausea, vomiting, bone marrow suppression, hepatotoxicity, anaphylaxis, hypotension, altered glucose metabolism

CHART
16-4

HOME CARE CHECKLIST

Chemotherapy Administration

At the completion of the home care instruction, the patient or caregiver will be able to:	PATIENT	CAREGIVER
• Demonstrate how to administer the chemotherapy agent in the home.	✓	✓
• Demonstrate safe disposal of needles, syringes, IV supplies, or unused chemotherapy medications.	✓	✓
• List possible side effects of chemotherapeutic agents.	✓	✓
• List complications of medications necessitating a call to the nurse or physician.	✓	✓
• List complications of medications necessitating a visit to the emergency department.	✓	✓
• List names and telephone numbers of resource personnel involved in care (ie, home care nurse, infusion services, IV vendor, equipment company).	✓	✓
• Explain treatment plan (protocol) and importance of upcoming visits to physician.	✓	✓

NURSING ALERT

If extravasation is suspected, the medication administration is stopped immediately, and dependent on the drug, an attempt is made to aspirate any remaining drug from the extravasation site through the existing needle.

Institutional nursing policies should be available to identify nursing intervention and an extravasation kit should be readily available with all of the emergency equipment and antidote medication, as well as a quick reference for how to properly manage an extravasation of the specific vesicant agent used. Application of heat or cold is very dependent on the drug administered, and nurses should refer to their hospital policy. In general, cold compresses are indicated for doxorubicin extravasation but are of no benefit for taxane or oxaliplatin (Eloxatin) extravasation. Warm compresses are recommended for vinca alkaloid extravasation. Depending on the guidelines for specific agents, extravasation management may include aspiration of any infiltrated medication from the tissues and injection of a neutralizing solution into the area to reduce tissue damage. Selection of the neutralizing solution depends on the extravasated agent. Recent research has suggested that dexrazoxane (Totect) IV infusion for 3 days has benefit in treatment of anthracycline (ie, doxorubicin) extravasation with prevention of tissue necrosis (Schulmeister, 2007). Application of topical ointments, such as dexamethasone (Decadron) ointment, has been reported with variable levels of effectiveness. Recommendations and guidelines for managing vesicant extravasation have been issued by individual medication manufacturers, pharmacies, and the Oncology Nursing Society, and they differ from one medication to the next (Gullatte, 2007; Sauerland, et al., 2006).

Prevention of extravasation is essential and relies on vigilant nursing care. Vesicant chemotherapy should never be administered in peripheral veins involving the hand or wrist. Peripheral administration is permitted for short duration infusions only, and placement of the venipuncture site should be on the forearm area using a soft, plastic catheter. For any frequent, or prolonged administration of antineoplastic vesicants, right atrial silastic catheters, implanted

venous access devices, or peripherally inserted central catheters (PICC) should be inserted to promote safety during medication administration and reduce problems with access to the circulatory system (Figs. 16-3 and 16-4). Indwelling or subcutaneous catheters require vigilant nursing care. Complications associated with their use include infection and thrombosis (Arch, 2007).

Hypersensitivity Reactions

Most of the available chemotherapeutic agents have the potential to cause hypersensitivity reactions; however, the overall incidence of hypersensitivity reactions to these agents is only about 5%. Understanding and managing hypersensitivity reactions is critical when caring for patients receiving chemotherapy because these reactions are potentially

Figure 16-3 Right atrial catheter. The right atrial catheter is inserted into the subclavian vein and advanced until its tip lies in the superior vena cava just above the right atrium. The proximal end is then tunneled from the entry site through the subcutaneous tissue of the chest wall and brought out through an exit site on the chest. The Dacron cuff anchors the catheter in place and serves as a barrier to infection.

Figure 16-4 Implanted vascular access device. **(A)** A schematic diagram of an implanted vascular access device used for administration of medications, fluids, blood products, and nutrition. The self-sealing septum permits repeated puncture by Huber needles without damage or leakage. **(B)** Two Huber needles used to enter the implanted vascular port. The 90-degree needle is used for top-entry ports for continuous infusions.

life-threatening. Prevention is the first line of defense, and nurses need to have a clear understanding of which agents have the potential for precipitating hypersensitivity reactions, determining the patient's responses to certain agents via skin testing, and providing appropriate premedication before administering agents with a high potential for causing hypersensitivity reactions. Education of patients should emphasize the importance of adhering to prescribed self-administered premedication before presenting to the infusion center and recognizing and reporting the signs and symptoms to the nurse once their infusion has started. Early intervention can prevent progression of a reaction to systemic anaphylaxis. Most reactions coincide with chemotherapy agent administration, but some reactions can be delayed or occur after several uneventful courses of therapy. Although patients may react to the first infusion of a chemotherapy agent, repeated exposure increases the likelihood of a reac-

tion along with other predisposing risk factors such as pre-existing allergic reactions to food, blood products, and other medications. Emergency medication and resuscitation equipment should be easily accessible.

