Check medication label three times before administering the medication:

- When retrieving the medication from storage area.
- When preparing the medication.
- When returning the medication to storage area.

- Determine if any calculation is necessary to prepare the correct dosage.
- Calculate client's dosage based on strength of medication, if indicated. Have another nurse double check your calculation. (See page 626 for formulas.)
- Prepare medication as indicated for nonparenteral or parenteral route, checking drug label before, during, and after preparation.

▲ Check individually wrapped medication against client's MAR.

Converting Dosage Systems

Procedure

- To make conversions from the metric to apothecaries' or household systems, it is necessary to memorize or refer to equivalency tables.
- To convert milligrams to grains, use the following formula:

$$\frac{1 \text{ grain}}{\text{milligrams per grain}} = \frac{\text{Dose desired}}{\text{Dose on hand}}$$

$$\frac{1}{60} = \frac{X}{180}$$

$$60X = 180$$

$$X = 3 \text{ grains}$$

- You may also use ratio and proportion to calculate dosage:

$$1 \text{ gr}:60 \text{ mg} :: X \text{ gr}:180 \text{ mg}$$

$$60X = 180$$

$$X = 3 \text{ gr}$$

- To convert milligrams to milliliters, you can set up a direct proportion and, following the algebraic principle, cross multiply.
- Check Conversion Tables in the Drug Supplement at the end of the chapter.

Calculating Dosages

Equipment

- Orders for dosage of medication needed
- Dosage of medication on hand

Procedure

- To calculate oral dosages, use the following formula. (D and H must be in same unit of measure.)

$$\frac{D}{H} = X$$

where D = dose desired; H = dose on hand; and X = dose to be administered.

Example: Give 500 mg of ampicillin sodium when the dose on hand is in capsules containing 250 mg.

$$\frac{500 \text{ mg}}{250 \text{ mg}} = 2 \text{ capsules}$$

- To calculate dose when in liquid form, use the following formula:

$$\frac{D}{H} \times Q = X$$

where D = dose desired; H = dose on hand; Q = quantity; and X = amount to be administered

Example: Give 375 mg of ampicillin when it is supplied as 250 mg/5 mL.

$$\frac{375 \text{ mg}}{250 \text{ mg}} \times 5$$

$$1.5 \times 5 = 7.5 \text{ mL}$$

- To calculate parenteral dosages, use the following formula:

$$\frac{D}{H} \times Q = X$$

Example: Give client 40 mg gentamicin C complex sulfate. On hand is a multidose vial with a strength of 80 mg/2 mL.

$$\frac{40}{80} \times 2 = 1 \text{ mL}$$

- To calculate dosages for infants and children using BSA:

$$\frac{\text{BSA}^*}{1.7} \times \text{adult dose} = \text{pediatric dose}$$

*BSA = body surface area.

See *Pediatric Nursing*, 3rd ed., by Jane Ball and Ruth Bindler, 2003, Prentice Hall, for complete description of method to determine body surface area.

- To calculate dosages for infants and children using Clark's weight rule:

$$\text{Child's dose} = \frac{\text{Child's wt. in lbs.}}{150} \times \text{Adult dose}$$

- Check your calculations before drawing up the medications.

NOTE: Calculation of Solutions is in the Drug Supplement section at the end of the chapter.

Using the Narcotic Control System

Equipment

- Medication record sheet
- Narcotic sign-out sheet
- Medication

Procedure

For Client Administration

- Check client's medication sheet for narcotic order.
- Check dose and time last narcotic was administered.
- Unlock and open narcotic drawer and find appropriate narcotic container.
- Count the number of pills, ampules, or prefilled cartridges in container.
- Check the narcotic sign-out sheet, and check that the number of narcotics in drawer matches the number on

specific narcotic sign-out sheet. ► **Rationale:** Laws on controlled substances require careful monitoring of narcotics.

- Correct any discrepancy before proceeding with narcotic administration.
- Sign out for the narcotic on the narcotic sheet after taking narcotic out of drawer.
- Lock drawer after dispensing medication.
- Administer medication according to specific oral or parenteral procedure.
- Document narcotic on client's medication record according to agency procedure. Include client's sedation level and pain rating (e.g., 8/10) before and after narcotic administration according to agency policy.

▲ Lock narcotic drawer after removing medication. Keep key with you at all times.

For Unit Narcotic Stock

11. Check narcotic counts every 8 hr. One off-going and one on-coming *licensed* nurse must check the narcotics together. The number on each narcotic sign-out sheet must match the number of that particular narcotic remaining in the drawer.
12. Explore any discrepancy in stock and recorded dispensed narcotic numbers. ► **Rationale:** Counts must balance. It is the nurse's responsibility to account for all controlled substances dispensed.

▲ User ID and password or scanned fingerprint control access to medications.

▲ Sign on specific narcotic sign-out sheet after taking narcotic out of drawer.

13. Licensed nurses cosign the narcotic record if the count is accurate.

Clinical Alert

If the narcotic depresses breathing, note client's level of sedation and respiratory rate before administering, and document assessment.

▲ Validate that client's MAR matches selected medications and dose on screen.

Using an Automated Dispensing System

Equipment

Automated dispensing system (e.g., PYXIS)
Client's medication record

Preparation

See Medication Preparation (Unit 1), all procedures.

Procedure

1. Touch the screen to activate the system.
2. Enter your ID code number and user password or scanned fingerprint. ► **Rationale:** This process controls access to medications.
3. From the main menu, select command on medication management station (e.g., *remove, waste, return*).

4. Select client's room number, medication, and name and additional identifiers (e.g., *birth date, hospital number*).
5. Touch/select medication desired from client's displayed list of ordered medications.
6. Validate that client's medication record matches selected medication and dose on monitor screen.

Clinical Alert

The usual checks and balances between nurses and pharmacists may be bypassed with automated dispensing systems, increasing the risk for medication errors.

Dispensing Medications—Safe Practices

No technology system eliminates the risk for error. Never become complacent about what technology can do to support safe practice.

No computer has your ability to think critically, to understand whether an ordered drug is appropriate for your client.

Technology (e.g., bar codes) increases the amount of time spent administering medications, but does reduce time spent in documentation.

7. Type in quantity (#) of doses desired if indicated by a range of possible doses ordered.
8. Enter a witness ID/scan (by another nurse) to validate wasted medication (if partial dose is needed).
9. Remove the medication from the automated delivery system.

Hazardous Waste Disposal

Health care produces biohazardous waste, chemical waste, pharmaceutical waste, and other toxins, with each source having environmental consequences. Scientists have found concentrations of antibiotics, hormones, antineoplastic agents, and other chemical products in our water supplies due to improper disposal of pharmaceuticals into the sink, toilet, or trash. Best practice waste management is consistent with regulations mandated by the Environmental Protection Agency:

- Discard pharmaceutical waste into a Medical Waste receptacle (black box):
 1. Any unused oral medication not in package
 2. Unused IV medication that has been partially infused (unused IV fluid with electrolytes and TPN are excluded)
 3. Unused medication in syringes or vials (empty vials, empty IV bags and tubing are discarded in the trash)

Medication Safety Measures

- Accurately and completely reconcile the client's medications across the continuum of care.
- Keep all medications in locked carts or cabinets.
- Limit access to and use special safeguards with "high alert" drugs (those causing significant client harm if used in error; e.g. hypoglycemic, anticoagulant, anesthetic agents, narcotics, paralytic agents, chemotherapy drugs, certain cardiac drugs). This list is periodically updated by the Institute for Safe Medication Practices (ISMP).
- Keep narcotics in double-locked cabinets or PYXIS. Count all narcotics with oncoming staff at the end of each shift.
- Separate topical medications from parenteral or oral medications.
- Clearly label all prepared medication containers (syringes, medicine cups, solutions).
- Check with another nurse (1) mathematical calculations for dosages and (2) dispensed/prepared "high alert" drugs and those for high-risk clients (e.g., insulin, anticoagulants, concentrated electrolytes, digoxin, and hemodynamic agents if not premixed).
- Do not leave any medication at client's bedside unless there is a specific physician's order to do so.
- Report any errors in drug administration to charge nurse and client's physician immediately. Monitor the client closely for adverse effects. Document the drug given, and complete an anonymous written variance report.
- Provide complete instruction to clients regarding medications to be used at home.

▲ Discard pharmaceutical waste into Medical Waste receptacle (black box).

- Chemotherapy Waste Container (yellow) is used to discard any trace chemotherapy (containers, tubing, contaminated PPE).

10. Close drawer/storage door, and exit the system.
11. Prepare medication and administer according to route.

NOTE: Certain medications (e.g., cough syrup and other client-specific multiple-dose medications) may be dispensed by pharmacy and placed in the client's medication drawer rather than being accessed through the automated system.

Clinical Alert

All Joint Commission–accredited agencies must have protocols developed for documenting and reconciling medications across the continuum (admission, transfer, discharge). A list of the client's home medications is compared with the admitting medication orders. Upon transfer, medications being taken are compared with orders in the new unit. Upon discharge, medications taken in the hospital are compared with the discharge medication orders. Verification, clarification, and reconciliation of discrepancies help prevent adverse drug events throughout the client's hospitalization.

Administering Medication Protocol

Equipment

- Prepared medication
- Gloves (if indicated)
- Stethoscope and sphygmomanometer, if indicated

Preparation

See Preparation (Unit 1), all procedures.

Procedure

1. Check client's name and room number against the medication record and lock the medication cart before entering client's room, if cart is used. ► **Rationale:** Locking cart is a safety measure.
2. Check client's Ident-A-Band and ask client to state name and birth date.
3. Provide privacy.
4. Explain procedure and purpose of medication to client.

▲ Check client's name and room number against medication record.

5. Assist client to appropriate position for medication administration.
6. Check client's vital signs if indicated before administering medication. ► **Rationale:** Medication's effects may cause hemodynamic instability if client's vital signs are at the high or low extreme of normal.

Clinical Alert

Use at least two client identifiers other than room number when administering medications or providing treatments (e.g., stated name and birth date or hospital number).

7. Perform hand hygiene and don gloves if indicated. ► **Rationale:** Parenteral and enteral medication administration may require the use of gloves, as well as preparation and administration of oral antineoplastic agents.

▲ Check client's Ident-A-Band and ask client to state name and birth date.

8. Administer medication according to route procedure and adhering to the “six rights” of medication administration.
9. Dispose of equipment appropriately; then remove gloves, if used, and wash your hands.
10. Record administered medications in client’s record; the time, medication given, dosage, and route (including site of injection); and any relevant assessment findings.

EVIDENCE-BASED PRACTICE

Medication Errors—A Growing Problem

- Medication errors originate across the spectrum of care: prescribing, 39%; transcribing, 17%; dispensing, 11%; and administering, 38%. Nurses must identify errors before administering medications: both the mistakes of others, and their own.

Source: Cohen, H. (2008, April). Let’s work together to improve medication safety. *Nursing*, 38(4), 6.

Medication Administration Errors

- In a study involving 400 staff nurses, 30% of full-time staff reported making at least one error in a 28-day period, and another 33% reported a near error. The majority of errors or near errors involved medication administration. Of these events, 25% involved giving the wrong dose, with nurses citing interruptions and distractions during preparation.

Source: Professional Update (2005). *RN*, 68(3), 20.

EVIDENCE-BASED PRACTICE

Wristband Placement

It is best to place all wristbands on the same arm, but best practice requires the nurse to check both arms, and also the ankles since placement here may be required.

Source: Cizek KE, Estrade N, Allen J, Elsholz T. A crystal clear call to standardize color-coded wristbands. *Nursing* 2010; 40 (5) 57-59.

Bar Code Medication Administration

Medication administration errors account for 34% of preventable adverse drug events. Bar code medication administration (BCMA) technology can improve client safety by reducing these errors. The central feature of this point-of-care system is barcode labeling of medications and client wristbands. In order to facilitate implementation, vendors and hospitals usually customize these systems to interface with existing electronic medical records.

Failure to adhere to the steps of the BCMA process may expose the nurse to fraud charges. Hazardous shortcuts (“workarounds”) may lead to patient harm and legal pitfalls.

Steps to take before medication administration:

- Compare the medication order in the client’s medical record against each medication on the eMAR.
- Obtain medication from the automated dispensing cabinet.

▲ Scan the bar code on the client’s ID band.

- Perform a “five rights” check against the eMAR while removing the medication. *Note:* The sixth right is *documentation* and does not apply here.

Steps to perform at the client’s bedside:

- Check client’s Ident-A-Band and ask client to state name and birth date.
- Perform a second “five rights” check of selected medications against the eMAR.
- Scan barcode on client’s Ident-A-Band, then scan bar code on *unopened* medication packaging and bar code on client’s Ident-A-Band.
- Obtain confirmation of bar code matching by the software system and attend to any alarms or cues.
- Prepare scanned medication.
- Administer the medication promptly.
- Document medications administered.

▲ Scan the bar code on the unopened medication packaging to confirm matching.

EVIDENCE-BASED PRACTICE

Interruptions Linked to Medication Errors

This study of 98 nurses administering 4,271 medications to 720 adult clients showed that nurses who are interrupted while preparing and administering medications may have increased risk of making medical errors. Interruptions require switching from one task to another, completing the interrupting task and then returning to the interrupted task. For each interruption there is an increase in procedural (e.g., technique) and clinical error (e.g., dosage). Frequency of interruption was associated with increased severity of error. While some interruptions are excusable when directed toward provision of safe patient care, there is a need to better understand the reasons for high interruption rates.

Source: Barclay, Laurie (2010). Interruptions linked to medication errors by nurses. *Archives of Internal Medicine*, April 26, 2010.

Clinical Alert

Report any actual or potential error (e.g., look-alike/sound-alike drug names, confusion over abbreviations) to the Institute for Safe Medication Practices at 1-800-FAIL-SAF(E) or complete the form at www.ismp.org/orderforms/reporterrortoISMP.asp. All communications are kept confidential. This agency publicizes warnings and notices in response to submitted information to help alert other professionals to potentially dangerous medication pitfalls.

Source: Nurse Advise-ERR, July 2009.

Legal Considerations

Transcription Error and Reconciliation Failure (*Robert Ferguson v. Baptist Health System, Inc, 2005*)

Robert Ferguson brought medical malpractice action against Baptist after experiencing drug toxicity due to a medication (Dilantin) transcription error on the part of the pharmacist and failure on the part of the nurse to conduct reconciliation between the MAR entry and the doctor's order. The physician's order was for Dilantin, 300 milligrams "po QHS." The MAR was generated by pharmacy for Dilantin, 300 milligrams, "t.i.d." The agency policy dictated that any time a new medication order was entered, the nurse initially undertaking to administer the medication was responsible for comparing the MAR to the actual order to "reconcile" the two. In this case, the pharmacy error was not detected by the reconciliation process. Subsequent erroneous doses were administered, but none of the nurses administering the Dilantin detected the error "due to the fact that there were no additional checks, balances, or other safeguards in place to prevent the repetition of the error." No one ever checked the original physician's order "despite the unusually large amount of Dilantin being administered." None of the nurses suspected that Ferguson's symptoms represented Dilantin toxicity. Ferguson was awarded compensatory damages and punitive damages.

McMunn v. Mount Carmel Health et al, 1998

Plaintiff was awarded \$433,415.00 for wrongful death of William Muncney, age 39, resulting from improper administration of morphine and failure to monitor and guard the client from adverse effects of the drugs he received, those known to cause respiratory depression. The client presented to Mount Carmel ED at 1635 with severe pain due to kidney stones. He received 5 mg of morphine IV at 1653, at 1700, and again at 1740. His respiratory rate was 24 and SpO₂ was 92%.

He then received additional 5 mg of intravenous morphine at 1805 and 1820, whereupon his SpO₂ dropped to 86%. The client was placed on oxygen therapy and by 1935 his SpO₂ had increased to 94%.

At 2015 he was admitted as an inpatient. His vital signs were taken at that time, but not again for the evening shift. The nurse had not been advised that the client's O₂ saturation had dropped while he was in the ED. At 2215, the nurse administered 15 mg of morphine sulfate and 50 mg Phenergan by injection. At 2300 it was documented that the client was sleeping, but no vital signs were taken.

At 0105, the nurse was notified that Mr. Muncney was unresponsive and had no pulse or respirations. A "Code Blue" was called, Narcan was given, but the client died. At autopsy, spinal fluid and blood levels of morphine were supportive of death from a respiratory depressant effect of morphine, with levels unusually high explained by the combination of depressant drugs he had received.

Three areas of nursing care were found to fall below the accepted standard: coordination and communication of assessment and care, monitoring of a client receiving narcotics, and documentation of assessments for a client receiving narcotics.

CRITICAL THINKING Application

Expected Outcomes

- Rationale for medication administration is clear.
- Client's MAR matches physician's orders.
- Dosage calculations are accurate.
- Medication sign-out sheet matches remaining stock.

- Medication is administered according to the "Six Rights."
Note: Six rights is correct here because it includes documentation.

Unexpected Outcomes

Medication or dosage on MAR does not fit client's clinical picture.

Alternative Actions

- Compare new MAR with previous MAR.
- Compare new MAR with recent physician's orders.
- Discuss concerns with agency pharmacist.
- Contact physician for clarification.

Nurse is unsure of dosage calculation.

- Utilize helpful calculation formulas.
- Use a calculator.
- Request that another nurse check calculation or conversion.
- Seek agency pharmacist's assistance.

Medication sign-out sheet does not correspond to remaining stock.

- Check with other nurses who may have dispensed stock medication.
- Check MARs for unclaimed stock that may have been administered.
- Complete discrepancy report if sign-out sheets and stock cannot be reconciled.

Client receives the wrong medication.

- Document the medication administered on client's MAR.
- Monitor client closely for potential undesired effects and document findings.
- Notify client's physician and document.
- Complete anonymous variance report according to agency policy.
- Always check two client identifiers before administering medication.

Chapter 18

UNIT 2

Oral Medication Administration

Nursing Process Data

ASSESSMENT Data Base

- Check that medication is to be given by oral route.
- Determine that client is not NPO.
- Determine that client is able to take medication orally.
 - Client is alert.
 - Swallow/gag reflex is present.
 - No risk of aspiration exists.
 - Client is not nauseated/vomiting.
- Determine that medication can be safely altered if necessary for administration.

PLANNING Objectives

- To provide an easy, inexpensive, and convenient route for administering medications
- To ensure that client is able to take oral medication
- To safely administer an altered oral medication
- To facilitate administration of oral medication to the client with swallowing difficulty (dysphagia)
- To administer oral medication to an adult or child

IMPLEMENTATION Procedures

- Preparing Oral Medications 585
 - *For Liquid Medications* 585
 - *For Crushing or Altering Medications* 585
- Administering Oral Medications 587
- Administering Medications per Enteral (NG or NI) Tube 587

EVALUATION Expected Outcomes

- Client takes medication orally without difficulty.
- Client experiences intended therapeutic drug effect.

- Critical Thinking Application** 589
- Expected Outcomes 589
 - Unexpected Outcomes 589
 - Alternative Actions 589

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Preparing Oral Medications

Equipment

Oral medication: tablet, capsule, or liquid from bottle or unit dose.

Client's preference of water, juice, milk, or other vehicle (e.g., jelly, yogurt, pudding) to assist swallowing (if not contraindicated for drug absorption)

Mortar and pestle to crush or pill cutter to divide medication if necessary

Measuring spoon, *calibrated* dropper, syringe or medicine cup

Gloves, for oral antineoplastic agents

Preparation

1. Follow all steps for Medication Preparation (Unit 1).
2. Perform hand hygiene.

Procedure

For Liquid Medications

1. Remove bottle lid and place topside down to avoid contamination.
2. Hold bottle with label facing palm to avoid dripping medication onto label.
3. Set medication cup on firm surface and pour liquid medication; read fluid dispensed at eye level, *read at lowest point of meniscus*. ► **Rationale:** This reading ensures accurate dose of medication.
4. Wipe bottle lip before replacing cap. Check medication label again. ► **Rationale:** This safety check ensures correct drug and dosage.
5. Return multidose bottle to storage area. Sign out for any narcotic dispensed on narcotic sheet with date, client's name, room number, physician's name, dosage, your signature, and any wasted narcotic (co-signed by another nurse/witness).
6. Remember to check the label three times:
 - a. When taking the medication container from storage place.

▲ Palm the label while pouring liquid medication.

▲ Pour liquid at eye level to read dose correctly.

- b. When placing medication into medicine cup.
- c. When returning medication container to storage place.

For Crushing or Altering Medications

1. Leave pill in unit dose packaging and place on firm surface. ► **Rationale:** Labeled packaging maintains identity and prevents loss of medication. If client does not take medication, it can be returned to drawer.
Or:
2. Place pill between two soufflé cups and pound with pestle or other tool to crush, pulverizing thoroughly ► **Rationale:** The cups confine the medication. *Note: This is the preferred method for crushing medication to be given enterally.*
3. Remove any uncrushed pill coating if medication is to be given per feeding tube. ► **Rationale:** To prevent tube clogging.
4. Check orders for partial dose medication. Place tablet in pill cutter or break tablet if scored.
5. If giving orally, mix pulverized medication (or powder from opened capsule) carefully in small amount of soft food (pudding, jelly, applesauce). ► **Rationale:** For many clients with swallowing difficulty, soft food is easier to swallow than liquid.

▲ Place med cups with tablet between to pulverize with crusher.

▲ Place pill in crusher to crush tablet, or pulverize/crush pill in unit dose container.

▲ Mix pulverized medication (for powder from opened capsules) carefully in *small* amount of soft food (pudding, jelly, applesauce).

▲ If partial dose is ordered, place tablet in pill cutter to be cut in half.

6. Open capsule and sprinkle “beads” over soft food to administer. Warn client not to chew the “beads.”
 - ▶ **Rationale:** Beads are formulated for a sustained timed release therapeutic effect.
7. Ensure client has received all of medication.
8. Offer liquid or food to cleanse palate.

General Precautions for Altering Oral Medications

Unsafe Actions

- *Do not* crush enteric coated or gel-coated tablets.
 - ▶ **Rationale:** Coatings allow intestinal absorption of the drug, protect the medication from stomach acid, or protect the stomach from the medication.
- *Do not* crush long-acting tablets. ▶ **Rationale:** Sustained action over hours is the advantage of extended-release versions of drugs. Crushing could yield a toxic dose and eliminate the sustained action needed through the day.
- *Do not* try to open sealed capsules.
- *Do not* crush contents of capsules (e.g., spansule) with beads or pellets. ▶ **Rationale:** These are intended for sustained-release action.
- *Do not* give sublingual formulations orally.
 - ▶ **Rationale:** Ingredients may be inactivated by stomach acid.
- *Do not* crush sublingual formulations.
- *Do not* give oral medications sublingually.
 - ▶ **Rationale:** This could yield a toxic dose since the medication would be absorbed directly into the bloodstream and skip intended first pass through the liver for early metabolism before entering the bloodstream.
- Do not alter (crush, split) tablets or open capsules of antineoplastic agents. ▶ **Rationale:** To avoid sending drug particles into the air where they could be inhaled.

Safe Actions

- Scored tablets may be split. Unscored tablets may be cut unless they are:
 - extended release
 - a combination product
 - a critical dose product
 - film-coated
 - crumbled with cutting

Note: Dispose of unused medication in the Medication Waste receptacle.

- Chewable medications *can be* crushed safely.
- If a capsule opens easily, powder from the capsules *can be* mixed with food or liquid.
- Liquid-filled capsule contents *can be* (a) squeezed out through a hole punched with a large gauge needle, or (b) aspirated, then mixed with food or liquid. *Liquid-filled capsule contents should not be administered sublingually.*
- Beads from readily opened capsules *can be* sprinkled over soft food to administer, *but should not be chewed.*
- A sublingual formulation still *can be* given sublingually if the client is NPO.

Administering Oral Medications to Adults

Equipment

See Equipment for Preparing Oral Medications.

Preparation

1. Follow steps for Administering Medication Protocol, Unit 1.
2. Follow procedure for Preparing Oral Medications.
3. Perform hand hygiene.

Procedure

1. Take medication tray/cart to client's room; check room and bed number against medication record.
2. Check client's Ident-A-Band and ask client to state name and birth date so you are sure you have correct client.
3. Assist client to sitting position.

4. Explain type of medication you are giving and purpose.
5. Determine if specific assessment is indicated before administering medication (e.g., vital signs) and assess client.
6. Remove medication from packet and place into medication cup.
7. Hand medication cup to client if assessment findings do not contraindicate administration.
8. Offer water or other liquid. ► **Rationale:** Aids swallowing, dilution, and absorption of medication.
9. Make sure client swallows medication.
10. Discard used medicine cup.
11. Record medication on client's record, including assessment findings, if indicated.
12. Continue to assess client for desired drug action and possible side effects or adverse reactions.

Administering Medications per Enteral (NG/NI) Feeding Tube

Equipment

See Equipment for Preparing Oral Medications.

Sterile water for diluting and flushing

50-mL irrigating piston (oral) syringe

Clean gloves

Preparation

1. Follow steps for Administering Medication Protocol in Unit 1.
2. Stop any continuous tube feeding for 15 minutes and flush tube with 15 mL of sterile water.

▲ Administer each medication separately, flushing before with 15 mL sterile water. Allow to flow through tube by gravity, then flush tube again with 15 mL sterile water.

▲ Flush tube with 15 mL sterile water after each medication and record total amount on I&O sheet.

▲ For closed system, use medication/irrigation port. Administer each medication separately, flushing before and after with 15 mL sterile water or saline.

3. Follow procedure for Preparing Oral Medications.
4. Obtain liquid dosage form of medication if available.
5. Dilute each medication (crushed tablet, powder from capsule, or liquid medication) separately in 30 mL of warm sterile water (*considering client's fluid balance status*).

NOTE: Do not mix medications together. Do not add medication directly to an external feeding formula. ► **Rationale:** Reduces the risk of physical and chemical incompatibilities, tube obstruction, and altered drug responses.

6. Perform hand hygiene.

Clinical Alert

Consult with pharmacist before deciding to alter the form of *any* medication. Have pharmacist substitute liquid form of medication if available, or substitute a short-acting formulation that can be safely crushed for administration. Contact the physician for a substitute medication if formulation alternatives are unavailable.

Clinical Alert

Never use a parenteral (Luer-Lok) syringe for enteral tube administration. It may then be mistakenly administered IV. Oral syringes are incompatible with IV ports to prevent this hazard.

Procedure

1. Don gloves.
2. Disconnect NG tube from feeding delivery system or select port for decompression.
3. Insert 50-mL oral syringe into NI tube or NG tube decompression port, and aspirate to check residual volume. Return residual and flush tube with 15 mL of sterile water. ► **Rationale:** To validate enteral capacity for receiving medication.

NOTE: Do NOT administer medication through blue pigtail of Salem sump tube (See Chapter 19.)

4. Administer each medication separately, allowing to flow through tube by gravity.
5. Flush tube with 15 mL of sterile water after each medication, monitoring amount of flush to record on I&O sheet. ► **Rationale:** Flushing reduces risk of drug incompatibilities and tube clogging.
6. Restart tube feeding at appropriate time. ► **Rationale:** to avoid altering bioavailability of medication and to avoid compromising client's nutritional therapy.
7. Rinse and replace syringe to storage area at client's bedside.
8. Remove gloves and perform hand hygiene.

(NOTE: See also Chapter 19.)

DOCUMENTATION for Oral Medications

Client's Medication Record

- Name of medication
- Vital signs if indicated
- Dosage
- Route
- Time administered
- Initials of nurse administering medication
 - *Intake and Output record: Amount of sterile water used for medication dilution and administration.*
- Signature of nurse identifying initials

Nurses' Notes

- Client's assessment parameters
- Record PRN, STAT, and one-time-only medications
- Name of medication, dosage, route, time administered
- Client's response
- Signature of nurse

Legal Considerations

Nimodipine capsules were dispensed to the clinical area where they were used for patients who could not swallow. In one case, a nurse softened the gelatin capsule in hot water, withdrew the medication into a parenteral syringe, and the dose was inadvertently

administered as IV instead of via a feeding tube. Subsequently, the patient died. A boxed warning has now been added to the nimodipine labeling to caution about this type of administration error.

Source: ISMP Medication Safety Alert, *Nurse Adviser*, April 2010.

CRITICAL THINKING Application

Expected Outcomes

- Client takes medication orally without difficulty.

Unexpected Outcomes

Client has an allergic or anaphylactic response to medication.

Client has difficulty swallowing medication.

Client is nauseated and oral medications have not been taken.

- Client experiences intended therapeutic drug effect.

Alternative Actions

- Immediately stop or hold medication.
- Notify physician at once; prepare to administer epinephrine to dilate bronchi and support blood pressure.
- If reaction is severe:
 - Keep client flat in bed with head elevated.
 - Take vital signs every 10–15 minutes; stay with client.
 - Assess for hypotension or respiratory distress.
 - Establish airway, if necessary.
 - Have emergency equipment available.
 - Provide psychologic support to client to alleviate fears.
 - Record type and progression of reactions.
- Offer water before administering oral medication.
- Crush medications if appropriate and administer mixed with food such as applesauce, pudding, or jelly.
- Consult pharmacist to dispense same medication in liquid form.
- If difficulty continues, consult physician for altered route of medication delivery (rectal, parenteral).
- Request swallow study.
- Hold medication. Notify physician for antiemetic medication order and alternate route for administering necessary medications.
- Administer antiemetic if ordered, then administer medication when client's nausea is relieved.

Chapter 18

UNIT 3

Topical Medication Administration

Nursing Process Data

ASSESSMENT Data Base

- Assess for proper route of medication administration.
- Observe skin for open lesions, rash, or redness.
- Determine drug manufacturer's recommended site for transdermal application.
- Assess that area for transdermal application is dry, hairless, intact.
- Assess for allergies as reported by client or noted in client's chart.
- Assess condition of ear or eye and surrounding area.
- Determine purpose for eye or ear irrigation.
- Assess client's ability to cooperate with eye/ear medication administration or irrigation.

PLANNING Objectives

- To provide local anesthetic, anti-inflammatory, or anti-infective effect to a specified part of the body
- To provide slow continuous transdermal absorption of medication
- To decrease intraocular pressure
- To prevent unwanted systemic effect of topically applied eye medication
- To provide pupil dilation to facilitate eye examination or therapeutic procedure
- To remove debris or neutralize chemical action and minimize eye injury
- To soften and remove cerumen (ear wax)

IMPLEMENTATION Procedures

- Applying Topical Medications 591
- Applying Creams to Lesions 591
- Applying Transdermal Medications 592
- Instilling Ophthalmic Drops 593
- Administering Ophthalmic Ointment 594
- Irrigating the Eye 594
 - For Bilateral Irrigation. 595
- Administering Otic Medications 595
- Irrigating the Ear Canal 596

EVALUATION Expected Outcomes

- Topical medication has intended effect.
- Client self-administers eye medication according to instructions.
- Ear canal irrigation removes cerumen.

- **Critical Thinking Application** 597
 - Expected Outcomes 597
 - Unexpected Outcomes 597
 - Alternative Actions 597

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Applying Topical Medications

Equipment

- Medication container (tube or jar)
- Soap and water to cleanse skin
- Clean gloves
- Tongue blade
- Gauze or transparent dressing (as indicated)
- Tape
- Pen (to label dressing, if indicated)

Preparation

See Medication Preparation (Unit 1).

Procedure

1. Take medication container and dressing supplies to client's room.
2. Check room and bed number against client's record and check client's Ident-A-Band, asking client to state name and birth date.
3. Provide privacy.
4. Explain procedure and purpose to client.
5. Perform hand hygiene and don clean gloves.
6. Cleanse skin site with soap and water and dry thoroughly.
7. Squeeze medication from tube or use a tongue blade to take cream/ointment from medication container.
8. Spread small quantity of medication smoothly and evenly with gloved hand over client's skin following

▲ Apply dressing; then label with date, time, and initials.

- direction of hair follicles. ► **Rationale:** Gloves facilitate smooth application.
9. Apply dressing if indicated. ► **Rationale:** Dressing may ensure that medication is not rubbed off.
10. Label dressing with date, time, and your initials.
11. Remove gloves and perform hand hygiene.
12. Check that client is comfortable.
13. Return medication container to storage area.

Clinical Alert

Systemic absorption of topical medication from open lesions can result in toxic reactions.

Applying Creams to Lesions

Equipment

- Medication container (tube or jar)
- Sterile normal saline for cleansing
- Sterile gauze for cleansing site
- Sterile tongue blade
- Mask (see agency policy)
- Sterile gloves
- Sterile gauze or transparent dressing (or commercially prepared burn dressing)
- Kerlix gauze wrap or stretch net to secure dressing
- Pen for labeling dressing

Preparation

See Applying Topical Medications.

Procedure

1. Take medication to client's room; check room and bed number against medication record.
2. Check client's Ident-A-Band and ask client to state name and birth date.
3. Provide privacy.
4. Perform hand hygiene, don mask and clean gloves.
5. Remove previous dressing if present.
6. Note characteristics of site and cleanse area as ordered with sterile gauze pads and saline. Remove gloves.
7. Open medication container.
8. Don sterile gloves.
9. If no dressing is ordered, use gloved hand to apply medication directly to lesion; apply medication sparingly to 1/16-inch thickness. ► **Rationale:** To provide an occlusive effect.
10. If dressing is ordered, apply thin layer of medication to sterile gauze, then apply dressing to lesion area.
11. Secure dressing with Kerlix wrap or net if large area is involved.
12. Label dressing with date, time, and your initials.

▲ Use premeasured paper to measure medication dosage.

13. Check to ensure that client is comfortable after procedure.
14. Remove gloves and perform hand hygiene.

▲ Wear gloves to prevent drug absorption through fingertips.

15. Return medication container to appropriate storage area.

Applying Transdermal Medications

Equipment

- Medication patch or tube
- Gloves
- Premeasured medication administration paper
- Soap and water
- Clear plastic wrap (optional)
- Tape and pen for labeling dressing

Preparation

See Medication Preparation (Unit 1).

1. Obtain transdermal patch or premeasured paper that accompanies medication tube.
2. Carefully read the manufacturer's directions for application. ► **Rationale:** Directions as well as application areas of the body differ.

Procedure

1. Take medication to client's room, and check room and bed number against medication record.
2. Check Ident-A-Band, and ask client to state name.
3. Provide privacy.
4. Perform hand hygiene.

Clinical Alert

- Never cut a transdermal patch. Doing so releases the entire dose of medication to the client at once. Overdose and accidental death may occur.
- Manufacturers' directions for application of transdermal agents differ significantly. Body temperature and blood flow to different regions influence the suggested application site. Always adhere to the manufacturer's specific guidelines and precautions when administering these systems.

5. Don gloves. ► **Rationale:** Gloves prevent you from absorbing transdermal medication.
6. Alternate areas with each dose of medication to prevent skin irritation. Remove previous medicated paper/patch, fold patch in half with sticky side in, and discard in biohazard box.
7. Cleanse area before applying new dose at another site.
8. Place prescribed medication directly on paper (usually ½–1 in. strip).
9. Apply medicated paper to clean, dry, hairless, intact skin.
10. Use paper to spread medication paste over a 2-in. area. Secure paper with tape or cover medicated area with plastic wrap and tape.

Clinical Alert

The use of heating pads or hot tubs can increase the absorption rate of transdermal medications.

The nonadhesive backing of some drug patches contains metal that may not be visible. These may become heated during MRI and can cause second-degree burns. Warnings may be missing from patch labels. Patches should be removed before MRI.

Self-improvement patches purporting to deliver herbs or other substances (marketed on TV or the Internet) are not FDA regulated. Counterfeit patches also endanger clients. Refer clients to www.fda.gov/counterfeit.

- For patch, remove protective covering and immediately apply patch to clean, dry, hairless, intact skin.

- Press patch with palm for 30 seconds to attain a good seal.
- Remove gloves and perform hand hygiene.

Clinical Alert

Dispose of used transdermal patch by folding sticky sides together and discarding in Medical Waste receptacle to protect others from exposure to medication. Do not flush used patches down the toilet because trace amounts of the drug may appear in treated water.

- Label patch or paper with date, time, and your initials.
- Return medication tube to appropriate storage area.

Instilling Ophthalmic Drops**Equipment**

- Eye medication in Ocumeter container
- Gloves
- Tissues

Preparation

- See Medication Preparation (Unit 1).
- Gather necessary equipment.
- Compare the label on the medication container to the medication record. ► **Rationale:** This is a safety check to ensure that medication is for ophthalmic instillation.

Procedure

- Take medication to client's room; check room and bed number against medication record.
- Check Ident-A-Band, and ask client to state name and birth date.
- Perform hand hygiene and don gloves.
- Explain procedure and purpose of medication to client.
- Tilt client's head slightly backward and ask client to look up. ► **Rationale:** The cornea is protected as client looks up.
- Uncap Ocumeter, placing cap on its side.
- Give tissue to client for wiping off excess medication.

Clinical Alert

Apply pressure to inner canthus for 2 minutes to prevent rapid drug absorption if eyedrops have potential systemic effects (e.g., bradycardia due to timolol maleate [Timoptic] drops for glaucoma).

▲ Use nondominant hand to pull lower lid down. Drop eye medication in the center of lower conjunctival trough.

Clinical Alert

Occult blood developer bottles are the same size and shape as eyedrop bottles. Never leave occult blood developer in the client's room where it could be confused with the client's ophthalmic drops.

- Place Ocumeter $\frac{1}{2}$ – $\frac{3}{4}$ in. above eyeball with dominant hand. ► **Rationale:** This position reduces risk of dropper touching eyeball and causing injury.
- Place nondominant hand on cheekbone and hand holding dropper on top.
- Expose lower conjunctival trough by pulling lower lid down on cheek.
- Drop prescribed number of drops into center of conjunctival trough. ► **Rationale:** Placing medication directly on cornea could cause injury to cornea.

12. Apply pressure to inner canthus, if indicated.
13. Ask client to close eyelids and move eyes. ► **Rationale:** This distributes solution over conjunctival surface.
14. Very gently massage closed lid for client who cannot cooperate (e.g., comatose client).
15. Remove excess medication with tissue.
16. Remove gloves and perform hand hygiene.
17. Replace medication in appropriate place.

Clinical Alert

Promoting Safe Practice

Abbreviations for eye medication administration should not be used as they may be mistaken for ear administration (OS as AS, OD as AD, and OU as AU). Always check that the medication label states **ophthalmic** for use in the eye (ISMP 2006: www.ISMP.org).

Administering Ophthalmic Ointment

Equipment

Eye ointment in tube
Tissues
Gloves

Preparation

See Instilling Ophthalmic Drops.

Procedure

1. Take medication to client's room, check room and bed number against medication record.
2. Check Ident-A-Band and ask client to state name and birth date.
3. Explain procedure and purpose to client.
4. Perform hand hygiene and don gloves.
5. Take protective guard off medication tube and lay on its side.
6. Expose conjunctival trough by pulling lower lid down on cheek or grasping lower lid below client's eyelashes to form a trough.
7. Instruct client to look upward. ► **Rationale:** To keep cornea out of way of medication administration area.
8. Place medication tube tip $\frac{1}{2}$ – $\frac{3}{4}$ in. above exposed conjunctival trough.
9. Squeeze ribbon of ointment along middle third of lower lid trough.

10. Ask client to close eyelids and move eyes or gently massage closed lid to distribute medication.
11. Remove excess medication from client's eye area with tissue.
12. Caution client that ointment will cause vision to be temporarily blurred.
13. Recap and replace medication.
14. Remove gloves and perform hand hygiene.

▲ Squeeze ointment along middle third of lower conjunctival trough and ask client to close eyes.

Irrigating the Eye

Equipment

500 mL bag of sterile normal (isotonic) saline or bottle of sterile pH-balanced commercial eye irrigating solution (e.g., Dacriose)
IV administration tubing
IV fluid pole for elevation
Nasal cannula (as for oxygen delivery)

Tape
Sterile gauze pads
Absorbent pad or towel
Clean gloves

Preparation

1. Check physician's order for irrigation.

2. Perform hand hygiene.
3. Gather equipment.
4. Warm irrigating solution to body temperature by placing container in dry heating pad.

Procedure

1. Take equipment to client's room, and check room and bed number against medication record.
2. Check client's Ident-A-Band and ask client to state name and birth date.
3. Provide privacy.
4. Explain procedure and purpose to client.
5. Place client in semi-Fowler's position, turned to side of client's affected eye.
6. Have client hold curved basin on cheek under affected eye.
7. Don gloves.
8. Using your thumb and forefinger, open client's eye to expose lower conjunctival trough by pulling the lower lid down toward cheek.
9. Place eye irrigation bottle spout tip $\frac{3}{4}$ in. above client's inner canthus, pointing downward toward the outer canthus.
10. Squeeze bottle, allowing irrigating solution to flow into client's conjunctival trough to remove debris.
11. Continue irrigating for 10 minutes or until eye is cleansed completely.
12. Note results of debris returned with irrigation.
13. Wipe client's eyelid with gauze, wiping from inner to outer canthus.
14. Dispose of equipment in appropriate area.
15. Remove gloves and perform hand hygiene.
16. Assist client to comfortable position.
17. Document irrigation and results.

For Bilateral Irrigation

1. Spike saline bag with IV tubing and hang bag on pole.
2. Affix end of IV tubing to nasal cannula, then fit cannula around client's head (or around ears as for oxygen administration) securing prongs at bridge of client's nose with tape.
3. Start flow of saline solution from IV bag and allow to flush client's eyes to neutralize a chemical exposure.
4. Increase flow rate, then continue wide open irrigation until 500 mL has been used over a 10-minute period.
5. Follow steps 12–17 above.

Administering Otic Medications

Equipment

- Ear wick, if ordered
- Prescribed ear medication
- Dropper for instilling medication
- Gloves (optional)

Preparation

1. See Medication Preparation (Unit 1).
2. Gather necessary equipment.
3. Remove the medication from the medication cart.
4. Compare the label on the medication bottle to the medication record. ► **Rationale:** Safety check.
5. Before preparing medication for administration, warm medication bottle to body temperature. ► **Rationale:** Instillation of cold medication can cause vertigo.

Procedure

1. Take medication to client's room, and check room number against medication card or sheet.
2. Check Ident-A-Band, and ask client to state name and birth date.
3. Explain procedure and purpose to client.
4. Perform hand hygiene.
5. Don gloves.
6. Position client on side, with ear to be treated in the uppermost position. ► **Rationale:** This position allows medication to enter external ear canal by gravity.
7. Fill medication dropper with prescribed amount of medication.
8. Prepare client for instillation of ear medication as follows:
 - a. *Infant.* Draw the pinna gently downward and backward. ► **Rationale:** This separates the drum membrane from the floor of the cartilaginous canal.

▲ Lift pinna upward and backward to instill eardrops in an adult.

- b. *Adult*. Lift pinna upward and backward. ► **Rationale:** This position straightens the ear canal.
9. Insert ear wick if ordered. ► **Rationale:** Medication is absorbed into the ear wick. Ear wick enhances medication delivery directly to the entire ear canal.
10. Instill medication drops, holding dropper slightly above ear. ► **Rationale:** This position protects dropper from contamination.

11. Instruct client to remain on side for 5–10 minutes after instillation. ► **Rationale:** Prevents medication from escaping and facilitates distribution.
12. Dispose of gloves and perform hand hygiene.

NOTE: The ear wick normally extrudes spontaneously in 12–36 hr (after edema subsides).

Irrigating the Ear Canal

Equipment

Asepto or irrigating syringe
 Prescribed irrigating solution or tap water
 2 basins: round basin, curved basin
 Absorbent pad or towel
 Cotton ball

Preparation

(Client may have instilled wax-softening eardrops several hours before irrigation.)

1. See Medication Preparation (Unit 1).
2. Perform hand hygiene.
3. Gather equipment.
4. Warm irrigating solution to body temperature.
 ► **Rationale:** Cold solution can precipitate nausea and vertigo.

Procedure

1. Take equipment to client's room, and check room and bed number against medication record.
2. Check client's Ident-A-Band and ask client to state name and birth date.
3. Provide privacy.
4. Explain procedure and purpose to client.
5. Don clean gloves.

Clinical Alert

Ear canal irrigation should be performed only when the tympanic membrane can be visualized because of the risk that debris may cover an unseen perforation.

6. Place client in Fowler's position and place absorbent towel over client's chest and shoulders.
7. Pour irrigating solution into round basin.
8. Place curved basin under ear to catch irrigating solution.
9. Fill syringe with irrigating solution.
10. Open and straighten client's ear canal by pulling the pinna up and backward for adult or down for an infant or child. ► **Rationale:** This action allows the solution to flow into ear canal.
11. Hold irrigating syringe at entrance to ear canal without occluding meatus. ► **Rationale:** Entering ear canal can cause impaction.
12. Push plunger, directing flow of solution toward the top of the canal. ► **Rationale:** This action allows the flow to reach the entire length of canal.
13. Note return flow throughout procedure.
14. After solution has ceased to flow, dry outside of ear.
15. Return client to comfortable position and place cotton ball in ear canal to absorb excess fluid. ► **Rationale:** This reduces risk of external otitis.
16. Return used equipment to appropriate area.
17. Remove gloves and perform hand hygiene.
18. Document irrigation and results.

Clinical Alert

Ensure that client's tympanic membrane is intact before irrigating the ear. Water should not be used to irrigate the ear to remove an organic foreign body (e.g., insect or bean) since water may cause the object to swell.

DOCUMENTATION for Topical Medications

Client's Medication Record

- Time administered
- Name of medication
- Dosage
- Route and site of application
- Initials of nurse administering medication
- Signature by nurse which identifies initials

Nurses' Notes

- Record PRN, STAT, and one-time-only medications
 - Time administered, name of medication, dosage, route, site
 - Client's response to application
 - Condition of area treated
 - Signature of nurse
-

CRITICAL THINKING Application
Expected Outcomes

- Topical medication has intended effect.
 - Client self-administers eye medication according to instructions.
 - Ear canal irrigation removes cerumen.
-

Unexpected Outcomes

Client develops adverse reaction to topical medication (e.g., itching, inflammation).

Obese client fails to obtain pain relief from topical analgesic patch.

Client is reluctant to use eye medication ointment because it causes "blurred vision."

Client complains of nausea and vertigo after ear irrigation.

Alternative Actions

- Rotate sites of medication system application.
 - Consult physician or pharmacist for alternative route of medication administration (e.g., oral).
 - Consult pain management team.
 - Consider weight-based dosage.
 - Change route of analgesic administration since adipose tissue has decreased perfusion and topical medication uptake is unpredictable.
 - Suggest client apply eye ointment at bedtime.
 - Assist client to create safe means for urination at night (e.g., night lighting, safety rails, bedside commode, urinal).
 - Warm irrigating solution to body temperature.
 - Consult physician to order wax-softening eardrops to instill before irrigation to facilitate removal of cerumen and shorten process.
-

Chapter 18

UNIT 4

Mucous Membrane Medication Administration

Nursing Process Data

ASSESSMENT Data Base

- Assess that drug can be administered sublingually.
- Assess client's ability to understand and follow directions.
- Assess vital signs, SpO₂, relevant to medication action.
- Assess for dyspnea, labored breathing, wheezing.
- Determine possible undesired systemic effects of inhaled agents (tremor, nausea, tachycardia).
- Review physician's orders for medication and diluent to be administered, and frequency of treatments.
- Observe amount and character of expectorated sputum.
- Determine need for other respiratory techniques.
- Assess client's breath sounds before and after each treatment.
- Assess client's bowel elimination pattern.

PLANNING Objectives

- To provide appropriate surface for rapid absorption of medication for systemic effect
- To confine drug action to a local area
- To facilitate ease and consistency of self-administration of medication
- To decrease client's work of breathing
- To provide alternate route of medication administration when client is NPO/nauseated
- To promote bowel elimination
- To combat infection
- To deliver aerosolized medications
- To temporarily decrease the work of breathing
- To promote better ventilation
- To loosen secretions

IMPLEMENTATION Procedures

- Administering Sublingual Medications 599
- Instilling Nose Drops 599
- Administering Metered-Dose Inhaled (MDI) Medications 600
- Using MDI With Spacer 601
- Administering Dry Powder Inhaled (DPI) Medication. 602
- Administering Medication by Nonpressurized (Nebulized) Aerosol (NPA). 603
- Administering Rectal Suppositories 604
- Administering Vaginal Suppositories 604

EVALUATION Expected Outcomes

- Chest pain is relieved due to rapid systemic response to sublingual medication administration.
- Desired local effect of medication is achieved without undesired side effects.
- Suppository has desired effects/results.

Critical Thinking Application 605

- Expected Outcomes. 605
- Unexpected Outcomes 605
- Alternative Actions 605

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX[®]-style practice questions and Skill Checklists

Administering Sublingual Medications

Equipment

Sublingual medication (e.g., nitroglycerin tablets in a dark bottle). *Tablets lose potency when exposed to light; opened bottle should be replaced in 3 months.*

or

Nitrolingual aerosol spray in canister

Preparation

1. See Medication Preparation (Unit 1).
2. Assess vital signs if administering sublingual nitroglycerin. (*Systolic BP should not be lower than 90 mmHg.*)
3. Place client in a sitting position.

Procedure

1. Follow steps for preparing and administering oral medications, *except*:
 - a. Explain that client must not swallow drug or eat, smoke, or drink until medication is completely absorbed.
 - b. Ask client to place tablet under the tongue or to hold tongue up so tablet can be placed under tongue.
 - **Rationale:** Absorption is rapid and complete due to the vast network of capillaries in this area.
 - c. Alternate: hold Nitrolingual canister vertically with spray opening as close to mouth as possible. Deliver 1 or 2 metered sprays onto or under tongue, then have client close mouth immediately. Tell client not to inhale medication.

▲ Sublingual medication is placed under client's tongue for rapid absorption.

2. Evaluate client for drug action and possible side effects (e.g., headache).

Clinical Alert

Assess client's chest discomfort: quality, location, radiation, intensity, duration and precipitating factors. When administering rapid-acting (sublingual) nitroglycerin, monitor client's response and vital signs. If chest discomfort is not relieved in 5 minutes, notify physician. Obtain order for opiate analgesic (morphine sulfate), EKG, ST-segment monitoring, and cardiac biomarkers. No more than 3 doses of nitroglycerin should be administered in a 15-minute period because of potential hypotensive effect ($BP \leq 90$ mmHg) or bradycardia ($HR \leq 50$) as this would preclude adequate dosage of morphine sulfate for pain control.

EVIDENCE-BASED PRACTICE

ACC/AHA Guidelines—Nitroglycerin

It is recommended by the American College of Cardiology and the American Heart Association that clients who have been previously prescribed nitroglycerin be advised to take ONE dose sublingually promptly for chest discomfort/pain. If symptoms *do not* improve, or worsen in 5 minutes after ONE nitroglycerin dose, the client should call 9-1-1 immediately to access EMS. For clients with chronic stable angina, if symptoms are significantly improved after ONE nitroglycerin dose, repeat nitroglycerin dose every 5 minutes for a total of 3 doses and call 9-1-1 if symptoms have not totally resolved.

Source: Antman, E.M., Anbe, D. T., Armstrong, P. W., Bates, E. R., Green, L. A., Hand, M., ... Ornato, J. P. (2004). ACC/AHA guidelines for the management of patients with ST-elevation myocardial infarction: A report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines. *Journal of American College of Cardiology*, 44(3): E1–E211 ([http:// www.acc.org/clinical/guidelines](http://www.acc.org/clinical/guidelines)).

Instilling Nose Drops

Equipment

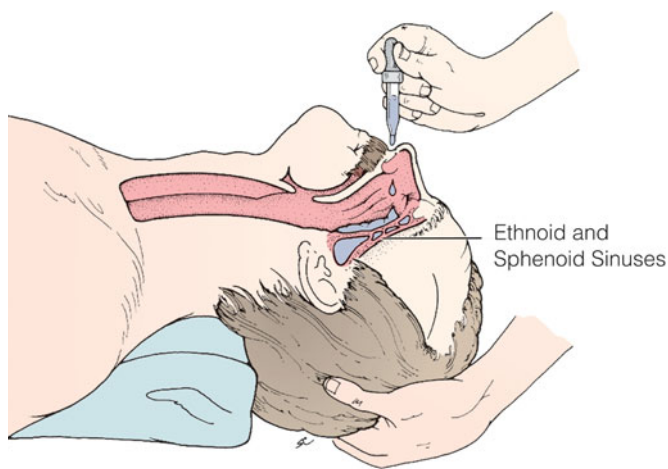

Medication bottle
Dropper
Tissues

Preparation

1. See Medication Preparation (Unit 1).
2. Perform hand hygiene.

Procedure

1. Take equipment to client's room; check room and bed number against medication record.
2. Check client Ident-A-Band and have client state name and birth date.
3. Place client in sitting position with head tilted back or in supine position with head tilted back over pillow.
4. Fill dropper with prescribed amount of medication.

▲ Instruct client to tilt head backwards and place dropper inside nares when instilling nose drops.

5. Place dropper just inside the naris and instill correct medication dosage. Repeat procedure in other naris.
6. Wipe away any excess medication with tissue.
7. Instruct client not to sneeze or blow nose and to keep head tilted back for 5 minutes to prevent medication from escaping.

▲ Tilt client's head back for nose drops to reach maxillary and frontal sinuses.

8. Check to see that client is comfortable before leaving room.
9. Perform hand hygiene.
10. Return medication to appropriate storage area.

Administering Metered-Dose Inhaled (MDI) Medications

Equipment

- Prescribed medication canister
- Metered-dose inhaler (MDI) dispenser (actuator or holder)
- Spacer or holding chamber (if ordered)
- Tissues

Clinical Alert

Check inhaler medication label for number of actuations (propellant-driven medication doses, e.g., 200). Have client maintain a record of actuations and discard after the number indicated. Final puffs may be nothing but propellant, which would not dilate airways in an emergency situation.

EVIDENCE-BASED PRACTICE

MDI Canister Actuations—Client Monitoring

A study evaluated how clients determined that their MDI canisters were empty. Of the clients studied, 74% did not know how many actuations were in their canisters and used their MDIs until they could no longer “hear” the medication when actuating. Additionally, while 78% knew to shake the canister before actuating, only half did so. The conclusion was that clients are likely to use the medication for up to twice the intended duration, using canisters with no active ingredients more than 50% of the time. The authors concluded that dose counters appear to be the only practical solution.

Source: Rubin B., & Durotoye, L. (2004). How do patients determine that their metered-dose inhaler is empty? *Chest*, 126, 1134–1137.

▲ Depress inhalation device while inhaling slowly (3–5 seconds) and deeply through mouth.

Preparation

1. See Medication Preparation (Unit 1).
2. Perform hand hygiene.
3. Gather equipment.
4. Compare label of drug canister to client's medication record.

Procedure

1. Take medication canister and MDI dispenser to client's room.

Client Teaching

- Canister must be shaken before each puff so that propellant and medication are adequately combined. Priming sprays are performed only with a new canister (canister volume allows for this).
- Prime new MDI by spraying into the air four times. Prime inhaler that has not been used for 4 weeks by spraying once into the air.
- Tell client to keep track of number of puffs (actuations) used in order to plan for refill of prescription.

2. Check client's Ident-A-Band and have client state name and birth date.
3. Provide privacy.
4. Explain procedure and purpose to client.
5. Assist client to standing or sitting position.
6. Insert canister (stem down) into longer part of metered-dose dispenser. (For new canister, test spray [prime] MDI into air one or two times. ► **Rationale:** This is done *only* with new canister to ensure patency of unit.)
7. Shake MDI with canister to mix medication and propellant. (*Shake canister before each MDI puff*). ► **Rationale:** Without shaking propellant, little or no medication will be delivered.

NOTE: Canisters typically contain propellants and other inert ingredients in addition to the actual drug; a client may believe a canister contains medication when none is actually present.

8. Instruct client to remove mouthpiece and hold inhaler 2 in. away from mouth (following manufacturer's instructions). Mist is to be *inhaled* into airways. **Alternately**, place mouthpiece in mouth, holding canister upright.
9. Instruct client to exhale through pursed lips. ► **Rationale:** Exhaling through pursed lips increases exhaled volume, allowing room for a greater *inspiratory* volume.
10. Instruct client to depress inhalation device, releasing a puff of medication while inhaling slowly and deeply (3–5 seconds). ► **Rationale:** With slow deep inhalation, medication goes to lower respiratory tract.

11. Tell client to hold breath for 10 seconds, then remove unit and slowly exhale through pursed lips. ► **Rationale:** Holding the breath allows time for the medication to be absorbed.
12. Assess client's breathing and reaction to medication. ► **Rationale:** With certain drugs, heart rate may increase.
13. Provide tissues. ► **Rationale:** Inhaled medication may stimulate coughing.
14. Instruct client to wait 1 or 2 minutes between inhalations and to *shake canister* before each puff. ► **Rationale:** Waiting between doses helps prevent paroxysmal bronchospasm.
15. Have client replace mouthpiece cap.
16. Caution client not to increase dose without physician's order. ► **Rationale:** Potential side effects of an increased dose could be serious.
17. Have client rinse mouth after using MDI that contains steroids.
18. Teach client to remove canister and to clean mouthpiece *daily*, washing with soap and water and allowing to air dry. ► **Rationale:** These devices are sites for microbial growth.
19. Instruct client to rinse mouth after use and to not swallow the water.
20. Review medication side effects with client. ► **Rationale:** Client continues home therapy and should be aware of self-monitoring needs.
21. Perform hand hygiene.
22. Document procedure and results.

Inhaled Medications

- Inhaled medications provide relief for bronchospasm, wheezing, asthma, or allergic reactions.
- Medications include bronchodilators, steroids, and antimediators.
- Common systemic side effects include tremors, nausea, tachycardia, palpitations, nervousness, and dysrhythmias.

Using MDI With Spacer

Equipment

See Administering Metered-Dose Inhaled (MDI) Medications.

Preparation

1. See Administering Metered-Dose Inhaled (MDI) Medications.
2. Perform hand hygiene.

Procedure

1. Assemble medication canister in MDI.
2. Insert MDI mouthpiece into spacer. ► **Rationale:** Research indicates an MDI inhaler fitted into a spacer improves airway delivery of medication because large drops do not fall into the mouth.
3. Remove mouthpiece cover from spacer.
4. Hold upright and shake MDI with spacer to mix medication and propellant.
5. Instruct client to exhale slowly through pursed lips.
6. Instruct client to close lips around spacer mouthpiece. ► **Rationale:** Spacer eliminates need for simultaneous hand action and mouth inspiration coordination.
7. Activate MDI canister, pressing down with fingers, pushing it farther into plastic adapter. ► **Rationale:** This releases metered dose of medication into spacer.
8. After activation, instruct client to inhale slowly and deeply through mouth and hold breath for 10 seconds.
9. Instruct client to exhale and relax.
10. Provide water mouth rinse after inhaled corticosteroids. ► **Rationale:** To prevent oral candidiasis.
11. Remove drug canister and clean mouthpiece and spacer daily, washing with soap and water.

▲ Hold canister upright when using MDI with spacer.

EVIDENCE-BASED PRACTICE**Why Use a Spacer With MDI?**

Only 10%–15% of inhaled (MDI) medications reach the small airways, but use of a spacer can increase this by about 12%.

Source: Togger, D., & Brenner, P. (2001). Metered dose inhalers. *American Journal of Nursing*, 101(10), 29.

Clinical Alert

If several types of medications are used, follow this sequence: Quick-acting bronchodilator (e.g., albuterol sulfate); slower-acting bronchodilator (e.g., ipratropium bromide [Atro-vent]); antidiemators (e.g., steroids).

Administering Dry Powder Inhaled (DPI) Medication**Equipment**

- Dry powder capsule intended for oral inhalation
- Medication package insert (instructions)
- Handheld inhalation device intended for medication to be given

Preparation

1. See Administering Metered-Dose Inhaled (MDI) Medications.
2. Review medication package insert instructions.
3. Perform hand hygiene.

Procedure

1. Take dry powder capsule package and inhalation device to client's room.
2. Check client's Ident-A-Band and have client state name and birth date.
3. Provide privacy.
4. Explain procedure and purpose to client.
5. Assist client to a sitting position.
6. Remove capsule from package, peeling back foil cover to expose only one capsule. ► **Rationale:** Capsules should

be used immediately; unused capsules exposed to air may lose effectiveness.

7. Open the outer cap of inhaler device (pull cap upward).
8. Open the mouthpiece.
9. Insert the capsule into center of chamber of the inhalation device.

▲ Insert capsule into center of chamber of the inhalation device.

10. Hold the device upright, and, leaving the outer cap open, close mouthpiece/lid firmly until a click is heard and leave the outer cap open.
11. Press the side mounted piercing button in completely, then release. ► **Rationale:** The piercing button punctures the capsule, allowing medication to be released upon inhalation.
12. Have the client breathe out completely.
13. Have the client keep his/her head in upright position and place lips tightly round the mouthpiece.
14. Have client breathe slowly and deeply with sufficient energy to hear the medication capsule vibrate. ► **Rationale:** As long as the capsule rattles, the client's inhalation is fast enough.
15. Have the client hold the deep breath as long as comfortable, then return to normal breathing.
16. Have client repeat Steps 12 through 15 if indicated in medication package insert. ► **Rationale:** Repeating the steps may be necessary to get the full dose of medication.
17. Open mouthpiece and discard remaining capsule.
18. Close mouthpiece and outer cap and store at client's bedside.
19. Clean unit only as necessary, using warm water and allowing device to air dry *thoroughly* before next use. ► **Rationale:** No cleaning agents should be used and the device should not be wet when used.

NOTE: Some DPIs require a fast initial inhalation to activate the medication distribution.

Administering Medication by Nonpressurized (Nebulized) Aerosol (NPA)

Equipment

- Nebulizer medication chamber
- T-piece, mouthpiece or mask
- Corrugated tubing
- Air flow tubing
- Prescribed medication (e.g., bronchodilator)
- Prescribed diluent (normal saline)
- Wall source (or other source) for compressed air, or oxygen with flowmeter

Preparation

1. See Medication Preparation (Unit 1).
2. Perform hand hygiene.
3. Dilute medication as ordered and place in nebulizer chamber.
4. Attach one end of tubing to compressed air source.
5. Attach other end of tubing to nozzle at side or bottom of nebulizer.

▲ Nonpressurized aerosol (NPA) treatment in progress.

6. Keep nebulizer chamber vertical, and connect top of chamber to mask or T-piece sidearm.
7. Hold mouthpiece in its protective cover, and attach to one end of T-piece.
8. Attach corrugated tubing to other end of T-piece.

Procedure

1. Turn on air or oxygen (8 L/min) source, and observe for mist flow.
 - a. If the client is receiving 3 L/min or less of oxygen therapy, deliver aerosolized medications with compressed air (yellow wall outlet).
 - b. If the client is receiving 4 L/min or more of oxygen therapy, deliver the aerosol medication with the oxygen flowmeter (green wall outlet) set at 8 L/min.
2. Have client place mouthpiece in mouth and close lips.

Clinical Alert

The plastic containers with respiratory medications for nebulizers are similar to the plastic containers for single-dose eyedrops. Both products have the drug name molded into the plastic, but it is difficult to see.

3. Instruct client to breathe normally in and out of mouthpiece or mask.
4. Have client take a deep breath and hold for several seconds, then exhale slowly every 3–5 breaths. (Treatment is complete when all medication is used and no mist is seen.)
5. Turn power (air or O₂ flow) off, and unplug compressor (if used), or reset prescribed O₂ flow rate.
6. Clean mouthpiece, and place equipment in plastic bag at bedside. (Dispose of and replace components according to agency policy.)

Administering Rectal Suppositories

Equipment

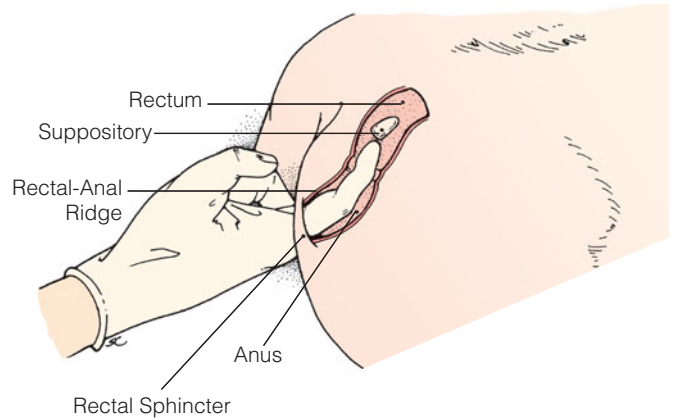

- Suppository as ordered from refrigerator
- Clean gloves
- Water-soluble lubricant
- Paper towel

Preparation

1. See Medication Preparation (Unit 1).
2. Compare the medication record with the most recent physician's order.
3. Perform hand hygiene.
4. Gather necessary equipment.
5. Retrieve medication from refrigerator if indicated.
6. Compare the medication label with client's MAR.
7. Place suppository, lubricant, and paper towel on a tray if not using medication cart.

Procedure

1. Take equipment to client's room.
2. Check room number against client's MAR.
3. Check client's Ident-A-Band and have client state name and birth date.
4. Explain procedure and purpose to client.
5. Provide privacy.
6. Place client in dorsal-recumbent or side-lying position.
7. Squeeze dollop of lubricant onto paper towel.
8. Remove foil wrapper from the suppository.
9. Moisten suppository tip with warm water or lubricant to facilitate insertion.

▲ Insert rectal suppository beyond the anal-rectal ridge to ensure it is retained.

10. Don clean gloves and inspect anal area for hemorrhoids.
11. Instruct client to bear down to identify anal opening and insert the suppository about 1½ in. into the rectal canal beyond the anal sphincter. ► **Rationale:** Prevents suppository from slipping out.
12. Instruct client to lie quietly for 15 minutes while medicine is absorbed and that suppository may take up to 1 hour to be effective.
13. Dispose of equipment and gloves and perform hand hygiene.
14. Return after 15 minutes to ensure client is comfortable.
15. Chart medication and results obtained.

Administering Vaginal Suppositories

Equipment

- Prescribed vaginal suppository
- Client's applicator (should be kept in client's room)
- Clean gloves

Preparation

1. See Medication Preparation (Unit 1).
2. Compare the medication record with the most recent physician's order.
3. Perform hand hygiene.
4. Gather necessary equipment.
5. Remove the medication from medication cart.
6. Compare the medication label to the client's MAR.

▲ Insert vaginal suppository at least 2 inches into vaginal canal using applicator as shown.

Procedure

1. Take equipment to client's room, and check room number against client's MAR.
2. Check client's Ident-A-Band and ask client to state name and birth date.
3. Provide privacy.
4. Explain procedure and purpose to client.
5. Don gloves.
6. Place client in dorsal recumbent or side-lying position.
7. Remove foil wrapper from suppository. Insert into applicator.
8. Don clean gloves.
9. Insert applicator with suppository into the vaginal canal at least 2 in. ► **Rationale:** Prevents suppository from slipping out.
10. Instruct client to lie quietly for 15 minutes until the suppository is absorbed.
11. Discard equipment, wash applicator, and return to appropriate place in client's room.
12. Remove gloves and perform hand hygiene.
13. Chart medication and assessment findings (e.g., discharge, odor).

DOCUMENTATION for Mucous Membrane Medications**Client's Medication Record**

- Time
- Medication administered
- Route of administration
- Initials of nurse administering medication
- Signature of nurse identifying initials

Nurses' Notes

- Time
- Name of medication, dosage, route pre- and post-administration assessment findings (chest discomfort, vital signs, SpO₂, breath sounds)
- Physician notification, if done
- Results of suppository action

CRITICAL THINKING Application**Expected Outcomes**

- Angina is relieved with ONE dose of sublingual nitroglycerin.
- Chest pain is relieved due to rapid systemic response to sublingual medication administration.
- Desired local effect of medication is achieved without undesired side effects.
- Suppository has desired effects/results.

Unexpected Outcomes

Client's chest discomfort is not relieved with ONE dose of sublingual nitroglycerin.

Alternative Actions

Client's discomfort is not relieved with sublingual nitroglycerin.

- Provide anticipatory instructions.
- Check bottle for expiration date—potency is lost 3 months after opening bottle.
- Recognize associated symptoms of acute MI such as dyspnea, nausea, cold sweat, lightheadedness. (www.nhlbi.nih.gov/actintime).
- Don't take a "wait and see" approach or deny symptoms indicative of acute MI.
- Check bottle for expiration date—potency is lost 3 months after opening bottle.
- Administer second tablet in 5 minutes—if discomfort continues, administer opiate analgesic, call Rapid Response Team, notify physician, and obtain stat ECG.
- Administer no more than three tablets/sprays in a 15-minute period.
- Monitor for blood pressure effect—hold medication if systolic BP is less than 90 mmHg.
- Consult with physician for blood test for possible myocardial injury and need for continuous cardiac monitoring.

Client states that breathing has not improved after using inhaler.

- Place client in Fowler's position. Validate that MDI/spacer/NPA device is functioning properly (e.g., canister shaken before use).
- Check number of actuations left in MDI canister.
- Validate that client's lips have tight fit around MDI mouthpiece so mist is inhaled.
- Instruct client to hold breath 10 seconds after MDI use and to wait 2 minutes between puffs.

Client using MDI reports painful white patches in mouth.

- Instruct client to use spacer with MDI steroid medication.
- Instruct client to rinse mouth with water and expectorate after administering MDI steroid.
- Notify physician of findings.

Client fails to have BM post-laxative suppository administration.

- Reassess abdomen and check client for rectal fecal impaction.
- Consult with physician to order oil-retention enema or cleansing enema.
- Teach client ways to prevent constipation.

Client is unable to retain vaginal suppository.

- Administer vaginal suppository at bedtime to prevent medication leakage.
-

Parenteral Medication Administration

Nursing Process Data

ASSESSMENT Data Base

- Check that appropriate method for administration of drug was ordered.
- Assess condition of administration site for presence of lesions, rash, inflammation, lipid dystrophy, ecchymosis.
- Assess client’s understanding of medication action.
- Check client’s written history and ask for oral history for past allergic reactions. (Do not rely solely on client’s chart.)
- Review client’s chart noting previous injection sites.

PLANNING Objectives

- To ensure proper route of drug administration
- To protect self from harm when administering parenteral injections
- To administer medication parenterally according to the “Six Rights”
- To reduce discomfort with medication injection
- To alternate injection sites for consistent absorption of medication
- To observe and report side effects/adverse reactions of drug administration

IMPLEMENTATION Procedures

- Preparing Injections 608
 - For Withdrawing Medication From a Vial 610
 - For Combining Medications in one Syringe Using Two Vials 611
 - For Withdrawing Medication From an Ampule 611
 - For Combining Medications Using Alternative Method . . 612
 - For Preparing Prefilled Medication Cartridge 612
- Administering Intradermal Injections 612
- Administering Subcutaneous Injections 613
- Preparing Insulin Injections 614
 - For Newly Diagnosed Diabetic Client 614
 - For One Insulin Solution 614
 - For Two Insulin Solutions 615
- Using an Insulin Pen 617
- Administering Subcutaneous Anticoagulants (Heparin, LMWH, Arixtra) 619
- Administering Intramuscular (IM) Injections 621
- Using Z-Track Method 623

EVALUATION Expected Outcomes

- Injection is administered without complications.
- Injection is as painless as possible.
- Medication therapeutic effect is achieved.

Critical Thinking Application 624

- Expected Outcomes 624
- Unexpected Outcomes 625
- Alternative Actions 625

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Preparing Injections

Equipment

- Medication in vial or ampule
- Vial of compatible diluent (if necessary)
- Syringe of closest capacity to hold medication.
- Filter needle for withdrawing medication from ampule or rubber-topped vial
- Appropriate-size needle for injection
- Antimicrobial wipe
- Dry gauze sponge
- Label for prepared injection

Preparation

See Medication Preparation (Unit 1).

Procedure

1. Perform hand hygiene.
2. Obtain equipment.
3. Assemble the syringe and filter needle, maintaining sterility.
4. Fill syringe with medication
5. Attach appropriate-size needle for injection, considering route, desired site, client's size, and viscosity of medication. ► **Rationale:** The larger the gauge number, the *smaller* the needle lumen. Larger gauges produce less tissue trauma and are used for aqueous solutions. Smaller gauges are required for viscous solutions such as hormones.
6. Unless administering immediately, apply identifying label to prepared syringe. ► **Rationale:** Lack of labeling has been cited as a major risk for medication administration errors.

Clinical Alert

Federal needlestick safety legislation **requires** healthcare facilities to implement devices that protect against accidental needlesticks.

EVIDENCE-BASED PRACTICE

Needlestick Injuries

Six percent of needlestick injuries involve safety devices with shielding, retracting, or blunting safety features. Most injuries occur after use and before disposal. In some cases, the protective features are not activated. Puncture-proof sharps disposal containers continue to play an important role in preventing injury.

Source: Jagger, J., & Perry, J. (2002). Realistic expectations for safety devices. *Nursing* 2002, 32(3), 72.

Clinical Alert

Change needle after withdrawing medication from ampule or vial.

▲ Health care facilities must use safety needles to conform to needlestick safety legislation.

▲ Discard syringe in biohazard container following injection.

▲ Three types of syringes: tuberculin, insulin, and 3-mL.

▲ Safety syringe with retractable needle (bottom image) and needle retracted into barrel (top image).

Sites for Injections

Site is the single most consistent factor associated with complications and injury. One must consider client's age, size, medication type, and medication volume.

Intradermal Injections

- Injection sites: inner aspect of forearm or scapular area of back; upper chest; medial thigh.
- Purpose: to test for antigens (tubercle bacillus, allergens).
- Amount injected: ranges from 0.01 to 0.1 mL.
- Absorption rate: slow.

Subcutaneous Injections

- Injection sites: fatty tissue of abdomen, lateral and posterior aspects of upper arm or thigh, scapular area of back, upper ventrodorsal gluteal areas.
- Purpose: for medications that are absorbed slowly.
- Amount injected: variable—no more than 2 mL. If repeated doses are necessary, alter site accordingly.

Intramuscular Injections

- Purpose: to promote rapid absorption of the drug; to provide an alternate route when drug is irritating to subcutaneous tissues.
- Amount injected: variable—may be large amount of fluid. If more than 5 mL for adult or 3 mL for child and 1 mL for infant, divide dose into two syringes.
- Absorption rate: depends on circulatory state of client.
- Injection sites:

Ventrogluteal Injection Site (preferred site for IM injection for all clients over age 7 months)

1. Place client in side-lying or supine position.
2. Use right hand for left anterior hip, or left hand for right anterior hip.
3. Identify greater trochanter and place palm at site.
4. Keep palm on greater trochanter and point index finger toward client's anterior superior iliac spine and fan out other three fingers.
5. Form "V" area with index finger separated from other three fingers.
6. Inject medication at 90° angle within "V" area.

Vastus Lateralis Injection Site

1. Place client in supine position with thigh exposed.
2. Identify greater trochanter and lateral femoral condyle.
3. Using middle third and anterior *lateral* aspect of thigh, select site.
4. Inject medication directly into muscle at 90° angle.

Deltoid Injection Site (solution must be nonirritating)

1. Expose client's upper arm.
2. Deltoid site is two fingerbreadths below acromion process.
3. Place left hand on acromion process and right index finger two fingerbreadths below.
4. Inject limited medication volume (0.5–1 mL) in deltoid IM site at 90° angle.

Clinical Alert

Do Not Use These Sites

- The dorsogluteal site is no longer recommended for IM injection. There is a high risk for injury to the sciatic nerve and major blood vessels due to difficulty palpating appropriate bony landmarks in this area. Variation of thickness of subcutaneous tissue at this site makes inadvertent injection into subcutaneous tissue, altered drug absorption, and tissue injury possible.
- Do not use the rectus femoris (anterior thigh) muscle for injection.

Selecting the Appropriate-Size Needle for Injection

- *Intradermal injections:* 1 mL tuberculin syringe with short bevel, 25–27 gauge, 3/8–1/2 in. needle.
- *Subcutaneous injections:* 0.5–3 mL syringe with 25–29 gauge, 3/8–5/8 in. needle.
- *Intramuscular injections:* 1–5 mL syringe with needle gauge and length appropriate for muscle site and fat thickness; deltoid muscle requires 23–25 gauge, 5/8–1 in. needle; needle sizes for the vastus lateralis and ventrogluteal muscle vary from 18 to 23 gauge, needle lengths, 1–1½ in.

▲ Insert needle at 45° or 90° angle into tissue for subcutaneous injection.

▲ Insert needle at 15° angle just under the epidermis for intradermal injection.

▲ A special filter needle should be used to prevent aspirating particulate matter when withdrawing solution from an ampule or vial.

For Withdrawing Medication From a Vial

1. Remove the vial cap.
2. Open antimicrobial wipe, and cleanse the rubber top of the vial. ► **Rationale:** Manufacturer does not guarantee sterility of rubber top.
3. Tighten filter needle to syringe. Remove needle guard.

▲ Inject prescribed amount of air into vial.

▲ Invert vial to extract desired amount of medication.

4. Pull back on plunger to fill syringe with an amount of air equal to amount of solution to be withdrawn. ► **Rationale:** The displacement of solution with air is necessary to prevent the formation of a vacuum in the sealed vial.
5. Insert filter needle into upright vial. Inject air into vacant area of vial, keeping needle bevel above surface of medication. ► **Rationale:** Air creates positive pressure within vial, allowing accurate withdrawal of medication.
6. Invert vial, and pull plunger to extract desired amount of medication. Touch only syringe barrel and plunger tip. ► **Rationale:** This prevents contamination of the plunger, inside of barrel, and medication.
7. Expel any air bubbles from syringe at this time by tapping the side of syringe sharply with your finger or pen below the air bubble. ► **Rationale:** Air bubbles form in syringe due to dead air space in needle hub. Removing air bubbles while needle remains within the inverted vial avoids accidental contamination of needle and facilitates easy removal of air and accurate withdrawal of solution.
8. Recheck amount of medication in syringe.

▲ Slide prefilled, sterile cartridge into syringe barrel; then turn and lock.

Clinical Alert

If multiple-use vials are opened, they must be marked with the date and time the container is entered and nurse's initials. Consult the product label or package insert to determine whether refrigeration is necessary. Unless contamination is suspected, the Centers for Disease Control and Prevention (CDC) recommends that the vial be discarded either when empty or on the expiration date set by the manufacturer.

9. Turn vial to upright position and remove needle. ► **Rationale:** Removing needle from inverted vial may cause leaking of medication from needle insertion site.

10. Replace filter needle with needle for injection.
11. Recheck medication label and dosage against medication record and any dosage calculation.
▶ **Rationale:** This is a second safety check.
12. Replace or dispose of medication vial, checking label once again. ▶ **Rationale:** This is a third safety check.

For Combining Medications in One Syringe Using Two Vials

1. Prepare both vials by removing caps and cleansing tops with separate antimicrobial wipes.
2. Draw air into syringe equal to amount of solution to be removed from *second* vial. Inject air into *second* vial. Do not withdraw medication at this time. ▶ **Rationale:** Air creates positive pressure within the vial, allowing withdrawal of solution.

Clinical Alert

Check appropriate text or consult agency pharmacist to ensure compatibility of medications before combining in a syringe for injection.

Reconstituting Powdered Medication

- Insert filter needle into upright powdered medication vial.
 - Remove the amount of air equal to desired quantity of diluent; this provides space for the diluent.
 - Inject diluent into upright powdered medication vial.
 - Remove needle and cover with guard.
 - Rotate powdered medication vial with diluent between palms. Do not shake vial because shaking creates air bubbles and may cause difficulty withdrawing medication dose.
 - Withdraw medication from vial.
 - Replace filter needle with needle for injection.
3. Draw air into syringe equal to amount of solution to be removed from *first* vial and inject it into *first* vial.
 4. Invert first vial and withdraw ordered amount of medication without removing syringe.
 5. Expel all air bubbles from syringe.
 6. Recheck amount of solution and remove syringe from vial.
 7. Insert needle into *second* vial, invert, and carefully withdraw exact amount of solution ordered. ▶ **Rationale:** Withdrawing excess solution from second vial results in an inaccurate dosage of medication. If this occurs, syringe must be discarded and procedure begun again.
 8. Replace filter needle with needle for injection.

▲ Using alcohol swab or dry gauze square, grasp and snap off stem of ampule, breaking away from you.

▲ Tilt or invert ampule to withdraw appropriate amount of medication, using filter needle.

For Withdrawing Medication From an Ampule

1. Move solution from neck to body of ampule by tapping stem sharply or holding neck of ampule between thumb and forefinger and flicking wrist.
2. Using a pad, grasp neck (stem) of ampule between thumb and forefinger of one hand and grasp body of ampule with other hand. Break stem away from you. (If ampule is not scored, partially file neck of ampule.)
▶ **Rationale:** Gauze pad protects hands, and breaking away from you prevents injury from glass fragments. Alternatively, slip a nipple from a baby bottle over the stem to prevent injury.
3. Set the ampule upright. It is not necessary to add air before withdrawing the medication.
4. Use a special filter needle to withdraw solution.
▶ **Rationale:** Filter needle prevents aspiration of glass when withdrawing solution from ampule, especially if the ampule is inverted.

5. Remove needle guard and insert needle into ampule without touching sides of ampule and withdraw medication. Alternatively, invert ampule and withdraw appropriate amount of medication. ► **Rationale:** Surface tension prevents solution from leaking out of inverted ampule.
6. Withdraw needle with ampule in upright position.
7. Tap syringe barrel below bubbles to dislodge air bubbles to hub of syringe.
8. Eject air with syringe in an upright position. If amount of solution is overdrawn, invert syringe and remove excess solution into the Medical Waste (black box) receptacle. ► **Rationale:** Appropriate waste disposal is mandated by the EPA.
9. Cover needle with guard, using scoop method.

For Combining Medications Using Alternative Method

1. Draw up ordered dose from each vial or ampule into two separate syringes. First syringe must be able to hold entire volume of combined medications.
2. Remove needle from first syringe.
3. Pull back plunger of first syringe to allow space for volume of second medication to be added.
4. Insert needle of second syringe into hub of first syringe.
5. Slowly inject medication of second syringe through first syringe hub, then withdraw needle.
6. Attach new needle to first syringe.
7. Discard needles and second syringe.

For Preparing Prefilled Medication Cartridge

1. Hold barrel of cartridge syringe (e.g., Tubex) in one hand and pull back on plunger with other hand.
2. Insert prefilled medication cartridge, needle first, into cartridge barrel.
3. Twist cartridge syringe flange clockwise until it is secure.
4. Screw plunger rod onto screw at bottom of medication cartridge until it fits firmly and tightly into rubber stopper.
5. Remove needle guard and any air bubbles.
6. Determine if dosage in cartridge is greater than required amount. If so, invert Tubex and gently expel excess medication into Medical Waste receptacle, being careful to maintain sterility of needle. ► **Rationale:** If permanent needle is contaminated, the cartridge becomes contaminated and must be discarded.
7. Replace needle guard, using scoop method.

Administering Intradermal Injections

Equipment

Medication (e.g., 0.1 mL Purified Protein Derivative Antigen for tuberculin testing)

Unit dose (1 mL) tuberculin syringe with 1/4–3/8 in. 27-gauge needle

Antimicrobial wipes

Gauze sponge

Clean gloves (if indicated)

Pen to mark injection site

▲ Insert needle with bevel up for intradermal injection.

▲ Inject solution to form wheal on skin.

Preparation

Follow steps for Preparing Injections.

Procedure

1. Take prepared injection to client's room, checking room and bed number against client's medication record.
2. Check client's Ident-A-Band and ask client to state name and birth date.
3. Explain procedure and purpose to client.
4. Perform hand hygiene and don gloves if exposure is anticipated.
5. Select lesion-free injection site on undersurface, upper third of forearm for skin testing.
6. Cleanse area with antimicrobial wipe and allow to dry.
7. Remove needle guard.
8. Grasp the client's dorsal forearm to gently pull the skin taut on ventral forearm.
9. Holding syringe almost parallel to skin, insert needle at a 10°–15° angle with bevel facing up, about 1/8 in. Needle point should be visible under skin. DO NOT ASPIRATE.
10. Inject medication slowly, observing for a wheal (blister) formation and blanching at the site. ► **Rationale:** This indicates that the medication was injected within the dermis. If no wheal develops, injection was given too deeply.
11. Withdraw needle at same angle as inserted. Pat area gently with dry gauze sponge, but DO NOT MASSAGE. ► **Rationale:** Massaging could disperse medication.
12. Activate needle safety feature and discard syringe unit in puncture-proof container.
13. Mark injection site with pen for future assessment.
14. Return client to comfortable position.
15. Dispose of gloves and perform hand hygiene.
16. Record site and antigen in client's record.

Clinical Alert

For tuberculin testing, instruct client to return and have the site checked by the healthcare provider in 48–72 hr.

Administering Subcutaneous Injections**Equipment**

Nonirritating medication
 3-mL syringe with 5/8-inch needle (usual 25–27 gauge)
 Antimicrobial wipe
 Dry gauze sponge
Clean gloves if indicated

Preparation

See steps for Preparing Injections.

Procedure

1. Take prepared injection to client's room, checking room and bed number against client's medication record.
2. Check client's Ident-A-Band and ask client to state name and birth date.
3. Explain procedure and purpose to client.
4. Perform hand hygiene and don gloves.
5. Select fatty site for injection (e.g., abdomen, avoiding 2-in. radius around umbilicus), alternating sites for each injection. ► **Rationale:** This prevents repeated trauma to tissue.
6. Cleanse area with antimicrobial wipe and allow to dry.
7. Remove needle guard.
8. Use thumb and forefinger and gently grasp loose area ("pinch an inch") of fatty tissue on appropriate site (e.g., posterior-lateral aspect, middle third of arm). ► **Rationale:** This ensures insertion of medication within subcutaneous tissue, not muscle.

Gloving Protocol for Injections

The CDC has no regulations concerning the wearing of gloves during injections. OSHA recommends that gloves are not necessary when administering IM or subcutaneous injections, as long as bleeding that could result in hand contact with blood (or other potentially infectious material) is not anticipated.

The practice of whether or not to wear gloves for subcutaneous or IM injections is based on judgment. Hospital policy may dictate gloving protocol for injections.

If wearing gloves for mass inoculations, nurses must change gloves between clients and perform hand hygiene. Therefore, nurses may choose *not* to wear gloves in these situations (OSHA & CDC).

NOTE: This action is not necessary when there is substantial fatty tissue.

9. Hold syringe like a dart between the thumb and forefinger.
10. Insert needle at a 45° or 90° angle. A 90° angle is used more commonly due to short needles on prepackaged syringes. ► **Rationale:** Angle varies with the amount of subcutaneous tissue, selected site, and needle length.
11. Continue to hold tissue and aspirate 5 to 10 seconds by pulling back on plunger with thumb of dominant hand. If no blood appears, administer injection. If blood appears, withdraw needle, activate safety feature and discard, then prepare a new injection. ► **Rationale:** Blood indicates needle has entered a blood vessel. Injecting the drug IV may be dangerous.
12. Inject medication slowly, 10 seconds per mL.
13. Wait 10 seconds, then withdraw needle and activate needle safety feature.
14. Release tissue and massage area with dry gauze sponge (if indicated). ► **Rationale:** Massaging area aids absorption.

Clinical Alert

Irritating medications such as Vistaril must not be administered subcutaneously, as or tissue necrosis may result. Such medications should be administered intramuscularly in the ventrogluteal site using the Z-track method.

15. Discard needle/syringe unit in puncture-proof container.
16. Return client to position of comfort.
17. Discard gloves and perform hand hygiene.
18. Record medication and site used.

Preparing Insulin Injections

Equipment

Insulin(s) vials

Unopened vials of insulin should be stored in refrigerator

Opened vial of insulin may be refrigerated or kept at room temperature; recommend discard after 28 days

Insulin should not be exposed to light, or to temperatures over 80° F

Do not use insulin that has clumping, frosting, or precipitation

Insulin syringe: available in 3/10 mL, ½ mL, and 1 mL sizes (*Note:* syringes are no longer called U40, U100, etc.)

Needles: 29–31 gauge short needles

Antimicrobial swab

Dry gauze sponge

Clean gloves if indicated

Preparation

1. Follow steps for Preparing Injections.

2. Obtain client's blood glucose level *before preparation* to determine appropriate administration of insulin. See Chapter 20 (Specimen Collection) for finger stick blood.

For Newly Diagnosed Diabetic Client

- a. Explain to client that the dose of short-acting insulin must be adjusted according to blood glucose test results.
- b. Explain that there is a variation in levels—the lowest blood glucose level is before meals and highest 1–2 hr after meals.
- c. Goal of treatment is to eliminate wide swings in glucose levels.

Procedure

For One Insulin Solution

1. Perform hand hygiene.
2. Turn intermediate or long-acting (cloudy) insulin vial top-to-bottom 10 times. ► **Rationale:** This brings cloudy insulin solution into suspension. Clear insulins do not require this.

▲ Select site on lateral aspect of mid-upper arm for subcutaneous injection.

▲ Insert needle at 45° or 90° angle, using short needle for subcutaneous injection.

▲ Sites for subcutaneous injections given routinely. (Avoid umbilicus area.) Abdomen site preferred for insulin injection as absorption is more predictable.

3. Wipe top of insulin bottle with antimicrobial swab.
4. Remove needle guard and place on tray.

Clinical Alert

Hypoglycemia (blood sugar <60) is the most common adverse effect of insulins. Client should wear Med-Alert bracelet/ID to alert others. The client should be instructed to carry at least 15 g of fast-acting sugar (e.g., glucose tablet, 1 T sugar, jelly, honey) to be taken in the event of a hypoglycemic reaction.

Clinical Alert

Do not shake insulin vial, as this destroys insulin potency. Rolling the vial fails to bring insulin into suspension. Turn the vial top to bottom 8 to 10 times instead.

▲ Types of insulin syringes used based on unit dosages required.

▲ Use upper shaded triangle for IM injection in upper arm; use lower shaded area for subcutaneous injection.

5. Pull plunger of syringe down to desired amount of medication (e.g., 12 units). With vial upright, inject amount of air into air space, not into insulin solution.
 - ▶ **Rationale:** Injecting air directly into insulin solution causes bubbles.
6. Withdraw ordered amount of insulin into syringe.
7. Validate medication record, insulin bottle, and prepared syringe with an RN for accuracy.
 - ▶ **Rationale:** Double-checking insulin helps safeguard against errors.
8. Remove needle from vial and expel air from syringe.
9. Replace needle guard.
10. Take medication to client's room.
11. Follow steps for administration of medications by subcutaneous injection.

For Two Insulin Solutions

1. Check medication orders.
2. Perform hand hygiene.
3. Follow steps for combining medications in one syringe using two vials.
4. Turn cloudy insulin **Bottle (A)** top to bottom 8–10 times.
 - ▶ **Rationale:** This brings cloudy solution into *suspension*.
5. Wipe top of both insulin bottles with alcohol swab.
6. Take needle guard off and place on tray.

Clinical Alert

The IV route is superior for administering RAPID OR SHORT-ACTING insulin to an obese client. Adipose tissue slows onset of insulin action.

Clinical Alert

Long-acting insulin, LANTUS (glargine) and Levemir (detemir), are clear solutions. These are *not* to be mixed with any other type of insulin or solution. They are administered subcutaneously and are not intended for IV use.

TABLE 18-1 Insulin Types and Therapeutic Action (in Minutes/Hours*)

Types	Inject**	Onset	Peak	Duration
Very Rapid Acting (clear solution)				
Humalog® (lispro) NovoLog® (aspart)	Within 15 min AC or immediately PC Within 5–10 min AC	5–15 min	30–90 min	3–5 hr
Apidra® (glulisine)	15 min AC or within 20 min after <i>starting</i> a meal			
Short Acting (clear solution)				
Novolin R Humulin R	Per order Within 30–60 min AC	0.5–1 hr	2–4 hr	5–7 hr
Intermediate Acting (cloudy solution)				
Humulin N (NPH) Novolin N (NPH)	Per order Per order	1–2 hr	6–10 hr	16–24 hr
Mixtures (cloudy solution)				
Novolin 70/30 (70% NPH, 30% Regular) Humulin 70/30 (70% NPH, 30% Regular) Humulin 50/50 (50% NPH, 50% Regular)	Per order Within 30–60 min AC	30 min	R- 2–4hrs N-6–10 hr	24 hr
Humalog 75/25 (75% lispro protamine suspension, 25% lispro) Humalog 50/50 (50% lispro protamine suspension, 50% lispro) NovoLog 70/30 (70% aspart protamine suspension, 30% aspart)	Within 15 min AC Within 15 min AC Within 15 min AC	15 min	1 hr	
Long Acting				
Lantus (glargine) (<i>clear solution</i>) Levemir (detemir) (<i>clear solution</i>)	Daily	4–6 hr	No peak	24 hr

*The time of insulin action may vary significantly in different clients and in the same client at different times.

**AC = before meals; PC = after meals.

Insulin is biologically engineered through the process of recombinant-DNA technology. Insulin is produced by different companies who use different names for short-, intermediate-, or long-acting forms of insulin or their mixtures.

NPH = neutral protamine Hagedorn

- Pull plunger of syringe down to prescribed units of cloudy insulin.
- Insert needle and inject air equal to cloudy dose into upright **Bottle A** (*cloudy*) insulin.
- Withdraw needle.
- Pull plunger of syringe down to prescribed units of clear insulin.
- Insert needle and inject air equal to clear dose into upright **Bottle B** (*clear*) insulin.
- Invert vial and withdraw medication. ► **Rationale:** Withdrawing *clear* insulin first prevents inadvertent injection of intermediate-acting insulin into rapid- or short-acting insulin bottle, which would slow its rapid action.
- Double-check your preparations with another nurse.

- Withdraw needle from bottle and expel all air bubbles.
- Invert **Bottle A** and insert needle. Take care not to inject any rapid or short-acting (*clear*) insulin into intermediate-acting (*cloudy*) insulin bottle. This can be avoided by holding steady pressure on plunger when inserting needle into bottle.
- Pull back on plunger to obtain exact prescribed amount of intermediate or long-acting insulin. The total insulin dose now includes both the clear insulin, previously drawn up into syringe, and the intermediate cloudy insulin you have just drawn up.

Clinical Alert

Do not massage site after injection of certain drugs such as insulin or heparin because this hastens absorption and drug action and may cause tissue irritation.

- Withdraw needle from bottle and replace needle guard.
- Follow protocol for administration of medications by subcutaneous injections.

▲ Step 1: Inject prescribed amount of air into intermediate-acting (cloudy) insulin vial—withdraw needle without needle touching solution.

▲ Step 2: Inject prescribed amount of air into rapid- or short-acting (clear) insulin vial. Do not withdraw needle.

▲ Step 3: Invert vial of rapid or short-acting insulin; withdraw prescribed amount of medication and withdraw needle from vial.

▲ Step 4: Invert intermediate-acting insulin vial and withdraw exact amount without injecting insulin into bottle.

Premixing Types of Insulin

- Mixtures of rapid-acting (Humalog) and intermediate- or long-acting insulin should be administered within 10 minutes before a meal.
- Mixtures of NPH and regular (short-acting) insulin should be administered 20 to 30 minutes before a meal.
- Mixtures may be stored in refrigerator for up to 30 days and should be gently resuspended before injection.

Clinical Alert

Insulin type and brand should remain consistent for an individual client.

▲ Double-check insulin dose with a second nurse to help prevent errors in preparation.

EVIDENCE-BASED PRACTICE

The Importance of Double-Checking Drug Dose

- Double checks have revealed that up to 4.2% of *prescriptions* are filled erroneously.
- Double checks help the nurse identify mistakes that are difficult for someone alone to recognize.
- Double checks work best when each nurse calculates desired dosages *independently* rather than having another nurse “*verify*” what has been prepared.

Source: Cohen, M. (2002). Double checking for errors. *Nursing* 2002, 32(3), 18.

Using an Insulin Pen

Equipment

Insulin delivery device labeled with client’s name:
Prefilled pen or cartridge with correct insulin type with instructions for use

Device-compatible needle
Antimicrobial swab

Clinical Alert

Insulin injection “dial a dose” pens contain a prefilled multidose cartridge available with various types of insulin.

- The pen is intended for single-client use.
- Do not aspirate contents out of the pen cartridge with a needle as pen calibration will no longer be accurate.
- A sterile disposable needle is attached for each injection.
- An “air shot” primes the needle before the appropriate dose (units) of insulin is dialed for injection.

After initial use, device may be kept for 28 days. Most devices are not to be stored in the refrigerator nor to be exposed to excessive heat.

Preparation

1. Perform hand hygiene.
2. Identify client.
3. Complete the first “Five Rights” validation again before administering insulin. Note: The sixth right is documentation and is not indicated here. ► **Rationale:** The client may be receiving more than one type of insulin.