The usual chemotherapy hypersensitivity reaction is categorized as a type I immediate, immunoglobulin E mediated reaction. Type I hypersensitivity reactions may present as a local reaction and then rapidly progress to systemic anaphylaxis, or the initial presentation may be an acute life-threatening anaphylaxis. Symptoms include generalized itching with localized or generalized urticaria; flushing of the face, hands, or feet; chest tightness; agitation; nausea and vomiting; dyspnea and bronchospasm; difficulty speaking; feeling of impending doom; and hypotension (Gobel, 2005; Wilkes & Barton-Burke, 2007). The medication should be discontinued immediately and emergency procedures initiated. Many institutions have developed specific protocols for responding to hypersensitivity reactions including standing orders for administration of emergency medications (de Lemos, 2006). Chapter 53 presents further discussion of allergic reaction.

For some chemotherapeutic agents, especially if they are essential in the treatment plan, desensitization procedures may be possible, and the patient is retreated with the agent at reduced dosages or slower infusion rates. Premedication regimens including corticosteroids, histamine-1 and histamine-2 antagonists, and antipyretics are routinely preadministered for certain chemotherapy agents to prevent or minimize potential reactions.

Doxorubicin or daunorubicin can create localized allergic reactions referred to as flare reaction. Patients typically experience a hot, flushed sensation with urticaria and pruritis. The nurse must confirm that the reaction is indeed a flare and not an extravasation. The infusion can be temporarily discontinued and restarted at a slower infusion rate after consultation with the physician and IV administration of hydrocortisone (Solu-Cortef Hydrocortone).

Toxicity

Toxicity associated with chemotherapy can be acute or chronic. Cells with rapid growth rates (eg, epithelium, bone marrow, hair follicles, sperm) are very susceptible to damage, and various body systems may be affected as well.

Gastrointestinal System. Nausea and vomiting are the most common side effects of chemotherapy and may persist for as long as 24 to 48 hours after its administration. Delayed nausea and vomiting may persist for as long as 1 week after chemotherapy.

A number of mechanisms are responsible for the occurrence of nausea and vomiting, including activation of receptors found in the chemoreceptor trigger zone (CTZ) of the medulla, stimulation of the peripheral autonomic and vestibular pathways, cognitive stimulation, or a combination of factors. Medications that can decrease nausea and vomiting include serotonin blockers, such as ondansetron (Zofran), granisetron (Kytril), dolasetron (Anzemet), and palonosetron (Aloxi), which block serotonin receptors of the gastrointestinal tract and CTZ, and dopaminergic blockers, such as metoclopramide (Reglan), which block dopamine receptors of the CTZ. Newer agents include

neurokinin 1 receptor antagonists (eg, aprepitant [Emend]), which block the activity of substance P, a potent neurotransmitter involved in stimulating nausea and vomiting (Jordan, Sippel & Schmoll, 2007).

Nausea and vomiting involve multiple pathways; therefore, corticosteroids, phenothiazines, sedatives, and histamines are helpful, especially when used in combination with serotonin blockers to provide improved antiemetic protection. Delayed nausea and vomiting that occur longer than 48 to 72 hours after chemotherapy are troublesome for some patients. To minimize discomfort, some antiemetic medications are necessary for the first week at home after chemotherapy. Nonpharmacologic approaches such as relaxation techniques, imagery, and acupuncture (Dribble, Luce, Cooper, et al., 2007) can also help decrease stimuli contributing to symptoms. Small frequent meals, bland foods, and comfort foods may reduce the frequency or severity of these symptoms.

The epithelium that lines the oral cavity is susceptible to the effects of chemotherapy; as a result, stomatitis is common. The entire gastrointestinal tract is susceptible to mucositis (inflammation of the mucosal lining), and diarrhea is a common result. Antimetabolites and antitumor antibiotics are the major culprits in mucositis and other gastrointestinal symptoms, including diarrhea, which can be severe in some patients.

Hematopoietic System. Most chemotherapeutic agents cause **myelosuppression** (depression of bone marrow function), resulting in decreased production of WBCs (leukopenia), granulocytes (neutropenia), red blood cells (RBCs) (anemia), and platelets (thrombocytopenia) and increased risk of infection and bleeding. Depression of these cells is the usual reason for limiting the dose of the chemotherapeutic agents. Myelosuppression is predictable, and patients usually reach their nadir counts (point at which blood counts are lowest) 7 to 14 days after chemotherapy has been administered. At this time nurses anticipate associated toxicities, especially febrile neutropenia (fever associated with neutrophil count less than 1500 cells/mm^3). Frequent monitoring of blood cell counts is essential and strategies are implemented to protect patients from infection and injury, particularly while blood cell counts are depressed (Duong & Loh, 2006; Nirenberg, et al., 2006).

Other agents, called colony-stimulating factors (granulocyte colony-stimulating factor [G-CSF] and granulocyte-macrophage colony-stimulating factor [GM-CSF]), can be administered after chemotherapy to stimulate the bone marrow to produce WBCs, especially neutrophils, at an accelerated rate, thus decreasing the duration of neutropenia. G-CSF and GM-CSF decrease the episodes of infection and the need for antibiotics and allow for more timely cycling of chemotherapy with less need to reduce the dosage. Erythropoietin (EPO) stimulates RBC production, thus decreasing the symptoms of chronic anemia and reducing the need for blood transfusions. Interleukin 11 (IL-11) stimulates the production of platelets and can be used to prevent and treat thrombocytopenia (platelet count less than 100,000) but has had limited use because of toxicities such as fatigue, edema, dysrhythmias, and syncope (Burcat & McAdams, 2007; Hurter & Bush, 2007; Nirenberg, et al., 2006).

Renal System. Chemotherapeutic agents can damage the kidneys because of their direct effects during excretion and the accumulation of end products after cell lysis. Cisplatin, methotrexate (Trexall, Rheumatex), and mitomycin are particularly toxic to the kidneys. Rapid tumor cell lysis after chemotherapy results in increased urinary excretion of uric acid, which can cause renal damage. In addition, intracellular contents are released into the circulation, resulting in hyperkalemia, hyperphosphatemia, and hypocalcemia. (See later discussion of tumor lysis syndrome.)

Monitoring blood urea nitrogen (BUN), serum creatinine, creatinine clearance, and serum electrolyte levels is essential. Adequate hydration, diuresis, alkalinization of the urine to prevent formation of uric acid crystals, and allopurinol may be used to prevent these side effects (Duong & Loh, 2006; Gullatte, 2006). Amifostine has demonstrated an ability to minimize renal toxicities associated with cisplatin, cyclophosphamide (Cytosan), and ifosfamide (Ifex) therapy (Hogle, 2007).

Hemorrhagic cystitis is a bladder toxicity resulting from cyclophosphamide and ifosfamide therapy. Hematuria can range from microscopic to frank bleeding with symptoms ranging from transient irritative urination, dysuria, suprapubic pain, to life-threatening hemorrhage. Protection of the bladder focuses on aggressive IV hydration, frequent voiding, and diuresis. Mesna (Mesnex) is a cytoprotectant agent that binds with the toxic metabolites of cyclophosphamide or ifosfamide in the kidneys to prevent hemorrhagic cystitis (Hogle, 2007; Wilkes & Barton-Burke, 2007).

Cardiopulmonary System. Anthracyclines (daunorubicin and doxorubicin) are known to cause irreversible cumulative cardiac toxicities, especially when total dosage reaches 600 mg/m^2 and 550 mg/m^2 , respectively. If these agents are administered in the presence of thoracic radiation therapy or other agents with cardiotoxicity potential, their cumulative dose limit is reduced to 450 mg/m^2 . Dexrazoxane (Zinecard) has been utilized as a cardioprotectant when doxorubicin is needed in individuals who have already received a cumulative dose of 300 mg/m^2 and continuation of therapy is deemed beneficial (Wilkes & Barton-Burke, 2007; Hogle, 2007). Cardiac ejection fraction (volume of blood ejected from the heart with each beat) and signs of heart failure must be monitored closely.

Bleomycin (Blenoxane), carmustine (BCNU), and busulfan (Busulfex, Myleran) have cumulative toxic effects on lung function, resulting in pulmonary fibrosis. Therefore, patients are monitored closely for changes in pulmonary function, including pulmonary function test results. Total cumulative doses of bleomycin should not exceed 400 U, and carmustine should not exceed 1400 mg.

Capillary leak syndrome with resultant pulmonary edema is a toxic effect of cytarabine (DepoCyt, Tarabine) (AraC), mitomycin C, cyclophosphamide, and BCNU. Subtle onset of dyspnea and cough may progress rapidly to acute respiratory distress and subsequent respiratory failure (Wilkes & Barton-Burke, 2007).