Procedure

1. Remove pen cap and insert insulin cartridge (if indicated).
2. Turn pen up and down at least 10 times if indicated. ► **Rationale:** To create suspension of cloudy insulin.
3. Wipe pen’s rubber stopper with antimicrobial swab before placing pen needle.
4. Remove needle cap and screw needle onto the pen immediately before injecting.

▲ Air shot clears cartridge and needle of air and primes needle for injection.

5. Pull cover off needle.
6. Hold pen with needle up and tap cartridge to move air bubbles to top of cartridge.
7. Dial pen dose selector to 2 units.
8. Keeping needle pointing upward, press push button until dose selector returns to “0”. ► **Rationale:** This will allow an “air shot” to clear cartridge of air and prime needle before injection. A drop of insulin should show at the needle tip. *Do not recap after priming needle.*
9. Check that dose selector is set at “0”, then dial required number of insulin units to be injected; listen for a click for each unit dialed.
10. Swab client’s injection site.
11. Insert needle perpendicular (90° angle) to the skin, maintaining constant pressure. The needle is in the subcutaneous tissue when the shield completely retracts (1/2 in.) and touches the insulin reservoir.
12. Using your thumb, press pen “push button” completely and keep depressed, counting to 10 after plunger has returned to “0” position before removing needle from skin.

NOTE: There may be a drop of residual fluid left on skin after injection due to fall back into shield with priming.

13. Do not massage the area.
14. Remove retracted pen needle from device and dispose in sharps container. ► **Rationale:** A new needle must be used for each injection.
15. Replace pen/device cap and store according to directions.

Clinical Alert

An FDA alert reminds healthcare providers that single-patient insulin pens and insulin cartridges must not be used for multiple patients, even if needles are changed, due to risk of transmitting bloodborne pathogens.

▲ Press pen firmly on client’s abdomen to engage needle; inject dialed units and hold 10 seconds before releasing. Remove needle, dispose in sharps receptacle. Recap and return pen to storage area for future use.

The Client With an Insulin Pump

- Continuous Subcutaneous Insulin Infusion (CSII) is a form of intensive insulin therapy utilized as an alternative to multiple daily injections in an attempt to achieve optimal glycemic control and decrease risk of long-term complications of diabetes. Insulin pumps are manufactured by a number of companies that provide 24-hr emergency and clinical specialists to assist clients with start-up of their pump. All models consist of a battery-powered pump with insulin reservoir, an infusion catheter, and microcomputer that allows programming to deliver basal and bolus doses according to the physician orders. Only rapid-acting or short-acting insulin is used.
- CSII more closely mimics release of insulin by the pancreas with continuous-delivery basal and bolus insulin infusion.
- Basal rate/rates: amount of insulin delivered (units per hour) to keep blood glucose levels in target range between meals and overnight.
- Bolus: additional amount of insulin delivered immediately before meals or for episodes of hyperglycemia, the greatest risk associated with insulin pump therapy.
- The client should be referred to a certified diabetes educator before the start of pump use. Insulin

▲ MiniMed 507 Insulin Pump attached to infusion set. Abdominal site is preferred because insulin absorption is faster and most predictable.

boluses will be based on blood glucose readings and carbohydrate grams intake.

- The client performs frequent fingerstick blood glucose checks: before adjusting any insulin dose, fasting, before meals, 2 hr after eating, at bedtime, and at 3 AM weekly.
- Lifestyle advantages: flexibility; insulin needs can be tailored to changes in schedule (meal time, exercise, or sleep).

Clinical Alert

Insulin pump management and education should be done by a certified diabetes educator who is also a certified insulin pump trainer.

Clinical Alert

If insulin must be discontinued (e.g., for MRI, CT scan), the pump should be disconnected. Blood glucose level should be checked before disconnecting and upon reconnecting. Ketoacidosis can occur within 2 hr if insulin delivery is interrupted.

Administering Subcutaneous Anticoagulants (Heparin, LMWH, Arixtra)

Equipment

Heparin in vial (*carefully note units per mL*)
 1-mL tuberculin syringe or unit-dose syringe with small (25–29) gauge needle
 or
 Low-molecular-weight heparin (LMWH) or Arixtra in prefilled syringe
 Antimicrobial swab
 Dry gauze sponge
 Gloves (if indicated)

Preparation

1. See Preparing Injections.

2. Double-check heparin calculated dose with another nurse.
3. Perform hand hygiene.

NOTE: To avoid loss of drug, do not clear prefilled syringe needle of air before injecting LMWH or Arixtra

Clinical Alert

Heparin is available in a variety of strengths (e.g., 1,000, 2,500, 5,000, 10,000, 25,000 units per mL vials). *Carefully* check vial units per mL before drawing into syringe and have another nurse double-check your calculations and prepared injection.

Clinical Alert

Subcutaneous injection of low-molecular-weight heparin (LMWH) or Arixtra involves low doses that help prevent clot formation but do not alter blood coagulation studies and do not require coagulation monitoring as does unfractionated heparin.

Clinical Alert

To prevent tissue damage and bruising, do not aspirate or massage anticoagulant injections.

Procedure

1. Check client's record for site of previous injection.
 - ▶ **Rationale:** Injections should be rotated to prevent local post-injection complications.
2. Take prepared injection to client's room, and check room and bed number against client's MAR.
3. Check client's Ident-A-Band, and ask client to state name and birth date.
4. Provide privacy.
5. Explain procedure and purpose to client.
6. Don gloves (if indicated).
7. Assist client to supine position.
8. Select site on client's lower abdomen (at least two fingerbreadths from umbilicus) or select area of fatty tissue above iliac crest. ▶ **Rationale:** Anticoagulants should not be administered IM or in the extremities.
9. Avoid ecchymotic area or lesions.
10. Cleanse site gently with antimicrobial swab, and allow to dry.
11. Gently pinch an inch of subcutaneous tissue (fat roll) between thumb and forefinger of nondominant hand and hold fat pad throughout injection.
12. Hold syringe between thumb and forefinger of dominant hand and insert full length of needle into skinfold at a 90° angle.
13. Inject medication slowly *without* aspirating first.
 - ▶ **Rationale:** Aspiration can rupture small vessels and increase risk of bleeding into tissue.
 - Note: Press prefilled syringe plunger rod firmly as far as it will go.*
14. Wait 10 seconds before gently withdrawing needle at same angle in which it entered skin. ▶ **Rationale:** This allows medication to absorb into tissue and minimizes bruising.

NOTE: Release of Arixtra plunger will cause needle to retract into the security sleeve as it automatically withdraws from the skin.

▲ Activate needle safety feature; then, dispose of syringe in sharps container.

Administering Intramuscular (IM) Injections

Equipment

- Medication vial or ampule
- 3-mL syringe with 1–1½ in. needle (21–23 gauge)
- Antimicrobial swab
- Dry gauze sponge
- Gloves (if indicated)

Preparation

See Preparing Injections.

Intramuscular

▲ Insert needle at 90° angle for IM injections into muscle.

▲ Overlay of hand shows area of injection into ventrogluteal site for IM injections (client's right side).

Procedure

1. Check client's record for site of previous IM injections.
 - ▶ **Rationale:** IM injections should be rotated to prevent local post-injection complications.
2. Take prepared injection to client's room. Check room and bed number against client's MAR.
3. Check client's Ident-A-Band, and have client state name and birth date.
4. Explain procedure to client.
5. Provide privacy for client.
6. Perform hand hygiene and don gloves, if indicated.
7. Select injection site, identifying bony landmarks. Consider client's size and amount and viscosity of medication being injected. Alternate sites each time injections are given.
8. Cleanse area with antimicrobial swab and allow to dry.
9. Spread skin taut between thumb and forefinger (grasping muscle is acceptable in pediatric and geriatric clients with less fatty tissue) to ensure needle placement in muscle belly.

▲ Locate greater trochanter and anterior superior iliac spine.

▲ Place palm at trochanter and index finger at anterior superior iliac spine; fan remaining fingers posteriorly.

▲ Shaded area indicates site location for vastus lateralis injection.

▲ Select site one hand breadth below greater trochanter and one hand breadth above knee for vastus lateralis injection.

10. Insert needle perpendicular (90° angle) to the muscle, using a quick, darting motion. ► **Rationale:** This angle facilitates medication reaching muscle.
11. Pull back on plunger for 5 to 10 seconds; if blood returns, discard and prepare a new injection. ► **Rationale:** The appearance of blood indicates needle has entered a blood vessel. Medication must not be injected directly into bloodstream.
12. Inject medication slowly (10 seconds per mL). ► **Rationale:** This allows time for medication to disperse through tissue.

▲ Site is middle third an anterior-lateral aspect of thigh. Avoid the rectus femoris muscle (anterior thigh).

▲ Inject medication at 90° angle directly into muscle.

13. Hold needle in place for 10 seconds, then withdraw needle and massage area with dry gauze sponge.
14. Activate needle safety feature.
15. Dispose of syringe/needle unit in puncture-proof container.
16. Return client to comfortable position.
17. Discard gloves and perform hand hygiene.
18. Chart medication and site of injection.

Techniques for Minimizing Pain During IM Injections

- Encourage client to relax.
- Use a new needle for injection.
- Place client on side with upper knee flexed for ventrogluteal injection.
- Have client place hand on hip to relax deltoid muscle.
- Avoid injecting into sensitive or hardened tissue.
- Apply pressure to site for 10 seconds before injecting.
- Ensure that needle length reaches muscle for IM injection.
- Prevent antiseptic from clinging to needle during insertion by waiting until skin prep is dry.

- Reduce puncture pain by “darting” needle quickly into muscle.
- Use as small a gauge needle as possible.

▲ Locate deltoid site in the area between two fingerbreadths below the acromion process and anterior axillary fold.

- Inject medication slowly (10 seconds per mL).
- Hold needle in place for 10 seconds after injecting medication.
- Maintain grasp on syringe; do not move needle once inserted.
- Withdraw needle quickly after injection.
- Use Z-track technique.
- EMLA cream may be applied 30 to 40 minutes before injection.

▲ Inject medication into deltoid area site.

EVIDENCE-BASED PRACTICE

Choose the Right Needle Size

A 5/8-in. needle won't reach deltoid muscle in 17% of men and 50% of women. A 1-in. needle is better for men (130–260 lb) and women (132–198 lb).

Source: Zuckerman, J. N. (2000, November 18). The importance of injecting vaccines into muscle. Different patients need different needle sizes. *BMJ*, 321(7271), 1237–1238.

Using Z-Track Method

Equipment

- Syringe
- Filter needle for preparation
- 2-in. needle for injection
- Medication
- Antimicrobial swab
- Dry gauze sponge
- Gloves (if indicated)

Preparation

See Preparing Injections.

Procedure

1. Use filter needle to draw up prescribed medication into syringe.

Z-Track Injection

- ▲ Z-track injection. Maintaining displacement, insert needle at 90° angle. Aspirate by pulling back on plunger, checking to see if needle is in blood vessel. If blood is aspirated, discard and prepare new injection.

▲ Z-track injection, after displacement released. Method is used to prevent backflow of medications into subcutaneous tissue.

2. Attach new 2-in. sterile needle to syringe. ► **Rationale:** A new needle prevents introducing medication that could be irritating to tissue. A long needle allows medication to go deep into the muscle.

Clinical Alert

The Z-track method prevents “tracking” and is recommended for administering medications into the ventrogluteal or vastus lateralis sites.

3. Take medication to client’s room; check room number against MAR.
4. Check Ident-A-Band, and ask client to state name.
5. Provide privacy.
6. Explain procedure and purpose to client.
7. Perform hand hygiene and don gloves (if indicated).
8. Position client for ventrogluteal or vastus lateralis injection.

9. Cleanse site with antimicrobial swab.
10. Pull skin 1–1½ in. laterally away from injection site. ► **Rationale:** This tissue displacement creates a track that keeps medication from seeping into subcutaneous tissue.
11. Maintain displacement and insert needle at a 90° angle. Aspirate by pulling back on plunger (5 to 10 seconds) to see if needle is in blood vessel. If so, discard and prepare new injection.
12. Inject medication slowly (10 sec per mL) and wait 10 seconds, keeping skin taut. ► **Rationale:** Permits muscle relaxation and absorption of medication.
13. Withdraw needle and release retracted skin. ► **Rationale:** Lateral tissue displacement interrupts needle track and seals medication in the muscle when the tissue is released.
14. Apply light pressure with dry gauze sponge. Do not massage. ► **Rationale:** Massage may disperse medication into subcutaneous tissue and cause tissue irritation.
15. Activate needle safety feature.
16. Return client to a position of comfort and safety.
17. Discard gloves and equipment in appropriate area.
18. Perform hand hygiene.
19. Document administration of medication in the medication record.

Clinical Alert

If client is obese, use a 2–3-in. needle so that medication is absorbed into muscle (not fat) tissue and blood level of drug is achieved.

DOCUMENTATION for Parenteral Medications

Client’s Medication Record

- Time administered
- Name of medication
- Dosage
- Route
- Injection site
- Initials of nurse administering medication
- Signature by nurse (to identify initials)

Nurses’ Notes

- Record PRN, STAT, intradermal, and one-time-only medications
- Name of medication, dosage, route, site, time administered
- Client’s pre- and post-injection assessment findings (sedation and pain rating, any relevant laboratory data)
- Signature of nurse

CRITICAL THINKING Application

Expected Outcomes

- Injection is administered without complications.
- Injection is as painless as possible.
- Medication therapeutic effect is achieved.

Unexpected Outcomes

Ecchymosis occurs after heparin injection.

Client experiences pain with IM injection.

Medication is administered using wrong parenteral route.

Client has allergic or anaphylactic response to medication.

Obese client fails to obtain pain relief from subcutaneous injection.

Alternative Actions

- Rotate injection site. Do not inject medication into ecchymotic area.
- Do not aspirate before injection or massage site after needle withdrawal.
- Do not pinch tightly when forming fat pad in preparation for injection site.
- Apply ice to area before injecting heparin.
- Use Z-track method for ventrogluteal or vastus lateralis sites to prevent medication from leaking into subcutaneous tissue.
- Use new needle for injection.
- Inject medication slowly (10 sec/mL) to allow medication to diffuse.
- Hold needle in place for 10 seconds after injection.
- Use a dry gauze sponge to apply pressure to site after withdrawing needle.
- Notify physician; medications may need to be administered to reverse the action of the medication.
- Monitor client's response closely and report adverse findings immediately.
- Medication administered IM or IV rather than subcutaneous route leads to faster absorption rates; therefore ongoing assessment must be done to determine effects. (IV administration has immediate action.)
- Complete unusual occurrence report according to agency policy.
- Call rapid response team immediately.
- Maintain a patent airway and follow ABCs of emergency care.
- Notify client's physician.
- Document incident; place allergy alert bracelet on client.
- Complete unusual occurrence report according to agency policy.
- Consult pain management team.
- Consider weight-based dosage.
- Obtain order to change to IV route for analgesic administration since adipose tissue has decreased perfusion and subcutaneous medication uptake is unpredictable.

GERONTOLOGIC Considerations

Older clients take more medications than any other age group, largely because of chronic illness. Risk of adverse drug events rises with comorbidity. *Major problems with prescriptive drugs in the elderly include the following:*

- Drug–drug interactions—seniors may use multiple physicians and pharmacies, each unaware of what others have prescribed, creating risk of taking two or more medications to treat the same condition.
- Medication errors—the more medications a person takes, the greater risk of medication error (people over age 75 take an average of 17 prescriptions annually).
- Poor adherence—not taking right dose at right time or discontinuing drug without consultation; common due to lack of understanding about reason to take drug and general knowledge base of drug action. Elders may have difficulty reading labels and directions and opening medicine containers.
- Unpredictable drug action—age-related physiologic changes and comorbid conditions affect drug utilization (absorption, distribution, metabolism, and elimination).
- Drug side effects not recognized—elderly not aware or do not understand potential dangerous side effects of drugs.
- Inadequate monitoring—elderly are often alone or not monitored consistently, so drug problems are not identified.
- Cost of drugs—multiple medications are costly for many elderly, so they may reduce the frequency of dosing or stop taking a drug.

The Elderly Are at Risk for Drug Toxicity

- Drug absorption is altered; oral route is slower, but complete; topical route absorption may increase due to thin skin.
- Drug distribution is altered; increased percentage of body fat in the elderly results in longer storage of fat-soluble medications. The elderly have proportionately less body water, so blood levels of a water-soluble drug may be higher than usual.
- Decreased blood flow through the liver slows medication metabolism.
- Altered renal excretion, slows drug excretion.

- Reduced protein level (increased ratio of fat to muscle) decreases medication binding and increases free circulating drug levels.
- Increased CNS sensitivity to drugs that interfere with neurotransmitters that regulate brain function.

Drugs the Elderly Should Avoid:

- Sedatives/hypnotics
- Tranquilizers (antianxiety medications)
- Anticholinergics (belladonna alkaloids, antispasmodics)

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- Registered and licensed vocational nurses are responsible for administering oral and parenteral medications to clients. In some nonacute facilities, such as residential homes, geriatric technicians may administer medications following standard procedures.
- Individuals administering medications must be knowledgeable about the RATIONALE for their use. This insight cues the need for specific pre- and post-administration individual client assessment (responses such as vital signs, lab values, adverse reactions) as an integral part of this deceptively simple skill.
- Unlicensed assistive personnel are not trained (or expected) to obtain and interpret essential client data

necessary for decision making when administering medications. However, if they are assigned to administer daily care, they should be informed what to observe for and report to the RN or LVN/LPN.

Communication Matrix

- *Immediately report to physician:*
All errors in medication administration (and complete agency variance report)
Ineffective client responses to medication including adverse responses (vital signs, rash, paradoxical reaction, etc.)
Reports of abnormal relevant lab data (e.g., toxic drug levels)
- *Report to relief staff:*
All of the above PLUS:
Any new or discontinued medication orders PRN, STAT, and one-time-only medications given
Effectiveness of medication therapy

Drug Supplement**Calculations of Solutions****Types of Solutions**

1. Volume to volume (vol/vol): a given volume of solute is added to a given volume of solvent.
2. Weight to weight (wt/wt): a stated weight of solute is dissolved in a stated weight of solvent.
3. Weight to volume (wt/vol): a given weight of solute is dissolved in a given volume of solvent, which results in the proper amount of solution.

Preparing Solutions**Solutions of Varying Strengths**

Determine the strength of the solution, the strength of the drug on hand, and the quantity of solution required.

Use this formula for preparing solutions:

$$\frac{D}{H} \times Q = X$$

where D = desired strength; H = strength on hand; Q = quantity of solution desired; and X = amount of solute.

Example: You have a 100% solution of hydrogen peroxide on hand. You need a liter of 50% solution.

$$\frac{50}{100} \times 1,000 \text{ mL} = 500 \text{ mL (solute)}$$

If the strength desired and strength on hand are not in like terms, you need to change one of the terms.

Example: You have 1 L of 50% solution on hand. You need a liter of 1:10 solution. 1:10 solution is the same as 10%.

$$\frac{10\%}{50\%} \times 1,000 \text{ mL} = 200 \text{ mL (solute)}$$

Add 200 mL of the drug to 800 mL of the solvent to make a liter of 10% solution.

Volume-to-Volume Solutions

Use the formula:

$$\frac{D}{H} \times Q = X$$

Example: Prepare a liter of 5% solution from a stock solution of 50%.

$$\frac{5\%}{50\%} \times 1,000 \text{ mL} = 100 \text{ mL}$$

Add 100 mL to 900 mL of diluent to make 1 L of 5% solution.

Solutions From Tablets

Use the formula:

$$\frac{D}{H} \times Q = X$$

where X = amount per number of tablets used.

Example: Prepare 1 L of a 1:1000 solution, using 10-gr tablets.

$$\frac{1/1000}{10 \text{ gr}} \times 1,000 \text{ mL} = X$$

First convert 10 gr to grams so the numerator and denominator are in the same unit of measure. 1 g = 15 gr; therefore 10 gr = 2/3g. Now substitute the new numbers in the formula and solve for X.

$$\frac{1/1000}{2/3} \times \frac{1000}{1} \text{ mL} = X$$

$$\frac{3}{2000} \times \frac{1000}{1} = X$$

$$X = 2/3 \text{ or } 1\frac{1}{2} \text{ tablets}$$

Place 1½ tablets into the liter of solution and dissolve.

Abbreviations and Symbols

aa	of each	oob	out of bed
a.c.	before meals	oz	Ounce

Abbreviation Alert

Abbreviations to Avoid: Entries marked* are prohibited by The Joint Commission

@ (at) misinterpreted as a 2. Write out “at.”

AU (each ear) misinterpreted as OU (each eye). Do not use AU. Also avoid AD (right ear) and AS (left ear).

cc (cubic centimeter) misinterpreted as units. Write “mL” for milliliters.

D/C misinterpreted as discharge or discontinue. Write out “discharge” or “discontinue.”

Dram symbol (ʒ) misinterpreted as a 3. Write out “dram.”

Per os (orally) misinterpreted as OS (left eye). Use “PO.”

IN (intranasal) misinterpreted as IM (intramuscular) or IV (intravenous), or as inhaled. Write out “intranasal” and “inhaled.”

*IU (international unit) misinterpreted as IV. Write “international unit.”

Large doses without properly placed commas (e.g., 100000). Place commas appropriately.

*MS, MSO₄, or MgSO₄ confused for one another. Write “morphine sulfate,” “magnesium sulfate.”

*Q.D. (each day) misinterpreted as qid (four times a day). Write “daily.”

*Q.O.D., (every other day) misinterpreted as four times a day. Write “every other day.”

qhs (at bedtime) misinterpreted as qh (every hour). Write “at bedtime.”

SC or SQ, sub q (subcutaneous) misinterpreted as SL for sublingual. “sub q 2 hours before surgery” has been misinterpreted as “every 2 hours before surgery.” Write “subcutaneously.”

ss̄ (one-half) misinterpreted as 55. Write “one-half.”

SSRI (sliding scale regular insulin) misinterpreted as selective-serotonin reuptake inhibitor Write out.

*Trailing zero after a decimal point (e.g., 5.0). Use a zero before a decimal point, never after.

*U (unit) misinterpreted as cc, or 0. Write “unit.”

µg (microgram) mistaken for milligram. Write “mcg.”

X4d (for 4 days) misinterpreted as times three doses. Write out “for four days.”

0.008 g	or	8 mg	=	gr ⅓
4 g			=	1 dr
30 g			=	1 oz
1 kg			=	2.2 lb

CRITICAL THINKING Strategies

Scenario 1

Your client has recently suffered a “brain attack” (stroke), which has caused him to have difficulty swallowing (dysphagia) and places him at risk for aspiration. When the previous shift nurse attempted to have him take his oral medications with water, he coughed and choked violently, so the nurse discontinued efforts to complete his medication administration. One of this client’s most important medications is Inderal LA 80 mg, a timed-release capsule that

is given once a day. This long-acting capsule cannot be opened and its contents emptied for convenient administration without interfering with the timed-release property of its formulation.

1. What types of consult would provide assistance in decision making about this client’s swallowing problem and medication administration?

2. What actions would facilitate this client's swallowing and decrease the risk of aspiration?
3. What alternative method is there for administering the Inderal LA?
4. How will the nurse communicate adjustments in administration to the other staff members?

Scenario 2

This is Nancy Drew's third hospitalization for diabetic ketoacidosis this year. She has been an insulin-dependent diabetic for 5 years (since age 9). For several years, Nancy has controlled the condition using two daily insulin injections, a combination of regular and NPH (intermediate-acting) before breakfast and dinner.

This year Nancy made the cheerleading A squad—quite an achievement and an honor—requiring practice before and after school, enrollment in gymnastics class, and participation at evening and weekend games, some of which were out of town. In addition, Nancy must attend cheerleading camp this summer and is preparing for all-state competition trials.

Nancy's condition is stabilized during hospitalization, and shortly before discharge she confides in you that she hates needles, that "the shots really hurt," and, in fact, she prepares the syringes and sometimes just throws them away. In addition, she has experienced low blood sugar on occasion while cheerleading and knows that something happens with her insulin "overreacting" at these times; it makes her uncoordinated and "confused," but she just can't take time out to ingest sugar. She is afraid of losing her position on the A squad—she worked so hard to get there.

1. Based on this data, identify Nancy's psychosocial needs and developmental tasks at age 14.
2. What are the implications of insulin absorption and action as influenced by exercise and site of administration?
3. Describe actions that can decrease pain associated with medications.
4. Suggest an alternative way for Nancy to maintain her insulin coverage without discomfort and erratic absorption rates.

Scenario 3

Your elderly client takes many medications at the same time, all for a variety of chronic disorders. She sees several physicians for these various conditions and uses several pharmacies to have prescriptions filled.

When you visit her, she asks you how she can remember to take all her medications, states that she doesn't take all the pills she should each day, and says that she feels fine anyway, without taking her medications.

1. Why do the elderly take so many medications (polypharmacy)?
2. Identify drugs that frequently cause adverse effects in the elderly.
3. Why are the elderly more susceptible to adverse drug events?
4. Identify some ways to protect elderly clients from adverse drug events due to polypharmacy.
5. How can the client's medication regimen be simplified to help prevent adverse drug events?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. The most common cause of injury due to medication errors is
 1. The wrong client.
 2. The wrong medication.
 3. The wrong dosage.
 4. The wrong route.
2. Before administering a medication that appears to be inappropriate for the client, the nurse should
 1. Consult the pharmacist.
 2. Consult the ordering physician.
 3. Consult the drug manufacturer.
 4. Recheck the medication against the MAR.
3. In general, agents that lower the blood pressure should be held if the client's systolic blood pressure is less than
 1. 110 mmHg.
 2. 100 mmHg.
 3. 95 mmHg.
 4. 90 mmHg.
4. Which of the following alterations of oral medications are acceptable?

Select all that apply.

 1. Capsules should never be opened.
 2. Beads from capsules may be chewed.
 3. Liquid from capsules can be mixed with food.
 4. Sublingual tablets may be given to the client who is NPO.
 5. Gel-coated tablets can be dissolved to ease swallowing.
5. The inner canthus is pressed to slow absorption of eye drops which
 1. Can cause systemic effects.
 2. Cause a burning sensation.
 3. Dilate the pupil.
 4. Treat eye infections.
6. When administering ear drops to an adult, the nurse positions the pinna
 1. Upward and backward.
 2. Downward and backward.

3. Upward and forward.
4. Downward and forward.
7. Bony landmarks for administering a ventrogluteal injection include
Select all that apply.
 1. Acromion process.
 2. Anterior superior spine of iliac crest.
 3. Posterior superior spine of iliac crest.
 4. Greater trochanter.
 5. Gluteal fold.
 6. Upper outer quadrant of buttocks.
8. Clients should keep track of the number of MDI actuations performed because
 1. The canister's remaining contents may have expired.
 2. The canister's remaining contents may be active ingredient only.

3. The canister's remaining contents may be propellant only.
 4. Clients become drug tolerant before the canister is empty.
 9. When preparing an insulin injection using two solutions, the following order should be used
 1. Add equivalent amount of air to the clear insulin.
 2. Add equivalent amount of air to the cloudy insulin.
 3. Withdraw the cloudy solution.
 4. Withdraw the clear solution.
 10. The greatest risk associated with use of an insulin pump is
 1. Site infection.
 2. Lipodystrophy.
 3. Insulin shock.
 4. Ketoacidosis.
-

Nutritional Management and Enteral Intubation

LEARNING OBJECTIVES

1. List the essential nutrients necessary to sustain life.
2. Describe the functions of the gastrointestinal system and accessory organs.
3. Identify the categories important for a total nutritional assessment.
4. Discuss feeding techniques and precautions used for dysphagic clients.
5. Identify clients who are candidates for modified diets.
6. List foods that are restricted or supplemented for clients who are receiving modified diets.
7. Outline steps for inserting a nasogastric tube.
8. Describe ways to determine placement of a nasogastric/intestinal tube.
9. Outline the steps of administering a tube feeding.
10. List possible complications of GI tract decompression.
11. Describe emergency management to decontaminate the GI tract of toxins/poisons.
12. Compare and contrast aspects of gastric versus intestinal tube feedings.
13. Discuss problems that may occur with tube feedings.

TERMINOLOGY

Alimentary of or pertaining to nutrition.

Anabolism reaction in which small molecules are put together to form larger ones—repairing or building up cells.

Anorexia loss of appetite for food.

Aspirate to remove fluids or gases by suction.

Aspiration accidental inspiration of fluid or a foreign body into the airway.

Calorie the amount of heat necessary to raise the temperature of 1 kilogram of water 1°C. This is the “small” calorie. The dietary, or large, Calorie represents 1,000 of these calories, or 1 kilocalorie.

Carbohydrates a group of chemical substances, including sugars, glycogen, starches, dextrans, and celluloses, that contain only carbon, oxygen, and hydrogen.

Cardio prefix pertaining to the heart.

Carina point at which the trachea divides into the right and left bronchi.

Cardiovascular term that pertains to the heart and blood vessels as cardiovascular system.

Catabolism reaction in which large molecules are broken down into smaller ones—process of breaking down cells.

Diabetic one who has inadequate production and/or use of insulin.

Diet liquid and solid food substances regularly consumed.

Digestion the process by which food is broken down mechanically and chemically in the gastrointestinal tract.

Diverticulosis diverticula of the colon without inflammation or symptoms.

Dumping syndrome symptoms that develop due to rapid entry of undigested food into the jejunum.

Dysphagia difficulty swallowing.

Emaciation a condition characterized by extreme leanness or thinness.

Emesis the act of vomiting.

Enteral nutrition provision of nutrients via the gastrointestinal tract (includes oral feedings).

Enterostomy opening into the stomach or jejunum through which a feeding tube can be inserted.

Fat substance made up of carbon, hydrogen, and oxygen, occurring naturally in most foods but especially in meat and dairy products.

Food supplement a preparation added to the regular diet that aids nourishment.

Gavage introduction of nourishment into the GI tract by mechanical means.

Gastrointestinal term that pertains to the stomach and intestines.

Hematemesis vomitus containing blood.

Hydrogenation a chemical process by which hydrogens are added to monounsaturated or polyunsaturated fats, making the fats more saturated, termed *trans fats*.

Hyperalimentation the process of nourishing the body through parenteral means.

Hyperglycemia condition characterized by an increase in blood sugar.

Hypertonic solution having a higher osmotic pressure or tonicity than a solution to which it is compared.

Hypoglycemia condition characterized by a deficiency of sugar or glucose in the blood.

Ileus obstruction of the intestine caused by paralysis of the intestinal muscles.

Ingest the process of taking material into the gastrointestinal tract.

Jejunostomy surgical creation of a permanent opening into the jejunum.

Kwashiorkor a type of protein-energy malnutrition primarily associated with hypermetabolic acute illness such as burns, trauma, sepsis.

Lavage to wash.

Lumen the inner open space of a tube.

Malnutrition a condition characterized by a lack of necessary food substances or improper absorption and distribution of food substances in the body.

Marasmus a type of protein-energy malnutrition due to long-term calorie and protein deprivation resulting in cachexia or severe muscle/fat depletion (COPD, HF, cancer, AIDS).

Minerals inorganic elements or compounds.

Nasogastric tube a tube that is passed through the nose and into the stomach.

Nasointestinal tube small-bore flexible tube passed through the nose and advanced to the proximal intestine to be used for short-term feeding.

Nausea a feeling of sickness accompanied with the urge to vomit.

Nutrient nourishing; food item that supplies the body with necessary elements.

Obstruction blocking of a structure that prevents it from functioning normally; obstacle.

Parenteral nutrition process of providing nutrition via a route other than the alimentary canal, such as intravenous.

PEG percutaneous endoscopic gastrostomy.

Polyunsaturated term usually referring to a fat, indicating that the carbon chain has more than one double bond. These fats tend to have higher densities (HDL) than saturated fats.

Projectile vomiting the expulsion of vomitus with great force.

Proteins substances that contain amino acids essential for growth and repair of tissues.

Renal term that pertains to the kidney.

Saturated fatty acid fatty acid carrying the maximum possible number of hydrogen atoms.

Sepsis Systemic inflammatory response to an infection or cellular injury process.

Trans fat a partially hydrogenated mono- or polyunsaturated fat.

Trauma an injury or wound.

Unsaturated fatty acid fatty acid that lacks hydrogen atoms and has at least one double bond between carbons (includes polyunsaturated and monounsaturated fatty acids).

Uremia toxic condition associated with end-stage renal disease and the retention of nitrogenous substances in the blood.

Vitamin organic substance essential for life.

NUTRITIONAL MANAGEMENT

Food is undeniably necessary for maintenance of life, and is, as a symbol, equally important to man’s psychological health. Food has powerful social meaning as it promotes hospitality, companionship, and kinship, and perpetuates ethnic heritage and traditional customs. While these emotional and social aspects are influential in food choices, they are not necessarily based on an awareness of the importance of nutrition in health.

Nutrition is the science of foods, the nutrients and other substances they contain and how they act in our body. These include carbohydrates, fats, proteins, fat-soluble and water-soluble vitamins, minerals, and water, all of which are necessary for life. The body requires a proper balance of nutrients, vitamins, and minerals for energy, growth and development, tissue repair and regulation, and maintenance of body processes. Malnutrition occurs when this balance is disrupted.

TABLE 19-1 Body Mass Index (BMI) Table

BMI	Normal						Overweight					Obese

Source: Adapted from Evidence Report of Clinical Guidelines on the Identification, Evaluation, and Treatment of Overweight and Obesity in Adults, 1998. NIH/National Heart, Lung, and Blood Institute (NHLBI). Centers for Disease Control and Prevention, United States Department of Health and Human Services.

The body can make some but not all nutrients, and some are made in insufficient amounts. Therefore, it is essential that a person obtain and consume the essential nutrients from exogenous sources. A deficiency of one nutrient causes abnormalities that will usually disappear if the deficiency is corrected. Deficiencies may be the result of decreased dietary intake, a disease condition, or even drug interactions.

RDA and DRIs

Standards have been established that recommend the amounts of energy, nutrients, other dietary components, and physical activity that best support health. These recommendations are called Dietary Reference Intakes (DRIs), which consist of several component values such as Recommended Dietary Allowances (RDAs). Established Energy Recommendations for dietary energy intake (kilocalories per day) have also been established. These recommendations are based on the requirements of an average healthy person of a particular age, gender, weight, height, and physical activity level so that energy intake does not exceed energy needs in order to help prevent obesity (excess amount of body fat). Obesity is associated with increased morbidity and mortality. It is recommended that body mass index (weight in kilograms, divided by height in meters squared, or weight in pounds multiplied by 704, divided by height in inches squared) should be kept within the range of 18.5 to 24.9.

Energy-producing nutrients, called macronutrients, include carbohydrates, fats, and proteins. The percentage of each macronutrient range recommended to provide adequate energy and nutrients, and to reduce risk of chronic diseases, follows:

45%–65% from carbohydrate	(4 kilocalories per gram)
20%–35% from fat	(9 kilocalories per gram)
10%–35% from protein	(4 kilocalories per gram)

The recommended intakes for nutrients are generous and probably should not be exceeded. Food labels now incorporate a column providing macronutrient and micronutrient (vitamins A and C, calcium, and iron) “% Daily Value.” This assists in calculating the particular food’s stated serving size energy-yielding nutrient contribution to the total diet (based on a 2,000-kilocalorie daily recommendation).

MACRONUTRIENTS

Carbohydrates

Carbohydrates are the chief source of energy and contain carbon, hydrogen, and oxygen. Carbohydrates include simple sugars, starches, and cellulose. Simple sugars (refined carbohydrates) such as white sugar, white rice, and white flour are easily digested. They cause fluctuations in blood sugar and create a feeling of hunger that can lead to overeating. Starches, which are more complex, require more sophisticated enzyme processes and are more slowly reduced to glucose, the end product of carbohydrate metabolism. Examples include whole grains and some fruits and legumes.

Glucose (converted sugars and starches) appears in the body as blood sugar and is “burned” as fuel by the tissues.

Glucose is the only energy source for red blood cells and is the preferred energy source for the central nervous system, placenta, and fetus. A minimum of 100 grams of carbohydrate is essential for daily brain function and to prevent ketosis. Some glucose is processed by the liver, converted to glycogen, and stored by the liver for later use.

The acceptable macronutrient range for carbohydrate is 45%–65% of total calories. Ingesting too many carbohydrate (sugars) supplies calories, but few if any nutrients. The greater the number of high-carbohydrate foods consumed, the more difficult it is to take in essential nutrients without weight gain. It is recommended that individuals select fiber-rich fruits and vegetables and whole grains often, and prepare food with little added sugar. Too few carbohydrates may lead to loss of energy, depression, ketosis, and a breakdown of body protein.

Fats

Fats or lipids are the second important group of nutrients. When oxidized, fats are the most concentrated sources of energy and, as such, furnish the calories necessary for survival. Fats also act as carriers for the fat-soluble vitamins, A, D, E, and K. The optimal percentage of fat in the diet is 20%–35% of our daily caloric intake. Consuming too much fat can lead to weight problems. High-fat diets may increase the risk of developing atherosclerotic cardiovascular disease and cancer.

Fatty acids are the basic components of fat and comprise two main groups: saturated fatty acids and unsaturated fatty acids. Saturated fatty acids usually come from animal sources.

Essential Body Nutrients

- Carbohydrates
 - Monosaccharides
 - Glucose, fructose, galactose
 - Disaccharides
 - Sucrose, lactose, maltose
 - Polysaccharides
 - Starch, dextrin, glycogen, cellulose, hemicellulose
- Fats
 - Linoleic acid, linolenic acid, arachidonic acid
- Proteins
 - Amino acids
 - Phenylalanine, lysine, isoleucine, leucine, methionine, valine, tryptophan, threonine, and histidine (required by infants, not adults)
- Vitamins
 - Fat-soluble
 - Vitamins A, D, E, and K
 - Water soluble
 - B and C vitamins
- Minerals
 - Calcium, chloride, iron, magnesium, phosphorus, potassium, sodium, sulfur
- Water
 - Trace elements

It is recommended to limit total fat and trans fat intake and *substitute* saturated (hydrogenated) fats with polyunsaturated and monounsaturated fats. Saturated fats typically are solid at room temperature and should not exceed 10% of calories; cholesterol and trans fat consumption should be limited to less than 300 mg daily. Unsaturated fatty acids primarily come from vegetables, nuts, or seed sources. The unsaturated group provides two essential fatty acids: linoleic and linolenic acid. These acids are called “essential” because they are necessary for health and growth and the body cannot manufacture them. They must therefore be obtained from the diet.

Proteins

Proteins, the third essential group of nutrients, are complex organic compounds that contain amino acids. Proteins are critical to all aspects of growth and development, necessary for building muscles, blood, skin, internal organs, hormones, and enzymes, and are also a source of energy when there is insufficient carbohydrate or fat in the diet. Protein is either used for tissue repair and maintenance or converted by the liver and stored as fat.

When digested and broken down, proteins form 20 amino acids. Amino acids are then absorbed from the intestine into the bloodstream and carried to the liver for synthesis into tissues and organs of the body. If just one amino acid is missing, protein synthesis is impaired. All but nine of the amino acids are produced by the body. These nine must be obtained from the diet. Eight essential amino acids are required by all, while infants require one more, histidine. If all are present in a particular food, the food is a “complete protein.” Foods that lack one or more of these essential amino acids are called “incomplete proteins.” Most meat and dairy products are complete proteins, and most vegetables and fruits are incomplete. When several incomplete proteins form the major portion of a person’s diet, they should be combined carefully so that the result is a balance yielding complete protein. For example, the combination of beans and rice is balanced to give a complete protein food.

It is difficult to determine the exact amount of protein needed to supply all of the essential amino acids because there are many variables. Height and weight, level of activity, and nutritional and health status all influence the amount of protein necessary for any individual. The National Research Council recommends that 0.42 gram (g) of protein be consumed per day per pound of body weight or 56 g/day for men and 45 g/day for women. The optimal healthy diet should be 10% to 12% protein.

Protein deficiency can affect the entire body—organs, tissues, skin, and muscles—as well as certain body processes. If a child is deficient in protein, he or she may suffer from kwashiorkor, a disease resulting in physical and mental impairment and, if severe enough, death. If an adult is deficient in protein, ability to recover from illness or surgery may be affected.

Protein is very plentiful in the body. It is an integral part of all cells and essential for growth and development. Just like fats and carbohydrates, adequate protein must be consumed in balance with other nutrients for human survival.

Water

Although not specifically a nutrient, water is essential for survival. Water is involved in every body process, from digestion and absorption to excretion. It is a major portion of circulation and is the transporter of nutrients throughout the body.

Body water performs three major functions: it gives form to the body, constituting 50%–75% of the body mass; it provides the necessary environment for cell metabolism; and it maintains a stable body temperature.

Almost all foods contain water that is absorbed by the body. The average adult body contains about 53 liters of water and loses 2.8 liters a day. If a person suffers severe water depletion, dehydration can result and can eventually lead to death. A person can survive several weeks without food, but only days without water. In order to prevent dehydration (water loss exceeding water intake), a general requirement is to drink 2–3 liters of water daily, or 1 mL/kcal expenditure. Measures of intake and output assist the healthcare team in identifying and correcting body water imbalances.

MICRONUTRIENTS

Vitamins

Vitamins are organic food substances and are essential in small amounts for growth, maintenance, and the functioning of body processes. Vitamins are found only in living things—plants and animals—and usually cannot be synthesized by the human body.

Vitamins can be grouped according to the substance in which they are soluble. The fat-soluble group includes vitamins A, D, E, and K. Excessive amounts of vitamins A and E can be quite toxic. The water-soluble vitamins include eight B complex vitamins, vitamin C, and the bioflavonoids. These are usually measured in milligrams.

Vitamins have no calorie value, but they are as necessary to the body as any other basic nutrient. Currently, there are about 20 substances identified as vitamins, but recent research is concerned with identifying even more of these substances since they are so essential to survival.

Minerals

Minerals are inorganic substances, widely prevalent in nature, and essential for metabolic processes. Minerals are grouped according to the amount found in the body. *Major minerals* include calcium, magnesium, sodium, potassium, phosphorus, sulfur, and chlorine, all of which are measured in milligrams. A second group—*trace minerals*—include iron, copper, iodine, manganese, cobalt, zinc, fluorine, selenium, and molybdenum. These minerals are measured in micrograms. Minerals form 60%–90% of all inorganic material in the body and are found in bones, teeth, soft tissue, muscle, blood, and nerve cells.

Minerals act as catalysts for many metabolic processes, and all minerals work synergistically with other minerals; their

actions are interrelated. A deficiency of one mineral, therefore, affects the action of others in the body. It is essential that adequate minerals be ingested because a mineral deficiency can result in serious illness. A balanced diet that includes a variety of foods provides most fat-soluble and water-soluble vitamins and minerals.

Refined foods such as rice, pasta, cereals, and products that include these may suffer loss of nutrients during processing. To compensate for these losses, many foods are *enriched* with iron, thiamin, riboflavin, and niacin. Since the 1940s, all grain products are enriched, with folate being added in 1996 to help prevent birth defects. Food labels indicate such enrichment. Additionally, some foods are *fortified* by the addition of nutrients that are not present or are present in insignificant amounts in a food, such as orange juice fortified with calcium and vitamin D.

While some nutritionists and biochemists recommend taking a daily basic vitamin–mineral supplement to ensure adequate levels, the intake of supplements in excess of the Tolerable Upper Level Intake can have toxic systemic effects. Tolerable Upper Intake levels represent the maximum amount of a nutrient that is safe for most people on a daily basis.

As new knowledge surfaces about the importance of nutrients for basic health, the recommended intake reflects this increased awareness.

NUTRITIONAL ASSESSMENT

Healthy individuals can satisfy essential nutrient recommendations by following a personalized approach to healthy eating and exercise. The *Dietary Guidelines for Americans 2005* MyPyramid, published by the U.S. Department of Agriculture, includes daily intake recommendations for the five food groups (grains, vegetables, fruits, milk, and meat and beans) and liquid oils, symbolized by color bands of different widths. A figure climbs steps up the pyramid as a reminder of the importance of regular physical activity. Color bands emphasize a variety of food groups. The wider base represents foods with little or no solid fats or added sugars. These should be selected more often than the foods at the narrow tip of the pyramid, which contain added sugars and solid fats. More active individuals can add more of these pyramid tip foods to their diet.

These recommendations consider an individual's size, age, and activity level, then estimate daily calorie needs, serving sizes, and activity requirements to prevent weight gain and sustain weight loss, as well as to reduce risk for major chronic diseases. Endorsement of a diet rich in fruits and vegetables provides greater than the median requirement of vitamins and minerals so that supplemental therapy of micronutrients is not necessary. The MyPyramid Food Guidance System provides options to help individuals make healthy food choices and to incorporate physical activity into daily living. Web-based interactive and print materials for consumers are available at www.mypyramid.gov.

Steps to a Healthier You

▲ Pyramid symbolizes a personal approach to healthy eating and exercise. *Source:* MyPyramid.gov; USDA, 2005.

No single parameter is sufficient to determine a client's nutritional status. Initial screening of the hospitalized client is performed by the professional nurse on admission.

In general, the nurse asks the client about a recent change in body weight of 10 pounds or more in the last 6 months, nausea, vomiting, diarrhea lasting more than 5 days, any declining food intake, difficulty chewing or swallowing, and time/duration of recent hospitalizations. If results of this initial screening (within 24 hr of hospital admission) classify the client at "nutrition risk," dietitian consult is indicated. Unfortunately, many clients are unable to provide the essential subjective information.

Objective measures of nutritional status include weight in relation to height (body mass index), monitoring dietary intakes with calorie counts, examination for signs of micronutrient deficiencies, and laboratory tests such as serum albumin, transferrin, and prealbumin; tests of cellular immunity; and total lymphocyte count. Other measures include evaluation of body composition by visual inspection or anthropometric measurements (triceps skin fold, mid-arm muscle circumference). See Nutritional Assessment Parameters, Table 19-2.

EVIDENCE-BASED PRACTICE

The Mini Nutritional Assessment (MNA) is an assessment tool that helps identify older adults who are at risk of malnutrition. A PDF is available, and a video demonstration is posted by the source listed below.

DiMaria-Ghalili, Rose Ann, & Peggi A. Guenter, (February 2008). *The American Journal of Nursing*, 108(2): 50–59.

TABLE 19-2 Nutritional Assessment Parameters

Clinical Assessment	Normal	Abnormal
Dietary Data		
Appetite	Remains unchanged	Increased or decreased recently Particular cravings
Nutritional intake	Adequate foods and fluids to supply body nutrients Nonallergic response to major food groups	Elimination of certain food categories that results in limited nutrients Emphasis on some food groups (sugar) to the exclusion of others (vegetables) Allergic response to certain foods
Caloric intake	Average 28 kcal/kg/day	Constant use of fad diets to lose weight Use of drugs or chemicals that interfere with appetite or nutrient assimilation
Meal patterns	3–6 home-prepared meals/day Adequate time and calm atmosphere for meals	Fast-food or packaged foods Missed meals, constant snacking, or overeating Eating “on the run” or hurried
General Appearance		
	Alert, responsive, healthy-appearing eyes and skin	Listless, dull, nonresponsive Skin and eyes appear unhealthy
Physical factors	Adequate chewing and swallowing capability Mouth and gums healthy so food can be ingested Physical exercise adequate for calorie intake	Teeth or gums in poor condition or ill-fitting dentures Swallowing impairs ingestion Inadequate physical exercise to burn calories
Presence of disease	No disease process that interferes with nutrient assimilation No congenital condition or postsurgery condition that interferes with nutrient assimilation	Disease present that interferes with ingestion, digestion, assimilation, or excretion Congenital condition, rehabilitation phase, or postsurgery that interferes with food assimilation
Elimination schedule	Regular, adequate elimination of foods Absence of constant flatus, discharge, or mucus	Irregular or painful elimination Presence of constant flatus Presence of discharge, blood, or mucus
Anthropometric Measurements		
Height	For bedridden clients, measure arm span—fully extend arms 90° angle to body and measure from tip of one middle finger to the tip of other middle finger for estimated height	Loss of 2–3 inches in height may indicate osteoporosis
Weight—compared to ideal and usual body weight.	Ideal body weight 100 lb (female); 106 lb (male) for 5 feet height + 5 lb for each 1 inch over 5 feet (female) and 6 lb for each 1 inch over 5 feet (male). Small frame minus 10% Large frame plus 10%	Changed—markedly increased or decreased recently: important indicator of changed nutritional status Loss of more than 10% weight for prior 6 months should be clinically evaluated
Body Mass Index Ratio of weight in kilograms and height in meters.	18.5–24.9	Less than 18.5—underweight 25–29—overweight 30–39—obese
Triceps skinfold measurement (mm)	Standard values—male to female 12.5–16.5	If values change over months, may indicate a chronic condition
Circumference of upper arm (cm)	29.3–28.5	
Midarm muscle circumference (cm)	25.3–23.2	Hydration status may influence results

Continued

TABLE 19-2 Nutritional Assessment Parameters (Continued)

Clinical Assessment	Normal	Abnormal
Biochemical Assessments*		
Serum albumin	3.5–5.0 g/dL	Examples of possible disease conditions: Decrease signifies lowered nutritional status—protein deficient
Serum transferrin binds iron to plasma and transports to bone marrow	200–430 mg/dL	Reduced levels may indicate chronic diseases and protein deficiency Elevated levels—anemias, liver damage, lead toxicity
Hemoglobin	Male—13.5–17 g/dL Female—12–15 g/dL	Decreased related to iron deficiency (anemias and leukemia)
Prealbumin (PA) serum	20–50 mg/dL	Decreased—protein wasting diseases, malnutrition (<10.7 indicates severe nutritional deficiency) Elevated—Hodgkin’s disease
Blood urea nitrogen/creatinine	10:1–20:1	Nitrogen imbalance, inadequate renal functioning; ratio increased in heart failure, decreased renal perfusion.
24-hr urinary nitrogen	Positive balance	Inadequate protein intake
Sociocultural Data		
Cultural–religious factors	Ability to afford adequate foods in all food categories Cultural beliefs that do not eliminate whole food groups Religious beliefs that do not eliminate whole food groups	Economic position that precludes purchase of adequate food Religious or cultural beliefs that interfere with receiving balanced diet (macrobiotic diets) Inadequate knowledge, experience, or intelligence to prepare healthy meals
Ethnicity	Traditional foods that do not eliminate whole food groups	Beliefs and ethnic preference that eliminate major nutrients from the diet
Lifestyle	Well-balanced meals that include all nutrients Food does not lose all nutrient value in preparation	Fast-paced stressful lifestyle that incorporates fast food or convenience foods deficient in nutrients or imbalanced (high-fat)

*Laboratory test parameters differ among laboratories. Check the reference range for the specific lab where the client’s blood or urine was tested.

ASSIMILATION OF NUTRIENTS

Nutrients must be broken down by the body. This process is called digestion. It starts in the mouth and continues in the stomach and small intestine.

The total daily energy requirement of an individual is the number of calories needed to replace the energy loss from the metabolic rate, plus loss from a person’s physical, emotional, and mental output. The number of calories ingested should be directly related to maintaining an adequate energy level and supporting the body’s metabolic processes.

Gastrointestinal System

The gastrointestinal system is comprised of the mouth, esophagus, and intestines, plus accessory organs. The main functions of the gastrointestinal system are the secretion of hormones, enzymes, and hydrochloric acid to digest ingested materials; the movement of the ingested contents through the system; their absorption into the blood; and the storage or elimination of the end products of digestion.

Mechanical digestion begins with chewing of food. When food reaches the stomach, both mechanical and chemical digestive processes occur.

The average meal remains in the stomach for 3 hr, where digestion continues. The stomach’s secretion of hydrochloric acid and pepsin break down proteins, while the *acid pH* environment helps protect against ingested pathogens. Vomiting or suction removal of *acid* gastric contents (primarily HCl, Na, and K) can lead to fluid and electrolyte imbalance with metabolic *alkalosis* (high bicarbonate and elevated pH on arterial blood gases [ABGs]). H₂ receptor antagonists (e.g., cimetidine) make gastric secretions less acid, so their administration reduces the risk of metabolic alkalosis and electrolyte disturbance in clients who require gastric secretion suction (decompression).

The stomach’s mechanical processes occur with intervals of peristalsis and relaxation of the pyloric sphincter as gastric content (chyme) moves into the small intestine (duodenum). Digestive processes continue within the small intestine (duodenum, jejunum, ileum) as enzymes break down protein to amino acids, fats to glycerol and fatty acids, and carbohydrates to

monosaccharides. Here, most nutrients and water are absorbed into the circulation. While 7–10 liters of electrolyte-rich secretions mix with the chyme, only 600–800 mL enters the large intestine. Small intestine secretions have an *alkaline pH*, making this environment more vulnerable to bacterial invasion. *Alkaline intestinal fluid loss* (e.g., due to diarrhea, intestinal decompression) can lead to fluid and electrolyte imbalance with metabolic *acidosis* (low bicarbonate and low pH on ABGs).

The ileocecal valve separates the small intestine from the large intestine. In the large intestine, fluids and electrolytes continue to be absorbed to solidify the stool, and mucus is secreted to lubricate waste as it moves toward the rectum for storage and final elimination of stool, which contains approximately 200 mL water.

The Accessory Organs

The accessory organs of the gastrointestinal tract also play an important role in the utilization of nutrients.

The liver has a major role in the metabolism of carbohydrates, fats, and proteins. In carbohydrate metabolism, the liver converts glucose to glycogen and stores it. The liver then can reconvert glycogen to glucose when the body requires higher blood sugar. The process of releasing carbohydrates (end products) into the bloodstream is called glycogenolysis.

The liver metabolizes fats through the process of oxidation of fatty acids and the formation of acetoacetic acid. Also, the liver forms lipoproteins, cholesterol, and phospholipids and converts carbohydrates and protein to fats.

The liver metabolizes proteins by deamination of amino acids. In this process, the urea and plasma proteins are formed.

The gallbladder functions as a reservoir for bile, which is produced by the liver. When food enters the duodenum, it releases cholecystokinin, which causes the gallbladder to contract and release bile, while the sphincter of Oddi relaxes so that bile enters the duodenum. Here, the bile acids emulsify and digest lipids, which are then absorbed by the intestine.

The pancreas secretes enzymes into the small intestine for the digestion of carbohydrates, fats, and proteins. The enzyme trypsin acts on proteins to produce peptones, peptides, and amino acids. Pancreatic amylase acts on carbohydrates to produce disaccharides, and pancreatic lipase acts on fats to produce glycerol and fatty acids.

In summary, the gastrointestinal tract's primary function is to provide the body with a continuous supply of nutrients by the processes of ingestion, digestion, and absorption.

GASTROINTESTINAL DYSFUNCTIONS

Dysphagia

The voluntary and involuntary actions of swallowing require coordination of several muscles and brain areas. Dysphagia (difficulty swallowing) commonly affects the elder population, especially those in nursing home facilities. Difficulty may be due to dysfunction of neurologic pathways or from dysfunction of muscles of the swallowing tract such as occurs with stroke, dementia, and Parkinson's disease. Dysphagia resulting

from stroke is usually temporary, whereas it progresses as part of a general decline in those with dementia or Parkinson's disease. Others who experience dysphagia are those with esophageal obstructive disorders or reflux, and chronic neurologic disorders such as cerebral palsy, multiple sclerosis, polio, amyotrophic lateral sclerosis, and myasthenia gravis.

The most serious complication of dysphagia is aspiration of oropharyngeal secretions, liquid, or food into the lungs, creating an environment conducive to bacterial growth (aspiration pneumonia). This occurs in more than 50% of those with dysphagia. A protective cough normally prevents aspiration, but 50% of clients who aspirate do so silently, *without* coughing, so aspiration goes undetected until pneumonia develops. A complex disorder, dysphagia requires an individualized diagnosis and management by collaborative experts: speech–language pathologist, dietitian, radiologist, and occupational therapist.

GI Hemorrhage

The gastric blood from GI hemorrhage is an irritant that usually triggers vomiting, which may aggravate the bleeding. Clients with impaired liver function are an example of those most likely to experience a gastric bleed, but these clients are also unable to process the protein load created by digestion and absorption of blood. The digestion of blood can cause a precipitous rise in serum ammonia, which can lead to altered neurologic function (somnolence, loss of coordination, coma). Lavage (washing) per gastric intubation removes blood to prevent this “metabolic encephalopathy,” and also allows estimation of the client's acute blood loss.

Intestinal Obstruction

When gastrointestinal processes are disrupted, intestinal “obstruction” develops. Cessation of peristalsis (ileus) due to neurogenic impairment (traumatic stress), abdominal pathology, electrolyte imbalance (hypokalemia), or bowel manipulation (as in surgery) may alter GI movement and absorption, allowing secretions and gas to accumulate. The small intestine is the first site to regain motility after surgery (24 hr), then the stomach (2–4 days), and finally the colon (3–7 days). The presence or absence of bowel sounds, however, does not relate to feeding tolerance. Early postoperative nasointestinal or direct small bowel feeding is thought not only to be safe, but also important for maintaining bowel integrity and preventing sepsis. Temporary decompression to remove fluids and gas *may* be necessary in some instances because progressive accumulation of gases and fluid distends the bowel, compresses bowel wall capillaries, and can lead to septic shock, as well as hypovolemic shock. Decompression *may* also alleviate pain, nausea, and vomiting, and reduce the possibility of aspiration.

Decompression Decompression requires the insertion of a nasogastric tube, which is connected to continuous or intermittent negative pressure suction while the client is kept NPO and given IV fluids. Since gastrointestinal secretions are isotonic with extracellular fluid, a guideline for fluid replacement is to administer a volume of normal saline (or one-half normal saline with KCl) equivalent to the previous day's

drained secretions. A unique feature of the GI tract is that its nutrition is derived directly (rather than from the bloodstream), so early ambulation, termination of decompression, and resumption of PO intake are recommended. The passage of flatus, bowel movement, and tolerance of oral intake are indicators that GI function has returned and is able to accommodate PO intake.

NORMAL AND THERAPEUTIC NUTRITION

Normal nutrition is based on recommended daily dietary allowances designed for the maintenance of health. While these standards have been established for nutrition requirements of an average healthy person, therapeutic modification of nutritional needs may be based on a client's disease condition associated with an excess or deficiency of a particular nutrient. Therapeutic diets may include alterations of minerals, vitamins, proteins, carbohydrates, fats, and fluids, as well as alterations of their consistency to facilitate the client's intake. Whether a normal or therapeutic diet has been ordered based on the client's physiologic status, the client's cultural, socioeconomic, and psychologic influences must also be taken into account. The nutritional requirements must be considered within the context of the total needs of the individual client.

Eating and mealtime are considered by many to be a "social" event. Hospitalized clients, however, may be isolated from others, so that eating is not a pleasure. Painful or uncomfortable procedures should be planned so that they are not immediately before or after meals. The client should be in a position as near to normal as possible: sitting in a chair or with the head of the bed elevated 90°. The environment should be bright and free of offensive odors. Client allergies should be noted; personal preferences and cultural or religious restrictions should be honored. Food trays should be checked for compliance with the physician's order. If the client is NPO, a sign may be posted on the unit door so that the client does not receive a tray.

When you are preparing to assist the client to eat, lower the side rail and place the tray table over the client's lap low enough so that he or she can see what is on it. If the tray is not neatly arranged, rearrange it. Food appearance and presentation influence appetite. Assist the client with whatever is needed, such as cutting meat. If the client is unable to drink from a glass, provide a straw or special cup.

Be sensitive to the client's response to food, and continually attempt to orient feeding to meet the client's needs. If the client has impaired vision but is able to self-feed, tell the client what is on the tray and the position of each item. Often, it is clearer to describe position of foods by a clock; for example, chicken at 12, green beans at 3 o'clock.

When therapeutic diets are ordered, it is critical to be sensitive to the client's acceptance of any restrictions or supplements and to help the client understand their purpose. The nurse is most closely involved with the client and can best determine the client's actual intake. The nurse should ensure that the client is not receiving inappropriate foods from other sources and that the client is actually eating the foods prescribed.

Nutrition Problems in the Hospital

Nutrition may be overlooked as a vital component of a hospitalized client's care. For clients who seem to be stable on admission and give no history of nutrition-related problems, the usual hospital diet is adequate; however, all clients must be reassessed periodically to detect and prevent nutritional problems. Fear, anxiety or depression, poorly fitting dentures, and even medications and therapies may limit a client's ability to eat or may interfere with his or her appetite. Some clients may have the desire to eat and have a good appetite, but shortly after eating certain food, experience cramps, pain, or diarrhea or feel nauseated or vomit. This may lead to decreased food intake. Clients may become more malnourished the longer they remain in a hospital for a variety of reasons that limit food intake.

Well-nourished clients can tolerate a short period of caloric balance deficit such as that occurring with a brief illness or surgery, because the body's fat stores provide calories during such periods. Nutrient guidelines for healthy persons, however, are not meant to meet the needs of clients whose nutritional status is altered by illness that affects oral intake and nutrient digestion, absorption, or utilization. Protein-energy malnutrition is widely seen in hospitalized clients due to acute illness and protein-deficient diets (kwashiorkor) or long-term calorie and protein deprivation with cachexia or severe muscle/fat depletion (marasmus). Protein-energy malnutrition is commonly seen in the obese or diabetic client as well, and while the client may not appear to be malnourished visually, nutrition parameters reveal a malnourished state.

Studies indicate that malnutrition (protein-energy deficiency) is present in as many as 50% of hospitalized clients and that clients become more malnourished the longer the hospital stay. Clients with negative nitrogen balance (reduced serum albumin, reduced prealbumin) have already lost structural and functional proteins and have poor surgical outcome, increased infection rates, and prolonged hospital stays. As malnutrition progresses, all major organ systems, fluids and electrolytes, and immune system dysfunction develops.

Enteral Feeding for Nutritional Support

Enteral nutrition may be prescribed for clients who are unable or unwilling to eat or those who need a supplement to ingested food, as well as for clients in catabolic states with intensive caloric requirement (e.g., burn, trauma clients).

Enteral feeding is preferred over parenteral (intravenous) nutrition because it is safer, less expensive, and associated with fewer complications. It helps to maintain GI function and speeds regeneration of the small intestine, which receives its nutrition from food directly rather than from the bloodstream. Enteral nutrition preserves production of humoral antibodies, reduces gut bacterial overgrowth, and, by helping to maintain the gut's protective mucosal barrier, promotes gut motility, and reduces risk of sepsis. Since the small intestine is less prone to ileus than the stomach and large intestine, postoperative feeding into the small intestine is feasible even though the client is NPO.

Enteral formulas come in powder form to reconstitute or as ready-to-use liquids. They contain all or just one of the following: protein, carbohydrates, fat, electrolytes, and vitamins and minerals, depending on the client's needs. Isotonic formulas provide 1 cal/mL and are most commonly used. Modified

formulas are available for clients with specific nutritional requirements: lactose-free or lactose-containing, fiber-containing, elemental (predigested), or modular formulations that provide additional macronutrient components (lipid, carbohydrate, or protein). Specialized formulas are also available for trauma clients or those with pulmonary disease, renal failure, diabetes, liver failure, or immune deficiency.

Many types of nasogastric/nasointestinal tubes are available for enteral feeding. Large-bore nasogastric tubes are inserted for short-term (1 week) intermittent feedings which are delivered by gravity through a syringe or by an infusion pump 4–6 times daily. If nutritional support is indicated for an extended period (4 weeks), a long, soft, flexible, small-bore tube made of silastic or polyurethane is placed naso or orointestinally (advanced beyond the pylorus). Small-bore tubes are more comfortable for the client. Since feeding is by continuous infusion using a pump, the client’s position must be kept with head of bed elevated 30° or greater to decrease risk of aspiration. Feeding into the small intestine is associated with greater risk of infection due to the intestine’s alkaline (less protected) environment.

For clients with a history of gastric reflux or tube feeding–related aspiration pneumonia, a small-bore jejunostomy tube may be placed surgically or by laparoscopy. Special “dual-purpose tubes” (e.g., Moss tube) can be placed at the time of surgery to provide gastric decompression and simultaneous (early postoperative) feeding into a functional small intestine while the client is NPO.

For *extended nutritional support* (feeding over 4 weeks), tube enterostomies are created surgically through the abdominal wall, directly into the stomach (gastrostomy, percutaneous endoscopic gastrostomy [PEG], or small intestine jejunostomy). Directly placed tubes are secured by stabilizing bars

(bumpers), a large mushroom tip, or a balloon inflated with water (similar to a urinary retention catheter).

CULTURAL AWARENESS

Cultural Accommodations for Special Diets

When a special diet is prescribed, it should be consistent with the client’s cultural preferences and religious practices. For example, Jewish people do not combine certain foods. So, to comply with kosher laws, do not combine meat and dairy products at the same meal.

Food Is One of the Most Interesting Aspects About Any Culture

- American acculturation tends to replace traditional habits, tastes, and preferences with a detrimental switch to highly processed foods.
- This may account for increased rates of illness and death from heart disease and cancer in some populations.
- While not all cultural food habits are healthy, they are usually higher in fiber and vitamins than the typical American diet and should be encouraged.

General Recommendations

- Food preferences should be maintained.
- Focus education on food practices and preparation, possible health hazards, and importance of role modeling for children.

NURSING DIAGNOSES

The following nursing diagnoses are appropriate to use on client care plans when the components are related to nutritional problems or nutritional health maintenance.

NURSING DIAGNOSIS	RELATED FACTORS
Aspiration, Risk for	CVA, neuromuscular disease, NG intubation, artificial airway, decreased level of consciousness, oral/cervical surgery
Dentition, Impaired	Poor oral hygiene, oral surgery, injury, ill-fitting dentures
Knowledge, Deficient	Lack of appropriate dietary information, misinterpretation of information, cognitive limitation, inadequate motivation
Noncompliance	Chronic illness, disease-related symptoms, side effects of therapy, financial status, cultural practices
Imbalanced Nutrition: Less Than Body Requirements	Impaired swallowing, faulty metabolism, altered level of consciousness, inadequate absorption, eating disorders
Imbalanced Nutrition: More Than Body Requirements	Lack of basic nutritional knowledge, excessive intake in relation to metabolic requirements, decreased activity patterns, decreased metabolic needs, eating disorders
Impaired swallowing	Esophageal obstructive disorder, chronic neurologic disorder (multiple sclerosis, ALS, myasthenia gravis), muscle dysfunction (stroke, dementia, Parkinson’s disease)

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. Remember to wash your hands or use antibacterial gel before and after each and every client contact.

IDENTIFY CLIENT Before every procedure, check two forms of client identification, not including room number. These actions prevent errors and conform to the Joint Commission standards.

Chapter 19

UNIT 1

Modified Therapeutic Diets

Nursing Process Data

ASSESSMENT Data Base

- Refer to general assessment parameters (physical and laboratory findings) in chapter introduction.
- Assess client’s dietary preferences.
- Assess client’s health status that necessitates diet modification.
- Identify disease state, which may necessitate dietary modification (e.g., cardiac, pulmonary, renal disease).
- Determine whether registered dietitian has consulted to assist with diet design.

PLANNING Objectives

- To meet nutritional needs of clients with altered health status
- To provide a therapeutic diet that is acceptable to client’s taste and cultural orientation
- To provide specialized dietary information to promote client’s adherence

IMPLEMENTATION Procedures

- Restricting Dietary Protein 643
- Restricting Dietary Fat 643
- Restricting Mineral Nutrients (Sodium, Potassium) 643
- Providing Consistent Carbohydrate Diets 644
- Providing Nutrient Enhanced Diets 644
- Providing Progressive Diets 645
 - For Dietary Fiber 645
 - For Postoperative Diet Progression 645
- Providing Altered Food Consistency Diets 646
 - For Bland Diet 646
 - For Mechanical Soft Diet 646
 - For Pureed Diet 647
 - For Blenderized Liquid Diet 647

EVALUATION Expected Outcomes

- Therapeutic diet assists in management of client’s altered health status.
- Client accepts therapeutic diet prescribed to help manage altered health status.
- Client demonstrates understanding (verbalized knowledge) of dietary information provided.

Critical Thinking Application 647

- Expected Outcomes 647
- Unexpected Outcomes 647
- Alternative Actions 647

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Restricting Dietary Protein

1. A **restricted protein diet** is used for clients with renal insufficiency, hepatic coma, and cirrhosis (according to individual requirements).
 - a. Control end products of protein metabolism (nitrogenous waste) by limiting protein intake.
 - b. Protein allowance is decreased to 0.5–0.6 gm/kg/day (pre-dialysis).
 - c. Limits high-protein foods, such as eggs, meat, milk, and milk products.
2. A **PKU diet** is an amino acid metabolism abnormality diet used for phenylketonuria (PKU), galactosemia, and lactose intolerance.
 - a. Reduce foods that contain compounds that cannot be metabolized correctly.
 - b. Avoid milk and milk products.
 - c. Provide substitutes to meet daily allowances.

Restricting Dietary Fat

1. A **restricted fat diet** is used to reduce risk for and to manage cardiovascular diseases, diabetes mellitus, and high serum cholesterol levels. It focuses on restriction of saturated (hydrogenated) fats, trans fats (found in fast and fried foods), and cholesterol to treat dyslipidemia and reduce risk for atherosclerosis. These fats are solid or semi-solid at room temperature.
 - a. Lipid levels goals = total cholesterol < 200mg/dL, LDL-C < 100 mg/dL, HDL-C > 45 males and 55 females mg/dL, and triglycerides < 150 mg/dL.
 - b. Restrict total fat to less than 30% of calories, achieve normal body weight by reducing calorie intake; restrict saturated fat to 7% of calories and reduce cholesterol to 200 mg per day.
 - c. Higher percentage may be allowed if saturated and trans fats are substituted with monosaturated fats found primarily in plant products (olive oil, canola oil, avocados, pecans, almonds); use low-fat or nonfat products; increase intake of fruits and vegetables, whole grains, legumes, and seeds.
 - d. Limit high-cholesterol foods found in animal products, such as egg yolk, red meat, shellfish, organ meats, bacon, and pork.
2. A **modified-fat diet** is used according to individual tolerance in malabsorption syndromes (cystic fibrosis, gallbladder disease, obstructive jaundice, pancreatitis, and liver disease).
 - a. Attempt to lower fat content in diet when there is inadequate absorption of fat or when excessive fat aggravates a condition.
 - b. Avoid such foods as gravies, fatty meat and fish, cream, fried foods, rich pastries, whole-milk products, cream soups, salad and cooking oils, nuts, and chocolate. Allow eggs (3–5 per week), lean meat, and small amount of butter or butter substitute.

Restricting Mineral Nutrients (Sodium, Potassium)

1. A **restricted sodium diet** is used to manage hypertension, liver disease, heart failure (edema), and renal insufficiency.
 - a. Correct or control the retention of sodium and water in the body by limiting sodium intake. May include restriction of salt in the diet or in combination with medications.
 - b. Sodium restriction may allow lower dosage of diuretic use.
 - c. Restrict salt in cooking or at the table. May prohibit any product containing sodium, such as soda bicarbonate (typical diet provides 4–6 g of sodium/day).
 - d. Explain sodium restrictions in diet.
 - Mild: 2–3 g of sodium (no added salt provides 2–3 g of sodium/day)
 - Moderate: 1,000–1,500 mg of sodium
 - Strict: 500 mg of sodium
 - Be aware of sodium content of some medications (e.g., antacids).
2. Potassium may be restricted for the renal client.

Foods High in Sodium and Potassium

Foods High in Sodium

- Table salt and all prepared salts, such as celery salt
- Smoked meats and salted meats
- Most frozen vegetables or canned vegetables with added salt
- Butter, margarines, and cheese
- Quick-cooking cereals
- Shellfish and frozen or salted fish
- Seasonings and sauces
- Canned soups
- Chocolates and cocoa
- Beets, celery, and selected greens (spinach)
- Anything with salt added, such as snack chips, popcorn

Foods High in Potassium

- Fruit juices, such as orange, grapefruit, banana, raw apple
- Instant, dry coffee powder
- Egg, legumes, whole grains
- Fish, fresh halibut, codfish
- Pork, beef, lamb, veal, chicken
- Milk, skim and whole
- Dried dates, prunes
- Bouillon and meat broths
- Salt substitute

Providing Consistent Carbohydrate Diets

1. Nutrition is one of the cornerstones of treatment for diabetes.
 - a. Foods included on the diet are balanced and provide protein, fat, and carbohydrates in relation to an individual's needs.
 - b. Foods limited are refined or simple sugars.
 - c. Counting grams of carbohydrates and using the glycemic index (describes how much blood glucose level rises with a specific food when compared with an equivalent amount of glucose) are nutritional tools for managing diabetes.
 - d. Equal (consistent) amount of carbohydrate is provided at each meal to ease management of blood sugars.
2. Reactive hypoglycemia occurs when the pancreas over-secretes insulin post-prandially and most of the glucose moves from blood into cells, resulting in abnormally low blood glucose levels.
 - a. Foods prescribed are a combination of foods high in protein and a variety of complex carbohydrates, consumed in five or six small meals per day.
 - b. Foods restricted are simple carbohydrates; for example: juices, white sugar, white rice, and white flour.

Providing Nutrient-Enhanced Diets

1. An **increased potassium diet** is used to compensate for potassium loss due to certain diuretics or steroids, burns, vomiting, fever, and COPD and may have an antihypertensive effect.
 - a. Replace potassium loss from the body with specific foods high in potassium or a potassium supplement.
 - b. Severe loss is managed with intravenous replacement therapy.
 - c. Avoid no specific foods unless there is a sodium restriction (some foods high in potassium are also high in sodium).
 - d. Reduced sodium intake reduces potassium loss.

Refeeding Syndrome

The *refeeding syndrome* first noted in individuals refeed after famine and war is a potentially life-threatening complication of aggressive specialized *nutrition repletion/support*. This complication can occur regardless of the route of feeding, whether parenteral, enteral, or even oral. Semistarved marasmic or fasting clients, those with morbid obesity, anorexia nervosa, or chronic alcoholism whose bodies have adapted to using free fatty acids and ketone bodies for energy can develop hypophosphatemia, hypokalemia and hypomagnesemia, altered glucose metabolism, and fluid shifts associated with hematologic, neuromuscular, cardiac, and respiratory dysfunction when large amounts of carbohydrate feedings are reintroduced. Sudden expansion of extracellular (intravascular) fluid can result in cardiac decompensation, and administration of dextrose can result in hyperglycemia with osmotic diuresis and dehydration.

When nutritional support therapies are initiated in malnourished clients, caloric goals should be achieved gradually (3–4 days) while the client's cardiopulmonary response, serum electrolytes, and glucose are closely monitored.

Source: Gottschlich, M., ed. (2001). Chapter 9: Complications of Enteral Nutrition Therapy. *The Science and Practice of Nutrition Support*. American Society for Parenteral and Enteral Nutrition. Dubuque, Iowa: Kendall/Hunt Co.

2. A **high-iron diet** is used to manage anemias (blood loss, nutritional), and malabsorption syndrome.
 - a. Replace a deficit of iron caused by inadequate intake or chronic blood loss.
 - b. Include foods high in iron content, such as meats (especially organ meats), egg yolks, seafood (especially shellfish), and plant-based sources such as whole-wheat products, leafy vegetables, nuts, dried fruit, and legumes.
 - c. Vitamin C enhances absorption of plant-based iron.
3. A **high-calcium diet** is used to prevent osteoporosis and prevent and treat hypertension.
 - a. Increases normal adult intake of 1 g/day to 1.5 g/day for postmenopausal female.
 - b. Recommends use of *fortified* low-fat and nonfat dairy products, fruit juices, and oatmeals.
 - c. Clients who are lactose intolerant should use leafy green vegetables and nonliquid dairy products (cheese, yogurt) or lactose-free dairy products, fish products, and almonds.

Providing Progressive Diets

For Dietary Fiber

1. There are two types of fiber: Insoluble fiber found in cell walls of plants does not dissolve in water, so it speeds elimination of waste products, and soluble fiber (oat bran) dissolves in water and decreases intestinal speed, decreases blood cholesterol levels, and slows absorption of glucose, so blood sugar levels are reduced in diabetes.
2. A *low-fiber diet* is used during phases of intestinal diseases and may be used preoperatively and postoperatively during transition to a regular diet.
 - a. Long-term fiber restriction is discouraged.
 - b. Inform client that low-fiber foods are ground meat, fish, broiled chicken without skin, limited fat, refined strained cereals, white bread, and possibly limited milk products.
3. A *high-fiber diet* is prescribed to treat constipation and diverticulosis.

- a. Includes foods high in fiber such as beans, fruits, vegetables, nuts, whole grain breads and cereals, and especially unrefined bran.
- b. Fluid intake should be increased as fiber is increased in the diet.

For Postoperative Diet Progression

1. A special postoperative surgical diet may be necessary to promote wound healing, to avoid hypovolemia due to decreased plasma proteins and circulating red blood cells, and to prevent edema.
 - a. For tissue repair and extensive stress states, energy needs should be determined by a specialist for tissue repair needs and extensive stress states.
 - b. Fluid intake is 2–3 liters per day for uncomplicated surgery and 3–4 liters for sepsis. Clients with extensive wound drainage may require more fluid intake.

Nutrient Requirements for Healing*

- Total calories per day:
 1. 2,800 for tissue repair
 2. 6,000 for extensive repair
- Protein:
 1. 40–50 g/day average person
 2. 50–75 g/day early in postoperative period
 3. 100–200 g/day if needed for new tissue synthesis
- Carbohydrates:
 1. 55%–60% of calories—sufficient in quantity to meet calorie needs and allow protein to be used for tissue repair
- Fat:
 1. 25%–30%—not excessive as it leads to poor tissue healing and susceptibility to infection
- Vitamins:
 1. Vitamin C—up to 1 g/day for tissue repair
 2. Vitamin B—increased above normal for stress management
 3. Vitamin A—adjuncts autoimmune system
 4. Vitamin E—increases O₂ to tissues
- Minerals:
 1. Zinc—tissue repair
 2. Selenium—cell repair
 3. Calcium/magnesium—relaxes nerves and maintains electric function

*This is an example of nutrients necessary for healing. Each diet should be individualized and a dietary consult is required.

2. Diet progression may consist of nothing by mouth (NPO) the day of surgery and advance to a regular diet as soon as tolerated. A progressive diet may include the following diets:
 - a. **Clear liquid diet** 1,000–1,500 mL/day of liquid foods such as water, tea, broth, gelatin, and pulp-free juices or clear carbonated beverages.
 - b. **Full liquid diet** lacks many nutrients, so is used temporarily. Includes any food that is liquid at room temperature—clear liquids, milk and milk products, custard, puddings, creamed soups, sherbet, ice cream, and any fruit juice.
 - c. A **surgical soft diet** is full liquid plus pureed vegetables, eggs (not fried), milk, cheese, fish, fowl, tender beef, veal, potatoes, and cooked fruit. Include foods that are easy to chew and digest and limited in fiber; do not include gas-formers.
 - d. **General diet:** Take into consideration client's tolerance and preferences.

Providing Altered Food Consistency Diets**For Bland Diet**

1. A bland diet is used to promote the healing of the gastric mucosa by eliminating food sources that are chemically and mechanically irritating. Bland diets may be used to manage duodenal ulcers, gastric ulcers, and postoperative gastric surgery.
 - a. Instruct client that bland diets are presented in stages with the gradual addition of certain foods.
 - b. Provide frequent, small feedings during active stress periods.
2. Establish regular meals and food patterns when condition permits.
3. Foods allowed include:
 - milk, butter, eggs (not fried), custard, vanilla ice cream, cottage cheese
 - cooked refined or strained cereal, enriched white bread
 - gelatin; homemade creamed, pureed soups
 - baked or broiled potatoes

4. Examples of foods that are eliminated include:
 - spicy and highly seasoned foods
 - raw foods
 - very hot and very cold foods
 - gas-forming foods (varies with individuals)
 - coffee, alcoholic beverages, carbonated drinks
 - high-fat-content foods (some butter and margarine allowed)

For Mechanical Soft Diet

1. A mechanical soft diet is used when clients
 - a. Are edentulous.
 - b. Have poorly fitted dentures.
 - c. Have difficulty chewing.
 - d. Do not chew food thoroughly.
2. Any food that can be easily digested can be included in this diet. It allows clients variations in tastes that are not allowed on a soft diet (chili beans).

For Pureed Diet

1. A pureed diet provides food that has been mashed, minced, or ground.
 - a. Used for clients with dysphagia.
 - b. Used for clients with limited chewing ability.
2. When assisting clients with this type of diet, talk with them about the meal, describing the different foods. When the texture is all the same, distinguishing between foods is difficult.
3. Do not mix all pureed food together or feed out of one bowl or dish. Try to keep foods separate and feed alternately, with dessert last.

For Blenderized Liquid Diet

1. Contains food and liquid that are blenderized to liquid form.
2. Used for persons who cannot chew, swallow, or tolerate solid food; or may be used for gastrostomy feeding.

DOCUMENTATION for Modified Therapeutic Diets

- Type of diet provided
- Client's daily weight
- Intake and output
- Client's understanding of dietary restriction
- Any client or family teaching provided
- Nutritional consult requested
- Client's tolerance of diet progression
- Community agency referral offered

CRITICAL THINKING Application**Expected Outcomes**

- Therapeutic diet assists in management of client's altered health status.
- Client accepts therapeutic diet prescribed to help manage altered health status.

- Client demonstrates understanding (verbalized knowledge) of dietary information provided.

Unexpected Outcomes

Client does not adhere to diet.

Alternative Actions

- Elicit client's feelings to determine reason for nonadherence.
- Check method of diet preparation and administration to see if it is attractive and appealing.
- Ensure that environment is conducive to eating.
- Notify dietitian to discuss diet with client.

Client with sodium-restricted diet states that food has no taste.

- Recommend use of lemon, herbs, and spices to add flavor to foods.
- Encourage client to avoid processed foods, frozen entrees, salty snacks.
- Inform client that salt craving decreases over time with change in diet.
- Consult physician for recommendation of potassium-containing salt substitute.

Client states that fat is fat and all fats are to be avoided in preference to carbohydrates.

- Suggest client remove all visible fat from and limit intake of red meats.
- Encourage to substitute poultry (skin removed) and fish for red meat.
- Limit intake of butter, salad dressings, trans fat (partially hydrogenated) products.
- Use low-fat or nonfat products.
- Increase intake of fruits, vegetables, and legumes.

Postmenopausal client has lactose intolerance but is concerned about need for increased calcium to prevent osteoporosis.

- Consult with registered dietitian.
- Encourage intake of nonliquid dairy products (yogurt, cheese) or lactose-free dairy products.
- Suggest intake of leafy vegetables, canned fishes.
- Calcium carbonate supplements are best absorbed.
- Recommend calcium carbonate supplement in low dose (500 mg or less), several times/day for better absorption and efficacy.

Chapter 19

UNIT 2

Nutrition Maintenance

Nursing Process Data

ASSESSMENT Data Base

- Check physician’s or consultant’s diet order.
- Determine client’s sociocultural orientation.
- Obtain client’s diet history and determine eating habits and food preferences.
- Determine if client is candidate for dietitian or speech pathologist consultation.
- Assess client’s risk for aspiration.
- Check for specific instructions for positioning and feeding technique for the dysphagic client.

PLANNING Objectives

- To provide a diet that meets nutritional requirements and is acceptable to client
- To assist the visually impaired client to self-feed
- To assist the dysphagic client to eat

IMPLEMENTATION Procedures

- Serving a Food Tray649
- Assisting the Visually Impaired Client to Eat649
- Assisting the Dysphagic Client to Eat650

EVALUATION Expected Outcomes

- Diet meets nutritional requirements and is acceptable to client’s taste and cultural orientation.
- Visually impaired client is able to self-feed.
- Dysphagic client is able to eat using adaptations to prevent aspiration.

Critical Thinking Application 651

- Expected Outcomes 651
- Unexpected Outcomes 651
- Alternative Actions 651

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Serving a Food Tray

Equipment

- Diet slip completed
- Diet tray
- Over-bed table
- Utensils
- Protective covering (e.g., towel)

Preparation

1. Check client's chart for physician's diet order.
2. Obtain dietary consult, if necessary, to meet client's needs.
3. Elicit food preferences of the client.
4. Check all diet trays before serving to ensure the diet provided is the one ordered.
5. Ensure that hot food is hot and cold food is cold.
6. Keep food trays attractive. Avoid spilling liquids on tray.
7. Assist client to empty bladder (if needed) and perform hand hygiene.
8. Remove unpleasant objects from area.

Procedure

1. Identify client by checking Ident-A-Band and having client state name and birth date.
2. Perform hand hygiene and assist client to do so.

3. Assist client to sit in a chair, or elevate the head of the bed to 90°.
4. Place protective covering over client's chest.
5. Place food tray on over-bed table and adjust the table so client can see the food.
6. Assist client as needed (cut meat, open containers).
7. Leave call light in client's reach and check on client periodically.
8. Reposition tray table at bedside when meal is completed.
9. Assist client with hand and oral hygiene if desired.
10. Position client for comfort.
11. Note percentage and type of food eaten.
12. Remove food tray from room.
13. Document percentage and type of food eaten and, if indicated, amount of liquid intake on I&O record.
14. Perform hand hygiene.

Clinical Alert

Clients sensitive to latex have potential for serious allergic reactions to some plant proteins. Cross-reactivity to latex has been shown with foods such as avocado, banana, papaya, chestnuts, kiwi, potatoes, and tomatoes. Clients with allergy to these foods may have latex allergy and vice versa.

Assisting the Visually Impaired Client to Eat

Procedure

1. Check client chart for ordered diet.
2. Identify client and check allergy band.
3. Perform hand hygiene.
4. Raise head of bed to HIGH position, or assist client to sit in chair if possible.
5. Assist client to perform hand hygiene.
6. Place protective covering over client's chest.
7. Place food tray on client's over-bed table and adjust to client and caregiver's comfort.
8. Stand or sit facing client.
9. Assist client by using the following technique:
 - a. Use the clock face to describe food arrangement on the plate.
 - b. Tell the client the time on the clock at which each food item is placed; for example, "The corn is at 4 o'clock, chicken is at 8 o'clock."
 - c. Encourage the client to feed self, but remain with client if possible.
10. Encourage the client to hold glass, bread, finger foods.
11. Allow client time to chew and swallow.
12. Provide fluids throughout meal.
13. Alternate foods; rather than one complete item at a time.
14. Allow client to rest at intervals during the meal.
15. Talk with client during meal. ► **Rationale:** Talking makes mealtime more pleasant and promotes relaxation.
16. Reposition tray table at bedside when meal is completed.
17. Assist client with hand and oral hygiene if desired.
18. Raise side rail if it has been lowered.
19. Position bed for comfort. Lower bed if it is raised.
20. Note percentage of food eaten.
21. Remove food tray from room.
22. Perform hand hygiene.
23. Document amount eaten. If necessary, record fluid intake on I&O record.
24. Place call bell within client's reach.

Assisting the Dysphagic Client to Eat

Equipment

- Provision for oral care and hand hygiene
- Towel
- Penlight to inspect oral cavity
- Oral suction catheter connected to suction source

Preparation

1. Note specific instructions for feeding technique (diet and positioning) prescribed by speech or swallowing specialist; for example, cornstarch, Thickit, or rice cereal to thicken food, as prescribed. ► **Rationale:** Clients with swallowing problems find it easier to swallow thickened liquids.
2. Check if client is receiving both oral and enteral feeding; stop the enteral solution about 1 hr before oral feeding.
3. Check that client has not recently received sedating medication.
4. Eliminate environmental distractors such as television, radio.
5. Provide a 30-minute rest period before mealtime.
6. Ensure that temperature of food is appropriate.

Procedure

1. Complete hand hygiene.
 2. Check client's Ident-A-Band and allergy bracelet and have client state name and birth date.
 3. Provide client privacy.
 4. Maintain bed in LOW position.
 5. Assist client to sit upright (90°) in a chair, or in bed with hips flexed, shoulders and face slightly forward, and chin parallel to the floor or slightly tucked. ► **Rationale:** Gravity assists proper bolus movement to the stomach.
- NOTE:** Prescribed position is different for specific forms of dysphagia. Some types of dysphagia necessitate client positioning to one side, or with head rotated toward the stronger or weaker side, or even side-lying. Instructions should be placed in client's record, care plan, and posted at client's head of bed.
6. Assist client to perform hand hygiene before eating.
 7. Place towel over client's chest.
 8. Place tray on over-bed table and towel under plate. ► **Rationale:** This stabilizes plate while feeding.
 9. Suction oral secretions before feeding, if necessary.
 10. Sit at client's side, or sit facing client.
 11. Encourage self-feeding.
 12. Instruct client to take (or offer) small portions of food at first (0.5 to 1 tsp at a time), bites manageable in size but large enough to require chewing.

13. Instruct client to eat food first, without accompanying liquid, reserving *all* liquid intake until after finishing food. ► **Rationale:** Using liquids to wash down boluses of food pushes the food down too rapidly, although some authorities recommend alternating solids with liquids.
14. Instruct client to perform an exaggerated sucking motion at the beginning of each swallow with chin tucked slightly. ► **Rationale:** Decreases risk of aspiration.

NOTE: Clients with advanced dementia may not remember how to chew or swallow. Demonstrating chewing and gently stroking the area under the client's chin with a downward motion during swallowing may be helpful cues.

15. Allow client to concentrate on swallowing *without* distractions such as conversation or television. ► **Rationale:** For the dysphagic client, swallowing takes concentration; talking increases risk for aspiration.
16. Avoid rushed or forced feeding and make sure client is swallowing every mouthful.
17. Visually inspect oral cavity and under dentures for retained food. ► **Rationale:** Buildup may occur on weak side of mouth or pharynx.
18. Observe client closely for evidence of aspiration (e.g., cough, drooling, voice change such as hoarseness or a gurgling noise after swallowing), and suction oropharynx if indicated.
19. Help with feeding only if client shows signs of weakness, fatigue.
20. Provide positive reinforcement for accomplishment.
21. Assist with oral care and hand hygiene after meal. ► **Rationale:** To reduce oral colonization with pathogens and risk of aspiration pneumonia.
22. Remove food tray and raise side rails as indicated.
23. Place call bell in reach.
24. Record percentage of food eaten and amount of liquid intake (if indicated).
25. Maintain client's sitting position for 30 minutes after eating.
26. Carefully observe client with impaired communication for 30 minutes after the first few servings.

Clinical Alert

The use of a straw increases risk of aspiration because the dysphagic client has less control over the amount of fluid intake. Similarly, the dysphagic client should not be fed with a syringe.

DOCUMENTATION for Nutrition Maintenance

- Appetite
- Food intake (percentage eaten)
- Tolerance to diet
- Weight
- Liquid intake
- Feeding techniques for the dysphagic client

CRITICAL THINKING Application

Expected Outcomes

- Diet meets nutritional requirements and is acceptable to client's taste and cultural orientation.
- Visually impaired client is able to self-feed.

Unexpected Outcomes

Client is nauseated and vomits.

Visually impaired client only eats food on one half of food tray.

Client has signs of aspirating food (coughing, drooling, hoarseness, noisy breathing).

- Dysphagic client is able to eat using adaptations to prevent aspiration.

Alternative Actions

- Withhold food if client is nauseated or vomiting.
- Provide antiemetic or client's preferred comfort measures (cold cloth to throat, soda drink).
- Identify potential sources for nausea: specific foods or odors, experience of pain, side effects of medication (e.g., morphine sulfate), or positional changes.
- Client may have *homonymous hemianopia* due to stroke and is unable to see the half of the tray on client's paralyzed side.
- Move food tray so that ignored side is within client's restricted range of vision (move tray leftward if client has had a left CVA and right side of tray has been ignored).
- Encourage client to turn head so that client's visual field includes the half of tray with food that has not been seen or eaten.
- Request speech pathologist consult for swallow evaluation.
- Ensure that assistive personnel are following individualized feeding instructions/precautions (e.g., client positioning, use of thickening agents, and avoiding use of straws).
- Remind client not to talk while eating and to concentrate on swallowing.

Chapter 19

UNIT 3

Nasogastric Tube Therapies

Nursing Process Data

ASSESSMENT Data Base

- Validate order for NG tube type and purpose.
- Assess overall status necessitating NG decompression (gastric surgery, intestinal obstruction).
- Assess status of GI function (presence of nausea, vomiting, abdominal distention, presence/absence of passage of flatus or bowel movement).
- Assess patency of nares.
- Assess risk for aspiration.
- Assess client's I&O balance and relevant lab data (electrolytes, hemoglobin and hematocrit, coagulation studies).
- Assess type of IV fluid replacement therapy client is receiving.

PLANNING Objectives

- To remove fluid and gas from the gastrointestinal tract
- To maintain decompression tube patency
- To perform gastric lavage to remove blood, fluid, or particles, or to prevent digestion and absorption of poison

IMPLEMENTATION Procedures

- Inserting a Large-Bore Nasogastric (NG) tube 653
 - For Testing Blood in Gastric Specimen 655
 - For Decompressing the GI Tract 655
- Flushing/Maintaining Nasogastric (NG) Tube 657
- Performing Gastric Lavage 659
- Administering Poison Control Agents 659
- Removing an NG or Nasointestinal (NI) Tube 660

EVALUATION Expected Outcomes

- NG tube is placed without complication.
- NG tube functions effectively (gastric contents are decompressed).
- Toxic substances are removed by lavage/not absorbed.

- Critical Thinking Application** 662
- Expected Outcomes 662
 - Unexpected Outcomes 662
 - Alternative Actions 662

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Inserting a Large-Bore Nasogastric (NG) Tube

Equipment

- Tapered plug for tube (if indicated for single-lumen tube)
- Single-lumen Levin tube or double-lumen Salem sump tube with anti-reflux valve (30–36 in.)
- Water-soluble lubricant
- Tape (2.5 cm or 1 in.) or commercial tube holder
- pH chemstrip or Gastrocult test card and developer
- Towel
- Emesis basin
- Tissues
- Safety pin and rubber band
- Tongue blade
- Glass of water with straw
- 50-mL catheter-tip syringe
- Clean gloves
- Indelible pen or piece of tape for marking tube
- Spindle adapter
- Suction tubing and suction source

Preparation

1. Check physician's order and client care plan for inserting an NG tube.
2. Check client's Ident-A-Band and have client state name and birth date.
3. Discuss procedure with client. ► **Rationale:** Demonstration and display of items to be used helps to allay client's fear and to gain cooperation.
4. Provide privacy.
5. Gather equipment.

Procedure

1. Perform hand hygiene. Don clean gloves.
2. Position client at 45° angle or higher with head of bed elevated.
3. Examine nostrils, and select the most patent nostril by having client breathe through each one. ► **Rationale:** The nostril with greater airflow should be chosen for insertion.
4. Place a towel over client's chest, an emesis basin and tissues within reach; establish a cueing signal for client to use to stop you momentarily. ► **Rationale:** Client may experience discomfort or gag during tube insertion.

Clinical Alert

Nurses never insert or withdraw an NG tube for clients recovering from gastric surgery. The suture line could be interrupted, and hemorrhage could occur. The physician should be notified of dislodgement.

Never insert an NG tube in a client after nasal, craniofacial, or hypophysectomy surgery.

Gastric (Salem) Sump Tube

This gastric tube is a double-lumen radiopaque plastic tube. One lumen is used for decompression. The blue lumen with a blue pigtail provides an air vent to allow atmospheric pressure to enter the stomach to prevent tube adherence to gastric mucosa when the tube is attached to suction. It is NOT used for irrigation, obtaining a specimen, etc. However, if the vent lumen is blocked and requires flushing, after the flush, the pigtail should be cleared with an injection of 20 mL air. The pigtail should be kept above the level of the client's stomach to prevent stomach contents from siphoning into the air vent lumen, making it dysfunctional.

Salem Sump Tube With Gientri Port

This nasogastric system has selector knobs to allow a change in modes for suctioning (decompression), feeding, irrigating, and medication administration all through one closed port. The anti-reflux valve/air vent lumen allows atmospheric air to enter the stomach similar to the way the double lumen tube with blue pigtail functions.

▲ Salem Sump with Gientri port.

5. Measure from tip of client's nose to earlobe to xiphoid (NEX) process of sternum to determine appropriate length for tube insertion.
6. Mark determined distance on tube with tape or pen if tube does not have markings.
7. Coil end of tube over fingers. ► **Rationale:** This softens tube and facilitates insertion.
8. Lubricate first 4 in. of tube with water-soluble lubricant. ► **Rationale:** Oil-based lubricant could cause respiratory complications.
9. With client's head slightly extended, carefully insert tube through nostril to back of throat. Aim the tube toward the ear on that side and downward toward the nasopharynx. ► **Rationale:** Advancing tube this way conforms to anatomic passageways.
10. Instruct client to flex head forward. ► **Rationale:** This position helps prevent tube entering clients airway.
11. Suggest client sip water while advancing tube until predetermined mark is reached. ► **Rationale:** Swallowing opens upper esophageal sphincter and allows tube to enter esophagus.
12. Listen at tube end for air exchange at 25-cm (carina) level; if no sound is heard, advance tube. ► **Rationale:** If sound is heard, tube may be advancing into airway and should be removed.
13. Continue advancing tube, having client dry swallow or giving client sips of water, until mark is reached.
14. Determine tube placement by aspirating gastric contents with 50-mL syringe to check color and pH. See page 668, Determining Gastric pH; if it is 5 or less, color is green or clear with tan *mucus shreds*, tube is in stomach. (Small bowel aspirate indicates a pH range of 6–7 and color is golden yellow to brownish green, consistency is thick. Pulmonary tree aspirate indicates pH of 6 or greater and color is white or pale yellow and watery consistency.) ► **Rationale:** The outcome of pH testing is useful only if the fluid aspirated tests acidic (<5).

Clinical Alert

Coughing and choking are normal responses for some clients; however, choking and coughing plus *cyanosis* or inability to speak indicate that the tube may be in the airway.

EVIDENCE-BASED PRACTICE

Determining Proper NG Tube Placement

A number of methods have been proposed to determine whether a tube has been inadvertently placed into the pulmonary tree, including air insufflation, observation of respiratory symptoms, pH testing of aspirated fluid, visual inspection of aspirated fluid, detection of carbon dioxide in the tube, and x-ray tube location verification. The best method of confirming the location of a blindly inserted gastrointestinal tube is by chest/abdominal x-ray.

Rauen, C. A., Chulay, M., Bridges, E., Vollman, K. M., & Arbour, R. (2008). Seven evidence-based practice habits: putting some sacred cows out to pasture. *Critical Care Nurse*, 28(2), 98–123.

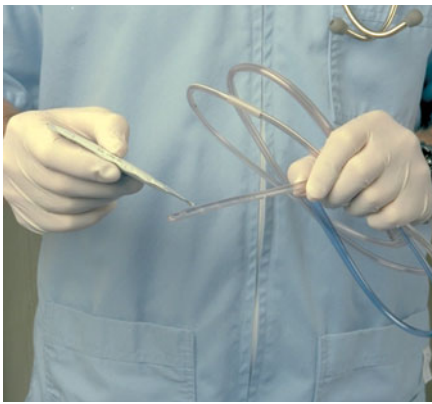

▲ NG tube inserted through naris to stomach.

▲ NG tube-measuring (A) Nose to earlobe, (B) Earlobe to xiphoid.

▲ Lubricate first 4 inches of NG tube with water-soluble lubricant.

▲ Insert NG tube through client's more patent nostril.

▲ Instruct client to flex head forward and take sips of water as tube is advanced.

▲ Aspirate gastric contents to check color and pH.

▲ Tape tube securely to client's nose to prevent tube migration.

▲ Secure tube by pinning to client's gown so blue pigtail is stabilized.

For Testing Blood in Gastric Specimen

- a. Note color of secretions. ► **Rationale:** Coffee ground appearance may represent digested blood, while bright red color may indicate active bleeding or ingestion of red food.
- b. Place one drop of aspirate onto Gastrocult test area. (See photo in Method of Determining Gastric pH in Unit 4.)
- c. Apply two drops of Gastrocult developer directly over the sample in the Gastrocult test area.
- d. Read occult blood results within 60 seconds; any blue color indicates presence of blood.

▲ StatLock-NG Securement Device prevents tissue trauma.

NOTE: To determine if reagents in developer are functioning properly, add one drop of developer between positive and negative areas. The positive Performance Monitor area should turn blue within 10 seconds and the negative area should not turn blue.

15. Tape tube securely to nose or use an attachment device. (StatLock-NG Securement Device is flexible, yet resistant to tearing and adheres strongly to skin.) ► **Rationale:** When tube is taped securely, tissue trauma caused by pull on sides of nostril will be minimized.
 - a. Cut tape about 3 in. long.
 - b. Split half of tape lengthwise.
 - c. Place unsplit end of tape over bridge of nose, with bifurcated ends hanging free.
 - d. Wrap each end of tape around the tube where it exits from the nose.
16. Plug end of tube or connect it to suction tubing using tapered adapter.
17. Mark tube at client's nostril. ► **Rationale:** To note possible tube migration.

For Decompressing the GI Tract

- a. Connect suction tubing to suction source.
- b. Set suction on *intermittent low* (40 mmHg) for decompression. ► **Rationale:** Intermittent suction

allows gastric tube suction force to be intermittently released, thereby reducing risk of mucosal erosion.

Or

- c. Connect clear lumen of Salem sump tube to *continuous low* suction (30–40 mmHg) or to *intermittent high* suction (120 mmHg). ► **Rationale:** Continuous suction can be used because air vent lumen prevents excessive negative pressure from developing in stomach.

▲ Connect suction tubing to suction source.

▲ Insert blue side of anti-reflux valve into Salem sump tube blue pigtail.

▲ Closed all-in-one enteric system port allows feeding, suctioning, irrigating, and medication administration. The built-in antireflux valve prevents gastric wall invagination during suction, replacing blue “pigtail” function.

▲ Tapered adapter is inserted to connect NG tube to suction tubing.

Oral/Nasal Hygiene for NG/NI Tube Clients

- Clients who are unable to ingest food or take fluids by mouth should receive regular oral and nasal hygiene to keep mucous membranes moist and to help prevent infection of the parotid glands.
- Oral hygiene also reduces the risk of aspiration pneumonia, as it decreases the number of pathogens in oropharyngeal secretions.
- Chewing gum or sucking on sugar-free candy also helps stimulate salivation, but excessive use can stimulate gastric secretions and cause electrolyte imbalance.

▲ Provide regular nasal and oral hygiene to keep mucous membranes moist and help prevent parotiditis and bacterial colonization of the upper respiratory tract.

- Secure tube with tape/rubber band pinned to client's gown, leaving slack for head movement.
- Implement procedure below when double-lumen (Salem sump) tube is used.
 - Stabilize blue pigtail above level of stomach.
 - ▶ **Rationale:** Helps to prevent siphoning into sump (pigtail) tubing.
 - Insert anti-reflux valve (blue tip) into blue pigtail of Salem tube. ▶ **Rationale:** Anti-reflux valve allows air to enter tube, yet prevents leakage of gastric secretions.
- Provide oral and nasal hygiene.
- Remove gloves and perform hand hygiene.
- Position client for comfort.

Flushing/Maintaining Nasogastric (NG) Tube

Equipment

- Disposable irrigation set with 50-mL syringe with catheter tip
- Emesis basin
- Towel
- Normal saline irrigation solution
- I&O record sheet
- Clean gloves

Preparation

1. Check orders and client care plan.
2. Perform hand hygiene.
3. Check client's Ident-A-Band and have client state name and birth date.
4. Provide privacy.
5. Explain procedure to client.
6. Place client in semi-Fowler's position.

Procedure

1. Don clean gloves.
2. Disconnect NG tube from suction source if used.
3. Place towel under NG tube to protect sheets and place emesis basin nearby.

▲ Aspirate secretions to check tube placement before instilling saline solution.

2. For irrigating NG tube, draw up 20–30 mL normal saline into irrigating syringe.

4. Check for NG tube placement by following Step 14 in previous skill. ► **Rationale:** Solution could be instilled in lungs if NG tube is not in the stomach.
5. Draw up 20–30 mL normal saline into irrigating syringe.

3. Gently instill normal saline into NG tube by syringe, or allow to flow by gravity.

4. Follow Salem tube irrigation with injection of air into blue pigtail to clear; then reinsert blue end of antireflux valve.

Clinical Alert

- If water rather than normal saline is used to flush enteral decompression tubes, the production of gastric secretions will increase and increasing amounts of electrolytes will be washed out. Similarly, if the client is NPO but ingests ice chips ad lib, electrolyte imbalance due to washout can occur, causing metabolic alkalosis.
- Limit the use of ice chips by substituting chips made from an electrolyte solution, and provide oral hygiene to keep the client's mucous membranes moist for comfort.
- If the client is receiving adequate parenteral hydration (IV fluids), excessive thirst should not be experienced.

6. Gently instill normal saline into NG tube or remove syringe plunger, pour NS into syringe barrel, and allow solution to flow in by gravity.
7. Repeat procedure if necessary.
8. Reconnect NG tube to suction or plug tube.
9. Record instilled amount on I&O record.
10. Remove gloves and perform hand hygiene.
11. Reposition client for comfort.

Clinical Alert

If secretions siphon into blue vent lumen, clear it by instilling 20 mL of normal saline followed by 20 mL of air. Air vent must be cleared of secretions to restore proper functioning.

Performing Gastric Lavage

Equipment

- Large-bore (37–40 Fr) soft Ewald or orogastric tube (client must have cuffed endotracheal tube in place if comatose)
- Large irrigating syringe with adapter
- Container for aspirate
- Lavage fluid, normal saline, or lukewarm water
- Activated charcoal for drug/toxin adsorption
- Container for specimen
- Water-soluble lubricant
- Standby suction available
- Towel
- Pen and tape
- Gloves

Preparation

1. Check physician's orders for gastric lavage and solution to be used.
2. Determine if client is alert or comatose.
3. Gather equipment.
4. Perform hand hygiene and don gloves.

Procedure

1. Per agency protocol (physician may insert) measure for tube insertion using the following guidelines:
 - a. Measure distance from bridge of nose to earlobe to xiphoid process (NEX).
 - b. Mark with pen or tape.
2. Place client in head-down, left side-lying position.
 - ▶ **Rationale:** This reduces risk of aspiration if client vomits.
3. Lubricate tube with water-soluble lubricant.
4. Insert tube nasogastrically or orogastrically (about 50 cm or 20 in.).
5. Aspirate gastric contents with syringe before instilling solution. **Save specimen for analysis.**

Clinical Alert

Gastric lavage used to remove unabsorbed poison or drug ingestion is generally ineffective if more than 60 minutes have passed, and the procedure may delay administration of activated charcoal or antidotes; therefore, it is not recommended to manage overdose. It is not used for corrosive agents or petroleum distillates due to risk of aspiration, and induced vomiting is no longer considered safe.

6. Repeatedly instill 50–100 mL normal saline or water and aspirate contents ▶ **Rationale:** Some authorities recommend water to lavage the stomach of blood since it breaks up clots more easily than saline solution, is less expensive, and is readily available.
7. Carefully monitor volume instilled and character and volume of aspirated contents. ▶ **Rationale:** This will assist in determining net volume if there is blood loss.
8. Continue repeating process until gastric return is clear, or as ordered.
9. Stomach will be left empty for decontamination. Activated charcoal may be instilled (as ordered) or a saline cathartic may be given. ▶ **Rationale:** Activated charcoal adsorbs drugs in the stomach or intestine.
10. Pinch tube for removal, wrap in towel, and dispose of equipment.
11. Remove and dispose of gloves and perform hand hygiene.
12. Record vital signs frequently and monitor client's response closely.

EVIDENCE-BASED PRACTICE

Erythromycin, 250 mg IV bolus given 20 minutes before upper GI endoscopy (EGD), speeds gastric emptying and is first-line choice for clearing gastric contents in clients with GI bleed.

Source: DiMaio, D. J., & Stevens, P. D. (2007). Nonvariceal upper gastrointestinal bleeding. *Gastrointestinal Endoscopy Clinics of North America*, 17(2), 253–272.

Administering Poison Control Agents

Equipment

- Large (37–40 Fr) Soft Ewald tube (physician may insert); comatose client must have endotracheal tube in place.
- Lukewarm tap water or saline for lavage
- Container for aspirated contents
- Large irrigating syringe with catheter tip
- 60–100 g of activated charcoal in aqueous slurry consistency to administer orally or through gastric tube
- Or
- Balanced polyethylene glycol–electrolyte solution (e.g., GoLYTELY) for mechanical bowel cleansing.

Preparation

See Preparation for Inserting a Nasogastric Tube

Procedure

1. Place comatose *intubated* client in a head-down, left side-lying position or place cooperative alert client on commode.
2. Insert large bore (37–40 Fr) flexible tube nasogastrically or orogastrically.
3. Aspirate gastric contents and save specimen for analysis.
4. Lavage repeatedly with 50–100 mL of fluid until return is clear.

Activated Charcoal for Ingested Poisons

Activated charcoal adsorbs significant amounts of certain poisons in the stomach and intestines. The earlier charcoal is given, the more effective it is. The amount given is 60–100 g orally or per gastric tube. Repeated doses (20–30 g) may be given every 3–4 hr.

Clinical Alert

For a known toxin, one should call a regional poison control center by dialing 800-222-1222.

- Administer activated charcoal slurry and repeat if ordered or, for cooperative client, administer balanced electrolyte solution per NG tube at a rate of 1–2 L/hr until rectal run-out is clear.

Removing an NG or Nasointestinal (NI) Tube**Equipment**

- Towel, paper towel
- Stethoscope
- Container of sterile normal saline solution
- 50-mL syringe with catheter tip
- Tissues
- Gloves
- Tube plug

Preparation

- Check physician's orders for NG tube removal.
- Assess client to determine presence of bowel sounds (auscultate to right of umbilicus as alternative to all four sites). Signs more indicative of GI function include passage of flatus, bowel movement, absence of nausea or vomiting, and presence of hunger.
- Prepare client for tube removal by explaining that it may cause some nasal discomfort, coughing, sneezing, or gagging.
- Perform hand hygiene and don gloves.

Procedure

- Provide tissues and place towel over client's chest.
- Disconnect NG tube from suction tubing if indicated.
- Flush NG tube with 20 mL normal saline (sterile water or saline for NI tube). ► **Rationale:** To clear tube so that GI contents do not inadvertently drain into esophagus on tube removal.

▲ To determine return of GI function, assess client for presence of bowel sounds passage of flatus or bowel movement, absence of nausea, presence of hunger.

▲ Clamp tube, unpin tube from gown, and loosen tape on nose securing NG tube.

▲ Have client hold breath and remove NG tube with continuous steady pull.

▲ Offer oral and nasal hygiene after removing tube.

4. Follow saline flush with a bolus of air. ► **Rationale:** To free tube from stomach/intestinal lining.
5. Unpin tube from client's gown and loosen tape that secures tube to client's nose.
6. Plug tube or clamp it by folding it over in your gloved hand.
7. Pinch tube close to client's naris, have client take a deep breath and hold it while you withdraw the tube.
 - **Rationale:** Holding breath closes glottis and helps prevent aspiration.
8. Wrap tube in paper towel to remove from client's view.
9. Offer oral and nasal hygiene.
10. Empty and record amount and character of drainage.
11. Discard disposable equipment and return reusable equipment to appropriate area.
12. Remove and dispose of gloves and perform hand hygiene.

EVIDENCE-BASED PRACTICE

Postoperative GI Motility

Nurses in this practice project discontinued bowel sound assessment to determine the return of gastrointestinal motility after abdominal surgery, since bowel sounds reflect the normal activity of the small intestine alone but do not represent return of functional GI motility. Primary indicators of the return of GI motility include return of flatus, bowel movement, client's tolerance of oral intake without nausea or vomiting, return of appetite, and absence of abdominal distension, bloated feeling, and cramps. Recent work on early feeding and reducing the routine use of nasogastric tubes has also contributed to a growing body of evidence on recovery of postoperative GI motility.

Source: Madsen, D., Sebolt, T., Cullen, L., Folkedahl, B., Mueller, T., Richardson, T., & Titler, M. (2005). Listening to bowel sounds: An evidence-based practice project. *The American Journal of Nursing, 105*(12), 40–49.

DOCUMENTATION for Nasogastric Tube Therapies

- Type of tube inserted
- Technique used to assess NG tube placement
- Character and amount of drainage
- Type of suction and pressure setting used
- Frequency and solution used for flush or irrigation
- Gastrointestinal assessment findings (e.g., passage of flatus, bowel movement)
- Net return for lavaged client (amount of irrigant instilled subtracted from amount of aspirated return)
- Frequent vital signs (if indicated)
- Nasal and oral hygiene measures
- Client's tolerance of decompression
- Results of gastric specimen testing (blood, pH)
- Decontaminating agents instilled

CRITICAL THINKING Application

Expected Outcomes

- NG tube is placed without complication.

- NG tube functions effectively (gastric contents are decompressed).
- Toxic substances are removed by lavage/not absorbed.

Unexpected Outcomes

NG tube is difficult to advance.

Alternative Actions

- Select more patent nostril: Have client compress each nostril and breathe in to determine which is more patent.
- Rotate tube or withdraw slightly, then try to advance, but do not force.
- Relubricate tube and try again.
- Curl tube around fist and hold under warm running water to soften for easier insertion.
- Have client hold ice chips in mouth for a few minutes to numb nasal passage and suppress gag reflex.

Client coughs, is unable to speak and becomes cyanotic during tube insertion.

- Remove tube immediately as these indicate that tube is being advanced into client's airway.

Salem sump pigtail leaks gastric contents.

- Flush pigtail with normal saline, then with air to clear.
- Keep blue pigtail at level above client's stomach.
- Maintain anti-reflux valve plug insertion (blue side into blue pigtail lumen).

Client has ingested a large number of tablets which cannot be removed by lavage.

- Whole bowel irrigation is more effective for ingestion of enteric coated or sustained-release tablets.
- Repeated dose of activated charcoal may be indicated to speed drug elimination.
- Prepare for possible arrangement for hemodialysis.

Enteral Feeding

Nursing Process Data

ASSESSMENT Data Base

- Assess client's nutritional status.
- Check physician's order for enteral feeding.
- Determine rationale for prescribed enteral feeding.
- Ensure appropriate placement of NG/NI tube using a variety of means.
- Assess client's gastrointestinal status (passage of flatus, bowel movement).

PLANNING Objectives

- To provide nutrients to the client who is temporarily unable to ingest food
- To correct nutritional deficiency in selected clients
- To provide nutrients to the client who requires continuous enteral feeding
- To maintain gastrostomy tube site

INTERVENTIONS Procedures

- Administering an Intermittent Feeding via Large-Bore Nasogastric Tube664
For Intermittent Feeding via Gastrostomy Tube665
- Dressing the Gastrostomy Tube Site669
- Inserting a Small-Bore Feeding Tube669
- Providing Continuous Feeding via Small-Bore Nasointestinal/Jejunostomy Tube671

EVALUATION Expected Outcomes

- Client's nutritional needs are met with nasogastric feeding.
- Client's nutritional needs are met with continuous enteral feeding.
- Gastrostomy tube site is free of signs of irritation/inflammation.

Critical Thinking Application 675

- Expected Outcomes 675
- Unexpected Outcomes 675
- Alternative Actions 675

Guidelines for Provision and Assessment of Nutrition Support Therapy in the Adult Critically Ill Client

1. Traditional nutrition assessment tools (albumin, prealbumin, and anthropometry) are not validated in critical care. Before initiation of feedings, assessment should include evaluation of weight loss and previous nutrient intake prior to admission, level of disease severity, co-morbid conditions, and function of the GI tract.
2. Nutrition support therapy in the form of enteral nutrition should be initiated in the critically ill client who is unable to maintain volitional intake.
3. Enteral nutrition is the preferred route of feeding over parenteral nutrition for the critically ill client who requires nutrition support therapy.
4. Enteral feeding should be started early within the first 24–48 hr following admission. The feedings should be advanced toward goal over the next 48–72 hr.
5. In the setting of hemodynamic compromise (clients requiring significant hemodynamic support including high dose catecholamine agents, alone or in combination with large volume fluid or blood product resuscitation to maintain cellular perfusion), enteral nutrition should be withheld until the client is fully resuscitated and/or stable.
6. In the ICU client population, neither the presence nor absence of bowel sounds nor evidence of passage of flatus and stool is required for the initiation of enteral feeding.
7. Either gastric or small bowel feeding is acceptable in the ICU setting. Small bowel access should be used in clients at high risk for aspiration, or those with repeated high gastric residual volumes.
8. Inappropriate cessation of enteral nutrition should be avoided. Holding enteral nutrition for gastric residual volumes <500mL in the absence of other signs of intolerance should be avoided. NPO periods for diagnostic tests or procedures should be minimized to prevent inadequate delivery of nutrients and prolonged periods of ileus.
9. If early enteral nutrition is not feasible or available the first 7 days following admission to the ICU, no nutrition support therapy should be provided. In the patient who was previously healthy prior to critical illness with no evidence of protein-calorie malnutrition, use of parenteral nutrition should be reserved and initiated only after the first 7 days of hospitalization.
10. If there is evidence of protein-calorie malnutrition on admission and enteral nutrition is not feasible, it is appropriate to initiate parenteral nutrition as soon as possible.

Journal of Parenteral and Enteral Nutrition, 33(3), May–June 2009, 277–316.

Administering an Intermittent Feeding via Large-Bore Nasogastric Tube

Equipment

- Pen to mark date and time on equipment
- Prescribed nutritional formula/product (check expiration date)
- Calibrated container for measuring formula
- Irrigating syringe (50 mL) with catheter tip (date and discard in 24 hr)
- pH indicator strip
- Warm water for flushing, towel
- Antimicrobial swab
- Gloves
- Clean dressing for gastrostomy site, if needed

Preparation

1. Check physician's order for type, amount, and frequency of feeding.
2. Wipe unopened formula container top with swab.
3. Pour prescribed amount of formula into container (if refrigerated, warm formula by placing container in hot water; do not use microwave to warm formula).

▲ Aspirate gastric contents to determine residual volume; then return contents to stomach to prevent electrolyte imbalance.

4. Cover, date, and refrigerate opened formula (discard in 24 hr).
5. Perform hand hygiene.
6. Maintain artificial airway cuff inflation during feeding (if indicated).

Procedure

1. Check client's Ident-A-Band and have client state name and birth date.
2. Provide privacy and explain procedure and purpose to client.
3. Assess that client does not have abdominal distention, nausea or pain, and has bowel elimination or flatus.
4. Check mark on tube at exit site. ► **Rationale:** To check for possible migration of tube.
5. Don gloves.
6. Elevate client's head of bed 30°–45° angle or high Fowler's.
7. Place towel under work area.
8. Remove white tip of antireflux valve from NG tube if indicated.

Clinical Alert

Always flush the NG tube with warm water after checking residual volume to prevent tube clogging.

9. Insert syringe into NG tube to validate gastric placement. ► **Rationale:** Tube could have migrated between feedings.
 - a. Check color, character, and test pH of aspirate (once every 8 hr after first 24 hr of tube placement).
 - b. Aspirate gastric contents to determine residual volume. ► **Rationale:** Further client assessment is indicated if residual volume is greater than 500 mL and client shows other signs of intolerance.

Residual Volume Considerations

Gastric residual volumes do not correlate well to incidence of pneumonia, measures of gastric emptying, or to incidence of regurgitation and aspiration. There is potential for inadequate nutrition support when feedings are delayed or withheld based on residual volumes under 500 mL. Assessment of tolerance should include absence of abdominal distention, nausea, pain, and presence of bowel elimination/flatus.

Source: McClave, S. A., Martindale, R. G., Vanek, V. W., McCarthy, M., Roberts, P., Taylor, B., ... Cresci, G. (2009). Guidelines for the provision and assessment of nutrition support therapy in the adult critically ill patient: Society of Critical Care Medicine (SCCM) and American Society for Parenteral and Enteral Nutrition (A.S.P.E.N.). *Journal of Parenteral and Enteral Nutrition*, 33(3), 277–316.

- c. Return aspirated contents to stomach. ► **Rationale:** This helps prevent electrolyte imbalance.
10. Pinch tubing. ► **Rationale:** This procedure prevents air from entering stomach.
11. Remove plunger from barrel of syringe, and attach barrel to NG tube.
12. Flush tube before feeding with 30 mL of warm water.
13. Fill syringe barrel with formula.
14. Hold container no more than 18 in. above client's stomach. ► **Rationale:** Holding container too high increases flow rate; rapid infusion can cause diarrhea/aspiration.

EVIDENCE-BASED PRACTICE

Aseptic Technique for Enteral Feeding

Enteral feeding should always adhere to principles of medical asepsis; however, *surgical* asepsis may be more appropriate for critically ill or immune suppressed clients.

Source: Padula, C., Kenny, A., Planchon, C., & Lamoureux, C. (2004). Enteral feedings: What the evidence says. *The American Journal of Nursing*, 104(7), 62–69.

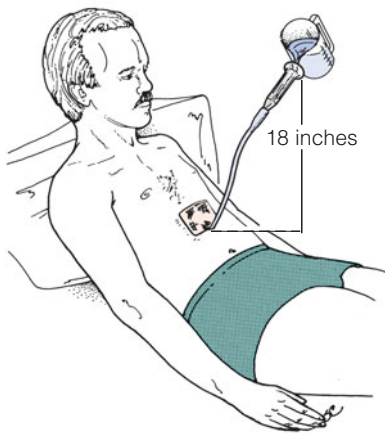

15. Allow formula to infuse slowly (between 20 and 35 minutes) through the tubing. Clamp tubing or continue to fill syringe before syringe empties; do not allow syringe to “run dry.” ► **Rationale:** If syringe runs dry before the addition of more formula, air enters stomach.
16. Follow tube feeding with 30 mL warm water flush. ► **Rationale:** Water cleans tube and prevents obstruction with formula.
17. Reinsert antireflux valve.
18. Maintain head of bed elevation at least 1 to 2 hr.
19. Wash, rinse, and dry equipment after each feeding. Mark date and *change syringe daily*.
20. Return equipment to client's bedside.
21. Give prescribed amount of water between feedings, if tube feeding is sole source of nutrition.
22. Provide regular oral hygiene.
23. Remove gloves and perform hand hygiene.

For Intermittent Feedings via Gastrostomy Tube

1. Check length of exposed tubing.
2. Aspirate to check residual volume. ► **Rationale:** Increased residuals may indicate delayed gastric emptying or that gastrostomy tube's internal stabilizer has migrated and is obstructing pyloric outlet.
3. Hold syringe no higher than 18 in. above client's stomach and administer 30 mL of warm water to flush and test patency of tubing. Clamp tubing by folding before syringe empties. ► **Rationale:** To prevent administering air into client's stomach.

▲ Allow feeding to flow by gravity and clamp tubing before syringe empties, or continuously fill syringe before it completely empties.

▲ Allow feeding to flow by gravity through gastrostomy tube.

4. Remove plunger, insert empty syringe barrel into gastrostomy tube, and administer feeding no higher than 18 in. above client's stomach, allowing formula to flow slowly by gravity.
5. Proceed as in previous skill with flushing, then reinsert tube plug.

NOTE: Gastrostomy site may be left open to air.

Clinical Alert

If gastrostomy tube residual is unobtainable, the tube may be displaced between client's stomach and abdominal wall, in which case administration of feeding could result in peritonitis.

6. Remove dressing (if present) around gastrostomy site.
7. Wash, rinse, and dry skin. Assess skin condition.
8. Apply clean dressing. (See Dressing the Gastrostomy Tube Site.)
9. Maintain head of bed elevation for 1–2 hr.

Clinical Alert

The use of blue food coloring as a marker for aspiration and use of glucose oxidase strips to test tracheal secretions for glucose are invalid measures to test for aspiration of enteral formulations.

EVIDENCE-BASED PRACTICE

• Safety Issues for Gastric Feeding

Studies show that clients receiving gastric feedings require intact gag and cough reflexes and adequate gastric emptying. Small bowel access for continuous enteral nutrition should be obtained for clients with tracheal aspiration, reflux esophagitis, gastroparesis, gastric outlet obstruction, or previous gastric surgery. Prokinetic drugs (metoclopramide and erythromycin) or narcotic antagonists (naloxone, alvimopan) should be initiated to promote motility where clinically feasible.

Source: McClave, S. A., Martindale, R. G., Vanek, V. W., McCarthy, M., Roberts, P., Taylor, B., ... Cresci, G. (2009). Guidelines for the provision and assessment of nutrition support therapy in the adult critically ill patient: Society of Critical Care Medicine (SCCM) and American Society for Parenteral and Enteral Nutrition (A.S.P.E.N.). *Journal of Parenteral and Enteral Nutrition*, 33(3), 277–316.

• PEG Tube Feedings Influence on Health Status

In a study of 150 patients (mean age of 78.9), 70% of those receiving PEG tube feedings had no significant improvement in functional, nutritional, or overall health status.

Source: Callahan, C. M., Haag, K. M., Weinberger, M., Tierney, W. M., Buchanan, N. N., Stump, T. E., & Nisi, R. (2000). Outcomes of percutaneous endoscopic gastrostomy among older adults in a community setting. *Journal of American Geriatric Society*, 48(9), 1048–1054.

• Enteral Feedings—Gastric pH

Studies show that normal gastric pH (1.5–2.5) destroys ingested organisms. More alkaline secretions (pH >3.5) promote bacterial proliferation and may increase risk of nosocomial infection.

Source: Padula, C., Kenny, A., Planchon, C., & Lamoureux, C. (2004). Enteral feedings: What the evidence says. *The American Journal of Nursing*, 104(7), 62–69.

TABLE 19-3 Comparison of Enteral Tube Feeding Methods

	Advantages	Disadvantages
Nasogastric	<ul style="list-style-type: none"> • Easily placed. • Intermittent feeding is possible, so client is less confined. • Large-volume feeding may be delivered less often. • Tube placement does not require x-ray confirmation. • Acid environment may reduce infection. • Less risk of dumping syndrome. • Uses normal gastric emptying, preventing intestinal overload. • Less expensive; no feeding pump required. 	<ul style="list-style-type: none"> • Limited to 1 wk use. • Gastric retention, reflux, and aspiration are possible. • Requires x-ray confirmation of placement before feeding unless aspirate is definitely acidic (< 5 pH). • Large tube is uncomfortable and visible to others. • Naris ulceration may occur. • Allows regurgitation by interfering with normal upper and lower esophageal sphincter function. • Gastric ulceration or fistulae may occur.
Gastrostomy or PEG	<ul style="list-style-type: none"> • Long-term use is possible. • Allows intermittent feeding. • Normal gastric emptying occurs. • Tube is not visible to others. • Medication administration is easier. • Less risk of infection. • Client can ambulate. • Esophageal irritation is avoided. 	<ul style="list-style-type: none"> • Requires surgical placement with sedation or local anesthetic. • Requires local skin care. • May ulcerate gastric mucosa.
Nasointestinal	<ul style="list-style-type: none"> • Smaller tube is more comfortable. • Less risk of reflux and aspiration. 	<ul style="list-style-type: none"> • Requires x-ray confirmation before feeding or flushing. • Tube is more difficult to place. • Client is still at risk for aspirating nasopharyngeal and gastric contents. • Elevated position must be maintained. • Constant infusion used; intermittent feeding not recommended because of osmotic response of small intestine. • Cramping, vomiting, distention, and diarrhea more common. • Requires pump; more expensive. • Tube can displace back into stomach (with constant infusion, this increases risk of aspiration). • Medication administration is difficult (liquid form preferred). • Greater risk of infection due to alkaline environment. • Limited to 4-wk use.
Jejunostomy	<ul style="list-style-type: none"> • Tube position is guaranteed. • Tube is not visible. • Possibly less risk of reflux and aspiration. 	<ul style="list-style-type: none"> • Requires general anesthesia for placement. • Continuous infusion is required. • Local skin care is required. • Cramping, vomiting, distention, and diarrhea are more common. • Other disadvantages associated with nasointestinal feeding.

Determining Gastric pH

Gastric pH is used to help determine NG tube placement, to assess gastric contents, and to evaluate and treat certain disease conditions. It is useful to determine placement only if aspirated secretions are acidic.

▲ Aspirate 5–10 mL of gastric secretions to test pH.

▲ Dip test paper into gastric secretion to test pH. *Note:* Normal gastric pH is 1.5 to 2.5.

Equipment

50 mL syringe with catheter tip
Emesis basin

▲ Place small drop of secretion on card to check pH.

Applicator
pH test paper (e.g., Gastrocult card)

Procedure

- Complete initial steps as for any procedure: gather equipment, explain procedure to client, perform hand hygiene, and don gloves.

Note: When testing for pH, wait at least 1 hr after administering medication or an NG feeding.

- Attach a 50-mL syringe with catheter tip to the NG tube and flush with 20 mL of air.
- Aspirate 5–10 mL of gastric secretions.
- Note color of secretions—gastric secretions are greenish to tan or off-white; respiratory secretions are clear to light yellow with mucus; duodenal samples are usually deep yellow. *Color of secretions does not guarantee correct placement.*
- Place 5 mL of gastric aspirate into a small cup or emesis basin and dip test pH paper into the cup, place a sample on the pH test paper, or using applicator, apply one drop of gastric sample to pH test area on Gastrocult card.
- Read chemstrip pH within 30 seconds by comparing the color of the paper with the pH color guide.
- Gastric contents are usually pH 5 or less. If the NG tube is in the pulmonary tree, it will be 6 or more. If the NG tube has passed into the small intestine, the pH is more than 6 and could be 7.0–8.0.
- If clients are receiving medications that raise gastric pH, or have gastric bleeding or esophageal reflux, pH measurement may be unreliable.
- Document result of gastric specimen (pH).

Dressing the Gastrostomy Tube Site

Equipment

- Normal saline; dated and initialed container left at client's bedside.
- 4 × 4 gauze squares or swabs
- Protective skin barrier (if indicated)
- Prepared split gauze dressing (occlusive dressing encourages fungal growth)
- Gloves
- Tape
- Pen to label dressing

Preparation

1. Gather equipment.
2. Perform hand hygiene.

Procedure

1. Check client's room number and Ident-A-Band and have client state name and birth date.
2. Provide privacy and explain procedure and purpose to client.
3. Don gloves.

▲ Change tube dressing when wet, or daily, placing dressing over external crossbar.

4. Remove old dressing and discard.
5. Inspect exit site for signs of irritation or leakage.
6. Open packet of gauze squares and saturate with normal saline.
7. Cleanse around exit site, then rotate external bumper 90°. ► **Rationale:** To prevent skin irritation, ulceration beneath bumper.
8. Dry site.
9. Apply thin layer of protective skin barrier paste to site (if irritated). ► **Rationale:** To protect the skin from leakage.
10. Place split dressing over (*not under*) external bar. ► **Rationale:** Dressing placed under the external bar can cause erosion of gastric tissue or abscess of the abdominal wall due to pressure on the internal bar within the stomach.
11. Secure dressing with tape (if necessary) and if external tube is long, secure it to dressing with tape. ► **Rationale:** To prevent tube drag and erosion or ulceration of the internal mucosa from tension on the inner retaining piece.
12. Mark dressing with initials, date, and time.
13. Remove gloves and perform hand hygiene.
14. After 1 week, cleanse site with soap and water and leave open to air, according to physician's orders.

Low-Profile Gastrostomy Tube

Clients requiring *sustained* enteral feeding may prefer a low-profile gastrostomy tube. These tubes are inserted several (3+) months after the gastrostomy tract (stoma) has healed. They fit close to the skin, so are less apt to be pulled out or get in the way of daily activities. In addition, some incorporate a one-way anti-reflux valve that opens for feedings and also prevents backflow of gastric contents.

Since products differ, refer to the manufacturer's instructions for the specific tube your client has had inserted.

Inserting a Small-Bore Feeding Tube

Equipment

- Small-bore (8–12 Fr) radiopaque enteral feeding tube (43–60 in.) with stylet
- Administration set with pump or controller
- 60 mL catheter tip syringe
- Sterile water or saline
- Clean gloves
- Water-soluble lubricant (if needed)
- Tape or other device to secure tube

- Glass with water and straw, if appropriate
- Towel and tissues
- Safety pin or clip
- Emesis basin
- pH chemstrip
- Pen for marking tube
- Prepared prokinetic agent (metaclopramide by IV injection or Erythromycin by IV infusion) if ordered
- Antimicrobial swab

▲ Check that guidewire (stylet) does not protrude through holes in feeding tube. Reposition guidewire if necessary.

Clinical Alert

This skill may be performed using surgical asepsis for critically ill or immune-suppressed clients.

Preparation

1. Validate physician's orders.
2. Gather equipment.
3. Check client's room number and Ident-A-Band. Have client state name and birth date.
4. Provide privacy.
5. Administer prokinetic agent injection or infusion (if ordered for duodenal advancement) 10 minutes before tube insertion.

Procedure

1. Perform hand hygiene.
2. Explain procedure to client.
3. Elevate head of bed at least 45°. Place towel over chest; provide tissues and emesis basin.
4. Determine length of tube for insertion into stomach. Use distal end of feeding tube, and measure from tip of nose to earlobe to xiphoid process (NEX) for gastric placement.

NOTE: For small bowel placement, all but 10 cm of tube is inserted.

5. Note NEX marking on tube and place tape or mark with pen.
6. Seat stylet connector firmly into tube connector.
7. Check that guidewire does not protrude through holes in feeding tube. Reposition guidewire if necessary.
 - ▶ **Rationale:** This prevents trauma to mucosa during placement.

NOTE: Use of stylet is optional and may not be necessary in a conscious cooperative client.

8. Don clean gloves.
9. Lubricate tip of feeding tube with water-soluble lubricant, or for tube with surface lubricant, moisten tip in water to activate lubricant.
10. Assess nares to determine patency. ▶ **Rationale:** Select the more patent nare for tube insertion.
11. Instruct client to momentarily hyperextend neck.
12. Insert feeding tube through patent nostril, gently advancing tube—advance parallel to nasal septum.
13. Ask client to flex head forward and swallow when tube reaches pharynx. ▶ **Rationale:** Hyperextension at this stage may open airway, and tube could advance into the trachea.
14. Pull back on tube if client begins to cough or shows signs of respiratory distress or cyanosis. ▶ **Rationale:** Tube may have entered trachea. Wait several seconds, then advance tube asking client to swallow sips of water with tube advancement.
15. Listen at tube end for air exchange at carina level.
 - ▶ **Rationale:** If air exchange is heard, tube may be in respiratory tract. If no sound is heard, advance tube.
16. Advance tube to premeasured (NEX) position.
17. Tape tube securely in place.
18. Flush tube side port with 30–50 mL of AIR then attempt to slowly aspirate gastric contents; reposition client to *left side* and repeat aspiration if necessary to obtain a specimen.
19. Test aspirated specimen for color, character, and pH.
 - ▶ **Rationale:** Gastric specimen should have pH <5. As tube advances into small intestine, pH becomes higher (>5).
20. Obtain x-ray to determine feeding tube placement.
21. If gastric placement is confirmed, use a rotating motion to gently advance tube to all but 10 cm and retape securely.

NOTE: This may be facilitated by injections of 30 mL of air to free the tube away from the intestine.

22. For stylet removal, activate internal lubricant before removing stylet. Cap access port and flush tube through the stylet connector with 10 mL sterile water.
 - ▶ **Rationale:** Reinsertion of stylet into the enteral tube.

Clinical Alert

Do not initiate feeding or any flush until desired placement is confirmed and guidewire is removed. *Most tubes migrate into small intestine in 24 hr; advancement may be facilitated manually.*

Clinical Alert

Presence of an endotracheal tube may tend to guide feeding tube into the trachea. The use of glucose oxidase reagent strips to monitor pulmonary secretions for aspiration lacks adequate specificity.

should not be attempted because this can perforate tube and client's esophagus.

23. Once desired position is validated, swab feeding tube port, and attach administration set.
24. Swab port, then *gently* flush feeding tube (side port) with 20 mL of sterile water (using 60-mL catheter tip syringe) every 4 hr, and before and after each medication administered. ▶ **Rationale:** To maintain patency of the tube. Smaller syringe and vigorous flushing could cause pressure exceeding bursting pressure of the tube.
25. Check tape that secures tube to nose daily. Keep nares clean. Provide slack, securing tube by pinning or clipping to client's gown.
26. Replace small-bore tube every 4 weeks or as ordered, alternating nostrils. ▶ **Rationale:** Small-bore tubes can become contaminated or obstructed.
27. Provide frequent and regular oral hygiene. ▶ **Rationale:** Prevents parotiditis and respiratory complications.
28. Remove gloves, perform hand hygiene, and make client comfortable.

Safety Concerns: Continuous Enteral Feedings

Limit formula hang to 8 hr for an open system and 48 hr for a closed system if sterile technique is used.

Change administration sets and syringes used for flushing daily.

Do not add new formula to any formula remaining from previous administration. Flush bag with tap water before refilling.

Disinfect ports with antiseptic swab before and after handling.

Clinical Alert

The pH method for determining tube placement may not be useful during *continuous* NG/NI feeding because the infused formula raises gastric pH and lowers intestinal pH. The continuous-feeding aspirate will look like formula; it may be curdled or bile stained. A sudden increase in residual volume may indicate that a nasointestinal tube has become displaced upward into the stomach.

Clinical Alert

Potential Feeding Contamination

Open systems or opening a "closed system" (formula exposed to the environment) can invite contamination by numerous exogenous sources, hands being the main source. Do not touch any part of the system that contacts formula.

Source: Padula, C., Kenny, A., Planchon, C., & Lamoureux, C. (2004). Enteral feedings: What the evidence says. *The American Journal of Nursing*, 104(7), 62–69.

EVIDENCE-BASED PRACTICE

Client Positioning for Tube Migration

Positioning clients right side-lying has *not* been demonstrated to increase spontaneous tube migration into the small bowel. Prokinetic agents given before, but not after, tube insertion may facilitate tube passage into the small bowel.

Source: *Journal of Parenteral and Enteral Nutrition* (2002, Jan-Feb.). Section VIII, Access for administration of nutrition support.

EVIDENCE-BASED PRACTICE

Feeding Tube Positioning

Studies have shown that x-ray confirmation of *feeding tube* tip position should be obtained after placement of a small bore feeding tube and before any flushing or feeding is initiated.

Rauen, C. A., Chulay, M., Bridges, E., Vollman, K. M., & Arbour, R. (2008). Seven evidence based practice habits: Putting some sacred cows out to pasture. *Critical Care Nurse*, 28(2), 98–123.

Providing Continuous Feeding via Small-Bore Nasointestinal/Jejunostomy Tube

Equipment

- Prescribed formula in closed container ready to infuse system (preferred). Note expiration date.
- Antimicrobial swabs
- Formula reservoir or bag if necessary for open system (date and replace daily)
- Container of ready to use sterile formula (cover, label for client, refrigerate unused portion, and discard in 48 hr) or closed-system formula

- Administration tubing compatible with pump (replace daily)
- Infusion pump (not to exceed 40 psi)
- Label or pen
- 60-mL sterile syringe
- Sterile water or saline
- Gloves
- Mask (if caregiver has URI)

▲ Closed system formula can hang for 48 hours if sterile technique is used.

Preparation

1. Check physician's order for feeding formula type and rate of administration.
2. Check x-ray report. ► **Rationale:** Validates desired tube placement.
3. Check length of exposed tubing. ► **Rationale:** An increase in length may indicate tube tip has dislocated upward, from duodenum to stomach, or from stomach into the esophagus.
4. Perform hand hygiene.
5. Gather equipment.
6. Don clean gloves and mask if indicated.

Procedure

1. If using reservoir or bag for continuous intestinal feeding, rinse bag with sterile water, and fill with enough formula to limit hang time to 8 hr. *Note: Bring unused formula to room temperature before use.* ► **Rationale:** To reduce risk of infection. Advancement of tube to intestine places it in less protected (alkaline) environment.

Clinical Alert

Obese clients cannot efficiently mobilize fat stores, but use protein as a primary source of energy, have marked loss of muscle and lean body mass, and become nutrient-depleted when critically ill. Nutrient support, however, can cause *refeeding syndrome* in these as in other protein-deficient clients. This adverse response is characterized by volume overload, heart failure, pulmonary edema, glucose intolerance, excess carbon dioxide production (by-product of glucose metabolism), increased respiratory work, and respiratory failure.

2. Disinfect ports with antiseptic swab before and after handling.
3. Connect administration tubing to formula reservoir (container or bag) and prime tubing per manufacturer's instructions.
4. Thread tubing through pump per manufacturer's instructions.
5. Note mark on client's feeding tube to determine if migration has occurred.
6. Connect primed formula tubing to client's small-bore feeding tube. Initiate feeding with isotonic (300 mOsm) or slightly hypotonic formula. ► **Rationale:** To prevent dumping syndrome (cramping and diarrhea).

NOTE: Alternate method is to connect formula tubing to client's surgically established jejunostomy feeding tube.

7. Start feeding at slow constant infusion rate (25–50 mL/hr). ► **Rationale:** Slow increase in feeding volume is better tolerated. (Maximum rate is 100–150 mL/hr.)

▲ Thread tubing through pump per manufacturer's instructions. Pump must not exceed 40 psi.

▲ Connect continuous feeding system to client's surgically placed jejunostomy tube.

8. If client tolerates feeding, increase rate in 8–24 hr (increase by 25–50 mL/hr to prescribed rate).

▲ Maintain head of bed elevation at 30–45° to reduce risk of aspiration in clients receiving continuous enteral feeding.

▲ The Kangaroo enteral feeding pump provides a preset water flush volume at programmed time intervals reducing need of manual flush and risk of misconnecting various devices.

▲ Use 60 mL syringe to flush tube with 15 mL sterile water or saline every 4 hours and before and after each medication administered. Do not use tap water.

9. Keep client's head of bed elevated at 30–45°, or maintain obese client in reverse Trendelenburg position. ► **Rationale:** To lower intra-abdominal pressure and reduce risk of aspiration.
10. Prep side port with antimicrobial swab and, using 60 mL syringe, flush small-bore continuous feeding tube with 20–30 mL sterile water or saline every 4 hr; flush before and after each medication administered with 15 mL sterile water or saline. ► **Rationale:** To prevent tube clogging.
11. Check residual volume regularly. ► **Rationale:** Small-bore feeding tube residuals are usually less than 10 mL. Residuals as much as 50 mL may indicate upward displacement from the bowel into the stomach.

Safety Alert for Enteral Feeding

- Prefilled enteral feeding containers should be accompanied with enteral administration sets and should be labeled “Non-IV Compatible.”
- Use only enteral feeding sets/pumps so that IV pumps are not used for enteral delivery.
- Enteral pumps should feature an automatic flush mode so that there is no need to manually flush lines and to reduce risk of misconnecting adapters or Luer devices.
- Use oral syringes rather than Luer syringes to draw up and deliver medications into the enteral feeding system.
- Identify and confirm a solution’s label (3-in-1 parenteral nutrition solution may look similar to an enteral nutrition formulation bag).
- Label bags with bold statements “WARNING! For Enteral Use Only – Not for IV Use.”

Clinical Alert

Enteral nutrition via naso/oro-intestinal infusion should be withheld if the client is hypotensive (MAP < 60 mmHg), especially if receiving catecholamine agents to maintain hemodynamic stability. Signs of intolerance may indicate gut ischemia.

Clinical Alert

Many devices, both enteral and parenteral are the color purple. While *enteral* connectors have gone to purple in an attempt to have the nurse note that this is not an IV device color, two manufacturers’ PIC catheters use purple and thus the risk for enteral misconnection may be increased. *American Society for Parenteral and Enteral Nutrition (A.S.P.E.N.) 2006.*

Minimizing Risk of Misconnections

- Only those knowledgeable about the device should make a connection/reconnection.
- Enteral equipment should not mate with female Luer connectors—avoid GI tubes with female Luer connectors.
- Ensure that all connections are made under proper lighting conditions.
- IV and feeding devices should not be modified/adapted (this may compromise the safety features incorporated into their design).
- Trace line back to their origins when making connections.
- Recheck connections and trace all tubes when the client arrives at a new setting or as part of a hand-off process.
- Route IV lines toward the client’s head; route enteric lines toward the client’s feet.
- “Package” all parts needed for enteral feeding; reduce availability of additional adapters and connectors to reduce risk of improperly connecting dissimilar tubes or catheters.
- Label feeding tubes and connectors.

Guenter, P., Hicks, R. W., & Simmons, D. (2009). Enteral feeding misconnections: An update. *Nutrition in Clinical Practice*, 24(3), 325–334.

Clinical Alert

- If client is receiving continuous feeding, maintain HOB elevation at 30°–45° at all times. Turn off feeding 1 hr before client must be repositioned at less than 30° elevation for any procedure or transport.
- Transition from nutrition support to oral feeding requires careful monitoring. Enteral tubes or parenteral access should not be removed until the client has tolerated oral nutrition for 2–3 days.

DOCUMENTATION for Enteral Tube Feedings

- Date and time of procedure
- Placement of small-bore enteral tube and x-ray validation of proper placement
- External length of exposed tubing
- Methods of validating tube placement
- Quantity and character of aspirated residuals (color, pH, other tests)
- Amount and type of formula administered
- Head of bed elevation during and after feeding
- Frequency of tube irrigation and irrigant used
- Abdominal assessment findings (distention, nausea, vomiting, flatus, bowel movement)
- Bowel elimination pattern and characteristics
- Daily weight
- Intake and output
- Tube exit site assessment
- Application of dressing to exit site
- Oral hygiene provided

CRITICAL THINKING Application

Expected Outcomes

- Client's nutritional needs are met with intermittent nasogastric feeding.

Unexpected Outcomes

NG tube feedings are delayed/skipped due to large residual volumes.

Client develops diarrhea with enteral feeding.

Small-bore feeding tube fails to advance into duodenum.

Small-bore feeding tube becomes clogged; occlusion alarm sounds.

Gastrostomy tube site becomes irritated.

- Client's nutritional needs are met with continuous enteral feeding.
- Gastrostomy tube site is free of signs of irritation/inflammation.

Alternative Actions

- Assess for adequate GI function (no abdominal pain or distention; no nausea or vomiting, presence of flatus, bowel movement). If residual is < 500 mL, continue feeding but closely monitor client's response.
- Change to continuous rather than intermittent feeding.
- Continue measures to prevent aspiration.
- Consider post-pyloric feeding.
- Use closed system if possible to prevent contamination.
- Don clean gloves when setting up or opening system; use sterile technique if client is immunocompromised or critically ill.
- Flush bag before refilling with formula.
- Use prepackaged, ready-to-use sterile feeding formulas. If using open system, cover, label, and refrigerate unused formula and discard in 24 hr.
- Disinfect ports before and after any handling.
- Consult dietitian about osmolarity of formula (hyperosmolar or high-fiber formula may cause diarrhea).
- Determine if gastric feeding is acceptable (client does not have gastroparesis, reflux esophagitis, high risk for aspiration, absence of gag or cough reflex).
- Administer prokinetic agent before rather than after tube insertion.
- Suggest tube be advanced under fluoroscopy.
- Do not let formula bag run dry.
- Use warm sterile water in 50-mL syringe with a gentle push/pull technique for flushing tube. Do not use vigorous pressure.
- Do not flush with cola or acidic pH juices such as cranberry juice, as this can precipitate protein and cause tube clogging.
- Papain, combinations of activated pancreatic enzymes, and sodium bicarbonate mixed with water may declog the tube.
- Flush tube with sterile water every 4–6 hr and before and after any medication administered.
- Crush medications fully—ensure proper dilution and administer each medication separately.
- Consider use of papain and sodium bicarbonate with water for flush.
- Use declogging system suggested by tube manufacturer—do not reinsert guidewire to unclog tube.
- Replace long-term tube every 4 weeks using alternate nostril.
- Apply plain antacid (e.g., Mylanta) to area if condition is mild.
- Use skin prep barrier followed by antifungal powder followed by skin prep barrier.
- Request tube with external bar or disc be replaced with plain tube that is sutured into place (bars and discs may embed into skin).

GERONTOLOGIC Considerations

Dietary Needs of the Elderly

Energy (caloric) requirement: 2,000–2,400 kcal/day (may adjust to energy expenditure and physical activity).

Protein: 10% of energy requirement, increases to 20% of energy requirement during periods of stress (surgery, infection, burn).

Fiber: 20–35 g/day of fiber (five servings of fruit per day).

Fluids: 1,500–2,000 mL of water/day or 30 mL/kg body weight.

Vitamins: same as for younger adult except for vitamins D, B₆, and B₁₂. *Significant deficiencies in serum levels of vitamins and minerals are rare in healthy older adults.*

Vitamin D requirement is 10 mg/day for adults 51–70 and 15 mg/day for those over age 70.

Vitamin B₆ intake should be 1.7 mg/day for men and 1.5 mg/day for women over age 51 (25% of elderly are deficient in vitamin B₆).

Vitamin B₁₂ intake should be 2.4 mg for all adults over age 51 (about 15% of elderly are deficient in vitamin B₁₂).

Minerals: increased need—10 mg/day of iron.

The elderly are at high risk for malnutrition due to age-related physiologic changes, healthcare status, and lifestyle factors.

Physiologic Changes Associated With Aging

- Between ages 25 and 70, percentage of body fat doubles and lean body mass decreases by about one-third.
- Metabolic rate decreases 20% in men and 13% in elderly women; energy requirements decrease, there is reduced hunger and increased satiety due to increased levels of cholecystokinin, so food intake decreases.
- Esophageal and intestinal motility decrease.
- Saliva production decreases.
- Gastric secretions decline by 30% in adults over age 65, increasing risk for malabsorption of vitamin B₁₂, calcium, iron, folate, and possibly zinc.
- Lactose intolerance (more prevalent in elderly than younger adults) increases risk for calcium and vitamin D deficiency.
- Gastric emptying is slowed.
- Protein reserves may be inadequate for periods of stress, sepsis, or injury, leading to protein-calorie malnutrition.
- Loss of sense of smell (in more than 50% of those age 65–80 and 75% of those older than age 80).
- Decline in thirst drive (risk for dehydration).

Health Status Factors

- Poor dentition (up to 37% of elderly are edentulous). Loss of dentition is not due to the normal aging process but to improper oral hygiene and or inadequate nutrition beginning at an earlier age.
- Ill-fitting dentures causing pain limiting variety and quantity of intake.
- Swallowing or self-care deficit disorders (e.g., neuromuscular disorders, Parkinson's, Alzheimer's).
- Psychological changes (depression, cognitive impairment).
- Effect of medications (altered metabolism, anorexia, nausea, diarrhea, cognitive disturbance).
- Inappropriate diet prescription (low-salt, low-cholesterol, or low-calorie diet).
- Medical conditions (e.g., COPD, heart failure, cancer resulting).

Lifestyle Factors

- Alcoholism
- Inadequate income
- Decreased physical activity, lack of transport, isolation
- Cultural values
- Lack of monitoring/caregiving

Assessment parameters for nutritional status of the elderly client in addition to the above risk factors include:

- Anthropometric values:
 - Ideal body weight = men should weigh 106 lb for 5 feet plus 6 lb for each additional inch in height. Women should weigh 100 lb for 5 feet plus 5 pounds for each additional inch in height. Significant weight loss is more than 10% of body weight over the last 6 months or more than 7.5% over the last 3 months or more than 5% over the last month.
 - Body mass index risk for malnutrition:
 - Mild = BMI is 17.0–18.4
 - Moderate = 16.0–16.9
 - Severe = less than 16.0
- Biochemical indicators of *malnutrition* include:
 - Serum albumin below 3.5 mg/L (increased risk for infection, pressure ulcers, prolonged hospitalization)
 - Low serum cholesterol
 - Serum creatinine (reflects muscle mass)
 - Moderate deficit if 60%–79% of predicted
 - Severe deficit if less than 60% of predicted

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- The professional nurse is responsible for the client's basic nutritional assessment (an evaluation tool) if a dietician is not available. An unlicensed (CNA or UAP) is not trained to assess this information. A periodic nutritional assessment should be completed for any client who is hospitalized for a long period of time.
- The UAP (unless specifically trained by a swallowing specialist) should not be allowed to feed or assist in feeding the dysphagic client. The licensed professional should monitor and evaluate the UAP's adherence to client-specific feeding instructions.
- Generally, serving a food tray or feeding a client is assigned to the unlicensed staff. These staff should be reminded to report any unusual complaints or poor intake of food based on the client's care plan.
- Insertion of NG tubes is performed by a physician, an RN, or an LVN/LPN. A CNA or UAP may measure and record drainage from an NG tube and provide oral hygiene.
- Enteral feedings should be given by professional nurses, but some facilities do allow trained nonprofessionals to administer the feedings.
- If medication is administered through a (double lumen) tube, refer to agency protocol to determine who may administer the medication. According to some facilities, it is only an RN or LVN/LPN who may administer medication.

Communication Matrix

- Changes in GI therapy or nutritional support orders as well as significant changes in client data regarding tolerance of

nutritional therapies (including laboratory data client's elimination pattern) should be communicated to all staff.

- NPO or positioning requirements should be posted at the client's head of bed (HOB) and communicated to all attending staff (orally and by written plan of care).
- Specific instructions and special techniques for feeding the dysphagic client should be posted at the client's HOB.
- The UAP should report to the nurse when a feeding pump alarm sounds, or when additional formula is needed.
- The UAP should report to the nurse if a client's NG tube is leaking or if the client becomes nauseated or vomits.
- Clients who are taking enteral feedings should be working with a Nutrition Support Team (NST) in accordance with the American Society for Parenteral and Enteral Nutrition. The nursing staff should work with and communicate through this team, because they are trained to follow this aspect of the care plan.
- The nurse assigned to the client is the essential link between the client and the team; thus both verbal and written reports are important for continuity of care and assessment of the nutritional status of the client.
- It is also important for the nurse to teach the client and his or her family about the need for and aspects of nutritional support through enteral feedings.
- After initial nutrition screening by the admitting nurse or speech pathologist, the Nutrition Support Team for individualized assessment of clients should be contacted. Referral concerns include:
 - Nutrition risk on initial screening
 - Extended ICU stay
 - Any nutrition support (tube feeding, TPN)
 - Latex allergy
 - 75 years and older and having surgery
 - Liquid diet or NPO for more than 72 hr
 - Pregnant or lactating but not admitted for delivery

CRITICAL THINKING Strategies

Scenario 1

Mrs. Ramsey, age 62, has been admitted to the hospital with complaints of painful abdominal distention and signs of dehydration after 2 days of vomiting. She is diagnosed with small bowel obstruction due to adhesions (scar tissue) from a remote abdominal hysterectomy.

1. What are the pathophysiologic effects of intestinal obstruction?
2. What potential fluid and electrolyte problems occur with small bowel obstruction?
3. How does the loss of gastric secretions differ from the loss of intestinal secretions?

4. What are the body's normal compensatory mechanisms for acid-base imbalances due to loss of gastrointestinal fluids?
5. What interventions help to correct these imbalances?

Scenario 2

An elderly client (age 64) is admitted to the hospital for a hip replacement. When you are taking a history, you note that she appears to be malnourished.

1. What additional dietary information would be important to include in the database for this client?
2. Evaluate the assessment parameters in terms of the nutritional needs of the elderly and examine how this client fits into the model.

- Identify the primary parameters to be included in the discharge plan for this client.

Scenario 3

Mr. Bradley has been diagnosed with cancer of the liver and is admitted to the hospital with brain metastases. He complains of no appetite, refuses most meals, and is becoming significantly malnourished with drastic weight loss. Impairment of his hepatic and neurologic status has caused intermittent periods of nonresponsiveness and inability to eat.

Mr. Bradley's family is asking about alternative nutrition options and the physician is requesting that they make decisions about the treatment options.

- If nutritional support is indicated, what are the processes normally followed?
- Who has the primary decision-making power about medical treatments such as nutritional support?
- Do healthcare providers have an obligation to provide extraordinary care?
- Once initiated, can healthcare providers discontinue artificial feeding?
- In what ways can healthcare providers provide symbolically significant care?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

- Trans fats are polyunsaturates and monounsaturates that
 - Have been hydrogenated.
 - Are unsaturated.
 - Primarily come from vegetables, nuts, and seeds.
 - Come from animal sources.
- Which of the following clients would mostly likely be placed on a potassium restricted diet?
 - Heart failure client
 - Renal failure client
 - COPD client
 - Burn client
- Which of the following are helpful for the dysphagic client?

Select all that apply.

 - Swallowing liquid foods.
 - Eating food accompanied by liquids.
 - Swallowing thickened liquids.
 - Eating food without accompanying liquid.
 - Using a straw for liquids.
 - Being fed with a syringe.
- The purpose of the Salem NG decompression tube's blue lumen is to
 - Prevent esophageal reflux of gastric contents.
 - Allow siphoning of gastric contents if they stagnate.
 - Provide a port for continuous feeding.
 - Prevent tube adherence to the gastric mucosa.
- Which of the following is the least reliable indicator of the return of bowel function?
 - Appetite
 - Bowel sounds
 - Presence of flatus
 - Bowel movement

- The best way to determine NG tube placement with continuous feeding is to
 - Auscultate for injected air sound over the epigastrium.
 - Aspirate secretions and check for an acid pH.
 - Note the character of aspirated secretions.
 - Use capnography to detect presence of carbon dioxide.
- An intermittent NG tube feeding should be withheld if the residual volume is
 - 50 mL.
 - 100 mL.
 - 150 mL.
 - >200 mL.
- The best way to prevent clogging of a small bore feeding tube is to
 - Flush frequently with cola.
 - Flush frequently with cranberry juice.
 - Flush frequently with warm water.
 - Replace the tube weekly.
- The most effective way to promote small bore feeding tube advancement into the small intestine is to
 - Place the client right side-lying.
 - Place the client left side-lying.
 - Administer prokinetic medication before tube insertion.
 - Reinsert guidewire to advance the tube.
- The most appropriate method for extended nutritional support is
 - Nasogastric tube feeding.
 - Nasointestinal tube feeding.
 - Gastrostomy tube feeding.
 - Parenteral nutrition.

20

Specimen Collection

LEARNING OBJECTIVES

1. Discuss the nursing responsibilities for reporting abnormal laboratory values.
2. Describe the major client instructions that ensure an uncontaminated midstream urine specimen.
3. State the purpose for testing urine for ketone bodies.
4. State two objectives for obtaining a stool specimen.
5. List four precautions that must be carried out when obtaining a stool specimen for parasite identification.
6. Demonstrate the procedure for testing for occult blood.
7. State necessary documentation when collecting a stool specimen.
8. Explain the objectives for collecting a sputum specimen.
9. Outline the steps of collecting a sputum specimen from a suction trap.
10. Compare and contrast obtaining an aerobic and anaerobic culture.
11. State purpose for obtaining a blood specimen for glucose testing.
12. Write two nursing diagnoses that are relevant for specimen collection.
13. Demonstrate the removal of blood using a Vacutainer.
14. List specimen collections requiring specific consent forms.
15. State two critical-thinking solutions for the problem of blood not flowing into the syringe when withdrawing blood.
16. State the nursing action when a hematoma occurs at the puncture site.
17. Describe procedure for testing presence of HIV antibodies.

TERMINOLOGY

Aerobe a microorganism that lives and grows in the presence of free oxygen.

Albuminuria the presence of albumin in the urine.

Anaerobe an organism that lives and grows in the absence of molecular oxygen.

Antimicrobial an agent that prevents the multiplication of microorganisms.

Antimicrobial preventing the development or pathogenic action of microbes.

Asepsis prevention of contact with microorganisms.

Aspiration the removal of fluids or gases from a cavity by the application of suction.

Autolet a small instrument with lancet used to obtain a capillary blood specimen; usually used to measure blood glucose level.

Bacteria unicellular plant-like microorganisms lacking chlorophyll.

Cannula a tube for insertion into a duct or cavity.

Culture to grow microorganisms or living tissue cells in a special medium.

Dermis synonym for corium; the skin layer beneath the epidermis; contains vascular connective tissue.

Excoriation a breakdown of the epidermis.

Expectorant an agent that facilitates the removal of the secretions of the bronchopulmonary mucous membrane.

Exudate material obtained from a wound as the result of the inflammatory process.

Genitourinary pertaining to the genital and urinary systems.

Glucose a monosaccharide, the end product of carbohydrate metabolism; also known as dextrose; found in the normal blood.

Glycosuria the presence of sugar in the urine.

Granulocytes a granular leukocyte.

Hematuria blood in the urine.

HIV antibodies produced by the immune system and present in the blood when individual is exposed to HIV.

Hypovolemia diminished circulating fluid volume.

Inflammatory process localized response when injury or destruction of tissue has occurred; destroys, wards off, or dilutes the causative agent or the injured tissue.

Intracellular inside the cell.

Micturition the process of emptying the urinary bladder; voiding.

Occult blood blood in minute quantities, can be recognized only by microscopic examination or by chemical means.

Parasite an organism that lives within, on, or at the expense of another organism, known as the host.

Patency the state of being freely open.

Pathogen disease-producing organism.

Pinworm oxyurid parasite of the intestine, usually *Enterobius vermicularis*. Commonly found in children. Piperazine is drug of choice.

Polyuria the excessive production and elimination of urine.

Purulent containing pus, or caused by pus.

Pus an inflammation product containing leukocytes and exudate.

Septic pertinent to pathologic organisms or their toxins.

Septicemia presence of pathologic bacteria in the blood.

Skin turgor the tension or fullness of the cells and resistance against deformation.

Specific gravity weight of a substance compared with an equal volume of water. Water is 1.000.

Specimen a sample taken to show or to determine the character of the whole, as a specimen of urine.

Sputum substance expelled by coughing or clearing the throat.

Stool waste matter discharged from the bowels.

Transtracheal passage of a tube or needle through the wall of the trachea.

Urinary tract infection (UTI) an infection of the urinary tract, including all or part of the organs and ducts participating in the secretion and elimination of urine.

Vacutainer a plastic adapter that fits onto a double-ended needle for obtaining a venous blood sample.

Venipuncture puncture of a vein with a needle or catheter.

Venous pertaining to the veins; unoxygenated blood.

Viscosity resistance offered by a fluid; property of a substance that is dependent on the friction of its component molecules as they slide by each other.

LABORATORY TESTS

Laboratory tests are an adjunct for diagnosing healthcare problems and assessing the health status of clients. Test findings can reveal occult problems, determine the stage of disease, estimate the activity of the disease process, and measure the effect of therapy. Multiple laboratory tests are usually ordered not only to assist in diagnosing problems, but also to rule out certain disease states.

Laboratory tests can be analyzed individually or as a part of a screening panel. For example, a routine urinalysis screens for the chemical makeup of the urine, as well as color, clarity, and presence of abnormal cells. Blood chemistry components can be tested individually, as well as in combination through a multiparameter test. These tests provide data on 8, 12, or 16 different elements of blood, depending on the laboratory equipment. It is more cost-effective when all the tests are run simultaneously with one blood specimen. For example, a “panel 12” analyzes the following tests: total protein, albumin, calcium, inorganic phosphorous, cholesterol, glucose, blood urea nitrogen (BUN), uric acid, creatinine, total bilirubin, alkaline phosphatase, and serum glutamic oxaloacetic transaminase (SGOT).

Every laboratory establishes its own normal values for each test. The normal values are generally printed on each laboratory slip to facilitate comparisons with the client’s findings. Healthy clients do not always fall within the calculated laboratory norms. The physician, considering other variables, must judge the value and diagnostic implications of these tests.

Point-of-Care Testing (POCT)

An important component of client care has always been bedside nursing. Now, and in the future, this will include procedures to obtain laboratory results at the bedside. Immediate lab results will save crucial time and allow for quick decision making. For example, if the nurse knows, through POCT, that a critically ill client’s glucose level is elevated, an immediate intervention of IV insulin and monitoring may immediately improve the client’s status.

The most common POCT performed at the bedside are glucose levels, coagulation, blood gas, electrolytes, pregnancy tests, and urine dipstick tests. Most POCT in facilities are coordinated by a laboratory according to regulatory protocols. For example, the Clinical Laboratory Improvement Amendment regulates at the federal level who may perform the test and which ones may be included in POCT.

The Joint Commission and the College of American Pathologists set additional standards. More tests will, in the future, be incorporated into these protocols because their immediate results at the bedside will greatly improve client outcomes.

Nursing Responsibility

Nursing responsibilities associated with the collection of specimens range from client education to reporting abnormal laboratory findings to the appropriate health team member. When specimens are ordered, it is essential that the client understand

the full importance of how and why the specimen is to be obtained. If sterile or clean technique is required, client teaching can provide an understanding of the process. If the client is involved with obtaining the specimen, precise instructions should be given.

To prevent unnecessary lost time and cost to the client, the nurse must be well informed of the correct procedure for obtaining, handling, and processing each specimen. If the nurse is unfamiliar with the procedure, he or she should refer to the nursing procedure or laboratory manual for the healthcare facility. Specific directions are written for most tests performed by the laboratory. If there is any question about the procedure, the laboratory should be called for directions before obtaining the specimen.

The physician should be notified immediately of any abnormal laboratory findings that could be potentially life-threatening. Verbal communication is the most appropriate and efficient method. When the nurse leaves written messages on the chart, several hours may elapse before the physician sees the findings.

The nurse should also document when abnormal results are reported to the physician. Documentation should include date, time, tests, and the orders taken. If results were left with another person such as office personnel, the name of the person receiving results should be documented.

All clients admitted to a healthcare facility have at least one laboratory specimen collected during their hospitalization. The most frequent laboratory tests ordered are those involving the urine and blood.

It is the nurse’s responsibility to be aware of any and all legal implications of specimen collection. Reporting certain tests, such as HIV testing, requires a specific consent; likewise, certain test results are required to be reported to ensure public safety. It is important to remember that all client information, including laboratory results, is confidential.

Urine Tests

Nursing responsibilities include collecting, temporarily storing, and performing tests on the urine specimen. Timed urine specimens are usually left in the nursing unit until completion of the test. When urine specimens are retained in the nursing unit, the nurse must take special care in the storing and handling of the specimen to ensure reliable results. Generally, urine specimens collected over a period of hours must be refrigerated or have preservatives added to the specimen to ensure accurate results. Preservatives, such as hydrochloric acid or thymol, prevent deterioration of the specimen.

Most urine specimens are collected as clean-catch, or midstream, specimens and sent directly to the laboratory. Single urine specimens are obtained through random sampling. It is best to obtain the first voided specimen in the morning for routine urine tests. This specimen is more concentrated, and the pH is more acidic. The midstream method of urine collection necessitates that proper instructions be given to the client in cleansing the genitalia and obtaining the specimen.

When timed specimens are ordered, the nursing role encompasses not only the handling of the urine specimen,

but also precise instructions to the client for collecting the specimen. The collection of urine needs to start and finish at the designated time. Timed tests vary from 2 hr to 24 hr. Assessment for amylase and bilirubin can be done on a 2-hr collection. Creatinine clearance and estriol determination require a 24-hr specimen. A 24-hr urine specimen that is started at 9 AM must be finished at 9 AM the next day in order to obtain accurate results. Instructions to the client include voiding at 9 AM, discarding that urine specimen, and collecting the rest of the urine at 9 AM the next morning.

Clinitest, Acetest, and the test for specific gravity are usually performed by the nurse and are not done by the laboratory. Nurses should follow the specific procedures for each test to obtain accurate results.

Blood Tests

Even though blood studies are carried out on venous, capillary, or arterial blood, the usual sample is obtained from venous blood. Capillary blood specimens are usually used to obtain specimens from infants and neonates. In adult clients, blood glucose and hemoglobin levels can be determined from capillary blood. Arterial samples are obtained for blood gas determination and cultures.

Venipunctures must be carried out keeping in mind that hemoconcentration and hemolysis can occur if the procedure is done improperly. Hemoconcentration results from prolonged use of a tourniquet. Hemolysis may occur from using a small-bore needle for the venipuncture of rapidly infusing blood into the specimen tubes. Using a larger bore needle for performing the venipuncture and taking the cap off the specimen tubes is recommended to prevent hemolysis.

If a needle and syringe are used for drawing blood, the top may be removed from the blood tube. After removing the top, slowly inject the blood into the test tube to prevent hemolysis.

Blood specimens are placed in specific blood tubes according to the type of test ordered and sent to the laboratory for

analysis. Each healthcare facility has a list of blood tests that are analyzed from blood in a specific color-top test tube. The colored top on the test tube indicates whether or not the tube contains a preservative. When whole blood is required for the test, an anticoagulant, such as heparin or trisodium citrate, is placed in the test tube to keep the blood from clotting. When serum is needed for the laboratory test, no preservative is added to the blood as the clot is used for the test. If the test tube contains a preservative, the tube should be gently rotated back and forth with palms of hands to prevent the blood from clotting.

Some blood tests require that the client fast for several hours before obtaining the specimens. Other blood tests have no special requirements for collection. Blood studies requiring a fasting specimen for accuracy include fasting blood sugar, lipid panels, glucose tolerance tests, and insulin levels.

▲ These are examples of color-identified blood specimen tubes. Each color indicates the specific test ordered and contains the appropriate additive/preservative.

TABLE 20-1 Collection Blood Sample Types

Purpose	Common Tests	Tube Color	Draw Volume	Additives
Whole blood studies	Blood culture	Yellow*	12 mL	Acid citrate Dextrose/nutrient Broth or preservative
Prothrombin times (PT)	Coagulation studies on plasma	Blue (or black)	3 to 5 mL	Sodium citrate (Sodium oxalate)
Chemistry, therapeutic drug monitoring, blood type	Serum studies	Red	2 to 20 mL	None
Chemistry (including lipids)	Plasma	Green	2 to 15 mL	Lithium heparin
Hematology CBC – CSR	Whole blood studies	Purple/ Lavender	2 to 10 mL	K ₂ or K ₃ EDTA anticoagulant
Glucose on serum or plasma	Plasma	Gray	3 to 10 mL	Anticoagulant Sodium fluoride Sodium oxalate

*Requires sterile technique.

▲ Blood specimens are usually drawn by a special technician according to the physician's orders.

Clinical Alert

Order of tube draw is important because there may be a small amount of residual or tube coating, called "carryover," which could invalidate the results.

Tube Order: Yellow (Sterile), Blue, Red, Green, Purple, Gray.

Cultures

Specimens from the throat, eyes, nose, vagina, wounds, sputum, stool, urine, and blood are often ordered to be cultured for pathogens. Special tubes or containers with culture media are used for organism growth. The culture is prepared in the laboratory according to the type of test ordered. It is essential that the proper technique be used to place the specimen in the appropriate container to ensure accurate results. Specimens obtained for culture and sensitivity require immediate processing and must be sent directly to the laboratory after they are obtained. If a time lapse occurs, the specimen may need to be discarded and a new one obtained. If the specimen is allowed to dry before the examination, the organism cannot be transferred to the slide and thus to the culture medium.

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to include in a client care plan when the components are related to collecting specimens.

NURSING DIAGNOSIS	RELATED FACTORS
Anxiety	Dread of unknown outcome, results of specimen tests
Ineffective Coping	Fear, external stress, situational crisis
Infection, Risk for	Invasive procedure, contamination from poor technique of specimen collection
Deficient Knowledge	Inaccurate collection of specimen (e.g., instruction not clear, unable to hear or see well enough to complete collection)
Noncompliance	Inadequate understanding of the purpose or value of diagnostic test (e.g., language and cultural barriers)
Acute Pain	Invasive procedure, altered body function, recent surgery

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. Remember to wash your hands or use antibacterial gel before and after each and every client contact.

IDENTIFY CLIENT Before every procedure, check two forms of client identification, not including room number. These actions prevent errors and conform to the Joint Commission standards.

Chapter 20

UNIT 1

Urine Specimens

Nursing Process Data

ASSESSMENT Data Base

- Assess client's ability to understand instructions and to obtain specimens properly.
- Identify if signs and symptoms of urinary tract infections are present: frequency, urgency, dysuria, hematuria, flank pain, fever, and cloudy urine with sediment.
- Determine the purpose for which the specimen is being obtained.
- Determine how the collection is to be obtained.
- Assess parents' understanding of the purpose for collecting infant's urine.
- Assess client's ability to test own urine for ketone bodies.

PLANNING Objectives

- To instruct the client in the method for obtaining a specimen
- To obtain an uncontaminated urine specimen for culture and sensitivity
- To obtain urine specimen for routine hospital admission or as a preoperative urine sample
- To maintain the collection of urine for 24 hr
- To successfully teach client to test urine for ketone bodies

IMPLEMENTATION Procedures

- Collecting Midstream Urine 685
 - For a Male* 685
 - For a Female* 685
- Collecting 24-Hour Urine Specimen 686
- Collecting a Specimen From an Infant 686
- Teaching Clients to Test for Urine Ketone Bodies 687

EVALUATION Expected Outcomes

- Client understands rationale and procedure for collecting urine specimen.
- Uncontaminated urine specimen is collected.
- Collection of 24-hr urine specimen is successful.
- Client learns how to test for ketone bodies.
- A clean, uncontaminated urine specimen is collected from a child.

- Critical Thinking Application** 688
- Expected Outcomes 688
 - Unexpected Outcomes 688
 - Alternative Actions 688

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Collecting Midstream Urine

Equipment

- Soap and water or hand cleanser
- Cleaning swab or bactericidal soap
- Sterile specimen container
- Label for container
- Clean gloves

Procedure

1. Gather equipment.
2. Perform hand hygiene.
3. Identify client by checking two forms of client ID.
4. Explain procedure to client.
5. Don clean gloves and provide perineal care as needed.
6. Instruct client to collect specimen in bathroom or place on bedpan.
7. Instruct client to clean the urinary meatus and obtain urine specimen. (See procedure below: *For a Female*, a-e.)

Clinical Alert

Do not use alcohol-containing wipes for cleansing before collecting urine for suspected drug abuse.

For a Male

- a. Don clean gloves and open container.
- b. Cleanse end of penis with cleansing swab using circular motion and moving from middle toward outside. ► **Rationale:** Always swab from clean to dirty area to decrease bacteria levels.

▲ Sterile urine specimen container.

- c. Ask client to initiate urine stream.
- d. After single stream achieved, pass specimen bottle into stream and obtain urine sample. At least 30 mL must be obtained for adequate specimen. ► **Rationale:** The microorganisms which accumulate at the urinary meatus have been flushed out with the original stream of urine and are not collected in the specimen.

For a Female

- a. Don clean gloves and open container.
 - b. Spread labia minora with nondominant hand.
 - c. Cleanse area with disinfectant swab, beginning above the urethral orifice and moving posteriorly.
 - d. Ask client to initiate urine stream. Hold labia open throughout the voiding process.
 - e. After single stream achieved, pass specimen bottle into the stream and obtain sample of at least 30 mL (half full).
8. To prevent contamination of specimen with skin flora, instruct the client to remove the bottle before the flow of urine stops and before releasing the labia or penis.
 9. Instruct client to completely empty bladder.
 10. Wipe off outside of container after replacing cap.
 11. Remove gloves and perform hand hygiene.
 12. Label the specimen (as appropriate) with client's name, room number, medical record number, date, time, and physician's name.
 13. Take specimen to laboratory within 15 minutes. If this is not possible, refrigerate specimen. ► **Rationale:** Delays in testing may decrease glucose ketone, bilirubin, and urobilinogen values. Falsely elevated bacteria counts can also occur if specimen is not refrigerated.

Clinical Alert

A contaminated specimen is the single most common reason for inaccurate reporting on urinary cultures and sensitivities. To prevent contamination, place cap of container with sterile side up while collecting specimen and do not touch inside of container.

Collecting 24-Hour Urine Specimen

Equipment

- Urine specimen container
- Preservative, if required
- Requisition slip
- Label for specimen
- Sign that urine collection is in progress
- Container with ice, if needed

NOTE: 24-hour urine specimens must be collected for the entire time ordered. To obtain accurate finding, the laboratory needs the entire urine specimen. The start and stop dates and times should be reported at change of shift.

Clinical Alert

Note any dietary restriction or medication precautions in preparation for 24-hr urine collection.

Procedure

1. Explain procedure to client and check two forms of client ID. Stress the importance of saving all urine for 24 hr.
2. Place sign in client's bathroom stating that 24-hr urine specimen is in progress, with start and stop date and time.
3. Collect urine specimen and discard it. ► **Rationale:** The first specimen is considered "old urine" or urine in the

bladder before test began. Test begins with an empty bladder.

4. Record date and time of first specimen on label, and place bottle in appropriate area. Depending on hospital protocol, specimens may be refrigerated, placed on ice, or left in the client's bathroom.
5. Add preservative, if required.
6. Post sign in appropriate place, if other than client's bathroom.
7. Place all urine voided in specimen container. Instruct client *not* to urinate directly into the large collection container.
8. Request client to void exactly 24 hr after first specimen was obtained. Place voided urine in container.
9. After the last voided specimen is placed in the container, cover and send entire specimen to the lab with the proper requisition.
10. Remove sign, and remind client that the test is completed.
11. If a specimen is accidentally discarded, obtain a new container, note the new date and time, and restart the procedure. Notify lab of lost urine.

NOTE: For creatinine clearance test: Instruct client to avoid caffeine-containing drinks including coffee, tea, and most soft drinks. Drink plenty of water before and during 24-hr collection.

Collecting a Specimen From an Infant

Equipment

- Cleansing solution
- Towel
- Pediatric urine collector

▲ Remove adhesive backing from urine collection bag and place securely over penis.

- Diapers
- Appropriate specimen containers
- Clean gloves (2 pair)
- Clean specimen container
- Label for specimen

Procedure

1. Gather equipment.
2. Perform hand hygiene. Don clean gloves.
3. Identify correct child by checking two forms of infant ID.
4. Cleanse and dry child's perineum.
5. Remove paper backing from the adhesive on the urine collector.
6. Apply urine collector to child's perineum, avoiding extension over anus to prevent contamination.
 - a. *Male:* Place child's penis through the opening of the collector.
 - b. *Female:* Place the opening of the collection bag over the child's urinary meatus.
7. Remove gloves.

8. Place a diaper on the child to help hold the collector in place.
9. Perform hand hygiene.
10. Check the collector every 15 minutes until a specimen is obtained.
11. Don clean gloves.
12. Remove the collector and place in a urine specimen container.
13. Place clean diaper on child.
14. Send the urine specimen to the lab by either placing the urine collection bag in a urine container or pouring urine from collection bag into the urine container.
15. Remove gloves and perform hand hygiene.
16. Label the container with the child's name, date and time of collection, and the initials of the nurse doing the collection.

Teaching Clients to Test for Urine Ketone Bodies

Equipment

- Urinal or container
- Test tube
- Urine testing kit (test tube, dropper)
- Color charts
- Paper towel
- Watch for timing

Procedure

1. Type 1 diabetics, when blood glucose is over 200, will need to check urine for ketone bodies.
2. Instruct client to void in urinal or container to collect urine specimen. ► **Rationale:** Specimen should be fresh because urine collected overnight will not accurately reveal concentration of ketone bodies.
3. Empty small amount of urine into test tube or dip Keto-Diastix strip into urine. Wait 15 seconds.

▲ Place one drop of urine on Acetest tablet to check for ketone bodies.

▲ Keto-Diastix strips are checked against the chart for ketone bodies.

4. *Alternative method:* Place ketone (Acetest) tablet on a piece of paper towel. ► **Rationale:** White towel reflects color and absorbs more efficiently.
 - a. Wait 30 seconds.
 - b. Compare color of tablet and chart.
5. Compare strip against color chart and note findings. ► **Rationale:** Instruct the client to notify client's physician if ketone bodies are moderately present.

Clinical Alert

Ketones in urine may be negative or present in small, moderate, or large amounts. If there are more than moderate ketones and the client does not feel good or has nausea and vomiting, client should immediately contact physician.

DOCUMENTATION for Urine Specimens

- Method used to obtain specimen
- Color, consistency, and odor of urine
- Amount of urine obtained (record this amount on the intake and output record also)
- Time specimen sent to laboratory
- Refrigeration, if required
- Exact time for 24-hr specimen
- Results of client teaching to test for ketone bodies

CRITICAL THINKING Application

Expected Outcomes

- Client understands rationale and procedure for collecting urine specimen.
- Uncontaminated urine specimen is collected.

Unexpected Outcomes

Client is unable to assist with obtaining a sterile specimen.

Urine specimen contaminated with feces or toilet paper.	<ul style="list-style-type: none"> • Collection of 24-hr urine specimen is successful. • Client learns how to test for ketone bodies. • A clean, uncontaminated urine specimen is collected from a child.
Client cannot void on command at completion of test.	<h3>Alternative Actions</h3> <ul style="list-style-type: none"> • Place female client in bed and, after cleaning perineum thoroughly, place on sterile or clean bedpan. Cleanse perineal area with swab and obtain specimen according to procedure. • Assist client into bathroom. Assist client to cleanse perineum, instruct to start urine stream, and place the sterile specimen container under the stream to collect specimen. • For male clients, cleanse the penis, and place a sterile or clean urinal under the client. Instruct to start stream of urine and then place sterile container under stream. • Notify physician. Consider catheterization.
Urine specimen discarded before 24-hr sample collected.	<ul style="list-style-type: none"> • Instruct client on need for accuracy and compliance to urine collection. • Instruct client to void as close to time as possible. • Chart exact time when last specimen collected on both urine bottle and lab slip. Notify lab of findings.
Infant's urine specimen is lost because collector does not adhere.	<ul style="list-style-type: none"> • If time period is close to 24 hr, call laboratory to determine whether test can be completed on sample collected. • If 24-hr sample must be started again, instruct client of necessity to save all urine. • Place signs indicating 24-hr test collection in progress on bathroom door and client's bedside stand. • Mark in bold or underlined print in Kardex indicating 24-hr urine collection in progress.
Infant specimen is lost because collection bag is the wrong size.	<ul style="list-style-type: none"> • Obtain a new collection bag and repeat the procedure. • Tape bag in place with nonallergenic paper tape if necessary.
Infant specimen cannot be obtained with a collection bag.	<ul style="list-style-type: none"> • Obtain appropriate size bag and repeat the procedure. • Notify the physician that you are unable to obtain urine specimen. • If possible, keep diapers off and observe when infant urinates; attempt to obtain specimen.
Strips or tablets are discolored or moist.	<ul style="list-style-type: none"> • Sensitivity is lost. They need to be disposed of and new strips or tablets used. • Keep tablets and strips away from moisture by keeping them in tightly covered container (original bottle for tablets and baby food jar for tape). • Always check tablet before using to ensure accurate results.
Ketones are present in urine specimen.	<ul style="list-style-type: none"> • Check expiration date on strip; an expired product will not yield accurate results. • Check that client understands what actions to take if moderate or above ketones are present in the urine. • Be sure client is aware that a low-carbohydrate or a high-fat diet may cause false-positive results; certain drugs may also cause a false positive.

Stool Specimens

Nursing Process Data

ASSESSMENT Data Base

- Determine the purpose for the test.
- Check whether the specimen must be sent to the laboratory immediately.
- Determine the eliminatory status of the client (i.e., liquid vs. formed stools).
- Assess gastrointestinal tract dysfunction.

PLANNING Objectives

- To obtain stool specimens for diagnosing dysfunction in bowel elimination
- To assess for perforation or bleeding from a gastric ulcer
- To detect presence of ova and parasites
- To determine presence of pinworms

IMPLEMENTATION Procedures

- Collecting Adult Stool Specimen690
- Collecting Stool for Ova and Parasites690
- Collecting Infant Stool Specimen691
- Testing for Occult Blood691
 - For *Gamma Fe-Cult Plus*691
 - For *Hemoccult*692
 - For *Gastrocult*692
- Collecting Stool for Bacterial Culture692
- Teaching Parents to Test for Pinworms692

EVALUATION Expected Outcomes

- Client understands purpose of test.
- Client is able to follow procedure of collection when appropriate.
- Dietary restrictions (if appropriate to test) were adhered to by client before test.
- Specimen collected is adequate for test.

Critical Thinking Application 693

- Expected Outcomes 693
- Unexpected Outcomes 693
- Alternative Actions 693

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Collecting Adult Stool Specimen

Equipment

- Waxed cardboard or plastic container with cover
- Tongue blade
- Label for container
- Clean bedpan or bedside commode
- Clean gloves
- Two signs for over client's bed and in bathroom stating, "Save All Stool."

Procedure

1. Check two forms of client ID, and explain the procedure to the client.
2. Determine if dietary restrictions are required before specimen collection.
3. Before collecting stool specimen, ask the client to void. Tell client not to void on the specimen. ► **Rationale:** This prevents contamination of specimen with urine, which could result in inaccurate test results.
4. Don gloves.
5. Clean out all urine from the bedpan or bedside commode.
6. Raise the head of the bed so that client can assume a squatting position on the bedpan, or help client sit on the bedside commode.

Clinical Alert

Do not allow urine or water to come in contact with the stool specimen.

7. Provide privacy until client has passed a stool.
8. Remove the bedpan or bedside commode. If necessary, help the client clean perineum.
9. Use tongue blade to obtain and place a small portion (2 teaspoons) of the formed stool in a waxed cardboard or plastic container. (For some tests you may need to collect the entire specimen.) Do not contaminate inside of container.
10. Wrap tongue blade in paper towel, discard remaining stool, and clean bedpan or bedside commode.
11. Remove gloves, and perform hand hygiene.
12. Label container with client's name.
13. Fill out laboratory request for appropriate test.
14. Take specimen to laboratory immediately. ► **Rationale:** Specimen may need to be refrigerated or examined immediately after collection.

Collecting Stool for Ova and Parasites

Equipment

- Waxed cardboard or plastic container with cover
- Tongue blade
- Label for container

▲ Equipment necessary for collection ova and/or parasite specimen.

- Clean bedpan or bedside commode
- Clean gloves

Procedure

1. Follow the steps for *Collecting Adult Stool Specimen*. Don clean gloves to collect stool specimen.
2. Collect exudate, mucus, and blood with all specimens.
 - a. Place stool into container (with a preservative fluid).
 - b. Mash the specimen in the container until mixed well with preservative. ► **Rationale:** Parasites thrive in this type of medium.
3. Replace and tighten cup. Shake the contents until mixed well.
4. Keep specimens at body temperature to be examined within 30 minutes. ► **Rationale:** Organisms must be seen in their active stages, as loose, fluid stools are likely to contain trophozoites or intestinal amoebas and flagellates.
5. There is usually no need to maintain well-formed or semiformed stool specimens at body temperature or to examine them quickly even though they may contain ova or cystic form of parasites.

- Collect complete stools after purgative medications are administered.
- When the presence of tapeworms is suspected, all stools must be examined in their entirety in order to find the head of the parasite.
- Do not give barium, oil, and laxatives containing heavy metals that interfere with the extraction process for 7 days before stool examination. ► **Rationale:** Ova or cysts are not revealed.
- Use only normal saline solution or tap water if an enema must be administered to collect specimens. Do not use soap suds or other substances.
- Do not contaminate the specimen with urine as it kills amoeba.
- Collect three random, normally passed stool specimens to ensure accurate test results.
- Provide air freshener, if needed.

Collecting Infant Stool Specimen

Equipment

- Diaper
- Plastic diaper liner
- Waxed cardboard or plastic container with cover
- Cotton swabs
- Label for container
- Clean gloves

Procedure

- Perform hand hygiene and identify infant using two forms of ID.

- Place a clean, disposable diaper on the child or infant.
- Check diaper frequently so that you obtain a specimen that is not contaminated with urine.
- If child is passing liquid stools, place a plastic liner inside the diaper.
- Don clean gloves before taking diaper off child and collecting specimen.
- Use cotton swabs to procure the specimen.
- Place specimen in stool container.
- Remove gloves, perform hand hygiene, label, and send to lab immediately with client's name and medical record number.

Testing for Occult Blood

Equipment

- Clean bedpan or bedside commode
- Tongue blade
- Guaiac test (Hemocult) or gamma Fe-Cult packet
- Guaiac solution
- Glacial acetic acid
- Hydrogen peroxide
- Clean gloves

Procedure

- Explain need for stool specimen to client and check two forms of client ID.
- Provide privacy.
- Position client on bedpan or commode.
- Don clean gloves.
- Take stool specimen to bathroom or utility room.
- Prepare slide for testing according to packet instructions:

For Gamma Fe-Cult Plus

- Smear thin layer of stool on panel number 1.
- Obtain second specimen from a different part of stool specimen and smear thin layer on panel number 2.
- Turn packet over, and remove perforated flap (marked Not to Be Opened by Patient).

- Add 2 drops of Fe-Cult developing solution to test area over smear of stool.

▲ Supplies needed for testing stool for occult blood.

- e. Read and record test results within 30 seconds.
 - ▶ **Rationale:** Color reaction fades within 2–3 minutes. Any trace of blue indicates a positive result. No trace of blue indicates a negative result.

For Hemocult

- a. Follow steps a and b for Fe-Cult Plus test.
 - b. Wait 3–5 minutes before processing test.
 - c. Turn packet over, and lift flap.
 - d. Apply two drops of Hemocult developer over each smear.
 - e. Read and record test results within 60 seconds.
 - f. Apply 1 drop of Hemocult developer between the + and – quality monitor test strip (orange section at bottom of packet).
 - g. Interpret results within 10 seconds. If the positive side turns blue, the test slide is accurate.
7. Discard filter paper or packet.

8. Remove gloves and perform hand hygiene.
9. Check facility policy for testing. Some laboratories conduct studies.
10. Document stool smear results and confirm quality monitor test.

For Gastrocult

NOTE: See procedure in chapter 19, Nutrition Management and Enteral Intubation, p.655.

Clinical Alert

Overt bleeding from hemorrhoids or menstrual bleeding renders the Hemocult test inaccurate.

Clinical Alert

A hemocult processing test cannot be used for gastric contents. A Gastrocult test must be used.

Collecting Stool for Bacterial Culture

Equipment

- Waxed cardboard container with cover
- Tongue blade
- Label for container
- Clean bedpan or bedside commode
- Clean gloves

Procedure

1. Follow steps for *Collecting Adult Stool Specimen*. Don clean gloves before collecting stool specimen.

2. Collect exudate, mucus, and blood with all specimens.
3. Place a small amount of feces in a waxed cardboard container (if entire specimen is not needed).
4. Remove gloves, perform hand hygiene, and send entire specimen to the laboratory immediately after collection. If there is any delay, the specimen must be iced.
5. Report and calculate on the basis of daily output any stool specimens that are to undergo chemical analysis.

Teaching Parents to Test for Pinworms

Equipment

- Specimen container with paddle
- Clean gloves

Procedure

1. Explain procedure to child and parent.

NOTE: This test is rarely done or seen in hospital settings, so if pinworms are suspected, the parents can be taught how to obtain specimen at home.

2. Parents may choose to wear clean gloves.
3. Instruct parents to make collection upon arising in the morning before bathing, cleansing, or passing a bowel movement.

NOTE: For very active children, specimens may be collected a few hours after going to bed, while the child is sleepy and more cooperative. ▶ **Rationale:** Pinworms, when present, migrate out of the anus to lay eggs during sleep.

4. Remove cap in which is inserted a plastic paddle with one side coated with a nontoxic, adhesive material. This side is marked “sticky side.” Do not touch this side with fingers.
5. Separate buttocks and press the sticky side against several areas around anus using moderate pressure.
6. Replace the paddle in tube. Be sure there is no stool on paddle.

7. Label container with your full name, medical record number, and date.
8. Keep specimen at room temperature until all specimens are collected (on consecutive days). Return all tubes to the doctor.

Clinical Alert

After treatment (drug of choice is mebendazole) and to prevent reinfection, use meticulous cleaning practices and teach parents of child to do the same.

DOCUMENTATION for Stool Specimens

- Date and time specimens collected
- Date and time specimens sent to laboratory
- Number of specimens sent to laboratory
- Description of stool: color, amount, odor, and any purulent patches or blood noted
- Dietary restrictions imposed
- Condition of perianal skin, if client is having diarrhea
- If serial stool specimens are needed, record each specimen on the Kardex card as well as the chart

CRITICAL THINKING Application

Expected Outcomes

- Client understands purpose of test.
- Client is able to follow procedure of collection when appropriate.

- Dietary restrictions (if appropriate to test) were adhered to by client before test.
- Specimen collected is adequate for test.

Unexpected Outcomes

Client is embarrassed by having to give stool specimen.

Alternative Actions

- Place a bedpan or other collection device under the toilet seat in bathroom to obtain specimen.
- If client is confined to bed, pull sheets over client's legs and draw curtains around the bed until procedure is completed.
- If odor occurs from passage of stool, spray room with air freshener.

Client is unable to pass adequate stool for specimen collection.

- Notify physician to obtain order to give a normal saline or tap water enema.

Client passes liquid stools.

- Determine if part or entire specimen is required for test.
- Obtain a plastic container with a cover and several large cotton swabs. Dip cotton swabs into the liquid stool. Place swabs in plastic container. After procedure, pay close attention to skin care. A protective ointment may be necessary to protect skin from liquid stools.

Chapter 20

UNIT 3

Blood Specimens

Nursing Process Data

ASSESSMENT Data Base

- Check order for blood withdrawal in client's chart.
- Note specific requirements for the test (e.g., fasting or administration of medications before the test).
- Check to see if the test is routine or urgent.
- Assess veins for venipuncture site.