Reproductive System. Testicular and ovarian function can be affected by chemotherapeutic agents, resulting in possible sterility. Normal ovulation, early menopause, or permanent sterility may occur. In men, temporary or permanent

azoospermia (absence of spermatozoa) may develop. Because treatment may damage reproductive cells, banking of sperm is often recommended for men before treatment is initiated. Patients and their partners need to be informed about potential changes in reproductive function resulting from chemotherapy. They are advised to use reliable methods of birth control while receiving chemotherapy and not to assume that sterility has resulted.

Neurologic System. Chemotherapy-induced neurotoxicity can affect the CNS, peripheral nervous system (PNS), the cranial nerves or a combination; it is a dose-limiting toxicity. The blood–brain barrier can protect the CNS and PNS from the toxic effects of most water soluble chemotherapy agents, but neurotoxicity characterized by metabolic encephalopathy can occur with ifosfamide, high-dose methotrexate, and cytarabine. With repeated doses, the taxanes and plant alkaloids, especially vincristine, can cause peripheral neurologic damage with sensory alterations in the feet and hands. These sensations can be described as tingling, pricking, or numbness of the extremities, burning or freezing pain, sharp, stabbing, or electric shock–like pain and extreme sensitivity to touch. If unreported by patients or undetected, progressive motor axon damage can lead to loss of deep tendon reflexes, with muscle weakness, loss of balance and coordination, and paralytic ileus. Although usually reversible, these side effects may take many months to resolve. Along with the usual paresthesias of the hands and feet, oxaliplatin has a unique and frightening neurotoxicity presentation that is often precipitated by exposure to cold and is characterized by pharyngolaryngeal dysesthesia consisting of lip paresthesia, discomfort or tightness in the back of the throat, inability to breathe, and jaw pain. Patients receiving oxaliplatin must be instructed to avoid drinking cold fluids or going outside with hands and feet exposed to cold temperatures to avoid exacerbation of these symptoms. Cisplatin may cause peripheral neuropathies and hearing loss due to damage to the acoustic nerve (Wilkes & Barton-Burke, 2007). The ability of cytoprotectant agents to prevent these significant neurotoxicities, including amifostine, is being studied (Hogle, 2006; Wilkes & Barton-Burke, 2007).

Fatigue. Fatigue, a distressing side effect for most patients that greatly affects quality of life, can last for months after treatment. Assessment and nursing management of fatigue are discussed in the Nursing Care of Patients With Cancer section of this chapter. In 2006, the Oncology Nursing Society conducted an exhaustive review of evidence-based interventions for fatigue management to provide guidelines for nurses to effectively intervene and assist their patients (Mitchell, Beck, Hood, et al., 2007).

Nursing Management in Chemotherapy

Nurses play an important role in assessing and managing many of the problems experienced by patients undergoing chemotherapy. Chemotherapeutic agents affect both normal and malignant cells, meaning that these problems are often widespread, affecting many body systems.

Assessing Fluid and Electrolyte Status

Anorexia, nausea, vomiting, altered taste, mucositis, and diarrhea put patients at risk for nutritional and fluid and

electrolyte disturbances. Therefore, it is important for the nurse to assess the patient's nutritional and fluid and electrolyte status frequently and to use creative ways to encourage an adequate fluid and dietary intake.

Modifying Risks for Infection and Bleeding

Suppression of the bone marrow and immune system is expected and frequently serves as a guide in determining appropriate chemotherapy dosage but increases the risk of anemia, infection, and bleeding disorders. Nursing assessment and care address factors that would further increase the patient's risk. The nurse's role in decreasing the risk for infection and bleeding is discussed further in the Nursing Care of Patients With Cancer (see p. 366).

Administering Chemotherapy

The local effects of the chemotherapeutic agent are also of concern. The patient is observed closely during its administration because of the risk and consequences of extravasation, particularly of vesicant agent. Local difficulties or problems with administration of chemotherapeutic agents are brought to the attention of the physician promptly so that corrective measures can be taken immediately to minimize local tissue damage. (See previous discussion of extravasation.)