PLANNING Objectives

- To obtain an uncontaminated blood specimen
- To obtain a blood sample without complications, such as hematoma formation or excessive oozing at the site
- To obtain specimens of blood that can be used to diagnose the client's illness
- To obtain and transfer specimens without destroying red blood cells
- To ensure accurate test results by making sure the client follows all requirements for the test (e.g., fasting)
- To ensure accurate test results by selecting the right tube for the right test
- To ensure that uncontaminated blood specimen for culture is obtained
- To obtain an accurate blood glucose level

IMPLEMENTATION Procedures

- Withdrawing Venous Blood (Phlebotomy) 695
- Using Vacutainer System 696
- Understanding Blood Chemistry Tests 698
- Withdrawing Arterial Blood 698
- Understanding Arterial Blood Gases (ABGs) 699
- Collecting a Blood Specimen for Culture 700
- Calibrating a Blood Glucose Meter (One Touch Ultra) 700
- Obtaining Blood Specimen for Glucose Testing (Capillary Puncture) 701
- Monitoring Glucose: Sure Step Flexx 702
 - *For Quality Control* 702
 - *For Monitoring Blood Glucose* 703

EVALUATION Expected Outcomes

- Blood sample is collected without complications. Uncontaminated blood specimen is collected.
- Blood is collected according to designated test tube colored top.
- Client follows all requirements for test (for example, fasting before collection).
- Client understands and learns steps of procedure when necessary (glucose levels).
- Accurate blood glucose level is obtained.

- **Critical Thinking Application** 704
 - Expected Outcomes 704
 - Unexpected Outcomes 704
 - Alternative Actions 704

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Withdrawing Venous Blood (Phlebotomy)

Equipment

- 5-mL or 10-mL safety syringe
- 20-gauge 1-in. needle(s)
- Antimicrobial wipe (with blood alcohol specimen, use nonalcohol solution)
- Appropriate plastic laboratory tubes
- Dry, sterile sponges
- Tourniquet
- Absorbent pad or towel
- Clean gloves
- Laboratory slip

Preparation

1. Check physician's orders for tests to be obtained.
2. Perform hand hygiene.
3. Gather equipment.
4. Open sterile packages.

Procedure

1. Identify client by two identification methods; introduce yourself and explain the procedure.
2. Don clean gloves (see box on OSHA protocols).
3. Place extremity straight and in dependent position, if possible.
4. Place absorbent pad or towel under arm. ► **Rationale:** This prevents soiling the linen with blood.
5. Place equipment close to work area.
6. Place a tourniquet 4–6 in. above the client's elbow. Tighten the tourniquet and tell the client to open and close fist. ► **Rationale:** Muscle contraction increases blood flow to arm.
7. Cleanse antecubital fossa (inner aspect of elbow) with antimicrobial wipe starting at vein site and moving in a circular motion about 2 in. away from vein.

▲ Clamp vein down by placing forefinger below puncture site and insert needle at 15–30° angle.

- **Rationale:** A larger vessel is more appropriate than a smaller vessel for blood draw.
- 8. Let site dry. ► **Rationale:** This reduces bacteria on skin surface when dry.
- 9. Hold skin taut with nondominant hand. Perform a venipuncture with bevel of needle pointed up at a 30° angle.
- 10. Lower needle toward skin after needle has entered vein. ► **Rationale:** This decreases risk of accidentally penetrating the other side of vein.
- 11. Thread needle along path of vein. Watch for backflow of blood in syringe.
- 12. Pull syringe plunger back gently, and check for placement of the needle in the vein. If placement is correct, release tourniquet, wait a few seconds to allow fresh blood to flow into the vein, and then pull back gently on the plunger.
- 13. Fill syringe to desired amount.
- 14. Remove needle from vein, cover venipuncture site with a sterile sponge, and press the sponge firmly on the site for 2–3 minutes. (Client may be able to hold sponge in place.)
- 15. Choose one of two methods to transfer specimen.
 - a. Do not remove top from laboratory tube. Place needle straight through top. ► **Rationale:** Needle can be inserted through rubber stopper of test tube if 20-gauge needle is used.
 - b. Gently eject blood down the side of the tube. Do not allow blood to foam or splash. ► **Rationale:** Red blood cells can be destroyed if the blood sample is not handled carefully.
 - c. Rotate blood gently to mix blood with tube contents.

Clinical Alert

If client has a fistula or has an IV inserted, place the tourniquet *on the other arm*.

OSHA Glove Protocol When in Contact With Blood Pathogens

- Routine gloving for phlebotomies is not necessary.
- Gloves are required when:
 1. The employee has cuts, scratches, or other breaks in the skin.
 2. Hand contamination with blood may occur.
 3. The employee is receiving training in phlebotomy.

Source: Standard OSHA Protocol. <http://www.osha.gov>

16. *Alternate method.*
 - a. Remove top of test tube(s).
 - b. Remove needle from syringe and gently inject blood down side of tube. ► **Rationale:** Inject blood slowly to prevent hemolysis of red blood cells.
 - c. Gently rotate tube back and forth to mix additive.
17. Label tube promptly. Write client's name, date, and time. You may also need to write initials of the person who drew the specimen if this information is required by hospital policy.
18. Check client's venipuncture site for oozing. Continue to press sponge firmly over site if clots have not begun to form at site.
19. Dispose of shielded needle and syringe in biohazard receptacle.
20. Remove gloves, perform hand hygiene.
21. Take blood specimens to a designated station or laboratory according to hospital procedure.

Using Vacutainer System

Equipment

Vacutainer assembly with shielded or blunting needle
 Antimicrobial wipe (with blood alcohol specimen, use nonalcohol solution)
 Plastic vacuum blood collection tubes, placed in order of collection
 Dry, sterile sponges
 Double-ended needle that screws into the adapter
 Clean gloves
 Tourniquet
 Tape
 Laboratory slip

Preparation

1. Check physician's orders for tests to be obtained.
2. Perform hand hygiene.
3. Obtain plastic adapter, double-ended needle that screws into the adapter, and appropriate vacuum specimen tubes.
4. Screw the double-ended needle into the plastic adapter, with the shorter needle facing the plastic adapter.
5. Explain procedure to client.
6. Don clean gloves.

▲ When blood begins to fill tube, tell client to relax fist and release tourniquet.

Procedure

1. Follow steps 1–12 in *Withdrawing Venous Blood*.
2. Once the needle is positioned inside vein and blood return is visualized, insert blood collection tube into plastic holder while holding the plastic adapter steady. Press the vacuum tube firmly into the short needle so that it pierces the top of the tube. Blood should begin to spurt quickly into the tube until the tube is filled or vacuum is used.
3. Instruct client to relax fist and release tourniquet. ► **Rationale:** Hemolysis occurs with prolonged tourniquet use.

▲ Place vacutainer with safety needle attached into biohazard container.

4. Release the tube, and set it aside. Attach another tube to Vacutainer, or prepare to remove needle.
5. Place sponge over needle site, and remove needle while applying gentle pressure to site.
6. Hold sponge on site for 2–3 minutes. Do not have client bend elbow. ► **Rationale:** Bending the elbow can facilitate formation of a hematoma.
7. Place Vacutainer with needle in biohazard container.
8. Check if tube contains additive, gently invert to mix and label specimen tubes.
9. Remove gloves, and perform hand hygiene.
10. Complete laboratory slip, and take specimen to designated station or laboratory.

TABLE 20-2 Routine Blood Chemistry Tests

Test	Purpose	Normal Values
Erythrocytes		
Red blood cell count (RBC or erythrocytes)	Determines actual number of formed blood elements in relation to volume Identifies abnormalities; monitors RBC count	Males: 4.5–6.2 million/mm ³ Females: 4.0–5.5 million/mm ³ Children: 3.2–5.2 million/mm ³
Hematocrit (HCT)	Measures percentage of red blood cells per fluid volume of whole blood	Males: 40–54/100 mL Females: 37–47/100 mL Children: 29–54/100 mL
Hemoglobin (Hgb)	Measures amount of hemoglobin/100 mL blood to determine oxygen-carrying capacity; assists in diagnosing anemia	Males: above 13–18 g/100 mL Females: above 12–16 g/100 mL
Platelet count	Determines number of platelets	Adults: 150,000–450,000/mm ³
Prothrombin time (PT)	Evaluates thrombin generation or how long it takes for a fibrin clot to form Detects deficiencies in extrinsic clotting mechanism; monitors anticoagulant therapy	10–13 seconds Prolonged values seen in liver disease, vitamin K deficiency, specific drugs, etc.
Activated partial thromboplastin time (APTT)	Evaluates adequacy of plasma-clotting factors—intrinsic clotting mechanism	20–38 seconds Prolonged values indicate coagulation factor deficiency, cirrhosis, vitamin K deficiency
Thrombin time	Screening test to detect abnormalities in thrombin fibrinogen reaction (Conversion to fibrin in stage 3 of clotting sequence)	10–15 seconds
Leukocytes		
White blood cell count (WBC or leukocytes)	Establishes quantity and maturity of white blood cell elements	Adults: 4,500–11,000/mm ³ Children: 5000–13,000/mm ³ Neutrophils: 3000–7500/mm ³ Band neutrophils: 150–700/mm ³ Basophils: 25–150/mm ³ Eosinophils: 50–450/mm ³ Lymphocytes: 1,500–4,500/mm ³ Monocytes: 100–800/mm ³
Erythrocyte sedimentation rate (ESR)	Measures rate of red blood cells settling from plasma—reflects inflammatory conditions	<i>Wintrobe Method</i> Males: 0–9 mm/hr Females: 0–15 mm/hr Children: 0–13 mm/hr <i>Westergren Method</i> Males: 0–15 mm/hr Females: (under 50 years) 0–20 mm/hr; (over 50 years) 0–30 mm/hr; Children: 0–20 mm/hr

Source: Smith, S. F. (2010). *Sandra Smith's Review for NCLEX-RN (12th ed)*. Los Altos, CA: National Nursing Review.

Understanding Blood Chemistry Tests

1. Read results of laboratory blood tests that were completed.
2. Evaluate client's test results and compare with normal values. (See Table 20-2, Routine Blood Chemistry Tests.)
3. Report abnormal values to team leader or physician.
4. Check Chem 7 (SMA 7) values—tests fluid balance, renal function and acid–base status. ► **Rationale:** When combined with the CBC, these tests give a view of how the entire body is functioning.
5. Standard values of Chem 7 (may vary from lab to lab; check own facility values).
 - a. Potassium: 3.5–5.3 mEq/L.
 - b. Sodium: 135–145 mEq/L.
 - c. Chloride: 98–106 mEq/L.
 - d. CO₂: 23–30 mmol/L.
 - e. Glucose (fasting): 65–110 mg/dL.
 - f. BUN: 7–18 mg/dL.
 - g. Creatinine: 0.6–1.3 mg/dL.

Withdrawing Arterial Blood

Equipment

A commercial ABG kit containing all of the equipment OR
 3-mL syringe with 22-gauge 1-in. needle with safety guard
 Syringe cap/stopper
 1:1000 solution heparin, 1 mL ampule
 Antimicrobial swabs (2)
 2 × 2 gauze pad
 Nonallergenic tape
 Plastic bag filled with crushed ice
 Clean gloves
 Goggles and mask
 Laboratory requisition
 Label for syringe
 Adhesive bandage

Preparation

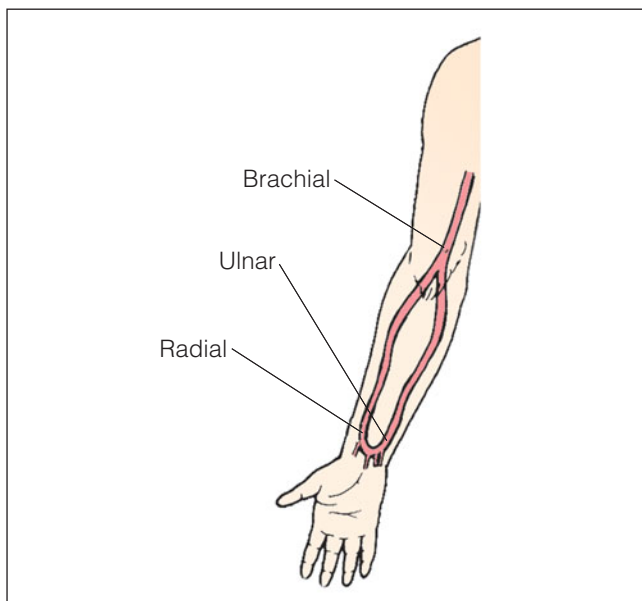

1. Check physician's orders for test to be performed. (Usual test is arterial blood gases.)
2. Call laboratory to apprise them of specimen being sent for ABGs according to hospital policy.
3. Assemble equipment.
4. Perform hand hygiene.
5. Wipe top of heparin bottle with antimicrobial swab.
6. Uncap needle and insert into heparin bottle.
7. Withdraw 0.5 to 1 mL of heparin solution into syringe.
8. Prepare syringe by pulling plunger back entire length of syringe; rotate syringe to allow heparin to coat syringe sides.
9. Express excess heparin into sink.

Procedure

1. Take equipment into room and place on over-bed table and check two forms of client ID.
2. Explain procedure and purpose of test.
3. Ask if client is taking aspirin or anticoagulant therapy. ► **Rationale:** These drugs will affect test results and should be documented.
4. Don clean gloves, goggles, and mask.
5. Palpate selected radial site (the site most frequently used) with fingertips. ► **Rationale:** To determine best site for puncture.

NOTE: Allen's test should precede an arterial puncture if there is a question of poor collateral circulation.

6. Hyperextend wrist slightly. ► **Rationale:** This position will stabilize radial artery.
7. Cleanse puncture site with antimicrobial swab using a circular motion beginning over the artery site. Place swab on inside of packet and in close proximity to site.
8. Keep fingertip of nondominant hand over puncture site. ► **Rationale:** To maintain puncture site location.
9. Pick up syringe and hold needle bevel in uppermost position and insert needle into artery at a 30 to 45° angle.

▲ An arterial blood sample requires puncture of the brachial, radial, or femoral artery or a sample from an arterial line.

10. Do not advance needle once blood is observed flowing into syringe.
11. Hold needle steady and allow blood to automatically fill syringe. Collect 1–5 mL of blood. Pulsations from artery will assist in filling syringe. Do not draw back on syringe. ► **Rationale:** Drawing back on syringe can cause air bubbles to fill syringe and inaccurate ABGs results will occur.
12. Place 2 × 2 in. gauze next to needle site and withdraw needle when syringe is filled.
13. Immediately apply pressure over site with gauze. Maintain pressure for 5–10 minutes. ► **Rationale:** Prolonged pressure over arterial puncture site will prevent bleeding.
14. Monitor puncture site for signs of oozing. When bleeding has stopped, place 2 × 2 gauze over site and apply adhesive bandage as you would for a pressure dressing.
15. Expel any air bubbles from syringe. Activate needle guard. Syringe contents should be airtight.
16. Label syringe.
17. Place syringe in plastic bag filled with ice. Close plastic bag.
18. Remove gloves and perform hand hygiene.
19. Complete laboratory requisition slip. Indicate client's temperature and oxygen percentage as necessary.
20. Take specimen to laboratory immediately.

Clinical Alert

If client is receiving anticoagulant therapy, apply pressure for 10 to 15 minutes after arterial puncture.

Allen's Test

Allen's test is performed to determine adequacy of collateral perfusion before arterial blood stick.

- Ask client to rest hands facing upward.
- Observe color changes in palm.
- Ask client to make a tight fist (to force blood from hand).
- Compress the radial and ulnar arteries by applying direct pressure using index and middle fingers (obstructs blood flow to hand).
- Ask client to clench and unclench fist several times.
- Ask client to relax hand in a slightly flexed position. Hand should appear blanched due to absence of blood flow.
- Release pressure on ulnar artery and note if fingers and palm flush within 5 minutes. This is a positive test for patency.
- If fingers and palm remain pale, do not use this site for arterial puncture; test other extremity.

Understanding Arterial Blood Gases (ABGs)

Procedure

1. ABG values are most often ordered for clients who have the following diagnoses: chronic obstructive pulmonary disease, pulmonary edema, myocardial infarction, pneumonia, or acute respiratory distress syndrome.
2. Check client's values against normal arterial values.
 - a. Oxygen saturation—93%–98%.
 - b. PaO₂—95 mmHg
 - c. Arterial pH—7.35–7.45 (7.4).
 - d. pCO₂—35–45 mmHg (40).
 - e. HCO₃ content—22–26 mEq/L.
 - f. Base excess—–3 to +3 (0).
3. Check acid–base imbalances (acid–base balance is the ratio of acids and bases in the body necessary to maintain a chemical balance conducive to life). See Table 20-3.
 - a. Acid–base ratio is 20 base to 1 acid.
 - b. Values are measured by an arterial blood sample and recorded as blood pH. Normal range is 7.35 to 7.45.

TABLE 20-3 Acid–Base Imbalances

Respiratory Acidosis	Metabolic Acidosis
a. pH—7.32.	a. pH—7.30.
b. pCO ₂ —52 mmHg.	b. CO ₃ —16 mEq/L.
c. pO ₂ —90 mmHg.	c. pCO ₂ —38 mmHg.
d. HCO ₃ —24 mEq/L.	d. pO ₂ —95 mmHg.
	e. Cl—120 mEq/L.
	f. K—5.5 mEq/L.
Respiratory Alkalosis	Metabolic Alkalosis
a. pH—7.51.	a. pH—7.50.
b. pCO ₂ —32 mmHg.	b. HCO ₃ —26 mEq/L.
c. pO ₂ —95 mmHg.	c. pCO ₂ —38 mmHg.
d. HCO ₃ —24 mEq/L.	d. pO ₂ —95 mmHg.
	e. K—3.0 mEq/L.
	f. Cl—88 mEq/L.

Collecting a Blood Specimen for Culture

Equipment

- Two sets of paired culture media bottles (aerobic and anaerobic)
- Blood withdrawal equipment (e.g., tourniquet, two needles, and syringe with attached needle)
- Povidone-iodine (Betadine) swab
- Two antimicrobial swabs
- Additional needles
- Clean gloves
- Laboratory request form and biohazard transport bag
- Small adhesive bandages

Preparation

1. Check physician's orders.
2. Perform hand hygiene.
3. Gather equipment. Check expiration dates on culture bottles.
4. Don clean gloves.

▲ Inject blood into both aerobic and anaerobic culture bottles.

5. Explain procedure to client and check two forms of client ID.

Procedure

1. Cleanse skin with antimicrobial wipe. Allow skin to dry.
2. Prepare skin with povidone-iodine. Cleanse starting at vein site and moving in circular motion outward 2 in.
3. Allow skin to dry.
4. Remove povidone-iodine with antimicrobial wipe.
5. Perform venipuncture.
6. Withdraw 10–20 mL of blood from vein without IV. Do not draw specimen through catheter. ► **Rationale:** Fluid from IV alters results.
7. Remove needle used for venipuncture and replace with new sterile needle. ► **Rationale:** Contamination may result if needle used to puncture skin is reused.
8. Swab top of paired blood culture bottles with povidone-iodine swab and then antimicrobial swab, and inject 5–10 mL blood into each bottle according to hospital policy. Gently rotate bottle to mix well. Change needle each time so new sterile needle is used for each bottle.
9. Draw a second sample of blood after 15 minutes or according to hospital policy. Use percutaneous stick if required by hospital policy. (Prepare skin with povidone-iodine solution again.)
10. Place in second set of paired blood culture bottles, using single sterile needle technique.
11. Remove gloves and perform hand hygiene.
12. Place bandage over puncture site.
13. Label bottles with your name, date, and time of collection and transport to lab immediately. Include site where blood specimens were obtained.
14. Discard syringes, needles, and gloves in appropriate container.

Clinical Alert

Check with physician—blood culture may be ordered prior to client beginning antibiotic therapy.

Calibrating a Blood Glucose Meter (One Touch Ultra)

Equipment

- Blood glucose meter
- Chemstrips including calibration strip
- Dry cotton ball
- Clean gloves

Procedure

1. Obtain container of Chemstrips and remove calibration strip. Check expiration date on strips.
2. Compare lot numbers on calibration strip to lot number on side of Chemstrip bottle. These must match.

3. Place calibration strip in meter by opening door and inserting top of strip into slot on right side of meter.
4. Insert strip until you hear a “click.”
5. Close door.
6. Push ON/OFF button. Numbers 888 should appear on screen.
7. Open door of monitor.
8. Push black button on the left side of door, and slide Chemstrip under strip guide with test pads facing up.
9. Close door quickly. Numbers 000 should be displayed on screen indicator. If not, open and close door again.
10. Open door and remove strip. Leave door open.
11. Don clean gloves and prepare to obtain blood specimen.

Obtaining Blood Specimen for Glucose Testing (Capillary Puncture)

Equipment

- Automatic lancet (i.e., Autolet or Glucolet)
- Penlet
- Soap and water
- Cotton ball, sterile sponges
- Clean gloves

Preparation

1. Gather equipment and take to bedside.
2. Perform hand hygiene.
3. Don gloves.
4. Identify client using two forms of client ID.

▲ Use soap and water or swab to cleanse finger before puncture.

▲ Insert test strip into monitor (you have 30 seconds to obtain a reading).

▲ Adjust penlet depth, place on side of finger, and release.

▲ After gently massaging finger, place large drop of blood on test strip.

▲ Wait 30 seconds and note reading on monitor.

Procedure

1. Wash client's fingertip (especially side of finger where lancet will puncture, or heel for infant) with soap and water and dry. ► **Rationale:** Use soap and water if repeated sticks are to be done, as alcohol toughens skin.

2. Insert test strip into monitor. (You have 30 seconds to obtain reading.)
3. Gently manipulate finger or heel to determine whether good blood supply is available.
4. Adjust Penlet to depth.
5. Place Penlet on side of finger and release. The lancet punctures the skin immediately.
6. Gently massage the base of the finger, stroking toward the puncture site. Do not squeeze or apply pressure to site. ► **Rationale:** Massaging increases blood flow to the fingertip.
7. Wait a few seconds to allow blood to collect at puncture site.
8. Place a large drop of blood onto test strip. (You have 30 seconds to obtain a reading.)
9. Wait 30 seconds and note reading on monitor.
10. Rotate finger tips when doing capillary punctures.
11. Wipe puncture site with cotton ball to seal.
12. Remove gloves and perform hand hygiene.
13. Document results.

NOTE: Many hospitals have changed to blood glucose meters that can “download” results, such as the Sure Step Flexx BG meter.

Monitoring Glucose: Sure Step Flexx

Equipment

- Sure Step Flexx blood glucose monitor
- Blood glucose test strips
- High and low control solutions
- Single use blood-letting device
- Antimicrobial skin preparation pad
- Lint free cloth, such as 2 × 2 gauze
- Prepackaged disinfectant towelette, moistened with 1:10 dilution of 5.25% sodium hypochlorite, i.e., “Gluco-Chlor” towelette
- Clean gloves

Procedure

For Quality Control

1. Turn on the meter.
2. Check the battery status to ensure adequate power.
3. Press “continue.”
4. Select Quality Control (QC) Test from main menu by touching appropriate area on the screen.
5. Select Control Test by touching “HIGH” or “LOW” area on the screen to indicate which control test is to be done.
6. Enter operator ID assigned by specific facility.
7. Select Control Solution Lot Number from list displayed, or enter it manually. Verify lot number on control solutions.

8. Select Test Strip Lot number (and code) from this list displayed, or enter in manually. Verify lot number (and code) on test strips.

▲ Sure Step Flexx blood glucose monitoring equipment.

Clinical Alert

Quality control for the Flexx (with documentation) is required on a regular basis to verify test results when client data are entered.

9. Shake Control Solution vial gently. Check confirmation dot on back of test strip to ensure it is completely blue.
10. Apply one drop of Control Solution to pink test square on test strip.
11. Insert test strip into test holder within 2 minutes of applying Control Solutions. The white side of test strip tip should be facing up. Firmly push strip into meter.
12. Check result, which appears in approximately 30 seconds. Control Solution test results should fall within expected ranges printed on test strip bottle. If Control Solution test results fall outside expected control range, press “ENTER NOTE” and follow recommendations.
13. Remove test strip and dispose of it according to facility policy and procedure.
14. Quality Control test must be completed for both “HIGH” and “LOW” controls.

For Monitoring Blood Glucose

1. Perform hand hygiene and don gloves.
2. Press power button to turn on meter.
3. Check battery status as status screen appears.
4. Press “CONTINUE.” Select “PATIENT TEST” from Main Menu.
5. Enter operator ID and press “OK.”
6. Check to ensure Code Number displayed on meter matches code number on test strip bottle.
7. Enter client’s ID (medical record number), and press “OK.”
8. Select Test Strip Lot Number (and code) from list displayed, or enter in manually. Verify lot number (and code) displayed on screen.
9. Follow steps in Obtaining Blood Specimen for Glucose Testing.
10. Apply drop of blood to test strip by carefully touching pink test square on test strip. Check “Confirmation Dot” on back of test strip to verify that it has turned completely blue.

Clinical Alert

The test strip must be *completely* inserted to receive accurate results.

11. Use 2 × 2 gauze pad and apply direct pressure to puncture site to control bleeding.
 12. Insert test strip completely into test strip holder within 2 minutes of applying blood. ► **Rationale:** Strip must be completely inserted to receive accurate results.
- NOTE:** Meters are institution specific—may require users to be certified once a year to use meters.
13. Check results which appear in approximately 30 seconds.
 14. Evaluate client results that fall above or below the Critical Lab Values limit.
 - a. Press “ENTER NOTE” and choose one to three comments, if indicated, that correspond to client’s current situation.
 - b. Follow appropriate nursing actions as determined by facility policy and procedure.
 15. Press “OK” and remove test strip from meter.
 16. Remove gloves and dispose of gloves and test strip according to facility policy.

Principles of Measuring Blood Glucose

- Bedside glucose testing is used only to monitor progress of treatment and not to establish a diagnosis of diabetes.
- Specimens used for glucose testing must be whole blood (capillary, arterial, or venous).
- Appropriate nursing actions need to be taken whenever client results exceed critical lab values (check facility policies).
- For a critical value, the FIRST action is to repeat the test.
- Test strip bottle should be dated when opened and recapped firmly between uses to protect strips.

DOCUMENTATION for Blood Specimens

- Date and time of blood withdrawal
- Date and name(s) of test(s) for which blood was drawn
- Any unusual conditions in either the client or specimen
- Site where blood cultures were obtained for capillary specimen
- Results of blood glucose reading
- Insulin administered: type, amount, location of injection
- Notification of physician of critical lab values, orders, or interventions

CRITICAL THINKING Application

Expected Outcomes

- Blood sample is collected without complications.
- Uncontaminated blood specimen is collected.
- Blood is collected according to designated test tube colored top.

Unexpected Outcomes

Veins roll away from needle when performing a venipuncture.

Blood does not flow into the syringe.

Blood does not flow into the vacuum tube.

Unable to get blood sample with Autolet.

Meter shows not enough blood.

- Client follows all requirements for test (for example, fasting before collection).
- Client understands and learns steps of procedure when necessary (glucose levels).
- Accurate blood glucose level is obtained.

Alternative Actions

- Stabilize vein by applying traction to skin below needle insertion site.
- Common occurrence in elderly. Use a 5°–15° angle when inserting needle into vein as elderly clients' veins are superficial.
- Check the position of the needle in the vein.
- Pull needle back slightly away from the wall of the vein. Rotate needle gently. Do not pull excessively on the plunger, especially if the vein is small, since this movement may cause the vein to collapse.
- Check the position of the needle in the vein. If vacuum in the tube is lost or if the vein is not large enough, discard the tube and get another.
- If there is pressure on the vein for vacuum pull, select a larger vein or use a syringe and needle instead of the Vacutainer method.
- Check that fingertip or heel is not toughened with overuse of alcohol sponges. Should use soap and water to clean area.
- Choose an alternative site and repeat the stick.
- Stroke gently from base of finger toward the tip. Do not apply firm massage as it can interfere with blood flow.
- Remove test strip, and insert new strip.
- Obtain new blood drop.
- Ensure blood drop is sufficient to form a round, shiny drop that covers entire strip.
- Complete procedure.

Sputum Collection

Nursing Process Data

ASSESSMENT Data Base

- Check diagnosis for indication of need for specimen.
- Observe client’s ability to cough up specimen. You may need to assist the client while obtaining a specimen, or suction equipment may be necessary.
- Determine the degree of pain the client can tolerate.
- Check client’s understanding of procedure so sputum and not saliva is obtained.

PLANNING Objectives

- To obtain adequate sputum specimen for laboratory examination
- To identify predominant organisms, if respiratory disease is present
- To maintain client’s respiratory status during and after procedure

IMPLEMENTATION Procedures

- Obtaining Sputum Specimen 706
- Using Suction Trap 707
- Collecting Specimen by Transtracheal Aspiration 707

EVALUATION Expected Outcomes

- Client understands and participates in specimen collection.
- Adequate amount of specimen is collected for the test ordered.
- Specimen collected is uncontaminated.

Critical Thinking Application 708

- Expected Outcomes 708
- Unexpected Outcomes 708
- Alternative Actions 708

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Obtaining Sputum Specimen

Equipment

- Sputum specimen container and label
- Biohazard bag for delivery of specimen to laboratory
- Tissues
- Laboratory requisition slip
- Clean gloves
- Gown, mask (HEPA or N95 if client has TB), goggles, if needed

Preparation

1. Identify client with two forms of ID.
2. Gather equipment.
3. Perform hand hygiene.
4. Provide privacy.
5. Place client in sitting position.

Procedure

1. Explain procedure and rationale to client.
2. Have client rinse mouth before coughing to remove any oral contaminants.
3. Don clean gloves. Don mask, gown, goggles if client requires assistance with procedure.
4. Instruct client to breathe in and out deeply 2 to 4 times, then give a series of low, deep coughs to raise sputum from the lungs. ► **Rationale:** Deep coughs produce sputum rather than saliva.
5. Obtain 1–2 teaspoons of sputum in container; close and seal lid.

▲ Instruct client to lift hinged lid of sputum collection system, and expectorate directly into sterile container.

6. Follow directions on specimen container to complete closing system.
7. Label specimen tube directly and place in biohazard transport bag.
8. If client is unable to produce sputum specimen, assist client by placing palms of your hands or a rolled pillow around incision area if client is inhibited by pain.
 - **Rationale:** Wrapping a sheet around chest or abdomen also provides support for body walls during coughing.
9. Remove gloves, gown, mask, and goggles and perform hand hygiene.
10. Evaluate client's status after procedure.
11. Deliver sputum to the laboratory within 30 minutes after collection. Obtain specimen during treatment if client is receiving IPPB or PVD.

Clinical Alert

A first specimen obtained in the early morning before eating or drinking provides the best sputum sample. Chest physiotherapy may be helpful in mobilizing secretions just before sputum collection.

Clinical Alert

Know what test the sputum is being collected for:

- Routine culture—sterile container
- Acid-fast bacilli (AFB)—sterile container
- Cytology—container contains a preservative warning; preservative is poisonous

▲ Instruct client to obtain 1–2 teaspoons of sputum, close and seal lid of container.

Using Suction Trap

Equipment

- Suction machine
- Sterile catheter and glove
- Sterile saline
- Sterile sputum trap
- Culture tube
- Biohazard disposal bag
- Clean gloves
- Gown, mask, goggles

Preparation

1. Check physician's orders and client care plan for type of equipment needed.
2. Perform hand hygiene.
3. Gather equipment.

▲ Two common types of suction traps used in client care.

4. Explain procedure to client and check client's identity with two forms of ID.
5. Provide privacy.
6. Don clean gloves, goggles, gown, and mask as appropriate.

Procedure

1. Set up suction equipment.
2. Attach sputum trap between suction catheter and tubing. Maintain trap in upright position throughout procedure.
3. Complete suctioning as for naso-oro-pharyngeal suctioning using sterile technique.
4. Place your thumb on top of sputum trap to monitor; remove your thumb and provide intermittent suction, lifting thumb at intervals until 3–5 mL specimen is collected.
5. Suction no more than 10 seconds at a time.
 - **Rationale:** This prevents removal of too much oxygen.
6. Turn off wall suction.
7. Label specimen container: client's name, date, time, and physician.
8. Cap suction trap and place it in biohazard bag. Follow agency protocol for double-bagging specimens before transporting to laboratory.
9. Remove gloves and other equipment (mask, gown, and goggles if used) and dispose of in appropriate receptacle.
10. Send specimen that was collected in trap to laboratory. (In many hospitals suction tube is also sent to the lab with specimen.)
11. Place client in a comfortable position.
12. Perform hand hygiene.

Collecting Specimen by Transtracheal Aspiration (Done by Physician)

Equipment

- No. 14 needle with polyethylene tubing or small intracatheter (IV catheter)
- Sterile saline and 3–5 mL syringe
- Skin-cleansing solution dictated by hospital policy
- Xylocaine injection
- Clean gloves

Procedure

1. Explain procedure and check identity with two forms of ID.
2. Collect equipment.
3. Provide privacy for client.
4. Perform hand hygiene and don gloves.
5. Position client by hyperextending client's neck and placing a pillow under shoulders.
6. Cleanse cricothyroid area of neck with antimicrobial solution.
7. Physician will anesthetize area with Xylocaine.
8. Physician will insert 14-gauge needle into cricothyroid area, thread polyethylene tubing through needle, withdraw needle, and leave tubing in place.
9. Attach syringe (3–5 mL) with 1–2 mL sterile saline into polyethylene tubing.

10. Inject saline into polyethylene tubing to initiate coughing response.
11. To obtain specimen, immediately pull back on barrel of syringe.
12. Withdraw catheter and apply pressure over puncture site.
13. Place sputum secretions in sterile container, label container, and send it to laboratory.
14. Remove gloves and perform hand hygiene.
15. Position client for comfort.

DOCUMENTATION for Sputum Collection

- Date and time of collection
- Amount, color, and consistency of sputum
- Mechanical sputum trap used for collection
- Client's tolerance of procedure

CRITICAL THINKING Application

Expected Outcomes

- Client understands and participates in specimen collection.

Unexpected Outcomes

Pain inhibits client from coughing.

Client develops coughing spasms during procedure.

Unable to obtain sputum specimen.

- Adequate amount of specimen is collected for the test ordered.
- Specimen collected is uncontaminated.

Alternative Actions

- If diagnosis permits, support painful area with rolled pillows or tight sheets so that external pressure equals internal pressure, thus minimizing pain and discomfort.
- Before beginning procedure, ask client to take several deep breaths. These breaths may trigger the cough reflex and aerate the lungs.
- Give client pain medication as ordered 15–30 minutes before obtaining the specimen.
- Press your third finger lightly over the client's trachea in the cricoid hollow. This pressure releases the nerve that innervates the coughing reflex.
- Report to physician to obtain an order for nebulization.
- Notify physician for orders: bronchodilator drugs, nebulization treatment.
- Perform chest physiotherapy to mobilize secretions for expectoration before obtaining sputum specimen.
- Attempt procedure early in the morning when mucus has collected during the night and is more easily expectorated.
- Obtain order for aerosol therapy.

Swab Specimens

Nursing Process Data

ASSESSMENT Data Base

- Identify appropriate container for specimen swabs or material.
- Determine time frame for expediting specimen to lab.
- Assess exact area for specimen.
- Assess client's ability to cooperate with procedure.
- Assess wound and drainage.

PLANNING Objectives

- To obtain an uncontaminated specimen for study
- To place specimen swab or material in container using appropriate techniques
- To send specimen to laboratory within specified time frame

IMPLEMENTATION Procedures

- Obtaining a Throat Specimen 710
- Obtaining a Gum Swab for HIV Antibodies 710
- Obtaining Wound Specimen for Aerobic Culture 711
- Obtaining Wound Specimen for Anaerobic Culture 712
- Collecting an Ear Specimen 713

EVALUATION Expected Outcomes

- Uncontaminated specimen is collected.
- The proper container (aerobic or anaerobic) is used for specimen collection.
- Specimen is sent to the lab within specified time.

Critical Thinking Application 713

- Expected Outcomes 713
- Unexpected Outcomes 713
- Alternative Actions 713

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
and Skill Checklists

Obtaining a Throat Specimen

Equipment

- Tongue depressor
- Culture tube with applicator stick
- Light source
- Clean gloves
- Laboratory request form and biohazard transport bag, if indicated

Preparation

1. Check physician's orders.
2. Gather equipment.
3. Explain procedure to client and check two forms of client ID.
4. Position client in Fowler's position.
5. Place treatment light or face client toward natural light source to provide good lighting.
6. Perform hand hygiene and don clean gloves.

▲ After swabbing throat, remove applicator stick, being careful not to touch any part of the mouth.

Procedure

1. Remove the sterile applicator from the culture tube by rotating cap to break seal.
2. Ask the client to tilt head back and open mouth.
3. Use tongue depressor if desired to depress tongue.
 - ▶ **Rationale:** Prevents tongue from contaminating the swab.
4. Swab the back of the throat along the tonsillar area from left to right. ▶ **Rationale:** Swab only one side of the throat. A second specimen of the other side may be taken; check hospital protocol.
5. Remove the applicator stick, and place in the specimen tube.
6. Push the stick into the tube until the swab is saturated with culture medium and cap reaches black dot.
 - ▶ **Rationale:** This places the applicator tip into the culture medium to preserve bacteria until laboratory can complete test.
7. Position client for comfort.
8. Remove gloves and perform hand hygiene.
9. Label specimen tube, and send to laboratory immediately. ▶ **Rationale:** To ensure accurate identification of microorganisms.

▲ Push applicator stick into specimen tube, being careful not to contaminate stick.

Obtaining a Gum Swab for HIV Antibodies

Equipment

- One of four testing kits:
 - OraQuick Advance Rapid HIV-Antibody Test
 - Reveal B₂ Rapid HIV-Antibody Test
 - Uni-Gold Recombigen HIV Test
 - Multispot HIV-1/HIV-2 Rapid Test
- Clean gloves

Procedure

1. Perform hand hygiene and don gloves.
2. Check two forms of client ID.
3. Swab outer gum with device included in kit.
 - ▶ **Rationale:** Device contains absorbent pad to absorb saliva.
4. Insert swab into vial containing special solution.

5. Check window display on device, and if antibodies are present, two red-purple lines will appear. ► **Rationale:** When a person is exposed to HIV, the immune system will produce antibodies.
6. Following preliminary positive results, instruct client to confirm results with a blood test (the Western blot analysis is the gold standard for HIV testing).
7. Refer client to appropriate consultation if results are positive.

Obtaining Wound Specimen for Aerobic Culture

Equipment

- Culture transport swab with transport medium (sterile)
- Laboratory slip
- Clean gloves, 2 pair
- Sterile gloves
- Dressing material
- Disposal bag
- Biohazard bag

Preparation

1. Check physician's orders and client care plan.
2. Perform hand hygiene.
3. Gather equipment.
4. Explain procedure to client and check two forms of client ID.
5. Open all sterile dressing material, and arrange for easy access during dressing change.

Procedure

1. Don clean gloves.

▲ Push tip of swab into liquid culture medium.

2. Remove and discard soiled dressing from wound into disposal bag.
3. Remove gloves, discard into disposal bag, and don clean gloves.
4. Rinse wound thoroughly with sterile normal saline. ► **Rationale:** Decreases risk of culturing normal flora, exudate, or eschar.
5. Remove swab, and wipe swab in wound avoiding wound edges. Obtain culture from active drainage area. ► **Rationale:** Touching skin edges or other surfaces will contaminate swab.
6. Return swab to container.
7. Crush transport medium vial, and push swab tip into contact with transport medium. ► **Rationale:** Specimen should be covered by medium.
8. Close container.
9. Place specimen in sealed biohazard bag. Label with specific anatomic site from which culture was taken.
10. Write any recent antibiotic or antifungal therapy on laboratory requisitions. ► **Rationale:** These drugs may lead to false-negative results from the culture.
11. Remove clean gloves and perform hand hygiene.
12. Don sterile gloves and replace dressing.
13. Remove gloves, discard, and perform hand hygiene.
14. Transport specimen to laboratory within 30 minutes. Do not refrigerate. ► **Rationale:** This ensures organisms are still viable.

NOTE: Determine whether wound should be cleaned with normal saline or whether area around wound should be cleaned with alcohol swab (do not use alcohol if client has a perineal wound, because it is irritating) before obtaining specimen.

Clinical Alert

Large wounds should have separate cultures taken from different areas of the wound.

Obtaining Wound Specimen for Anaerobic Culture

Equipment

- Anaerobic transport medium kit with swab
- Laboratory slip
- Clean gloves
- Sterile gloves
- Dressing material
- Disposal bag
- Plastic bag

Preparation

1. Check physician's orders and client care plan.
2. Perform hand hygiene.
3. Gather equipment.
4. Explain procedure to client and check two forms of client ID.
5. Open all sterile dressing material, and arrange for easy access during dressing change.

Procedure

1. Don clean gloves.
2. Remove dressing from wound, and discard in disposal bag.
3. Remove gloves and don clean gloves.
4. Rinse wound thoroughly with sterile normal saline.
 - ▶ **Rationale:** Increases chance of culturing microorganisms rather than normal flora or other exudate.
5. Remove specimen swab, insert deeply into wound, rotate it gently, and remove. Be sure you do not tip the anaerobic transport medium tube because it contains carbon dioxide. ▶ **Rationale:** Tipping "spills" the gas out, making it useless to transport anaerobic organisms.
6. Return swab to container. *Do not* touch sides of container with applicator.
7. Fill out or affix label to specimen and place specimen in sealed biohazard bag.
8. Write any recent antibiotic or antifungal therapy on laboratory requisition. ▶ **Rationale:** These drugs can lead to false-negative results.
9. Transport specimen to laboratory *immediately*. Do not refrigerate specimen.
10. *Alternative method:*
 - a. Draw up 1 to 5 mL of exudate in sterile 10 mL syringe with all air expelled or have a physician aspirate the wound.
 - b. Inject drainage into anaerobic culture tube.
 - c. Transport specimens to laboratory *immediately*.
 - ▶ **Rationale:** Anaerobic organisms may appear on gram stain even though they are not grown in the culture.

11. Remove clean gloves, perform hand hygiene, don sterile gloves.
12. Replace sterile dressing following protocol.
13. Remove sterile gloves.
14. Perform hand hygiene.

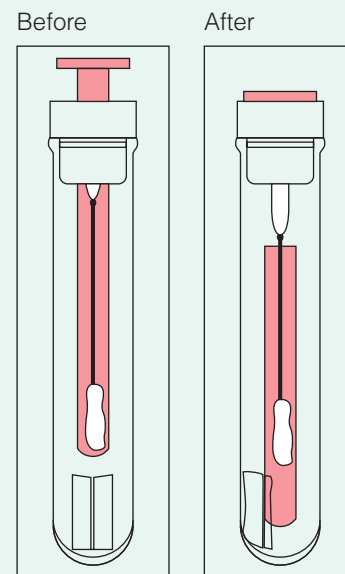

Clinical Alert

Obtain wound specimen for both aerobic and anaerobic organisms during scheduled dressing change before any medication or antimicrobial agents have been applied.

Using an Anaerobic Specimen Collector

Anaerobic specimens must be transported in tubes filled with carbon dioxide, because most anaerobes die when exposed to oxygen. A special carbon dioxide-filled, rubber-stopped container with a small inner tube and a swab attached to a plastic plunger is used.

Before specimen collection, the inner tube is held in place with the plunger rubber stopper. After collecting the specimen, quickly replace the swab into the inner tube, and push on the plunger. This will force the inner tube down, away from the plunger, and into the carbon dioxide environment of the outer tube. The rubber stopper will maintain the overall tube seal.

▲ Anaerobic specimen collector tube.

Collecting an Ear Specimen

Equipment

- Normal saline solution
- 2 × 2 gauze pads
- Gloves
- Sterile swabs
- Labeled sterile culture tube with medium
- Laboratory request form
- Biohazard transport bag

Procedure

1. Perform hand hygiene and don gloves.
2. Check two forms of client ID.

3. Cleanse ear with normal saline and gauze pad.
4. Insert sterile swab into ear canal and rotate gently along ear walls without pressing on eardrum.
5. Withdraw swab and place into sterile culture tube.
6. Remove gloves and complete hand hygiene.
7. Complete laboratory request form and send biohazard bag to the laboratory.

NOTE: If a middle ear specimen is ordered, the physician will puncture the eardrum with a needle and aspirate fluid into a syringe, which will be sent in a container to the laboratory.

DOCUMENTATION for Obtaining Specimen for Culture

- Assessment of wound and drainage
- Date and time specimen collected
- Type of culture obtained (aerobic or anaerobic)
- Site where culture obtained
- For wound specimens, document an assessment of wound and drainage
- Time specimen sent to lab

CRITICAL THINKING Application

Expected Outcomes

- Uncontaminated specimen is collected.
- The proper container (aerobic or anaerobic) is used for specimen collection.

- Specimen is sent to the lab within specified time.

Unexpected Outcomes

Inner surface of collection container contaminated while inserting swab into the culture medium container.

Swab becomes contaminated.

Anaerobic specimen not sent to laboratory immediately.

Anaerobic specimen not sent in appropriate container with hydrogen gas.

Wound culture produces false-negative results.

Testing kit for HIV antibodies shows positive.

Alternative Actions

- Obtain new specimen and send to laboratory.
- Touch only sterile items with replaced swab.
- Obtain new specimen.
- Obtain new specimen and send to laboratory.
- Obtain appropriate container and send new specimen to laboratory.
- Check if antibiotics or antifungal medications had been administered. If so, notify laboratory and provide specific drugs administered.
- Counsel client to repeat test.
- Refer client to appropriate entity for treatment and support.

GERONTOLOGIC Considerations

- Elderly clients may not clearly hear and understand the directions given regarding specimen collection. Ask specific questions to ensure compliance.
- Determine client's ability to follow directions for obtaining specimens such as urine and stool. Hearing and vision may be impaired, thereby interfering with their ability to follow through on specimen collection.
- Assess client's ability to accurately use blood glucose–monitoring equipment. Finger dexterity may be altered due to stroke, arthritis, or other chronic conditions, thus preventing them from being able to use the equipment or obtain the blood specimen.
- Residual urine may increase as a result of changes in the bladder tone, leading to urinary stasis and potential bacterial proliferation. This leads to bladder infections, necessitating accurate identification of bacteria. This is

accomplished through analysis of urine obtained from specimens free of contamination. Ensure client understands the procedure for obtaining an uncontaminated urine specimen. The nurse may need to obtain the specimen if the client is unable to do so without contaminating it.

- Avoid obtaining blood specimens from client's arm if neurological or vascular alterations are present.
- Clients receiving anticoagulant/antiplatelet therapy require a longer pressure time over the venipuncture site to prevent bleeding.
- Elderly clients have large rolling veins that make it appear easier to perform a venipuncture. In fact, the veins tend to collapse and rupture quite easily. Elderly clients may not require a tourniquet for venipuncture.
- Minimize the amount of tape used over IV site to prevent skin breakdown.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- CNAs can be assigned to obtain specimens that are nonsterile and noninvasive. Examples of these specimens include urine and stool collections.
- Unlicensed Assistive Personnel (UAP) and CNAs have been instructed in some areas to take blood measurements using the Accu-Chek and Glucometer machines. You will need to check with the facility policy and procedure manual for directions. Most states consider this an invasive technique and do not allow this level of healthcare worker to perform the task.
- LVN/LPNs can obtain most specimen collections except withdrawing blood. This task requires that they have additional education and be IV certified in order to obtain the blood specimens.

Communication Matrix

- It is very important that all staff members be aware of clients needing specimen collection. Many of the specimens, particularly blood specimens, require fasting. Shift and team reports should identify those clients with special needs relative to obtaining all specimens.
- When 24-hr specimens are being collected, ensure that signs are posted in the client's room to remind all healthcare workers to save the specimens. This is usually for a 24-hr urine specimen collection.
- Remind LVN/LPN to notify the RN of blood glucose findings, even if they are administering the insulin. It is the RN's responsibility to know these facts and to document because there are legal aspects to these interventions.
- Remind all healthcare workers to notify the nurse manager when any specimen has been collected. Follow the procedure for the facility for sending the specimen to the laboratory. Some facilities have personnel who pick up specimens from the nursing unit; others require the unit staff to take the specimen to the laboratory.
- Inform the healthcare workers about specimens that must be taken to the laboratory immediately after collection.

CRITICAL THINKING Strategies

Scenario 1

You have been assigned to collect specific specimens on several clients. Ms. Saunders is scheduled to have a 24-hr urine specimen collected.

1. When will you start collecting the specimen? List parameters necessary for accurate collection.
2. If the 24-hr urine specimen becomes contaminated with stool, what nursing action is indicated?

Scenario 2

Mrs. Block has orders for a stool specimen to be collected for presence of amoeba. When you collect the specimen from her, urine is mixed with the stool.

1. What is the nursing action?

Scenario 3

Mr. Jarvis has recently been diagnosed with diabetes, and you are assigned to collect a blood specimen for glucose testing.

1. Describe the activities you would perform to complete this assignment.
2. If the results exceed critical lab values, what is the implication of this result?
3. What actions will you take?

 **NCLEX® Review Questions**

Unless otherwise specified, choose only one (1) answer.

1. The nurse is teaching a client how to obtain a sputum sample. Which one of these statements is a critical factor in the instruction?
 1. Rinse the mouth before obtaining the sample.
 2. Obtain the sample in the morning after breakfast.
 3. Have client hold breath before coughing up sputum.
 4. Take an expectorant to help facilitate the cough.
2. When collecting a blood specimen for culture, the nurse should
 1. Draw the blood from the IV line.
 2. Wipe the sample site with alcohol.
 3. Wear gloves during the procedure.
 4. Use the venipuncture needle to inject blood into culture bottle.
3. A 4-year-old child with vomiting and diarrhea is admitted to the hospital. Which one of these statements regarding collecting stool specimens for ova and parasites is correct?
 1. Specimen or culture must be from first stool of the day.
 2. Clean-catch technique is used to collect stool sample.
 3. Specimen can be refrigerated up to 24 hr.
 4. Samples can be affected by laxatives containing heavy metals.
4. A client asks the nurse about the purpose of a guaiac test. The best response by the nurse is that it
 1. Detects the presence of bacteria.
 2. Tests for fat in the stool.
 3. Tests for hidden or occult blood.
 4. Determines whether pinworms are present.
5. During a 24-hr urine collection, the client discards a recent void. The nurse should
 1. Stop the collection.
 2. Extend the collection by 2 hr.
 3. Call laboratory to report the loss.
 4. Reinforce to the client to save urine.
6. A female client has collected a clean-catch urine sample. The sample is 50 mL, cloudy, odorless, and light yellow. Which one of the specimen's characteristics would be considered abnormal?
 1. Color.
 2. Clarity.
 3. Amount.
 4. Odor.
7. The nurse is withdrawing a venous blood sample from the antecubital fossa using a Vacutainer system. Which one of these statements would indicate the nurse is using correct technique in obtaining the sample?
 1. Place tourniquet 1–2 in. above client's elbow.
 2. Instruct client to keep fist clenched until needle is withdrawn.
 3. After needle removal, have client bend elbow and hold gauze on site.
 4. Cleanse site with antimicrobial wipe and allow to dry.
8. When drawing an arterial blood sample, the nurse should
 1. Flex the wrist to stabilize the vessel.
 2. Draw back on the syringe when blood is observed.
 3. Apply pressure for 1–2 minutes after needle is withdrawn.
 4. Perform Allen's test before arterial puncture.
9. The nurse is teaching a male client how to monitor his blood glucose using a One Touch meter. When observing his technique, which one of these actions would be cause for further instruction?
 1. Places the lancet on the lateral side of his finger.
 2. Washes his hands with soap and water.
 3. Adds additional blood to strip after test begins.
 4. After stick, strokes gently from base of finger to tip.
10. A client has a large, draining wound and the nurse is to obtain a specimen for an aerobic culture. When performing this procedure, the nurse should
 1. Note antibiotic or antifungal therapy on lab requisition.
 2. Wipe several areas of the wound with one swab.
 3. Place specimen in a paper cup to transport.
 4. Refrigerate specimen if unable to take immediately to lab.

Diagnostic Procedures

LEARNING OBJECTIVES

1. Describe the major components of client teaching for diagnostic studies.
2. Define interventional radiology (IR) and the nurse's role in IR.
3. List at least three preparatory functions for clients undergoing diagnostic studies.
4. Explain the importance of determining allergic responses to shellfish before clients undergo contrast media studies.
5. List the signs and symptoms that occur when the client experiences an allergic reaction.
6. Explain the reason for giving blocking agents before administering radioisotopes to clients.
7. Outline the nursing care responsibilities when a client returns from myelography.
8. Discuss the nursing care responsibilities when a client returns from arteriography.
9. Describe the care necessary after cardiac catheterization to prevent postprocedure complications.
10. Explain the steps you would take if a client is given medication before a GI series.
11. Describe client positions for at least four diagnostic procedures commonly performed at the bedside.
12. Compare and contrast postprocedure nursing observations for clients undergoing liver biopsy, paracentesis, and thoracentesis.
13. Explain the nurse's role during procedures that use fiberoptic scopes.
14. Describe how ultrasonography is used for diagnostic studies.
15. Describe the data that should be included in the charting for clients undergoing diagnostic procedures.
16. Describe the preparation clients must complete before an MRI.

TERMINOLOGY

Abscess a localized collection of pus in any part of the body.

Allergy an altered reaction of body tissues to a specific substance; essentially an antibody–antigen reaction and may be due to the release of histamine.

Amniocentesis puncturing the amniotic sac, usually by using a needle and syringe, to remove amniotic fluid for assessment of fetal maturity.

Antiemetic an agent that prevents or arrests vomiting.

Arteriography study using radiopaque dye injected into an artery to assess arteries.

Barium a radiopaque compound used in roentgenography of the gastrointestinal tract.

Bone densitometry Test used to determine bone mineral content and density; used to diagnose osteoporosis.

Bronchoscopy a visualization of the larynx, trachea, and bronchi through a flexible scope.

Catheterization use or passage of a catheter, a tube for evacuating or injecting fluids.

Centesis perforation or puncture through the skin to obtain fluid.

Cholangiography x-ray examination of the bile ducts.

Cholecystogram x-ray picture of the gallbladder.

Computed tomography (CT scan) a scanning technique that provides a series of detailed visualizations.

Contrast medium a radiopaque substance used during x-ray examination to provide a contrast in density between the tissue being filmed and the medium.

Contusion an injury in which the skin is not broken.

Craniotomy incision involving the skull.

Crepitus a crackling breath sound caused by air pockets in the subcutaneous tissue.

Diagnosis method or art of identifying the disease or condition a person has or is believed to have.

Diaphoresis profuse sweating.

Dissipate to scatter, disperse, dispel, disintegrate.

Dyspnea shortness of breath.

Endoscopy visualization of body organs and cavities using an endoscope (tubular instrument with light source and viewing lens).

Enema introduction of a solution through a tube into the rectum or colon.

Fiberoptic scope flexible scope that uses fiberoptic materials for visualization. These materials transmit light along its

course by reflecting it from the side or wall of the fiber. Devices using fiberoptic materials are used in endoscopic examinations.

Fluoroscopy type of examination using a screen to view shadows with the aid of x-rays.

Interventional radiology procedures formerly completed in perioperative settings that are now performed in radiology departments.

Lithotomy incision into the bladder for removing a stone.

Lumbar pertaining to the loins and lower vertebrae in the back.

Magnetic resonance imaging (MRI) a noninvasive test that uses a magnetic field with radio frequency waves to produce cross-sectional images of the body.

Mammography x-ray examination of breast used to detect breast cancer.

Myelography x-ray inspection of the spinal cord by the use of radiopaque medium.

Neoplasm a new and abnormal formation of tissue, as a tumor or growth.

NPO nothing by mouth.

Oliguria diminished amount of urine formation.

Paracentesis puncture of the abdominal cavity for the removal of fluid.

Peripheral outer part or surface of a body.

PET Scan imaging technique used to scan entire body or its various regions.

Pyelo pertaining to the pelvis of the kidney.

Pyelography x-ray study of the renal pelvis and ureter.

Scintillation the emissions from radiographic substances; a subjective sensation of seeing sparks.

Septicemia blood poisoning; septic products in blood and tissue.

Tachycardia fast pulse above 100 beats/min.

Thoracentesis surgical puncture of the chest wall for the removal of fluid.

Tumor uncontrolled new growth or tissue forming an abnormal mass that performs no physiologic function.

Urticaria a vascular reaction of the skin characterized by the eruption of pale, elevated wheals that are associated with severe itching.

Ventro denoting the abdomen or ventral (anterior) surface of the body.

Vertigo sensation of moving or having objects move when they are actually still.

CLIENT PREPARATION

Diagnostic tests play a major role in the diagnosis and care of clients. Diagnostic testing is as important as a thorough history and physical examination. The results from diagnostic tests can confirm or eliminate client diagnosis. In addition to assisting with the identification of disease states, diagnostic tests assist with monitoring diseases as interventions and treatments are established. With cost containment a major issue in health care today, it is imperative that tests be scheduled appropriately, the client be prepared for the tests, and specimens, if any, be collected and disseminated efficiently. Many tests are completed on an outpatient basis; therefore, very explicit information must be provided to the client. Many procedures begin the preparation 1 or 2 days in advance of the actual test. Clients must thoroughly understand this and be able to comply with the instructions in order to obtain an accurate result.

Nurses play a major role in client preparation for diagnostic tests. Client education is one of the most important means to promote an accurate test result. The educational process begins with a discussion of the test itself, the preparation necessary for an accurate result, and the posttest interventions if any.

Many types of diagnostic tests are being utilized in the healthcare industry today. This chapter contains only a few of the most common tests. There is a brief overview of pretest preparation and any posttest interventions commonly done after the test. As client education is a major role of the nurse, it is highlighted throughout the chapter.

The responsibility of the nurse begins with the initial scheduling of the test and continues after the results of the test are explained to the client. The physician explains the results of the test, but the nurse answers questions, interprets terminology, and listens to the client express his or her feelings or apprehensions.

The preparation of clients for diagnostic tests must be done on an individual basis. Some clients are well informed about the test they are scheduled to take. They know about diet and fluid restrictions, what to expect during the procedure, whether or not there is any discomfort with the test, and how long the procedure takes. Others need a great deal of explanation. Also, some clients prefer not to be given any explanation about the test. Nurses need to respect the client's preferences and provide only information requested, unless it in some way is a danger to the client.

Undergoing diagnostic tests can be frightening for clients; they are often unaware of what the procedure involves and worry about the outcome. Communication involves an active, verbal interchange of ideas, as well as an astute observation of the client's nonverbal cues, and can be hindered by this fear. One effective way to allow clients time to think about questions is to provide a printed form explaining the diagnostic test. The form may cover such information as how long a test takes, equipment used for the test, and any sensations experienced during the test. Leaving the form at the bedside can stimulate interest and prompt the shy, reserved client to ask questions when you return later.

Most diagnostic procedures are done on an outpatient basis. This makes it imperative that the nurse provide the necessary

information about the procedure. Instructions are sent home with the client that include preprocedural preparation. When the client arrives for the diagnostic test, time should be allotted to answer questions, reassure the client, and determine if the preprocedure preparation was followed.

Another important aspect of teaching involves the way in which the nurse approaches the client. The nurse should avoid giving the impression that she/he is in a hurry and that she/he has no time to answer any questions. On the other hand, be aware of the client's ability to pay attention to what you have to say. If the client seems distracted, he or she may be worried about finances, about who is watching the children, or whether or not their job will be waiting after discharge from the hospital. This preoccupation may prevent assimilation of knowledge and the client may be unprepared for the events that follow.

Remember, the client probably does not know medical jargon; therefore, explain procedures in terms the client can understand. If the client looks puzzled and does not ask any questions, evaluate how you presented the information.

Feedback is the only way in which you can evaluate the learner's knowledge. Feedback can be in the form of direct questioning about certain aspects of the test. Feedback can also be determined through direct observation of facial expressions, posturing, and activities.

X-Ray Studies

Many x-rays use the normal contrasts of the body, such as air, water in soft tissues, fat, and bone. These four densities observe varying degrees of radiation. Air has less density, causing dark images on the film, whereas bone has high density, producing light images. Plain radiology is performed without contrast material. These include x-rays of chest, skull, abdomen, and bones. Some tests do require a contrast medium. Several types of contrast media are used routinely, including barium sulfate, helium, carbon dioxide, iodized oils, and organic iodides.

One of the major problems with the use of some contrast media is the adverse reaction or sensitivity that can occur. This is more common when iodine preparations are used. The degree of reaction varies from mild (such as nausea) to severe (such as cardiovascular collapse). The usual symptoms include urticaria, hives, dyspnea, nausea, vomiting, and decreased blood pressure.

Clients allergic to food, especially shellfish, or drugs are often allergic to some dyes used in diagnostic studies, particularly those that are iodine-based. After injections of iodine dye, many tests are abnormal for varying lengths of time. Urine sodium, specific gravity, protein, and osmolality are abnormal for 16 hr. Urine catecholamines are also abnormal for 16 hr.

Barium sulfate is a radiopaque substance that blocks the passage of x-rays and provides excellent contrast to body structures. It can cause some uncomfortable feelings and problems with the gastrointestinal tract, but with proper postprocedure care, this condition can be greatly reduced. It is not used as frequently now as it was previously, due to the newer diagnostic equipment now available.

Fluoroscopy, x-rays that pass through the body to a fluorescent viewing screen, a sequence of x-ray films each representing a section of tissue at different levels, have been very important

in diagnosing and confirming clients' conditions. Two very common uses of fluoroscopy are upper GI barium swallow studies and angiography procedures to guide catheters to predetermined positions, such as in cardiac catheterization.

Computed tomography (CT) of various organs, particularly abdominal and renal organs, are noninvasive x-ray procedures used to diagnose pathologic conditions such as tumors, cysts, abscesses, inflammation, perforation, obstruction, and calculi. The CT scan image results from passing x-rays through the abdominal organs using several angles. CT scans are used as a guide to aspirate fluid from organs to obtain cultures and biopsies. There are newer scanners that can visualize the blood flow and degree of vascularity of the organ through arterial injection of dye to specific organs in the abdomen. This is termed dynamic CT scanning. A second scan, the helical CT scan, obtains images as the client passes through the scanner. A large advantage to this type of scanning is the speed with which the client passes through the scanner. A CT scan of the abdomen or chest is completed in less than 30 seconds. The procedure can be completed with the client holding only one breath.

Ultrasound Studies

Ultrasonography can be done alone or with other procedures. Sound waves produced by ultrasound differentiate normal from diseased tissue. The sound waves are transmitted through fluid, but not bone, air, or contrast material. It is usually performed in physicians' offices or outpatient settings. Ultrasound is painless, requiring only that the client lie quietly during the 15–30-minute procedure. There is no risk to the procedure; therefore, it can be repeated frequently without side effects. This procedure needs to precede barium studies because barium impedes transmission of sound waves. It requires that a gel be placed over the site of the organ to be tested. This provides an air-free barrier between the probe (which holds the transducer) and the skin. The probe, or transducer, is passed over the specific body area, and ultrasonic waves are transmitted through the tissue. The transducer converts the echoes to electric impulses and transforms them into visual images. There is no preprocedural or postprocedural care for the client because it is a noninvasive procedure, except for an ultrasound of pelvic organs. The client needs to drink four glasses of water to promote a full bladder. The full bladder enhances transmission of sound waves and thus improves visualization of organs.

Echocardiography is a procedure similar to ultrasound. It is a painless, noninvasive technique that uses transducers and oscilloscopes similar to those in ultrasound procedures. The echocardiogram records heart motion, not heart outline. There is no preparation or postprocedure alteration in activity for this procedure.

Doppler ultrasonography is used to evaluate blood flow through carotid arteries or peripheral blood vessels. Deep vein thrombosis and peripheral vascular disease are diagnosed using this diagnostic test. A handheld transducer transmits high-frequency sound waves to an artery or vein. The sound waves strike the moving RBCs and are reflected back to the transducer, which amplifies the sound and produces a graphic recording.

Nuclear Scanning

Radioisotopes distribute uniformly through normal tissue, but unevenly in pathologically involved or diseased tissue. The radionuclide atom emits radioactive particles (photons in the gamma radiation range), which have short half-lives. The most commonly used are gallium, thallium, and iodine. A scanning procedure involves less radiation exposure than a chest x-ray.

Radioisotopes tend to concentrate in specific organ tissues and thus are more effective when administered for scanning a particular organ. For example, technetium-99m is specifically used for thyroid scanning, while thallium-201 (^{201}Tl) is used to evaluate blood flow through vessels that are too small to visualize with a cardiac catheterization procedure. This is often termed a *myocardial perfusion scan*. Technetium-99m is also used for cardiac scanning. The newer thallium imagery is three-dimensional; the camera moves around the client in a 180° – 360° arc. The three-dimensional view is more precise in identifying abnormalities. Scanning allows visualization of organs that are unobservable by x-ray alone. Tumors present as areas of reduced radioisotopic activity. Radioisotope studies are contraindicated with pregnancy, breast-feeding mothers, or persons who are allergic to the radioisotopes.

The radioactive isotopes are administered intravenously or orally to the client. A specified time elapses before the scanning is done. This allows time for the radioactive material to reach the specific tissue under study. Then, a scanning device is used to record the concentration of radiation that emerges from the radioisotope. Equal or gray distribution is normal, but lighter or brighter areas, termed “hot spots,” indicate hyperfunction, and darker areas, “cold spots,” indicate hypofunction.

Some clients are given blocking agents before the administration of the radioisotope. This prevents the radioactive material from entering organs other than those being studied. A common blocking agent is Lugol's solution, which is given to a client who is having a study done on an organ other than the thyroid gland.

Microscopic Studies

Microscopic studies are necessary for diagnosis and treatment of many diseases and infectious processes. Specimens are collected from tissues, blood, organ biopsies, and secretions, in addition to other sources such as blood and urine.

Biopsies involve the physician's taking a piece of tissue from the designated area to be used for microscopic evaluation. Biopsies can be done on endometrial tissue, the lung and liver, and bone marrow aspiration, to name a few areas. Information obtained from the biopsy can indicate pathologic conditions, diseases, and treatment for infections.

Endoscopic Studies

An endoscopy refers to inspection of an internal body organ and cavities by introducing an instrument called an endoscope. Biopsies of suspicious tissue, removal of abnormal growths, injection of blood vessels, dilation and stent procedures, and surgical procedures can all be accomplished through the endoscope.

Endoscopes are either rigid or flexible and have a light source and viewing lens that allows the physician to observe the specified area. Scopes can be inserted through body orifices or through small incisions. Rigid scopes are used mostly for operative laparoscopic procedures. Flexible fiberoptic scopes are used in pulmonary and GI endoscopy. Because the scope is flexible, light can be transmitted around corners and thus provide a view of body structures not visible by older rigid scopes.

Fluid Analysis Studies

Normal body fluids can provide information concerning the client's health status. Body fluids frequently studied include CSF analysis and condition of the fetus and its environment. Abnormal accumulation of fluids within the body can be analyzed by aspirating the fluid and sending it to the laboratory for studies. The most common areas where fluid needs to be removed include the abdomen and pleural space. Most often, the fluid is removed for therapeutic purposes, although it may be removed for diagnostic purposes. Once fluid is removed, it is measured and samples are sent to the laboratory for analysis.

Magnetic Resonance Imaging (MRI)

The MRI procedure has revolutionized diagnostic medicine. It is a method of looking inside the body. It replaces the use of x-rays. The procedure identifies the distribution of hydrogen molecules in the body using a three-dimensional process. The images are translated by computer and differentiate normal from abnormal tissue structure and blood flow. It uses a strong magnetic field in conjunction with radio frequency waves to transmit signals from body cells to the computer. The computer produces cross-sectional images of the body. The procedure is noninvasive and does not involve harmful exposure to radiation. The MRI detects and describes soft tissue abnormalities and yields information about the chemical nature of the cells. Gray and white brain matter can be differentiated and brain tumors and vascular abnormalities identified. The MRI is the most sensitive technique for defining the structures of internal organs and for detecting edema, infarction, hemorrhage, tumors, and infection.

Even though the full usefulness of the MRI has not been totally determined, the MRI is the diagnostic procedure of choice for detecting most brain abnormalities and shows great promise in identifying abnormal blood flow through coronary arteries, assessing kidney flow, heart defects, and a myriad of other abnormalities and defects. This procedure has replaced the need for arthrography and myelography. It has been used as a diagnostic tool in the diagnosis of multiple sclerosis; however, it has limited ability to detect plaque as the client ages. The MRI scan may require the use of a contrast agent administered IV to assist in visualization of certain structures in the body.

Interventional Radiology

With the technological advances and changes in health care, many procedures performed exclusively in the perioperative settings are now being performed in the radiology department.

The usual procedures completed in the radiology department are those that have minimal incisions, are low risk, entail low pain, and have a short recovery time.

Interventional radiologists do the following: biopsies, cryotherapy, embolization, stenting, thrombolysis, vascular access procedures, and vertebroplasty.

The radiology team consists of the physician, technologist, and nurse. Selected radiology departments employ physician's assistants and nurse practitioners.

Role of the RN in Radiology The nurse working in the radiology department is a critical care RN who manages clients during interventional radiology procedures. This nurse must have experience in ICU or ER and be certified in both ACLS and administration of moderate sedation. Responsibilities include completing preprocedure assessments and preparation, intraprocedure monitoring and procedural sedation, postprocedure recovery from sedation, and monitored anesthesia care. The RN works in all modalities of radiology, including CT scan, ultrasound, PET, vascular radiology, MRI, and interventional radiology procedures including abdominal, bone, neurovascular, and thoracic.

Assisting the Physician During Tests

Nurses are frequently called on to assist the physician with procedures at the bedside. The procedures presented in this chapter are the most common ones performed in the hospital unit. It is important that the nurse be aware of the correct client positioning in order to facilitate the procedure, decrease complications, and decrease the time it takes to complete the procedure.

Some diagnostic tests frequently used in the past are used less frequently today. One such procedure is the lumbar puncture. Removal of fluid from the spinal tract may cause the brain, because of edema, to herniate down through the tentorium. Because of this complication, a lumbar puncture is not done on a client with head trauma or potential increased intracranial pressure. The CT scan is now frequently used to determine intracranial bleeding. If a lumbar puncture is ordered, the client may have the procedure done in the x-ray department.

CULTURAL AWARENESS

A cross-culture assessment questionnaire should be offered to clients who may have difficulty in understanding or following directions in preparation for diagnostic procedures. In some cultures, it is difficult for clients to admit they do not understand what is being said to them. Westerners are bold and direct when asking questions so they expect the same from clients of different cultures.

With the "push" to get clients in and out of procedure rooms, communication and understanding can be compromised. However, while preparing for the procedure, talking with the client can provide the comforting measures necessary to allow them to participate appropriately during the procedure. Ask clients which family member should be included in the discussion and client teaching regarding the diagnostic procedure. Pay close attention to what family members say.

They can provide valuable information regarding the client's understanding or fear of the procedure. In some cultures words such as cancer, surgery, or death are not used. In many Middle Eastern cultures you do not speak of death; it is viewed as a breach in the nurse–client relationship. Modesty is an issue with some cultures. This varies greatly among cultures and

individuals within those cultures. Be sensitive to this issue and allow the client to undress in private if at all possible.

Source: Heinekine, J., & McCoy, N. (2000, January). Establishing a bond with clients of different cultures. *Home Healthcare Nurse*, 18(1), 45.

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to include in a client care plan when the components are related to clients undergoing diagnostic procedures.

NURSING DIAGNOSIS	RELATED FACTORS
Anxiety	Apprehension regarding test or procedure outcome
Fear	Results of diagnostic test, change in health status, threat to self-concept
Risk for Deficient Fluid Volume	Reaction to contrast media, NPO status, side effects of medication
Deficient Knowledge	Misunderstanding of instructions or information, inadequate data or explanation of procedure (maintaining position after spinal tap, liver biopsy)
Noncompliance	Inability to follow directions as a result of poor health status, cultural influences, or patient's value system

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. *Remember to wash your hands or use antibacterial gel before and after each and every client contact.*

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to the Joint Commission standards.

Chapter 21

UNIT 1

Contrast Media and X-Ray Studies

Nursing Process Data

ASSESSMENT Data Base

- Assess client's knowledge of procedure to be done.
- Identify any history of drug or food allergies.
- Evaluate client's ability to follow directions before and during the test.
- Assess vital signs and document for baseline data.

PLANNING Objectives

- To determine if the client is physically prepared for the test
- To determine if the client is psychologically prepared for the test
- To determine if the client is at risk for an allergic reaction
- To determine if the client is able to cooperate with the preparation and completion of the test

IMPLEMENTATION Procedures

• Preparing for X-Ray Studies	723
• For All X-Ray Studies	723
• For Oral Cholecystography	723
• For Intravenous Pyelography (IVP)	724
• For Myelography	725
• For Arteriography	725
• For Computed Tomography (CT) Scan	726
• For Cardiac Catheterization	726
• For Bone Densitometry	727
• For Magnetic Resonance Imaging (MRI)	728
• For Mammography	729

EVALUATION Expected Outcomes

- Client acknowledges understanding of the scheduled procedure.
- Client is calm and emotionally prepared for procedure.
- Client is well prepared for x-ray study after client teaching.
- Client completes x-ray study without complications.
- Client did not experience allergic reaction to contrast media.
- Client describes posttest care upon discharge.

Critical Thinking Application

• Expected Outcomes	730
• Unexpected Outcomes	730
• Alternative Actions	730

 and Skill Checklists

Preparing for X-Ray Studies

Equipment

- Signed consent form
- Pajama bottoms and hospital gown
- Allergy Ident-A-Band, if needed
- Wheelchair

Clinical Alert

Ensure that female client is not pregnant nor is there a chance of being pregnant before performing any diagnostic tests using x-rays.

Procedure

For All X-Ray Studies

1. Identify the specific diagnostic test to be performed (Table 21-1).
2. Determine if any tests must precede others in order to schedule test appropriately.
3. Obtain client's history to determine allergies to food or drugs, and note these on the chart. Notify physician of findings.
4. Identify specific preparations that need to be carried out before the studies.
5. Monitor food and fluid restrictions that need to be altered for the studies.
6. Obtain special consent forms for all invasive diagnostic studies after the physician has explained the study to the client. The consent form must be signed before any medication is administered.
7. Provide client teaching regarding the purpose of the study, including any special preparation required and restrictions imposed by the study.
8. Provide psychological support and reassurance to the client.
9. Obtain orders regarding medications or nutrition for clients with special problems, such as diabetes or seizure disorders.
10. Carry out safety precautions immediately before the study:
 - a. Check two forms of client identification.
 - b. Have client void if necessary.
 - c. Remove client's hairpins, jewelry, and dentures if necessary.
 - d. Chart premedication given.
 - e. Monitor safe transfer from the bed to gurney or wheelchair.
 - f. Accompany client to x-ray department if needed. (Usually, nurses accompany critically ill clients.)

Clinical Alert

Clients taking metformin hydrochloride (Glucophage, Glucophage XR, or Riomet) are at risk for acute renal failure and lactic acidosis with iodinated contrast media. Instruct the client to STOP the metformin for 48 hr before and after the studies.

Clinical Alert

Clients scheduled for a diagnostic test using contrast media must have BUN and creatinine tests completed before the scheduled study. Nephrotoxicity is a side effect of the contrast media, particularly iodinated dyes.

For Oral Cholecystography

1. Explain purpose for procedure to client—x-ray provides visualization of gallbladder.
2. Identify allergies to shellfish or iodine. Notify physician if allergy is noted.

TABLE 21-1 Contrast Media and X-Ray Studies

Diagnostic Test	Rationale	Contrast Media
Oral cholecystography	To visualize shape and position of the gallbladder and to identify the presence of stones	Yes
Intravenous pyelography	To visualize structures of the urinary tract	Yes
Myelography	To visualize the subarachnoid space to identify abnormalities	Yes
Arteriography	To visualize abnormalities or obstructions in specific blood vessels	Yes
Computed tomography	To visualize a cross-section of the brain, chest, and abdomen to precisely localize lesions	Yes/No
Cardiac catheterization	To measure oxygen concentration, provide blood samples, determine cardiac output, and visualize coronary arteries	Yes
Bone densitometry	To determine bone mineral density and strength of bone	No
Magnetic resonance imaging	To visualize inner structures of body	Yes/No
Mammography	To determine presence of breast pathology	No

Informed Consent

- Informed consent indicates clients have received a full explanation of the procedure, including risks, complications, benefits, and alternatives.
- Obtaining informed consent is the responsibility of the physician. It is the nurse's responsibility to check that the consent is signed before the procedure.
- The nurse can be asked to witness the signature. Before witnessing the signature, the nurse must have been present during the client/physician discussion.

Clinical Alert

Symptoms of contrast media reactions:

- Urticaria, hives
- Nausea, vomiting
- Respiratory distress
- Decreased blood pressure

Clients allergic to food or drugs may also be allergic to contrast media used for diagnostic studies.

3. Obtain consent form.
4. Instruct client to eat low-fat meal evening before test.
5. Administer iodine radiopaque medication 2 hr after dinner. Drug: iopanoic acid (Telepaque). ► **Rationale:** It takes 12–14 hr for the dye to be concentrated in the gall bladder.
 - a. Number of tablets administered is based on client's weight.
 - b. Tablets are given 5 minutes apart with 8 oz. of water for each tablet. Usually six tablets are given.
 - c. Inform client that diarrhea is a common side effect.
6. Keep client NPO after administration of contrast medium. ► **Rationale:** This prevents contraction of gallbladder and expulsion of radiopaque dye.
7. Take client to x-ray department.
8. Explain details of procedure to client.
 - a. X-ray client in standing and lying positions for good visualization of gallbladder and common bile duct. Test takes about 1 hr.
 - b. Feed client a fatty meal to test ability of the gallbladder to contract.
 - c. If visualization does not occur, additional medications may be given and the test repeated the following day, or an IV cholangiogram may be done.

Clinical Alert

Do not schedule cholecystogram after barium study because the barium precludes visualization of gallbladder.

Clinical Alert

Ultrasound has replaced the oral cholecystogram test in most cases. It may still be used, however, if ultrasound results are inconclusive.

9. Explain postprocedure care to client.
 - a. Mild dysuria can occur. ► **Rationale:** Dye is excreted through the kidneys.
 - b. Observe for allergy symptoms from dye.

For Intravenous Pyelography (IVP)

1. Follow steps as appropriate in Preparing for X-Ray Studies.
 - a. Give client clear liquid diet the evening before the IVP and maintain NPO status after 12 midnight. Some facilities allow clear liquid diet in morning.
 - b. Give laxative or cathartic as ordered, usually the night before test. A cleansing enema may be ordered the morning of the test (check facility policy). ► **Rationale:** To eliminate feces and gas to provide better contrast.
 - c. Identify allergies to shellfish or iodine. ► **Rationale:** Other contrast material will be used in place of iodine contrast media.
 - d. Obtain consent.
 - e. Take baseline vital signs.
 - f. Take client to x-ray department when notified.
2. Explain details of procedure to client.
 - a. Client is positioned in supine position.
 - b. Flat plate of abdomen taken. ► **Rationale:** Ensure no residual stool, which could interfere with visualization of renal system.
 - c. Test dose of contrast medium may be injected intradermally for clients with a history of allergies. The contrast material is administered if there is no reaction within 15 minutes of test dose.
 - d. IV is inserted and contrast medium injected as a large single dose.
 - e. X-rays are taken over period of 30 minutes to 1 hr to determine extent to which dye is filtered through the kidneys.
3. Warn client that contrast medium can cause feelings of nausea, shortness of breath, and a hot, flushed effect.
4. Instruct client to void at end of test. An x-ray is taken to visualize residual dye in kidneys.
5. Return client to room and resume ordered activity level.
6. Encourage fluids, and resume usual diet. Fluids should include at least 24 ounces of water. ► **Rationale:** Increasing fluid intake prevents osmotic diuresis from contrast medium.
7. Monitor client for at least 24 hr for signs and symptoms of reactions to contrast medium such as oliguria, nausea, and vomiting.

For Myelography

1. Follow steps as appropriate in Preparing for X-Ray Studies.
 - a. Explain procedure to client—test identifies abnormalities of spine and subarachnoid space.
 - b. Client may have cleansing enema ordered.
 - c. Identify allergies to shellfish, iodine, or other contrast media.
 - d. Keep client NPO for 4–8 hr before test.
 - e. Obtain baseline levels of motor and sensory function and vital signs.
 - f. Assess for signs of increased ICP. ► **Rationale:** This test is contraindicated for clients with ICP. Brain herniation can occur.
 - g. Obtain consent form.
 - h. Medicate with sedative if ordered. ► **Rationale:** This provides client comfort.
 - i. Take client on gurney to x-ray department.
2. Explain details of procedure to client.
 - a. Client is placed either in prone position with pillow under abdomen or side-lying with knees drawn up to abdomen and chin on chest on fluoroscopic table, and secured to table with several straps. ► **Rationale:** This position allows physician to visualize ruptured disc or neoplasms.
 - b. A lumbar puncture needle is inserted between the vertebrae into the subarachnoid space.
 - c. A small amount of cerebrospinal fluid is sent to lab for study.
 - d. Contrast medium is injected, and client is tilted on table to allow flow of dye to designated areas of spine to visualize it by x-rays.
 - e. Oil-based contrast medium, Pantopaque, is removed through aspiration. Explain to client that sudden sharp pain in legs may occur.
 - f. Water-based contrast medium, metrizamide, is absorbed and excreted through kidneys. It is not removed by aspiration. Most facilities now use Omnipaque. ► **Rationale:** It has far fewer side effects.
 - g. Procedure lasts about 1 hr.
 - h. Client is returned on gurney to room.
3. After the test:
 - a. Keep client in prone position or supine position for 8 hr for water-based or 12 hr for oil-based contrast. May turn side to side. ► **Rationale:** This position prevents a headache and CSF leaks.
 - b. Keep head of bed elevated 30°–50° for 8 hr. If procedure has included water-soluble dye medium, client may be on bedrest for up to 24 hr. ► **Rationale:** This position reduces rate of upward displacement of dye.
4. Observe for seizure activity if metrizamide used for procedure. It can precipitate seizures. Do not give medications that can decrease seizure threshold.
5. Monitor vital signs and motor and sensory function.
 - a. Cervical myelogram: Check upper and lower extremities and bladder function.

Clinical Alert

A myelogram is performed less frequently today because of the wide use of the MRI and CT scanning. The MRI is more accurate for viewing spinal cord and surrounding structures.

- b. Lumbar myelogram: Check lower extremities and bladder function.
 6. Medicate for pain as ordered, usually with a mild sedative.
 7. Increase fluids to at least 2,500 mL each day for 2 days. ► **Rationale:** Fluids rehydrate and replace cerebrospinal fluid and may prevent headache after procedure. Offer diet.
 8. Monitor output, and observe for distention.
 9. Observe puncture site for 24 hr for bleeding, hematoma, or edema.
 10. Observe for complication of chemical or bacterial meningitis: fever, stiff neck, photophobia or delayed reaction to dye.
 11. Use comfort measures and relaxation techniques when needed.
- For Arteriography**
1. Follow steps as appropriate in Preparing for X-Ray Studies.
 2. Explain purpose of procedure to client—examination of arteries to determine abnormalities in blood flow.
 3. Identify allergies to shellfish, iodine, or any contrast media. Ask client if taking anticoagulants.
 4. Obtain baseline CBC, PT/PTT, and APTT, BUN, and creatinine. Anticoagulants must be discontinued before procedure.
 5. Obtain consent form.
 6. Keep client NPO for 2–8 hr or as ordered.
 7. Shave and scrub puncture site when ordered.
 8. Have client void before procedure. Remove dentures and metallic objects.
 9. Obtain vital signs and check peripheral pulses. ► **Rationale:** To provide comparison data after procedure.
 10. Administer preprocedure medications 1 hr before test, if ordered, and transport client to x-ray department.
 11. Explain details of procedure to client.
 - a. Client is positioned supine on x-ray table.
 - b. IV for fluid administration may be started. ► **Rationale:** For use in emergency situations.
 - c. Puncture site will be scrubbed and a local anesthetic administered. Catheter is inserted into brachial or femoral artery.
 - d. Contrast medium will be injected to visualize abnormalities or obstruction to specific vessels. Inform client that a warm flush may be felt when dye injected.

- e. Client may be instructed to hold breath for x-rays. Procedure takes about 1–2 hr if an automatic film changer is used.
- f. Catheter is removed and pressure dressing applied over site.
12. Monitor vital signs, pulses, and puncture site, as with surgical clients. ► **Rationale:** To identify potential complications.
13. Observe for signs of shock and presence of pain, which indicate hemorrhage or thrombosis.
14. Observe for symptoms of delayed allergic reaction to dye, such as nausea, vomiting, tachycardia, sweating, rash, or hives. ► **Rationale:** Delayed reactions can occur up to several hours after the procedure.
15. Notify physician immediately if unusual symptoms are present. ► **Rationale:** Immediate medical intervention is necessary to prevent anaphylaxis.
16. Do not flex the involved extremity.
17. Maintain bedrest with head elevated slightly for at least 6–8 hr depending on site of puncture. Check hospital policy for time.
18. Offer fluids and diet as ordered and tolerated. Fluids should be 1 to 2 liters. ► **Rationale:** To facilitate elimination of contrast media.
19. Provide comfort measures as needed.

For Computed Tomography (CT Scan)

1. Explain purpose of procedure to client—CT scans give outlines of bone tissue and fluid structures due to tumors and hematomas. Tomography can be performed on abdomen, brain, chest, or bones and joints.
2. Identify allergies to shellfish or iodine if contrast medium is used.
3. Obtain consent if contrast medium is used or facility requires.
4. Place client on NPO for 4 hr if contrast medium is used. ► **Rationale:** Dye can cause nausea; NPO prevents emesis and potential aspiration.
5. Administer preprocedure medication if ordered. A mild sedative may be ordered for client to alleviate anxiety.
6. Remove all metal objects, such as hair clips, necklace, and jewelry. ► **Rationale:** Metal objects block bony structures on the film.
7. Take client on gurney to x-ray department.
8. Explain equipment and procedure to client.
9. Explain client will have IV injection of contrast material if enhanced study is to be done. Explain that a warm, flushed feeling or nausea can occur.
10. Explain that client will be placed in an encircling body scanner.
11. Instruct client to lie very still during the procedure and to not touch area to be scanned. Scan takes 15 minutes. ► **Rationale:** Movement causes artifact on the image.
12. Return client to room.

Xenon Computed Tomography

This test is used to evaluate cerebral blood flow. This technique precisely measures blood flow to various areas of the brain. It can define the degree and extent of ischemia in acute neurologic conditions such as stroke. This technology detects changes hours to days before changes can be seen on the MRI or CT. The client inhales a xenon/oxygen gas mixture for approximately 4–5 minutes, during which time CT data are obtained. The xenon gas travels to regions of the brain where it is distributed to tissue in proportion to blood flow and lipid content (xenon is fat soluble). A computer actually calculates blood flow to many different areas of the brain, and within minutes the computer provides precise measurements of cerebral blood flow. This scan is used to determine brain death.

13. Provide diet and encourage fluids to 3,000 mL or as ordered. ► **Rationale:** Increasing fluids assists in eliminating the contrast medium more quickly.
14. Observe for signs of delayed allergic reaction if contrast study is done.

For Cardiac Catheterization

1. Explain purpose and risk factors of procedure to client—to visualize heart structures and coronary blood flow and measure oxygen saturation, cardiac output and heart pressures. Angioplasty or stent placement is done through cardiac catheterization. Used most often to determine the cause of chest pain in adult clients. Procedure takes about 1 hr.
2. Obtain consent form.
3. Identify allergies to drugs, iodine, shellfish, or any other contrast media.
4. Check if client is on anticoagulants. Contact physician for instructions related to drug administration.
5. Complete prep and shave of groin or brachial area (or both). Mark peripheral pulses for post catheterization assessment.
6. Establish baseline data for vital signs, peripheral pulses, coagulation studies (PTT, PT), ACT, BUN, creatinine, renal function tests, and ECG pattern.
7. Place client on NPO 6–8 hr before test.
8. Keep client NPO for medications 6–8 hr before test, unless physician orders otherwise. Oral anticoagulants are discontinued or dosage reduced. ► **Rationale:** To prevent bleeding.
9. Before procedure, obtain vital signs, take weight, and have the client void. ► **Rationale:** Weight is used to calculate amount of dye required for the test.
10. Administer preprocedure medication, usually Valium and atropine, 30 minutes to 1 hr before procedure.

11. Remove dentures.
12. Take client on gurney to cardiac catheterization lab.
13. Explain equipment and details of procedure to client.
 - a. Client is strapped onto a table. ECG leads and blood pressure equipment are applied.
 - b. IV is started using D5W at TKO rate. ► **Rationale:** For use in emergency.
 - c. ECG monitoring is initiated to monitor heart rate and rhythm.
 - d. Groin or brachial area is scrubbed and injected with Xylocaine.
 - e. Catheter is placed in femoral or brachial artery and advanced to cardiac chambers.
 - f. When contrast medium is injected for coronary artery visualization, explain to client that a warm, flushed feeling, shortness of breath, or nausea can occur.
 - g. Instruct client to report any chest pain immediately.
 - h. Client is asked to hold breath about 10 seconds during contrast medium injection.
 - i. Reinforce that client will not fall off table as he or she may be turned on side for cineangiography. Total procedure takes 30 minutes to 3 hr.
 - j. After catheterization, pressure is applied to puncture site for 10–15 minutes.
14. Transport client on gurney to room.
15. Provide post–cardiac catheterization care.
 - a. Monitor vital signs, puncture site, heart and lung sounds, and peripheral pulses as with a surgical client.
 - b. Elevate extremity used for catheterization site. Keep extremity extended. ► **Rationale:** Position promotes blood supply back to heart and prevents thrombus formation.
 - c. Apply pressure dressing to puncture site if bleeding continues.
 - d. Encourage fluids and diet when vital signs are stable and no evidence of nausea or drowsiness is present.
 - e. Monitor for signs and symptoms of allergic response.
 - f. Monitor for signs of clot induced stroke or myocardial infarction.
 - g. Administer analgesics for pain.
16. Position client for comfort. Place on back for several hours after the procedure, then turn from side to side.

For Bone Densitometry

1. Discuss procedure with client before scheduled test and ask pertinent questions for the record.
 - a. Determine whether barium studies have been done within last 10 days. ► **Rationale:** Barium may falsely increase bone density of lumbar spine.
 - b. Instruct client that no specific pretest fasting, blood work, or sedation needs to be done. A consent form may be required.
 - c. Instruct client to go to outpatient x-ray or hospital facility according to instructions (there are no preparations for study, so it is usually not important to come early for test).
 - d. Instruct client not to wear jewelry, belt buckles, or zippers to x-ray department and to remove coins and keys from pocket; clothing need not be removed for test.
 - e. Determine whether client has had previous bone density tests or fractures. Document findings for physician.
2. Explain that there is no pain or discomfort associated with test. It is used to detect early osteoporosis. The bones usually examined include lumbar spine, neck of femur, and heel. Test takes approximately 30–60 minutes.
3. Explain that false-positive results can include previous fractures and previous bone scans.
4. Explain procedure to client.
 - a. Client will be placed on an imaging table with legs supported on padded box. ► **Rationale:** Position flattens pelvis and lumbar spine. Radiation source is below, with detector above the table that measures the bone's radiation absorption.
 - b. Images of lumbar and hip bones are projected on a computer monitor.
 - c. Each machine scans the bones of the finger, heel, and forearm differently, so specific instructions will be given according to machine descriptions.
 - d. After computer screen calculates bone mineral density, it is compared with existing data from healthy 25–35-year-old women and a T score is determined. The T score indicates the strength of the bone. The positive T score indicates a bone that is stronger than normal. A negative T score indicates the bone is weaker than normal. Z scores are also obtained. These scores compare clients matched for age, sex, race, height, and weight.
5. Instruct client that no specific postprocedural care is required. There are no side effects or complications associated with the test.

Procedures Done During Cardiac Catheterization

Transluminal Coronary Angioplasty: Specially designed catheter is introduced into the coronary arteries and placed across the stenotic area of the artery. The artery is then dilated by controlled inflation of the balloon for a few seconds. Coronary stents can be placed at the site of the stenosis after angioplasty. The stent is used to keep the coronary artery patent.

Laser Arterectomy: Permanent procedure to open coronary arteries that have plaque deposits using laser therapy.

Angioplasty: Catheter is placed in a stenotic area and a balloon is inflated and forcefully dilates the stenotic area. The client is monitored during the procedure using ECG tracings. If myocardial ischemia is present during the procedure, the balloon is removed.

For Magnetic Resonance Imaging (MRI)

1. Evaluate client for following conditions.
 - ▶ **Rationale:** These conditions exempt clients from having MRI because the magnet can move and displace metal, such as clips and staples, or cause a malfunction.
 - a. Clients with pacemakers, insulin pumps, nerve stimulating devices, or implanted devices (i.e., Port-a-Cath, PAS Port).
 - b. Clients with hip prostheses, cardiac surgery, or metal implants.
 - c. Clients with vascular clips and staples from recent surgery.
 - d. Pregnant clients should not be scanned even though there is no definitive evidence of harm to fetus.
 - e. Clients with cardiac or respiratory complications may be excluded.
2. Check for allergies if contrast medium is to be used. Two common contrast mediums are gadodiamide and gadolinium Magnevist.
3. Instruct client to remove all metal or magnetically sensitive objects: jewelry, glasses, wallets, watches, hair clips, credit cards. ▶ **Rationale:** The magnetic field can damage watches.
4. Describe MRI machine and procedure to client—it provides a clear picture of the inner structures of the extremities, brain, and spinal cord, and it clearly reproduces soft tissue, ligaments, and nerves; often used for determining response to radiotherapy and chemotherapy.

NOTE: Newer implanted devices may be compatible with the use of MRI. Each client needs to be assessed for type of device.

Vessel Closure Devices

There are several arterial closure devices on the market; however, the Perclose ProGlide Suture-Mediated Closure System is the most commonly used. These devices provide a monofilament suture knot that is easily advanced to the opening in the artery and delivers a pretied knot to close the access site in the femoral artery after a catheterization procedure. If needed, the physician can easily reopen the access site in the vessel for repeat or additional procedures.

This secure stitch provides rapid hemostasis (the cessation of bleeding) and allows a shorter recovery time. This is more cost effective for the facility.

However, in spite of using this device, not all clients should be considered for early discharge. Suture-mediated closure is not risk-free. There are complications associated with the procedure.

NOTE: Newer implanted devices may be compatible with use of MRI. Each client needs to be assessed for type of device.

Clinical Alert

Clients who are extremely claustrophobic may require conscious (moderate) sedation or may be moved to a nonenclosed MRI. If sedated, client must be monitored for at least 1 hr before discharge. The open MRI is also used for obese clients, confused clients, or a child. Clients must remain still. This MRT uses a lower-field magnet; therefore, lesser quality images are usually produced.

- a. Client is placed in a padded plastic cradle or on a pillow. The table then slides into the scanner so that the whole body is encased in the machine.
 - b. Client needs to lie flat, still, and relax inside the tube magnet. ▶ **Rationale:** Movement can produce artifact on image.
 - c. The client is instructed to hold his/her breath for up to 30 seconds.
 - d. Explain that during the procedure the client will hear rapidly repeating, loud thumping noises coming from the walls of the scanner. **Rationale:** Noises are caused by changing magnetic fields.
 - e. During the time the client is in the machine he/she can talk to and hear staff. Prism glasses may be worn so client can see outside scanner.
 - f. Inform client he or she will have ear plugs in place but will be able to communicate with MRI staff through microphone. ▶ **Rationale:** This allays feelings of claustrophobia.
 - g. Instruct client in relaxation techniques.
 - h. Procedure lasts 20–90 minutes.
5. Instruct client to void before procedure. ▶ **Rationale:** This prevents the need for client to void while undergoing procedure.
 6. Administer premedication as ordered, usually Valium.

Claustrophobia has been thought to be the reason that clients are uncomfortable and not able to lay still while in the MRI. Through new research, it has shown that the amount of distress is caused by the mattress pads currently available on the MRI, PET, CT nuclear medicine, and x-ray tables. Traditional pads wear out quickly and fail to provide sufficient support and comfort for the client. The Tempur® material has been incorporated into the Patient Comfort Systems Pads, knee wedges, and positioners. The pads mold into the client's body shape and contour; pressure is redistributed away from the weight-bearing contact points, thus reducing pressure on the body. The redistribution improves blood flow, which reduces the client's overall pain and discomfort.

Source: Kusza, J. Seeing Solace: Leading MRI facilities benefit from comfort pads. Patient Comfort Systems. www.patientcomfortsystems.com.

Infection Control in the MRI Suite

Challenges in Preventing MRSA and Other Infections in the MRI Suite

Infection occurs as a result of hospitals prohibiting cleaning crews from entering to clean the pads and the suite due to its high magnetic field. Most facilities just change the sheet on the table and the pillow case. This will not prevent contamination of the pads. An average MRI scans 3,000–5,000 clients each year. Many of these clients are infected with MRSA, and 30%–50% of all clients carry less virulent staphylococcus on their skin. Direct contact with personnel also leads to the spread of infection. Most clients undergoing an MRI have IVs inserted, which can lead to blood getting onto the sheets.