Protecting Caregivers

Nurses involved in handling chemotherapeutic agents may be exposed to low doses of the agents by direct contact, inhalation, or ingestion. Urinalyses of personnel repeatedly exposed to cytotoxic agents have demonstrated mutagenic activity. Although long-term studies of nurses who handle chemotherapeutic agents have not been conducted, it is known that chemotherapeutic agents are associated with secondary formation of cancers and chromosome abnormalities. In addition, nausea, vomiting, dizziness, alopecia, and nasal mucosal ulcerations have occurred in health care personnel who have handled chemotherapeutic agents. The Occupational Safety and Health Administration, Oncology Nursing Society, hospitals, and other health care agencies have developed specific precautions for health care providers involved in the preparation and administration of chemotherapy (Chart 16-5) (Polovich, et al., 2005; Wilkes & Barton-Burke, 2007). Nurses must be familiar with their institutional policies regarding personal protective equipment, handling and disposal of chemotherapeutic agents and supplies, and management of accidental spills or exposures. Emergency spill kits should be readily available in any treatment area where chemotherapy is prepared or administered. Precautions must also be taken when handling any bodily fluids or excreta from the patient, as many agents are excreted unaltered in urine and feces. Nurses have a responsibility to educate patients, caregivers, assistive personnel, and housekeepers concerning these precautions.

Bone Marrow Transplantation

Although surgery, radiation therapy, and chemotherapy have improved survival rates for patients with cancer, many cancers that initially respond to therapy recur. This is true of hematologic cancers that affect the bone marrow and solid tumor cancers treated with lower doses of antineoplastics to

Chart 16-5 • Safety in Administering Chemotherapy

Safety recommendations from the Occupational Safety and Health Administration (OSHA), Oncology Nursing Society (ONS), hospitals, and other health care agencies for the preparation and handling of antineoplastic agents follow:

- Use a biologic safety cabinet for the preparation of all chemotherapy agents.
- Wear surgical gloves when handling antineoplastic agents and the excretions of patients who received chemotherapy.
- Wear disposable, long-sleeved gowns when preparing and administering chemotherapy agents.
- Use Luer-Lok fittings on all intravenous tubing used to deliver chemotherapy.
- Dispose of all equipment used in chemotherapy preparation and administration in appropriate, leak-proof, puncture-proof containers.
- Dispose of all chemotherapy wastes as hazardous materials.

When followed, these precautions greatly minimize the risk of exposure to chemotherapy agents.

spare the bone marrow from larger, ablative doses of chemotherapy or radiation therapy. The role of bone marrow transplantation (BMT) for malignant and some non-malignant diseases continues to grow.

The process of obtaining donor cells has evolved over the years. Donor cells can be obtained by the traditional harvesting of large amounts of bone marrow tissue under general anesthesia in the operating room. However, a second method, referred to as peripheral blood stem cell transplantation (PBSCT), has gained widespread use. This method of collection uses apheresis of the donor to collect peripheral blood stem cells (PBSCs) for reinfusion. It is a safe and cost-effective means of collection rather than the traditional harvesting of marrow, which requires general anesthesia and an operative procedure.

Types of Bone Marrow Transplant

Types of BMT based on the source of donor cells include:

- **Allogeneic:** from a donor other than the patient; donor may be a related donor (ie, family member) or a matched unrelated donor (national bone marrow registry, cord blood registry)
- **Autologous:** from the patient
- **Syngeneic:** from an identical twin

Allogeneic BMT (AlloBMT), used primarily for disease of the bone marrow, depends on the availability of a human leukocyte antigen–matched donor. This greatly limits the number of possible transplants. An advantage of AlloBMT is that the transplanted cells should not be immunologically tolerant of a patient's malignancy and should cause a lethal **graft-versus-tumor effect**, in which the donor cells recognize the malignant cells and act to eliminate them.

AlloBMT may involve either ablative (high-dose) or nonablative (mini-dose) chemotherapy. In ablative AlloBMT, the recipient must undergo ablative doses of chemotherapy and possibly total body irradiation to destroy all existing bone marrow and malignant disease. The har-

vested donor marrow or PBSCs are infused intravenously into the recipients, and they travel to sites in the body where they produce bone marrow and establish themselves. Once engraftment is complete (2 to 4 weeks, sometimes longer), the new bone marrow becomes functional and begins producing RBCs, WBCs, and platelets. In nonablative AlloBMT, the chemotherapy doses are lower and are aimed at suppressing the recipient's immune system to allow engraftment of donor bone marrow or PBSCs. The lower doses of chemotherapy create less organ toxicity and thus can be offered to older patients or those with underlying organ dysfunction for whom high-dose chemotherapy would be prohibitive. After engraftment, it is hoped that the donor cells will create a graft-versus-tumor effect (Rodriguez, Tariman, Encio, et al., 2007; Saria & Gosselin-Acomb, 2007). Before engraftment, patients are at high risk for infection, sepsis, and bleeding. Side effects of the high-dose chemotherapy and total body irradiation can be acute and chronic. Acute side effects include alopecia, hemorrhagic cystitis, nausea, vomiting, diarrhea, and severe stomatitis. Chronic side effects include sterility, pulmonary dysfunction, cardiac dysfunction, and liver disease.