To prevent the spread of infection, hand hygiene must be completed frequently and the pads cleaned with antiseptic solutions after each client. To check efficacy of the cleansing process, the pads can be visualized under ultraviolet wavelengths, which detect biological material such as blood, bacteria, and bodily fluids.

Rothschild, P. (2007). Sick sense. *Advances for imaging and oncology administrators*. MRI Infection Control Paper. <http://www.mrinet.net/cpcommerce/product>

7. Place client in a comfortable position on table.
8. Instruct client on feelings of warmth or shortness of breath if contrast medium is used during procedure.
9. Transport client to room after procedure.
10. Observe for symptoms of delayed reaction to contrast material if used during procedure.

For Mammography

1. Instruct client to not wear deodorant, ointments, or talcum powder. ► **Rationale:** It can interfere with the reading of the mammogram, and false-positive results can occur.
2. Instruct client not to wear jewelry around neck.
3. Review client's history regarding breast implants or previous breast surgery, lumps, or unusual findings on monthly examinations. ► **Rationale:** Included on health record so radiologist has an accurate assessment of mammogram findings. The mammogram is contraindicated for pregnant clients.

Clinical Alert

Mammography only suggests a possible diagnosis of breast cancer. The diagnosis must be confirmed with histological examination of breast tissue obtained through a biopsy.

Digital Mammography

Digital mammography is a newer method of breast imaging in which images are captured electronically and viewed on a computer monitor. The radiologist is able to manipulate the contrast and brightness of the images, which increases the chance of identifying cancers. Portions of the breast image can be magnified with computer manipulation rather than with repeated films.

Standardization of Mammography Reports

Class I: Negative

Class II: Benign

Class III: Benign; short-term follow-up suggested

Class IV: Suspicious for cancer; further evaluation suggested

Class V: Cancer highly suspected

Recommendation of the American College of Radiology (ACR).

4. Explain procedure to client—may cause some momentary discomfort when x-ray cone compresses breast tissue; discomfort does not last after release of cone. ► **Rationale:** Compression of breast provides better visualization of breast tissue.
5. Explain that there is minimal radiation exposure from this procedure.
6. Instruct client to take off clothing above waist, including bra, and put x-ray gown on so it ties in front.
 - a. One breast is placed on x-ray plate and the cone is brought down on breast to compress it.
 - b. The breast will be placed in different positions to view the entire breast tissue.

Nuclear Medicine Breast Imaging (Scintimammography)

Scintimammography is a nuclear medicine breast imaging test that is considered supplemental to a breast exam and mammography. The test is often referred to as the Miraluma Tc-99m test. It assists the physician to determine the presence of cancer in the breast. It is used in some clients to investigate breast abnormalities, especially if the client has dense breast tissue, which makes it difficult to interpret. It is also used if the client has a palpable mass or when multiple tumors are suspected. A radioactive tracer is injected intravenously; the dye accumulates differently in noncancer and cancer tissues.

- c. The second breast is done in same manner.
 - d. The test takes 15–30 minutes.
7. Instruct client to wait when mammography is finished until films are processed. ► **Rationale:** Sometimes additional films will need to be taken; this prevents client from having to return to the department.
 8. Instruct client in self breast examination, if necessary, and answer questions before client leaves.
 - a. Test results are usually mailed to client.
 - b. If the mammography is being done for diagnostic purposes, the mammogram may be read and results are immediately available for client.

EVIDENCE-BASED PRACTICE

Diagnostic Performance of Digital Versus Film Mammography for Breast Cancer Screening

A study of 49,528 asymptomatic women had screening mammography at 33 sites in the United States and Canada. They underwent both digital and film mammography. Of these clients, 86.3% had all relevant information available for the study.

The mammograms were interpreted by two radiologists. A breast biopsy was completed 15 months after the start of the study or a follow-up mammogram was obtained at least 10 months after the initiation of the study.

The accuracy of digital mammography was significantly higher than film mammography among women under the age of 50, women with heterogeneously dense or extremely dense breasts on mammography, and premenopausal or perimenopausal women.

Source: Pisano, E. D., Gatsonis, C., Hendrick, E., Yaffe, M., Baum, J. K., Acharyya, S., ... Rebner, M. (2005). Diagnostic performance of digital versus film mammography for breast-cancer screening. *The New England Journal of Medicine*, 17(353), 1773–1783.

DOCUMENTATION for X-Ray Studies

- Client's history
- Preparation completed (e.g., NPO, clear liquid dinner)
- Client teaching completed
- Medication administered
- Allergies noted
- Unusual anxiety or fears of client
- How client transported to test
- Time sent and returned from test
- Postprocedure care
- Appearance of dressing or puncture sites

CRITICAL THINKING Application

Expected Outcomes

- Client acknowledges understanding of the scheduled procedure.
- Client is calm and emotionally prepared for procedure.
- Client is well prepared for x-ray study after client teaching.

Unexpected Outcomes

Client has allergic reaction.

Client is given meal when on NPO status.

- Client completes x-ray study without complications.
- Client did not experience allergic reaction to contrast media.
- Client describes posttest care upon discharge.

Alternative Actions

- Follow protocol or standing orders for allergic reactions.
- Start O₂ at 6 L/min unless otherwise contraindicated. Use nasal cannula.
- Place in semi- or high-Fowler's position if not contraindicated.
- Administer medications as outlined in protocol or according to physician's orders.
- Provide reassurance and encouragement.
- Have client take slow, deep breaths.
- If nausea or vomiting occur, obtain an order for an antiemetic from the physician.
- Call x-ray and change time of test. If possible, arrange for test to be done later in the day to avoid additional hospitalization, or return visit.
- Instruct client on what NPO means.

(Continued)

Unexpected Outcomes

Client very apprehensive and refuses test at last minute.

Alternative Actions

- Identify reasons for anxiety and attempt to allay fears.
- Notify physician and ask if he or she wants to cancel or postpone test to later time. Do not attempt to “talk client into it.”
- Discuss use of sedation during test.

Bleeding or hemorrhage occurs from arteriogram puncture site.

- Notify physician.
- Apply direct pressure until pressure dressing can be applied.
- Monitor amount of blood loss and possible signs and symptoms of shock.
- Elevate and keep extremity in extension position.
- Monitor vital signs.

Client develops irregular pulse after cardiac catheterization.

- Notify physician immediately
- Start IV if not in place.
- Prepare for possible code and IV administration of medication.
- Monitor vital signs frequently.

Bleeding occurs at catheter insertion site after cardiac catheterization.

- Apply pressure dressing.
 - Elevate extremity.
 - Monitor peripheral pulse and vital signs.
 - If bleeding does not subside, notify physician.
 - Monitor ECG findings.
-

Chapter 21

UNIT 2

Nuclear Scanning

Nursing Process Data

ASSESSMENT Data Base

- Assess client's understanding of nuclear imaging and the specific diagnostic test he or she is to receive.
- Assess client's ability to tolerate procedure (e.g., swallowing iodine solution, fasting).
- Determine client's psychologic needs in relation to the nuclear scan.
- Identify any allergies the client may have to radioactive materials.
- Assess need to remain with client during procedure.
- Assess vital signs and document for baseline data.

PLANNING Objectives

- To diagnose tumors, metastatic disease, abnormal conditions, and cardiac and other organ abnormalities via noninvasive method
- To prepare the client physically for the nuclear diagnostic test
- To prepare the client psychologically to prevent undue stress
- To complete client teaching to ensure the client understands the procedure

IMPLEMENTATION Procedures

- Preparing for Nuclear Scans 733
 - For Bone Scan 733
 - For Lung Scan 734
 - For PET Scan 734
 - For Nuclear Cardiology 735
 - For Thyroid Scan 735
- Teaching for Nuclear Scans 736

EVALUATION Expected Outcomes

- Client is physically and psychologically prepared for the scan.
- Client demonstrates understanding of the purpose of the test and potential side effects from the radionuclide material.
- Client completes procedure without complications.

- **Critical Thinking Application** 736
 - Expected Outcomes 736
 - Unexpected Outcomes 736
 - Alternative Actions 736

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Preparing for Nuclear Scans

Equipment

- Signed consent form
- IV equipment (for most scans)
- Hospital gown and pajama bottoms

Preparation

1. Identify the specific diagnostic test that is to be performed (Table 21-2).
2. Determine if any tests must precede others in order to schedule test appropriately.

NOTE: Technetium-99m, gallium, thallium, and iodine are used commonly for scanning. Technetium-99m is used extensively because it has a 6-hr half-life and emits low levels of gamma rays.

3. Identify specific preparations that need to be carried out before the studies. Check for recent exposure to radionuclides. ► **Rationale:** May interfere with current study.
4. Monitor fluid alterations that need to precede the studies.
5. Obtain special consent forms if required by facility after the physician has explained the study to the client.
6. Provide client teaching regarding the study, including any special preparation required for the study.
7. Provide psychologic support and reassurance to the client.
8. Explain that radiation exposure is minimal and limited.
9. Record client's height and weight.
10. Carry out safety precautions immediately before the study:
 - a. Check two forms of client identification.
 - b. Check for allergies.
 - c. Chart premedication if given.
 - d. Monitor safe transfer from the bed to gurney or wheelchair.
 - e. Accompany client to nuclear medicine department if needed. (Usually, nurses accompany critically ill clients.)

▲ Magnetom Large Bore MRI, 1.5 magnet strength.

For Bone Scan

1. Follow steps as appropriate in *Preparing for Nuclear Scans*.
 - a. Explain purpose of procedure to client—usually done to detect metastatic cancer, early bone disease, osteomyelitis, detect fractures or abnormal healing of fractures. If client is of child-bearing age, determine whether she is pregnant. If so, test cannot be done.
 - b. No fasting or sedation is required.
 - c. Have client ready for injection of radionuclide material, probably technetium-99m, 1–3 hr before scan.
 - d. Force fluids between injection of isotope and scan.
 - e. Have client void before going to x-ray.
 - f. Take client to nuclear medicine department.
2. Explain procedure.
 - a. Client is positioned supine under scintillation camera (camera records radiation emitted by skeleton).
 - b. Instruct client to remain very still for 20 minutes to ensure observation of bone abnormalities.
 - c. Client will be repositioned to prone and lateral positions during scan.
 - d. Return client to room.

TABLE 21-2 Nuclear Studies

Diagnostic Test	Rationale
Bone scan	To diagnose metastatic bone disease, osteomyelitis, or fractures
Lung scan	To diagnose pulmonary embolism or pneumothorax or to assess pulmonary status before lung surgery
PET scan	To scan whole body or its various areas; used in diagnosis; especially useful in diagnosing epilepsy
Cardiology scan	To diagnose coronary artery disease, cardiomyopathy, valvular heart disease, or to assess cardiac status and analyze ventricular function
Thyroid scan	To diagnose thyroid nodules, abnormal function, or thyroid cancer

3. Instruct client to resume activities and diet. ► **Rationale:** There is no problem with radiation exposure because only tracer doses of radioisotopes are used.
4. Force fluids for 2–3 hr after scan. ► **Rationale:** To promote renal filtering of excess tracer. Trace elements are excreted in 6–24 hr.

For Lung Scan

1. Follow steps as appropriate in Preparing for Nuclear Scans.
 - a. Explain purpose of procedure—used to detect pulmonary embolism, tumors, COPD.
 - b. Obtain consent if required.
 - c. Obtain chest x-ray 24–48 hr before scan.
 - d. Transport client to nuclear medicine department.
 - e. Ensure all jewelry is removed.
2. Explain details of procedure.
 - a. Explain equipment to client:
 - Closed-breathing system is used when ventilation scan is done.
 - Scintillation camera.
 - b. Client is injected intravenously with a tracer amount of radioactive material—usually, radionuclide-tagged MAA (macroaggregated albumin with technetium) is used.
 - c. Client is positioned in several ways to obtain clear images.
 - d. Client is instructed to breathe through a closed system until all radioactive gas is cleared from the system.
 - e. Instruct in use of mouthpiece or nose clips if used.
 - f. Client is instructed to lie quietly for 30 minutes as radiography is completed—gamma ray detector is passed over client, records radionuclide uptake on film.
3. Transport client on gurney to room.
4. Instruct client to resume prestudy activities.

For PET Scan

1. Follow steps as appropriate in Preparing for Nuclear Scans.
2. Explain that purpose of test is to scan the whole body or its various regions for early detection of recurrent tumor or cancer that has spread. PET scans can determine what heart tissue is still alive after a suspected heart attack. It aids in determining focal area for seizure activity and is used to help diagnose epilepsy. It is also useful in determining brain region for surgical removal of affected area when medication resistance is present.
3. Assess client and take complete history to determine if client is pregnant. Determine if client is claustrophobic or anxious. ► **Rationale:** Test cannot be performed if client is pregnant. Client must be able to lie still during

▲ Nuclear scanner used for cardiac thallium scans.

- the entire process, including a minimum of 45 minutes with his or her head inside scanner.
4. Premedicate with nonaspirin analgesia if client has arthritis or lower back pain that could prevent client from lying still for prescribed time. ► **Rationale:** Sedatives are avoided if at all possible because they alter metabolism. If necessary, chloral hydrate could be used; it has fewest adverse effects.
5. Instruct client to stay NPO for 6–8 hr.
6. Instruct client to void 1–2 hr before the test.
7. Instruct client to avoid caffeine, alcohol, and nicotine for 24 hr before test.
8. Explain procedure:
 - a. Reassure client that there is no discomfort except lying on a hard surface for up to 3 hr.
 - b. Ensure client has not taken aspirin or other anticoagulants for several days before scan.
 - c. Explain that an arterial line will be inserted to obtain blood samples.
 - d. Explain that a peripheral intravenous catheter will be inserted to inject radioisotope. One hour after injection, client will be placed in scanner.
 - e. Instruct client to lie quietly for 45 minutes. Lights will be dim. ► **Rationale:** This is time for radioisotope uptake to occur, as isotopes are circulating to the brain.
 - f. Monitor vital signs as indicated.
 - g. Explain that actual scan time is about 15–75 minutes. He or she must remain quiet with head in scanner during this entire time. ► **Rationale:** Any motion, moving, or talking can detract from the quality of image.

- h. Explain that arterial blood samples may be drawn from arterial line during scan.
 - i. Place blindfold on client to keep client from being distracted during certain brain studies. The head is also placed in a holder to restrain movement.
 - j. Place Velcro straps on clients with heart or abdominal studies. **Rationale:** To prevent movement.
9. Provide postprocedural instructions.
- a. After scan, IV and arterial lines will be discontinued.
 - b. Client can resume normal activities and meals.
 - c. Monitor for signs of seizure activity or adverse effects if seizure did occur during scan.
 - d. If sedative was given, do not allow client to drive or engage in any hazardous activities until sedative has worn off. Instruct client to have someone drive him/her home.

For Nuclear Cardiology

1. Follow steps as appropriate in Preparing for Nuclear Scans.
2. Instruct client that radioactive tracer substances are used to detect and evaluate cardiovascular abnormalities. Alterations of left ventricular muscle function and coronary blood flow are evaluated.
3. Instruct client in specific activities related to the test (i.e., exercise on a treadmill, holding certain medications, fasting). See Step 2 for specific cardiology test.
4. Explain that short fasting time may be necessary.
5. After isotope injection, scan will be performed 15 minutes to 4 hr later.
6. Instruct client in nuclear medicine department.
 - a. Gamma ray detector is placed over heart.
 - b. Detector is placed in several positions during scan.
 - c. Scan records images of heart.
7. Evaluate client's status after the scan.
 - a. Encourage fluids to excrete isotopes.
 - b. Apply pressure over venipuncture site if necessary.

For Thyroid Scan

1. Follow steps as appropriate in Preparing for Nuclear Scans.

PET provides information about the body's metabolism, unlike CT scans or MRIs, which only show body structure. Metabolic change occurs before structural changes. Some studies have shown that up to 60% of invasive tests or surgeries can be eliminated using the PET scan.

Source: Valk, P. (2000). Randomized controlled trials are not appropriate for imaging technology evaluation. *Journal of Nuclear Medicine*, 41(7), 1125–1126.

Common Tests in Nuclear Cardiology

Technetium pyrophosphate scan. This binds with calcium and creates an area of increased radionuclide uptake. The client receives an injection into the antecubital vein. He or she then waits 2 hr while the renal system clears the drug. A special camera scans the heart to identify areas of increased uptake of the radioisotope. The radioisotope accumulates in damaged areas of the heart and shows any evidence of a recent MI. Scan is also called a myocardial infarction scan.

Thallium scan. A medication (^{201}Tl) is injected into the antecubital vein and scanning is done within 4–10 minutes. Necrotic or ischemic tissue does not reflect the radioisotope as tissue with normal blood supply and healthy cells does. To detect myocardial scarring and perfusion, an acute or chronic MI, or the evaluation of prior cardiac surgery are the primary purposes for this test.

Thallium scan with exercise. When this test involves exercise, it takes 1 hr and 15 minutes; 3 hr later, a 30-minute resting scan is performed. Imaging with exercise may demonstrate perfusion problems not apparent when the client is at rest.

Gated cardiac blood pool scan. The client receives an intravenous injection of a red blood cell tagging agent, and ECG leads are positioned on him or her. The computer is then synchronized with the ECG reading. This test evaluates left ventricular function.

2. Purpose of scan is to diagnose thyroid nodules, abnormal thyroid function, or thyroid cancer.
3. Explain procedure to client.
 - a. Instruct client not to consume any iodine compounds (vitamin or mineral supplements that may contain iodine or iodized table salt) or eat any foods that contain iodine—especially seafood, which has a high iodine content, for at least 3 days.
 - **Rationale:** Consuming iodine products interferes with the test.
 - b. Instruct client not to take thyroid or antithyroid drugs or x-ray contrast medium before the test, usually 3 days before test. ► **Rationale:** These materials interfere with the thyroid scan.
 - c. Instruct client to remain NPO for 2 hr after oral iodine administration.
 - d. Tell client that after the initial oral radioactive technetium he or she must return to the lab 24 hr later. Some labs do scanning after 2 hr of ingestion of technetium.
 - e. Instruct client that no isolation is needed after scan.

Teaching for Nuclear Scans

Procedure

1. Inform client that test is to be performed in the nuclear medicine department.
 - a. The department name alone may be frightening to the client.
 - b. Taking the client to the department ahead of time may help to decrease anxiety.
 - c. Instruct client to remove jewelry or metal objects in the area of the study.
2. Explain to the client that he or she will be receiving an injection of a radioisotope through a vein. The exceptions to this procedure are a lung scan in which the isotope is administered through an oxygen mask and a gastric-emptying scan in which the isotope is given orally with food.
 - a. Inform client that this isotope emits a harmless amount of radiation.
 - b. Inform client that the camera used for scanning does not emit radiation. The camera detects a small and harmless amount of radiation from the isotope as it is lodged in the part of the body being imaged.
- c. The radioactive substance usually leaves the body in 6–24 hr.
3. Explain to the client that he or she will be lying on a table (he or she will not be confined in an enclosed space) while the camera is positioned above or below the table. He/she may be asked to change positions during the test.
4. Assure the client that someone will be with him or her throughout the test, contrasting this procedure with x-rays for which the technician must leave the room or with the MRI for which the client enters a tube-like structure.
5. Tell the client that if he or she is in pain, he or she may receive an analgesic during the procedure, as he or she must remain still while the camera is scanning the body.
6. The scanning usually takes 30–60 minutes.

DOCUMENTATION for Nuclear Scanning

- Client teaching completed
- Client's emotional state
- Any radioisotopes given on the unit
- Preprocedural preparation completed (i.e., enema or laxative)
- History regarding earlier tests or studies
- NPO status
- Means by which client transported to nuclear medicine department
- Time client sent to and returned from scan

CRITICAL THINKING Application

Expected Outcomes

- Client is psychologically and physically prepared for the scan.
- Client demonstrates understanding of the purpose of the test and potential side effects from the radionuclide material.

Unexpected Outcomes

Client appears not to understand purpose of diagnostic test.

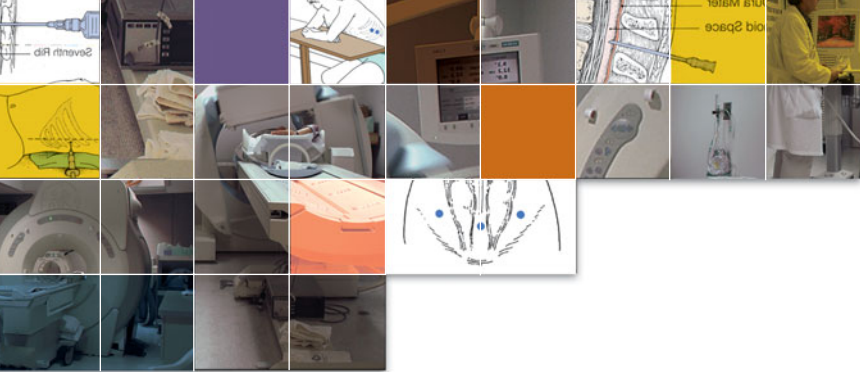

Client is unable to cooperate during the procedure.

Client is uncomfortable during procedure.

- Client completes procedure without complications.

Alternative Actions

- Observe for nonverbal cues or misunderstandings in order to clarify purpose of the test.
- Provide alternative teaching aids.
- Show client the equipment if necessary.
- Ask client to repeat explanation to you.
- If not contraindicated by condition, ask physician for sedation order.
- Nursing staff members may be asked to help client remain quiet. If so, wear lead apron shield.
- Reposition client for comfort if possible. (It may not be possible depending on area of body to be scanned.)
- Provide support by propping client in position needed for scanning.
- Assist client to focus on other things (e.g., the ball game, weather, or something pleasant).

Barium Studies

Nursing Process Data

ASSESSMENT Data Base

- Assess results of laxative and enema administration to ensure a clean colon for the study. Notify physician if client is unable to “hold” enema solution.
- Evaluate client’s ability to cooperate with test.
- Evaluate client’s knowledge of test.

PLANNING Objectives

- To determine the client’s ability to understand the preparatory process
- To clean out colon in order to ensure visualization of colon
- To prepare the client psychologically for the test

IMPLEMENTATION Procedures

- Preparing for Barium Studies 738
 - *For Barium Enema* 738
 - *For Barium Swallow Study* 738
 - *For Small Bowel Follow-Through* 739

EVALUATION Expected Outcomes

- Client is able to cooperate with test.
- Client’s bowel is clean and free of stool, promoting an accurate barium study.
- Client is prepared and knowledgeable about what to expect during procedure.
- Client’s study is completed without complications.
- Client successfully expels barium following test.

- **Critical Thinking Application** 739
 - Expected Outcomes 739
 - Unexpected Outcomes 739
 - Alternative Actions 739

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Preparing for Barium Studies

Equipment

- Signed consent if agency requires
- Enema tube and bag
- Ordered solution for enema
- Laxative
- Wheelchair

Procedure

1. Identify the specific diagnostic test that will be performed (Table 21-3).
2. Explain purpose of procedure to client.
3. Obtain consent for specific test to be performed.
4. Instruct client to refrain from smoking for 8–12 hr.
5. Instruct client to withhold medications for 8 hr before test unless otherwise indicated. Narcotics and anticholinergics are withheld for 24 hr. ► **Rationale:** To avoid intestinal immobility.
6. Instruct client to prepare for test.
 - a. Stay on low-residue diet 2 to 3 days before test and a clear liquid diet from lunch the day before test. No dairy products.
 - b. Take one glass of water or clear fluid every hour for 8–10 hr.
 - c. Administer one full bottle (10 oz) of magnesium citrate or X-prep at 2 PM day before test.
 - d. Administer three 5-mg Dulcolax tablets at 7 PM, evening before test.
 - e. Keep NPO after Dulcolax tablets.
 - f. Administer a suppository or a cleansing enema (or both if necessary) in early morning on day of test. Ensure bowel is clear; liquid return should be clear. If not, notify x-ray department.
7. Carry out safety precautions immediately before the procedure:
 - a. Check two forms of client identification.
 - b. Monitor safe transfer from bed to gurney or wheelchair.

For Barium Enema

1. Transport client to radiology department, usually via wheelchair.
2. Explain details of procedure to client.

Clinical Alert

If client has suspected bowel obstruction, no cathartics are given.

Clinical Alert

Barium studies should follow IVPs, ultrasound examinations, and arteriograms because barium interferes with visualization of other structures. Barium enema should precede barium swallow.

- a. A balloon rectal tube is inserted and balloon is tightly inflated against anal sphincter. ► **Rationale:** To keep barium in rectum during study.
 - b. Client is turned side to side while dripping barium into rectum using gravity flow for infusion.
 - c. Barium flow is monitored by fluoroscopy continuously and colon is examined as barium goes through colon.
 - d. Barium is drained out and an x-ray is taken to determine whether barium has been expelled.
 - e. Entire procedure takes 15 minutes to 1 hr.
3. Transport client to room.
 4. Force fluids with electrolytes unless contraindicated.
 5. Administer laxative or enema as ordered. ► **Rationale:** To facilitate bowel evacuation.
 6. Ensure client has bowel movement within 2–3 days.

For Barium Swallow Study

1. Explain purpose of procedure to client.
2. Instruct client to stay on low residue diet 1–3 days before procedure, if ordered and to stay NPO for 8 hr before test.

Small Bowel Enema

Barium is injected into a tube positioned in the small bowel. This procedure provides better visualization of the entire small bowel because the barium solution is not diluted by juices from the GI tract. This test is used when bowel obstruction is suspected.

TABLE 21-3 Barium Studies

Diagnostic Test	Rationale
Lower GI Studies	
Barium Enema	To visualize the lower GI tract for contour, patency, position and mucosal pattern of colon
Upper GI Studies	
Barium Swallow	To visualize the esophagus
Small Bowel Follow-Through	To visualize the duodenum, jejunum, and ileum

Clinical Alert

Gastrografin, a water-soluble contrast material, should be used if there is a risk of leakage of contrast material through a perforation of the GI tract. Usual dose is 16–20 ounces.

3. Administer laxative or enema the evening before procedure, particularly if this test follows barium enema study.
4. Instruct client not to smoke. ► **Rationale:** Smoking causes an increase in flow of digestive juices.
5. Transport to radiology department.
6. Explain details of procedure to client.
 - a. Client is instructed to drink a cup of flavored barium, usually in milkshake-like form, under fluoroscopic exam.
 - b. Client is instructed to turn to several positions while x-rays are obtained.
 - c. X-rays are taken every 30 minutes as barium advances. Procedure can take up to 4–6 hr.

Clinical Alert

Obtain specific orders for enemas when client has severe abdominal pain, ulcerative colitis, or history of megacolon. Do not follow general preprocedural orders.

NOTE: Upper GI series, or barium enema, provides better visualization of the bowel. Large tumors and perforations of the bowel can be identified with the CT scan.

For Small Bowel Follow-Through

- a. Barium swallow may be extended to examine duodenum and small bowel.
- b. Films can be taken as long as 24 hr later.
7. Transport client to room.
8. Force fluids unless contraindicated.
9. Administer cathartic.
10. Ensure bowel movement within 2–3 days. Enema may need to be administered.

DOCUMENTATION for Barium Studies

- Laxative administered
- Type, amount of fluid, number of enemas administered
- Enema result, consistency of stool, color of returning enema solution
- Unusual symptoms such as pain, bleeding, or nausea associated with enemas
- Color of stool after test

CRITICAL THINKING Application**Expected Outcomes**

- Client is able to cooperate with test.
- Client's bowel is clean and free of stool, promoting an accurate barium study.

Unexpected Outcomes

Barium is unable to be expelled even after administration of laxatives and enemas.

Laxatives or enemas (or both) are ordered for clients with ulcerative colitis or severe abdominal pain.

Client's medications are administered in error.

- Client is prepared and knowledgeable about what to expect during procedure.
- Client's study is completed without complications.
- Client successfully expels barium after test.

Alternative Actions

- Obtain order for and administer oil-retention enema.
- Administer tap water enema following oil-retention enema.
- Continue to administer laxatives until barium is expelled.
- Do not administer either the laxative or enema without checking with the physician.
- If physician confirms order, carefully administer small amount of enema fluid, and observe and document effects on client.
- Chart the type of pain, if any, characteristics of stool, and any symptoms noted while enema is administered.
- If client complains of excruciating pain, stop procedure and notify the physician.
- Notify x-ray department, and ask for specific orders regarding what action needs to be taken regarding the test.
- Inform physician, complete a medication error form, and send to nursing office. An unusual occurrence may need to be completed as well.
- If this is a frequent problem on the unit or in the hospital, an in-service education program should be given that includes a discussion of when medications should be given and when held.

Chapter 21

UNIT 4

Endoscopic Studies

Nursing Process Data

ASSESSMENT Data Base

- Assess vital signs before and during studies, if indicated. Some studies require general anesthesia or conscious (moderate) sedation, and scope is used that could result in perforation and bleeding.
- Assess client's knowledge of procedure to be done.
- Evaluate baseline laboratory tests, particularly those for potential bleeding problems, if biopsy is to be done.
- Evaluate if client is at risk for complications, especially infection (antibiotics may need to be ordered).
- Assess biopsy site for indications of bleeding.
- Evaluate for signs of infection after procedure.

PLANNING Objectives

- To provide information regarding procedure to decrease client's anxiety
- To determine if previous studies were completed using barium
- To evaluate potential for complications following procedure
- To position client on table correctly to facilitate optimal visual outcome and aid in diagnosing condition

IMPLEMENTATION Procedures

• Preparing for Endoscopic Studies	741
• For Arthroscopy	741
• For Bronchoscopy	742
• For Colonoscopy	742
• For Cystoscopy	743
• For Gastrointestinal Tract Endoscopy	743
• For Laparoscopy	744
• For Sigmoidoscopy	744

EVALUATION Expected Outcomes

- Client is prepared psychologically and physically for endoscopic procedure.
- Client experiences no sequelae after moderate sedation.
- Client does not experience pain or discomfort with procedure.
- Client diagnosis is confirmed with endoscopic study.

Critical Thinking Application	745
• Expected Outcomes	745
• Unexpected Outcomes	745
• Alternative Actions	745

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

TABLE 21-4 Endoscopic Procedures

Diagnostic Test	Rationale
Arthroscopy	To evaluate meniscus cartilage or ligament injury; to differentiate arthritic inflammation from injury
Bronchoscopy	To visualize larynx, trachea, bronchi, and alveoli; to diagnose bleeding sites and obtain sputum specimens
Colonoscopy	To visualize rectum and colon; to obtain tissue biopsy and remove polyps
Cystoscopy	To visualize urethra, bladder, ureters, prostate; to place stents
Gastrointestinal tract endoscopy (EGD)	To visualize esophagus, stomach, and duodenum; to obtain specimen for cell studies
Laparoscopy	To visualize abdominal cavity; to perform surgical interventions
Sigmoidoscopy	To visualize anus, rectum, sigmoid colon; to remove polyps, obliterate hemorrhoids

Preparing for Endoscopic Studies

Procedure

1. Identify client using two forms of identification and explain test to client.
2. Obtain signed consent form.
3. Complete preparation according to endoscopic test being performed.
4. Place on NPO status for 8–12 hr for gastroscopy and as directed for other procedures.
5. Remove dentures for bronchoscopy, gastroscopy procedures.
6. Provide bowel prep for laparoscopy, sigmoidoscopy, or colonoscopy to cleanse all fecal material from colon.
▶ **Rationale:** Allows adequate visualization of mucosa.
7. Obtain lab results for CBC, bleeding and clotting factors, Hgb, Hct, electrolytes if potential bleeding could occur or possible biopsy will be done with endoscopy.
8. Withhold medications that interfere with coagulation, such as ASA, NSAIDs, iron medications, and alcohol 1 week before test.
9. Complete physical assessment to determine risk factors for possible complications and allergies.
10. Notify special procedure room staff and physician of potential problems with client's condition that could interfere with procedure.

Clinical Alert

Conscious sedation is a preferred method for anxiety and pain relief during therapeutic and diagnostic procedures, particularly in the radiology department.

Versed is the most common drug used for sedation, and fentanyl is commonly administered for pain control.

Both are short-acting drugs with duration of 30–60 minutes.

See also Moderate Sedation, chapter 26, p. 983.

For Arthroscopy

1. Follow steps in Preparing for Endoscopic Studies as it applies to this procedure.
2. Explain that arthroscopy allows direct visualization of specific anatomic site (i.e., knee joint). Small trocars are placed into joint and surgical procedure is completed with direct vision of a camera attached to arthroscope.
3. Explain that client usually receives local anesthesia and procedure takes 30 minutes to 2 hr.
4. Instruct client to remain NPO from midnight if general anesthesia is to be given.
5. Instruct client in use of crutches, if necessary.
6. Shave hair 6 in. above and below involved joint, if ordered.
7. Explain procedure to client.
 - a. Anesthesia is given, either local or general.
 - b. Leg is scrubbed, elevated, and wrapped in elastic bandage from toes to lower thigh. ▶ **Rationale:** Reduce blood flow from lower extremity.
 - c. Physician places tourniquet or instills saline solution in client's knee before insertion of scope. ▶ **Rationale:** To reduce bleeding.
 - d. Knee is placed at 45° angle.
 - e. Small incision is made in skin around knee and scope is inserted into joint space.
 - f. Procedure is completed, joint is irrigated, and medication to decrease inflammation is injected into knee.
 - g. Sutures or butterfly tapes are placed on skin with pressure dressing applied over site.
8. Assess client's neurovascular status immediately after procedure.
9. Assess vital signs and observe site for potential complications (i.e., bleeding, edema, or excessive drainage).
10. Provide discharge teaching.
 - a. Elevate knee at all times when sitting, minimize use of joint for several days.
 - b. Apply ice packs according to physician's orders.

- c. Instruct client to observe for potential complications: fever, redness around site, excess drainage, or alteration in color of drainage, pain, increased edema.
- d. Ambulation with crutches is usually allowed on same day as surgery.
- e. Remind client to make postop physician appointment according to orders.

For Bronchoscopy

1. Follow steps for Preparing for Endoscopic Studies as it applies to this procedure.
2. Explain purpose of procedure to client.
3. Explain that test provides endoscopic visualization of larynx, trachea, and bronchi through insertion of flexible fiberoptic bronchoscope. Biopsies may be taken and cultures obtained during procedure. Procedure is done under local anesthetic.
4. Place client on NPO for 6–8 hr before procedure.
 - ▶ **Rationale:** This decreases risk of aspiration while gag reflex is blocked during the procedure.
5. Instruct client to practice good oral hygiene.
6. Remove dentures. ▶ **Rationale:** This prevents damage or lodging of dentures in the throat during procedure.
7. Remove contact lenses and jewelry.
8. Obtain baseline data: vital signs and respiratory assessment. ▶ **Rationale:** This provides comparison data after procedure.
9. Premedicate client with sedative and atropine if ordered. ▶ **Rationale:** These medications inhibit vagal stimulation, suppress gag reflex, and decrease the client's anxiety.
10. Assist client to relax and decrease anxiety. Instruct client to breathe through nose.
11. Client is placed in sitting or supine position in operating room or special procedure room.
12. Explain procedure to client.
 - a. Physician sprays nasopharynx and oropharynx with topical anesthetic. ▶ **Rationale:** This prevents laryngospasm, depresses gag reflex, and prevents discomfort when scope is inserted.
 - b. Client is instructed to avoid swallowing anesthetic agent. Instruct client to expectorate into emesis basin.
 - c. Bronchoscope is inserted into mouth and advanced to trachea and bronchi.
 - d. Tissue specimens or secretions are collected and sent to laboratory for study.
 - e. Bronchoscope is removed. Procedure takes about 1 hr.
13. Cleanse client's nose of lubricant after removal of scope.
14. Provide postprocedure care.
 - a. Monitor vital signs and respiratory status as with a surgical client. ▶ **Rationale:** To identify possible complications, such as bleeding or hypoxia.
 - b. Assess for respiratory difficulties (dyspnea, wheezing, apprehension, and decreased breath sounds). Call physician if this occurs.

- c. Elevate head of bed, place in side-lying position if not alert.
- d. Monitor for bloody sputum. ▶ **Rationale:** Bleeding can occur as a result of the bronchoscopy. Notify physician immediately if this occurs.
- e. Instruct client not to eat or drink until gag reflex returns, usually 1–2 hr. ▶ **Rationale:** Aspiration can occur when gag reflex is absent.
- f. Explain hoarseness and/or sore throat can occur after procedure.

For Colonoscopy

1. Follow steps in Preparing for Endoscopic Studies as it applies to this procedure.
2. Explain that procedure visualizes rectum, colon, and small bowel to detect pathologic conditions. It is used for cancer screening. Ensure barium studies were completed 10–14 days before fast. ▶ **Rationale:** Barium can decrease visualization of colon.
3. Place client on liquid diet and Dulcolax tabs 2 days before procedure, if ordered. May use just 1-day prep with Colyte. Keep on NPO for 8 hr.
4. Instruct client to drink electrolyte laxative solution (Go-lytely or Nu-lytely) the day before procedure. Take according to directions, usually 8 ounces every 15 minutes until 1 gallon taken. Entire gallon should be taken in 4 hr. Solution should be chilled (more palatable) and swallowed quickly. ▶ **Rationale:** This osmotic solution works quickly and produces a clear colon in about 4 hr if directions are followed accurately. Watery diarrhea usually begins 30–60 minutes after first glass taken.

NOTE: If client has diabetes, an implantable cardioverter defibrillator, pacemaker, or prosthetic heart valve, instruct him/her to call physician before buying bowel prep.

5. Explain side effects of nausea and fluid and electrolyte imbalance to client, especially elderly clients.
6. Instruct client to not take any routine or PRN medications when drinking electrolyte solution. ▶ **Rationale:** The medications will not be digested.
7. Obtain baseline vital signs.
8. Start peripheral IV and medicate client with a narcotic analgesic (usually Versed) as ordered.
9. Take client to special procedure room. Procedure takes 15–60 minutes.
10. Explain procedure to client.
 - a. Position client on left side with legs drawn up.
 - b. Flexible fiberoptic or video colonoscope is inserted through rectum and advanced through the sigmoid, descending, transverse, and ascending colon.
 - c. Client may experience discomfort when air is instilled into colon to open colon and advance scope.
 - d. Monitor vital signs and oxygen saturation during procedure, if needed.
 - e. Valium may be administered if client is anxious.

- f. Biopsy forceps or brush is inserted through scope to obtain specimens for study.
 - g. Tissue or secretions obtained are placed in specimen container.
 - h. Scope is removed and rectal area cleaned and dried.
11. Instruct client in discharge teaching: to report any rectal bleeding, abdominal pain, distention, or purulent rectal drainage. ► **Rationale:** These symptoms indicate possible bowel perforation or hemorrhage.
- a. Instruct client to resume normal diet and force fluids after test.
 - b. Instruct client that he or she may experience flatulence from air instillation.
12. Monitor vital signs as with any client. ► **Rationale:** Vital sign changes indicate complications, especially increased temperature and pulse and decreased blood pressure.

For Cystoscopy

1. Follow steps in Preparing for Endoscopic Studies as it applies to procedure. Review assessment to determine if cystitis or prostatitis is present. ► **Rationale:** Sepsis could occur; therefore, antibiotics may be ordered.
2. Explain that cystoscopy is used to evaluate conditions associated with urinary tract: urethra, bladder, lower ureters. It is used for both diagnostic and therapeutic procedures. Test takes 30–60 minutes.
3. Instruct in bowel prep, if ordered.
4. Keep client NPO for 8 hr if general anesthesia is given. Otherwise, a full liquid breakfast can be given. Several glasses of water may also be ordered.
5. Administer preprocedural medications 1 hr before test. Ensure consent form was signed before giving medication.
6. Place client in lithotomy position. Provide covering to preserve modesty and prevent chilling.
7. Prepare external genitalia with antimicrobial swabs.
8. Explain procedure to client.
 - a. Local anesthetic may be instilled into urethra before scope is inserted if under local anesthesia.
 - b. Cystoscope is inserted through the urethra to inspect bladder and urethral wall and facilitate a biopsy.
 - c. Bladder is filled with sterile irrigating solution to assist in distending the bladder and irrigating bladder of clots. ► **Rationale:** Irrigation allows for better visualization of bladder.
 - d. Biopsy forceps may be passed through cystoscope to obtain tissue.
 - e. Bladder is emptied, and scope removed.
9. Provide posttest instructions. Instruct client to:
 - a. Observe closely for signs of septicemia (i.e., chills, fever, flushed feeling).
 - b. Force fluids unless contraindicated.
 - c. Monitor urine for persistent bright red color. ► **Rationale:** Bleeding can occur; if present, notify physician.

EGD and ERCP

The esophagogastroduodenoscopy (EGD) can be used therapeutically for cautery and injection of sclerosing agents on bleeding varices.

Endoscopic retrograde cholangiopancreatography (ERCP) provides visualization of the bile and pancreatic ducts. Stones can be removed and stents placed in the bile ducts to drain bile.

- d. Assess for severe pain (colicky pain is normal with urethral catheterization), continual burning, and frequency.
10. Monitor vital signs.
 11. Palpate client for bladder distention and ensure client voids before discharge. ► **Rationale:** Urinary retention can be caused by edema from instrumentation.
 12. Monitor urine output for 48 hr. If client's output is less than 200 mL in 8 hr, increase fluid intake. ► **Rationale:** Anuria can indicate urinary retention due to blood clots or urethral stricture.

For Gastrointestinal Tract Endoscopy

1. Follow steps in Preparing for Endoscopic Studies as it applies to this procedure.
2. Explain that this procedure is used to visualize upper GI tract by inserting flexible fiber-optic–lighted scope.
3. Keep NPO for 6–12 hr.
4. Remove dentures.
5. Explain procedure to client.
 - a. Client taken to special procedure room.
 - b. Client is awake during procedure, usually takes 20–30 minutes.
 - c. Cardiac monitoring and pulse oximetry are done.
 - d. Throat is anesthetized by swabbing with local anesthetic, usually Xylocaine. ► **Rationale:** To decrease gag reflex.
 - e. Client is sedated with intravenous medication (usually Valium or Versed). Atropine may be administered to decrease secretions.
 - f. Client is placed in left lateral recumbent position.
 - g. Endoscope passed through esophagus to the duodenum. Can evaluate all structures as scope goes through the GI tract (termed EGD).
 - h. Air is introduced through scope to distend upper GI tract. ► **Rationale:** To maximize visualization.
 - i. Specimens may be taken and sent to lab.
6. Provide postprocedure care.
 - a. Monitor vital signs as for surgical client.
 - b. Check for signs and symptoms of bleeding or perforation. ► **Rationale:** Sharp, intense pain in stomach or chest and cool, pale skin indicate perforation.

- c. Check gag reflex. ► **Rationale:** May take 2–3 hr before gag reflex returns.
- d. Keep side rails up until effects of medications have subsided.
- e. Provide ice chips or throat lozenges for sore throat.

For Laparoscopy

1. Follow steps in Preparing for Endoscopic Studies as it applies to this procedure. Ensure consent form is signed.
2. Explain that scope is inserted through abdominal wall and into peritoneum to visualize abdominal and pelvic organs—used to assist in diagnosing pathologic conditions of pelvic and abdominal area.
3. Instruct client to discontinue anticoagulant therapy 5–7 days before test.
4. Complete bowel prep as ordered.
5. Instruct in NPO status after midnight. Client receives general anesthesia.
6. Shave and prep abdomen as ordered.
7. Start a peripheral IV as ordered. Medications may be given during procedure.
8. Have client void just before surgery. ► **Rationale:** To prevent accidental penetration of distended bladder during procedure.
9. Insert Foley catheter and NG tube before or after anesthesia administration, according to facility policy. ► **Rationale:** To prevent complications associated with penetration of distended stomach or bladder with needle placement.
10. Explain procedure to client.
 - a. Client is placed in supine position on operating room table.
 - b. Skin preparation is completed using antimicrobial swabs.
 - c. Blunt-tipped needle is inserted through small incision in periumbilical area and into peritoneal cavity.
 - d. Peritoneal cavity is filled with CO₂. ► **Rationale:** Separates abdominal wall from intra-abdominal viscera to allow better visualization of pelvic and abdominal structures.
 - e. Laparoscope with light camera is inserted through trocar and procedure completed.
 - f. Scope is removed and CO₂ is allowed to escape. It takes 24 hr to be totally eliminated.
 - g. Incision is closed with butterfly tape, spray tape, or sutures and covered with transparent dressing.
11. Provide general postop care.
12. Instruct client in discharge teaching.
 - a. Observe site for signs of infection, bleeding, increased pulse rate or fever. Notify physician immediately if these signs occur.
 - b. Instruct client that he or she will have shoulder or subcostal discomfort for 24 hr. Medicate for pain as needed.

- c. Instruct client not to do physical exercise for 4–7 days.

For Sigmoidoscopy

1. Follow steps in Preparing for Endoscopic Studies. Ensure consent form is signed.
2. Explain that test allows for visualization of rectum and sigmoid colon. Used for screening for colon polyps.
3. Ensure barium studies have not been given up to 3 days before test.
4. Administer tap water or disposable (e.g., Fleet's) enema as ordered the morning of the procedure. Clients with ulcerative colitis will not have an enema ordered. Oral cathartic may also be given.
5. Provide light dinner the night before test and then place client on NPO. Avoid heavy meat, vegetables, and fruit for 24 hr before test.
6. Have client void before procedure.
7. Explain procedure to client.
 - a. Client is placed on special table in special procedure room or in physician's examining room.
 - b. Position in a knee–chest position if using examination table and rigid scope. Place on left side with right leg bent and placed over left leg if using flexible scope.
 - c. Drape client to provide for modesty and warmth.
 - d. Physician examines the rectum digitally first.
 - e. Lubricated flexible sigmoidoscope is advanced through anus into the rectum to visualize any abnormality of rectum, sigmoid colon, and large bowel.
 - f. Client may feel pressure and need to have a bowel movement. Assure client this is usual feeling.
 - g. Air may be introduced to increase visualization of bowel wall.
 - h. Suction equipment passed through the scope may be used to remove secretions for better visualization of colon.
 - i. Biopsy may be obtained by passing a snare through scope.
 - j. Scope is removed, and client's rectal area is cleaned and dried.
 - k. Gloves are applied if nurse is assisting with cleaning. Remove gloves and wash hands.
 - l. Have client remain flat for 10–15 minutes before leaving room. Procedure takes 15–30 minutes.
8. Instruct client in discharge teaching.
 - a. Resume preexamination activities.
 - b. Monitor stools for bleeding. Bloody stools are normal first 1–2 days after test.
 - c. Instruct client to avoid enema or barium studies for at least 1 week.
 - d. Observe for signs of increased abdominal distention, increased tenderness, or rectal bleeding. ► **Rationale:** These are symptoms of bowel perforation.

DOCUMENTATION for Endoscopic Studies

- Test preparation completed
- Client teaching completed and client's ability to understand procedure evaluated
- Client's tolerance of procedure
- Preprocedure and postprocedure vital signs, if required
- Record type of specimen taken and sent to lab
- Specific postprocedure care given and client's response to treatment
- Specific signs and symptoms indicating potential complications

CRITICAL THINKING Application

Expected Outcomes

- Client is prepared psychologically and physically for endoscopic procedure.
- Client experiences no sequelae after moderate sedation.
- Client does not experience pain or discomfort with procedure.
- Client diagnosis is confirmed with endoscopic study.

Unexpected Outcomes

Lower gastrointestinal tract not clear and sigmoidoscopy not completed.

Vertigo occurs while maintaining knee–chest position during sigmoidoscopy.

Upper gastrointestinal bleeding begins when scope inserted.

Potential colon perforation after endoscopic procedure.

Potential infection after cystoscopy.

Client goes from minimal sedation to anesthesia when administering Versed for conscious sedation.

Alternative Actions

- Repeat laxative and enemas per physician orders.
- Observe results of enema; if solution not clear, notify physician.
- Have client lie in supine position for few minutes.
- Have client assume standing position slowly.
- Have client assume Sims' position.
- Insert nasogastric tube, and apply suction.
- Monitor vital signs for evidence of shock.
- Place in semi-Fowler's position.
- Assess for abdominal distention, tenderness, and pain.
- Notify physician immediately.
- Ensure client has a patent IV line, if not, insert peripheral line.
- Instruct client to force fluids to maintain constant flow of urine and prevent accumulation of bacteria in bladder.
- Instruct client on signs and symptoms of sepsis: fever, flushing, chills, increased pulse rate, and feeling faint. Instruct client to notify physician immediately if any of these occur.
- If client has been given prophylactic antibiotics, instruct in taking them as ordered. Do not stop taking the medication; take entire prescription.
- Call the Rescue Team.
- Have Code Cart available.
- Maintain respirations with Ambu bag or rescue breathing.
- Infuse additional IV fluids.
- Administer flumazenil as an antidote if ordered.

Chapter 21

UNIT 5

Fluid Analysis and Microscopic Studies

Nursing Process Data

ASSESSMENT Data Base

- Assess vital signs before, during, and after the procedure.
- Assess client’s ability to maintain position necessary for procedure.
- Assess client’s knowledge of the procedure to be performed.
- Review pertinent laboratory tests before procedure.
- Evaluate signs and symptoms that indicate a potential problem could exist if test performed.

PLANNING Objectives

- To provide reassurance for clients undergoing diagnostic tests
- To position the client in a manner that facilitates the introduction of a needle through the skin surface to obtain a fluid or tissue sample
- To obtain tissue or fluid to determine presence of infection or diseases
- To obtain body fluids for specific disease analysis
- To aspirate fluid to relieve pressure on body organs

IMPLEMENTATION Procedures

- Assisting With Lumbar Puncture 747
- Assisting With Liver Biopsy 748
- Assisting With Thoracentesis 749
- Assisting With Paracentesis 750
- Assisting With Bone Marrow Aspiration 751
- Assisting With Vaginal Examination and Papanicolaou (Pap) Smear 751
- Assisting With Amniocentesis 752

EVALUATION Expected Outcomes

- Client is prepared psychologically and physically for procedure.
- Diagnostic tests performed with minimal discomfort and no untoward effects.
- Specimens from studies sent to laboratory according to hospital policy, in appropriate container and in a timely manner.

Critical Thinking Application 753

Prepare for success with NCLEX®-style practice questions and Skill Checklists

TABLE 21-5 Diagnostic Procedures

Diagnostic Test	Rationale
Lumbar puncture	To obtain a cerebrospinal fluid specimen to determine presence of microorganisms, RBCs, or WBCs
Liver biopsy	To obtain a specimen to determine presence of tumor or disease
Thoracentesis	To remove fluid from the thoracic cavity; to obtain a specimen for cell study
Paracentesis	To remove fluid from the abdominal cavity; to obtain a specimen for cell study
Bone marrow aspiration	To study cells obtained from the specimen
Vaginal examination and Papanicolaou smear	To determine cell changes through a smear; to obtain a specimen for venereal disease identification
Amniocentesis	To remove amniotic fluid for studies of fetal maturity and genetic abnormalities

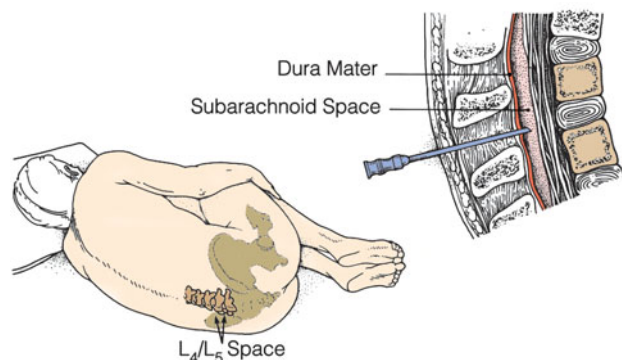

Assisting With Lumbar Puncture

Equipment

- Diagnostic tray or equipment specific for procedure
- Bath blanket
- Sterile collection bottles or test tubes if indicated and not on tray
- Sterile gloves
- Xylocaine injection or EMLA cream if not on tray
- Examining light
- Clean gloves
- Dressing or band aid

Procedure

1. Identify client using two forms of identification and explain that a lumbar puncture (LP) is used for diagnosis of tumors, hemorrhage, infection, and autoimmune diseases involving CNS.
2. Explain procedure—a hollow core needle is placed in the subarachnoid space at L3–4 or L4–5 to facilitate measuring CSF pressure and obtaining fluid for testing.
3. Obtain history of client's complaints, including known allergies and current medications.

▲ Place client in Sims' position to facilitate needle insertion for lumbar puncture.

Clinical Alert

This procedure is contraindicated in clients with increased intracranial pressure. A reduction in pressure may cause a herniation of the brainstem. It is also contraindicated if infection is present at puncture site or client is uncooperative.

4. Obtain consent.
5. Instruct client to empty bowel and bladder.
6. Perform hand hygiene.
7. Obtain tray and any additional equipment needed, such as sterile gloves, bath blanket.
8. Position client in lateral recumbent position with back at the edge of the examining table. Cover with bath blanket, exposing only client's back.
9. Open sterile tray if requested by physician. Pour antiseptic solution into sterile medicine cup if needed.
10. Instruct client to pull knees up to abdomen and flex chin on chest. Assist client to maintain position, by nurse standing in front of the client, reaching across to support client behind neck and knees. ► **Rationale:** This position widens the space between the spinous processes of the lower lumbar vertebrae for ease of needle insertion.
11. Place pillows between knees. ► **Rationale:** This prevents upper legs from sliding off lower legs.
12. Assist client in relaxation exercises or instruct in deep, slow breathing through the mouth.
13. Use Xylocaine or EMLA cream around site before needle insertion by physician.
14. Explain that he or she must remain still without movement during test.
15. Assist physician with the Queckenstedt's test when requested. After opening pressure is obtained, apply compression to neck veins with your fingers.
16. Don clean gloves and assist physician as directed.

Clinical Alert

Queckenstedt's test is used to identify blockage of CSF flow in the spinal subarachnoid space. Generally when neck pressure is applied, there is a rapid rise in pressure level on the manometer with a return to normal within seconds when pressure is released.

17. Label cerebrospinal fluid samples with number on each specimen container.
18. After removal of needle, apply Band-Aid to puncture site.
19. Remove gloves and perform hand hygiene.
20. Fill out lab slips for appropriate test (i.e., cell count, serology).

21. Instruct client to lie flat for 4–24 hr, depending on hospital policy. Head is to remain flat and even with position of body. ► **Rationale:** To reduce CSF leakage.
22. Encourage fluids if not contraindicated by client's condition. ► **Rationale:** To reduce chance of headache.
23. Observe for spinal fluid leak from puncture site.
24. Check for headaches or alterations in neurologic status.
25. Document cerebrospinal fluid (CSF) characteristics, including color and clarity. Record opening pressure.

Assisting With Liver Biopsy**Equipment**

Same as for Assisting With Lumbar Puncture

Procedure is often done through ultrasound to guide the needle to pathologic site.

Tray with equipment, sterile gloves, 2 × 2 dressing, and tape

Preparation

1. Obtain lab values before scheduled test: prothrombin time, bleeding time, and platelet count if ordered. ► **Rationale:** Liver is vascular and if these lab results are abnormal, bleeding may occur after procedure.
2. Determine if a blood typing and crossmatching is needed.
3. Determine if client is to be NPO. Need to be NPO for 6 hr.
4. Identify client using two forms of identification and explain that tissue will be removed after special needle is inserted into liver. Tissue will be studied to determine presence of disease.
5. Obtain consent.
6. Assess whether client has any allergies to topical anesthetic agents.

Procedure

1. Perform hand hygiene.
2. Take vital signs. ► **Rationale:** This provides baseline data to compare with postprocedure data.
3. Administer sedative as ordered.
4. Obtain tray and any additional equipment needed, such as sterile gloves, sandbag, bath blanket.
5. Place client in supine position at the right edge of the bed. Raise right arm and extend it over the left shoulder

▲ Instruct client to raise arm over head to facilitate needle insertion for liver biopsy.

behind the head. If possible, turn head to left side.

► **Rationale:** This position provides maximal exposure of right intercostal space.

NOTE: Left lateral position can be used for biopsy.

6. Open sterile tray if requested by physician.
7. Local anesthesia is used around puncture site.
8. Instruct client to inhale and exhale deeply several times and then exhale and hold breath while physician inserts the biopsy needle. ► **Rationale:** Holding the breath prevents the needle from tearing the diaphragm or lacerating the liver as it descends during exhalation.

Clinical Alert

A liver biopsy is contraindicated in clients with platelet counts below 50,000/mm³ or prolonged prothrombin time. Bleeding can occur after the procedure.

9. Instruct the client to breathe normally after the physician removes the needle.
10. Don clean gloves and place Band-Aid or small dressing over puncture site.
11. Position client on right side for 2–4 hr. A folded blanket may be placed under client's right side to provide hemostasis. ► **Rationale:** This position compresses the liver against the chest wall, thereby decreasing risk of hemorrhage.
12. Remove gloves and perform hand hygiene.
13. Instruct client to remain on bed rest for 24 hr.
14. Assess for signs of hemorrhage at least every hour for 12 hr.
15. Monitor vital signs as you would for a surgical client (e.g., every 15 minutes for 1 hr).
16. Assess rate, rhythm, and depth of respirations.
17. Assess breath sounds and check for signs of dyspnea and restlessness. ► **Rationale:** Lung may be punctured during biopsy.
18. Send specimen to lab.

Assisting With Thoracentesis

Equipment

Same as for Assisting With Lumbar Puncture

Vacutainer

Interventional radiologist may perform biopsies using CT or ultrasound (paracentesis and thoracentesis) for better visualization of organs.

Sterile gloves

Sterile pressure dressing and tape

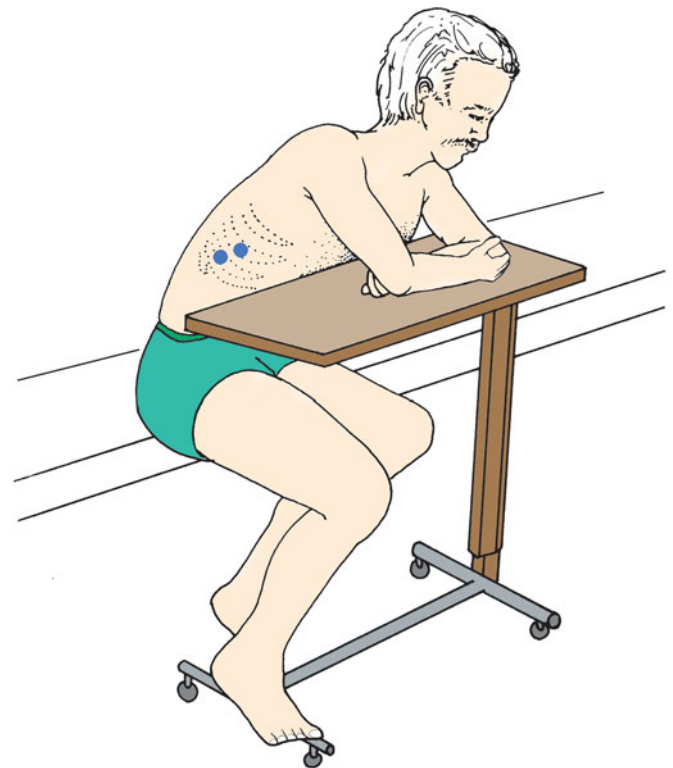

Preparation

1. Identify client using two forms of identification and explain purpose of procedure to client.
2. Explain that needle is inserted into pleural space for removal of fluid for either diagnostic tests or to relieve pleural pressure.
3. Obtain consent.
4. Ensure chest x-ray film has been taken. ► **Rationale:** This film is used to compare with the film taken after the procedure.
5. Assess if client has any allergies to topical anesthetic agents.
6. Explain that movement or coughing must not be done during procedure to prevent lung or pleural damage.
7. Ensure client has IV for emergency medication administration.

Procedure

1. Perform hand hygiene.
2. Take vital signs, and complete a respiratory assessment. ► **Rationale:** This information provides postprocedure comparisons and early identification of potential complications.
3. Administer sedative as ordered.
4. Position client on edge of bed with arms crossed and resting on the overbed table. ► **Rationale:** This position provides good access to the intercostal spaces and facilitates fluid removal.

NOTE: Client can be placed in side-lying position on unaffected side if unable to sit up.

▲ Place client in a leaning forward position to expose intercostal space for thoracentesis.

5. Provide adequate warmth and covering for client using bath blanket.
6. Place unwrapped sterile tray on bedside stand.
7. Open sterile gloves as indicated. Maintain sterile technique throughout procedure.
8. Assist physician as needed with skin prep.
9. Don clean gloves. Instruct client not to cough, take a deep breath, or move during placement of needle by the physician.
10. After insertion of needle into pleural space, observe client for pallor, dyspnea, tachycardia, chest pain, or vertigo. Report these findings immediately to the physician. ► **Rationale:** These symptoms occur with a pneumothorax.

11. Connect tubing to vacutainer, allowing fluid to be drawn from cavity.

NOTE: Blunt-tip, soft catheter-over-needle is used more often than a needle to prevent pneumothorax.

12. Apply pressure dressing (as determined by policy) after fluid and needle are removed. Remove gloves and perform hand hygiene.
13. Observe client every 5 minutes for half hour for pulmonary edema (blood-tinged sputum), crepitus, cardiac distress (changes in respirations, pulse, or color), or a shift in the mediastinum.
14. Place client on unaffected side with head elevated 30° for at least 1 hr.
15. Monitor vital signs and breath sounds as with postoperative clients for 2 hr.
16. Observe dressing, change as needed. ► **Rationale:** Drainage is a common occurrence after a tap.
17. Obtain chest x-ray after procedure to check for pneumothorax.
18. Record color, amount, consistency, and samples of fluid obtained.
19. Complete lab slips, and send specimen to lab.

Assisting With Paracentesis

Equipment

Same as for Assisting With Lumbar Puncture

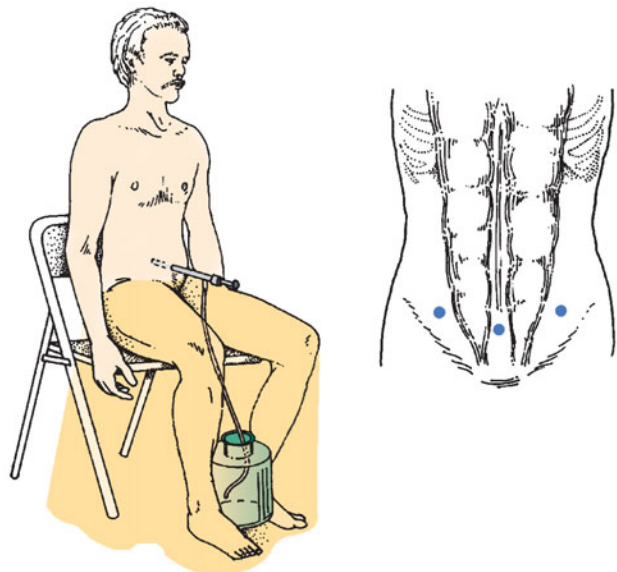

Sterile tray
 Vacutainer
 Chair
 Drape
 Sterile gloves
 Bucket
 Dressing-elastic adhesive patch
 Blood pressure equipment
 Clean gloves

Preparation

1. Identify client using two forms of identification and explain purpose of procedure to client.
2. Explain that needle is inserted into peritoneal cavity and fluid removed for fluid analysis or to remove fluid from cavity to promote comfort and increase respiratory status.
3. Obtain consent.
4. Assess whether client has any allergies to topical anesthetic agents.
5. Assess whether client has coagulation abnormalities or bleeding tendencies. (Procedure is contraindicated in these clients.)
6. Perform hand hygiene.
7. Assess client's abdominal girth and bowel sounds.
 ► **Rationale:** This information provides postprocedure comparisons and early identification of potential complications.
8. Have client empty bladder. ► **Rationale:** This prevents accidental puncture of the bladder during the procedure.
9. Weigh client. ► **Rationale:** This information can be used to assess fluid loss after the procedure.

Procedure

1. Place client in Fowler's position on chair or on edge of bed with legs spread apart.
2. Drape client, and provide adequate warmth and covering with a bath blanket.
3. Obtain vital signs, and observe client for pallor and vertigo during procedure. ► **Rationale:** These symptoms are indicative of shock.
4. Position and open tray on over-bed table.
5. Open sterile gloves if needed.
6. Assist physician in preparing skin with antiseptic solution and topical anesthesia or as needed.
7. Don clean gloves.
8. Physician inserts trocar needle, or cannula through small incision. Plastic tubing is attached to cannula

▲ Position client in chair to facilitate trocar insertion and drainage for paracentesis.

and other end of tubing is placed in the collection receptacle. Vacutainer may be used to provide gentle suction of fluid from cavity.

9. Observe total amount of fluid aspirated. Usually no more than 2000 mL (2 L) is removed at one time.
 - ▶ **Rationale:** Removing larger amounts of fluid can lead to hypotension and hyponatremia.
10. Apply pressure dressing after removal of needle.
 - ▶ **Rationale:** This prevents bleeding from puncture site.
11. Remove gloves, and place in appropriate receptacle.
12. Perform hand hygiene.
13. Return client to bed and place in semi- to high-Fowler's position. ▶ **Rationale:** These positions usually are most comfortable for client and promote lung expansion.
14. Observe for leakage at puncture site or scrotal edema in male client.
15. Monitor vital signs and observe closely for signs of hypotension. Monitor urine output and color and dressing every 15 minutes for at least 2 hr; every hour for 4 hr; every 4 hr for 24 hr.
16. Assess bowel sounds, and measure abdominal girth.
 - ▶ **Rationale:** To monitor for signs of perforated bowel or peritonitis.
17. Weigh client when vital signs are stable. ▶ **Rationale:** This prevents hypotension.
18. Reinforce or change dressings as needed.
19. Monitor serum protein and electrolytes, particularly sodium. ▶ **Rationale:** Fluid contains high levels of protein that is removed with this procedure.
20. Record color, amount, consistency, and samples obtained from paracentesis, and send to laboratory.

Assisting With Bone Marrow Aspiration

Equipment

Same as for Assisting With Lumbar Puncture
Two slides
Green or lavender top tube
Preservative spray
Sterile gloves

Procedure

1. Identify client using two forms of identification and explain purpose of procedure.
 2. Explain procedure.
 3. Client will experience discomfort or pressure when needle is inserted.
 4. Obtain consent
 5. Obtain tray and provide any additional equipment needed, such as specimen container.
 6. Assess coagulation studies and report unusual findings to physician.
 7. Premedicate client with prescribed drugs.
 8. Position client in supine position if sternum or anterior iliac crest is the biopsy site or prone if posterior iliac crest is the biopsy site. Place a sandbag under iliac crest area if physician requires.
 9. Open tray on over-bed table.
 10. Assist physician as needed.
 11. Physician injects local anesthetic at site.
- NOTE:** A large-bore needle containing a stylus is inserted into bone, about 3 mm deep. Stylus is removed and 10-mL syringe is attached to needle. About 0.5 to 2 mL of bone marrow is removed as specimen, spread on slides, and sprayed with preservative. Remainder is placed in green or lavender top tube.
12. Perform hand hygiene and don sterile gloves.
 13. Apply direct pressure for 5–15 minutes after removal of needle. ▶ **Rationale:** To prevent bleeding.
 14. Cover puncture site with sterile pressure dressing. Ice pack may be applied to help control bleeding.
 15. Remove gloves and perform hand hygiene.
 16. Monitor vital signs, and observe puncture site for drainage, edema, or pain, as with surgical client. ▶ **Rationale:** To monitor for signs of infection. Call physician for temperature above 101°F.
 17. Position the client for comfort.
 18. Properly label specimens and send to laboratory.
 19. Evaluate client for signs of hemorrhage, shock, or infection.

Assisting With Vaginal Examination and Papanicolaou (PAP) Smear

Equipment

Two slides
Cytology container
Fixative agent
Vaginal speculum, several sizes
Gloves

Water-soluble lubricant jelly
Examining light

Preparation

1. Identify client using two forms of identification and explain purpose of procedure.

2. Explain that test is performed to detect neoplastic cells in cervical and vaginal secretions. Procedure takes 10 minutes.
3. Instruct client not to douche, insert vaginal medications, or take tub bath for 24 hr before exam.
4. Instruct client that test should be done 2 weeks after start of last menses.
5. Instruct client to refrain from sexual intercourse for 24–48 hr before exam, according to physician's orders.
6. Foods or fluids are not restricted.

Procedure

1. Instruct client to empty bladder.
2. Assist client to examination room.
3. Instruct client to remove clothing including underwear and don gown.
4. Position client on examining table in lithotomy position using stirrups.
5. Provide adequate coverings to preserve modesty and prevent chilling.
6. Open speculum package, gloves, and lubricant. Place on tray. Place cytology slides and container on tray.
7. Label two slides with client's name and area from where specimen is obtained.
8. Position light for good exposure.
9. Stay with client if she is a child or physician is a male.
10. Assist physician as needed. A lubricated speculum is inserted into vagina.
11. Instruct client that material is collected from cervical canal by rotating either a cotton swab moistened with saline or a wooden spatula.
12. Wipe swab across a clean glass slide to disperse cells.
13. Affix to slide either by immersing the slide in equal parts of 95% alcohol and ether or by using a commercial hair spray. ► **Rationale:** Secretions must be fixed before drying to prevent abnormal interpretation of smears.
14. Place slides in cytology container and send to the lab. Complete all cytology forms. Client's medical history and reason for examination are written on request form.
15. Assist client in perineal care.
16. Provide perineal pad if bleeding occurs.
17. Assist client to dress if necessary.

Assisting With Amniocentesis

Procedure

1. Identify client using two forms of identification and explain purpose of procedure to client.

NOTE: Test is to withdraw fluid for analysis to check fetal maturity status, sex of fetus, genetic or chromosomal abnormalities, hereditary metabolic disorders, anatomical abnormalities, or fetal distress.

2. Obtain consent, both client and her partner.
3. Explain that foods and fluids are not restricted. Have client void before test. ► **Rationale:** This prevents injury to the bladder. Before 20 weeks of gestation, bladder may be kept full to support the uterus.
4. Transport client to treatment room.
5. Instruct client to lie quietly in supine position for 30 minutes.
6. Obtain fetal heart tones and mother's blood pressure.
7. Open amniocentesis tray and gloves. Place Xylocaine nearby if not included on tray. ► **Rationale:** Procedure is performed under sterile conditions to prevent infection.
8. Explain details of procedure to client.
 - a. Physician prepares abdomen with antiseptic solution or alcohol.
 - b. Xylocaine injection provides local anesthesia for needle insertion area.
 - c. Placenta and fetus are located manually or by ultrasound.
 - d. A 22-gauge spinal needle with a stylet is inserted through the midabdominal wall and 5 to 15 mL of amniotic fluid is withdrawn.
 - e. Amniotic fluid is placed in light-resistant specimen container and labeled with client's name. Appropriate lab slips are completed. ► **Rationale:** To prevent breakdown of bilirubin.
 - f. Procedure takes about 10 minutes.
9. Perform hand hygiene and don sterile gloves and place small dressing or Band-Aid over needle site.
10. Remove gloves and perform hand hygiene.
11. Monitor fetal heart tones and observe for signs of labor.
12. Observe puncture site for bleeding or other drainage.
13. Instruct client to notify physician of any unusual occurrences, signs of labor, or signs of infection.
14. Give RhoGAM if woman is Rh-negative. ► **Rationale:** There is a risk of immunization against fetal blood (hemolytic disease).
15. Explain that test results will be available in 2 weeks.

DOCUMENTATION for Fluid Analysis and Microscopic Studies

- Preparation completed for test
- Client teaching completed and client's ability to understand procedure evaluated
- Consent form signed
- Client's tolerance of procedure
- Fluid or specimens sent to laboratory for analysis
- Preprocedure and postprocedure vital signs if required
- Color and amount of fluid withdrawn from paracentesis, thoracentesis, or lumbar puncture
- Fetal heart tones before and after amniocentesis
- Type of dressing applied
- Specific position assumed after procedure as indicated
- Abnormal findings after procedure indicating potential complications

CRITICAL THINKING Application

Expected Outcomes

- Client is prepared psychologically and physically for procedure.
- Diagnostic tests performed with minimal discomfort and no untoward effects.
- Specimens from studies sent to laboratory according to hospital policy, in appropriate container and in a timely manner.

Unexpected Outcomes

Client has spinal fluid leak after lumbar puncture.

Alternative Actions

- Keep client in supine position.
- Notify physician.
- Keep sterile dressing over puncture site. Do not allow dressing to become wet.
- If leak persists, physician may place client in Trendelenburg's position to prevent headache. This position is contraindicated in clients with increased intracranial pressure or after a craniotomy.

Client complains of shortness of breath or expectorates blood-tinged sputum after a thoracentesis.

- Place client in Fowler's position.
- Assess vital signs.
- Administer oxygen.
- Monitor breath sounds.
- Notify physician and check on order for chest x-ray.
- Have chest tube insertion tray available.
- Allay client's fears and provide emotional support.

Urine output is blood-tinged after paracentesis or amniocentesis.

- Notify physician at once; bladder may have been punctured during procedure.
- Monitor vital signs for shock.
- Maintain client on bed rest.
- Observe for urine output.

GERONTOLOGIC Considerations

Elderly Clients Requiring Diagnostic Tests Are at Risk for the Following Problems:

- Dehydration can result from fluid restriction, use of contrast agents for the tests, and bowel preparation using enemas. Osmolar imbalances and hypovolemia can result from the dehydration.
- Extracellular fluid volume excess can occur if large volumes of fluid are required for the test. Renal studies, which usually require the use of large volumes of fluid, should not be considered if the client is at risk for circulatory overload. Elderly clients may have a compromised cardiorespiratory status. A secondary choice of tests may need to be considered, such as a CT scan.
- Renal dysfunction resulting from multiple tests using contrast agents should be avoided. Acute renal failure can result from multiple tests with contrast agents in elderly clients who already have a compromised renal system. Spacing tests over time helps prevent this problem.

Nursing Responsibilities for Elderly Clients Requiring Diagnostic Tests Should Include the Following:

- Carefully monitor fluid and electrolyte balance.
- Adequately hydrate client before and after tests unless contraindicated.

- Monitor laboratory tests, such as electrolytes and osmolarity.
- Monitor intake and output frequently.
- Monitor vital signs.
- Weigh clients who are at risk for fluid volume disturbances.
- Complete physical assessment, including mental status, each shift, and report unusual findings to physician.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- LVNs/LPNs and RNs may both be assigned to care for clients undergoing diagnostic tests. Nurses are frequently working in x-ray and diagnostic procedure laboratories today and assisting physicians with invasive procedures. Technicians are also educated to work in areas such as cardiac catheterization labs. These technicians are not nursing personnel. In most cases, radiologic technologists assist with the various procedures within the x-ray and diagnostic procedure labs.
- When invasive procedures such as liver biopsy and paracentesis are performed on the nursing unit, either an LVN/LPN or RN is assigned to assist the physician.
- Preprocedure and postprocedure interventions are assigned to the LVN/LPN or RN for direct responsibility. A CNA may assist the nurse by taking vital signs.

- Only RNs can transport clients who have received conscious sedation for a procedure.

Communication Matrix

- All staff members must be aware of clients undergoing diagnostic tests. This information is disseminated through shift and team reports. It is also written on the Kardex card or is on the client's information sheet on the computer. If premedication is required, this information is found on the Medication Administration Record as well. If the client is NPO for the test, a sign must be placed in the client's room indicating this status.
- Specific directions must be given to the staff member assigned to the client to inform them of their client care responsibilities both pre- and postprocedure.
- The RN must assess the knowledge base of the staff member assigned to assist the physician with any procedure being performed on the unit. This is to ensure safety for the client.
- The RN collaborates with the physician to identify any specific equipment or needs he or she may have for the procedure being performed on the unit.

CRITICAL THINKING Strategies

Scenario 1

Mr. Michael Spicer, a 72-year-old retired fireman, is scheduled for the following diagnostic procedures as an outpatient. He has started his testing with a barium enema. You have been asked to call him and instruct him about the procedures.

Diagnostic Tests to be Completed

- IV pyelography
 - Bone scan
 - Sigmoidoscopy
1. What is the priority question you should ask? Provide rationale for your answer.
 2. When beginning the discussion about the IVP, what is your priority question? Provide rationale for your answer.
 3. Identify the most important postprocedure client education regarding the IVP. Provide rationale for your answer.
 4. The client asks you if he will be radioactive and a risk to his family after the bone scan. What is your best response?
 5. Briefly explain the preprocedure prep for the sigmoidoscopy.

Scenario 2

A young 30-year-old client has been referred to the surgeon for further evaluation of a lump in the upper, outer quadrant of her left breast. You work with the physician and are obtaining the history from the client. She tells you she noticed the lump about 1 month ago. When you examine the breast you feel a quarter size lump without dimpling of the nipple.

1. The client asks you how will they know if it is benign or malignant? Your best response is:
2. She is very anxious and asks you questions about the various procedures that they do now to determine whether surgery is necessary. Explain the various diagnostic tests that are completed and prioritize the tests according to usual protocol for completion of the tests.
3. Describe the preprocedural instructions for the procedures listed in #2.

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. Nurses' major responsibility with interventional radiology is related to
 1. Assisting the radiologists in preparing the client for the procedure.
 2. Managing procedural sedation, monitoring, and postprocedure recovery.
 3. Monitoring vital signs during the procedure.
 4. Providing client education about the procedure.
2. Dynamic CT scanning is best defined as
 1. Visualizes blood flow and degree of vascularity of organs via dye injection to specific organs.
 2. Using sound waves produced by ultrasound to differentiate normal from diseased tissue.
 3. Observation of internal body organs and cavities by introducing the endoscope and then obtaining scans of the organs or cavities.
 4. A scan that uses a strong magnetic field in conjunction with radiofrequency waves to transmit signals from body cells to the computer.
3. Which one of the following preparations would not be included in the procedure for x-ray studies?
 1. Determine, if several studies are ordered, which one needs to be completed first.
 2. Ensure informed consent form is signed.
 3. Inform the client there is no restriction to food or fluid necessary before the tests.
 4. Determine need for withholding medications before the x-ray.
4. What are the client instructions when undergoing an intravenous pyelography (IVP)?

Select all that apply.

 1. "You should not eat anything after 6 PM but you can take fluids until early morning."
 2. "Do you have any allergies to shellfish or iodine?"
 3. "Dye injection material can cause nausea, shortness of breath, and a hot, flushed feeling."
 4. "Drink at least 24 ounces of water immediately after the IVP."
5. Which of the following baseline lab values need to be obtained before an arteriography?
 1. Hemoglobin and hematocrit.
 2. WBC, RBC, SGOT, SGPT.
 3. BUN, creatinine, PT/PTT, APTT.
 4. MVP, platelets, blood smear.
6. You are obtaining a history before scheduling the client for a bone scan. The most important question to ask is
 1. "Have you had a barium study done in the last 10 days?"
 2. "You have had a bone scan before; do you have any questions?"
 3. "Do you suffer from claustrophobia?"
 4. "Do you have someone who can take you home after the test?"
7. Printed instructions frequently provided a client scheduled for a mammogram include
 1. Remain NPO for at least 6 hr before the test.
 2. Refrain from wearing deodorant.
 3. Remove jewelry from neck and wrists.
 4. Wear easy to remove clothing as it must all be removed.
8. As you observe the catheter insertion site after a cardiac catheterization, which of the following interventions would be considered a priority to implement?
 1. Apply a pressure dressing over the site.
 2. Call lab to order a CBC, HGB, and HCT.
 3. Elevate the extremity.
 4. Monitor peripheral pulses.
9. A major reason why PET scans are used in place of the CT scan or MRI is
 1. It is not necessary to have an IV or dye injection for the PET scan.
 2. Metabolic changes, which are visualized on the PET scan, occur before structural changes.
 3. It takes only a few minutes for a PET scan, whereas it can take up to 75 minutes for an MRI.
 4. Foods or fluids do not need to be restricted with the PET scan.
10. A client is very fearful and asks you about the arthroscopy he is scheduled to have in the afternoon. Which of the following responses would be most appropriate?
 1. "You will receive general anesthesia, not local anesthesia, so you will not experience any pain."
 2. "The procedure will take about 2 to 3 hours."
 3. "The incision will probably be under the knee cap and you will have sutures to hold the tissue in place."
 4. "You will most likely be able to ambulate with crutches the same day."

Urinary Elimination

LEARNING OBJECTIVES

1. Describe the process of urine production.
2. List four alterations that result in urinary elimination problems.
3. State two nursing diagnoses that relate to urine elimination.
4. Complete an intake and output bedside record.
5. Compare and contrast the steps for inserting a straight catheter in a male and female client.
6. Describe the major parameters needed to preserve a sterile environment when inserting a catheter.
7. Demonstrate the clamping protocol used for clients with suprapubic catheters.
8. Explain how a catheter is attached to a leg bag.
9. Identify the most important advantages of a suprapubic catheter.
10. List the major steps of irrigating by opening a closed urinary system.
11. Outline the steps necessary to obtain a urine specimen from a closed urinary drainage system.
12. Outline the steps for applying a urinary diversion pouch.
13. Describe rationale for renal replacement therapy.
14. List safety precautions for maintaining a fistula or graft for vascular access for hemodialysis.

TERMINOLOGY

Albuminuria the presence of albumin in the urine.

Anemia a condition in which the number of circulating red blood cells, or hemoglobin, is reduced.

Antibiotic a substance that inhibits or kills bacteria.

Antidiuretic Pituitary hormone that causes water reabsorption by the distal tubule of the nephron.

Anuria suppression of urine production (less than 100 mL/day).

Arteriovenous extracorporeal circuit created with arterial to venous blood flow. The client's blood pressure forces blood through a hemofilter and back to a venous return access.

A-V fistula anastomosis of a vein with an artery as an access site for hemodialysis.

Azotemia increased levels of BUN and creatinine in the blood.

Bactericidal able to kill bacteria.

Calyx cuplike portion of the kidney pelvis.

Catheterization insertion of a tube for the injection of or removal of fluids from a vessel or body cavity.

Coude Catheter an elbowed catheter used for draining urine from bladder.

Dehydration the process of losing excessive water.

Dialyzer artificial kidney.

Distention stretching or inflating a structure such as the bladder.

Diuresis the excessive production of urine.

Dysuria painful urination.

Edema a condition of excess fluid in the interstitial space.

Electrolyte a substance that develops an electrical charge when dissolved in water.

End-stage renal disease the loss of 90% of kidney nephrons resulting in accumulation of nitrogenous wastes in the blood and uremia necessitating dialysis.

Excoriation a breakdown of the epidermis.

Foley catheter a self-retaining indwelling tube that is used to provide continuous drainage, usually from the bladder.

Genitourinary pertaining to the genital and urinary systems.

Hemodialysis process of removing excess fluid and accumulated wastes and electrolytes from the blood.

Hydrostatic pressure pumping force created by the mean arterial blood pressure, or a pump.

Incontinence inability to retain urine.

Indwelling urethral catheter a retention, or Foley, catheter.

Infection condition in which the body or a part is invaded by pathogens.

Irrigation the flushing of a tube or area with solution.

Micturition the process of emptying the urinary bladder; voiding.

Nocturia urination during the night.

Oliguria diminished production of urine (400 mL/day).

Patency the state of being freely open.

Peri prefix meaning around or about.

Peristalsis a progressive wavelike movement that occurs involuntarily in hollow tubes in the body.

Polyuria the excessive production of urine (output >2 liters/day).

Pyuria the presence of pus in the urine.

Renal pertaining to the kidney.

Sediment a substance settling at the bottom of a liquid.

Sepsis presence of pathogens or their toxins in the blood.

Septicemia presence of pathogens in the blood.

Shock a state of inadequate tissue perfusion.

Specific gravity weight of a substance compared with an equal volume of water. Water is 1.000.

Stoma surgically created opening.

Ultrafiltrate fluid collection from the blood which is isotonic and devoid of red blood cells or protein.

Urethra a canal for the discharge of urine from the bladder to the outside.

Urinary diversion an alternate route for urine elimination.

Urinary tract infection (UTI) an infection of the urinary tract, including all or part of the organs and ducts.

Venovenous extracorporeal circuit created using a dual-lumen hemodialysis catheter inserted into a central vein. Blood flow through the dialysis circuit is pump-controlled.

URINARY SYSTEM

The structures of the urinary system are the kidneys, ureters, bladder, and urethra. Each kidney produces urine, which is carried to the bladder by a ureter that is about 25 cm (10 in.) long and 0.6 cm in diameter. Peristaltic waves, pressure, and gravity propel urine through the ureters so that it can be discharged into the bladder.

The bladder serves as a reservoir for urine until voiding takes place. When voiding, or urination, occurs, urine passes through two sphincters and is transported from the bladder to the external environment through the urethra. The kidneys are essential to life, but the urine collection system is not.

The anatomic position of the bladder and the structure of the urethra differ in males and females. The bladder is posterior to the symphysis pubis. In a female the bladder is anterior to the vagina and the neck of the uterus. In a male the bladder is anterior to the rectum. The urethra of the female is about 4 cm (1.5 in.) long, and the male urethra is 20 cm (8 in.) long.

The urethra, bladder, ureters, and kidney pelvis are lined with a continuous layer of mucous membrane. Because there is continuity of the lining, bacteria introduced into the normally sterile system can spread throughout the urinary tract. When the bladder is empty, its lining falls into folds that provide pockets where bacteria can multiply. Since the membrane is highly vascular, bacteria can easily enter the bloodstream and septicemia can result.

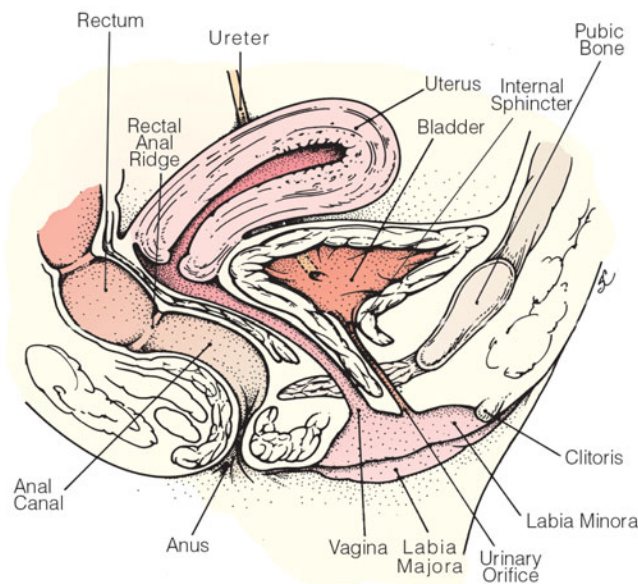

Urine Production

Nephrons, the functional units of the kidneys, produce urine. Each nephron consists of a renal corpuscle (Bowman's capsule) and a renal tubule, which is surrounded by a capillary bed. Each kidney has approximately a million nephrons.

Urine formed in the renal tubules enters collecting ducts, which empty urine into the kidney calyx. As urine collects in the renal pelvis, it flows to the bladder. If movement of urine from the pelvis is interrupted, infection, hydronephrosis, or formation of calculi may occur.

Blood is circulated to kidneys by way of the renal artery. This artery branches into arterioles, which supply a capillary tuft (glomerulus) filter. Under the influence of blood pressure, plasma is forced through the glomerulus and enters renal tubules. Filtered blood then passes from the glomerulus through an efferent arteriole and finally a capillary system that surrounds the renal tubules (peritubular capillaries). Kidneys filter approximately 140 liters of blood each day, but only 1500 mL of urine is produced. As blood pressure falls, urine production decreases.

The plasma that is filtered into the renal tubule contains water, glucose, electrolytes, and nitrogenous wastes. This "filtrate" is then modified as it moves through the tubular system. Substances such as medications are secreted from the peritubular capillaries and into the filtrate for elimination. Most of the plasma fluid is reabsorbed into the bloodstream

▲ Female genitourinary system.

▲ Male genitourinary system.

TABLE 22-1 Tubular Alterations of Filtrate

Proximal tubule and descending limb	Obligatory water reabsorption, which accounts for about 80% of the absorption of water, occurs in the proximal tube and descending limb. Glucose, amino acids, vitamins, and sodium are actively reabsorbed. Chloride, sulfate, phosphate ions, and urea are passively reabsorbed. Bicarbonate is actively reabsorbed in relation to systemic pH. Water is reabsorbed with these substances, leaving the filtrate osmotic pressure unchanged.
Loop of Henle	Sodium is actively transported from the filtrate in the ascending limb into the medullary interstitial fluid, thus raising its osmotic pressure. This rising pressure causes more water to be reabsorbed from the descending limb and the collecting duct and results in the concentration of the urine.
Distal tubule and collecting ducts	Facultative or optional reabsorption of water, which accounts for about 10%–15% of the absorption of water, occurs in the distal tubule and collecting ducts. Sodium is actively reabsorbed in exchange for secreted potassium or hydrogen. As water continues to be reabsorbed, the filtrate becomes more concentrated and its volume is greatly reduced.

by way of peritubular capillaries, and excess fluid is removed along with acid waste products (urea, creatinine, hydrogen ion) in the form of urine. Through this process, kidneys maintain fluid and electrolyte and acid–base balance. In addition to urine production, kidneys play an important role in maintenance of blood pressure by secreting renin, activation of vitamin D to facilitate calcium absorption, and stimulation of red blood cell production by erythropoietin. It is easy to appreciate that loss of kidney function has a profound and widespread effect on homeostasis since it influences elimination of waste products, bone metabolism, blood pressure, tissue oxygenation (RBC production), acid–base balance, and fluid and electrolyte balance.

Micturition

Micturition (urination or voiding) is a voluntary response to pressure changes within the bladder. When urine begins to collect, the muscular walls of the bladder are relaxed, with little change in pressure. After about 300 mL of urine accumulates, pressure increases. This rising pressure stimulates receptors in the bladder wall, which send impulses to the spinal cord. After 400–500 mL of urine is collected, the bladder walls contract and the internal sphincter relaxes, causing a sense of needing to void. Under voluntary control, urine enters the urethra, the external sphincter relaxes, and voiding occurs.

Micturition can occur sooner if the tone of the bladder is increased because of such factors as emotional stress or infection. Micturition can be delayed by voluntary contraction of the external sphincter or pelvic floor muscles. Once the volume of urine reaches about 700 mL, however, most individuals lose their ability to delay micturition.

If an individual is unable to void, as much as 1000 mL of urine can accumulate in the bladder. When a large volume of urine is retained, the bladder's lining and blood vessels can be damaged by the increased stretching and pressure. When this happens, an individual experiences pain, restlessness, chilling, flushing, headache, diaphoresis, and a rise in blood pressure.

ALTERATIONS IN URINARY ELIMINATION

Alterations in urinary elimination can result from changes in the intake and output of fluids, obstructions to the flow of urine, changes in the secretion of antidiuretic hormone (ADH), and changes in blood volume or blood pressure.

Alterations Related to Fluids

The average person takes in approximately 2600 mL of fluid each day: 1200 mL from drinking, 1100 mL from the water content of food, and 300 mL from metabolism. An increase or decrease in fluid intake results in a parallel increase or decrease in urine output.

Healthy individuals rarely experience decreases in urine output because they take in more fluids whenever they are thirsty. Individuals who are ill, however, may experience decreases in urine output because they are unable to respond to thirst, their intake is limited due to testing that requires NPO preparations, or their IV fluid intake is insufficient to balance fluid losses.

Fluid is lost from the body not only through urine, but also through respiration, perspiration, and feces. On a daily basis, most individuals lose approximately 2400 mL of fluid: 1500 mL through urine output, 200 mL through respiration, 600 mL through perspiration, and 100 mL through the elimination of feces. Individuals who are ill may also lose fluids through vomiting, bleeding, wound drainage, and suctioning/decompression.

Alterations Related to Obstructions

A decrease in the output of urine may also be caused by an obstruction (tumor, clot, tissue hypertrophy) to the flow of urine from the bladder. If the obstruction is great enough, the bladder does not empty completely. Instead, it retains fluid and, over time, becomes distended. Individuals who have urinary outlet obstructions experience the need to void more frequently. When they do void, however, they eliminate only very small amounts of urine.

Alterations Related to Aldosterone and Antidiuretic Hormone

Changes in the secretion of ADH and aldosterone also alter urine output since these hormones control the amount of water that is reabsorbed in the distal renal tubules and collecting ducts. Common factors that increase the secretion of ADH and aldosterone and reduce urine output include the physiologic stress response to accidental or surgical trauma, pain, hemorrhage, decreased cardiac output, anesthesia, and drugs, such as morphine and barbiturates. Factors that reduce the secretion of ADH and thus increase urine output include alcohol, caffeine, cold, and disease states and medications such as diuretics.

Alterations Related to Changes in Blood Volume

Because the production of urine is influenced by the volume of blood perfused to the kidneys, decreases in perfusion lead to reduction in the output of urine. Hemorrhage, dehydration, and shock reduce the flow of blood to the kidneys and cause decreased glomerular filtrate. If the volume of filtrate is reduced substantially, oliguria, or even anuria and accumulation of nitrogenous wastes (azotemia), may occur.

Other factors that may increase or decrease urine production include pathophysiologic states of the kidneys or other body systems, drugs, treatment modalities, diet, and metabolic rate.

Alterations in Disease States

Urinary outlet diversion is required when the bladder is obstructed or has been removed due to disease or trauma. Diversion can be created anywhere along the urinary pathway, and is named for the structure involved in the diversion. The most common urinary diversion is the ileal conduit, named because it uses the ileum of the bowel to form the conduit. A segment of the ileum close to the ileocecal valve is resected with its mesentery intact to create the conduit. The proximal end of this segment is closed and the distal segment is brought out through the lower quadrant of the abdominal wall to form the stoma. The ureters are anastomosed to the ileal segment at the proximal end or side of the conduit. This type of diversion is an incontinent urinary diversion. Clients with incontinent diversions must wear a pouch for urine collection.

TABLE 22-2 Urine Exam: What to Look For

Urine color: pale yellow to amber
Clarity and odor: clear with minimal odor
Urine pH: 4.5–8
Urine specific gravity: 1.005–1.020
Protein, glucose, and ketone bodies
Urine sediment: abnormal; red and white blood cells, casts, crystals, and bacteria

Ileal reservoirs are continent diversions that do not require the use of a collection device. The ileal reservoir is created with valves that allow it to function as a “bladder,” which is regularly emptied by client self-catheterization through the abdominal stoma.

The “neo bladder” is created by connecting the ureters to a segment of ileum that is connected to the urethra. The client has no stoma; therefore, no collection device is required. The “bladder” is emptied by timed voiding or urethral self-catheterization.

Alterations Related to Chronic Renal Failure

A number of disease states and socioeconomic factors place clients at risk for chronic renal failure. Nephron loss is irreversible as it progresses through five stages of deterioration marked by a declining glomerular filtration rate, glomerular leakage of protein into urine, and the retention of nitrogenous wastes in the blood (rise in the serum creatinine).

The presence of microalbuminuria (Stage 1) is the initial indicator to manage risk factors (e.g., diabetes and blood pressure control). With stage progression, proteinuria worsens and the glomerular filtration rate is reduced from a normal 120 to below 15 mL per minute (Stage 4). Unfortunately, the chronic decline in renal function is often asymptomatic until the client has reached this fourth stage when the kidneys are unable to maintain their homeostatic role and are unable to excrete wastes or excess water. It is at this stage that the client is usually referred to a nephrologist to prepare for lifelong renal replacement therapy (hemodialysis, peritoneal dialysis, or transplantation).

In the final fifth stage, the client has become uremic, having lost 90% of nephrons. The retention of nitrogenous wastes and loss of renal homeostatic processes alters all body system functions and is responsible for a constellation of signs and symptoms. *End-stage renal disease* is a term used for clients treated with dialysis or transplantation (renal replacement therapy), but does not actually define a stage of severity of renal disease.

NURSING INTERVENTIONS

The primary purpose for performing nursing interventions associated with urinary elimination is to maintain the integrity of the urinary system, which eliminates excess fluid and wastes and thereby promotes homeostasis.

Aseptic technique is essential whenever performing procedures that could introduce bacteria into the urinary tract. Handwashing, using sterile gloves, and maintaining a closed urinary collection system decrease the incidence of ascending bladder contamination and subsequent urinary tract infection. Maintaining aseptic technique throughout dialysis procedures is necessary to prevent infection in grafts, fistulae, and catheters.

Indwelling Catheters

Millions of Americans have bladder dysfunction every year. Twenty-five percent of these individuals are older adults in acute-care hospitals; 7% of clients are in long-term care facilities. Due to the dysfunction, they require urinary drainage systems (UDS) to drain and collect urine. The median time of UDS usage in home care is 3 to 4 years.