To prevent **graft-versus-host disease (GVHD)**, patients receive immunosuppressant drugs, such as cyclosporine (Sandimmune), methotrexate, tacrolimus (Prograf), or sirolimus (Rapamune). In allogeneic transplant recipients, GVHD occurs when the T lymphocytes from the transplanted donor marrow or PBSCs become activated and mount an immune response against the recipient's tissues (skin, gastrointestinal tract, liver). T lymphocytes respond in this manner because they view the recipient's tissue as "foreign," immunologically different from what they recognize as "self" in the donor. GVHD may occur acutely or chronically. Clinical manifestations of acute GVHD include diffuse rash progressing to blistering and desquamation similar to second-degree burns; mucosal shedding with subsequent diarrhea that may exceed 2 L per day; and biliary stasis with abdominal pain, hepatomegaly, and elevated liver enzymes progressing to obstructive jaundice. GVHD accounts for approximately 10% of all BMT deaths (Saria & Gosselin-Acomb, 2007).

The first 100 days or so after AlloBMT are crucial for patients; the immune system and blood-making capacity (hematopoiesis) must recover sufficiently to prevent infection and hemorrhage. Most acute side effects, such as nausea, vomiting, and mucositis, also resolve in the initial 100 days after transplantation. Patients are also at risk for venous occlusive disease (VOD), a vascular injury to the liver caused by high-dose chemotherapy, leading to hepatic outflow obstruction and portal hypertension, in the first 30 days or so after BMT, acute liver failure, and death (Saria & Gosselin-Acomb, 2007).

Autologous BMT (AuBMT) is considered for patients with disease of the bone marrow who do not have a suitable donor for AlloBMT and for patients who have healthy bone marrow but require bone marrow–ablative doses of chemotherapy to cure an aggressive malignancy. Conditions include non-Hodgkin and Hodgkin lymphoma, multiple myeloma, neuroblastoma, sarcoma, and germ cell tumors. Stem cells are collected from the patient and preserved for reinfusion; if necessary, they are treated to kill any malignant

cells within the marrow, called purging. The patient is then treated with ablative chemotherapy and, possibly, total body irradiation to eradicate any remaining tumor. Stem cells are then reinfused and engrafted. Until engraftment occurs in the bone marrow sites of the body, there is a high risk of infection, sepsis, and bleeding. Acute and chronic toxicities from chemotherapy and radiation therapy may be severe. The risk of VOD is also present after autologous transplantation. No immunosuppressant medications are necessary after AuBMT because the patient does not receive foreign tissue. A disadvantage of AuBMT is the risk that tumor cells may remain in the bone marrow despite high-dose chemotherapy (conditioning regimens).

Syngeneic transplants result in less incidence of GVHD and graft rejection; however, there is also less graft-versus-tumor effect to fight the malignancy. For this reason, even when an identical twin is available for marrow donation, another matched sibling or even an unrelated donor may be the most suitable donor to combat an aggressive malignancy.

Nursing Management in Bone Marrow Transplantation

Nursing care of patients undergoing BMT is complex and demands a high level of skill. Transplantation nursing can be extremely rewarding yet extremely stressful. The success of BMT is greatly influenced by nursing care throughout the transplantation process.

Implementing Pretransplantation Care

All patients must undergo extensive pretransplantation evaluations to assess the current clinical status of the disease. Nutritional assessments, extensive physical examinations, organ function tests, and psychological evaluations are conducted. Blood work includes assessing past antigen exposure (eg, hepatitis virus, cytomegalovirus, herpes simplex virus, human immunodeficiency virus [HIV], and syphilis). The patient's social support systems and financial and insurance resources are also evaluated. Informed consent and patient teaching about the procedure and pretransplantation and posttransplantation care are vital.

Providing Care During Treatment

Skilled nursing care is required during the treatment phase of BMT when high-dose chemotherapy (conditioning regimen) and total body irradiation are administered. The acute toxicities of nausea, diarrhea, mucositis, and hemorrhagic cystitis require close monitoring and constant attention by the nurse.

Nursing management during bone marrow infusion or stem cell reinfusions consists of monitoring the patient's vital signs and blood oxygen saturation; assessing for adverse effects, such as fever, chills, shortness of breath, chest pain, cutaneous reactions, nausea, vomiting, hypotension or hypertension, tachycardia, anxiety, and taste changes; and providing ongoing support and patient teaching. During stem cell reinfusion, patients may experience adverse reactions to the cryoprotectant dimethyl sulfoxide (DMSO) used to preserve the harvested stem cells. These reactions may include nausea, vomiting, chills, dyspnea, cardiac dysrhythmias, and hypotension progressing to cardiac or respiratory arrest (Rodríguez, et al., 2007).