Preventing antibiotic resistance by avoiding catheter-associated urinary tract infections (CAUTIs):

- Unnecessary use and misuse of antibiotics leads to antibiotic resistance.
- CAUTIs comprise the largest institutional reservoir of antibiotic-resistance pathogens.
- Hospital-acquired urinary tract infections (UTIs) account for more than 40% of all hospital-acquired infections.
- More than 70% of HAIs are resistant to at least one of the drugs most commonly used to treat them.
- Clients infected with drug-resistant organisms are prone to longer hospitalization and require treatment with second or third choice drugs that may be less effective, more toxic, and/or are more expensive.
- Use of anti-infective Foley catheters with silver alloy coating and hydrogel decreases the incidence of CAUTIs.
- Use of the silver alloy coating and anti-infective catheters reduces the use of antibiotics by 40% to 50%.

Indwelling catheters are invasive devices with significant complications. Infection and encrustation are common. Long-term use of catheters provides access for bacteria from a contaminated environment. As a result, catheter-associated urinary tract infections (CAUTIs) occur. Eighty percent of infections are the result of *Escherichia coli*.

ADAPTATIONS FOR HOME CARE

Home care clients who require assistance with emptying their bladders are usually placed on intermittent clean catheterization protocols rather than having an indwelling catheter. This procedure assists in preventing penoscrotal abscess formation, overwhelming infection, and altered body image. Fluid intake needs to be monitored and restricted to 1500 mL per day to avoid bladder distention. If spontaneous voiding returns, frequency of catheterizations can be extended to every 12 hr and discontinued when the residual urine is consistently less than 100 mL in 24 hr.

When an indwelling catheter is used, it is important to be aware that it may lead to urinary tract infection. The nurse must teach the client and family to observe for signs and symptoms of urinary tract infections and sepsis. They should note odor, color, and consistency of the urine; burning pain; and flank pain. Catheter changes are the responsibility of the nurse and are usually performed once a month. Encouraging fluids becomes a major role assumed by family members and monitored by the nurse. Urinary antiseptics are adjunctive measures when catheterizations are required.

Home care dialysis is common in many areas of the country. The principles and procedures are similar to those in a hospital or free-standing dialysis unit. The major change is the advent of portable dialysis methods such as continuous ambulatory

peritoneal dialysis (CAPD) and continuous cycling peritoneal dialysis (CCPD). These procedures allow individuals to participate in a normal lifestyle. However, use of these methods requires monitoring by the nurse and specific teaching of the essential components to prevent complications and promote health. Peritoneal dialysis (PD) reflects more normal kidney function than hemodialysis. Fluid and electrolytes are removed gradually and, therefore, clients have fewer complications with blood pressure alterations and disequilibrium syndrome. There are fewer dietary and fluid restrictions, allowing clients to lead a more normal life. PD provides the client with a more flexible schedule, allowing him or her to work, travel, and participate in activities. One major restriction, besides ensuring the ordered number of exchanges each day, is the monthly appointment at the dialysis center for lab work and consultation with the physician or nurse.

The catheter is placed in a dependent position in the peritoneal cavity to minimize the chance of catheter obstruction or erosion into other abdominal organs. The other end of the catheter is placed outside of the abdomen to decrease infections. There are several devices that are placed around the catheter that prevent fluid leak from the peritoneal cavity. These devices impede the migration of bacteria.

There are three types of PD: continuous ambulatory peritoneal dialysis (CAPD), continuous cycling peritoneal dialysis (CCPD), and intermittent peritoneal dialysis (IPD). The two most common types for home care clients are CAPD and CCPD.

CAPD does not require a machine and can be done almost anywhere that is clean and well lighted. The client performs 4–5 exchanges daily that take approximately 30–45 minutes for each exchange. Each exchange allows a prescribed amount of a dextrose solution, termed *dialysate*, 1500–2000 mL for adults, to flow into the abdomen. The dialysate remains in the abdomen, called dwell time, for approximately 4 hr, and then it is drained out of the abdomen for about 10 minutes. The last exchange of the day is before bedtime. The dialysate remains in the abdomen overnight.

CCPD requires a portable machine that connects to the catheter and automatically fills and drains the dialysate from the abdomen at night while the client sleeps. This procedure usually takes 10–12 hr every night.

IPD is similar to CAPD except that it is done for about 10 hr each day for 3–4 days each week. The exchanges take place hourly, with approximately 2 liters of fluid for each exchange. This type of dialysis is usually done in an outpatient setting.

CULTURAL AWARENESS

- African-Americans have a more rapid decline in glomerular filtration rate than do Caucasians.
- Hypertensive African-Americans have decreased renal excretion of sodium, making sodium restriction an important factor in treatment.
- Hypertension, diabetes, and end-stage renal disease (ESRD) are 3–4 times more common in African-Americans and American Indians than in Caucasians.

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to use on client care plans when the components are related to promoting urine elimination.

NURSING DIAGNOSIS	RELATED FACTORS
Disturbed Body Image	Alteration in body appearance, urinary diversion stoma, use of appliance, catheter presence, fear of rejection, psychosocial factors
Ineffective Coping	Poor adjustment to illness or treatment, chronic disease state
Deficient Fluid Volume	Inadequate knowledge base, denial of health status, cultural or spiritual beliefs
Excess Fluid Volume	Increased urine output, decreased fluid intake
Infection, Risk for	Decreased urine output, renal system dysfunction, decreased cardiac output
Noncompliance	Vascular access site, altered immunity, urine retention, presence of catheter, malnutrition
Impaired Urinary Elimination	Inadequate knowledge base, inability to manage equipment for irrigation, denial of health status, cultural or spiritual beliefs
Stress Urinary Incontinence	Inability to retain urine related to stress, surgery, anatomical or functional problems, infection, motor or sensory impairment
Urinary Retention	Inability to retain urine related to stress, surgery, anatomical or functional problems, infection, motor or sensory impairment
	Inability to void, bladder distention or atony, surgical repair

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. *Remember to wash your hands or use antibacterial gel before and after each and every client contact.*

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Intake and Output

Nursing Process Data

ASSESSMENT Data Base

- Assess whether strict measurement of intake and output is ordered.
- Assess client's ability to assist in keeping intake and output record.
- Assess all potential sources of intake (e.g., IVs, oral fluids, tube feeding) and output (e.g., urine, emesis, diarrhea, drainage from tubes).
- Observe color, clarity, and odor of urine.
- Assess for signs of dehydration or fluid excess.
- Evaluate weight changes (most accurate assessment of fluid balance).

PLANNING Objectives

- To accurately measure all sources of fluid intake
- To accurately measure all sources of fluid output
- To identify alterations in fluid balance
- To record data on appropriate records

IMPLEMENTATION Procedures

- Measuring Intake and Output 764
 - *Fluid Intake* 764
 - *Fluid Output* 764

EVALUATION Expected Outcomes

- All sources of fluid intake and output are recorded.
- Client's intake and output balance.

Critical Thinking Application 765

- Expected Outcomes 765
- Unexpected Outcomes 765
- Alternative Actions 765

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Measuring Intake and Output

Equipment

- I&O bedside form
- Client's own graduated container
- Bedpan, urinal, or underseat basin for toilet ("hat")
- Hourly inline urine measurement device for client requiring frequent monitoring
- Clean gloves

Preparation

1. Perform hand hygiene
2. Explain purpose of keeping I&O record to client.
3. Instruct client to keep record of all fluids taken orally. Keep an I&O record at the bedside for the client to document intake.
4. Instruct client to void into bedpan, urinal, or underseat basin for toilet.
5. Instruct client not to place toilet tissue in bedpan or defecate in bedpan.

Procedure

Fluid Intake

1. Measure all fluid intake (including oral, IV, fluid medications, and tube feedings) according to hospital values (e.g., cup = 150 mL, glass = 240 mL).
2. Record time and amount of fluids in the appropriate space on bedside form.
3. Check bedside I&O record for approximate amounts of fluid containers.
4. Total 8-hr fluid intake on bedside I&O record.
5. Complete 24-hr intake record by adding together all three 8-hr totals.

Fluid Output

1. Don clean gloves to measure output from all sources.
2. Empty urinal, bedpan, or drainage bag into client's graduated container. ► **Rationale:** Measurement is only approximate from drainage bag or "hat." (Include other sources of output such as drainage, diarrheal stools, draining wounds, or emesis on output record.)
3. To drain urine collection bag:
 - a. Use client's individual (labeled) graduated receptacle.
 - b. Slide port opener clockwise to allow urine to drain.
 - c. Turn port opener counterclockwise to close.

If using drainage tube with plastic clips:

- a. Raise drainage tube to drain urine into collection bag.
- b. Hold bag over receptacle, squeeze green plastic pieces together gently. The clips will come out off edge of holder.

BEDSIDE INTAKE AND OUTPUT RECORD					
Name _____			Date _____		
Room # _____					
	Intake		Output		
	Oral	IV	Urine	Emesis	Drainage
7 am – 3 pm			7 am – 3 pm		
Total			Total		
3 pm – 11 pm			3 pm – 11 pm		
Total			Total		
11 pm – 7 am			11 pm – 7 am		
Total			Total		
24hr Total			24hr Total		

Measurements

Glass 240cc	Ice Cream 100cc
Cup 150cc	Jello 100cc
Bowl 150cc	Ice Chips 5cc/Cube
Juice Glass 100cc	
Coffee Pot 240cc	

▲ Bedside intake and output record.

▲ Empty urinal, bedpan, or Foley drainage bag into clients individual (labeled) graduate and note amount of urine.

- c. Slide green tube out of holder and point into receptacle.
 - d. Open metal clamp by pushing down on bottom metal pieces and wait until all urine has drained from bag.
 - e. Close clamp by pressing metal pieces together. Listen for click sound. ► **Rationale:** Clamp is now closed.
 - f. Clip drainage tube back into holder.
4. Remove gloves and perform hand hygiene.
 5. Record time and amount of output on bedside I&O record.
 6. Complete 24-hr output record by adding together all intermediate output totals during that 24-hr period, and place total on graphic sheet.
 7. Notify physician of any significant imbalance; more intensive monitoring may be indicated.

Clinical Alert

Hourly urine output less than 30 mL/hr for 2 consecutive hours or 24-hr urine output less than 500 mL can indicate dehydration or internal bleeding and can result in acute renal failure.

Methods to Stimulate Voiding

- Have client drink a cup of hot fluid such as coffee or tea.
- Run water in sink.
- Massage the lower abdomen.
- Place a hot washcloth on the abdomen.
- Pour warm water over the perineum with client positioned on toilet or bedpan.
- Obtain order for sitz bath.
- Put oil of wintergreen on a cotton ball in the bedpan or urinal.

Clinical Alert

Use client's own graduated receptacle when measuring output. Change gloves and perform hand hygiene between each client. The CDC calls for decontamination of hands after removing gloves. Gloves should also be *changed* and hands decontaminated when moving from a contaminated body site to a clean one on the same client.

DOCUMENTATION for Intake and Output

- Time and amount of all oral fluid intake
- 8-hr totals of all IV and enteral fluids
- 24-hr total of all fluid intake
- Time and amount of all urinary output
- Time and amount of all drainage (e.g., NG)
- 8-hr totals of all fluid output
- 24-hr total of all fluid output

CRITICAL THINKING Application

Expected Outcomes

- All sources of fluid intake and output are recorded.
- Client's intake and output balance.

Unexpected Outcomes

Client voids in toilet.

Alternative Actions

- Document "voided in toilet" on I&O record.
- Review instructions for accurate I&O monitoring with client.
- Post sign above toilet: "All urine must be measured and recorded."
- Place "hat" receptacle in toilet.
- Post sign indicating need to record all fluid intake.
- Remind family of importance of I&O monitoring; provide cups with measured increments and paper for them to record fluids given (unless fluids are restricted).

Family members obtain fluids for client without notifying staff.

Fluid intake and output do not balance (intake greater than output).

- Initiate daily weight measurement (weigh before breakfast, after voiding, same scale, same clothing).
- Compare losses or gains with client's daily weight measurement.
- Fluid intake and output generally are relatively equal (assuming numbers are accurate). Output should be about 500 mL less per 24 hr due to insensible fluid loss.
- Determine whether treatment goal is to rehydrate or diurese the client.
- Use graduated container to accurately measure output in "hat."
- Search for sources of unmeasured output (fever, wound drainage, diarrhea).

Fluid output is greater than intake.

- Analyze whether treatment goal (rehydration, diuresis) has been achieved.
 - Reposition client cautiously, monitoring for possible orthostatic hypotension.
 - Identify when "dry weight" has been achieved (intake balances output after therapy received).
 - Search for sources of unrecorded intake (family offerings, flush solutions, ice chips, full-liquid foods).
-

External Urine Collection System

Nursing Process Data

ASSESSMENT Data Base

- Assess that client is able to empty bladder completely and spontaneously.
- Assess the genital area for signs of irritation and edema during the use of condom catheter for urine collection.
- Assess activity level of client to determine when a leg bag or a continuous drainage system is necessary.

PLANNING Objectives

- To provide a means for managing incontinence
- To provide a means of collecting urine in a system that allows client ambulation
- To prevent skin breakdown due to incontinence of urine
- To prevent urinary tract infections in clients who are at risk and require a method of urine collection

IMPLEMENTATION Procedures

- Applying a Condom Catheter for Urine Collection . . . 768
- Attaching Urine Collection Condom Catheter to Leg Bag 768

EVALUATION Expected Outcomes

- Client remains dry with condom catheter for urine collection.
- Skin irritation does not occur with condom catheter use.

Critical Thinking Application 770

- Expected Outcomes 770
- Unexpected Outcomes 770
- Alternative Actions 770

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Applying a Condom Catheter for Urine Collection

Equipment

- Soap, water, towel, washcloth
- Commercial condom catheter; select appropriate size
- Leg bag or bedside drainage system
- Skin barrier prep
- Clean gloves
- Drape
- Scissors

Preparation

1. Check physician's orders and client care plan.
2. Gather equipment.
3. Identify client and explain procedure.
4. Perform hand hygiene and provide privacy.
5. Raise bed and lower side rail on working side of bed. Place client flat supine.
6. Don clean gloves.
7. Drape for privacy.
8. Wash genital area with soap and water, and dry area thoroughly. (If client is uncircumcised, gently attempt to retract foreskin, cleanse shaft beneath it, then replace foreskin to normal position.)
9. Clip hair from base of penis if necessary. ► **Rationale:** To avoid catching in adhesive strip.

Procedure

1. When commercial condom catheter is used, apply protective coating to skin on penile shaft and allow to dry completely (60 seconds).
2. If adhesive strip is required, peel off paper from one side of the adhesive strip according to product instructions. Spirally wrap the adhesive strip around the penile shaft starting behind the glans, then peel outer paper from adhesive strip.

▲ After unrolling condom onto penis, apply pressure to ensure smooth fit.

3. Take the condom catheter and place the prerolled sheath so funnel is against the glans, but *not* rubbing it.
4. Unroll the condom up the penis until it is completely over the adhesive strip.
5. Gently squeeze condom against strip to seal it after sheath is completely rolled over the penis. Do not wrinkle as wrinkles cause urine to leak through catheter.
6. Clip rolled portion of condom if necessary to prevent constriction at base of penis.
7. Connect condom to a drainage system. The drainage system can be a leg bag or a bedside drainage system depending on activity level and condition of client.
8. Lower bed, and raise side rail and/or assist client out of bed if he is to be ambulated.
9. Remove gloves and perform hand hygiene.
10. Assess penis 30 minutes after condom applied to check for edema, discoloration, and urine flow.
 - **Rationale:** This detects complication with application.

Attaching Urine Collection Condom Catheter to Leg Bag

Equipment

- Leg bag with Velcro straps (or stockinette to secure bag)
- Antimicrobial swabs
- Clean gloves

Preparation

1. Obtain order for leg bag from physician.

2. Gather equipment.
3. Identify client and explain procedure.
4. Provide privacy.
5. Raise bed, and lower side rail on working side of bed.
6. Perform hand hygiene and don clean gloves.

▲ Leg bag with Velcro straps to secure to leg.

▲ Connect longer tube from leg bag to condom catheter.

Procedure

1. Remove protective cap from connecting tube on top of leg bag.
2. Disconnect drainage tubing from indwelling or condom catheter.
3. Cap bedside drainage tubing end with protective cap from leg bag. ► **Rationale:** To maintain sterility of connecting parts.
4. Wipe leg bag and catheter connectors with swab, if not already sterile.
5. Connect tip of leg bag into catheter.
6. Secure leg bag to thigh by placing Velcro strap through bag and around leg. Alternately, secure with stockinette.
7. When removing leg bag, disconnect catheter from leg bag and wipe each connection end with antimicrobial wipes.
8. Take leg bag cap off drainage tubing and replace it onto leg bag.
9. Connect catheter to bedside drainage tubing.
10. Lower bed and raise upper side rails.
11. Rinse leg bag in warm soap and water, and place in bathroom to dry.
12. Remove gloves and perform hand hygiene.

▲ Maintain sterility when placing the tip of leg bag into condom catheter.

Clinical Alert

Use of an external urine collection system is recommended for incontinent men without urine retention. These devices are comfortable, and there is less chance of a urinary tract infection than with indwelling catheters.

DOCUMENTATION for External Urine Collection System

- Type and size of condom catheter applied
- Condition of genital area
- Protective coating (prep) applied to skin
- Type of drainage collection device attached
- Amount, color, and odor of urine obtained
- Client's tolerance of procedure and ability to perform self-care

 **CRITICAL THINKING Application****Expected Outcomes**

- Client remains dry with condom catheter for urine collection.
 - Skin irritation does not occur with condom catheter use.
-

Unexpected Outcomes

Condom catheter leaks.

Alternative Actions

- Use smaller size condom to provide *wrinkle-free* fit.
 - Replace adhesive strips for better condom adherence.
 - Make sure penis is thoroughly dry before applying condom system.
 - Ensure that drainage collection system is dependent of condom tubing to promote gravity flow.
 - Consider using a retracted penis pouch.
-

Penis becomes reddened with condom catheter use.

- Remove condom.
 - Notify wound care specialist/physician for topical medication order.
 - Apply adult brief and change frequently until problem resolves.
 - Make sure penis is clean and dry and protective coating is applied before condom application.
 - Clip rolled portion of condom to prevent constriction at base of penis.
-

Catheterization

Nursing Process Data

ASSESSMENT Data Base

- Assess the client’s bladder for distention.
- Assess purpose of catheterization or urine output monitoring.
- Check physician’s orders for method of catheterization to be done.
- Assess urinary meatus for exudate or inflammation.
- Assess character and amount of urine.
- Note client’s I&O balance.

PLANNING Objectives

- To prevent or relieve discomfort due to bladder distention
- To promote urinary elimination
- To obtain a sterile urine specimen
- To instill medication or provide continuous urinary bladder drainage
- To provide bladder irrigation
- To measure the amount of residual urine (post void)
- To monitor the output of a critically ill client

IMPLEMENTATION Procedures

- Using a Bladder Scanner772
- Draping a Female Client772
- Inserting a Straight Catheter (Female)773
- Inserting a Straight Catheter (Male)775
- Inserting a Retention Catheter (Female)777
- Inserting a Retention Catheter (Male)781
- Providing Catheter Care783
 - For Female783
 - For Circumcised Male783
 - For Uncircumcised Male784
- Removing a Retention Catheter784

EVALUATION Expected Outcomes

- Catheterization is avoided with use of bladder scanner.
- Sterile technique is maintained throughout catheterization procedure.
- Catheter enters bladder as evidenced by urine outflow.
- Client remains free of urine leakage around retention catheter.
- Urinary tract infection does not occur secondary to catheterization.

Critical Thinking Application785

- Expected Outcomes785
- Unexpected Outcomes785
- Alternative Actions785

Pearson Nursing Student Resources

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Using a Bladder Scanner

Equipment

- Ultrasound BladderScan device
- Ultrasound conducting gel
- Tissues

Preparation

1. Check physician's order to evaluate client's bladder.
2. Identify client and explain procedure and purpose.
3. If female, ask client if she has had a hysterectomy or is pregnant. If a hysterectomy is not documented, and settings are adjusted appropriately, results may be inaccurate. ► **Rationale:** Scanner is not indicated for pregnant clients.
4. Provide privacy.
5. Determine time and amount of last void or assist client to empty bladder if residual volume is to be evaluated.
6. Determine that client does not have an indwelling catheter. ► **Rationale:** Scanner reflects off the catheter bulb, giving an echo reading.
7. Perform hand hygiene.
8. Place client flat and supine, and palpate client's bladder to locate appropriate site.

Procedure

1. Turn the device on and press "SCAN."
2. Apply conducting gel to scanner head.
3. Select MALE or FEMALE mode on scan unit. Select **MALE MODE** if female client has had a hysterectomy.
4. Fanfold linens to expose client's suprapubic area.

▲ Handheld portable ultrasound bladder scanner.

5. Place head of scanner 3 cm above client's symphysis pubis, directed toward the bladder, and align the icon.
6. Press scan head button and hold scanner still until a beep is heard.
7. Scan until bladder image is lined up on cross-hairs.
8. Take several scans at different angles and press **DONE** when finished.
9. Press **PRINT** for a printout of client's bladder volume in milliliters.
10. Wipe gel from client's skin.
11. Reposition client for comfort.
12. Wipe ultrasound probe with antiseptic solution.
13. Perform hand hygiene.

Draping a Female Client

Equipment

- Bath blanket

Procedure

1. Bring bath blanket to bedside.
2. Identify client, and explain procedure.
3. Provide privacy.
4. Perform hand hygiene.
5. Place bed in **HIGH** position, and lower side rail nearest you.
6. Place bath blanket over client's top linen so that one corner of the blanket is pointed toward the client's head to form a diamond shape over the client.
7. Instruct client to hold onto bath blanket. Fanfold linen to foot of bed and place on chair.

▲ Use bath blanket to drape client before catheterization.

8. Request that client flex knees and keep them apart with feet firmly on bed.
9. Wrap lateral corners of bath blanket around feet in a spiral fashion until they are completely covered.
10. The corner of the blanket between knees and extending over perineum can later be folded back over the abdomen. ► **Rationale:** Draping provides for warmth and prevents unnecessary exposure of genital area until procedure is performed.

▲ Corner of blanket is folded back over abdomen to expose perineum.

Inserting a Straight Catheter (Female)

Equipment

Disposable catheterization tray with straight catheter (14 Fr), and specimen cup. Determine type of catheter to use. See Table 22-3, page 776.

Biohazard specimen transport bag

Bath blanket or turn sheet

Additional light source, if needed

If necessary for cleansing, towel, washcloth, basin with warm water and soap

Clean gloves

NOTE: If bladder scanner is not available, this skill may be indicated after client voids to determine residual volume.

Preparation

1. Bring equipment to client's room.

▲ Disposable kit includes equipment necessary for performing a catheterization. (Retention catheter/Foley is shown above).

2. Check lighting source.
3. Identify client, and explain procedure and need for client to keep knees positioned during procedure.
4. Provide privacy.
5. Perform hand hygiene.
6. Place bed in HIGH position, and lower side rail on working side.
7. Fold linens to foot of bed and cover client's lower body with bath blanket drape.
8. Provide perineal care, if necessary, with soap and water using clean gloves. Dry perineum thoroughly.
9. Discard towels and water and replace basin.
10. Dispose of gloves and perform hand hygiene.
11. Drape the client (see Draping a Female Client).
12. Have client bring knees up and out. May need assistance to keep knees in this position. ► **Rationale:** This position provides for good visualization of urinary meatus.
13. Fold up bath blanket drape corner to expose perineum.
14. Adjust light source to ensure that meatus is adequately visualized.

EVIDENCE-BASED PRACTICE

Regaining Voiding Ability

In hip surgery patients, those receiving intermittent catheterization regained satisfactory voiding quicker than those with an indwelling catheter.

Source: Cravens, D., & Zweig, S. (2000). Urinary catheter management. *American Family Physician*, 61(2), 369–375.

Procedure

1. Open sterile catheter set package by tearing the package on the lined edge of plastic wrap. Place plastic wrap at foot of bed for waste disposal.
2. Place catheter set on bed between client's legs.
3. Fold back drape to expose perineum.
4. Open white outer wrap away from sterile package with last turn toward client.
5. Remove sterile absorbent pad, and position plastic side down under client's buttocks. Have client lift buttocks if able. Position pad by holding corners of pad only.
 - ▶ **Rationale:** Pad creates a sterile field.
6. Put on sterile gloves.
7. Place fenestrated drape over client's perineum, exposing meatus (optional).
8. Place tray on sterile field, which may be enlarged by utilizing sterile wrapping, with care not to contaminate sterile field.
9. Open package, and pour antiseptic solution over cotton balls or open package of antiseptic-soaked swabs with stick ends up, according to hospital policy.
10. Uncap syringe filled with lubricant, or tear open lubricant package, pick up catheter tip, and lubricate the tip of the catheter generously. ▶ **Rationale:** Removing catheter from sterile container (tray) increases risk of contamination.
11. If specimen is required, uncap sterile specimen container.
12. Move catheter tray close to client on sterile field.
13. Prep client's meatus according to hospital policy.
 - a. Separate the client's labia minora with your nondominant hand (maintain separation throughout prep).
 - b. With your dominant hand, *use forceps* to pick up an absorbent ball that has been saturated with antiseptic solution. (If Betadine swabs are used, pick up one swab.)
 - c. Cleanse client's meatus using the procedure in the above note, or with one downward stroke of forceps or swab. ▶ **Rationale:** Using a downward stroke cleans from least contaminated to most contaminated area.
 - d. Discard absorbent ball or swab in the plastic cover at foot of bed. ▶ **Rationale:** Using a new cotton ball or swab with each downward stroke prevents transfer of microorganisms.
 - e. Repeat Step c at least three to four times.
 - f. Continue to hold client's labia apart until you insert catheter. ▶ **Rationale:** This prevents contamination of urinary meatus.
14. Using sterile gloved hand, pick up lubricated catheter, keeping drainage end in collection container, and insert 2 in. or until urine begins to flow.
15. Move nondominant hand from holding labia open to hold catheter in place.

▲ Anatomical view of female perineal area showing urethral orifice.

Estimating Bladder Fullness

- The bladder is not normally palpable until it contains more than 150 mL of urine.
- Normally, suprapubic percussion produces a hollow sound. A dull or flat sound indicates bladder distention.
- A bulge may be noted in the suprapubic area when the bladder contains 500 mL.
- Pain is often felt after bladder capacity has been reached, commonly after 400–500 mL.
- Subjective symptoms are not reliable indicators of bladder fullness.

▲ Female mini-catheter used to obtain sterile urine specimen.

16. Instruct client to take a deep breath. While client is exhaling, insert catheter. ► **Rationale:** Sphincter will relax, decreasing discomfort and resistance to insertion of catheter.
17. Place sterile specimen container under drainage end of catheter if specimen is needed, and fill container with approximately 30 mL of urine.
18. Replace catheter drainage end into collection container, and allow urine to flow until it ceases.
19. Pinch catheter closed when urine ceases to flow, and remove gently and slowly.
20. Remove drapes and dry the perineum.
21. Position client for comfort, put the bed in LOW position with the upper side rails raised.
22. Measure and record urine output on I&O bedside record.
23. Discard gloves and equipment appropriately.
24. Perform hand hygiene.
25. Label specimen, place in transport bag, and send to lab.
26. Document procedure.

EVIDENCE-BASED PRACTICE

Expert opinions indicate there is no advantage in using antiseptic preparation for cleansing the urethra before catheter insertion. Urethral trauma and discomfort will be minimized by cleansing with sterile, single-use lubricant or anesthetic gel.

Source: Dunn, S., Pretty, L., Reid, H., & Evans, D. (2000). *Management of Short Term Indwelling Urethral Catheters to Prevent Urinary Tract Infection: A Systematic Review*. Adelaide, Australia: The Joanna Briggs Institute For Evidence Based Nursing.

Inserting a Straight Catheter (Male)

Equipment

Same as for Inserting a Straight Catheter (Female)
15–20 mL, 2% lidocaine gel for lubricant, if ordered

Preparation

1. Follow Steps 1 through 6 in Inserting a Straight Catheter (Female).
2. Place client in a supine position with knees slightly apart. ► **Rationale:** This position relaxes abdominal and perineal muscles.
3. Drape client by placing a bath blanket or draw sheet over chest area and fanfold top linen down to cover lower extremities, exposing only genital area.
4. Don clean gloves, and wash genital area if necessary.
5. Remove gloves and perform hand hygiene.

Procedure

1. Open sterile package by tearing the package on the lined edge of plastic wrap. Place plastic wrap at foot of bed for waste disposal.
2. Place sterile kit at client's side near thigh.
3. Open outer wrap away from sterile package.
4. Don sterile gloves.
5. Place first drape over thighs and under penis.
6. Place fenestrated drape over penis.
7. Open antiseptic package and pour solution over cotton balls or open package of antiseptic-soaked swabs with stick ends up, according to hospital policy.
8. Open lubricant packet or syringe—eject onto prep tray, unless using procedure in Step 13b of procedure Inserting a Straight Catheter (Female) on page 774.

9. If specimen is required, uncap the specimen container.
10. Hold penis upright with your nondominant hand.

Clinical Alert

A Coudé or 12-Fr catheter may be easier to insert if the client has an obstruction.

11. With your dominant hand, use forceps to pick up cotton ball saturated with antiseptic solution or pick up Betadine swab.
12. Cleanse meatus with circular expanding stroke using cotton ball or swab. Discard cotton ball or swab into plastic bag at foot of bed.
13. Repeat circular cleansing motion prep around tip of penis. Cleanse three times using a new cotton ball or swab each time.
14. Continue to hold penis with your nondominant hand.
15. Discard forceps into plastic bag.
16. Lubricate catheter about 3–4 in. using generous amount of lubricant.
17. **Alternate Method:** Insert tip of lubricant syringe at urethral opening and instill lubricant (or 2% lidocaine gel if ordered) directly into urethra. (If cath tray does not have syringe, place sterile syringe on tray before gloving.) ► **Rationale:** Lidocaine gel facilitates catheter placement by expanding, anesthetizing, and lubricating the urethra.
18. Pick up catheter with sterile gloved hand about 8–10 cm (3–4 in.) from tip of catheter.
19. Lift penis to a 90° angle (perpendicular to body) and exert slight traction by pulling upward. ► **Rationale:** This

movement straightens the urethra for easier insertion of catheter.

20. Instruct client to take a deep breath and while client is exhaling, insert catheter. ▶ **Rationale:** Sphincter will relax, decreasing discomfort and resistance to insertion of catheter.
21. Insert catheter about 24.5 cm (10–12 in.) or until urine is obtained.
22. If catheter meets resistance, decrease angle of penis to 45° or less, and ask client to take a deep breath.
 - ▶ **Rationale:** Taking a deep breath helps relax external

sphincter. If persistent resistance is felt and catheter cannot be inserted without difficulty, remove catheter and notify physician.

23. Fill sterile specimen container from drainage end of catheter if specimen is needed.
24. Pinch tubing, and transfer end of catheter into collection container.
25. Allow urine to drain into collection container until flow stops.
26. Remove catheter, and place lid on specimen bottle.

▲ Place absorbent pad, with plastic side down, under penis to establish sterile field.

▲ Prep head of penis, starting at meatus and cleansing outward in a circular motion.

▲ Insert amply lubricated catheter 10–12 inches.

TABLE 22-3 Types of Catheters

Latex	Rubber, ideal for forming the core of an indwelling catheter, due to its flexibility. Comfortable for client. Can cause urethral trauma. Latex swells as it absorbs body fluids.
100% Silicone	Larger drainage lumen due to having a coating. Biocompatible with urethra mucosa and is resistant to encrustation. Major advantage is hypoallergenic. Less flexible than latex. Up to 50% water loss from balloon can occur due to gas diffusion. Can stay in place up to 12 weeks. Used for clients with latex hypersensitivity. Discomfort in removal can occur as a result of incomplete cuff deflation of the balloon.
Latex Catheter Coated With Hydro Gel	Gel is a polymer that absorbs water and forms a smooth surface on catheter. It is resistant to encrustation and settlement of bacteria, which diminishes risk of infection. Can stay in place up to 12 weeks. Used for clients with latex hypersensitivity.
Silicone–Elastomer	Coated latex catheter that is biocompatible and reduces urethra mucosal irritation. Flexibility provides comfort and can remain up to 12 weeks. Useful for clients with latex hypersensitivity.
PTFE Coated Catheter	Teflon is fixed onto a latex core to form a catheter; used short term. Client is more comfortable, decreased incidence of urethritis and encrustation. Can stay in place 28 days. Loss of balloon water occurs. Clients with latex hypersensitivity can use this catheter.
Silver Alloy	Lower incidence of bacteriuria than with silver oxide catheter. Clinically effective in reducing Catheter Associated Urinary Tract Infection (CAUTI) if used short term (14 days). Silver is an antiseptic and inhibits growth of gram-positive and gram-negative bacteria. Silver-coated catheters may reduce catheter-related infections and have a low risk for generating antibiotic resistance.
Antiseptic-Impregnated or Antimicrobial-Coated	Significantly prevents or delays onset of CAUTI. Both the outer wall and inner drainage lumen are impregnated with an antibacterial agent that exudes from the catheter over time.

27. Dry penis and remove drapes.
28. Make client comfortable. Place bed in LOW position with upper side rails raised.
29. Discard equipment in appropriate container.
30. Remove gloves and perform hand hygiene.
31. Send specimen to lab and document procedure.

EVIDENCE-BASED PRACTICE

Care Variances With Male Catheterization

At University of Colorado Hospital, there had been two cases involving care variances with male patient catheterization. While the nursing staff searched for evidence on why this occurred (since the nurses' competency had been verified), they consulted urology experts to document their best practices for male catheterization procedures.

This evidence-based project revealed that some nursing literature at the time of the study contained outdated facts about male catheterization, including out-of-date information on the distance to insert the catheter (6 to 8 in. when it should be 10 to 12 in.) and the "fact" that return of urine means the catheter is properly placed (incorrect, since there will be a residual urine return even when a catheter is not fully and properly placed). This evidence-based practice study was reported in *MedSurg Nursing*.

Source: Internet: CE Course 359, *Nurse Week*. (2005, Feb. 28).

EVIDENCE-BASED PRACTICE

Using Silver-Coated Catheters

In a base-case analysis, use of silver-coated catheters led to a 47% relative decrease in incidence of symptomatic UTI from 30 to 16 cases per 1,000 clients, and a relative decrease in the incidence of bacteremia from 4.5 to 2.5 cases per 1,000 clients, compared with standard catheters. Use of the silver alloy catheters reduces the cost savings of \$4.09/client compared with standard catheters. Silver-coated catheters provide clinical benefits over standard catheters in all cases.

Source: Saint, S., et al. (2000). The potential clinical and economic benefits of silver alloy urinary catheters in preventing urinary tract infections. *Archives of Internal Medicine*, Sept. 25, 2000, 160(17), <http://archinte.ama-assn.org/cgi/content/full>.

Inserting a Retention Catheter (Female)

Equipment

- Disposable retention catheter kit with appropriate size catheter (size 14–16 Fr for adult female, size 16–18 Fr for adult male with 10 mL balloons) and preconnected closed-system 2000-mL drainage bag with MONO-FLO antireflux device
- Closed drainage set with or without urimeter or urometer, if indicated
- Label for urine specimen if indicated
- Biohazard bag for specimen if indicated
- Additional lighting if needed
- Bath blanket or turn sheet
- Towels, washcloth
- Clean gloves
- Basin with warm water
- Soap
- Tape or commercial catheter securement (Bard Catheter leg strap, Dale Anchor Strap, Statlock Foley)
- Catheter tip shapes are either Coudé or Tiemann, and size of lumen is based on French scale (each unit equals 0.33 mm of internal lumen).

Preparation

Same as for Inserting a Straight Catheter (Female).

Procedure

1. Open sterile package by tearing the package on the lined edge of plastic wrap. Place plastic wrap at foot of bed for waste disposal.
2. Place catheter kit on bed between client's legs.
3. Open closed drainage set bag and place on bed near client (if indicated).
4. Fold back corner of bath blanket to expose perineum.
5. Open white outer wrap away from package with last turn toward client.
6. Remove sterile absorbent pad, and position under client's buttocks plastic side down. Have client lift buttocks if able. Position pad by holding corners of pad only. ► **Rationale:** Holding onto the edges keeps the center sterile.
7. Don sterile gloves.
8. Position fenestrated drape over the client to expose the genitalia (optional).

1 Open sterile package by tearing it along lined edge of plastic wrap.

2 Remove sterile absorbent pad and place it under client's buttocks.

3 Put on sterile gloves, being careful not to contaminate sterile field.

4 Position sterile fenestrated drape over client to expose genitalia (optional).

5 Test catheter balloon by inserting prefilled syringe and injecting sterile water through catheter side port, unless silicone catheter, and according to hospital policy.

6 Pour antiseptic solution completely over cotton balls. Use type of solution according to facility policy.

▲ 3 Uncap lubricant syringe and squeeze lubricant onto tray.

▲ 4 Cleanse meatus by using downward strokes with cotton balls or use single-use lubricant or anesthetic gel.

▲ 5 Lubricate tip of catheter to facilitate insertion without trauma

▲ 6 Hold labia apart while inserting catheter to prevent contamination.

▲ 7 Insert catheter gently into meatus until urine begins to flow; then advance another 1-2 inches (2.5-5 cm).

▲ 8 Inject water from prefilled syringe into catheter balloon after inserting catheter.

▲ Tape catheter to side of client's thigh using nonallergenic tape.

9. Separate prep tray from container, placing prep tray with cotton balls, antiseptic solution packet or according to hospital policy and lubricant onto sterile field toward client.
10. To test catheter balloon (check hospital policy, and brand of catheter to determine need for inflating balloon before insertion):

NOTE: Certain manufacturers of the balloon catheters (i.e., Bard) are now alerting facilities to instruct their staff NOT to pre-inflate to test the balloon before insertion, because it is pretested during the manufacturing process.

 - a. Remove rubber protector and insert tip of prefilled sterile water syringe into catheter side arm to inflate balloon.
 - b. Inject 10 mL of sterile water to inflate balloon to test balloon integrity. ► **Rationale:** The catheter can fall out if not secured with appropriately inflated balloon.
 - c. If balloon malfunctions with testing, obtain a new sterile retention catheter before continuing with procedure.
 - d. After testing balloon, pull back on plunger to remove fluid and deflate balloon, leaving syringe in place.

► **Rationale:** Testing is done to ensure that balloon inflates without leaking.

Clinical Alert

A silicone coated Foley catheter is not pre-inflated for testing before insertion because a ridge is present in the balloon when it is deflated, and ridges can lead to irritation of the urethra. Silicone catheters are used for clients with latex allergies. They are also used if a urethral stricture is present, and during radical prostatectomy surgery, as there is less meatus.

11. Open package and pour antiseptic solution over cotton balls.
12. Uncap syringe filled with lubricant and eject onto prep tray to lubricate catheter tip at time of catheter insertion, or open lubricant packet and insert catheter tip into lubricant, keeping catheter in tray.
13. Remove cap from specimen cup if indicated.

▲ Securement device (StatLock Foley) stabilizes catheter to minimize urethral trauma.

14. Prep client's meatus:
 - a. Separate client's labia minora with your nondominant hand.
 - b. With your dominant hand, *use forceps* to pick up an absorbent cotton ball that has been saturated with antiseptic solution, according to hospital policy. See 13c, page 774.
 - c. Cleanse client's meatus with one downward stroke of forceps or swab. Discard absorbent cotton ball or swab in plastic bag at foot of bed.
 - d. Repeat Step c at least three times.
 - e. Continue to hold the client's labia apart until you insert the catheter.
15. Discard forceps in plastic bag at foot of bed.
16. With uncontaminated hand, take catheter from container, lubricate tip, and insert gently into meatus 2 in. or until urine starts to flow.
17. Guide the catheter gently 1–1.5 in. just beyond the point at which urine begins to flow. ► **Rationale:** Inserting catheter further into bladder ensures it is beyond neck of the bladder.
18. Inject entire contents of prefilled (10–30 mL sterile water) syringe into the side arm of the catheter used for balloon inflation. ► **Rationale:** Underinflation can cause balloon distortion and catheter tip deflection.

Clinical Alert

Chronic irritation and inflammation of bladder mucosa due to long-term (more than 8 months) presence of an indwelling catheter (urethral or suprapubic) is associated with an increased risk for bladder cancer.

19. If client complains of pain on balloon inflation, immediately aspirate the sterile water. ► **Rationale:** The catheter may be in the urethra rather than the bladder.
20. Gently retract the catheter until you feel resistance.

► **Rationale:** This indicates the balloon is resting against the bladder neck and in the correct position.
21. Obtain urine specimen before attaching catheter to drainage tubing, if indicated.

⚠ Attach urine collection bag to nonmovable part of bed. Do not allow tubing to hang below collection bag.

22. Remove protective cap from drainage tubing and attach securely to catheter, if indicated.
23. Apply catheter holder or tape catheter to client's upper thigh. Place one piece of tape on thigh. Take second piece of tape and encircle catheter, leaving two "tails" on tape. Secure "tails" from tape on catheter to tape on leg. ► **Rationale:** To stabilize catheter and minimize urethral trauma and avoid tension on bladder neck.
24. Attach drainage bag to bed frame (not side rails); coil tubing to allow free gravity flow of urine.
25. Remove drapes.
26. Reposition client for comfort; put bed in LOW position with upper side rails up.
27. Remove equipment, including gloves, and discard disposable trash in appropriate container.
28. Perform hand hygiene.
29. Record urine output on I&O.
30. Label specimen and place cup in biohazard transport bag.
31. Send urine specimen to lab and document procedure.

TABLE 22-4 Indications for an Indwelling Catheter

- Short term for acute urinary retention.
- Sudden and complete inability to void.
- Need for immediate and rapid bladder decompression.
- Temporary relief of bladder outlet obstruction secondary to:
 - Enlarged prostate gland
 - Urethral stricture
 - Obstructing pelvic organ prolapse
 - Urologic or prolonged surgical procedure
- Chronic urethral obstruction or urinary retention and surgical interventions and/or the use of intermittent catheterization has failed or is not feasible.
- Irreversible medical conditions are present (e.g., metastatic terminal disease, coma, end states of other conditions).
- Presence of stage III or IV pressure ulcers that are not healing because of continual urine leakage.
- Instance where a caregiver is not present (usually in home care setting) to provide incontinence care.

Source: Newman, D. (2007). The indwelling urinary catheter: principles for best practice. *Journal of Wound, Ostomy and Continence: Nursing*, 34(6), 655–661.

NOTE: The optimal drainage system is a closed system with a one-way valve between the bag and tubing. ► **Rationale:** This system reduces UTIs for clients with a short-term indwelling urinary catheter.

Clinical Alert

Immediate assessment and documentation of the amount of urine obtained after inserting the retention catheter is important to document. If the client has urinary retention, it may alter clinical decisions.

Clinical Alert

Do not obtain a urine specimen from the catheter drainage bag. Pathogens in drainage bag do not necessarily represent those present in lower urinary tract.

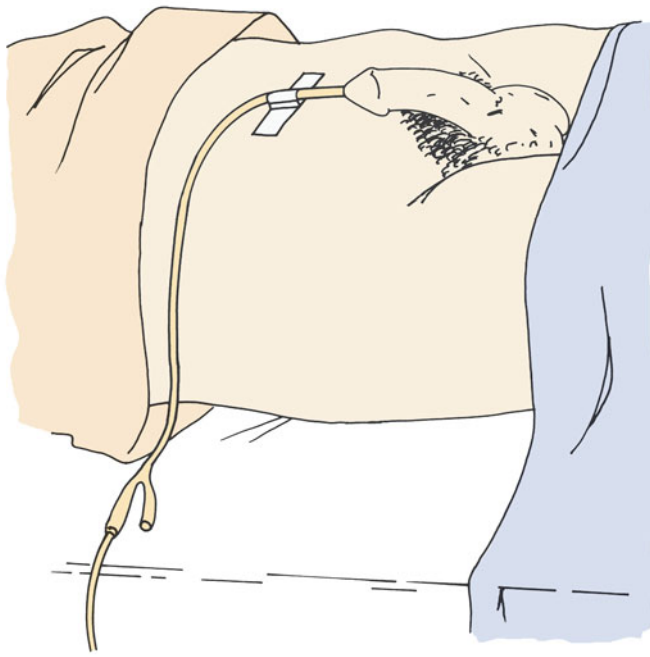

Inserting a Retention Catheter (Male)

Equipment

Same as for Inserting a Retention Catheter (Female)

Preparation

1. Follow Steps 1 through 6 in Inserting a Straight Catheter (Female).
2. Place client in a supine position with knees slightly apart. ► **Rationale:** This position relaxes abdominal and perineal muscles.
3. Drape client by placing a bath blanket or turn sheet over chest area and fanfold top linen down to cover lower extremities, exposing only perineal area.

▲ Tape catheter to abdomen to prevent pressure in penoscrotal angle if client on bedrest.

4. Don clean gloves and wash client's perineal area if necessary.
5. Remove gloves and prepare for catheterization.

Procedure

1. Open sterile package by tearing package on lined edge of plastic wrap. Place plastic wrap at foot of bed for waste disposal.
2. Place sterile kit on bed at client's side near thigh.
3. Open closed drainage set and place on bed near work area.
4. Open outer white wrap away from sterile package.
5. Place sterile drape over thighs and under penis.
6. Don sterile gloves and set fenestrated drape aside on sterile field.
7. Separate prep tray from container, placing prep tray with cotton balls, antiseptic solution packet, and lubricant onto sterile field toward client.
8. Test catheter balloon according to hospital policy:
 - a. Remove rubber protector and insert tip of prefilled sterile water syringe into catheter side arm to inflate balloon.
 - b. Inject 10 mL of sterile water to inflate balloon to test balloon integrity. ► **Rationale:** The catheter can fall out if not secured with appropriately inflated balloon.
 - c. If balloon malfunctions with testing, obtain a new sterile retention catheter before continuing with procedure.
 - d. After testing balloon, pull back on plunger to remove fluid and deflate balloon, leaving syringe in place.

► **Rationale:** Testing is done to ensure that balloon inflates without leaking.

9. Open package and pour antiseptic solution over cotton balls according to hospital policy.
10. Remove cap from specimen cup if indicated.
11. Uncap syringe filled with lubricant and eject onto rolling prep tray, or open lubricant package.
12. Lubricate catheter generously about 3–4 in., keeping catheter in tray, or, if using alternate method, insert lubricant directly into the urethra using a prefilled syringe.
13. Position fenestrated drape over the penis.
14. Hold penis upright with your nondominant hand. Hold sides of penis to prevent closing of urethra.
15. With your dominant hand, use forceps to pick up cotton ball saturated with antiseptic solution or pick up swab.
16. Cleanse meatus first with expanding circular stroke using the cotton balls held by forceps or Betadine swab. Check hospital policy for Betadine use.
17. Discard swab into plastic wrap at foot of bed.
18. Repeat circular prep around head of penis. Cleanse three times using a new cotton ball or Betadine swab each time. ► **Rationale:** Using a circular motion around head of penis prevents bacteria from entering urinary meatus.
19. Continue to hold penis with your nondominant hand.
20. Discard forceps into plastic bag.
21. Pick up catheter with sterile hand about 8–10 cm (3–4 in.) from tip of catheter.
22. Lift penis to a 90° angle (perpendicular to body) and exert slight traction by pulling upward. ► **Rationale:** This movement straightens the urethra for easier insertion of catheter.
23. Insert catheter about 10–12 in.
24. If resistance is met, lower angle of penis to 45° and ask client to take a deep breath. ► **Rationale:** Taking a deep breath helps relax external sphincter.
25. Guide catheter gently 1–2 in. beyond point at which urine begins to flow. ► **Rationale:** Inserting catheter further into bladder ensures it is beyond neck of bladder.

Foley Catheter Cautions

Some studies have shown that the standard Foley catheter with a solitary drainage hole at its tip (1.5 cm above the base of the balloon) allows residual urine to accumulate. This may lead to inaccurate measurement of urine output, and may increase risk for urinary tract infection.

Source: Fallis, W. (2005, April.) Indwelling Foley catheters: Is the current design a source of erroneous measurement of urine output? *Critical Care Nurse*, 25(2), 44–46, 48–51.

26. Inject entire contents of prefilled sterile water syringe into side arm of catheter for balloon inflation.
27. Gently retract catheter until you feel resistance of the balloon at neck of bladder.
28. Obtain urine specimen if indicated.
29. Remove protective cap from drainage tubing and attach securely to catheter if indicated.
30. Tape catheter to abdomen with 1-in. tape if client is not ambulatory, or use securement device made with Velcro strap. ► **Rationale:** This prevents pressure on the penoscrotal angle and ventral urethral meatus. Tape catheter to upper thigh if client is ambulatory.
31. Attach drainage bag to bed frame (not side rails).
32. Reposition client for comfort; put bed in LOW position with upper side rails raised.
33. Remove all equipment, including gloves, and discard disposable trash in the appropriate container.
34. Measure and record urine output in I&O bedside record.
35. Perform hand hygiene.
36. Label specimen cup, place in biohazard transport bag, and send to lab.
37. Document procedure, including amount of urine obtained.

Types of Securement Devices

Categories of securement devices for short- and long-term indwelling catheters:

- Improvised devices using adhesive tape, safety pins, and sutures.
- Manufactured devices with an adhesive backing and a mechanism for attaching catheter.
- Nonadhesive devices that incorporate Velcro and straps to secure the catheter to the upper thigh.

Note: Securement products developed specifically to hold indwelling catheters include the nonadhesive products that secure to the upper thigh or abdomen with a soft closure strap. These products are latex-free with hypoallergenic backing with the Velcro locking system that holds the catheter securely in place. Reusable leg anchors are available from several companies (Bard Medical Division, Posey Company, Dale Medical, Venetec, McJohnson).

Clinical Alert

Maintaining a sterile continuously closed and sealed urinary drainage system is critical to prevent CAUTI.

Optimal management of an indwelling catheter includes securing catheter to thigh or abdomen to prevent catheter or balloons from exerting excessive force on bladder neck or urethra.

Providing Catheter Care

Equipment

- Soap and water
- Washcloth
- Towel
- Clean gloves
- 1-in. tape or commercial catheter holder

Preparation

1. Check client care plan.
2. Gather equipment.
3. Identify client.
4. Provide privacy.
5. Perform hand hygiene.
6. Explain procedure to client.
7. Raise bed, and lower side rail on working side.

Procedure

1. Place client in supine position, and expose perineal area to easily visualize the meatus.

2. Remove catheter securing tape.
3. Don clean gloves.

For Female

- a. Cleanse urinary meatus using circular motion moving outward with washcloth, soap, and water.
- b. Dry area with towel.
- c. Re-secure retention catheter with tape or commercial holder.

For Circumcised Male

- a. With mitten washcloth, soap, and water, cleanse around urinary meatus.

Clinical Alert

Almost all clients will be bacteriuric after 1 month of catheterization. Indwelling urinary catheters promote UTIs by creating a portal of entry for microorganisms, and nosocomial UTIs increase mortality rate threefold. The client should be assisted to urinate by using noninvasive techniques before resorting to catheterization.

- b. Dry area with towel.
- c. Using separate washcloth, clean area between scrotum and rectal area, then dry.
- d. Place soiled linen in hamper.

For Uncircumcised Male

- a. Retract foreskin back away from catheter.
 - b. With mitten washcloth, soap, and water, cleanse around urinary meatus.
 - c. Dry penis with towel.
 - d. After drying, pull foreskin back around the catheter.
 - e. Place soiled linen in hamper.
4. Remove gloves and discard. Re-tape catheter.
 5. Position client for comfort.
 6. Lower bed and raise upper side rail.
 7. Perform hand hygiene.

Complications Associated With Long-Term Indwelling Catheter Placement

- Urinary tract infections
- Catheter leaks
- Bladder spasms
- Urethral erosion
- Urethritis
- Epididymitis
- Prostatitis
- Scrotal abscess
- Prostatic abscess
- Urinary stones
- Urethral sphincter damage
- Bladder cancer

EVIDENCE-BASED PRACTICE**Cranberry for Urinary Tract Infection Prophylaxis**

There is a growing accumulation of evidence-based information in support of use of cranberry in UTI prevention. Its beneficial effect is not by acidifying urine, but by inhibiting adherence of *E. coli* and other gram-negative uropathogens to urinary tract epithelial cells. A recent randomized controlled trial demonstrated that one tablet of concentrated cranberry extract (300–400 mg) twice daily or 8 oz of pure unsweetened cranberry juice three times daily is safe and effective for up to 12 months. Cranberry may increase urinary oxalate levels and so may increase risk of kidney stone formation in patients with a history of oxalate calculi.

Cranberry also seems to inhibit the aggregation of dental plaque bacteria.

Source: Lynch, D. (2004). Cranberry for prevention of urinary tract infections. *American Family Physician*, 70(11), 2175.

Removing a Retention Catheter**Equipment**

- 10-mL syringe without needle
- Paper towel
- Clean gloves
- Client's calibrated graduate

Preparation

1. Check physician's orders for removing catheter.
2. Perform hand hygiene.
3. Gather equipment.
4. Explain procedure to client.
5. Provide privacy.
6. Don clean gloves.

Procedure

1. Remove tape attaching catheter to client.
2. Insert syringe into balloon port of catheter. Do not cut port with scissors. ► **Rationale:** Balloon may not totally deflate if inflation port is cut.

Clinical Alert

Do not aspirate balloon vigorously. Doing so may collapse inflation lumen and prevent balloon deflation.

▲ Balloon must be deflated before removing to prevent damage to urethra.

▲ Insert syringe hub into balloon port and withdraw fluid from retention catheter balloon.

3. Withdraw fluid from balloon (usually 10 mL of water in balloon).
4. Pull gently on catheter to ensure balloon is deflated before attempting to remove. ► **Rationale:** Damage to urethra can occur if balloon is not totally deflated.
5. Hold paper towel under catheter with your nondominant hand.
6. If resistance is not met, slowly withdraw catheter, allowing it to fall into paper towel.

7. Disconnect urine drainage bag from bed frame.
8. Empty drainage bag into graduate and measure.
9. Record output on I&O bedside record.
10. Dispose of catheter in appropriate receptacle.
11. Position client for comfort.
12. Remove gloves and perform hand hygiene.
13. Instruct client to drink oral fluids as tolerated and observe for symptoms of urinary tract infection (burning, frequency, urgency).
14. Offer bedpan or urinal after removing catheter, until voiding occurs. Keep accurate I&O record of time and amount of postcatheterization voidings.
15. Report to physician if client has not urinated in 8 hr or is uncomfortable.

EVIDENCE-BASED PRACTICE

Reminder Reduces Urinary Catheterization Use

This study demonstrated that catheter use could be decreased if physicians received automatic computerized (or written) reminders that their clients had catheters and how long they had been in place. Because urinary catheters are a major source of nosocomial infection, their use should be as brief as possible.

Source: Saint, S., Kaufman, S. R., Thompson, M., Rogers, M. A., & Chenoweth, C. E. (2005). A reminder reduces urinary catheterization in hospitalized patients. *Journal on Quality and Patient Safety*, 31(8), 455–462.

DOCUMENTATION for Catheterization

- Time and purpose
- Type and size of catheter
- Amount, color, and odor of urine obtained
- Client's tolerance of procedure
- Specimen sent to lab (if ordered)
- Catheter care provided
- Catheter removed
- Voiding: time and amount after catheter removal
- Intake and output
- Residual volume amount and time since last void

CRITICAL THINKING Application

Expected Outcomes

- Catheterization is avoided with use of bladder scanner.
- Sterile technique is maintained throughout catheterization procedure.
- Catheter enters bladder as evidenced by urine outflow.
- Client remains free of urine leakage around retention catheter.
- Urinary tract infection does not occur secondary to catheterization.

Unexpected Outcomes

Bladder scan does not give reading.

Alternative Actions

- Make certain adequate conducting gel has been used.
- Have obese client bend knees so that feet are flat on the bed.
- Have thin client partially sit up to compress abdomen.
- Apply more pressure with scan head, depressing 1–2 in. into client's abdomen.

Catheter is contaminated during procedure.

- Obtain new kit (or sterile catheter) and repeat procedure.
- Keep catheter tip in lubricant packet until ready to catheterize.
- If catheter has tear-away sleeve, leave catheter within it while catheterizing client.

Catheter is inserted into female client's vagina.

- Leave the catheter in place and follow these actions:
 - Have someone obtain a new sterile catheter and gloves.
 - Reposition fingers to better visualize urethral meatus.
 - Obtain an assistant to provide direct lighting.
 - Insert new catheter pointing upward (toward client's umbilicus), as downward angle insertion tends to follow vaginal inlet.
 - Place obese client in side-lying position and flex upper leg for catheterization.

Catheter cannot be inserted into male client.

- Obtain new catheter kit and follow these actions:
 - Obtain order for intraurethral lidocaine gel.
 - Hold penis vertical to client's body, insert lidocaine gel.
 - Insert catheter while applying slight traction by gently pulling upward on the shaft of the penis.
 - If resistance encountered, rotate catheter, increase traction, and lower angle of penis.
 - Ask client to cough.
 - Try using a Condé or 12-Fr catheter.

Urine leaks around retention catheter.

- Obtain order for catheter irrigation to ensure patency of catheter.
- Inflate catheter balloon with full amount of sterile water in syringe (10 mL) to fill balloon and catheter inflation lumen as well.
- Do not increase catheter size, as this increases bladder irritation, spasm, and leakage.
- Obtain urine culture and sensitivity, as leakage may be sign of urinary tract infection.
- Obtain order for anticholinergic medication to relieve bladder spasms.

Client develops urinary tract infection while catheterized.

- Remind physician that client has a catheter; reevaluate need for continued use.
- Keep urine collection system below level of client's bladder—avoid any chance of bacteria entering system caused by retrograde flow from collections bag to bladder.
- Encourage fluid intake of 2–3 L/day unless contraindicated.
- Maintain client and system positioning so that continuous urine drainage is unobstructed.
- Make certain that catheter is secured properly (thigh of female, abdomen of male).
- Maintain/coil drainage tubing to allow straight drainage into urine collection bag.
- Provide daily perineal care with soap and water only.
- Don clean gloves to empty urine collection bag; avoid contamination of drain port.
- Suggest external collection system (condom catheter) for male client.

Bladder Irrigation

Nursing Process Data

ASSESSMENT Data Base

- Determine rationale for irrigation.
- Note rate of urine flow from bladder, color of urine, presence of clots or debris.
- Assess for distended bladder.
- Assess for bladder discomfort.
- Note client's I&O balance.

PLANNING Objectives

- To remove blood clots from client's bladder
- To ensure patency of drainage system
- To relieve bladder spasm discomfort

IMPLEMENTATION Procedures

- Irrigating by Opening a Closed System788
- Irrigating a Closed System789
- Maintaining Continuous Bladder Irrigation790

EVALUATION Expected Outcomes

- Continuous bladder irrigation is maintained to prevent clot formation and catheter obstruction.
- Client does not experience discomfort.

Critical Thinking Application791

- Expected Outcomes791
- Unexpected Outcomes791
- Alternative Actions791

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
and Skill Checklists

Irrigating by Opening a Closed System

Equipment

- Sterile irrigation set with catheter tip syringe (new set for each irrigation)
- Clean gloves
- Sterile normal saline irrigant (or solution as ordered)
- Catch basin
- Antiseptic swab
- Absorbent pad
- Sterile protective cap for tubing
- Pain or antispasmodic medication
- Tape for securing catheter

Preparation

1. Check physician's order for system irrigation.
2. Gather equipment.
3. Identify client.
4. Explain procedure and rationale to client.
5. Perform hand hygiene.
6. Premedicate client as indicated. ► **Rationale:** Manual irrigation causes painful bladder spasms.
7. Provide privacy and place client in a comfortable position. The dorsal-recumbent position is most convenient if client can tolerate this position. Raise bed and lower side rail if needed.

Procedure

1. Fanfold linen to expose catheter.
2. Palpate client's bladder to check for distention.
3. Open sterile irrigant container on overbed table. Maintain sterility of inside of the container.
4. Don clean gloves.
5. Place an absorbent pad under connection of tubing and catheter. ► **Rationale:** This will form a working field for irrigating catheter.

▲ Carefully remove sealing tape to access catheter.

6. Pour irrigant into sterile solution container.
7. Uncap tip of irrigation syringe and place into solution container. Do not contaminate syringe tip.
8. Place catch basin on pad to form working field.
9. Disconnect catheter from drainage tube. Place sterile protective cap over the end of the drainage tube. ► **Rationale:** This will prevent contaminating tip of tubing.
10. Coil tubing on bed.
11. Place catheter end into sterile irrigation set catch basin. ► **Rationale:** If end of catheter touches covers, underpad, exposed skin surfaces, or drainage tube, it will be contaminated.
12. Insert irrigating syringe into catheter and attempt to aspirate any obstructing debris. ► **Rationale:** If irrigation is performed without removing debris, debris can be forced into bladder and result in infection.
13. Withdraw irrigating solution into syringe.
14. Instill 30–50 mL of irrigant into catheter with a gentle pressure.
 - a. Aspirate instilled solution.
 - b. Continue to irrigate client's bladder with 30–50 mL of irrigant until fluid returns are clear.
15. Remove the protective cap from drainage tube.
16. Wipe end of catheter with an antiseptic sponge and reconnect the catheter to the drainage tube.
17. Ensure straight line from tubing to drainage bag. Curl excess tubing loosely on bed and secure tubing to linen. ► **Rationale:** If tubing hangs below drainage bag, urine will stagnate, increasing risk of urinary tract infection.
18. Tape catheter to inner thigh for a female and to abdomen for a male.
19. Lower bed and raise side rails.
20. Discard equipment and remove gloves.

▲ Disconnect catheter from drainage tubing; cover tubing end with sterile cap.

▲ Instill 30–50 mL of irrigant into catheter to irrigate an open system.

▲ Reconnect catheter to drainage tubing using aseptic technique.

21. Make sure client is clean and comfortable.
22. Perform hand hygiene.
23. Measure amount of return. Subtract amount of irrigating solution used to irrigate.
24. Record net amount on client's I&O record.

Clinical Alert

Opening a closed urinary drainage system is indicated as a last resort to reestablish catheter patency. Manual irrigation should be done carefully for a client with transurethral resection of a bladder tumor due to risk of bladder rupture.

Irrigating a Closed System

Equipment

- Irrigation set
- 30-mL syringe with needleless cannula
- Antiseptic swabs
- Ordered irrigating solution (sterile saline)
- Clamp for drainage tubing
- Clean gloves
- Prepared pain medication, if ordered

Preparation

1. Check physician's order and client care plan.
2. Identify client. Explain procedure and rationale.
3. Premedicate client if ordered.
4. Gather equipment.
5. Perform hand hygiene.
6. Provide privacy, and place client in dorsal-recumbent position, if tolerated.
7. Raise bed, and lower side rail on working side of bed.
8. Don clean gloves.
9. Empty client's urinary drainage bag and record amount.

NOTE: This method is less effective because most clots are larger than the cannula utilized for aspiration.

Procedure

1. Open sterile container. Maintain sterility on inside of the container.
2. Place absorbent pad under end of catheter to form a working field.
3. Pour irrigant into solution container.
4. Clamp tubing just distal to injection port.
5. Swab tubing injection port with antiseptic swab.
6. Insert the needleless cannula into tubing injection port.

▲ Prep injection port on catheter drainage tubing before inserting needleless cannula.

7. Attempt to aspirate obstructing clot or debris.
 - ▶ **Rationale:** Irrigation without first attempting removal of debris can force it into bladder, resulting in infection.
8. Withdraw irrigating solution into syringe.
9. Swab injection port again.
10. Inject solution slowly into port.
11. Remove syringe from injection port.
12. Unclamp drainage tube and lower catheter to allow solution to drain. ▶ **Rationale:** This facilitates drainage.
13. Repeat irrigation steps until return is free of clots and debris.
14. Lower bed and raise side rail.
15. Dispose of equipment and remove gloves.
16. Perform hand hygiene.
17. Measure amount of return. Subtract amount of irrigating solution to determine urine output.
18. Record net urine output on client's I&O record.

Maintaining Continuous Bladder Irrigation

Equipment

- Irrigating solution (2000 mL of sterile normal saline, or less than drainage bag volume) as prescribed
- IV tubing with roller clamp
- IV pole
- Antiseptic swabs
- Clean gloves

Procedure

1. Check physician's orders and client care plan.
2. Note if client has triple-lumen indwelling catheter and drainage bag.
3. Identify client.
4. Explain procedure to client and provide privacy.
5. Perform hand hygiene and don clean gloves.
6. Remove protective covering from spike on tubing, and insert spike into insertion port of solution container. Use aseptic technique.
7. Hang irrigating solution container on IV pole and prime tubing. Height of pole is usually 24–36 in. above bladder.
 - a. Remove protective cover from end of tubing using aseptic technique.
 - b. Open roller clamp, and allow irrigating solution to run through tubing until all air is expelled.
 - ▶ **Rationale:** This prevents air from entering bladder and causing discomfort.
 - c. Close roller clamp.
8. Connect tubing to catheter irrigating (indwell) lumen using aseptic technique.
9. Check for patency of catheter; ensure there is an absence of clots or foreign bodies that may obstruct catheter.
10. Remove gloves.
11. Adjust drip rate of irrigating solution by adjusting the clamp on the tubing to increase or decrease based on urine outflow color.
 - a. Infuse continuously to keep urine drainage pink to clear.
 - b. When drainage is dark red or contains tissue or blood clots, irrigate manually, then increase drip rate.
 - ▶ **Rationale:** Increased drip rate will clear the drainage and flush out debris and clots.

▲ Maintain continuous bladder irrigation by using a triple-lumen catheter for procedure.

▲ Hang irrigating solution on IV pole at height of 24–36 inches above bladder.

- c. Change irrigation solution bottle using aseptic technique.
12. Check for bladder distention or abdominal pain; note urine color.
 13. Monitor urine output at least every hour to observe patency of system.
 14. Empty drainage bag as needed. Subtract amount of irrigant infused from total output to obtain urine output and record.

15. Maintain catheter traction if taped to thigh.
 - ▶ **Rationale:** This promotes venous hemostasis.
16. Remove gloves and perform hand hygiene.

NOTE: Procedure is done to flush clots and debris from bladder or obstruction of catheter after prostatic surgery and to prevent catheter obstruction and promote patency. Immediately report bright red urine outflow, as this indicates an arterial bleed.

DOCUMENTATION for Bladder Irrigation

- Type and amount of solution administered for irrigation
- Rate of administration of irrigating solution
- Description of urinary output, including color and presence of clots or debris
- Any statements of discomfort or cramping
- Medication given for pain
- Amount of actual urine output (total urine output minus amount of irrigant instilled)

CRITICAL THINKING Application

Expected Outcomes

- Continuous bladder irrigation is maintained to prevent clot formation and catheter obstruction.
- Client does not experience discomfort.

Unexpected Outcomes

Irrigation flow is not infusing at prescribed rate.

Alternative Actions

- Raise or lower IV standard with attached irrigation bag to assist in regulating flow using gravity.
- Move flow adjuster clamp to new site on tubing.
- Suspect obstruction.
- Suspect obstruction:
 - a. Check tubing for kinks.
 - b. Have client change position.
 - c. Maintaining sterile technique, disconnect catheter outflow port, and gently aspirate solution from catheter to remove clots.
 - d. Instill 30–50 mL of irrigating solution to free clots.
 - e. Reconnect drainage system and observe for 30 minutes; bladder spasms may block outflow of urine.
 - f. Notify physician if problem is not resolved or client develops nausea, hypertension, bradycardia (client may develop TURP syndrome due to absorption of hypotonic irrigating solution).
- Increase irrigation inflow rate; monitor vital signs.
- Do not allow client to cough.

Irrigation outflow is less than expected.

Client's urine outflow is dark pink with blood clots.

- Keep client's catheter-taped leg straight to maintain traction on catheter inflation bulb.
- Suspect obstruction.
- Increase irrigation rate.
- Notify physician if problem continues.

Client experiences painful bladder spasms during irrigation.

- Notify physician to obtain order for urinary antispasmodic medication.
- Assist client to change position.

Chapter 22

UNIT 5

Suprapubic Catheter Care

Nursing Process Data

ASSESSMENT Data Base

- Observe for urine flow through catheter.
- Observe for excessive bleeding through catheter or at insertion site.
- Check that suture site is clean, dry, and intact.
- Check that straight drainage is maintained.
- Assess that fluid intake is at least 2000 mL daily.
- Assess client for pain, bladder distention, or spasms.
- Assess client's ability to assist with clamping procedure.
- Assess client's ability to tolerate catheter being clamped.

PLANNING Objectives

- To prevent urinary tract infection when a suprapubic catheter is inserted
- To maintain a patent suprapubic catheter
- To monitor the catheter clamping procedure
- To prevent infection at catheter insertion site
- To provide discharge teaching if catheter is to remain in place when client is discharged

IMPLEMENTATION Procedures

- Providing Suprapubic Catheter Care 793
 - For Removing the Suprapubic Catheter 794
 - For Reinserting at Established Suprapubic Catheter Site . . . 794

EVALUATION Expected Outcomes

- Suprapubic catheter remains intact.
- Client remains free of urinary tract infection.

Critical Thinking Application	794
• Expected Outcomes	794
• Unexpected Outcomes	794
• Alternative Actions	794

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
and Skill Checklists

Providing Suprapubic Catheter Care

Equipment

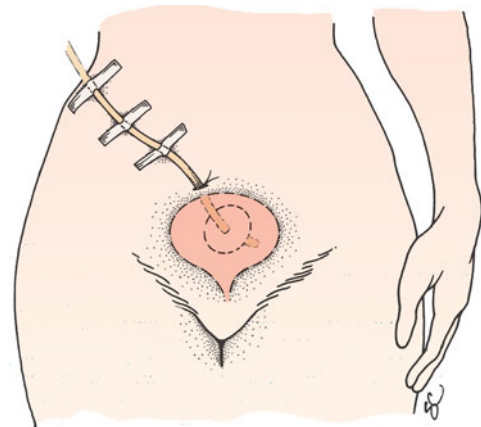

- Closed drainage system, including Foley catheter tubing and bag
- Catheter clamp and plug
- Dry sterile dressing and tape if ordered
- Cleansing solution
- Clean gloves
- Sterile gloves

Preparation

1. Check physician's orders and client care plan.
2. Identify client and explain purpose of catheter.
3. Describe procedure for continuous or intermittent urinary drainage.
4. Perform hand hygiene.
5. Provide privacy.

Procedure

1. Observe catheter for patency. ► **Rationale:** The most common problem with suprapubic catheters is occlusion with sediment or clots.
 - a. First 24 hr: check the catheter every hour to detect possible obstruction. Urine output should be in excess of 30 mL/hour.
 - b. Second day: check the catheter every 8 hr.
 - c. Third day: check the catheter when the catheter is unclamped.
2. Maintain a closed drainage system. Do not open system to irrigate or obtain urine sample.
3. Observe for signs of urinary tract infection (color, odor, presence of sediment).
4. Keep the dressing dry around site of insertion. Apply a new dressing, maintaining sterile technique, every morning and as necessary.
 - a. Place bed in high position.
 - b. Perform hand hygiene and don clean gloves.
 - c. Remove old dressing, discard gloves, and dispose in appropriate container.
 - d. Perform hand hygiene and open sterile supplies.
 - e. Open cleansing solution and pour over sterile gauze.
 - f. Don sterile gloves.
 - g. Assess skin surrounding suprapubic catheter.
 - h. Cleanse area with cleansing solution. Allow to dry.
 - i. Apply sterile dressing and secure with tape.
 - j. Remove gloves and supplies and discard in appropriate container.
 - k. Perform hand hygiene.
 - l. Replace bed in low position.
5. Perform clamping protocol according to physician orders for intermittent urinary drainage.
 - a. Explain the clamping procedure and ask client to help monitor the clamping.
 - b. Instruct client to report if he or she feels fullness in the bladder during clamping.
 - c. Don clean gloves.
 - d. Clamp the catheter.
6. Empty the drainage bag or remove drainage tubing from catheter, maintaining aseptic technique.
 - a. Place drainage tubing in sterile package to maintain sterility.
 - b. Place catheter plug in catheter end.
 - c. Remove gloves and perform hand hygiene.
 - d. Record urine output on I&O record.
 - e. Leave the catheter clamped or plugged for 3–4 hr depending on client's level of comfort and physician's orders.
7. At 3- to 4-hr intervals, or when client feels bladder fullness, ask client to void normally. Don clean gloves to measure the urine and record output on I&O bedside record.
8. Immediately after client voids, unclamp catheter and leave unclamped for 5 minutes, collecting the residual urine.
 - a. Don clean gloves to measure the residual urine after unclamping of the catheter.
 - b. Reclamp catheter.
 - c. If ordered, send a urine specimen to laboratory after the first clamping. ► **Rationale:** This checks for the presence of microorganisms.
9. Repeat clamping protocol every 3–4 hr according to physician orders. The catheter may be open to drainage from bedtime until 6 AM.
10. When the client is voiding normally, clamp the catheter throughout the night in preparation for its removal.
11. When the client's residual urine output is less than 100 mL or retains less than 20% of residual urine on two successive checks, notify the physician for removal of the catheter.
12. Cleanse insertion area with antimicrobial swab.

▲ Tape catheter and connect to a closed system.

13. Deflate balloon and remove catheter, if order written for nurse to remove.
14. Apply a 2 × 2 sterile dressing over the insertion site.
15. Dispose of the catheter in biohazard bag.
16. If the client is discharged from the hospital with the catheter, provide the following teaching for home care:
 - a. Instruct the client to drink one glass of fluid every hour while awake.
 - b. Instruct client to follow clamping procedure when awake or as instructed by physician.
 - c. Instruct the client to leave the catheter open to the drainage system at night. (Drainage system may be urinary tubing and bag or leg bag.)
 - d. Tell client to notify physician if dysuria occurs when voiding or if urine becomes cloudy, odorous, or has sediment.

For Removing the Suprapubic Catheter

- a. Don clean gloves.

- b. Prep the catheter and the insertion site with Betadine or antiseptic prep.
- c. Deflate balloon: Insert syringe into inflation tube of catheter and withdraw fluid from balloon, which will deflate.
- d. Gently withdraw catheter.
- e. Place 2 × 2 sterile dressing over the insertion site.

For Reinserting at Established Suprapubic Catheter Site

NOTE: In selected hospitals, nurses are now allowed to reinsert suprapubic catheters per physician's orders.

- a. Obtain same size suprapubic catheter as used previously. (Check size at distal end of catheter.)
- b. Insert new catheter 1.5–2 in. or add length if large amount of adipose tissue. There may or may not be urinary return with insertion of catheter.
- c. Inflate balloon with appropriate volume of sterile water.

DOCUMENTATION for Suprapubic Catheter Care

- Time catheter clamped
- Length of time clamped
- Client's ability to void spontaneously
- Client's feelings of fullness
- Time specimen sent to laboratory
- Color, amount, and odor of urine obtained
- Color, amount, and odor of residual urine

CRITICAL THINKING Application

Expected Outcomes

- Suprapubic catheter remains intact.
- Client remains free of urinary tract infection.

- Client is able to void naturally.

Unexpected Outcomes

Suprapubic catheter becomes dislodged.

Alternative Actions

- Place sterile dressing over catheter insertion site; do not attempt to replace catheter.
- Notify physician.
- Obtain new catheter to prepare for insertion by physician.

Client develops urinary tract infection.

- Note signs and symptoms of UTI: cloudy malodorous urine with sediment, bladder discomfort/spasms, elevated temperature.
- Notify physician to obtain order for urinalysis and antimicrobial therapy.
- Increase fluid intake to at least 2–3 L/day (unless contraindicated).
- Maintain continuous urine drainage per suprapubic catheter.

Client is unable to void spontaneously through urethra.

- Maintain suprapubic urine drainage.
- Notify physician.

Specimens From Closed Systems

Nursing Process Data

ASSESSMENT Data Base

- Assess the type of specimen needed.
Note: From a closed system, all will be sterile specimens—voided urine is a clean specimen.
- Identify amount of urine needed for specimen.
- Check to see if the closed urinary system has a port for obtaining a specimen.

PLANNING Objectives

- To prevent urinary infection by obtaining a urine specimen without interrupting a closed urinary drainage system
- To determine the specific microorganism causing a urinary tract infection
- To obtain a urine specimen for diagnostic purposes.

IMPLEMENTATION Procedures

- Collecting Specimen From a Closed System 796

EVALUATION Expected Outcomes

- Urine specimen is obtained from the closed urinary drainage system.
- Urine specimen remain sterile.

Critical Thinking Application 797

- Expected Outcomes 797
- Unexpected Outcomes 797
- Alternative Actions 797

and Skill Checklists

Collecting Specimen From a Closed System

Equipment

- Catheter tubing clamp or rubber band
- Kova specimen trap syringe *or* syringe with blunt cannula
- Sterile specimen container with label if necessary
- Label
- Biohazard bag
- Antimicrobial swab
- Clean gloves

Procedure

1. Gather equipment.
2. Identify client using two forms of identification.
3. Explain the procedure and rationale to the client.
4. Clamp (or crimp and bind) retention catheter drainage tubing a few inches distal to sample access port (approximately 15 minutes to allow urine to collect in tube). ► **Rationale:** This ensures urine specimen is adequate.
5. Perform hand hygiene and don gloves.
6. Wipe the sample access port of the drainage tubing with the antimicrobial swab.
7. Insert cannula of specimen trap syringe into port. Alternately, insert blunt cannula of syringe, or engage uncapped Luer-Lok syringe with port. ► **Rationale:** Different manufacturers recommend different equipment use with their products.
8. Aspirate urine sample (at least 2 mL) by gently pulling back on syringe plunger, then remove syringe.

▲ Luer-Lok syringe: Obtain specimen using Luer-Lok syringe and transfer urine to sterile specimen cup.

9. For Kova specimen syringe, cap syringe, completely retract plunger, snap it off from end of syringe barrel, and discard.
10. Apply identifying label to specimen syringe.
11. For syringe with blunt cannula or Luer-Lok syringe, transfer urine sample into specimen container and apply client label.
12. Remove drainage tubing clamp.
13. Remove gloves and perform hand hygiene.
14. Send specimen syringe or container in biohazard bag to laboratory as soon as possible, or place in unit refrigerator.

▲ Specimen trap syringe: Insert specimen collection syringe cannula into aspiration port and gently pull back on plunger to aspirate urine.

▲ Kova specimen syringe: Snap off plunger of Kova specimen collection syringe, place in biohazard bag, and send as self-contained unit to lab for urine analysis.

DOCUMENTATION for Specimens From Closed Systems

- Type and amount of specimen obtained
 - Type of specimen container/syringe used to obtain specimen
 - Color, consistency, and odor of urine
 - Time of urine collection
 - Time specimen sent to laboratory
-

CRITICAL THINKING Application

Expected Outcomes

- Urine sample is obtained from closed urinary drainage system.
-

Unexpected Outcomes

Insufficient amount of urine is obtained when collection is attempted.

Alternative Actions

- Check that client has had sufficient fluid intake.
 - Check for kinking of catheter.
 - Clamp catheter tubing for 45 minutes before specimen collection.
 - Reposition client.
-

Chapter 22

UNIT 7

Urinary Diversion

Nursing Process Data

ASSESSMENT Data Base

- Assess location of stoma on client's abdomen. (Depends on type of diversion.)
- Determine type of urinary diversion.
- Observe stoma color (same color as mucous membrane lining the mouth).
- Assess skin for condition.
- Assess presence of ureteral stents for new ileal conduit.
- Assess most appropriate pouching system for client. (System depends on client's age, manual dexterity, size of stoma, stoma location, presence of skin folds, and bony prominences.)
- Assess client's ability to manage self-care.
- Assess urine output (amount and character).

PLANNING Objectives

- To provide a pouching system that prevents skin irritation
- To instruct the client in self-care
- To monitor stoma for viability
- To obtain a sterile urine specimen

IMPLEMENTATION Procedures

- Applying a Urinary Diversion Pouch 799
- Obtaining Urine Specimen From an Ileal Conduit 801
- Catheterizing Continent Urinary Reservoir 802

EVALUATION Expected Outcomes

- Pouching system does not leak.
- Client demonstrates self-care skills.
- Urine specimen is readily obtained from urinary diversion system.
- Peristomal skin remains intact and healthy.

Critical Thinking Application	802
• Expected Outcomes	802
• Unexpected Outcomes	802
• Alternative Actions	802

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
and Skill Checklists

Applying a Urinary Diversion Pouch

Equipment

- One- or two-piece urinary pouch with skin barrier, flange, and spigot at bottom of pouch to empty urine
- Items to clean stoma (e.g., soft cloth or gauze sponges) and warm water
- Plastic bag for disposal of used equipment
- Gauze for drying skin and for wicking stoma
- Underpad to protect bedding
- Scissors if indicated
- Protective barriers such as skin prep, skin gel, or protective barrier film if necessary
- Stoma measuring guide
- Clean gloves

Preparation

1. Check physician's order and client care plan. Pouch should be changed every 3–7 days.
2. Gather equipment.
3. Perform hand hygiene.
4. Identify client and explain procedure.
5. Provide privacy.
6. Place client in a position that promotes visualization and self-care.
7. Place protective pad under client.
8. Place bath blanket over client's chest and position top covers over lower abdomen without impeding client's visualization of procedure.

Procedure

1. Don clean gloves.
2. Empty, then remove entire ostomy appliance by pushing the skin gently away from the appliance and peeling the appliance downward. Discard in plastic bag.
3. Wash stoma and peristomal skin with warm water and soap if needed, rinse well, and pat skin dry. **▶ Rationale:** Chemical or perfumed wipes can irritate skin or may interfere with pouch seal.

▲ One-piece and two-piece urinary diversion pouches.

▲ Cut wafer opening slightly larger than stoma.

NOTE: Stoma may bleed slightly when wiped.

4. Check stoma for healing; it should be bright but not dark red and moist, and raised 0.5–1 in. above skin surface (or may be flush). Check for mucocutaneous separation, ulceration, encrustation, and signs of infection, and sensitivities or allergies.
5. Check skin surrounding stoma to ensure urine hasn't been draining under wafer, causing skin irritation.
6. Prepare new urinary pouch. Place gauze over stoma to prevent urine from oozing onto skin. A wick can be placed in stoma, if needed. Measure stoma site with measuring guide, unless pouch has precut opening. **▶ Rationale:** To keep urine from contact with skin during pouch change.
7. Trace size of stoma on wafer and cut 1/16–1/8 in. larger than size. **▶ Rationale:** This small opening prevents leakage of effluent onto skin; however, the size is large enough to prevent pressure on the stoma from the wafer rubbing on skin.
8. Apply protective barrier (only if indicated) to skin surrounding stoma or to wafer. Do not use lotion. **▶ Rationale:** Protective barriers contain alcohol and

▲ Apply protective paste to wafer, only if indicated.

▲ Apply pouch and press firmly to facilitate seal.

cause burning and may interfere with seal. In addition, barrier must be removed with adhesive remover.

9. Let site dry thoroughly.
10. Remove paper from adhesive on wafer of one- or two-piece appliance.

▲ Cleanse stoma and peristomal skin; dry thoroughly.

11. Remove wick and center wafer over stoma; apply to dry skin, starting at bottom, and working up around stoma. Press wafer on skin for 3 minutes. ► **Rationale:** To promote adherence to skin. If two-piece pouch, attach pouch to wafer flange.
12. Remove air from clean pouch and close spout. Attach pouch to gravity drainage bag only while client is in bed. Empty pouch when one-third full.
13. Discard equipment in appropriate receptacle.
14. Remove gloves and perform hand hygiene.

Clinical Alert

Thin plastic tubes (stents) may be placed in each ureter during surgery. These exit stoma and remain in place for up to 10 days. They serve to maintain patency until swelling has subsided at ureteroileal anastomosis site (6–10 days). Their presence and length of exposure should be documented. The surgeon should be notified when they wash out into collection pouch.

Client Teaching for Emptying Pouch

Instruct client to:

- Empty pouch when one-third full.
- Use bathroom if possible.
- Place distal end of pouch between thighs or stand over toilet.
- Open drainage port to allow urine to drain.
- Dry drainage port with toilet paper.
- Close drainage port.
- Perform hand hygiene.

Types of Urinary Diversion

Nursing Considerations

I. Ileal or Colonic Conduit

- Urostomy constructed from portion of bowel—ileum is resected and an internal conduit formed and attached to abdominal wall.
- Ureters are connected to internal conduit.
- An external pouch collects urine.

- Care of urinary pouch.
- Monitor peristomal skin for breakdown.
- Monitor stoma.

II. Continent Urostomy

A. (Kock's Reservoir)

- Reservoir is constructed from ileum and ascending colon. Two nipple valves are created by pulling ileum back onto itself.
- Ureters are implanted near internal nipple valve (valve prevents reflux).
- Outlet valve is attached to abdominal wall and stoma.
- Reservoir is catheterized to drain urine.

- Instruct in clean intermittent self-catheterization every 2–4 hr.

Types of Urinary Diversion	Nursing Considerations
B. Indiana Pouch	
<ul style="list-style-type: none"> • Internal pouch is created from the ascending colon and terminal ileum. • Pouch is larger than Kock's reservoir. • Reservoir is catheterized to drain urine. 	<ul style="list-style-type: none"> • Instruct in clean intermittent self-catheterization every 2–4 hr. • Monitor for electrolyte imbalance; reservoir may absorb urea and electrolytes.
III. Neo Bladder	
<ul style="list-style-type: none"> • Created from cecum or ileum with ureters attached. • Has no stoma. • Requires no external appliance. • Urine exits via urethra. • Preserves normal body image. 	<ul style="list-style-type: none"> • Client may eliminate with timed voiding. • May require self-urethral catheterization.

Obtaining Urine Specimen From an Ileal Conduit

Equipment

Sterile catheter kit
 Prep solution
 Sterile saline or water
 Underpad
 New urinary pouch
 Supplies necessary to apply new pouch
 Bath blanket, towels
 Clean gloves
 Soap and water
 Pitcher of water and glass
 Biohazard bag

Preparation

1. Check physician's orders and client care plan.
2. Gather equipment.
3. Perform hand hygiene.
4. Explain procedure to client.
5. Provide privacy.
6. Place bath blanket over client's chest and position top covers over lower abdomen.
7. Place towels around stoma. ► **Rationale:** Urine will leak around catheter.
8. Don gloves.

Procedure

1. Open sterile packages.
2. Remove pouch or snap pouch off wafer flange.

NOTE: Do not use pouch contents to obtain urine specimen. Remove gloves.

3. Put on sterile gloves.
4. Place sterile drape over stoma.
5. Remove lid from specimen container and place end of catheter into container.
6. Apply lubricant to catheter.
7. Use forceps to pick up cotton ball and prep stoma with solution and rinse with sterile saline or water.
8. Insert tip of catheter into stoma approximately 1.5 in.
9. When urine specimen is obtained (usually not more than 5–25 mL), remove catheter. If no urine is obtained, have client drink water.
10. Return lid to specimen container and apply label.
11. If wafer removed, wash and dry peristomal area.
12. Replace pouch or apply new pouch.
13. Remove gloves and perform hand hygiene.
14. Place specimen container in biohazard bag and send specimen to lab immediately or refrigerate.

▲ Catheter is used to obtain specimen from ileal conduit.

Catheterizing Continent Urinary Reservoir

Equipment

- Sterile catheter (if client hospitalized)
- Water-soluble lubricant
- Clean gloves
- Bedpan (if client unable to use toilet)
- Warm water and soap
- Washcloth, towel

Preparation

1. Check physician's orders and client care plan.
2. Gather equipment.
3. Identify client and explain procedure.
4. Perform hand hygiene and don gloves.
5. Provide privacy.
6. Position client on chair facing toilet or place bedpan next to client if on bedrest.

Procedure

1. Open lubricant packet.
2. Lubricate tip of catheter, maintaining sterility.

3. Insert catheter 1.5–2 in. into stoma. Place distal end of catheter over toilet or bedpan.
4. Instruct client to take deep breath and gently insert catheter through nipple valve until urine returns.
 - **Rationale:** When the abdominal muscles are relaxed, it is easier to advance catheter through nipple valve.
5. Hold catheter in place until urine stops draining.
6. Remove catheter.
7. Wash and dry peristomal area with soap and water.
8. Assist client back to bed, or position for comfort.
9. Remove gloves and perform hand hygiene.

Clinical Alert

Irrigation: During the immediate postoperative period after formation of a continent reservoir, irrigation of the reservoir must be done. A mucous plug can block the catheter, leading to over-distention of the reservoir and perforation or disruption of the surgical reconstruction. Teach the client with a continent reservoir (Kock's or Indiana) to irrigate the reservoir with warm water daily using catheter and bulb or piston syringe to remove collected mucus. ► **Rationale:** Mucus produced by the bowel segment will accumulate in the reservoir.

DOCUMENTATION for Urinary Diversion

- Color and amount of urine obtained from catheterizing continent reservoir
- Catheter size used for catheterization
- Status of ureteral stents, if present
- Peristomal skin and stoma condition
- Client's acceptance of stoma, participation in self-care
- Type and method of drainage pouch applied
- Specimen sent to lab

CRITICAL THINKING Application

Expected Outcomes

- Pouching system does not leak.
- Client demonstrates self-care skills.

- Urine specimen is readily obtained from urinary diversion system.
- Peristomal skin remains intact and healthy.

Unexpected Outcomes

Pouching system leaks.

Alternative Actions

- Check area for crease or dip in skin, which allows urine to pool and leak out.
- Fill in dip area with skin barrier to prevent pooling.
- Apply belt to improve fit.
- Apply another type of pouch (e.g., convex).
- Change more frequently if leak is due to dissolving of skin barrier—or use different barrier.
- Advise client to avoid using soaps or wipes to clean area because they interfere with pouch adhesion.

Client is unable to manage own urinary diversion.

- Simplify pouch procedure if possible.
- Provide detailed instruction in more simplified manner.
- Include caregiver in teaching to assist and support client.
- Refer client to home health agency for follow-up care.

Client is offended by odor in urine collection system.

- Recommend urine-acidifying agent (e.g., vitamin C, 500 mg BID to TID); avoid alkaline ash citrus juices.
- Wash reusable equipment with mild soap and water and rinse in vinegar weekly or use commercial deodorant.
- Inform client that certain foods and drugs (asparagus, vitamin B complex) give odor to urine. Empty pouch frequently if these are ingested.
- Inform client that cloudy urine and strong odor may indicate urinary tract infection. Advise physician and collect sterile urine specimen.

No urine is obtained from conduit.

- Rotate catheter, or position client on side to allow urine to flow into catheter. As little as 1 mL is needed for urine culture and sensitivity testing.
- Have client drink water.

Erythematous vesicular rash appears on peristomal skin.

- Suspect possible allergic reaction; obtain patch test for allergy.
 - Avoid use of chemical wipes and perfumed soaps.
 - Suspect yeast infection; report to physician.
-

Chapter 22

UNIT 8

Hemodialysis (Renal Replacement Therapy)

Nursing Process Data

ASSESSMENT Data Base

- Review dialysis orders.
- Assess patency of vascular access.
 - Femoral vein catheter:* dual-lumen vascular device used for immediate vascular access in life-threatening situations.
 - Central venous dual-lumen catheter (DLC):* vascular device placed in internal jugular vein used for temporary access for acute hemodialysis clients.
 - Permanent dual-lumen catheter (PDLC):* vascular device inserted through internal jugular vein and advanced to superior vena cava (SVC).
 - Arteriovenous fistula:* surgically created internal anastomosis between an artery and vein; used for clients undergoing chronic hemodialysis.
 - Arteriovenous graft:* surgically implanted synthetic material (Gortex) or biologic material (human umbilical vein) used for anastomosis between an artery and vein for clients undergoing chronic hemodialysis.
- Review chart and laboratory reports for factors that may alter management of dialysis (especially potassium, sodium, calcium, and phosphorus levels; albumin; hemoglobin; hematocrit levels; BUN; and creatinine).
- Assess vital signs.
 - Assess causes of hypotension: fluid loss, hypoalbuminemia, large interdialytic weight gain.
 - Check serum electrolytes, BUN, and creatinine before and after dialysis according to physician orders.
 - Weigh client before and after dialysis to determine fluid loss.

PLANNING Objectives

- To remove end products of protein metabolism: urea, creatinine, and uric acid
- To remove excess fluid, thereby reestablishing fluid balance
- To maintain or restore normal level of electrolytes in the body
- To maintain a patent access site for hemodialysis
- To maintain patent catheters centrally placed
- To instruct the client in self-care

IMPLEMENTATION Procedures

- Providing Hemodialysis 805
 - For AV Fistula or Graft 805
- Providing Ongoing Care of Hemodialysis Client 807
- Terminating Hemodialysis 807
- Maintaining Central Venous Dual-Lumen Dialysis Catheter (DLC) 808

EVALUATION Expected Outcomes

- Dialysis proceeds without complication (excess fluids and wastes removed from blood).
- Vascular access site remains patent.
- Client demonstrates self-care after teaching.

Critical Thinking Application 810

- Expected Outcomes 810
- Unexpected Outcomes 810
- Alternative Actions 810

Pearson Nursing Student Resources

Find additional review materials at nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Providing Hemodialysis

Equipment

- Dialyzer (types are hollow fiber or cellulose acetate)
- 1000-mL bag of 0.9% normal saline IV solution
- Machine blood lines
- Fistula needles, 15/16 gauge, 1–1.5 in. in length
- Sterile gauze pads, alcohol swabs, and povidone–iodine or Chloraprep swabs
- Two 3-mL syringes
- Two 20-mL syringes
- Drape
- Client mask
- Hemostats, cannula clamps
- Tape
- Sterile gloves and clean gloves
- Gown
- Protective goggles and face mask or visor shield
- 12-mL syringe
- Heparin solution 1000 U/mL
- Hemastix

Preparation

1. Obtain dialysate bath composition as ordered.
2. Set up 1000-mL IV of normal saline using IV tubing in blood line set.
3. Load heparin pump (e.g., 8 mL heparin) per manufacturer's instructions. ► **Rationale:** Heparin is added to system just before blood enters dialyzer to prevent clotting. The clotting mechanism is activated when blood moves outside body and is in contact with foreign substances.
4. Check location of nearest emergency power outlet. ► **Rationale:** To maintain electric current if routine power fails.
5. Test dialysis machine for presence of bleach with Hemastix. ► **Rationale:** This detects presence of caustic agents that could result in client complications.
6. Prime dialyzer and arterial and venous blood lines with saline.
7. Hang additional IV solution of saline. ► **Rationale:** Saline infusions must be available immediately for rapid reversal of hypotension or discontinuation of dialysis.
8. Connect pressure monitor lines to both arterial and venous drip chambers. ► **Rationale:** This monitors the amount of hydrostatic pressure exerted on blood in the ultrafiltration process used to extract fluid throughout dialysis treatment.
9. Set the alarm pressures—high and low.
10. Connect air leak detector to venous drip chamber.
11. Test all machine alarms—venous and arterial pressure, air detector, and blood leak detector.

▲ Hemodialysis unit used to treat renal failure clients.

▲ Dialysis panel indicates settings and values.

12. Connect arterial and venous lines for recirculation with adapter, and turn blood pump to 200 mL/min.
13. Document alarm checks in dialysis log.

Procedure

For AV Fistula or Graft

1. Place blood line at the same level as the bed.
2. Don mask and gown. Put on goggles and perform hand hygiene.
3. Don clean gloves and remove dressing, if used. Remove and discard gloves and perform hand hygiene.

Clinical Alert

When a hemodialysis client is hospitalized:

1. Place an identifying bracelet on access arm.
2. Post safety precautions at head of bed (e.g., "Do not use access arm for blood pressure or venipuncture," and "Fluid restriction specified").
3. Notify dialysis specialty nurse of client's admission to hospital.

The Hemodialysis Process

Hemodialysis works by removing blood from the client's arterial access site (graft, fistula, or catheter). It travels through a blood pump and an arterial pressure monitor to a dialyzer (filter). In the dialyzer, the blood is separated from the dialysate by a synthetic semipermeable membrane. The dialysate (bath) runs against the blood flowing on the opposite side of the semipermeable membrane, leading to osmosis, diffusion, and ultrafiltration. Fluid, electrolytes, and toxins are removed from the blood. The blood then flows from the dialyzer through a tubing system to the client's venous access site. Fluid is removed through the use of hydrostatic pressure applied to the blood and a negative hydrostatic pressure applied to the dialysate bath. The difference between these two pressures is termed *transmembrane pressure*, and this results in the process of ultrafiltration.

▲ Arterial and venous needles placed in graft for hemodialysis.

4. Don sterile gloves.
5. Clean access site using Chloraprep or alcohol swab, then povidone-iodine swab. Using a circular motion, cleanse from needle insertion site outward. Allow to dry. ► **Rationale:** Cleansing occurs from cleanest to dirtiest area, preventing contamination of the site.
6. Insert needles into fistula or graft. Tape securely to extremity.
7. Obtain blood for predialysis blood samples as ordered by the physician. (Usually electrolytes, hematocrit, clotting time, etc.)
8. After blood is drawn for lab work, heparin bolus should be given to client according to physician's order—start heparin pump at ordered rate.
9. Prime the extracorporeal circuit with blood.
 - a. Connect arterial tubing of the blood line to client's arterial site.
 - b. Connect venous tubing.
 - c. Unclamp venous blood line.
 - d. Unclamp arterial blood line.
 - e. Clamp saline infusion line.
10. Note time of dialysis initiation.
11. Tape all connections securely; secure blood tubing to client's extremity.

Blood Flow for Dialysis

An adequate vascular access should permit blood flow to the dialyzer of 200–400 mL/min. Optimal blood access and blood flow to the dialyzer influences dialysis efficiency.

Safety Precautions for Fistula or Graft

- Feel for vibration (thrill) over access site regularly.
- Do not measure blood pressure on extremity.
- Do not perform venipuncture in extremity.
- Counsel client not to wear constrictive clothing on extremity.
- Counsel client to avoid lying on extremity.
- Avoid carrying heavy loads with access extremity.
- Immediately report swelling, discoloration, drainage, or coldness, numbness, or weakness of hand.

12. Set alarm pressures—high and low.
13. Establish blood flow rate (usually 200–400 mL/min) and the dialysate rate of 500 mL/hr. ► **Rationale:** These flow rates allow the imbalances in fluids and electrolytes to be corrected rapidly (3–4 hr per run and 2–3 times/week).
14. Ensure that access connections are visible.
15. Check client's blood pressure and pulse once dialysis has been initiated, then every 30 minutes unless otherwise indicated.
16. Assess client at least every 30 minutes for vital signs and potential complications.
17. Administer any ordered medication through the venous line. ► **Rationale:** Medication infuses into client, not machine.
18. Turn heparin infusion off last 30–60 minutes or as ordered.

Assessing Arteriovenous Fistula

- Perform hand hygiene.
- Position client's arm so fistula is easily accessed.
- Palpate the area to feel for thrill (vibration). This indicates arterial to venous blood flow and fistula patency.
- Auscultate with a stethoscope to detect a bruit (swishing noise). This indicates a patent fistula.
- Palpate pulses distal to fistula to check circulation.
- Observe capillary refill in extremity digits.
- Assess for numbness, tingling, coldness, pallor, or alteration in sensation in digits of fistula extremity.
- Assess for signs and symptoms of infection: redness, edema, soreness, warmth, or increased temperature.

Note: Vascular access promotes more efficient removal and replacement of blood during dialysis and fewer complications occur. Vascular access should be prepared weeks or months before using it for dialysis. This will stabilize the graft site and ensure adequate blood flow when used for dialysis.

Providing Ongoing Care of Hemodialysis Client

Procedure

1. Limit fluid intake to prescribed amount (e.g., 1500 mL/day).
2. Maintain individualized diet as prescribed: high-quality protein 1.1 g/kg ideal body wt/day; sodium 70 mEq/day; potassium, average 70 mEq/day.
3. Check blood pressure for hypertension/hypotension; check temperature for possible infection.
4. Auscultate heart and lung sounds for signs of fluid overload (pulmonary edema and pericarditis).
5. Provide access site care.
6. Observe mental status—indicative of fluid and electrolyte imbalance.
7. Administer Epogen, if ordered, to improve hemoglobin level (given at time of dialysis).
8. Encourage regular rest periods.
9. Weigh daily to assess fluid accumulation.
10. Use antibacterial soap and lotion to bathe. ► **Rationale:** This decreases risk of staphylococcal infections.
11. Determine that client understands when and how to take medications (e.g., Tums with meals).
12. Provide continued emotional support.
 - a. Allow for expression of feelings about change in body image and role performance.
 - b. Encourage expression of fears.
 - c. Encourage caregiver support.
 - d. Give support for required change in lifestyle.
13. Instruct client to prevent obstruction to blood flow on fistula arm.

NOTE: Dialysis adequacy is improved with increased prescription, conversion of catheters to grafts or fistulas, and by not shortening treatments.

Terminating Hemodialysis

Equipment

- Clean gloves
- Gown
- Goggles
- Mask
- Nonsterile pads
- Tubing clamps

Procedure

1. Don gloves, gown, goggles, and protective mask.
2. Remove tape and dressing to visualize needle insertion site.
3. Place pads under connectors.
4. Open IV of normal saline to return blood on the arterial side of tubing.

▲ Carefully remove tape from needle sites when terminating dialysis.

▲ Remove arterial and venous needles, using needle safety shields.

5. Start blood pump at 200 mL/min.
6. Return venous blood.
7. Clamp lines.
8. Remove needles according to unit protocol and apply pressure to sites.
9. Apply sterile dressing to needle sites maintaining aseptic technique. ► **Rationale:** Sepsis is the primary cause of client death for acute renal failure clients.
10. Remove protective gear, discard, and perform hand hygiene.
11. Measure and record postdialysis vital signs and weight.

▲ Apply pressure over needle site for 5 to 10 minutes.

EVIDENCE-BASED PRACTICE

Survival Rate in Hemodialysis Clients

This study revealed that elderly ESRD clients receiving hemodialysis during morning hours have a higher survival rate than those undergoing dialysis in the afternoon. Previously identified risk factors for this study did not account for these differences.

Source: Bliwise, D., Kutner, N. G., Zhang, R., & Parker, K. P. (2001). Survival by time of day of hemodialysis in an elderly cohort. *Journal of the American Medical Association*, 286(21), 2690–2694.

Maintaining Central Venous Dual-Lumen Dialysis Catheter (DLC)

Equipment

- Heparin 1000 U/mL
- Sterile normal saline for injection
- Betadine spray
- Sterile 4 × 4 gauze pads
- Sterile transparent occlusive dressings if indicated
- Tape
- Luer-Lok catheter caps
- Nonsterile drape
- Two 3-mL syringes
- Two 20-mL syringes
- Clean gloves
- Two masks
- Sterile gloves

Preparation

1. Perform hand hygiene.
2. Fill two 20-mL syringes with 20 mL each of normal saline, and two 3-mL syringes with 3 mL of 1000 μ/mL of heparin.

Clinical Alert

Femoral dialysis DLCs are only temporary and are rarely seen outside of the ICU setting. The client is not allowed to flex leg or ambulate.

3. Mask client and self, and don clean gloves.
4. Place drape under catheter lumens.
5. Remove gauze wrap from lumens, if present, and discard in appropriate receptacle.
6. Remove gloves and perform hand hygiene.

Procedure

1. Open sterile supplies.
2. Holding corner of 4 × 4, place under catheter lumens.
3. Spray lumens with Betadine and allow to dry.
4. Don sterile gloves.
5. Remove old lumen caps.
6. Use 4 × 4 gauze to pick up new caps and place on lumens.

▲ Maintain sterility while carefully removing dressing from dual-lumen catheter.

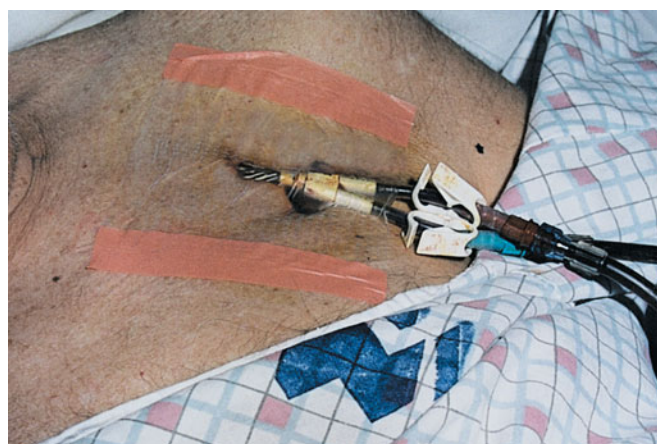

7. Unclamp and inject 20 mL of saline solution into each lumen using positive pressure technique.
8. Inject 3 mL of heparin into each catheter using positive pressure technique.
9. Reclamp lumens.
10. Remove old dressing and discard in biohazard receptacle.
11. Cleanse area surrounding catheter with antimicrobial swabs.
12. Place sterile transparent dressing over catheter insertion site.

NOTE: Provide catheter site care after each dialysis treatment. Dressing is not required after permanent catheter site epithelializes around catheter (about 2 weeks).

13. If desired, wrap lumens in gauze and tape. ► **Rationale:**
To prevent skin irritation from lumen clamps.
14. Dispose of equipment in biohazard receptacle.
15. Remove gloves and mask and discard.
16. Perform hand hygiene.
17. Monitor daily for signs of infection, bleeding, or displacement of catheters.

▲ Cleanse catheter insertion site with antimicrobial swabs.

▲ Monitor frequently for signs of infection, bleeding, or catheter displacement.

Clinical Alert

Central venous dual-lumen dialysis catheter (DLC) maintenance (heparin “pack” and site dressing) is performed *only* by the nephrology nurse after a dialysis treatment. These catheters are not maintained the way CVADs are. Instead, they are “packed” with *undiluted* heparin after dialysis, then “unpacked” (3 mL of blood withdrawn from catheter) before the next dialysis treatment.

DOCUMENTATION for Hemodialysis

- Predialysis assessment, subjective and objective data
- Status of fistula, graft, or catheter access site and distal circulation
- Time dialysis initiated and terminated
- Dialyzer type and dialysate used
- Volume of blood processed
- Any complications during procedure and actions taken
- Client symptoms at 30-minute intervals
- Vital signs every 30 minutes
- Postdialysis assessment

CRITICAL THINKING Application

Expected Outcomes

- Dialysis proceeds without complication (excess fluids and wastes removed from blood).

Unexpected Outcomes

Hypotension occurs during dialysis.

Alarms sound during dialysis.

Bleeding occurs during dialysis.

Client develops restlessness, confusion, seizures, headache, nausea, vomiting, or hypertension near end of dialysis session.

Client states hand feels weak; neither thrill nor bruit can be assessed in fistula or graft.

Client gains 7 pounds between dialysis sessions; blood pressure is elevated.

Client's predialysis phosphorus level is excessively elevated.

Client develops hypothermia and experiences chills while on dialysis.

- Vascular access site remains patent.
- Client demonstrates self-care after teaching.

Alternative Actions

- Administer normal saline, concentrated saline bolus, or albumin into extracorporeal circuit.
- Place client in shock position if tolerated.
- Consider using smaller volume dialyzer, less ultrafiltration, or intermittent normal saline doses to maintain BP in future dialysis sessions.
- Consider possible dialyzer reaction or myocardial infarction; notify physician for further assessment/diagnostic testing.
- Before dialysis, become familiar with alarm sounds, functions, and troubleshooting options.
- If blood leak alarm sounds, observe dialysate. If no blood is apparent, check dialysate with Hemastix since air bubbles can cause false alarms.
- If bleeding or blood leak is present, discontinue dialysis without returning client's blood.
- Suspect dialysis disequilibrium syndrome (usually only occurs in new clients).
- Consult physician and implement orders to slow blood flow rate or discontinue dialysis.
- Administer medications as ordered (hypertonic saline or mannitol) to relieve symptoms.
- For future sessions, consider earlier dialysis before BUN rises excessively or shorten the dialysis treatment and increase number of runs/week.
- Notify physician of potential clotting of fistula/graft (declotting should be attempted ASAP).
- Prepare to possibly send client to radiology for vascular procedure.
- Review safety precautions to prevent constriction of blood flow in access extremity.
- Assess client's understanding of fluid restriction (1500 mL/day); advise of hidden fluid in certain foods (ice cream, watermelon, etc.).
- Encourage client to control blood sugar (if diabetic) to help relieve thirst; decrease salt intake, but avoid salt substitute (KCl).
- Encourage client to weigh daily.
- Review foods high in phosphorus (colas, red meat, dairy products, eggs).
- Encourage client to continue calcium and vitamin D supplement as prescribed.
- Remind client to take phosphorus binder medication with meals; if not taking, inquire if constipation is reason and recommend stool softener.
- Place warm blanket on client.
- Place warmer on blood return line to client. Ensure client's room is set at a comfortable temperature.

Adaptation to Home Care

Nursing Process Data

ASSESSMENT Data Base

- Assess the client's bladder for distention.
- Assess the client's physical ability to cooperate with positioning.
- Assess urinary meatus and catheter for exudate, edema, inflammation, and general cleanliness.
- Assess need for perineal care before catheterization procedure.
- Assess dialysate solution for clarity.
- Assess dialysis returns for cloudiness.
- Assess family's ability to use gloving technique and maintain asepsis when needed.
- Assess need for suprapubic catheter care.
- Assess need for catheterization procedure.
- Assess for proper function of dialysis machine.

PLANNING Objectives

- To prevent or relieve discomfort due to bladder distention
- To promote urinary elimination
- To identify family's knowledge related to signs and symptoms of dialysis-related infections.
- To prevent urinary tract infections through aseptic catheter care
- To prevent infection at peritoneal catheter site
- To use aseptic technique when instituting CAPD
- To identify client's and family's knowledge base regarding CAPD or CCPD

IMPLEMENTATION Procedures

- Using Clean Technique for Intermittent Self-Catheterization 812
 - For Female Client 812
 - For Male Client 812
- Providing Suprapubic Catheter Care 812
- Administering Continuous Ambulatory Peritoneal Dialysis (CAPD) 813
 - For Draining Fluid 813
 - For Infusing Dialysate 814
- Changing Dressing for CAPD Client 815

EVALUATION Expected Outcomes

- Catheterization performed using aseptic technique.
- Bladder emptied when client is unable to void.
- Urinary tract infection prevented through aseptic catheter care.
- Aseptic peritoneal dialysis procedure used.
- Catheter site remains free of infection.
- Suprapubic catheter care is completed and client is free of urinary tract infections.

- **Critical Thinking Application** 815
 - Expected Outcomes 815
 - Unexpected Outcomes 815
 - Alternative Actions 815

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Using Clean Technique for Intermittent Self-Catheterization

Equipment

Straight catheters in clean container, plastic bag, or wrapped in aluminum foil
 Washcloth, soap, water
 Water-soluble lubricant (K-Y; Surgilube)
 Plastic bags
 Basin or container
 Mirror

Procedure

For Female Client

1. Attempt to urinate. If unable to do so, continue to follow these steps.
2. Perform hand hygiene and gather equipment. (Keep equipment in one large container.)
3. Assume sitting position on the bed or commode. (Place plastic under towel if bed is used.)
4. Separate labia with one hand while cleaning with soap and water front to back with other hand.
5. Position mirror to visualize urinary meatus.
6. Remove catheter from container (plastic bag or aluminum foil).
7. Lubricate end of catheter with water-soluble lubricant and place other end in container to catch urine.
8. While holding labia apart with one hand, insert catheter about 3 in. or until urine flows.
9. Press down with abdominal muscles to promote bladder's emptying.
10. Pinch off catheter after all urine has drained and withdraw gently, holding tip of catheter upright.
11. Wash and dry perineal area.
12. Wash catheter in warm, soapy water.
13. Rinse with clear water and dry outside with paper towel.
14. Place in plastic bag for storage.
15. Use catheters for 2–4 weeks and then discard.
16. Perform hand hygiene.

For Male Client

1. Attempt to urinate. If unable to do so, continue to follow these steps.
2. Perform hand hygiene and gather equipment. (Keep equipment in one large container.)
3. Assume sitting position on the bed or commode. (Place plastic under towel if bed is used.)
4. Retract the foreskin, if present, and wash tip of penis with soap and water.
5. Remove catheter from container (plastic bag or aluminum foil).
6. Lubricate the first 7–10 in. of catheter with water-soluble lubricant. Place other end in container to catch urine.
7. Hold penis at right angle to body, keeping foreskin retracted. Insert catheter 7–10 in. into penis or until urine begins to flow. Then insert catheter 1 in. further.
8. Press down with abdominal muscles to promote bladder's emptying.
9. Pinch off catheter after all urine has drained and gently withdraw, holding tip of catheter upright.
10. Wash and dry area. Replace foreskin, if present.
11. Wash catheter in warm, soapy water.
12. Rinse with clear water and dry outside with paper towel.
13. Place in plastic bag for storage.
14. Use catheters for 2–4 weeks and then discard.
15. Perform hand hygiene.

Providing Suprapubic Catheter Care

Equipment

Catheter plug and clamp
 Closed drainage system
 Sterile dressings if necessary
 Clean gloves
 Receptacle to drain urine from drainage bag
 Normal saline solution or mild soap and water
 White vinegar
 Applicator sticks

4 × 4 gauze pads
 Paper tape

Procedure

1. Instruct client to gather equipment for specific skill to be done.
2. Perform hand hygiene and don gloves.
3. Clean around catheter site with normal saline solution or mild soap and water. Use applicator sticks to remove material from around catheter opening.

4. Ensure catheter is not pulling on exit site. Tape catheter to skin so a gentle curve is present to prevent tugging on catheter.
5. Empty catheter bag. Some clients use leg bags. Empty into container and then dispose of contents in toilet or, if removing bag, empty directly into toilet.
6. Clean drainage bags with warm water and soap every day or two. Place one teaspoon of vinegar in rinse water to reduce odor.
7. Replace catheter bag on catheter.
8. Remove gloves and perform hand hygiene.
9. Instruct client in bladder testing:
 - a. Wash hands and catheter connections with soap and water.
 - b. Clamp the suprapubic tube so it does not drain. Use catheter plug or clamp.
- c. Have client attempt to void when client feels urge to urinate. Measure amount of urine.
- d. Unclamp the suprapubic tube immediately after voiding; empty urine into container and measure residual urine amount.
- e. Instruct client to keep a log of each voiding and residual amount.
- f. Call physician with findings when residual amount is less than 20% voided amount. Usually, this amount is about 60 mL. Usually, the suprapubic tube is removed when client is able to urinate without complications.
10. Instruct client to monitor carefully for signs of urinary tract infection and notify physician immediately. Check for bladder pain, bleeding, temperature over 100°F, chills, cloudy urine, drainage or edema around the suprapubic tube.

Administering Continuous Ambulatory Peritoneal Dialysis (CAPD)

Equipment

Sterile dialysate solution, 1–2 bags, warmed
 Heating pad
 Transfer set, either Y tubing or straight, and cap
 Hook on wall of room used for dialysis
 Clamp
 Paper towels
 Low stool or table
 Intake and output record
 Two pairs of sterile gloves
 Mask
 Antibacterial soap
 Cleansing solution for catheter
 Medication, if ordered

Preparation

1. Perform hand hygiene thoroughly; dry using paper towel.
2. Obtain container of sterile dialysate.
3. Check that strength and amount of solution are accurate as ordered.
4. Take equipment to clean area for assembly.

Procedure

For Draining Fluid

1. Perform hand hygiene and don gloves. ► **Rationale:** Infection control precaution for caregiver when there is potential contact with blood or body fluids.
2. Don mask.
3. Uncap catheter maintaining aseptic technique.

4. Attach sterile bag and transfer set to catheter for draining dialysate.
5. Place bag on low stool or table below level of client's abdomen. ► **Rationale:** This position allows fluid to drain by gravity from client's peritoneal cavity.
6. Unclamp tubing.
7. Allow fluid to drain into bag from abdomen until flow ceases, approximately, 10–20 minutes.
8. Reclamp tubing.
9. Examine drainage for discoloration or cloudiness. ► **Rationale:** Change in color may indicate presence of infection, or if white gelatin-like material is present, it indicates shredding of the peritoneal lining's old skin; an increase in this fibrin indicates potential peritonitis.
10. Disconnect tubing from drainage bag while maintaining aseptic technique. Unscrew catheter from tubing and attach Mini Cap, according to clinic's instruction. ► **Rationale:** The glucose in the dialysate solution predisposes the client to infections.
11. Weigh drainage bag on scale. Effluent should weigh at least 4.5 pounds. This is equal to 2 liters of fluid. ► **Rationale:** To ensure all fluid is drained from abdomen.
12. Dispose of effluent into toilet.
13. Double bag tubing and drainage bag. Place biohazardous label on bag. Discard by placing in biohazardous container. Tubing is usually disposed of after each exchange.
14. Remove and discard gloves and mask.
15. Perform hand hygiene.
16. Check blood pressure and pulse. ► **Rationale:** Rapid fluid shift may cause hypotension.

NOTE: Mini Cap disinfects dialysis tubing between exchanges.

Transfer Sets

Transfer sets are tubing that connects bag of dialysate solution to catheter. There are two types used for CAPD.

Straight Tubing

Straight tubing stays connected to the catheter. For each exchange, the “free” end is connected to the solution. With this type of transfer set, the empty bag from solution is rolled up and worn under clothing. That bag is then unrolled, placed on the floor, and used to drain dialysate from the abdomen. After draining is completed, tubing is disconnected from the straight transfer set and a new solution bag and tubing are connected to the catheter.

Y-Set Tubing

This type of tubing is disconnected between exchanges. The base of the Y is connected to the catheter. One branch of the Y is connected to a new bag of solution and the other to an empty bag. The base of the Y is closed, and a small amount of solution is drained from the full bag into the empty bag. This is done to rid the transfer set of any bacteria that might be in the tubing. The branch that leads to the empty bag is then closed, and the solution flows into the abdomen. Once the solution bag is empty, the Y-set is disconnected from the catheter. This removes the need to wear the bag around the waist while solution is in abdomen. The catheter is then reconnected to the Y-set and solution is drained into an empty bag to discard. A new bag of solution is hung and the process continues. The Y-set is filled with disinfectant when not in use. The disinfectant is flushed out with the used dialysate. The Y-set can be reused for several months.

For Infusing Dialysate

1. Warm dialysate. The bag can be encased in a heating pad for 1 hr. **DO NOT PLACE IN MICROWAVE.**
▶ **Rationale:** Microwave heating will produce uneven heating and can cause burning in the client.
2. Perform hand hygiene for 3 minutes with antibacterial soap. ▶ **Rationale:** To prevent contamination.
3. Gather equipment and don gloves.
4. Open plastic wrap on dialysate solution and inspect solution bag for expiration date and color and consistency of dialysate and assess bag for possible leaks.

Principles of Peritoneal Dialysis

- Works on principle of diffusion and osmosis.
 - Diffusion—particles move through semipermeable membrane from area of high to low solute concentration.
 - Osmosis—fluids move through a semipermeable membrane from an area of high solute concentration to an area of low solute concentration from the blood, creating a high osmotic gradient.
 - Peritoneal dialysis—used for chronic states of renal failure. Acute renal failure clients do not benefit due to the fact that it is not efficient or rapid enough to adequately remove the waste products such as urea when it accumulates in catabolic acute renal failure clients.
5. Add medications as ordered. Maintain sterile technique in this step. ▶ **Rationale:** Some clients add routine drugs to dialysate, such as insulin.
 6. Connect tubing to dialysate bag by removing protective cover from port and spiking into dialysate bag. Maintain sterility throughout this step. Each manufacturer has a slightly different mechanism for connecting the tubing and bag. Follow manufacturer’s directions. See Transfer Sets box.
 7. Hang new dialysate bag on hook, which is positioned above client at shoulder height.
 8. Open clamp and adjust height to ensure inflow of solution by gravity over a 10- to 20-minute period.
 9. Clamp tubing.
 10. Discard empty dialysate bag or place in a holding pouch at client’s waist, according to type of transfer set being used.
 11. Allow fluid to remain in peritoneal cavity approximately 4 hr.
 12. Remove gloves.
 13. Perform hand hygiene.
 14. Repeat procedure four times daily, the last time at bedtime, allowing fluid to remain in peritoneal cavity overnight.
 15. Ensure that client and caregiver are knowledgeable in strict aseptic technique.
 16. Instruct client to notify physician if there is evidence of infection.
 17. Document findings and bring to physician at each visit.

Changing Dressing for CAPD Client

Equipment

Dressing according to facility policy
 Antimicrobial swabs or sterile 4 × 4 dressings and
 Betadine solution
 Tape
 Sterile gloves (two pair)
 Forceps (optional)
 Povidone iodine ointment
 4 × 4 gauze pads and pre-cut drain dressings
 Warm soapy water, if needed

Procedure

1. Perform hand hygiene.
2. Don sterile gloves.
3. Remove old dressing with sterile gloves.

4. Remove any dried blood or drainage with warm, soapy water.
5. Saturate 4 × 4 dressings with Betadine solution or use swabs and clean skin around catheter, moving in concentric circles from the catheter site outward. Remove crusted material, if present.
6. Inspect site for infection (erythema, edema, warmth, exudate).
7. Apply povidone iodine ointment to catheter site using sterile dressings.
8. Change gloves.
9. Place two pre-cut drain dressings over catheter site, and tape dressing. ► **Rationale:** Secure dressings to prevent infection at site.
10. Remove gloves and perform hand hygiene.

DOCUMENTATION for Home Care

Use Appropriate Home Care Documentation Forms.

- Client's assessment appropriate for skill; suprapubic catheter care and catheterization
- Peritoneal catheter site assessment
- Peritoneal dialysis site fluid assessment
- Complications associated with skill
- Client's response to interventions
- Ability of client and family to participate in skill

CRITICAL THINKING Application

Expected Outcomes

- Client's peritoneal dialysis is efficient and promotes urinary waste removal.
- Client remains infection free from catheterizations and catheter changes.
- Peritoneal catheter site remains infection-free.

Unexpected Outcomes

Client's peritoneal catheter becomes occluded.

Instruct client and family on specific positions and interventions to increase dialysis outflow.

Vital signs are increased above normal.

Client experiences respiratory distress.

Alternative Actions

- Check tubing.
- Raise bag to higher level above abdomen to increase the inflow.
- Turn client to side-lying position to facilitate drainage.
- Notify physician to check position of catheter, or fibrin can be occluding catheter.
- If BP is elevated, check for retention of dialysate solution in abdomen.
- Temperature and pulse increase may be result of peritonitis.
- Instruct client and family on how to promote sterile technique when assisting with dialysis.
- Increased respirations and/or distress are a result of increased pressure in peritoneal cavity.
- Evaluate dialysate output.

Client experiences constipation.

- Caused by inflow-outflow complications.
- Administer stool softener or laxative.

Client experiences CAUTIs.

- Determine whether client can urinate without catheter.
- Promote toileting every 2 hr.
- Use external condoms for men instead of indwelling catheters.
- Use intermittent catheterization using sterile technique.

GERONTOLOGIC Considerations

Some changes in the urinary system that occur naturally with aging may be difficult to differentiate from pathologic processes.

Changes seen with aging include:

- Reduced activation of vitamin D results in decreased absorption of calcium from the gut.
- Reduction in glomerular filtration rate by 1 mL/min each year after age 40. The diabetic client loses 5 mL/min per year.
- Medications eliminated by the kidneys may require dosage modification; the elderly client should be monitored closely for signs of drug toxicity.
- Lower specific gravity of urine occurs due to decreased ability to concentrate urine; may cause nocturia.
- Any acute fluid loss may cause renal insufficiency.

- The bladder has reduced holding capacity, weaker smooth muscle contractility, and decreased sphincter tone, but lack of bladder control is *not* a normal part of aging.
- Urgency as well as urge incontinence and nocturia are common among all elderly clients due to decreased bladder capacity.
- In the elderly, postvoiding residual volume increases, but remains within the normal range, usually no more than 50 mL.
- Prostatic enlargement in men causes obstruction with resultant urinary retention, frequency, urgency, and UTIs.
- Reduced estrogen levels in women lead to atrophy of tissues that line and surround the urethra, bladder outlet, and vagina, contributing to urinary incontinence.
- Many elderly have coexistent urge and stress incontinence.
- Women may experience weakening of pelvic muscles, causing urethral shortening and urinary retention.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- CNAs may document intake and output findings on bedside records. Some facilities allow CNAs to chart these findings on flow sheets. Check the facility policies and procedures regarding this.
- UAPs may apply condom catheters and provide catheter care.
- Unlicensed Assistive Personnel (UAPs) may perform the same tasks as the CNA. In addition, many states are allowing “clean” catheterization on clients requiring long-term procedures. It is advisable to check the policy and procedure manual to determine the tasks UAPs may perform.
- Technicians may be trained to perform certain tasks in hemodialysis units. They may initiate the dialysis treatment and monitor clients while they are on dialysis but may not give medications or make nursing judgments.

- LVN/LPNs are assigned to care for clients requiring catheterization and instillation of medication into the bladder and irrigating a closed urinary system with a physician's order.
- LVN/LPNs may be assigned to clients with urinary diversion. They may change pouches and empty continent ileostomies.
- LVN/LPNs can work in a hemodialysis unit with additional training, much like the RN, but can make limited nursing judgments.

Communication Matrix

- It is very important that all staff be informed about which clients require intake and output recordings. I&O records should be at the bedside to remind everyone to record the findings.
- Hemodialysis grafts/fistulas and distal circulation of the involved extremity must be assessed frequently after the initial placement and regularly thereafter.
- Healthcare team members should report any complaints of pain or discomfort from the client, as well as unusual odor,

color, or abnormal findings from urinary catheter drainage systems.

- Urinary diversion pouches should be emptied when one-third full. If the facility policy does not allow ancillary personnel to complete this task, the nurse will instruct them to observe the amount of urine in the pouch and report when it needs to be emptied.
- Hemodialysis technicians must be instructed on client's parameters while on dialysis. They should be instructed to immediately report deviations from the norm to the RN. The RN is ultimately responsible for the care of all clients, regardless of who is assigned to monitor the dialysis treatment.

CRITICAL THINKING Strategies

Scenario 1

Your 55-year-old neighbor confides in you that every time she coughs or sneezes she loses urine. She asks if this is normal since so many of her friends have the same problem.

1. Describe various types and causes of urinary incontinence.
2. What lifestyle changes help to correct stress incontinence?
3. What noninvasive measures help to correct stress incontinence?

Scenario 2

Mrs. Christofferson, a 64-year-old female client, is a first-day postoperative client. She had a bowel resection yesterday. The

physician ordered her Foley catheter discontinued at 8 AM this morning. His additional order is to check for residual urine after her first voiding.

1. The client has not voided since the Foley catheter was removed 2 hr earlier. What is your priority nursing intervention?
2. The client voids 600 mL of urine 6 hr after the Foley catheter was removed. What further actions should the nurse take at this time?
3. Checking for residual urine, you obtain 120 mL of urine. What is your next intervention? What alternative action might you take if you suspect the client may exceed the normal amount of residual urine?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. The amount of urine production is directly related to
 1. Renal perfusion.
 2. Fluid intake.
 3. Bladder capacity.
 4. Metabolic rate.
2. A scanner is useful to reflect the client's bladder volume but is not reliable for assessing.

Select all that apply.

 1. Obese clients.
 2. Catheterized clients.
 3. Clients with hysterectomy.
 4. Pregnant clients.
 5. Male clients.
 6. Children.
3. For male catheterization, the catheter is inserted
 1. 2-4 in.
 2. 4-6 in.
 3. 6-8 in.
 4. 8-10 in.
4. For female catheterization, the catheter is inserted
 1. 1 in.
 2. 2 in.
 3. 3 in.
 4. 4 in.
5. Urine leakage in the client with a urinary retention catheter indicates
 1. The need for a larger size catheter.
 2. An additional 10 mL of water should be added to the retention balloon.
 3. A possible urinary tract infection.
 4. The client is now able to urinate normally.
6. Common causes of urinary tract infection associated with retention catheters are

Select all that apply.

 1. Long-term use.
 2. Break in aseptic technique.
 3. Inadequate catheter stabilization.
 4. Insufficient balloon inflation.
 5. Drainage tubing dependent of collection bag.
 6. Urine specimen sampling.

7. The purpose of continuous bladder irrigation (CBI) after prostate surgery is to prevent
 1. Catheter obstruction.
 2. Bladder infection.
 3. Bladder spasms.
 4. Postoperative bleeding.
 8. When applying a urinary diversion pouch, a protective barrier product should be used
 1. Only if absolutely necessary.
 2. For the client with sensitive skin.
 3. To ensure pouch adherence.
 4. Only with a two-piece pouch.
 9. A client with end-stage renal disease
 1. Has no functioning nephrons.
 2. Receives renal replacement therapy.
 3. Produces no urine.
 4. Is uremic.
 10. The nurse avoids taking blood pressure or performing venipuncture in the arm with a graft/fistula used for hemodialysis because
 1. Phlebitis and blood clot may occur.
 2. There is increased risk for infection.
 3. Undue pressure can cause graft/fistula rupture.
 4. There is insufficient blood flow in the extremity.
-

Bowel Elimination

LEARNING OBJECTIVES

1. Explain both the mechanical and chemical aspects of digestion.
2. Compare and contrast hypermotility with hypomotility.
3. Discuss what is meant by obstruction of the bowel.
4. Describe the anatomic locations for an ileostomy, cecostomy, or colostomy.
5. List the components of a good bowel training program.
6. Outline the essential steps in administering a tap water or saline enema to an adult client.
7. Describe the precautions necessary when performing digital stimulation to remove a fecal impaction.
8. Compare and contrast stoma care of an ileostomy and a colostomy.
9. Outline the steps for developing a regular bowel routine.
10. Describe at least three interventions used when skin is denuded from leakage.
11. Describe at least three precautions necessary when applying a fecal ostomy pouch.
12. Discuss the corking and intubation procedure for a client with a continent ileostomy.
13. Describe the precautions necessary when using a rectal tube.
14. Discriminate between clients who should have a rectal tube or bowel management system (BMS) in place.
15. Compare and contrast nursing interventions for clients with alterations in bowel elimination in home care and hospital.

TERMINOLOGY

Anal fissure a small linear ulcerated area in the anal area.

Bacteria unicellular plantlike microorganisms lacking chlorophyll.

Bowel the intestine.

Bowel movement the emptying of the intestinal tract.

Bowel management system placement of a fecal diversion to manage flow of loose stool, prevent contamination of wounds, and prevent skin breakdown.

Carminative an agent that removes gases from the gastrointestinal tract.

Cathartic a drug to induce emptying of the intestinal tract; a laxative.

Chyme the viscous, semifluid contents of the stomach present during digestion of a meal. Chyme then passes through the pylorus into the duodenum, where further digestion occurs.

Colitis inflammation of the colon.

Colon the large intestine, which extends from the cecum to the anus.

Colostomy an artificially created opening from the colon to the abdominal surface for the elimination of waste.

Constipation difficulty or straining in defecation and infrequent bowel movements over an extended period of time.

Defecation elimination of waste products of digestion from the body by evacuation of bowel.

Diarrhea the passage of unformed liquid stools.

Digestion the process by which food is broken down, mechanically and chemically, in the gastrointestinal tract.

Diverticulitis inflammation of diverticula in the intestinal tract causing stagnation of feces in the small, distended sacs (diverticula).

Diverticulum an outpouching of the mucous membrane of the intestine.

Emulsification the breaking down of large fat globules in the intestine to smaller, uniformly distributed particles.

Enema the introduction of fluid through a tube into the lower intestinal tract.

Fecal incontinence an involuntary or inappropriate passing of liquid or solid stool.

Feces intestinal waste products consisting of bacteria and secretions of the liver, in addition to a small amount of food residue.

Fistula an abnormal tubelike passage from a normal cavity or tube to a free surface or another cavity.

Flaccid relaxed, flabby; having defective or absent muscle tone.

Flatulence excessive gas in the stomach and intestines.

Gastrointestinal having to do with the stomach and intestines.

Hemorrhoids abnormally distended rectal veins due to a constant increase in venous pressure.

Hypermotility unusually quick motility in the gastrointestinal tract.

Hyperreflexia increased action of reflexes.

Hypertonic having a higher osmotic pressure than normal body fluid.

Hypomotility unusually slow motility of the gastrointestinal tract.

Ileostomy an artificially created opening from the ileum to the abdominal surface for the elimination of wastes.

Impaction condition of being tightly wedged into a place, as of feces in the bowel.

Integumentary relative to a covering, as the skin.

Laxative a mild-acting drug to induce emptying of the intestinal tract.

Mucosa mucous membrane.

Necrosis death of areas of tissue or bone caused by enzymatic action or lack of circulation.

Obstipation the act or condition of obstructing; extreme constipation due to obstruction.

Occlude to block off, obstruct.

Occult blood blood in such minute quantities that it can only be detected by a microscope or chemical means.

Ostomy a surgically formed artificial opening that serves as an exit site for the bowel or intestine.

Parasite an organism that lives within, on, or at the expense of another organism, known as the host.

Perforation the act or process of making a hole, such as that caused by an ulcer.

Peristalsis a progressive wave-like movement that occurs involuntarily as in the gastrointestinal tract.

Reflux a return of or backward flow.

Sphincter circular band of muscle fiber constricting a natural orifice.

Stoma an artificially created opening between two passages or between a passage and the body surface.

Stool waste matter discharged from the bowels.

Suppositories semisolid substances for introduction into the rectum, vagina, or urethra where they dissolve; serves as a vehicle for medicines to be absorbed.

Villi short filamentous processes found on certain membranous surfaces.

ANATOMY AND PHYSIOLOGY

The gastrointestinal system converts food into products that can be used as nutrients on the cellular level and disposes of wastes incurred in the process. The primary structures in this system include the mouth, esophagus, stomach, small intestine, and large intestine.

The mouth, esophagus, and stomach are the structures of the upper gastrointestinal tract, where the process of digestion begins. The small intestine, where digestion is completed and most absorption takes place, is a 12-foot tube composed of the duodenum, jejunum, and ileum. The large intestine is made up of the cecum, colon, and rectum. The cecum contains the ileocecal valve and the appendix. The colon is divided into the ascending, transverse, descending, and sigmoid colon. The rectum extends from the sigmoid colon to the anus. The terminal end of the rectum is called the anal canal and is guarded by the internal and external sphincter muscles. The chief functions of the colon are to reabsorb water and sodium and to store wastes.

Digestion is accomplished mechanically and chemically. Food is mechanically churned through the intestinal tract by sharp contractions, or peristaltic waves, of the circular and longitudinal muscles of the intestinal wall. Muscular sphincters and valves are located at strategic points throughout the intestinal tract. These structures help propel the food bolus or feces at appropriately timed intervals in a process called rhythmic segmentation. The sphincters and valves, when functioning properly, prevent reflux of contents. Peristaltic waves, coupled with rhythmic segmentation, allow maximal contact between food and the bowel wall so that chemical reactions can accomplish digestion and absorption can take place.

The chemical aspects of digestion in the small intestine begin in the duodenum with the introduction of pancreatic juices and bile. Pancreatic juices are rich in enzymes, which work to break down proteins and fats and to complete the

transformation of starch to sugar. Bile, secreted from the liver, aids in the emulsification and absorption of fats. These substances work in an alkaline medium that combines with the acidity of chyme to provide a neutral pH in the duodenum, thereby protecting the duodenal mucosa.

In the 20 feet of jejunum and ileum, approximately 3000 mL of digestive enzymes are secreted. These enzymes, which are secreted by the mucus glands of the intestines, complete the digestive processing of food before absorption. Again, the alkaline nature of these secretions works to protect the mucous membrane of the intestinal tract.

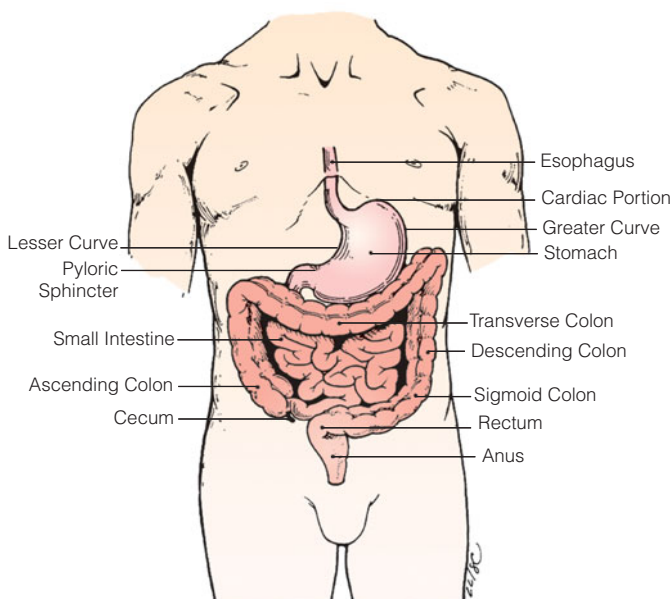

The peristaltic activity of the gastrointestinal tract, as well as its secretory functions, is governed, to a large degree, by parasympathetic and sympathetic nerve fibers. Stimulation of the parasympathetic system increases the activity of the intestinal tract, while stimulation of the sympathetic nervous system inhibits activity in the tract. The internal anal sphincter, however, is activated by sympathetic stimulation, whereas the external anal sphincter is under voluntary control.

Absorption, another primary function of the small bowel, is the passage of prepared materials from the gastrointestinal lumen to the blood and cells. Most absorption in the small intestine results from the churning action of the bowel. Chyme is continually exposed to the circular folds of the mucosal surface, which is lined with thread-like projections called villi. Villi serve as the sites of absorption of fluid and nutrients. The duration of contact between chyme and the mucosal surface of the bowel is very important in absorption. Hypermotility in the small intestine can result in decreased contact with the mucosal wall and deficient absorption; hypomotility can result in increased absorption of fluids, as well as problems with elimination.

The circulatory system delivers nutrients to tissue cells and transports the waste products of metabolism. Arterial circulation to the small bowel and colon is via the superior and inferior mesenteric arteries. Blood that contains absorbed nutrients is carried from the gastrointestinal tract by the superior and inferior mesenteric veins, which become a part of the portal system delivering blood to the liver. Each villus on the intestinal wall contains a network of small capillaries, which absorb sugar and amino acids, and a central lymph channel, which absorbs fatty acids and glycerol. When circulation is compromised, absorption is decreased and cells are lost.

By the time chyme reaches the ileocecal valve—the junction between the small and large intestines—most nutrients have been absorbed. Whereas 3 L of fluid passes through the small bowel, only 500 mL actually passes through the ileocecal valve. The semiliquid material received by the large intestine consists of living and dead bacteria, undigested food and residue, and cell debris. As residue is slowly passed along the colon by peristaltic-like mass movements, fluid is absorbed. These movements occur relatively infrequently (perhaps two or three times per day) and are stimulated by the entrance of food into the stomach by the gastrocolic reflex.

Absorption of fluid in the colon takes place primarily in the ascending and transverse colon. Fecal masses are stored in the sigmoid colon and move into the rectum with mass peristaltic movement. When the rectum fills and becomes

▲ Anatomy of the gastrointestinal tract.

sufficiently distended, centers in the sacral area of the spinal cord facilitate a defecation reflex, which contracts the rectum and relaxes the internal and external anal sphincters. The resulting urge, facilitated by the autonomic nervous system, leads to contraction of the abdominal, perineal, and diaphragmatic muscles. Willful defecation is a coordinated, learned habit. Voluntary inhibition of the act returns the stool to the sigmoid colon.

DEFECATION

Defecation is defined as elimination of waste products of digestion from the body by evacuation of the bowel. Excreted waste products are termed feces or stool. The pattern of defecation varies with each individual. It can occur from several times each day to two to three times each week. The type and amount of stool evacuated is also individualized. It is determined by such factors as diet and normal changes in the intestinal flora. Additional factors that influence bowel patterns include age, fluid intake, exercise, psychologic factors, alterations in lifestyle, and medications.

For healthy bowel elimination, the client needs to have sufficient bulk (cellulose and fiber) to produce adequate fecal volume. Food intake at specified times and food that does not produce flatulence are also important for healthy elimination. Daily fluid intake of 2000 to 3000 mL is essential to promote adequate urine output, as well as maintain a soft stool for easy elimination. Daily exercise stimulates peristaltic activity, facilitating bowel movements.

Normal feces are composed of about 75% water and 25% solid material. The stool is soft, but formed, and the color ranges from light to dark brown. The color of the stool is due to the presence of stercobilin and urobilin, derived from bilirubin. In the absence of bile pigment the stool takes on a characteristically clay-colored or white appearance. The action of bacteria in the colon plays a role in the color of the stool. Ingestion of certain foods, drugs, and vitamins can alter the color and consistency of the stool. The nurse must complete an accurate bowel history to determine normal or abnormal findings. Conclusions should not be made on observation alone. Iron supplements, vitamins with iron, beets, red peppers, licorice, grape juice, and spinach affect the color of the stool, which could lead to an incorrect conclusion of blood in the stool. Feces that are red or black in color can be a direct result of ingestion of these foods. Medications can also affect the color and consistency of the stool. General anesthetics block parasympathetic stimulation to the colon, leading to potential constipation. In addition to consistency and distinct color of the feces, there is an odor associated with the feces. The odor is a result of the action of microorganisms on the chyme.

Abnormal characteristics of the feces include the presence of exudate, parasites, fat, and large amounts of mucus. Large amounts of mucus are generally associated with an inflammatory process of the bowel. The stool appears slimy in this condition. Diseases, such as ulcerative colitis or Crohn's disease, produce a stool with large amounts of pus when inflammation is present. Stools with abnormally high fat content are

foul-smelling and float to the top of the water. Children with cystic fibrosis commonly produce this type of stool.

Constipation

Because many factors influence the development of constipation, the management of it is also individualized according to each client's need. There is acute and chronic constipation, each a result of certain problems and each requiring their own form of management.

Acute constipation is usually managed with suppositories, enemas, or osmotic laxatives to clear the rectum. A bowel program is usually indicated after the initial treatment. Usually, there is a modification of the diet and fluid intake in addition to education about bowel habits.

Chronic constipation requires the use of bulk-forming agents if the client has a low dietary fiber and no specific underlying cause for the constipation. Osmotic agents may be effective for immediate results, but the goal of the bowel management program is to establish regular bowel habits, using only small doses of laxatives.

Bowel (Fecal) Incontinence

Normal bowel function is based on the client having functioning muscles and nerves, a healthy bowel structure and tissues, normal bowel organisms, proper diet, adequate fluids, and physical activity.

Bowel incontinence can occur when any of these factors are not functioning properly. It can also be caused by disease, injury, stress, poor elimination habits, and side effects of medications. Structure and functional changes as a result of aging can result in bowel incontinence. Structural changes include rectal prolapse, surgical interventions of the bowel, colectomy, and prostate or rectal surgery. Functional causes are often related to an individual's lifestyle or behaviors. These causes may be related to medication effects or nerve damage. Common causes include severe diarrhea, leakage due to chronic constipation, stress, chronic laxative use, and general functional damage from a stroke or other debilitating condition.

Several medical tests are used to determine the cause of fecal incontinence. Before interventions are discussed, it is imperative that the etiology of the condition be determined. Examples of common tests include proctoscopy, ultrasonography, electromyography, and colonoscopy.

An older approach, the placement of a rectal tube, is not encouraged because of the major trauma to the anus and surrounding tissue with prolonged use. Three of the newer treatments for bowel incontinence are the Secca Procedure, the Zassi Bowel Management System (BMS), and the FlexiSeal Fecal Management System (FMS). A surgical procedure is also available. This procedure inserts an inflatable artificial sphincter in clients who have incontinence caused by a sphincter dysfunction or injury.

The new systems are used for long-term fecal diversion for clients with associated conditions such as skin breakdown, wounds or grafts in danger of contamination, or immobilized clients. The BMS system can be in place up to 29 days without removing and changing the catheter.

ALTERATIONS IN ELIMINATION

By-products of digestion must be continually eliminated to maintain normal body function. Alterations in normal elimination can result from changes in motility, obstruction of the lumen of the bowel, circulatory deficiencies, disease process, and surgically induced alterations to the structures of the intestinal tract.

Changes in Motility

Normal motility of the bowel provides peristaltic activity that pushes and churns food and chyme through the upper tract and feces through the lower tract at timed intervals.

Hypermotility may be caused by direct stimulation or irritation of the autonomic nervous system, as well as by inflammatory processes in the gastrointestinal tract. Stimulation of parasympathetic nerves promotes peristalsis and increases bowel muscle tone. Increased peristalsis speeds the propulsion of chyme through the upper tract, resulting in deficient absorption of nutrients. When increased peristalsis speeds the propulsion of feces through the lower tract, diarrhea occurs.

Stimulation of the autonomic nervous system may be psychic in origin. Anxiety, for example, may be mediated through either parasympathetic nerves, with resultant diarrhea, or through sympathetic nerves, with resultant constipation. The action on the parasympathetic nervous system of certain drugs may also cause hypermotility of the intestine. Antihypertensive drugs, such as reserpine, and cholinergic drugs can cause diarrhea by their stimulation of parasympathetic nerves.

Hypermotility caused by the stimulating effect of an irritant on intestinal peristalsis may arise from infectious agents, chemical agents, or inflammatory disease processes. The most common intestinal irritants are the products of certain bacteria that release toxins in the digestive tract. Chemical agents that irritate the intestinal mucosa include cytotoxic drugs, castor oil, and quinidine. Ulcerative and inflammatory disease processes include diverticulitis, tuberculous lesions, ulcerative colitis, and Crohn's disease.

Hypomotility may be caused by direct stimulation or blockage of the autonomic nervous system, intestinal muscle weakness, and chemical agents that inhibit peristalsis and induce flaccidity in the intestinal tract. Decreased peristalsis causes chyme to move sluggishly through the upper tract so that fluids are overabsorbed. Decreased peristalsis also slows the propulsion of feces through the lower tract and causes constipation, fecal impaction, and obstruction.

Stimulation or blockage of the autonomic nervous system may be congenital in origin, as is the case in Hirschsprung's disease, where the absence of parasympathetic nerve ganglia results in failure of peristalsis of the affected portion of the bowel. The effects of trauma or toxins on autonomic innervation of the intestine, which occur with paralytic (adynamic) ileus, inhibit motility to the point of obstruction.

Intestinal muscle weakness that results from disease processes, old age, or a lack of essential vitamins (notably the B group) or electrolytes (particularly potassium) may all contribute to hypomotility. Certain drugs, such as codeine and morphine, can also cause hypomotility by relaxing the smooth

muscles of the digestive tract and by increasing spasms of the intestinal sphincters.

Obstruction of the Lumen of the Bowel

Obstruction of the lumen of the bowel may be partial or complete. The severity of the obstruction depends on the region of the bowel that is affected, the degree to which the lumen is occluded, and the degree to which the circulation in the bowel wall is disturbed.

A small-bowel obstruction that occurs as a consequence of persistent vomiting (reverse peristalsis) can cause severe disturbances in the electrolyte balance of the body. Large-bowel obstructions, even if complete, are not as dramatic, provided that the blood supply to the colon is not disturbed.

The causes of intestinal obstruction are varied. In rare instances, obstruction may result when a foreign body, such as a large fruit stone or a mass of parasitic worms, becomes lodged in the bowel. Intestinal obstruction is more frequently caused by strictures, adhesions, hernias, volvulus, intussusception, polyps, neoplasms, and fecal impaction.

The physiology of an obstruction in the lumen of the bowel is generally the same, regardless of cause. As the lumen of the bowel is blocked, the body attempts to overcome the obstruction by increasing peristalsis. During this process, liquid feces move past the site of obstruction and cause diarrhea and increased obstruction, which leads to constipation. Within several hours peristalsis is reduced, and the bowel becomes flaccid. As intraluminal pressure builds up, fluid is retained and absorption decreases. The increased intraluminal pressure then leads to the compression of the bowel wall and its capillaries, which causes necrosis of the bowel wall.

Circulatory Deficiencies

An adequate circulatory flow is essential for maintaining the structure of the bowel and for carrying on cellular nutrition. Any interruption of the arterial blood supply inhibits the bowel function. An occlusion of the circulatory flow, also called an intestinal infarction, results in gangrene of the bowel unless surgical intervention is carried out. A partial occlusion of the mesenteric arteries due to atherosclerosis can cause intestinal angina, a condition that occurs when the blood supply is increasingly interrupted.

Surgically Induced Alterations in Bowel Elimination

When alterations in bowel elimination become life-threatening and medical management fails, surgical intervention becomes necessary. Diversionary surgical procedures of the bowel include cecostomy, ileostomy, and colostomy.

An ostomy may be temporary or permanent, depending on the etiology. The most common indication for a permanent ostomy is low cancer of the rectum or advanced metastatic cancer involving the colon. A temporary ostomy is usually created with the intent of reconnecting it in the future. The anatomy of the GI system is left intact. Many of these ostomies

▲ A sigmoid colostomy. An ileostomy.

are done as an emergency. The temporary ostomy may be performed because a bowel prep could not be done due to obstruction and/or perforation, or to protect a distal surgery of the colon. Reversal, or re-anastomosis, can be done at a later time when infection is unlikely and healing can take place. Ileostomy and colostomy are the most frequent type of fecal diversion. Today, both of these ostomies can be reversed as long as the anatomy of the GI system is left intact. Children with certain congenital intestinal disorders may require an ostomy. These are usually temporary and reversed once the child reaches a certain weight.

A cecostomy is a surgically created opening from the cecum through the abdominal wall. This procedure is a quick and temporary method to decompress the right side of the colon. This is usually done with the insertion of a catheter into the colon. This catheter requires frequent irrigation to ensure patency. If stool leaks around the site, a pouch should be applied to collect the output.

An ileostomy is a surgically created opening from the terminal ileum through the abdominal wall. The entire large intestine is bypassed or removed. Permanent ileostomies are usually performed on clients with Crohn's disease of the entire large intestine and those clients with a weakened rectal sphincter, which would leak stool if a pull-through procedure was performed. The stoma is smaller than the colostomy stoma as it is formed by the small intestine. The tip of the small intestine is brought to the skin's surface and folded back on itself. The

Potential Postoperative Complications

- Hemorrhage
- Shock
- Thrombophlebitis
- Pulmonary embolism
- Sepsis
- Paralytic ileus
- Intestinal obstruction
- Impaired intestinal absorptive capability
- Leaky anastomosis
- Stoma necrosis

stoma size is about the size of a quarter or fifty-cent piece. The effluent is a paste-like consistency, although it can be more liquid if fluid intake is abnormally high.

In recent years, new surgical procedures have eliminated many permanent ileostomies. Clients with polyposis or ulcerative colitis may choose to have a continent ileostomy or Kock Continent Ileostomy or Kock pouch, an internal reservoir of the ileum constructed at the rectum. The Kock reservoir consists of an internal pouch with two limbs of the ileum, one forming an internal valve. Continence occurs as a result of the stool collecting in the internal pouch. The pouch must be intubated four to six times a day to evacuate the stool. The rectal reservoir is created by joining the ileum to the anus after the colon is removed. The client will have four to ten stools a day and must have good sphincter control. Any of the surgeries that remove or bypass the large intestine produce a soft-to-watery effluent that contains water and many digestive enzymes that have not yet been absorbed by intestinal villi. The daily output varies from 500 to 2000 mL. Another type of continent internal reservoir is the Barnett Reservoir (BCIR). The pouch is made from the ileum, the last segment of the small intestine. A self-sealing valve mechanism and "living collar" is constructed from the intestine, which prevents leaking from the pouch.

The pouch stores liquid waste and is drained several times each day using a small catheter. The catheter is inserted through the opening on the abdomen into the pouch. The pouch holds about 1000 mL after a few months following surgical intervention.

A colostomy is a surgically created opening from the colon through the abdominal wall and can be created using any segment of the large intestine. With a colostomy, the diseased portion of the colon is bypassed or removed and a portion of healthy colon is brought to the outside of the abdomen to form a stoma. The type of stoma is named after the segment of bowel used to form the stoma; most colostomies are sigmoid colostomies. The farther to the right side of the colon the stoma is placed will determine the type of output from the stoma.

The most common surgery performed for cancer of the colon is a low anterior resection. In this procedure a wide excision of the tumor and surrounding lymph nodes is made and the remaining colon is reconnected. The client may have a diverting ostomy proximal to the resected area to protect the surgical site from leakage.

Abdominal-perineal resections with permanent sigmoid colostomy are usually done only when the tumor is located too low in the rectum for the client to maintain continence. Output from colostomies on the left side of the intestine will eventually become formed and firm, since most of the water has been absorbed by the time the feces reaches these portions of the colon.

A descending colostomy is usually temporary. It is seen frequently in children with congenital disorders. Adults may have a descending colostomy after trauma or severe diverticulitis when perforation is present.

A transverse colostomy can be located anywhere along the transverse colon. It is also usually temporary and is done for either a bowel obstruction or perforation.

TABLE 23-1 Comparison Chart for Ostomies

Colostomy	Ileostomy
Etiologic Factors	
Cancer of colon	Ulcerative colitis
Traumatic or congenital disruption of intestinal tract	Crohn's disease (regional ileitis)
Diverticulitis	Birth defects Trauma Protect distal surgery Distal obstruction
Surgical Procedure	
Portion of colon brought through abdominal wall	Portion of ileum brought through abdominal wall
Bowel Control	
Sigmoid—Sometimes	None
Ascending—No	
Stool Consistency	
Sigmoid—Formed	Liquid to semisoft
Ascending—Semiformed	
Irrigation for Bowel Control	
Sigmoid or descending colon, but rarely used	No
Use of Appliance	
Yes, use nondrainable, but only if evacuation pattern is not achieved	Yes
Nursing Care Priorities	
Maintain skin integrity a. Keep skin clean and dry b. Provide skin barrier c. Ensure proper fit of appliance	Same as colostomy
Fluid Requirement	
Sigmoid—Normal intake	8–10 glasses per day
Transverse—8–10 glasses per day	
Diet Control	
Avoid gas-forming foods	Same as colostomy
Eat in moderation odor-forming foods	
Chew food well	
Medications	
Sigmoid—none	Same as colostomy
Transverse—Avoid enteric coated meds	B ₁₂
May need Na replacement	
Vitamins, especially K minerals	
Psychosocial	
Promote self-image	Same as colostomy
Refer to Ostomy Club	

Colostomies can also be named for the way they are constructed. A loop colostomy is a very quick surgical procedure to exteriorize the bowel. A loop of intestine is brought out to the surface of the abdomen and some type of plastic bridge is placed

under the loop to prevent it from falling back inside the abdomen. This bridge is left in place for 7–14 days until the abdominal wall has sealed. In any of the surgeries in which the rectum is left the client can expect to pass any old stool remaining from before

surgery, plus mucus produced by the lining of the intestine on an ongoing basis. A double-barrel colostomy is one that has two stomas. One is the proximal or functional stoma. The second is the distal stoma that connects the remaining stoma and rectum. This stoma is often referred to as a mucus fistula. It may put out mucus or old stool from before surgery, especially if the client is totally obstructed distal to the stoma.

An end colostomy has only one stoma, which originates from the proximal portion of the bowel. The distal end of the colon is either resected or is closed off with sutures and remains in the abdomen. This can also be called a Hartman's procedure. All of these ostomies can be reversed once the distal site is healed and an adequate bowel prep can be done.

Another type of colostomy is the Pelvic Pouch or Ileo-Anal Pull-through, better known as the J Pouch, S Pouch, or W Pouch, depending on the stoma location in the intestine. There is no external stoma. An internal pouch is constructed from the rectum, allowing waste products to accumulate before being expelled in the normal manner, although bowel movements will be more watery and more frequent than usual. If the rectum is too diseased and the anal sphincter muscle was removed, the client is not a candidate for this pouch procedure. The J Pouch is also not recommended for those with Crohn's disease as the disease can return and infect the pouch, requiring removal of the pouch.

Colostomy irrigations are not commonly used today to establish regularity of bowel elimination. Clients usually reestablish bowel habits similar to those before the surgery. There may still be some clients who do perform daily irrigations; however, there are situations when irrigations must not be done. Irrigations are always contraindicated in clients with unstable fluid and electrolyte balance and in those clients in whom vagal stimulation is dangerous. Irrigations are also

contraindicated when clients are receiving radiation therapy or are experiencing chemotherapy-induced diarrhea.

ADAPTATION FOR HOME CARE

The actual care of clients requiring interventions for altered bowel elimination is basically the same for hospitalized clients as home care clients. Equipment may be slightly different, but it is similar enough to make it easy to teach clients and family members to perform the skills.

A major responsibility of the nurse is to provide client and family education in the care and management of the ostomy, bowel elimination interventions, and how to administer an enema. At the time of discharge from the hospital, most clients and family members need support in the management of an ostomy. The home care nurse will need to not only demonstrate and evaluate the performance and outcome of the ostomy care, but will need to provide emotional support as well.

CULTURAL AWARENESS

When providing nursing care for clients requiring an intervention for bowel elimination, remember that many cultures are very modest and do not like to talk about elimination issues. Respectful approaches and providing privacy during the procedure are critical for all clients, but especially for some cultures, in order for them to feel comfortable with the task that needs to be completed. This is especially true for Chinese-Americans, who may request to use the toilet and not a bedpan. Arab-Americans prefer to wash rather than use toilet paper after every urination and bowel movement. They may insist on using a bidet to wash up. Muslims may require additional bathing rituals.

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to use on client care plans when the components are related to alterations in bowel elimination.

NURSING DIAGNOSIS	RELATED FACTORS
Disturbed Body Image	Presence of stoma, fear of rejection, psychosocial factors
Constipation, Risk for	Inadequate intake of fluid or bulk, decreased exercise, disease states, medication, personal habits
Diarrhea	Nutritional intake, medication, disease state
Deficient Fluid Volume	Effluent from ileostomy is watery to semisoft; excessive use of enemas or laxatives
Grieving	Loss of body contiguity, operative procedure (colostomy, ileostomy)
Ineffective Health Maintenance	Cognitive impairment, depression, immobility, cultural beliefs, lack of social support
Deficient Knowledge	Inability to manage ostomy, constipation
Noncompliance	Inability to manage equipment, impaired manual dexterity, poor vision
Impaired Skin Integrity	Skin irritation or breakdown, poor pouching techniques, incontinence or diarrhea, poor-fitting equipment, economic situation

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. Remember to wash your hands or use antibacterial gel before and after each and every client contact.

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification not including room number. These actions prevent errors and conform to The Joint Commission standards.

Bowel Management

Nursing Process Data

ASSESSMENT Data Base

- Assess for symptoms indicating presence of impaction: nausea; headache; abdominal pain; malaise, abdominal distention, or bloating.
- Evaluate client's diet.
 - Amount of high-bulk foods.
 - Amount of fluid intake daily.
- Evaluate client's physical status.
 - Extent of physical exercise performed daily.
 - Ability to ambulate (i.e., spinal cord injury, CVA).
 - Ability to perform bed exercises, abdominal exercises.
 - Extent of disease process.
 - Medications routinely taken.
- Assess effectiveness of drugs, such as stool softeners, bulk formers, suppositories.
- Assess time of day client usually evacuates bowels, any changes in normal routine.
- Identify client's ability to adapt and psychologic readiness for the above program.
- Identify position most effective for bowel evacuation.
- Assess consistency and amount of stool for abnormal findings (diarrhea, fecal impaction, thin pencil-like stool, or blood in stool).
- Assess when client had last bowel movement.
- Assess perianal area for tears, ulcerations, or excoriation.
- Assess for fecal contamination of wounds or grafts.
- Assess for postoperative constipation.
- Assess the need for colostomy irrigation for home care client.

PLANNING Objectives

- To promote regular bowel evacuation
- To prevent constipation
- To promote removal of flatulence
- To remove a fecal impaction
- To promote colostomy evacuation at same time each day
- To establish a bowel program to which the client can easily adapt
- To develop a bowel program that the client can perform him or herself
- To prevent skin breakdown and/or wound contamination from fecal incontinence

- To manage stool elimination for clients with mobility issues
- To relieve pain and discomfort

IMPLEMENTATION Procedures

- Providing Assistive Digital Evacuation 828
- Providing Digital Stimulation 829
- Developing a Regular Bowel Routine 829
- Administering a Suppository 831
- Inserting a Rectal Tube 832
- Instructing Client in Colostomy Irrigation 832
- Instructing Home Care Client in Colostomy Irrigation 833
- Implementing the Zassi Bowel Management System 833
 - For Maintaining Bowel Management System 835
 - For Irrigating Bowel Management System 835
 - For Emptying Collection Bag 836
 - For Removing Catheter 836

EVALUATION Expected Outcomes

- Client establishes regular bowel evacuation program.
- Constipation is prevented.
- Fecal impaction is removed.
- Client is able to evacuate bowel at a convenient and consistent time.
- Client is free of pain, flatus, and discomfort.
- Digital stimulation is performed without cardiac complications.
- Rectal tube insertion relieves flatus.
- Colostomy irrigation promotes routine daily bowel evacuation.
- BMS is effective to prevent skin excoriation for clients with diarrhea.

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Providing Assistive Digital Evacuation

Equipment

- Clean gloves, 2 or 3 pair
- Water-soluble lubricant
- Absorbent pad
- Washcloth and towel
- Bath blanket
- Bedpan
- Basin of warm water

Preparation

1. Check physician's order for impaction removal if the client is at risk for possible complications from vagal stimulation (i.e., cardiac or spinal cord injured client).
 - ▶ **Rationale:** Vagal stimulation can result from manual removal of feces. It should be used only as a last resort and with specific physician's order. It causes a decreased pulse rate by decreasing conductivity at the sinoatrial (S-A) node and decreasing the rate of impulse firing at the node.
2. Gather equipment.
3. Introduce yourself, identify the client using two forms of identification, and explain procedure.
4. Provide privacy.
5. Perform hand hygiene.

Procedure

1. Obtain baseline pulse and blood pressure.
2. Place client on left side with knees flexed.
 - ▶ **Rationale:** Positioning on left side allows easier access to sigmoid colon.
3. Place absorbent pad on bed. Cover client with bath blanket.
4. Place bedpan next to client's buttocks.
5. Don gloves, and lubricate fingers of dominant hand. You may want to double-glove dominant hand to prevent contamination if glove tears.
6. Ask client to take a slow, deep breath and exhale slowly through the mouth as your index finger is gently inserted into rectum moving toward the umbilicus.
 - ▶ **Rationale:** Encouraging breathing assists in relaxing the sphincter.

Clinical Alert

Removal of fecal impaction is usually performed in small steps to reduce the risk of injury to the rectal tissue. A series of suppositories may be given between manual removal attempts to assist in clearing the bowel.

Clinical Alert

Stimulation of rectum could result in excessive vagal nerve (in rectal wall) stimulation with subsequent cardiac arrhythmias.

EVIDENCE-BASED PRACTICE

Assisted Bowel Evacuation

In a report by Powell in 2000, she stated that 8% of clients required assisted digital evacuation. In a published document in the Royal College of Nursing (London 2000), a list of indications for assisted evacuation was outlined. These indications included fecal impaction, inability to defecate, neurogenic bowel dysfunction, and clients with spinal cord injury. Very little is written about manual evacuation of stool. It is considered a nursing function, although there is a risk to the procedure, particularly vagal nerve stimulation, leading to bradycardia.

Even though manual fecal removal is a well-established procedure for clients with spinal cord injury, it is suggested by this author that further research into long-term bowel management in general and manual evacuation should be studied.

Source: Powell, M., & Rigby D. (2000). Management of bowel dysfunction: Evacuation difficulties. *Nursing Standard*, 14, 47–51.

7. Gently massage around stool and remove the hardened stool by working the forefinger into and around the mass to break it up.
 - ▶ **Rationale:** Smaller pieces allows for easier expulsion of stool.
8. Allow client to rest between digital removal if any untoward effects, such as palpitations or faintness, are exhibited.
9. Obtain vital signs if client complains of any discomfort.
10. Provide hygienic care, as needed.
11. When stool is removed, change gloves; wash and dry buttocks thoroughly.
12. Dispose of stool in toilet or send stool specimen to laboratory.

Clinical Alert

Due to risk factors, manual evacuation should be considered an acute intervention, not a regular intervention. Risk factors include autonomic dysreflexia, rectal trauma or perforation, rectal bleeding, and history of abuse.

Even though manual evacuation of stool is considered within the scope of practice for a registered nurse, nurses receive little or no training to perform the procedure. At a minimum, the practitioner should:

- be knowledgeable regarding the anatomy and physiology of the lower rectum.
- demonstrate awareness of common perineal and anal conditions.
- be able to discuss constipation management options.
- utilize critical synthesis of evidence-based practice and relevant literature.
- demonstrate professional accountability.

13. Clean bedpan and replace in appropriate area.
14. Remove gloves and perform hand hygiene.
15. Position client for comfort.
16. Perform hand hygiene.
17. Follow physician's orders for administering a cleansing enema or inserting a suppository. ► **Rationale:** These

procedures will assist in the removal of any remaining feces.

18. Instruct client in management of simple constipation, if appropriate. Include diet, exercise, and laxatives and/or stool softeners.

NOTE: An oil retention enema may be used before removing the impaction. ► **Rationale:** Helps soften and lubricate stool.

Providing Digital Stimulation

Equipment

- Bath blanket (optional)
- Clean gloves, 1 or 2 pair
- Lubricant
- Bedpan or commode
- Absorbent pad
- Washcloth and towel
- Medication if ordered
- Toilet tissue

Procedure

1. Check physician's orders and client care plan. Determine client's usual bowel habits and time of evacuation.
2. Perform hand hygiene.
3. Gather equipment.
4. Identify the correct client and explain procedure.
5. Provide privacy and place absorbent pad on bed as necessary.
6. Place client in position in the bed for bowel evacuation (bedpan in place). Place client in either left or right lateral position (if on right side, sigmoid is uppermost) and assist with feces removal.
7. Place bath blanket over client if appropriate.
8. Don gloves, and lubricate fingers of nondominant hand. You may want to double-glove to prevent contamination if gloves tear. ► **Rationale:** Lubrication reduces resistance by fingers moving through anal sphincter.
9. Insert finger into rectum 1.5–2 in.
10. Move your finger from side to side in a circular motion to slightly stretch the rectal wall. Move toward the spine and not the bladder to prevent injury to the

bladder. ► **Rationale:** Stimulates lower bowel and helps relax sphincter.

Clinical Alert

A daily routine should be set up for at least 2–3 weeks to establish a pattern.

11. Instruct client to take slow, deep breaths during procedure.
12. Continue stretching the rectal wall for 1–3 minutes until the internal sphincter muscle relaxes.
13. Work with client to discover an associated stimulus to help establish a good bowel routine. ► **Rationale:** Abdominal massage, coughing, deep inhalations, and tightening of abdominal muscles, in conjunction with digital stimulation, assist in bowel evacuation.
14. Repeat digital stimulation for 1–3 minutes at 5-minute intervals up to 20 minutes if a bowel movement does not occur.
15. Use two fingers if necessary to break up hard stool for evacuation to occur.
16. Place stool in bedpan as it is removed.
17. Assess vital signs if prolonged digital removal is required. ► **Rationale:** Vagal nerve stimulation can occur.
18. Assess for bleeding.
19. After bowel evacuation occurs, assist the client with cleaning and drying perineum.
20. Remove equipment from room.
21. Wash equipment and return to storage area.
22. Discard gloves and perform hand hygiene.
23. Position the client for comfort.

Developing a Regular Bowel Routine

Equipment

- Clean gloves, 1 or 2 pair
- Lubricant
- Bedpan or commode

- Absorbent pad
- Specific enema if ordered
- Washcloth and towel

Preparation

1. Check physician's orders and client care plan.
2. Identify the correct client and explain procedure.
3. Identify time of day client usually evacuates bowels.
4. Evaluate diet, exercise, and former use of medications for bowel evacuation.
5. Administer the following drugs as ordered:
 - a. Stool softener (Colace, Dialose, DCS, Coloxyl) daily.
 - b. Bulk former (Metamucil or FiberCon)—daily to TID.
 - c. Mild laxative (Senokot, Doxidan, Dulcolax) 8 hr before program.
 - d. Suppository (glycerin or Dulcolax) just before digital stimulation.
6. Perform hand hygiene.

Procedure

1. Don gloves. You may want to double-glove to prevent contamination if glove tears.
2. Perform digital stimulation one half hour after dinner or breakfast or according to client's time schedule for evacuation (see previous intervention).
 - ▶ **Rationale:** Food stimulates bowel activity.
3. Place client on toilet or commode. (Use bedpan if client is on bedrest.) ▶ **Rationale:** Assuming normal posture for bowel movement facilitates evacuation.
4. Encourage client to contract abdominal muscles or bend forward while bearing down. ▶ **Rationale:** Increases abdominal pressure and helps evacuate the bowel.
5. Remove gloves.
6. Perform hand hygiene.
7. Provide privacy and sufficient time for evacuation.
8. Don gloves.
9. Wash and dry perineal area if client is unable to do so.
10. Remove gloves.

11. Place client in wheelchair or bed and position for comfort.
12. Perform hand hygiene.
13. Wean client away from suppositories and laxatives when spontaneous bowel movements occur with digital stimulation.

Bowel Training

Good bowel training programs include:

- Initiation of defecation on demand with digital stimulation and abdominal massage.
- Evacuation at same time each day; best time 20–40 minutes after a meal.
- Proper diet, increased fiber and fluids.
- Daily physical exercise regimen.
- Client and family education.

Recommendations for Preventing Constipation in the Older Adult Population

- Assess constipation by obtaining the client's history, including information regarding the amount of fluid intake, food ingested, and dietary fiber.
- Review medications associated with an increased risk of developing constipation; screen for polypharmacy.
- Identify bowel patterns using a bowel diary.
- Increase fluids to 1500–2000 mL/day; minimize caffeine and alcohol intake.
- Promote regular consistent toileting.
- Tailor physical activity to client's physical abilities.

Source: Registered Nurses Association of Ontario. (2005, March). Prevention of Constipation in the Older Adult Population (revised). Toronto, Canada: Author. Available at: www.guidelines.gov.

EVIDENCE-BASED PRACTICE**Management of Constipation in Older Adults**

Studies conducted in Britain and the United States indicate that between 10% and 18% of otherwise healthy adults have frequent straining on defecation. Constipation appears to be more common in women than men, and about 20% of the elderly identify the problem. Constipation is not a physiological consequence of the aging process; however, decreased GI motility is a contributing factor to the prevalence in older adults. Constipation may occur secondary to other conditions, such as colorectal cancer or strictures. It is also associated with contributing factors such as inadequate fluid intake, absence of dietary fiber, caloric intake, and lack of exercise. In a recent study of clients who considered themselves constipated, 40% were using over-the-counter medications known to cause constipation. In addition to these factors, clients in the hospital may have a lack of privacy and inconvenience or lack of toilet facilities, which can lead to constipation.

A variety of products have been studied to determine whether any of them prevent constipation. Some studies support the effectiveness of supplementing the diet with bran, but its effectiveness has not been supported by randomized controlled trials.

Other studies suggest that fiber may be effective in improving bowel movement frequency in the ambulatory client, while stimulant and osmotic laxatives may be more effective than bulk-forming agents for the immobilized client. A current study supports establishing a bowel training program to establish regularity. Additional studies support incorporating regular exercise to reduce the risk of constipation.

Source: (a) (1999). Management of constipation in older adults, *Best Practice*, 3(1). (b) Hsieh, C. (2005). Treatment of constipation in older adults. *American Family Physician*, 72(11), 2277–2284.

Administering a Suppository

Equipment

- Clean gloves
- Lubricant
- Bedpan or commode
- Absorbent pad (optional)
- Suppository as ordered
- Washcloth and towel
- Paper towel

Procedure

1. Check physician's orders and MAR.
2. Perform hand hygiene.
3. Gather equipment.
4. Identify the correct client and explain procedure.
5. Provide privacy. Place client in Sims' position with upper leg flexed.
6. Place bed protector on bed if necessary. Fold back top bed covers.
7. Remove suppository foil; lubricate tip of suppository.
▶ **Rationale:** This prevents tissue damage and promotes easy insertion of suppository.
8. Don gloves; lubricate fingers of nondominant hand.
9. Place small amount of lubricant on paper towel.
10. Lift upper buttock to expose the rectal area.
11. Instruct client to breathe through mouth. ▶ **Rationale:** This relaxes anal sphincter.
12. Gently insert suppository (usually glycerin) with pointed end first, and place high in rectum beyond

external and internal sphincters, approximately 3–4 in. (approximately 10 cm). ▶ **Rationale:** This prevents expulsion of suppository.

13. Push the suppository against the side of the rectal wall. Ensure it is not placed into fecal mass. ▶ **Rationale:** It is ineffective if placed in feces because it cannot be absorbed.
14. Withdraw finger and press client's buttocks together for a few minutes. ▶ **Rationale:** To prevent expulsion of suppository.
15. Instruct client to stay in Sims' position for at least 5 minutes. ▶ **Rationale:** This position helps retain the suppository.
16. Remove gloves by turning inside-out and discarding in appropriate receptacle.
17. Perform hand hygiene.
18. Place client on toilet or commode. If bowel movement does not occur in 30 minutes, perform digital stimulation. A suppository is usually effective within 30 minutes.
19. Repeat with stronger suppository if ordered (Dulcolax) after 30 minutes if there are no results. Follow steps for inserting the suppository including donning gloves.
20. Allow client to retain Dulcolax suppository for 30 minutes. If no results, do digital stimulation again.
21. After bowel evacuation, cleanse and dry perineal area.
22. Remove gloves and perform hand hygiene.
23. Position client in wheelchair or bed.

Clinical Alert

If client has a spinal cord injury, observe for signs of autonomic hyperreflexia (goose pimples, pounding headache, hypertension, perspiration above level of spinal cord injury).

If signs and symptoms of autonomic hyperreflexia occur, discontinue digital stimulation, apply Nupercainal and Xylocaine ointment around anus and rectum as ordered. This anesthetizes the area and decreases the stimulation that caused the response. Wait 10 minutes for symptoms to decrease, and then gently remove the feces.

▲ Insert rectal suppositories beyond the rectal-anal ridge for retention.

EVIDENCE-BASED PRACTICE

Trial to Investigate Properties of Six Skin Protectants

In the treatment of incontinence dermatitis, a skin protectant primarily prevents skin breakdown due to moisture and biological irritants found in urine and feces. Six currently available skin hydration properties were studied in a controlled three-phase study in the United Kingdom. Eighteen volunteers addressed each product's efficacy against a known irritant, skin hydration potential, maintenance of skin barrier, and barrier efficacy against maceration. Each of the six products tested had different performance properties. Products containing petrolatum demonstrated protection against irritants and maceration and provided some skin hydration. Overall, only the water-in-oil petrolatum-based product performed efficiently in oil-tested parameters. This study suggested further testing and use of barrier products to provide additional evidence for appropriate product selection.

Source: Hoggarth, A. (2005). A controlled, three-part trial to investigate the barrier function and skin hydration properties of six skin protectants. *Ostomy/Wound Management*, 51(12), 30–42.

Inserting a Rectal Tube

Equipment

- Rectal tube: size 22–24 straight (French) for adults and size 12–18 French for children
- Small plastic bag or stool specimen container
- Hypoallergenic paper tape
- Water-soluble lubricant
- Bed protector
- Clean gloves, 2 pair
- Washcloth and towel

Procedure

1. Check physician's orders and client care plan.
2. Perform hand hygiene.
3. Gather equipment.
4. Identify the correct client with two forms of identification and explain the procedure.
5. Provide privacy. Place client on left side in a recumbent position and drape. **► Rationale:** This position facilitates insertion of tube following the normal curve of rectum and sigmoid colon.
6. Place bed protector under client.
7. Tape the plastic bag around the distal end of the rectal tube or insert the tube into the stool specimen container.
8. Vent the upper side of the plastic bag to prevent inflation.
9. Don gloves.
10. Lubricate the proximal end of the rectal tube with water-soluble lubricant.
11. Gently separate buttocks and ask client to take a deep breath. Gently insert the tube into the client's rectum, past the external and internal anal sphincters (2–4 in. in adults, 1–3 in. in children). Do not force the rectal tube. **► Rationale:** Taking a deep breath relaxes the anal sphincter and prevents tissue trauma during tube insertion.
12. With adults, gently tape the tube in place, using hypoallergenic paper tape. With children, hold the tube in place manually.
13. Remove gloves and place in appropriate receptacle. Perform hand hygiene.

▲ Insert rectal tube past the external and internal anal sphincters.

14. Take client's pulse. **► Rationale:** Alterations in pulse rate can indicate a vagal stimulation and the rectal tube may need to be removed. This can occur particularly in a client with a cardiac condition.
15. Leave the tube in place no longer than 20 minutes. **► Rationale:** Prolonged stimulation of the anal sphincter may result in a loss of the neuromuscular response. The prolonged presence of a catheter may cause pressure necrosis of the mucosal surface.
16. Don gloves.
17. Remove the tube and provide perianal care.
18. Help the client assume a comfortable position.
19. Clean the tubing, and replace in bathroom if to be reused. Remove and discard the plastic bag.
20. Instruct client that chewing gum, sucking on candy, drinking liquids through a straw, carbonated beverages, and smoking tend to promote the swallowing of air and increase abdominal distention.
21. Remove gloves and perform hand hygiene.

Clinical Alert

Rectal tubes should not be used to manage diarrhea, only for removal of flatus.

Instructing Client in Colostomy Irrigation

Equipment

- Solution container with 1000 mL warm water
- Irrigating tubing with cone
- Three pair of clean gloves
- Irrigating sleeve cut long enough to reach water level in toilet

- Items to clean skin and stoma (e.g., washcloths or gauze sponges)
- Plastic bag for disposal of used pouch
- Clean pouch and closure device
- Skin barriers
- Water-soluble lubricant
- Hook near toilet

Procedure

1. Instruct client in benefits of relaxing and taking periodic deep breaths.
2. Perform hand hygiene and don clean gloves.
3. Remove and dispose of used pouch in plastic bag.
4. Clean stoma and skin with warm water and soft cloth. Assess skin for signs of irrigation or breakdown.
5. Apply irrigation sleeve to peristomal skin, and place belt around waist.
6. Fill container with 1000 mL lukewarm water (500 mL for first irrigation). ► **Rationale:** Lukewarm water temperature is 105°–110°F. This temperature prevents injury from hot solutions and cramping from cold solutions.
7. Suspend container on bathroom hook at level of client's shoulders (no higher than 18 inches above stoma).
8. Open roller clamp and allow solution to run through tubing; close clamp. ► **Rationale:** This removes air from tubing and prevents discomfort for client.
9. Assist client to sit on toilet or on chair in front of toilet.
10. Place sleeve between client's thighs and direct end into toilet.
11. Lubricate cone tip with water-soluble lubricant.
12. Position cone in sleeve by placing through top opening. If cone cannot be inserted easily do not force it.
13. Hold cone snugly against stoma. ► **Rationale:** This prevents back flow of solution.
14. Open roller clamp on tubing and allow water to run through cone while inserting cone into stoma.
15. Instill solution (750–1000 mL) over 5–10 minutes. ► **Rationale:** The container height and rate of water flow affect results obtained. If client complains of feeling light-headed or has vertigo, take pulse and stop instillation. ► **Rationale:** These are symptoms of a vagal response.

Clinical Alert

Colostomy irrigations are done only if normal bowel evacuation cannot be achieved.

Instructing Home Care Client in Colostomy Irrigation**Procedure**

1. Instruct client and family on ostomy care.
2. Provide telephone number and address of supply vendors.
3. Refer client to community support groups for psychological support as needed.
4. Review infection control measures when carrying for ostomy pouches or dressings. Dispose of used equipment in appropriate receptacle.
5. Review potential skin and/or infection signs and symptoms and when to report findings to healthcare provider.

Implementing the Zassi Bowel Management System**Equipment**

- One hydrocolloid dressing, cut in half
- Two pieces of tape, 2-cm width
- One irrigation set
- One 20-mL syringe
- Bowel Management System Catheter; 4 cm or 6 cm
- Retention cuff
- Large-capacity collection bag
- Gloves, 2 pair
- Water-soluble lubricant
- Container with 100 mL of water
- 500 mL of lukewarm irrigant (water or saline)

Preparation

1. Identify the client using two forms of identification.
2. Review client history to determine whether a contraindication to catheter placement has occurred.
 - a. Severe strictures of distal rectum or anal canal.
 - b. Presence of impacted or formed stool.

► **Rationale:** Client must have loose stool flow before insertion of BMS.

- c. Recent history of rectal anastomosis (less than 6 weeks)
 - d. History of recent anal or sphincter reconstruction.
 - e. Compromised rectal wall integrity.
3. Explain procedure to client. RNs or MDs may insert catheter.
 4. Determine need for analgesia. If analgesia is necessary, notify MD or check orders to determine appropriate medication.

Procedure

1. Perform hand hygiene and don clean gloves.
2. Position client in left lateral, knee-chest position. ► **Rationale:** Provides maximal sphincter relaxation.
3. Perform digital rectal exam.
 - a. Assess rectum and anal canal for pathology, size, stool, fecal impaction.
 - b. Rectum must be cleared of stool.

▲ Equipment needed for inserting and managing Bowel Management System.

- c. Determine length of anal canal. If 2.5 cm or less, a 4-cm BMS is used. If greater than 2.5 cm, a 6-cm BMS is used. Follow directions on package.
4. Apply lubricant to perianal and anal canal.
 - **Rationale:** Aids in pre-dilation of anal canal.
5. Remove gloves and discard. Don new clean gloves.
6. Open package containing catheter and bag.
7. Check catheter for appropriate functioning of system:
 - a. Draw up 20 mL of air in syringe.
 - b. Inflate intraluminal balloon (red connector) with 20 mL of air. Disconnect syringe. Status of connector pilot balloon indicates inflated state of intraluminal balloon.
 - c. Fill syringe with 35–40 mL of water. Fill retention cuff (blue connector) with 35–40 mL of water. Disconnect syringe. Verify that pilot balloon indicates inflated state of retention cuff.
 - d. Inspect cuff and balloon for leaks and check pilot balloons to indicate the inflated state of the intraluminal balloon or retention cuff.
 - e. After verifying proper function, insert syringe and slowly and completely aspirate ALL fluid from cuff and balloon. Disconnect syringe. Connector pilot balloons indicate deflated state of intraluminal balloon and retention cuff.
 - f. Inject water through the irrigation lumen (clear connector) to confirm lumen patency. Close white tethered cap and continue with preparations for insertion.
 - g. Ensure the system does not come into contact with sharp edges such as lubricating packet. This could damage the system.

▲ Bowel Movement System Catheter.

8. Connect end of catheter drain tube to collection bag by inserting catheter connector into bag connector and twisting clockwise to lock in place after closing off collection bag drain tube with red clamp.
9. Draw up 25 mL of air into syringe, attach syringe to intraluminal balloon, and inflate balloon via red connector. Disconnect syringe.

NOTE: An additional 5 mL of air is infused for added rigidity to perform the introducer function. Normal inflation is 20 mL of air.

Zassi Bowel Management System

1. Drain tube connector and cup used to prevent leakage when bag disconnected.
2. Adjustable sheet clamp used to maintain the position of the drain tube.
3. Flush/Sampling port provides access for specimen collection and catheter cleaning.
4. Connectors are color coded and accept Luer-tip syringes. Pilot balloons on the intraluminal balloon and retention cuff indicate inflation status of catheter.
5. Transsphincteric catheter zone allows normal sphincter function during use and after removal.

Source: Courtesy of Zassi BMS/Zassi Medical.

10. Apply water-soluble lubricant generously over inflated intraluminal balloon, and fully collapse retention cuff around anus and anal canal.
11. Grasp the lubricated catheter directly behind the retention cuff with triple lumen connector tubing oriented anteriorly. At the time of maximum sphincter relaxation, insert the balloon end of the catheter into the distal rectum.
12. Maintain anterior orientation of the triple lumen connector tubing throughout insertion.
13. Fill the syringe with 35–40 mL of lukewarm water and insert into retention cuff via blue connector. Disconnect syringe. Connect catheter to collection bag.
14. After catheter placement insert syringe into red connector and aspirate 25 mL of air from intraluminal balloon. Disconnect syringe.
15. Confirm pilot balloon is fully collapsed.
16. Confirm catheter fit is tension-free with gentle tug and recoil to “seal” retention cuff (fit of 1 cm or greater gap between anchor strap faceplate and anus).
17. Secure catheter with anchor straps to “seat” retention cuff on rectal floor.
 - a. Apply hydrocolloid dressing to each buttock.
 - b. Check that catheter is not twisted, anchor straps are lateral, and triple lumen connector is anterior.
 - c. Tape anchor straps to hydrocolloid dressing.
 - d. Ensure straps do not apply tension on catheter.
18. Hang collection bag and position catheter to facilitate gravity drainage. ► **Rationale:** This allows for unobstructed flow of fecal matter from catheter to collection bag.
19. Secure catheter drain tube to sheet using sheet clip.
20. Maintain system by verifying system patency with open flow configuration (intraluminal balloon deflated) and irrigate with 50 mL of water.
21. Ensure client is in comfortable position.
22. Remove gloves and discard.
23. Perform hand hygiene.

For Maintaining Bowel Management System

1. Maintain system throughout catheter insertion. Catheters can remain in place up to 29 days.
2. Follow strict Stool Modification Plan and irrigation protocol.
3. Monitor deflated state of intraluminal balloon (via pilot balloon) at least three times per day.
4. Rinse catheter two times per day with 60 mL of water at room temperature, using the flush/sampling port.
5. Check BMS every 2 hr to ensure it is not occluded as a result of client lying on tube or tube being twisted.
6. Inspect BMS drainage tube near anus every 8–12 hr to verify that no column of irrigant and/or feces is in catheter. If irrigant or feces is present, milk into collection bag. Change bag every 8–12 hr.
7. Assess perianal region every 12 hr to observe for mucus or feces leakage in region. Cleanse area and place absorbent pad over area.

Clinical Alert

The BMS is contraindicated for use in clients with impacted stool. The BMS catheter must be removed and then the impaction removed before continuing use of the BMS.

8. Check retention cuff volume weekly or according to physician orders by aspirating all fluid from retention cuff and disconnect syringe; observe that cuff is deflated by checking pilot balloon; refill retention cuff with 35–40 mL of room temperature water.
9. Provide the following interventions to maintain a stool modification plan. ► **Rationale:** To maintain a functioning BMS system.
 - a. Add fiber either in a tube feeding or through use of bulk laxatives.
 1. Citrucel (methyl cellulose), psyllium, prune juice, 6 oz every 8 hr.
 2. Add water to the diet when administering fiber.
 - b. Add stool softeners such as docusate (Colace) 100–200 mg every 12 hr.
 - c. Administer osmotic laxatives such as Lactulose 30 mL every 12 hr or MiraLax, 17 grams daily for 14 days.

NOTE: Increasing the frequency and/or dose of stool-modifying agents may improve results.

For Irrigating Bowel Management System

Equipment

- 60-mL Luer-tip syringe
- Irrigation bag with connector
- Lukewarm irrigant 300 to 1000 mL per order

Procedure

1. Perform hand hygiene and don clean gloves.
2. Empty collection bag unless it can accommodate additional 2 L of irrigant.
3. Fill irrigation bag with 300–1000 mL lukewarm tap water or saline and hang from IV pole 50–100 cm above client’s anus.
4. Position client in Sims’ or left side position with knees up and bed tilted to a slight head down position.
5. Connect irrigation bag administration set to clear connector. Ensure the irrigation bag is connected to correct catheter connector.
6. Draw up 20 mL of air into syringe, and inflate intraluminal balloon via red connector. Inflate with 20 mL air only.
7. Infuse 500 mL of water in approximately 10 minutes. If flow rate is less than optimal, attempt to squeeze gravity bag to clear occlusion.
8. After irrigant infusion, allow solution to dwell for 5 to 10 minutes.
9. Connect syringe to red connector. Aspirate the 20 mL of air from the intraluminal balloon. Disconnect syringe and confirm pilot balloon is fully collapsed. ► **Rationale:** This allows drainage of fluid and feces out of rectum and colon.
10. Position client with head slightly raised and feet in downward position to facilitate gravity drainage, if necessary.

Clinical Alert

If the client experiences cramping or leakage, the irrigation solution may be too hot or too cold, or the infusion rate is too fast. Check the solution temperature and monitor the rate of infusion carefully. You may need to stop the infusion until the cramping is alleviated. If leakage occurs, infuse additional water into retention cuff (blue connector) to prevent leakage.

11. Disconnect administration set from clear connector upon completion of irrigation procedure.
12. Attach syringe to blue connector and completely aspirate all water from retention cuff and then refill to 35 to 45 mL of water if additional water was added to prevent leakage.
13. Milk all remaining feces and irrigant in catheter, from anchor straps to collection bag. Empty contents of bag.
14. Remove and dispose of gloves and perform hand hygiene.

For Emptying Collection Bag

1. Perform hand hygiene and don clean gloves.
2. Remove drain tube plug.
3. Remove drain tube clamp from holster by sliding upward.
4. Open drain tube clamp and empty bag into secondary container.

5. Reclamp drain tube and return clamp to holster after emptying completed.
6. Replace drain tube plug.
7. Dispose of contents according to facility policy, maintaining standard precautions.
8. Dispose of gloves and perform hand hygiene.

For Removing Catheter

1. Perform hand hygiene and don clean gloves.
2. Insert 20-mL syringe into intraluminal balloon via red connector and inflate with 20 mL of air. Disconnect syringe.
3. Insert 60-mL syringe into blue connector of catheter retention cuff and deflate by slowly aspirating all water from the retention cuff. Disconnect syringe.
4. Verify state of retention cuff by confirming blue connector pilot balloon is collapsed.
5. Grasp catheter at external retention faceplate, ask client to bear down, and apply steady traction to slide catheter out the anal orifice.
6. If catheter does not come out easily, add water-soluble lubricant to anal canal and attempt to slide catheter again.
7. Discard catheter in biohazard container, maintaining standard precautions.
8. Remove and discard gloves and perform hand hygiene.

**DOCUMENTATION for Bowel Management**

- Type and number of suppositories used
- Digital stimulation used
- Approximate time used for digital stimulation
- Amount, consistency, characteristics of stool
- Protocol for bowel evacuation for client
- Untoward complications of bowel training program
- Nursing interventions needed to correct complications
- Time rectal tube inserted, size of tube
- Amount, color, and consistency of feces collected
- Time rectal tube removed
- Presence, absence, or change in abdominal distention
- Client's reaction to procedure
- Any unexpected outcomes and measures taken to treat these outcomes
- Take pulse rate before and during procedure
- Colostomy irrigation, amount, color, and concentration of return solution
- BMS insertion and maintenance
- Interventions related to stool modification plan
- Irrigation solution; type and amount

CRITICAL THINKING Application**Expected Outcomes**

- Client establishes regular bowel evacuation program.
- Constipation is prevented.
- Fecal impaction is removed.
- Client is able to evacuate bowel at a convenient and consistent time.
- Client is free of pain, flatus, and discomfort.
- Digital stimulation is performed without cardiac complications.
- Rectal tube insertion relieves flatus.
- Colostomy irrigation is effective in promoting consistency in daily evacuation time.
- BMS is effective to prevent skin excoriation for clients with diarrhea.

Unexpected Outcomes

When digital stimulation is performed, client exhibits reflex spasm that prevents stool expulsion.

Client develops diarrhea.

Client exhibits signs and symptoms of vagal response during removal of fecal impaction.

Effective bowel evacuation program is not established.

No relief of abdominal distention.

Fecal impaction lower in rectum prevents insertion of rectal tube.

Client is impacted with stool even after stool modification program is instituted.

Stool becomes liquid when using the BMS.

Irrigant will not infuse or infuses slowly through BMS.

BMS catheter is expelled.

Alternative Actions

- Apply local anesthetic around rectum and anus, if ordered.
- Wait for spasm to relax, and then proceed with stimulation.
- Identify possible cause of diarrhea.
- Observe dietary intake for possible cause. Provide for bulk.
- Hold the laxatives and stool softeners temporarily.
- Instruct client to eat yogurt and drink milk if not contraindicated by condition.
- Inform physician of diarrhea and obtain orders for Kaopectate. Administer 2 teaspoons after each loose stool for 24 hours.
- Check with physician if medications should be readjusted for bowel training as needed.
- Immediately discontinue procedure.
- Place client in shock position.
- Monitor vital signs every 5–15 minutes until condition is stable.
- Notify physician of findings and request medication order for antispasmodic such as atropine.
- Be prepared for “Code” situation, even though it is not likely to occur.
- Ask dietitian for altered diet (including more fruits and vegetables).
- Check if contraindication exists for increasing fluids to 3000 mL daily.
- Obtain order from the physician to administer a different stool softener and bulk former or increase dosage.
- Have client increase physical activity, especially exercise of the abdominal muscles if not contraindicated by condition.
- Ensure that client begins bowel training program one half hour after a meal.
- Reposition client at an angle that raises the lower part of the body (e.g., in a prone position with the foot of the bed raised).
- Instruct client to circle, raise, and lower his or her legs.
- Reinsert the tube after 2–3 hr.
- Remove the tube and check for feces that may be clogging the outlet. Clean tube, and reinsert.
- Perform digital examination with gloved finger and water-soluble lubricant.
- Break up impaction if present.
- Position client on left side in Fowler’s position.
- Reinsert the rectal tube.
- Irrigate aggressively to loosen stool.
- Irrigate every 8–12 hr if necessary to maintain loose stool.
- Administer enema and/or laxatives.
- Obtain physician’s order for antidiarrheal agent.
- Use large-bore syringe to clear occlusion.
- Place 100–200 mL of irrigant into catheter through flush/sampling port, milk across anal canal, and douche to clear occlusion.
- Ensure that no external traction is applied to catheter (i.e., catheter is caught in bed linen).
- Clean catheter and reinsert but increase retention cuff pressure.