Until engraftment of the new marrow occurs, the patient is at high risk for death from sepsis and bleeding. A cluster of symptoms referred to as engraftment syndrome occurs during the neutrophil recovery phase in both allogeneic and autologous transplants. Clinical features of this syndrome vary widely but may include noninfectious fever associated with skin rash, weight gain, diarrhea, and pulmonary infiltrates, with improvement noted after the initiation of corticosteroid therapy rather than antibiotic therapy (Saria & Gosselin-Acomb, 2007). Until engraftment is well established, the patient requires support with blood products and hemopoietic growth factors.

Potential infections may be bacterial, viral, fungal, or protozoan in origin. During the first 30 days following transplant, the patient is most at risk for developing reactivations of viral infections including herpes simplex, Epstein-Barr, cytomegalovirus, and varicella zoster. Mucosal denudement poses a risk for *Candida* yeast infection locally and systemically. Pulmonary toxicities offer the opportunity for fungal infections such as *Aspergillus*. Renal complications arise from the nephrotoxic chemotherapy agents used in the conditioning regimen or those used to treat infection (amphotericin B, aminoglycosides). Tumor lysis syndrome and acute tubular necrosis are also risks after BMT. Nursing assessment for signs of these complications is essential for early identification and treatment (Burcat & McAdams, 2007; Rodríguez, et al., 2007; Saria & Gosselin-Acomb, 2007).

GVHD requires skillful nursing assessment to detect early effects on the skin, liver, and gastrointestinal tract. VOD resulting from the conditioning regimens used in BMT can result in fluid retention, jaundice, abdominal pain, ascites, tender and enlarged liver, and encephalopathy. Pulmonary complications, such as pulmonary edema, interstitial pneumonia, and other pneumonias, often complicate the recovery after BMT (Saria & Gosselin-Acomb, 2007).

Providing Posttransplantation Care

Caring for Recipients. Ongoing nursing assessment in follow-up visits is essential to detect late effects of therapy after BMT, which occur 100 days or more after the procedure. Late effects include infections (eg, varicella zoster infection), restrictive pulmonary abnormalities, and recurrent pneumonias. Sterility often results due to total body irradiation as part of the ablative regimen. Chronic GVHD involves the skin, liver, intestine, esophagus, eyes, lungs, joints, and vaginal mucosa. Cataracts may also develop after total body irradiation.

Psychosocial assessments by nursing staff must be ongoing. In addition to the stressors affecting patients at each phase of the transplantation experience, marrow donors and family members also have psychosocial needs that must be addressed.

Caring for Donors. Like BMT recipients, donors also require nursing care. They commonly experience mood alterations, decreased self-esteem, and guilt from feelings of failure if the transplantation fails. Family members must be educated and supported to reduce anxiety and promote coping during this difficult time. In addition, they must also be assisted to maintain realistic expectations of themselves as well as of the patient. As BMT becomes more prevalent, many ethical issues

become apparent, including those related to informed consent, allocation of resources, and quality of life.

Hyperthermia

Hyperthermia (thermal therapy), the generation of temperatures greater than physiologic fever range (greater than 41.5°C [106.7°F]), has been used for many years to destroy cancerous tumors. Malignant cells may be more sensitive than normal cells to the harmful effects of high temperatures for several reasons. Malignant cells lack the mechanisms necessary to repair damage caused by elevated temperatures. Most tumor cells lack an adequate blood supply to provide needed oxygen during periods of increased cellular demand, such as during hyperthermia. Cancerous tumors lack blood vessels of adequate size for dissipation of heat. In addition, the body's immune system may be indirectly stimulated when hyperthermia is used.

Hyperthermia is most effective when combined with radiation therapy, chemotherapy, or biologic therapy. Hyperthermia and radiation therapy are thought to work well together because hypoxic tumor cells and cells in the S phase of the cell cycle are more sensitive to heat than radiation; the addition of heat damages tumor cells so that they cannot repair themselves after radiation therapy. Hyperthermia is thought to alter cellular membrane permeability when used with chemotherapy, allowing for an increased uptake of the chemotherapeutic agent. Hyperthermia may enhance the function of immune system cells, such as macrophages and T cells (Milani & Noessner, 2006; van der Zee & van Rhoon, 2006).

Heat can be produced by using radiowaves, ultrasound, microwaves, magnetic waves, hot-water baths, or even hot-wax immersions. Hyperthermia may be local or regional, or it may include the whole body. Local or regional hyperthermia may be delivered to a cancerous extremity (for malignant melanoma) by regional perfusion, in which the affected extremity is isolated by a tourniquet and an extracorporeal circulator heats the blood flowing through the affected part. Hyperthermia probes may also be inserted around a tumor in a local area and attached to a heat source during treatment. Chemotherapeutic agents, such as melphalan (Alkeran), may also be heated and instilled into the region's circulating blood. Local or regional hyperthermia may also include infusion of heated solutions into cancerous body organs. Whole body hyperthermia to treat disseminated disease may be achieved by extracorporeal circulation, immersion of the patient in heated water or paraffin, or enclosure in a heated suit (Bruner, et al., 2006; van der Zee & van Rhoon, 2006).

Side effects of hyperthermia treatments include skin burns and tissue damage, fatigue, hypotension, peripheral neuropathies, thrombophlebitis, nausea, vomiting, diarrhea, and electrolyte imbalances. Resistance to hyperthermia may develop during the treatment because cells adapt to repeated thermal insult. Research into the effectiveness of hyperthermia is ongoing.

Nursing Management in Hyperthermia

Although hyperthermia has been used for many years, many patients and their families are unfamiliar with this cancer treatment. Consequently, they need explanations about the

procedure, its goals, and its effects. The nurse assesses the patient for adverse effects and acts to reduce the occurrence and severity of adverse effects. Local skin care at the site of the implanted probes is necessary.

Targeted Therapies

Recent scientific advances have led to an improved understanding of cancer development. Traditional therapies such as chemotherapy and radiation affect all actively proliferating cells. As a result, both healthy cells and malignant cells are subject to harmful systemic effects of treatment. **Targeted therapies** seek to minimize the negative effects on healthy tissues by disrupting specific cancer cell functions such as malignant transformation, cell communication pathways (called signal transduction), processes for growth and metastasis, and genetic coding. Actions of targeted therapies include stimulation or augmentation of immune responses through the use of biologic response modifiers, targeting of cancer cell growth factors, promotion of apoptosis, and genetic manipulation through gene therapy (Khoukaz, 2006; Rieger, 2006). Most of the currently available targeted therapies are categorized as either monoclonal antibodies or small molecule tyrosine kinase inhibitors.

Biologic Response Modifiers

Biologic response modifier (BRM) therapy involves the use of naturally occurring or recombinant (reproduced through genetic engineering) agents or treatment methods that can alter the immunologic relationship between the tumor and the cancer patient (host) to provide a therapeutic benefit. Although the mechanisms of action vary with each type of BRM, the goal is to destroy or stop the malignant growth. The basis of BRM treatment lies in the restoration, modification, stimulation, or augmentation of the body's natural immune defenses against cancer (Yarbro, et al., 2005).

Nonspecific Biologic Response Modifiers

Some of the early investigations of the stimulation of the immune system involved nonspecific agents such as bacille Calmette-Guérin (BCG) and *Corynebacterium parvum*. When injected into the patient, these agents serve as antigens that stimulate an immune response. The hope is that the stimulated immune system will then eradicate malignant cells. Extensive animal and human investigations with BCG have shown promising results, especially in treating localized malignant melanoma. In addition, BCG bladder instillation (intravesicular) is a standard form of treatment for localized bladder cancer (Creel, 2007). However, use of nonspecific agents in advanced cancer remains limited, and research is ongoing to identify other uses and other agents.

Monoclonal Antibodies

Monoclonal antibodies (MoAbs), another type of BRM, have become available through technologic advances, enabling investigators to grow and produce targeted antibodies for specific malignant cells. Theoretically, this type of specificity allows MoAbs to destroy the cancer cells and spare normal cells. The specificity of MoAbs is dependent on identifying key antigen proteins on the surface of tumors that are not present on normal tissues. These targets when

blocked lead to apoptosis by disrupting communication between cells. There are several categories of these tumor-associated antigens: oncofetal antigens such as CEA, a prominent tumor marker identified in colon cancer; growth factors such as EGFs and VEGFs; and oncogenes such as *C-erb* or *Bcr-Abl* (Kay, 2006). MoAbs bind with specific tumor cell antigens and block the ability of the tumor cell to reproduce, or deliver cytotoxic agents directly to the tumor cell causing cell death.

The production of MoAbs involves injecting tumor cells that act as antigens into mice. B cells in the spleen of the mouse produce immunoglobulin antibodies made in response to the injected antigens. Antibody-producing B cells are combined with a cancer cell that has the ability to grow indefinitely in culture medium and continue producing more antibodies.