Chapter 23

UNIT 2

Enema Administration

Nursing Process Data

ASSESSMENT Data Base

- Review client's present and past eliminatory status.
- Assess the need for an enema.
- Evaluate amount of solution a client can tolerate.
- Assess if fecal impaction is present.
- Assess the degree of abdominal distention.
- Assess degree of sphincter control.
- Assess current medical regimen.
- Assess dietary history.
- Assess vital signs before and after procedure, as necessary.

PLANNING Objectives

- To relieve constipation
- To relieve fecal impactions
- To cleanse the bowel before surgery or diagnostic examination
- To evacuate the bowel in clients with neurologic dysfunction
- To provide nutrients
- To introduce an exchange resin
- To relieve abdominal distention
- To stimulate peristalsis

IMPLEMENTATION Procedures

- Administering a Large-Volume Enema 839
- Administering an Enema to a Child 841
- Administering a Small-Volume Enema 842
- Administering a Retention Enema 843
- Administering a Return Flow Enema 843

EVALUATION Expected Outcomes

- Client experiences increased comfort and relief from abdominal distention.
- Enema administered without difficulty.
- Returns are clear if preparing client for diagnostic examination or surgery.
- Relief obtained from fecal impaction or constipation.
- Return of solution plus formed, soft feces is complete.

Critical Thinking Application 844

- Expected Outcomes 844
- Unexpected Outcomes 844
- Alternative Actions 844

Administering a Large-Volume Enema

Equipment

- Fluid container with attached rectal tube (size 22–30, straight, or French, for adults)
- Normal saline, tap water, soap (750–1000 mL of solution)
- Water-soluble lubricant
- Bath blanket, if desired
- IV pole
- Clean bedpan, commode, or toilet
- Bed protector pad
- Skin care items (e.g., soap, water, towels)
- Two pair of clean gloves
- Toilet tissue

Preparation

1. Check physician's orders and client care plan.
2. Gather equipment.
3. Identify correct client and explain the procedure.
Explain the benefits of relaxing and taking periodic deep breaths and that he/she will need to hold solution for specified time.
4. Provide privacy.
5. Perform hand hygiene.

Procedure

1. Fill water container with 750–1000 mL of lukewarm solution, 105°–110°F. ► **Rationale:** Solutions that are too hot or too cold or solutions that are instilled too quickly can cause cramping, damage to rectal tissues, and extreme shock.

2. Allow solution to run through tubing until air is removed. Clamp tube. ► **Rationale:** If air is instilled during procedure, client experiences discomfort as a result of distension of the colon.
3. Hang container on IV pole next to bed. Solution should hang 18 to 24 in. above buttocks.
4. Raise bed to HIGH position, and lower side rails on side where you will be working.
5. Don gloves.
6. Place bed protector under client.
7. Place bedpan within easy reach, or place commode near bed.
8. Place client on left side in Sims' position.
► **Rationale:** To facilitate flow of solution using contour of bowel.
9. Provide privacy, and drape client with bath blanket.
10. Lubricate tip of tubing 2–4 in. with generous amount of water-soluble lubricant.
11. Gently spread buttocks, instruct client to take a slow breath, and insert tubing 3–4 in.
12. Raise the solution container to a maximum height of 18 in. above rectum when giving a high enema and 12–18 in. when giving a low enema. ► **Rationale:** To assist in fluid movement, turn client to supine position midway through procedure, then to right side.
13. Open regulating clamp and allow solution to flow slowly. ► **Rationale:** If the flow is slow, client experiences fewer cramps. The client will also be able to tolerate and retain a greater volume of solution. If cramping occurs, lower container to slow influx of

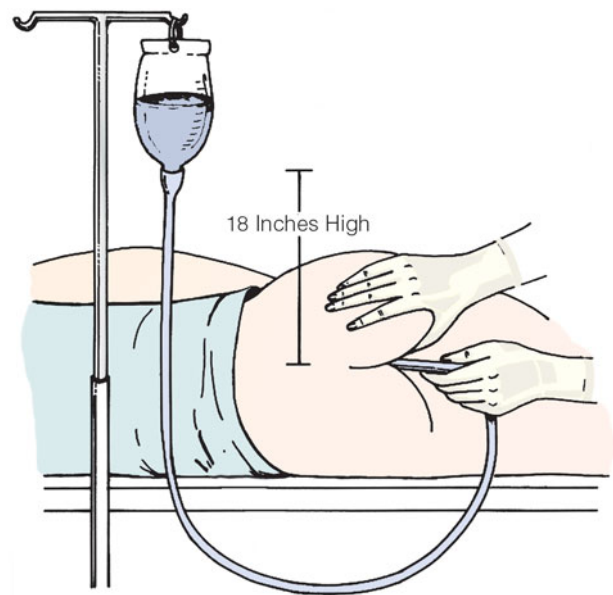

▲ Fill bag to 750 or 1000 mL with tepid solution.

▲ Allow solution to run through tubing to expel air.

▲ Lubricate tip of tubing to prevent rectal injury.

▲ Place enema solution container no more than 18 inches above rectum for safety.

solution to decrease cramping. When cramping decreases, raise container to 18 in. above buttocks.

14. Hold tubing in place in client's rectum at all times. Keep a bedpan nearby.

15. Lower solution container or momentarily clamp tubing if client experiences cramping, is unable to retain solution, or exhibits anxiety. Resume infusion of solution after a few minutes.

Types of Enemas

Cleansing

- Stimulates peristalsis through irritation of colon and rectum and by distention. Agents: Soap suds, tap water, and saline.
- *Soap suds*: Mild soap solutions stimulate and irritate intestinal mucosa. Strong soap solutions can cause severe irritation of the mucous membrane of the colon. Dilute 3–5 mL of mild soap in 1000 mL of water.
- *Tap water*: Give with caution to infants or to adults with altered cardiac and renal reserve. Tap water is a hypotonic solution.
- *Saline*: For normal saline enemas, use a smaller volume of solution. Hypertonic solutions draw fluid into the colon from the body tissues. These solutions are mildly irritating to the mucous membrane of the colon.

Retention

- Solution or nutrient is retained for specified time. Agents: mineral oil, olive oil, cottonseed oil, liquid petrolatum. Nutrient agent: dextrose solution.
- *Emollient (Oil)*: Lubricates the rectum and colon, protecting the intestinal mucous membrane. Feces absorb oil and become softer and easier to expel. Client retains enema for prescribed time, usually 30–60 minutes.

- *Nutritive*: Provides nourishment in temporary or emergency situations. Enema is retained.

Distention Reduction

- Provides relief from flatus causing distention. It improves ability to expel flatus. Types: carminative and return flow.
- *Carminative*: Two common types include: 1-2-3 enema (30 g of magnesium sulfate, 60 g of glycerin, and 90 mL warm water) and milk and molasses (180–240 mL of equal amounts).
- *Return flow*: Harris flush most common. Mild colonic irrigation using 100–200 mL of enema solution. After instillation, enema container is lowered and solution siphoned back into container.

Medicated

- Enemas containing drugs used for reducing bacteria or removing potassium. Agents: Kayexalate and neomycin.
- *Kayexalate*: A resin is introduced into the large intestine, removing the excess potassium by exchanging it for sodium ions.
- *Neomycin*: Antibiotic solution used to reduce bacteria before bowel surgery.

16. After you have instilled the solution, gently remove the tubing. Instruct client to hold solution for 10–15 minutes or as long as tolerated. ► **Rationale:** The longer the solution is retained, the more effective the results.
17. Clean and dispose of equipment.
18. Place client on bedpan, elevate the head of the bed so that client can assume a squatting position on bedpan, or assist to commode.
19. Remove gloves and perform hand hygiene.
20. Provide privacy until client has expelled total volume of instilled solution.
21. Don clean gloves before removing bedpan, or assist client to bed.
22. Remove bedpan when client is ready, and immediately empty, clean, and replace to proper storage area.

TABLE 23-2 Fluid Volume for Enema Administration

Infant	50–150 mL
Toddler	250–350 mL
Child	300–500 mL
Adolescent	500–750 mL
Adult	750–1000 mL

23. Assist client with perineal care, and help client to assume a comfortable position.
24. Lower bed and raise side rails.
25. If client is on strict I&O, measure returns. ► **Rationale:** To make sure total volume of the solution is expelled.
26. Remove gloves and perform hand hygiene.

Administering an Enema to a Child

Equipment

- Water container with attached rectal tube (size 14–18 straight [French] for children, and size 10–12 French or infant enema syringe with bulb for infants)
- Normal saline, tap water, soap solution
- Water-soluble lubricant
- Clean potty chair for children
- Bed protector
- Skin care items (e.g., soap, water, towels)
- Clean gloves

Preparation

1. Check physician's orders and identify client using two forms of identification.
2. Gather equipment.
3. Provide privacy for child.
4. Perform hand hygiene.
5. Identify correct client, and explain procedure to child or family. Inform an older child he/she will feel like he has to go the bathroom while the solution is flowing in. Take time to calm a frightened child and to answer the child's questions.
6. If child is toilet trained, place potty chair next to crib or bed.

Procedure

1. Fill water container with 100°F solution, using appropriate volume according to age.
2. Open clamp and allow solution to run through the tubing so that air is removed.
3. Clamp tube and hang solution container on IV pole.
4. Place bed protector under child.
5. Place child on left side or in knee–chest position.

► **Rationale:** To facilitate flow of solution using contour of bowel.

6. Don clean gloves.
7. Lubricate tip of tubing or infant enema syringe with bulb.
8. Gently separate buttocks and insert catheter or syringe into child's rectum (1–1.5 in. for infants, 2–3 in. for children) at an angle pointing toward the navel.
9. If there is resistance when inserting the tip or solution, carefully withdraw the tip and try a different angle.
10. Elevate solution container no more than 12–18 in. above the child's hips, according to hospital policy.
 - **Rationale:** Height increases pressure of solution entering colon—too much pressure may damage colon.
11. Open clamp and allow solution to flow slowly for 10–15 minutes. If the solution starts to ooze out of rectum, briefly squeeze child's buttocks firmly together around the tube.
12. After you have instilled the solution, close clamp and gently remove the tubing or syringe.
13. Hold child's buttocks together or tape them with hypoallergenic paper tape.
14. Retain solution 10–15 minutes for cleansing enemas.
15. Place the child on a potty chair or bedpan to expel solution.
16. Remove gloves and place in trash receptacle. Perform hand hygiene.
17. If there are no contraindications, you may gently massage child's abdomen to help child expel returns.
18. If the child wants to be left alone while expelling returns, provide privacy. Child should expel the total volume of the instilled solution.
19. Don gloves.
20. Remove the potty chair or bedpan.

21. Clean the child's perineal area, and help child assume a comfortable position.
22. Estimate returns of solution. ► **Rationale:** To determine that the child expelled the total volume of the solution.
23. Clean all equipment, and replace in appropriate area.
24. Remove gloves and perform hand hygiene.

Administering a Small-Volume Enema

Equipment

Commercially prepared enema
 Water-soluble lubricant
 Bedpan, commode, toilet
 Two pair of clean gloves
 Bed protector
 Skin care items (e.g., soap, water, towels)

Preparation

1. Check physician's orders and identify client using two forms of identification.
2. Gather equipment.
3. Perform hand hygiene.
4. Identify correct client and explain the procedure.
 Explain the benefits of relaxing and taking periodic deep breaths.
5. Place bed protector under client.
6. Place client on left side in a Sims' position.
7. Provide privacy.
8. Read directions on enema container.
9. Don clean gloves.

Procedure

1. Fold linen down to expose buttocks.

▲ Remove cap from container and ensure that it is lubricated.

2. Lubricate with water-soluble lubricant if necessary. (Usually rectal tube is self-lubricated.)
3. Expose the anal opening to assist you in inserting the tube without traumatizing the tissue.
4. After inserting rectal tube, gently squeeze the container, and empty entire 120 mL of hypertonic solution.
5. Keep pressure on container while removing from rectum. ► **Rationale:** To prevent solution from being drawn back into container.
6. Instruct client to hold solution 5–7 minutes.
7. When ready to expel solution elevate the head of the bed so that the client can assume a squatting position on the bedpan. If able, client may expel solution in toilet.
8. Remove and dispose of gloves.
9. Provide privacy until the client has expelled the total volume of the instilled solution.
10. Don gloves and remove bedpan if client using bedpan.
11. Assist client with perineal care, and help client to assume a comfortable position.
12. Measure returns if on strict I&O.
13. Dispose of equipment, and remove gloves.
14. Perform hand hygiene.

▲ Insert tip of container gently into rectum and expel all fluid.

Administering a Retention Enema

Equipment

Commercially prepared disposable oil retention enema
 Oil: Adult 150–200 mL, child 75–100 mL, 91°F
 Water-soluble lubricant
 Bedpan or commode
 Bed protector
 Skin care items (e.g., soap, water, towels)
 Clean gloves

Preparation

1. Identify and prepare client as for any enema.
2. Provide privacy.
3. Gather equipment—disposable oil retention enema is administered like a small enema. Read directions on enema container.

Procedure

1. Explain steps of procedure to client.
2. Raise bed to HIGH position.
3. Perform hand hygiene and don gloves.

4. Place bed protector on bed.
5. Expose anal opening, and gently insert rectal tube tip of container 3–4 in. Commercially prepared enemas are prelubricated.
6. Squeeze contents slowly, and empty entire amount into rectum.
7. Keep container compressed and remove rectal tube gently. ► **Rationale:** To prevent solution from being drawn back into container.
8. Lower bed.
9. Discard equipment and gloves, following Standard Precautions. Perform hand hygiene.
10. Explain to client that oil should be retained for 30–60 minutes before it is expelled. ► **Rationale:** Purpose of enema is to soften stool.
11. A cleansing enema may need to be given to remove oil and stimulate defecation.
12. Don gloves and provide hygienic care if needed. Discard washcloth and towel in laundry.
13. Remove gloves, discard in appropriate container, and perform hand hygiene.

Administering a Return Flow Enema

Equipment

Fluid container with attached rectal tube
 Normal saline or tap water at 105°–110°F
 Water-soluble lubricant
 Clean bedpan
 Bed protector
 Skin care items (e.g., soap, water, towels)
 Clean gloves

Preparation

1. Check physician's orders and identify client using two forms of identification.
2. Gather equipment.
3. Provide privacy.
4. Perform hand hygiene.
5. Fill fluid container with 100–200 mL of ordered solution; check that temperature is between 105°–110°. ► **Rationale:** Cool solutions increase cramping.
6. Allow solution to run through tubing so that air is removed. ► **Rationale:** If air is instilled during procedure, client experiences discomfort.
7. Hang container on IV pole.

Procedure

1. Explain procedure to client. Explain the benefits of relaxing and taking periodic deep breaths during procedure.
2. Raise bed to HIGH position, and lower side rails.
3. Don gloves.
4. Place bed protector under client.
5. Place client on left side in Sims' position with right leg flexed as much as possible. ► **Rationale:** This position facilitates instillation of fluid.
6. Lubricate tip of tubing with water-soluble lubricant.
7. Gently spread buttocks, and insert tubing 3–4 in. into client's rectum, past external and internal sphincters. Avoid traumatizing hemorrhoids during insertion. ► **Rationale:** Vagal nerve stimulation from enemas may cause cardiac arrhythmias.
8. Raise water container to a maximum height of 12–8 in. above rectum.
9. Open clamp and allow 200 mL of solution to flow slowly into rectum and sigmoid colon. If cramping occurs, clamp tube for a few minutes and then continue infusion.
10. Lower solution container 12–18 in. below level of rectum and allow all fluid to flow back into container.

11. Raise container 12–18 in. above rectum and allow solution to flow back into rectum.
12. Repeat inflow–outflow process 5–6 times, changing solution when it becomes thick with feces.
 - ▶ **Rationale:** This assists in stimulating intestinal peristalsis with expulsion of flatus.
13. Provide privacy until client has expelled total volume of instilled solution after last inflow–outflow series.
14. Assist client with perineal care, and help client assume a comfortable position.
15. If client is on strict I&O, measure returns to make sure total volume of solution is expelled.
16. Clean all equipment, and replace in bathroom or appropriate location.
17. Remove gloves and perform hand hygiene.
18. Lower bed and raise side rails.

DOCUMENTATION for Enema Administration

- Purpose of enema
- Time enema given
- Volume and type of solution used
- Results obtained: amount, consistency, and color
- Any unexpected outcomes and measures taken to remedy problems
- Client's reactions to procedure
- Relief of flatus and distension

CRITICAL THINKING Application

Expected Outcomes

- Client experiences increased comfort and relief from abdominal distention.
- Enema administered without difficulty.
- Returns are clear if preparing client for diagnostic examination or surgery.
- Relief obtained from fecal impaction or constipation.
- Return of solution plus formed, soft feces is complete.

Unexpected Outcomes

Client expels solution prematurely.

Alternative Actions

- Calm and ease client's distress by reassuring him or her as you clean the equipment.
- Place bedpan under client. Place client in semi-Fowler's position with knees flexed.
- Hold the rectal tube in client's rectum between thighs. Slow the water flow, and continue with the enema.

Client complains of severe and sudden abdominal pain, nausea, and distention.

- Remove tubing and notify physician immediately of possible perforation. (This is an uncommon complication.)
- Assess vital signs. If you suspect cardiac dysrhythmias, remove bedpan and notify physician immediately.
- Be prepared to administer emergency drugs, such as atropine.
- If an IV is not in place, start an IV of 5% dextrose in water (D₅W) using a large-bore needle for emergency use.

The flow of water is impeded or an obstruction is felt.

- Open clamp on tubing. Allow a small amount of solution to flow. (The warm solution may help relax the internal sphincter.)
- Withdraw tube slightly and reinsert.
- Gently perform a digital examination for the possibility of fecal impaction. Break up impaction if present. Ask physician for order to give a retention enema, followed by a cleansing enema 2–3 hr later.

Client cannot return enema solution.

- Gently massage client's abdomen if not contraindicated.
- Replace rectal tube. Lower the enema bag below the level of the bed.
- If client is not uncomfortable, do nothing. If client complains of discomfort or pain, notify physician.

Enema returns are not clear before surgery or diagnostic testing.

- Repeat enema. If, after three enemas, returns are still not clear, notify physician of findings.
- May need to give an enema with a stronger solution.
- Physician may need to order magnesium citrate or electrolyte solution (i.e., GoLYTELY).

Fecal impaction is not relieved.

- Check orders for oil retention enema.
 - Check catheter size needed.
 - Obtain order for and use digital stimulation and manual extraction of feces if not contraindicated by diagnosis of cardiac or neurologic involvement.
-

Chapter 23

UNIT 3

Fecal Ostomy Pouch Application

Nursing Process Data

ASSESSMENT Data Base

- Assess type and location of stoma (section of bowel used to create stoma).
- Observe stoma color, which should be beefy red and moist.
- Inspect client's abdomen for creasing, firmness, softness, contour, scars, folds, and incisions.
- Inspect client's peristomal skin for signs of erythema, excoriation, ulceration, and fistula formation.
- Assess how far stoma protrudes above skin surface; it should be 0.5–1 in.
- Assess size of stoma.
- Assess output of effluent including amount, consistency, odor.
- Assess client's learning abilities, age, manual dexterity, and visual acuity.

PLANNING Objectives

- To assist client to feel more confident that colostomy will not evacuate once appliance is intact
- To collect effluent for accurate assessment of output in the hospital
- To collect effluent for the comfort of the client
- To contain stool and odors to facilitate the client's return to a productive lifestyle, including the resumption of satisfying and meaningful relationships.
- To protect peristomal skin from erythema, excoriation, and infection
- To protect the client's clothing

IMPLEMENTATION Procedures

- Applying a Fecal Ostomy Pouch 847
 - *Changing One-Piece Fecal Ostomy Pouch* 848
 - *Applying Two-Piece Fecal Ostomy Pouch* 850

EVALUATION Expected Outcomes

- Pouch remains intact without leakage for 3–5 days.
- Pouching system provides maximal skin protection.
- Pouching system remains odor-proof for 3–5 days.
- Client gradually assumes an active role in applying the pouch.
- Client's skin remains free of erythema or excoriation and infection.

Critical Thinking Application 852

- Expected Outcomes 852
- Unexpected Outcomes 852
- Alternative Actions 852

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Applying a Fecal Ostomy Pouch

Equipment

- One- or two-piece transparent ostomy pouch with adhesive wafer
- Warm water and mild soap
- Soft cloths
- Bath blanket
- Plastic bag for pouch disposal
- Tail closure or night adaptor for pouch
- Clean gloves
- Graduate or bedpan
- Measuring guide
- Tissues
- Ostomy scissors and dark marking pen

Preparation

1. Check client care plan and identify client using two forms of identification.
2. Determine exact supplies client uses.
3. Gather equipment.

4. Explain procedure to client.
5. Provide privacy.
6. Raise bed to high position.
7. Perform hand hygiene and don gloves.

▲ Supplies needed to change two-piece pouches.

▲ Supplies needed to change one-piece pouches.

▲ Two-piece fecal pouches.

▲ Fabric pouches, convexity faceplates, pouch with filter.

▲ Viable stoma.

▲ Nonviable parastomal hernia.

Procedure

1. Place bath blanket over client. Place absorbent pad or towels under client. ► **Rationale:** To protect bed from spillage.
2. Observe placement of stoma. ► **Rationale:** To determine normal amount of output and consistency. (Immediately after surgery, all stomas will have very liquid stool and high flatus output.)
3. Empty old pouch into graduate, bedpan, or toilet.
4. Remove old pouch by pushing against skin as you pull backing from skin and discard in plastic bag. Save tail closure on bottom of pouch.

Changing One-Piece Fecal Ostomy Pouch

▲ Starting at upper corner, remove old pouch.

▲ As you remove old pouch, push against skin while pulling down on pouch.

▲ Clean skin with warm water; dry well.

▲ Measure stoma size.

▲ Remove plastic covering from one-piece pouch.

▲ Cut pouch opening to exact size of stoma.

▲ Remove paper from inner wafer. Save pattern for future pouch changes.

▲ Apply ring of paste to opening on pouch.

▲ Remove paper from outer adhesive ring of pouch.

Center and apply pouch to clean, dry skin.

After applying one-piece pouch, clamp bottom of pouch.

Clinical Alert

To promote the client's self-esteem and body image, be aware of your own body language. Even subtle changes in the way you look at the stoma could indicate disgust or disapproval and an altered self-esteem could result.

5. Measure output, if ordered.
6. Clean skin and stoma gently with warm water and soft cloth. ► **Rationale:** Oily substances can interfere with pouch adhesive. If adhesive doesn't come off, leave it on the skin. If you pick at it, the peristomal skin can be damaged.
7. Dry skin well with soft cloth. Keep tissues available if stoma functions while pouch is off.
8. Observe skin; it should be free of erythema or excoriation. The stoma is assessed for changes in size, ulceration, and color (stoma should be moist, pink, or beefy red). Notify the physician if stoma is black, blue, or purple. This indicates a nonviable stoma.
9. Measure stoma at the base with measuring guide.
10. Trace measured pattern on pouch.
11. Cut pouch to pattern, making sure opening is large enough (at least 1/8 in.) to encircle stoma without pushing on edges. ► **Rationale:** No skin should appear between the pouch edge and the stoma.
12. If using a two-piece pouch, snap the wafer and pouch together. (See photo sequence for alternate method of using two-piece pouch.)
13. Remove paper from skin barrier on pouch and save it. ► **Rationale:** This may be used as a pattern for next pouch change.
14. Apply a ring of skin barrier paste to opening on pouch.
15. Apply Stomahesive powder to denuded skin only.
16. Remove paper from outer ring.
17. Center and apply pouch to clean and dry skin. Smooth edges of adhesive to skin. ► **Rationale:** If adhesive is wrinkled, it may result in leakage from pouch. To promote optimum wear of the pouch, warm the adhesive by placing your gloved hand over the adhesive and gently hold it over the site for 1/2 to 1 minute. **Rationale:** This will activate the adhesive in the skin barrier.
18. Pouches can be applied over an incision. ► **Rationale:** Incisions are sealed within 24 hr of surgery.
19. Close and secure end of pouch with tail closure.
 - a. Ensure bowed end is next to body. ► **Rationale:** This provides a better fit to body, and prevents outpouching of clamp through clothing.
 - b. Lay hook on top of bag and fold bag 1 in. over end of pouch.
 - c. Squeeze clamp together to close.
20. Remove soiled pouch and tissues from bedside.
21. Remove gloves and perform hand hygiene.
22. Position client for comfort. Return bed to low position.
23. Put away supplies and reorder as necessary.

Clinical Alert

Clients with ostomies will need a nutritional consult and a written dietary guide. They need to limit the amount of hard-to-digest foods for at least the first 2–3 weeks post op. Also, limiting gas-producing foods will prevent gas-forming odors.

Applying Two-Piece Fecal Ostomy Pouch

1 Clean and dry skin thoroughly before applying two-piece.

2 Cut opening of a two-piece pouch to exact size of stoma.

3 Check size of opening to ensure proper fit.

4 Snap pouch onto wafer when using a two-piece pouch.

5 Check for secure fit by tugging at bottom of pouch.

6 Remove paper from inner barrier.

7 Apply paste to inner circle of wafer.

8 Remove paper from outer adhesive ring.

9 Center pouch over stoma and press onto skin.

▲ Secure adhesive to skin.

▲ Clamp bottom of pouch.

▲ Check that clamp is secure.

Client Teaching

- Empty pouch when one-third full of stool or flatus.
 - a. Empty into toilet.
 - b. Pouch should last for 3–4 days.
- Rinse pouch using room temperature water and a rubber ear syringe (squirt into pouch).
- Use pouch deodorant if desired.
- Empty each morning and last thing at night even if not one-third full.
- Check seal on daily basis for tight fit; change if needed.
- Instruct client to always carry a supply of ostomy equipment for emergency use.
- Instruct client on emptying and cleaning pouch, opening and closing clamp, observing and cleaning peristomal area, and changing pouch.
- Have client return demonstration until able to perform activities correctly.

Loop Colostomy with Rod

▲ A loop of bowel is brought onto abdomen and is supported by a plastic rod.

Loop Colostomy with Rod Removed

▲ Two openings are made in colostomy. Proximal loop is functional and discharges fecal material. Distal end is nonfunctional and discharge only mucus.

DOCUMENTATION for Fecal Ostomy Pouch Application

- Type of pouch and skin barrier used
- Time pouch applied
- Time pouch emptied
- Amount, color, and consistency of stool emptied from pouch
- Presence or absence of flatus through the stoma
- Location of stoma
- Client participation in and toleration of pouch application
- Condition of peristomal skin and stoma, including color and size
- Condition of incision line (i.e., any erythema or edema)
- Condition of abdomen (e.g., distention)
- Client teaching, which has been completed

CRITICAL THINKING Application

Expected Outcomes

- Pouch remains intact without leakage for 3–5 days.
- Pouching system provides maximal skin protection.
- Pouching system remains odor-proof for 3–5 days.
- Client gradually assumes an active role in applying the pouch.
- Client's skin remains free of erythema, excoriation, and infection.

Unexpected Outcomes

Stoma appears dark, dusky-colored, or black.

Stoma becomes ulcerated or cut.

Stoma remains a persistent pale pink.

Bleeding occurs when stoma is touched.

Erythematous rash at site of pouch.

Papular rash appears on peristomal skin.

Peristomal skin complications occur.

Alternative Actions

• Notify physician of findings, and document in chart. (Usually indicates stoma is ischemic.)

- Examine pouching system to see if opening of pouch may be cutting into stoma.
- Recut opening to exact size of stoma.

- Request physician to order Hgb, Hct (usually the result of low Hgb).
- Instruct client to monitor effluent for constipation if iron preparation ordered.

• Observe and note—usual occurrence postoperatively.

- Assess for allergic reaction to product being used.
- May need to change to different type of adhesive on pouch or change to a pouch with no adhesive.

- Assess for possible yeast sensitivity.
- Be sure skin is clean and dry before applying pouch.
- Do not rinse pouch with water because this traps water under wafer.
- May need to use antifungal powder on skin with each pouch change until skin clears.

- Evaluate cause of leakage.
- Be sure pouch is cut to correct size.
- Measure stoma at each pouch change for 4–6 weeks. Size will change as edema subsides.
- Measure stoma at base.
- May need to fill any creases around stoma with skin barrier paste.
- Apply thin layer of ostomy powder over area and seal with an alcohol-free coating.
- May need to use secondary skin barrier like Eakin seal.
- May need to attach belt to minimize lateral leakage.

Ostomy is flush or below the surface.	<ul style="list-style-type: none"> • Change to a product like Durahesive that swells around stoma, preventing leakage, and holds up well to liquid output. • Be sure pouch is emptied before it is more than one-third full of stool or flatus, since an overfull pouch can break seal of pouch. • Pouches should not be changed more than once daily.
Ostomy is in skin fold or crease.	<ul style="list-style-type: none"> • Apply convex pouch system to assist ostomy to protrude. • Apply ostomy belt.
Client experiences itching or burning under appliance.	<ul style="list-style-type: none"> • Apply a one-piece pouch for more flexibility. • Fill deep crevices with caulking material.
Client not coping with altered body image.	<ul style="list-style-type: none"> • May be a sign that stool is undermining seal of pouch. • Refer to United Ostomy Associations of America, Inc., the Crohn's and Colitis Foundation of America, American Cancer Society or the local Enterostomal Therapy nurse.

GERONTOLOGIC Considerations

- Elderly clients frequently have concomitant cardiac problems, which can be affected by vagal stimulation during fecal removal or enema administration. Check with the physician before these skills are performed on elderly clients. Monitor the pulse carefully during the procedure.
- Fecal impaction is not uncommon with elderly clients due to decreased mobility and exercise, dietary habits, and tendency to overuse enemas and laxatives.
- Encourage clients to decrease use of laxatives and enemas, increase fluid intake and fiber in diet, and increase exercise. Dehydration resulting from inadequate fluid intake leads to constipation and fecal impaction.
- To select the proper ostomy appliance for an elderly client, the nurse must determine whether the client has any physical limitations that could influence the type of appliance needed. These limitations include poor vision, use of only one hand, arthritis, and inability to perform cleaning and pouching procedure.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- A CNA or unlicensed assistive personnel (UAP) may be assigned to administer a disposable enema or tap water enema in most facilities. This information is presented in the CNA curriculum. These personnel are not allowed to administer enemas with medications or a Harris flush.
- An LVN/LPN may be assigned to insert a rectal tube, administer enemas, and perform colostomy care.
- In some rehabilitation settings, aides may be instructed to administer glycerine suppositories. This requires additional training. Check facility policy and procedure manuals to determine which healthcare worker may be assigned to this task.

- *A CNA cannot be assigned to perform a fecal impaction removal because of the risk of a vagal response during the procedure.*

Communication Matrix

- Information relative to bowel elimination is provided both through report and written information on the Kardex card.
- Before delegating any of the tasks associated with bowel elimination to a CNA or UAP, determine their knowledge base to perform the task. Ask them to explain the procedure if you are unsure of their ability to perform the task.
- When an LVN/LPN or RN is assigned to perform colostomy care or assist a physician with an intestinal tube insertion, ensure he or she is familiar with the procedure. Review the procedure as needed.
- Clients who require a bowel program need instruction on the process so they may become independent in the skill. If someone else will be assisting them with this procedure, they should be included in the teaching process. The RN is

responsible for establishing the teaching program. An LVN/LPN may assist in carrying out the plan.

- When special steps or supplies are needed to perform a task (i.e., colostomy care), information should be written on

the client care plan or clinical pathway. This allows all staff to perform the procedure the same way. Clients feel more secure when procedures are completed in a uniform method.

CRITICAL THINKING Strategies

Scenario 1

You are assigned to a 74-year-old man who had a transverse colostomy for cancer 4 days ago. During the night report, you heard the night nurse say his pouch is leaking and he is very angry with the staff for causing the mess. As you prepare to enter his room, you decide how to approach him.

1. Determine the most appropriate communication technique to use with the client. Provide rationale for your response.
2. As you observe the stoma and pouch, you determine the leak is at the bottom of the pouch.
 - a. State two reasons the pouch may be leaking.
 - b. Describe your initial nursing action after you assess the leaking pouch.
 - c. What steps do you take to ensure the new pouch will not leak?
3. After removing the first pouch, you assess the skin and determine the peristomal skin to be erythematous and the stoma reddened and slightly edematous.
 - a. What is your priority nursing intervention? Provide the rationale for your response.
 - b. After completing the priority intervention, what is your next action?

4. After the application of the new pouch, you determine that a teaching plan needs to be developed for the client.
 - a. Describe the method of developing a teaching plan for this client.
 - b. After developing a plan, indicate the first step the nurse should incorporate to implement the plan.
 - c. Describe your rationale for the first step of the teaching plan.
 - d. List at least three nursing diagnoses that are appropriate for this client's care plan.
 - e. Identify at least one community resource that is appropriate for a referral.

Scenario 2

You assess Mrs. Jacob, a 65-year-old who had a colostomy performed 6 days ago, for cancer of the descending colon. When you tell her you will be instructing her on how to apply a new pouch, she starts to cry and says, "No, I don't want to know how because all it does is leak everywhere."

1. Identify the initial nursing intervention and discuss additional actions you would take to resolve this problem.
2. Describe the assessment database that should be completed before a plan can be implemented.
3. Outline the steps in designing a client teaching plan for a client with an ostomy.

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. The client is undergoing diagnostic tests for fecal incontinence. You would expect to prepare the client for which of the following tests?

Select all that apply.

1. Ultrasonography.
 2. Electromyography.
 3. MRI.
 4. Colonoscopy.
2. The client is scheduled for surgery in the morning for an ileostomy. He asks you what to expect when he returns from surgery. Your best response is
 1. "You will need to ask the physician, I can't tell you."
 2. "You will have an opening through the abdominal wall where the stool will pass into a bag."

3. "You will have a drain in place from the abdominal incision until bowel function returns."
 4. "You will have a catheter inserted into the colon until the colon has healed."
3. One of the major differences in care of a client with a colostomy and one with an ileostomy is
 1. The stool of the ileostomy is liquid to semisoft, which requires increased fluid intake.
 2. Only the client with an ileostomy will require the use of a colostomy bag.
 3. The ileostomy is usually able to be reversed when the disease process heals.
 4. There are usually no dietary restrictions with either client.
 4. Just before removing a fecal impaction, the nurse
 1. Obtains a consent form for the procedure.

2. Infuses at least 500 mL of fluid through a rectal tube into the lower colon.
 3. Obtains baseline pulse and blood pressure.
 4. Gives the client a laxative to assist with the fecal removal.
5. The client requires a rectal suppository. Which of the following actions is appropriate when inserting the suppository?
1. Ask the client to bear down when you insert the suppository just beyond the external sphincter.
 2. Place the flat end of the suppository into the external sphincter.
 3. Insert the suppository into the fecal material if at all possible.
 4. Place the pointed end of the suppository 3–4 in. beyond the internal sphincter.
6. Contraindications for use of the Bowel Management System include
- Select all that apply.**
1. Recent sphincter reconstruction.
 2. Impacted or formed stool.
 3. Severe strictures of distal rectal or anal canal.
 4. History of severe diarrhea.
7. Place nursing actions in order they are to be carried out when inserting the BMS system.
1. Gently tug and re-coil catheter to “seal” retention cuff.
 2. Fill syringe with 35–40 mL of lukewarm water and insert into retention cuff using blue connector.
 3. Confirm pilot balloon is fully collapsed.
 4. Hang collection bag on side of bed.
8. The client has an enema ordered before surgery. Which one of the following nursing actions will you perform when administering a large volume enema?
1. Place client on right side in Sims’ position.
 2. Instruct the client to take in a slow deep breath and insert tubing 3–4 in.
 3. Raise height of enema solution to the level of the client’s shoulder.
 4. Instill solution over 5 to 10 minutes.
9. The student nurse has been instructed to teach the client and family the application procedure for a fecal ostomy pouch. In reviewing the skill, identify which action would not be considered appropriate for applying a pouch.
1. Remove old pouch by pushing against skin as you pull backing from skin.
 2. Cleanse skin and stoma with warm water and generous amount of soap.
 3. Cut new pouch at least 1/8 in. larger than stoma without pushing on edges.
 4. Apply ring of skin barrier paste to opening on pouch.
10. The student nurse is preparing to begin the leadership component of the nursing program. The student remembers that the appropriate delegation of nursing skills includes
1. Assigning the nursing assistant to complete a fecal impaction removal on an elderly client.
 2. Determining that the unlicensed assistive personnel cannot be assigned to care for a client requiring a tap water enema.
 3. Asking the RN team leader to administer a carminative enema to the client.
 4. Assigning the LVN to develop an ileostomy teaching plan for the client and family.
-

Heat and Cold Therapies

LEARNING OBJECTIVES

1. Describe the mechanisms responsible for the body's heat loss and heat production.
2. Discuss the role of the hypothalamus in thermoregulation.
3. List at least three adaptive processes that maintain the body temperature within a normal range.
4. Discuss how heat transfer occurs.
5. Identify various modes of heat therapy.
6. Describe the physiologic effects of local heat applications (thermotherapy).
7. Identify various modes of cold therapy (local cryotherapy and induced hypothermia).
8. Describe the physiologic effects of local cold applications (cryotherapy).
9. Identify indications and contraindications for various heat and cold therapies.
10. Predict the type of thermal agent that would be most therapeutic for a particular client's condition.
11. Discuss the rationale for induced hypothermia for special clients.
12. List four safety precautions to consider when applying heat and cold treatments.
13. State two nursing diagnoses related to thermal therapies.

TERMINOLOGY

Afterdrop drop in core temperature upon discontinuation of rewarming therapy.

Ambient temperature temperature of the air surrounding a person.

Antipyretic an agent that reduces fever.

Compress a pad of cloth applied firmly to a part of the body; compress may be dry or wet, cold or warm.

Conduction heat transfer between materials of different temperatures that are in direct contact with each other (e.g., hot or cold pack).

Convection heat transfer by contact with circulating gas or fluid of a different temperature (e.g., whirlpool, wind).

Core temperature the temperature of internal sites; may be increased in rectum or tympanic membrane.

Cryotherapy transfer of heat from the client by use of a cooling agent.

Cyanosis bluish coloring of the skin and the mucous membrane due to decreased oxygenation.

Erythema reddish color of the skin due to dilation of capillaries.

Evaporation absorption of heat (energy) as a result of conversion of a material from a liquid to a vapor state (e.g., sweating, spraying).

Fever regulated rise in body temperature to a new hypothalamic “set point”; usually mediated by internal stimuli (e.g., pyrogenic cytokines), often caused by infection. Metabolic rate is increased; shivering and diaphoresis occur.

Hyperemia increased blood supply to an area.

Hyperthermia nonregulated rise in core body temperature exceeding 41.1°C; due to dysfunction of thermoregulation caused by injury to the hypothalamus (central fever), or failure of the body’s ability to eliminate excess heat (e.g., environmental exposure, medications).

Hypothermia a reduction in core body temperature due to environmental exposure or thermoregulatory dysfunction: mild (33°–36°C) moderate (26°–32°C) deep (13°–25°C), profound (<12°C).

Insulator substance that is a poor conductor or a nonconductor of heat; a substance that helps prevent the escape or entrance of heat.

Mottling blue-gray to purplish blotches seen peripherally; usually the result of peripheral vasoconstriction.

Overshoot temperature over-compensation due to external temperature management therapy.

Pallor loss of reddish hue due to superficial vasoconstriction.

Radiation exchange of heat through the air without an intervening medium (e.g., heat lamp).

Shivering thermogenesis production of body heat by involuntary muscle activity, which increases metabolic rate and oxygen consumption and possible anaerobic metabolism with resulting acidosis.

Suppuration the process of pus formation.

Thermogenesis heat production by the body.

Thermotherapy transfer of heat to a client by use of a heating agent.

Vasoconstriction a narrowing of blood vessels.

Vasodilation expansion of blood vessels.

TEMPERATURE REGULATION

Body temperature is regulated and maintained by interrelated feedback systems, which can be altered by disease or environmental conditions. Temperature regulation is a homeostatic function that balances heat production and loss to maintain body temperature within a fairly constant range or “set point” (36.4°–37.3°C/97.5°–99°F), with temperature normally being lowest in the morning and highest in late afternoon. This function is controlled by the body’s thermostat, the hypothalamus.

Twenty percent of the body’s afferent temperature information reaches the hypothalamus indirectly through superficial thermal receptors in the skin and subcutaneous tissue by way of the spinal cord. Internal organs send core temperature information (80% of input) directly by circulating blood. The hypothalamus interprets information from both the superficial and internal (core) sources and triggers vasomotor responses to maintain a normal temperature through processes of conduction, convection, evaporation, and radiation.

As heat is gained through metabolism, exercise, or environmental factors, the body loses excess warmth through convection, conduction, radiation, or evaporation. In contrast, on sensing a loss of heat (cold), the body triggers one or more

processes to produce heat (thermogenesis) or conserve it. Although these dynamic processes cannot be observed, their resulting effects, such as shivering, are readily evident. In addition, we consciously and unconsciously alter levels of activity in response to the physiologic stimulus from the body’s thermostat, the hypothalamus. When we sense cold, we huddle or curl up and add clothing to decrease heat loss from the body

▲ The hypothalamus is located in the diencephalon portion of the brain. It controls the body’s thermostat.

surface. When warm, we extend our bodies, separate our limbs, and shed our clothes.

When the hypothalamus perceives cooling, the sympathetic nervous system is activated to conserve and produce heat. Release of norepinephrine causes vessel constriction (a heat-conserving mechanism), which removes warm blood from the skin. This, along with piloerection (hair-raising), reduces conductive heat loss to the cooler environment. Increased muscle tension and shivering increase the metabolic rate, and heat is produced (thermogenesis). These responses continue until the temperature, as sensed by the hypothalamus, has reached its thermostat “set point.” Extreme increases in tissue metabolism may result in metabolic acidosis.

In contrast, when the body perceives excess heat, opposite responses are activated. Peripheral vasodilation occurs and blood is brought to the surface, promoting radiation of heat away from the body. Behavioral responses (lighter clothing) expose the body for greater heat radiation into a cooler environment. A fan is used to assist heat convection.

Heat and cold therapies utilize physical principles/processes of conduction, convection, radiation, and evaporation to manipulate *heat transfer*.

Processes of Heat Transfer

Conduction is heat transfer when a warmer object is in direct contact with a cooler object (e.g., hot or cold pack, water-flow cooling blanket). The greater the temperature difference, the faster heat will transfer; however, very hot or very cold applications can cause tissue injury. Different objects have different heat conductivity. Metal conducts heat readily, but air has low conductivity. Therefore, metal objects should be removed from the treated area, and a towel may be placed under a hot or cold pack to trap air (insulate) and limit heat transfer in order to prevent tissue injury. The body’s superficial tissues transfer (conduct) heat readily, but cooling or warming the surface has little impact on changing the temperature of deeper tissues. Therefore, surface measures to alter core temperature have limited effectiveness.

Convection is heat transfer by direct contact with a circulating medium (agent in motion) and another material of a different temperature. Therapeutic examples include whirlpool, aquathermic pad, air-flow cooling or warm air blanket, irrigations, or infusions. Heat transfer by convection is more rapid than heat transfer by conduction, and convection modalities that circulate fluid are more effective than those that circulate air. The body utilizes convection by circulating warm blood away from and cooler blood into an area to stabilize tissue temperature.

Radiation is heat transfer through the air (no intervening medium) from a *warmer* to a *cooler* area. Since the exposed head is responsible for 65% of body heat loss, a head covering will help prevent radiant heat loss. An example is putting a cap on a newborn’s or operative client’s head.

Evaporation is heat transfer by conversion of a liquid to a vapor. Heat transfer by evaporation is more effective than heat transfer by air current (radiation). Evaporation of sweat serves to cool the body as long as the humidity of the environment is low enough to support evaporation. Another example is a moist open body cavity that evaporates heat to the cooler

environment of the surgical suite. Therapeutic examples of evaporation include tepid sponging or cold spraying.

CONDITIONS AFFECTING TEMPERATURE REGULATION

Fever

Fever, a temperature over 38.3°C, or 101°F is the most commonly encountered alteration of thermoregulation. Exogenous pathogens (viruses, bacteria) trigger the release of endogenous pyrogens or cytokines that cause the hypothalamus to reset its normal range (thermostat) higher. In response, the body perceives that it is cold and seeks to conserve and produce heat by peripheral vasoconstriction, piloerection, and shivering until the new set point is reached. Peripheral vasodilation follows as the thermostat is set to a lower temperature in response to a decrease in pyrogen concentration or antipyretic medication. This is accompanied by a feeling of warmth as the body cools by vasodilation and sweating until the lower set point is reached. Medications can lower hypothalamic set point as well as affect one’s ability to shiver or to exert vasomotor control.

While fever increases metabolic rate, oxygen utilization, and heart and respiratory work and increases risk for dehydration, many studies substantiate that fever, as a natural defense, correlates positively with a quicker recovery and improved survival rates. Although antipyretic agents do reduce fever, their benefit has not been established beyond that of making clients feel more comfortable. *External* cooling measures (tepid sponging and the use of cooling blankets) are ineffective antipyretics because they only lower skin temperature. If the hypothalamic set point is high, external cooling can induce adverse counteractive mechanisms (shivering). Shivering imposes a tremendous metabolic burden by increasing metabolic rate and oxygen demand four- to fivefold.

Hyperthermia (Body Temperature Exceeding 41.1°C)

Hyperthermia, sometimes called *central fever*, is a heat-related emergency that can cause irreversible brain damage. Hyperthermia may be caused by strenuous exercise, environmental exposure (heat stroke), or central nervous system injury. It differs from fever because it is not mediated by pyrogenic cytokines but develops when the body’s metabolic heat production or environmental heat load exceeds the body’s ability to lose heat. The body’s core temperature may exceed 41.1°C, even though the hypothalamic temperature set point is normal. No diurnal temperature variation, shivering, or sweating is observed.

In contrast to fever, which responds to antipyretic agents, hyperthermia (“central fever”) tends to be refractory to treatment, requiring external cooling measures that combine evaporation and convection, such as water spraying and warm air fanning. More aggressive cooling measures (e.g., hypothermia garment) may induce shivering by creating a skin-to-core temperature gradient. The cool skin initiates shivering before the brain temperature cools. Vasoconstriction and risk of resultant shivering can be reduced by insulating the client’s extremities and confining external cooling only to the torso. Additionally,

the use of various sedating and analgesic medications can inhibit shivering and its resultant metabolic burden.

Hypothermia (Body Temperature <math>< 36^{\circ}\text{C}</math> Measured by Bladder Catheter, Pulmonary Artery Catheter, or an Esophageal or Rectal Probe)

Unintentional *hypothermia*, a potentially lethal condition, may be caused by loss of heat due to environmental exposure to cold or vasodilation (general anesthesia, cold IV fluids), decreased heat production (hypothyroidism, neuromuscular blockade), or loss of thermoregulation secondary to CNS pathology/injury or multiple trauma. Hypothermia decreases respiratory drive; slows peripheral nerve conduction, myocardial repolarization, and GI motility; and impairs coagulation. The skin is colder than core tissues, creating a skin-to-core temperature gradient that results in vasoconstriction to conserve heat and shivering to generate heat. Altered cognitive and cardiorespiratory function occur, followed by deterioration of all body functions as body temperature continues to drop (see Table 24-2).

THE INFLAMMATORY RESPONSE

Inflammation is the immediate local adaptive response of the body to tissue injury (external or internal). The response is the same regardless of the cause of injury: physical (e.g., burn), metabolic (e.g., ischemia), biologic (e.g., bacteria), or chemical (e.g., acid). The purpose of inflammation is to minimize injury, kill offending agents, and dispose of debris so healing can take place. The response may be acute, subacute, or chronic.

Cardinal signs of inflammation are redness, swelling, heat, pain, and loss of function. These are due to the action of chemical mediators (histamine, bradykinin, prostaglandins, and cytokines) activated at the time of the primary injury. Vasodilation, circulatory slowing, and increased vascular permeability

allow the passage of protein-rich fluid (exudate) and white blood cells (neutrophils) into the site to initiate the process. These circulatory changes result in localized ischemia. Neutrophils destroy invaders by phagocytosis and enzymatic digestion, but this process results in production of oxygen free radicals and release of cytokines that may destroy other neutrophils and/or injure healthy adjacent tissue and perpetuate the inflammatory response (secondary injury). WBCs also initiate repair by inducing healthy cell division and new blood vessel growth.

Superficial heat and cold therapies are used to minimize or enhance the inflammatory response that accompanies acute tissue injury (e.g., musculoskeletal sprain, strain, fracture, or surgery). Cold (cryo) therapies reduce inflammation; heat (thermo) therapies enhance inflammation. For each degree centigrade increase or decrease in the injured site's temperature, the tissue metabolic rate is increased or decreased by 13%. The magnitude of this response is influenced by the temperature of the modality, duration of therapy, and surface area exposed to the treatment.

LOCAL HEAT THERAPIES (THERMOTHERAPY)

The physiologic effects of heat are generally opposite to those of cold. Heat applications are inappropriate during the acute inflammatory phase of musculoskeletal injury (with the exception of neck or back muscle strain), but are beneficial for subacute and chronic inflammation. Heat produces analgesia and sedation by promoting release of endorphins and by stimulating nerve endings to block pain transmission by the gate control theory of pain modulation. The benefits of heat therapy last only as long as the heat stimulus is applied. When removed, effects quickly disappear.

Heat facilitates soft tissue repair by increasing delivery of nutrients and oxygen and removal of cellular debris. Heat relaxes skeletal muscles, increases elasticity, and decreases

TABLE 24-1 Physiologic Effects of Heat and Cold Therapies

Thermotherapy	Cryotherapy
Increases superficial temperature	Reduces local tissue temperature
Increases local metabolic rate, oxygen consumption, may cause rewarming acidosis, arrhythmias	Decreases cellular metabolism and oxygen consumption
Dilates arterioles and capillaries, increases capillary permeability; may cause hypotension	Constricts arterioles, capillaries, reduces capillary permeability; may cause hypertension
Decreases blood viscosity; promotes bleeding Enhances blood flow to area (including nutrients and WBCs)	Increases blood viscosity; controls bleeding Decreases blood flow; reduces delivery of phagocytes Decreases secondary metabolic injury
Improves lymphatic and venous drainage of fluid and metabolites	Reduces venous and lymphatic drainage
Promotes inflammation	Blunts inflammatory response
Enhances flexibility of muscles, ligaments	Decreases muscle spasticity
Provides <i>analgesia</i> via gating mechanism; stimulates endorphin release	Has extreme <i>anesthetic</i> effect; slows nerve conduction via gating mechanism; stimulates endorphin release
Reduces edema <i>not</i> associated with acute inflammation	Reduces acute edema formation and accumulation

viscosity of connective tissue and thereby facilitates other treatments by producing relaxation.

Although tissue conduction of heat is limited to a depth of about 2 cm, burns can occur if heat application is too hot or prolonged or if the tissue is unable to mount the increased metabolic demand imposed. The body tends to acclimate to (annihilate) heat therapies; therefore, insulation is recommended with heat applications. Superficial heating therapies that get cooler during application (e.g., moist packs) are safer than therapies with a constant maintained temperature (e.g., heating pad).

A unique benefit of heat is its ability to inhibit sympathetic nervous system outflow. Heat promotes vasodilation both at the site of application and in distal cutaneous vessels (*consensual vasodilation*). By way of this spinal cord reflex, heat may be applied proximally (e.g., to low back) to increase peripheral circulation and facilitate healing in an area that lacks sufficient circulation or sensation to tolerate the direct application of heat.

LOCAL COLD THERAPIES (CRYOTHERAPY)

Cold therapies facilitate heat transfer from the body and are the treatment of choice immediately after local tissue injury and throughout the acute inflammatory phase. Cold applications are usually accompanied by compression and elevation of the affected area (see Orthopedic Interventions, Chapter 31).

The immediate benefit of cryotherapy is inhibition of local enzymatic/metabolic activity and limitation of secondary metabolic injury. Cold constricts vessels, controls bleeding, reduces edema formation, decreases nerve conduction velocity, increases the pain threshold, and decreases muscle spasticity. Paradoxically, cold-induced vasodilation may occur when applications to distal extremities (fingers, toes) exceed 15 minutes at temperatures below 1°C. The amount of vasodilation is usually small but should be avoided in

TABLE 24-2 Categories of Hypothermia and Heat Injuries

Categories of Hypothermia	Signs and Symptoms	Management
Mild (33°–36°C)	Tachycardia, tachypnea, hypertension, shivering	<i>Note: Rewarming the unintentionally hypothermic client should not exceed 2°C per hour.</i> Remove wet clothing, place in supine position, avoid excessive movement, monitor core temperature and cardiac rhythm <i>Passive rewarming</i> (blanket, head covering) <i>Active external rewarming</i> (heat pad to truncal areas only, forced air warmer, warmed blankets, radiant light, immersion in 40°C bath)
Moderate (26°–32°C)	Atrial arrhythmias, slow heart rate, hypotension, decreased reflexes	<i>Passive rewarming, plus active external rewarming</i> of truncal areas only <i>Active internal rewarming</i> (IV saline warmed to 40°–45°C/ 104°F–113°F, warm humid oxygen, 42°–46°C/ 107.6°F–114.8°F, endovascular warming device, extracorporeal blood warming, warm lavage of body cavities)
Severe (13°–25°C)	Oliguria, pulmonary edema, ventricular arrhythmias, nonreactive pupils coma, apnea Client appears to be dead; has no vital signs	Active rewarming, CPR, defibrillation/resuscitation until core temperature is at least 32°C
Categories of Heat Injury	Signs and Symptoms	Management
Dehydration	Sweating, ruddy appearance, signs of volume depletion	Rehydrate with caffeine-free or sugar-free beverages
Heat cramps	Painful leg or abdominal cramps associated with exercise in hot weather	Cease activity, move to cool location, rehydrate with cool fluids with electrolytes
Heat exhaustion (37°–40°C)	Tachycardia, normo- or hypotension, weakness, nausea, flushed skin, headache, concentrated or decreased urine output	Apply cool packs to neck, axilla, groin, or spray skin with cool water with warm fanning to speed evaporation. IV fluids may be necessary for rehydration
Heatstroke (>40°C)	Heatstroke is a medical emergency associated with hyperthermia and central nervous system dysfunction. Dizziness, delirium, confusion, seizures, coma, coagulopathies, and multisystem failure may develop	Seek emergency services. Provide oxygen, IV fluids, monitor core temperature, urine output, place NG tube. Immediate evaporative external cooling and internal cooling with chilled saline infusion, ice water lavage of body cavities to reduce body temperature to 38.3°–38.9°C in 1 hr

TABLE 24-3 Indications for Heat Therapies

Indications	Contraindications
Subacute or chronic inflammation	Acute musculoskeletal injury
Subacute edema	Acute pain or inflammation
Joint stiffness	Acute edema
Subacute or chronic pain	Impaired circulation (peripheral vascular disease)
Muscle soreness/spasm	Sensory impairment
Postherpetic neuralgia	Bruising or bleeding
Infection (supports suppuration)	Malignancy
Consensual vasodilation	Open wound
Chronic ulcer	

certain situations, and therapy time should be limited to 15 minutes or less when treating fingers and toes. Longer treatment durations may be used for other areas of the body. With cold therapy, the area temperature remains lower than normal for 1 or 2 hr after removal of the cooling modality, so cold therapies are usually applied for 30–60 minutes, then repeated every 1–2 hr.

While cryotherapy prevents acute edema formation (swelling) during the first 24–48 hr after injury, it cannot remove swelling that has occurred. Swelling only decreases as inflammatory exudate (free protein) is removed from the area by lymph flow. Cryotherapy is beneficial in the rehabilitation period as it produces anesthesia and facilitates exercise, which stimulates lymph flow.

INDUCED HYPOTHERMIA

Hypothermia may be therapeutically induced in certain situations to protect vital organs because it provides metabolic quiescence. Central (internal) cooling, during cardiac or neurosurgery, can also induce postoperative shivering. Rewarming the blood or infusing warmed saline before terminating surgery helps to warm core tissues and a forced warm air blanket (e.g., Bair Hugger) may be used for active external rewarming. Peripheral vasculature, however, remains constricted for some time, unable to receive the warmed blood. Later, peripheral vessels dilate and hypotension may occur. As cool blood from the periphery moves to mix with warmer blood in the core, central temperature drops 2°–5°C (*afterdrop*). Acidosis may also occur as accumulated tissue acids enter the central circulation. Even a combination of measures may fail to promote homogeneous body rewarming; therefore, pharmacologic agents that blunt hypothalamic responses may be necessary adjuncts to suppress shivering in the centrally cooled client postoperatively.

Fever, irrespective of its cause, has a deleterious effect on neurologic outcome in various types of neurologic injury. An increase in core temperature of 1°C results in a 10% increase in energy expenditure. A growing number of studies demonstrate that induction of mild induced hypothermia (32°–35°C) for 24 hr provides neuroprotection and dramatically improves

TABLE 24-4 Indications for Cold Therapies

Indications	Contraindications
Acute inflammation, acute or chronic pain	Impaired circulation (peripheral vascular disease)
Acute swelling or bleeding	Raynaud's disease/phenomenon
Muscle spasm	Hypersensitivity to cold/cold intolerance
Strain, sprain, or contusion	Decreased sensation
Joint stiffness	Open wound

rates of survival with meaningful neurologic recovery if applied as soon as possible to victims of postanoxic brain injury (those with return of spontaneous circulation after cardiac arrest). Controlled hypothermia also shows promise as a treatment for severe traumatic brain injury (Glasgow Coma Score <8), stroke, myocardial infarction, refractory intracranial hypertension, bacterial meningitis, and hepatic encephalopathy.

For each degree centigrade reduction in body temperature, the cerebral metabolic rate is decreased by 6%–7%. Additional mechanisms of neuroprotection include decreased neutrophil infiltration with reduced cytokine, leukotriene, and oxygen free radical production (secondary injury); increased blood–brain barrier stability; and decreased intracranial pressure due to vasoconstriction.

The four modes of heat transfer are utilized in a variety of hypothermia techniques, including surface cooling with ice packs, body wraps (most effective), and an isolated head cooling helmet; vascular cooling using chilled crystalloid infusion, endovascular heat exchange via central venous catheter, and hemodialysis; and intracavitary cooling including chilled lavage (gastric, bladder) and delivery of a nasopharyngeal coolant.

CULTURAL AWARENESS

Determining the client's perspective about illness and treatment practices may provide a framework for developing a plan of care that is therapeutic and acceptable to both the client and the caregiver.

The application of heat and cold would seem to be concordant with beliefs and practices of several cultures that seek a harmonious balance of life forces. Hot-cold theories of health and disease and the opposing force of therapies, however, do not relate to temperature, but rather to a therapy's symbolic strength.

To regain balance, a “cold” disease is treated by eating or exposing oneself to “hot” therapies, such as acupuncture and cupping. For some cultures, an orange (“hot”) medication may be more acceptable for a “cold” ailment than a blue (“cold”) medication.

African-Americans shiver at lower temperatures than Caucasians. Their fingers cool faster in water and their temperatures fall more before they start to warm, and they do not rewarm as much. Caucasians and clients with type O blood are more susceptible to frostbite.

NURSING DIAGNOSES

The following nursing diagnoses are appropriate to use on client care plans when the components are related to heat and cold therapies.

NURSING DIAGNOSIS	RELATED FACTORS
Impaired Comfort	Environmental exposure, tissue injury, inflammatory process
Hyperthermia	CNS injury, strenuous exercise, environmental exposure, medications
Hypothermia	CNS injury, diabetes, hypothyroidism, environmental exposure, major trauma, surgery, alcoholism, medications
Deficient Knowledge (Specify)	<i>Lack of understanding</i> about inflammatory process; rationale for and hazards of heat/cold therapies
Peripheral Neurovascular Dysfunction, Risk for	Prolonged application of heat or cold therapy to joints or areas with impaired circulation
Impaired Skin Integrity, Risk for	Prolonged use of cold or heat therapy, excessive temperature of therapy, impaired sensation, impaired circulation
Ineffective Thermoregulation	Anesthesia, medications, alcoholism, infection, CNS injury, environmental exposure

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infection is hand hygiene. *Remember to wash your hands or use antibacterial gel before and after each and every client contact.*

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Local Heat Therapies (Thermotherapy)

Nursing Process Data

ASSESSMENT Data Base

- Determine rationale for heat therapy.
- Review client’s history for possible circulatory problems (peripheral vascular disease, diabetes).
- Environmental exposure, induced central cooling.
- Determine site, type, and duration of therapy to be applied.
- Assess area to be treated.
- Determine client’s ability to sense temperature at site.
- Assess skin condition before and throughout therapy.

PLANNING Objectives

- To increase circulation to area
- To provide analgesia
- To promote inflammatory process
- To facilitate mobilization of interstitial fluid (noninflammatory edema)

IMPLEMENTATION Procedures

- Applying a Commercial Heat Pack 864
- Applying an Aquathermic Pad 864
- Applying a Hot Moist Pack 865
- Assisting With a Sitz Bath 866

EVALUATION Expected Outcomes

- Circulation is increased to area.
- Client reports decrease in pain.
- Inflammation/suppuration is enhanced.
- Tissue fluid is mobilized/edema reduced.

- Critical Thinking Application** 867
- Expected Outcomes 867
 - Unexpected Outcomes 867
 - Alternative Actions 867

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Applying a Commercial Heat Pack

Equipment

Prepackaged heat pack
Tape

Preparation

1. Check physician's orders for type and duration of heat treatment.
2. Gather equipment.
3. Perform hand hygiene.

Procedure

1. Check two forms of client ID and introduce yourself.
2. Explain procedure to client.
3. Provide privacy.
4. Remove heat pack from outer wrapper.

5. Break inner seal by holding pack tightly in the center and in an upright position.
6. Squeeze firmly to break seal. ► **Rationale:** Breaking the seal activates the chemical ingredients and produces the heat.
7. Check for leakage from pack. Remove pack immediately if leakage occurs. ► **Rationale:** Chemicals from the pack may burn the skin.
8. Gently shake the pack, then apply to treatment area.
9. Remove pack after 5 minutes and assess skin for erythema.
10. Replace pack and secure with tape. Keep in place 15–30 minutes or as ordered by physician.
11. Place call bell in client's reach.
12. Remove pack and discard in appropriate container.
13. Perform hand hygiene.

Applying an Aquathermic Pad

Equipment

Aquathermic reservoir container with pump
Aquathermic pad (disposable)
Distilled water
Tape

Preparation

1. Review physician's orders to determine treatment area, type of application, and temperature of treatment.
2. Perform hand hygiene.
3. Gather equipment, and check it for safety factors (e.g., frayed cords, water leaks).
4. Take equipment to client's room.
5. Check two forms of client ID and introduce yourself.

6. Connect aquathermic pad to pump hoses (male and female fittings).
7. Snap locking rings into place to ensure hose fittings are snug, then open hose clamps.
8. Fill reservoir two-thirds full with *room temperature* distilled water.
9. Place pump on bedside stand or other surface at or above level of the pad. ► **Rationale:** If pump is placed below pad level, water will drain back into pump when it is shut off.
10. Use plastic key to set reservoir temperature as ordered, then remove key. ► **Rationale:** Temperature range is 30°–42°C. Removing key prevents tampering.

▲ Connect Aqua-K pad to pump hoses.

▲ Aquathermic pad is a form of local heat therapy.

11. Plug pump into grounded wall outlet.
12. Turn pump power switch “ON.” Set temperature is reached in about 20 minutes.

Procedure

1. Explain procedure to client and provide privacy.
2. Apply aquathermic pad with its coiled surface against client’s extremity or over moist pack that has been placed on area to be treated.
3. Secure pad with tape if necessary; *do not use safety pins.*
▶ **Rationale:** Pins can pierce coils in pad.
4. Check client’s skin after 2–5 minutes. ▶ **Rationale:** To assess for possible skin reaction caused by a hot pad.
5. Instruct client to notify you if the pad feels too warm.
▶ **Rationale:** This prevents burning of skin.
6. Remove pad after 15–20 minutes. Observe area for redness, pain, or any untoward reaction.
7. When pad is used to keep dressings or soaks warm, continue treatment longer than 20 minutes if ordered. Treatment may be continuous when used for clients with subacute lower back or neck pain.
8. Turn pump “OFF.” Close hose clamps; hold hose with connectors above pump and pad. ▶ **Rationale:** Prevents water spillage.

Clinical Alert

Heat transfers more quickly than cold therapy. Do not allow the client to lie on a “constant heat source” such as a heating pad or aquathermic pad.

Clinical Alert

Contraindications to heat therapies include acute injury or inflammation, recent or potential hemorrhage, deep-vein thrombophlebitis, impaired circulation, impaired sensation, and impaired mentation.

When treating an area where skin is not intact, cover lesion with sterile gauze and insulating barrier before applying heat (see Wound Care, Chapter 25).

9. Remove aquathermic pad and join male and female connectors.
10. Place pad on bedside stand until next treatment or place in appropriate disposal area.
11. Reposition client for comfort.
12. Perform hand hygiene.

Applying a Hot Moist Pack

Equipment

- Box of 4 × 4 gauze sponges or other absorbent material necessary for size of area to be treated
- Hot tap water or ordered solution and container
- Plastic moisture barrier (plastic bag)
- Or
- Aquathermic pad (optional)
- Tape
- Bath thermometer
- Gloves

Preparation

1. Check physician’s order for type of hot moist treatment ordered, length of treatment, and time interval between treatments.
2. Gather specific equipment for type of hot moist pack ordered.
3. Place material in a warming solution (usually water).

Clinical Alert

Do not apply heat to an edematous area until the reason for edema has been determined.

4. Determine amount of time elapsed since last application.
5. Considering age of client, body part involved, and type of treatment, determine safe temperature of application to prevent burning. ▶ **Rationale:** Water temperature in hospitals is usually controlled at 43.3°C/110°F, but the individual client may require altered temperature.
6. Perform hand hygiene.

Procedure

1. Check two forms of client ID and introduce yourself.
2. Provide privacy.
3. Position client appropriately to expose and assess area to be treated. ▶ **Rationale:** Open wounds are generally *not* treated with heat application because heat increases the area’s need for oxygen and may injure granulation tissue. Heat therapy to a recent bruise can restart bleeding.
4. Assess client’s ability to sense touch and heat/cold at site to be treated. ▶ **Rationale:** Impaired skin sensation may contraindicate therapy.
5. Remove any jewelry from area to be treated.
▶ **Rationale:** Decreases risk of burn due to conductive potential of metal.
6. Open container of gauze sponges. Open ABD outer wrap if used.

7. Don gloves.
8. Saturate gauze sponges (or other selected material) with warm water (no greater than 43.3°C).
NOTE: Water in hospitals is usually controlled at 43.3°C to prevent injury.
9. Pick up soaked sponges and wring out excess solution.
10. Place warm moist pack over area to be treated.
11. Use plastic barrier or aquathermic pad to mold and secure pack to site. ► **Rationale:** Barrier helps maintain heat by preventing evaporative cooling.
12. Set aquathermic pad temperature at 41°C. ► **Rationale:** While the warm moist pack will cool quickly, the aquathermic pad maintains heat—this also increases the risk of burns.

13. Use tape to secure the barrier. Do not allow client to lie on pack or pad.
14. Ensure that nurse call system is in client's reach.
► **Rationale:** Client should summon nurse if discomfort is felt.
15. Assess area in 5 minutes for signs of redness, mottling, or blistering. ► **Rationale:** These may be signs of burning. Thermotherapy should be discontinued and a cool pack should be applied.
16. Remove and dispose of pack after 20 minutes or as prescribed.
17. Assess and dry the treated area. ► **Rationale:** Slight redness and warmth are expected responses.
18. Document procedure and client's response to treatment.
19. Discard gloves and perform hand hygiene.

Assisting With a Sitz Bath

Equipment

Disposable sitz bath with tubing and bag
Warm water (40°–43°C)

NOTE: Cold temperature may be indicated for client's situation.

Towels for drying
Thermometer
Clean gloves

Preparation

1. Verify physician's order for sitz bath, duration and frequency of treatments.
2. Raise toilet seat and place sitz bath basin with "FRONT" facing the front of the toilet bowl.
3. Fill basin with warm water (40°–43°C) one half to two thirds full.
4. Close flow tubing clamp.

▲ Individual disposable sitz bath units are used for infection control purposes.

5. Open top of plastic bag and fill with hot water (40°–43°C).
6. Hang bag at a level higher than the sitz basin so that fluid will flow by gravity.
7. Insert tubing through front or rear entry hole in sitz bath, then snap or secure tubing into channel or "eye" in bottom of basin.
8. Perform hand hygiene.

Procedure

1. Identify client by checking Ident-A-Band and asking client to state name.
2. Explain procedure and rationale for sitz bath.
3. Assist client to treatment area with accessible call bell.
4. Provide privacy by placing sign on door.
5. Check to ensure that temperature is 40.5°–43.3°C.
NOTE: Most hospitals control water temperature so that it will not exceed 110°F or 43.3°C.
6. Assist client to sit in sitz bath for 15–20 minutes.
7. Maintain water temperature by continually adding water of appropriate temperature to bag. ► **Rationale:** Overflow will drain into toilet through openings in back of basin.
8. Upon completion, assist client to dry area and allow client to sit briefly to allow normalization of blood pressure and to prevent hypotension upon standing.
► **Rationale:** Orthostatic hypotension may occur with rapid position change after warm sitz bath due to vasodilation.
9. Don clean gloves, empty and rinse client's sitz basin, and store in convenient location for future use.
10. Discard soiled linen.
11. Perform hand hygiene.

DOCUMENTATION for Local Heat Therapies

- Time of application
- Type of heat therapy applied
- Area of body treated
- Status of area pre- and post-treatment
- Positioning of area treated
- Duration of treatment
- Client's response to treatment

Legal Alert

Salter v. Deaconess Family Medicine Center, 1999

The nurse and hospital were found liable for injuries to an infant's foot after a nurse's application of a wet washcloth that had been heated for 1 full minute in a

microwave oven, then applied to the infant's heel to facilitate drawing blood. Application of the hot cloth was the proximate cause of second-degree burns to the infant's heel.

Source: Westlaw.com

CRITICAL THINKING Application

Expected Outcomes

- Circulation is increased to area.
- Client reports decrease in pain.
- Inflammation is enhanced.
- Noninflammatory edema is reduced.

Unexpected Outcomes

Client experiences pain, asks about alternative measures for relief.

Alternative Actions

- Cold therapy may be an option, or heat/cold alternating therapy as counterirritants; these therapies alter nerve transmission.
- Assess if application is too hot.
- Ensure that temperature is not over 110°F (43.3°C) if heating pad is used.
- Ensure that acute inflammation is not present, as heat therapy will not reduce swelling (exudate) due to acute tissue injury.
- Support venous return by elevating the part.
- Check reservoir water level; it may be low or empty.
- Be sure to use room temperature (not hot) distilled water in reservoir. Check that hoses are not kinked or hose clamps closed.
- Disconnect, label, and send to BioMed department.
- Obtain a different pump.

Swelling is not reduced with heat therapy.

Aquathermic pump signals "Over Temp."

Pump continues to signal "Over Temp" after previous actions.

Chapter 24

UNIT 2

Local Cold Therapies (Cryotherapy)

Nursing Process Data

ASSESSMENT Data Base

- Determine purpose for cryotherapy (acute injury, joint stiffness).
- Review client’s history for possible circulatory problems (Raynaud’s phenomenon, diabetes, peripheral vascular disease).
- Assess baseline data (peripheral circulation).
- Determine client’s ability to sense temperature at site.
- Assess skin condition before and throughout cryotherapy.
- Assess for adverse responses to cryotherapy.

PLANNING Objectives

- To reduce local tissue metabolic/oxygen demand and prevent secondary metabolic injury
- To promote vasoconstriction and reduce bleeding
- To control the inflammatory response (edema formation)
- To achieve an anesthetic effect
- To reduce muscle spasticity and promote motion
- To facilitate rehabilitation exercise to stimulate lymph flow and reduce inflammatory edema

IMPLEMENTATION Procedures

- Applying an Ice Pack/Commercial Cold Gel Pack . . . 869
- Applying a Disposable Instant (Chemical) Cold Pack . 870
- Applying a Circulating Cold Therapy Pad 871

EVALUATION Expected Outcomes

- Inflammatory response is controlled.
- Bleeding and edema formation are reduced/controlled.
- Local anesthetic response is achieved.
- Cryotherapy promotes rehabilitation exercise to reduce edema.
- Local cryotherapy causes no adverse effects.

- ### Critical Thinking Application 872
- Expected Outcomes 872
 - Unexpected Outcomes 872
 - Alternative Actions 872

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX[®]-style practice questions
and Skill Checklists

Applying an Ice Pack/Commercial Cold Gel Pack

Equipment

- Small plastic bag, ice bag, or glove (consider size to be treated and necessity to mold)
- Flaked or crushed ice from an ice machine (-1°C)
- Salt
- Or
- Reusable silicone gel cold pack that has been in freezer (-5°C) for at least 1.5 hr before initial use
- Cloth or towel
- Elastic bandage or towel
- Tape (*do not use pins*)
- Pillows

Preparation

1. Verify physician's order for type of cold pack, duration and frequency of therapy.
2. Fill ice bag one-half to two-thirds full. ► **Rationale:** Facilitates molding of pack to treatment area.
3. Remove excess air from bag. ► **Rationale:** Air interferes with cold conduction.
4. Add salt to ice if a colder slush mixture is needed.
5. Take equipment to client's room.
6. Perform hand hygiene.

Procedure

1. Check two forms of client ID and introduce yourself.
2. Provide privacy.
3. Explain procedure and rationale to client. Discuss sensory experiences to expect with cold therapy.
4. Position client to expose area to be treated and remove any jewelry if present.

Clinical Alert

- Frozen gel packs and crushed ice packs using ice frozen in a refrigerator or freezer (-16°C to -19°C) should not be applied directly to the skin.
- Packs with ice from an ice machine (-1°C) do not require insulation.
- During cryotherapy, erythema will occur.
- The client will experience four stages of cold progression: cold/stinging/burning/numbness.
- Discontinue therapy upon numbness.

5. Assess circulation and client's ability to sense touch and heat/cold at site to be treated. ► **Rationale:** Inadequate circulation or impaired sensory perception may contraindicate therapy.
6. Use pillows or other item to elevate area to be treated. ► **Rationale:** Elevation promotes venous return, reduces swelling and pain.

▲ Wrap and tape around pack to secure.

7. Place towel directly onto skin area. ► **Rationale:** Provides a barrier to protect the skin from extreme temperature.

NOTE: Packs with crushed ice from an ice machine may be applied directly to the skin.

8. Place ice/cold gel pack atop towel and mold it to fit the treatment area. ► **Rationale:** Manufacturer's instructions vary among products and must be followed for safe use.
9. Secure pack in place with toweling or elastic wrap using tape. ► **Rationale:** Outer wrap decreases warming effect of environmental air.
10. Place call bell within client's reach.
11. Assess client and treatment site in 5 minutes. ► **Rationale:** If pallor, blanching, mottling, or blisters occur, or client reports increased pain, burning, or severe numbness, discontinue pack immediately.
12. Limit treatment time to 10–15 minutes or longer as prescribed. ► **Rationale:** A reusable cold pack usually loses its effectiveness after 15 minutes. Application time can be increased if cold is applied over bandages or against a cast.

13. Assess treatment area for adverse signs (wheals, cyanosis, pallor, pain, or tingling/numbness *distal* to treatment over a superficial nerve such as the radial nerve at the lateral elbow).
14. Discard used towels in linen hamper.
15. Return reusable ice bag or cold pack to freezer for at least 30 minutes before reusing.

Clinical Alert

Never apply a fully cooled *reusable cold pack* directly to the skin; also, do not overinsulate the area.

Bony areas (knee, ankle, elbow) usually require half the treatment time as fatty areas. Superficial nerves at these joint sites are especially vulnerable to cold-induced neuropathy, especially if cold is combined with compression.

EVIDENCE-BASED PRACTICE

Postoperative Cold Therapy

While several studies have demonstrated that the use of cold over compression reduces bleeding and swelling and improves return to motion, this research study concludes that compression is just as effective as cold after total knee surgery and is more cost-effective.

Source: Smith, J., Stevens, J., Taylor, M., & Tibbey, J. (2002). A randomized, controlled trial comparing compression bandaging and cold therapy in postoperative total knee replacement surgery. *Orthopaedic Nursing*, 21(2), 61–66.

EVIDENCE-BASED PRACTICE

Clients receiving cold gel application four times a day for 14 days after soft tissue injury had less pain at rest and with movement and had less functional disability than those receiving a room temperature gel application.

Martin, S. N., Paulson, C. P., & Nichols, W. (2008). Clinical inquiries: Does heat or cold work better for acute muscle strain? *Journal of Family Practice*, 57(12), 820–821.

Applying a Disposable Instant (Chemical) Cold Pack

Equipment

- One time only use instant chemical cold pack (kept at room temperature)
- Moist cloth or towel (if indicated on pack instructions)
- Elastic bandage or towel
- Tape
- Pillows for elevation of part treated

Preparation

1. Review physician's order for local cryotherapy.
2. Gather equipment.
3. Perform hand hygiene.
4. Identify client by checking Ident-A-Band and having client state name and birth date.
5. Explain procedure.
6. Provide privacy and position client.

Procedure

1. Grasp top of cold pack and shake contents to bottom of bag.

Clinical Alert

Crushable chemical packs should be used as last resort because they are not as cold nor do they last as long as crushed ice.

Do *not* apply an instant chemical pack to the face and never use pins to secure pack. Leakage of chemical contents can cause serious injury. If contents are exposed to skin, immediately flush with copious amounts of water and notify physician.

▲ Follow manufacturer's instructions to activate chemical cold pack.

2. Hold package in the middle with both hands, or follow manufacturer's directions on package.
3. Locate inner pouch and squeeze the package firmly to break the inner pouch.
4. Shake the package gently to mix the chemicals together.
5. Check that package is not punctured or opened.
 - ▶ **Rationale:** If solution touches the skin, the chemicals can burn the skin.
6. Use pillows or other item to elevate part to be treated.
 - ▶ **Rationale:** Elevation promotes venous return, reduces swelling and pain.
7. Apply pack directly to skin, or place disposable cold pack atop towel (according to instructions).
 - ▶ **Rationale:** The degree of cold is not great with a chemical cold pack.
8. Mold pack to fit area and secure in place with taping or elastic wrap and tape.
 - ▶ **Rationale:** Outer wrap decreases warming effect of environmental air.
9. Place call bell within client's reach.

10. Assess client and treatment site in 5 minutes.
▶ **Rationale:** If mottling or blisters occur, or client reports numbness, discontinue pack immediately.
11. Limit treatment time to 30 minutes or as prescribed.
12. Dispose of “one time only use” pack. ▶ **Rationale:** Product cannot be reused by freezing as frostbite may result.
13. Perform hand hygiene.

Applying a Circulating Cold Therapy Pad

Equipment

- Cold therapy system (e.g., EBIce) for single client use (cooler, site-specific disposable pad and straps, hose with connectors, pump with temperature control module)
- Ice (4 quarts)
- Cold water (2 quarts)
- 8-ply gauze or towel for insulation

Preparation

1. Review physician’s order for application site.
2. Take cooler to client’s room.
3. Check two forms of client ID and introduce yourself.
4. Explain purpose of cold therapy (to reduce pain, swelling).
5. Place 2 quarts cold water into cooler to reach water line marker.
6. Add ice to ice line marker (the pump inside cooler must be completely covered with ice/water).
7. Join short connectors on treatment pad to connectors on end of cooler system hose (disconnect these to discontinue treatment if, for instance, client gets out of bed).
8. Plug DC power cord into jack on side of cooler.
9. Plug wall mount adapter into wall electrical outlet.
10. Turn system to coldest setting to initiate circulating cold water into treatment pad.
11. Place cooler at or slightly *below* the level of the treatment site.
12. Perform hand hygiene.

▲ Join connectors on treatment pad to connectors on end of cooler system hose.

Procedure

1. Place protective gauze or towel over area to be treated (e.g., knee). ▶ **Rationale:** Pad should not be placed directly on client’s skin.
2. Place treatment pad over area to be treated.
3. Secure pad and hose in place with enclosed straps.
▶ **Rationale:** Tight securing may restrict water flow through the pad.
4. Turn temperature control knob to 12:00 midpoint position. ▶ **Rationale:** Cold water will circulate into pad for 30 seconds, then stop for 70 seconds. Intermittent cycling helps prevent treatment from being too cold.
5. After 10 minutes, assess color and sensation of site.
▶ **Rationale:** If site is discolored or numb, discontinue the treatment and notify physician.
6. Adjust cold water on/off cycling frequency according to client’s comfort level. ▶ **Rationale:** Cycling periods may be 9, 30, or 52 seconds; off periods may be for 91, 70, or 48 seconds.
7. Periodically reassess client’s response to cold treatment.
8. To refill ice and water, disconnect power cord from wall mount and cooler. ▶ **Rationale:** Cooler provides approximately 3 hr of treatment.
9. Discontinue treatment by unplugging power cord from wall and cooler, remove treatment pad; empty ice and water from cooler; place system in storage carton.
▶ **Rationale:** System belongs to the individual client.
10. Position client for comfort.
11. Perform hand hygiene.

▲ Turn system to coldest setting to initiate treatment.

DOCUMENTATION for Local Cold Therapies

- Specific cold application used
- Area of body treated
- Positioning of area treated
- Duration and frequency of treatment
- Status of area pre- and post-treatment
- Client's response to therapy

CRITICAL THINKING Application

Expected Outcomes

- Inflammatory response is controlled.
- Bleeding and edema formation are minimized.
- Local anesthetic response is achieved.

- Local cryotherapy causes no adverse effects.
- Local cryotherapy facilitates rehabilitation therapies.

Unexpected Outcomes

Local edema is increasing.

Alternative Actions

- Elevate extremity above level of heart.
- Ensure that area is sufficiently covered with cold application to cause vasoconstriction. Check that area is not overinsulated.

Bleeding/bruising continues in spite of local cold applications.

- Reassess area for possible "bleeders," which may require cautery or ligation by the physician.
- Apply pressure to site to stop bleeding.
- Assess pulse distal to bleed.

Area to be treated is near superficial nerve.

- Use caution: reduce time and duration of cold application.
- Ask client to report any itching or tingling and discontinue therapy if these occur.

Hand develops waxy white sheen, mottling, and numbness during local cold therapy.

- Immerse part in moving water at 40°–42°C until area flushes (about 30 minutes).
- Do not apply dry heat; keep area uncovered at room temperature.
- Do not rub part; keep part elevated.

Cold cycling pad is not cooling properly.

- Examine if pad or hose is folded or kinked.
- Determine whether securing straps are too tight and restricting flow of cold water.
- Make sure pump inside cooler is completely covered with ice water.
- Check all connections between hose and treatment pad.
- If still not cooling properly, disconnect, label, and send to BioMed.
- Obtain different machine.

Temperature Management Therapies

Nursing Process Data

ASSESSMENT Data Base

- Determine purpose for ordered temperature management therapy.
- Assess medications client has received (e.g. sedative).
- Determine desired core temperature target.
- Assess client data (vital signs, neurologic status, cardiovascular status, CBC, serum chemistries, coagulation studies) before and throughout treatment (if indicated).
- Assess ECG tracings throughout treatment (if indicated).
- Assess that temperature management system is functioning properly.
- Assess for early signs of shivering.

PLANNING Objectives

- To maintain/restore normal body temperature
- To reduce body core temperature
- To reduce metabolic process/tissue oxygen demand
- To prevent secondary metabolic injury
- To improve neurologic outcomes after cardiac arrest and traumatic brain injury
- To ensure temperature management system functions properly
- To monitor for therapeutic or adverse responses to therapy

IMPLEMENTATION Procedures

- Using a Neonatal Incubator/Infant Radiant Warmer 874
- Using a Warm Air Blanket 875
- Providing Tepid Sponging 875
- Using a Cooling Blanket 876
 - For Automatic Control 878
 - For Manual Control 878
- Using a Hypothermia Garment (Body Wrap) 879
 - For Cooling 879
 - For Rewarming 880

EVALUATION Expected Outcomes

- Target core body temperature is achieved.
- Tissue oxygen demand is reduced.
- Secondary metabolic injury is minimized.
- Neurologic outcomes are optimized.
- Temperature management system functions properly.
- Client has no adverse responses to therapy (arrhythmias, bleeding, shivering, afterdrop, or rebound hyperthermia).

Critical Thinking Application 881

- Expected Outcomes 881
- Unexpected Outcomes 881
- Alternative Actions 881

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Using a Neonatal Incubator/Infant Radiant Warmer

Equipment

Radiant warmer with skin probe and temperature gel patch to secure probe to infant's skin

Bedding and positioning aids appropriate for bed and infant

Preparation

1. Follow manufacturer's operating instructions for safety. (Several different radiant warmers/infant care centers are available.)
2. Check caster locks to make certain that each is in locked position.
3. Adjust bed to desired position.

▲ Giraffe bed in radiant warmer mode, offering quick and easy access to the critically ill neonate.

4. Plug cord into three-prong receptacle.
5. Turn power switch on; bed will take approximately 30 seconds to power up.
6. Set bed to manual control mode for desired temperature. ▶ **Rationale:** This allows bed to warm up prior to placing infant on bed.

Procedure

1. Plug temperature probe into bed. ▶ **Rationale:** To obtain a digital recording of the infant's skin temperature.
2. Place infant on bed, then set bed to skin control mode.
3. Attach skin probe with polished surface over a location of fatty tissue on infant's body, avoiding any bony prominence.
4. Attach temperature gel patch to secure probe to infant's skin; do not use adhesive tape. ▶ **Rationale:** To prevent skin irritation. The infant's skin is very thin and fragile.
5. Allow 3 to 5 minutes for probe to reach infant's temperature.
6. Monitor placement of skin probe:
 - a. Validate appropriate skin temperature reading. ▶ **Rationale:** If reading is not at desired temperature, probe may need to be repositioned.
 - b. Inspect infant's skin under probe at regular intervals. ▶ **Rationale:** Infant's skin is delicate and irritates easily.
 - c. Change probe location if irritation begins to appear.

▲ Giraffe bed in incubator mode, offering a quiet, neutral thermal environment.

Using a Warm Air Blanket

Equipment

Means for continuous core body temperature monitoring (rectal, esophageal, bladder, pulmonary artery catheter), cable and module to monitor depending on thermometer used

Cardiac monitor

Automated blood pressure unit

Disposable warm air temperature management blanket with control unit and tubing

Gown or sheet and bath blanket

Preparation

1. Review order or agency protocol for client rewarming.
2. Obtain equipment and take to client's bedside.
3. Perform hand hygiene.
4. Check two forms of client ID and introduce self.

▲ A forced warm air convection blanket provides active rewarming. Client's temperature should increase gradually (2–3°C/hr).

5. Provide privacy and explain purpose of rewarming blanket and associated monitoring.
6. Establish continuous core body temperature, cardiac and blood pressure monitoring.
7. Obtain baseline vital signs.

Procedure

1. Remove seal from warm air blanket port and insert corrugated tubing connected to unit.
2. Remove all client covering or apply light gown or place sheet over client (not both). ► **Rationale:** Warm air must have close contact with client's skin.
3. Place warm air blanket (perforated side down) over client.
4. Apply bath blanket over warm air blanket. ► **Rationale:** To secure air blanket.
5. Clamp unit corrugated tubing to sheet or bed. ► **Rationale:** To prevent dislodgement and heat loss.
6. Set unit for overheat (rapid warming), high (43°C), medium (38°C), or low (32°C).
7. Turn system ON and reassure client that hum sound is due to air flow.
8. Monitor core temperature, cardiac rhythm, and blood pressure every 15 minutes. ► **Rationale:** Client's temperature should increase gradually (2°–3°C/hr). Hypotension may occur due to vasodilation with rewarming; arrhythmias may occur.
9. Discontinue procedure when client's core temperature is 37°C, but continue to monitor. ► **Rationale:** Afterdrop (drop in temperature) or overshoot (overcompensation) may occur.
10. Dispose of single-use warm air blanket and return reusable equipment to appropriate area for cleaning and storage.
11. Perform hand hygiene.

Providing Tepid Sponging

Equipment

Water or other coolant at prescribed temperature

Basin or tub

Washcloth and towels

Bath blanket

Electric fan

Automated blood pressure unit

Core temperature thermometer, cable and module to monitor

Preparation

1. Review order for cooling method.
2. Gather equipment and bring to client's room.

3. Check client's Ident-A-Band and have client state name and birth date.
4. Provide privacy and explain procedure.
5. Perform hand hygiene.
6. Establish continuous core temperature monitoring (rectal, esophageal, bladder, or pulmonary artery), if indicated.
7. Establish ongoing blood pressure and cardiac monitoring.

Procedure

1. Remove client's clothing to allow for cooling and observation. Use bath blanket for privacy.

2. Monitor skin color and vital signs every 15–30 minutes during cooling. Immerse washcloths or material for sponging in ordered solution, generally 21°–27°C.
 - ▶ **Rationale:** Cool applications reduce heat by conduction.
3. Wring out excess solution and place cloths on neck, axillae, groin. ▶ **Rationale:** The vascularity of these areas promotes cooling.
4. Depending on type of bath, change cloths every 5 minutes. ▶ **Rationale:** This prevents cloths from warming and losing effectiveness.

Clinical Alert

Do not immerse the client in cold or ice slush. Resulting peripheral vasoconstriction will impair body cooling and induce shivering, which produces heat.

5. Cool the ambient temperature to 68°–72°F. ▶ **Rationale:** This enhances therapy by convection and evaporation.
6. Direct a warm fan onto client to promote evaporation.
 - ▶ **Rationale:** This enhances cooling by evaporation.
7. Assess client for early signs of shivering (ECG tremor artifact, palpable jaw line “hum” or trapezius muscle tension).
8. Stop treatment if client has early signs of shivering and notify physician. ▶ **Rationale:** Shivering raises

core temperature, defeating purpose of cooling intervention. The physician may order a narcotic or benzodiazepine for sedation.

9. Monitor client’s temperature frequently. When temperature has decreased to desired level, dry skin and replace light covering over client and reposition for comfort. ▶ **Rationale:** A thin client will cool faster than one with more subcutaneous fat.
10. Continue to monitor vital signs, cardiac rhythm, I&O, electrolytes.
11. Provide fluids and a high-calorie diet. ▶ **Rationale:** Increased temperatures increase metabolic rate.
12. Place cloths in linen hamper and return equipment to storage area.
13. Perform hand hygiene.

Rapid Noninvasive Cooling

- Remove clothing.
- Place client in lateral recumbent position for maximal skin surface exposure.
- Spray entire body with water (20°C), direct a fan onto client to enhance evaporation.

Using a Cooling Blanket

Equipment

- Thermal (heating/cooling) unit
- Sterile or distilled water
- Low reading (below 34.4°C) thermometer: Rectal probe and lubricant, esophageal probe, urinary retention catheter, or pulmonary artery catheter with cable and module for continuous core temperature monitoring, depending on thermometer used
- Clean gloves
- Disposable thermal (cooling) blanket
- One sheet or thin blanket
- Covering for client
- Four towels to wrap client’s lower arms and legs
- Tape
- Leg or foot compression wraps
- Sphygmomanometer and stethoscope or automated BP monitoring equipment
- Continuous ECG monitoring (See Circulatory Maintenance, Chapter 31)
- Supplemental oxygen therapy equipment

Preparation

1. Check physician’s orders for desired client temperature.
2. Identify medications client has received (narcotic, sedative).

3. Gather equipment and take to client’s room.
4. Connect power cord to grounded outlet.
5. Ensure that reservoir (sterile or distilled water) level is adequate.
6. Perform hand hygiene.
7. Check client’s Ident-A-Band and have client state name and birth date.
8. Provide privacy and explain procedure.
9. Obtain baseline vital signs.

Procedure

1. Place the cooling blanket on bed, and connect it to the Temperature Control Unit machine. ▶ **Rationale:** The cooling blanket increases heat transfer from client and reduces body temperature by conduction.
 - a. Push the tubing tab to insert male tubing connector of the cooling pad into inlet opening. Release the tab.
 - b. Repeat connection using the outlet opening.
 - c. Turn the unit ON by pushing power switch.
 - d. Enter client’s target temperature set point
2. Place a sheet or a thin bath blanket over the cooling blanket.
3. Place client on the cooling blanket.
4. Apply leg or foot compression wraps. ▶ **Rationale:** To prevent thrombus formation and reduce edema.

5. Wrap client's lower arms and hands, lower legs, and feet (and scrotum, if indicated) in towels; tape to secure.
 - ▶ **Rationale:** This prevents stimulation of skin thermoreceptors that initiate shivering.
6. Establish continuous core temperature monitoring.
7. Set the master temperature control to either automatic or manual operation.
 - ▶ **Rationale:** There are two separate temperature controls, one for automatic and one for manual operation.

▲ Disposable cooling blanket is covered by sheet to protect the client's skin.

▲ Connect two ends of tubing—one from blanket, the other from machine.

▲ After machine is powered and connected to blanket, push unit ON button.

▲ After checking fluid level, select desired mode: heat, cool, automatic, or monitor.

▲ Set fluid temperature to ordered set point, and press START.

EVIDENCE-BASED PRACTICE**Hypothermia Improves Stroke Outcome**

A study of stroke patients indicates that induced hypothermia to 32°C for a 3-hr period with cooling blankets and ice water/alcohol bath improved outcomes. Hypothermia reduces ischemic damage and reperfusion injury after thrombolysis and reduces bleeding risk associated with administration of tPA. It may also help prevent hyperthermia associated with shift of the third ventricle during an intracerebral hemorrhage.

Source: Mitka, M. (2001). Playing it cool in stroke research. *Journal of the American Medical Association*, 285(10), 1282.

Clinical Alert

Effectiveness and safety of cooling blankets for treatment of fever are poorly demonstrated. Use of a cooling blanket is discouraged except for environmental hyperthermia or cerebral damage.

For Automatic Control

- a. Don clean gloves.
- b. If using rectal thermometer probe, digitally examine client's rectum to determine it is empty of stool.
 - ▶ **Rationale:** Rectal temperature probe must make contact with mucosa.
- c. Insert lubricated temperature probe into client's rectum 2 inches.
- d. If using bladder retention catheter with integrated temperature probe, determine that urine output is at least 20 mL/hr. ▶ **Rationale:** Probe actually measures urine temperature.
- e. Set temperature control at the desired temperature (fluid temperature set point).
- f. Turn automatic mode light on and press "START."
 - ▶ **Rationale:** The pad fluid temperature will adjust automatically to bring client's temperature to a selected set point.
- g. Check that the pad temperature limits are set as ordered.

For Manual Control

- a. Observe that the *manual* mode light is on.
 - b. Monitor the fluid set point, which indicates temperature of pad. ▶ **Rationale:** This ensures pad temperature is maintained at desired level.
8. Set the temperature control to 37°C, and begin lowering temperature 1°C every 30 minutes to 1 hr as tolerated to prevent shivering, until 33° or 34°C or set temperature is reached. ▶ **Rationale:** Blanket will cool

client to set temperature independent of client's temperature. Gradual cooling helps prevent shivering.

9. Monitor client's temperature. ▶ **Rationale:** To prevent excessive cooling.
10. Assess client every 15 minutes for early signs of shivering: ECG muscle tremor artifact, jaw line "hum," trapezius muscle tension.
11. If early signs of shivering occur, discontinue therapy and notify physician or refer to agency hypothermia protocol. ▶ **Rationale:** Shivering causes an increase in core temperature, thus defeating the purpose of treatment. Shivering imposes a heavy metabolic burden and increases oxygen demand.

Mild	32°–37°C	89.6°–98.6°F
Moderate	28°–32°C	82.4°–89.6°F
Severe	20°–28°C	68.0°–82.4°F

12. Monitor vital signs every 15–30 minutes during therapy.
 - ▶ **Rationale:** Bradycardia may occur. Blood pressure usually remains elevated due to vasoconstriction.
13. Monitor ECG for possible arrhythmias. ▶ **Rationale:** Potassium shifts into cells with induced hypothermia.
14. Monitor client's serum glucose. ▶ **Rationale:** Insulin levels are decreased with induced hypothermia. Glucose levels may rise with shivering. An *insulin drip* may be necessary to maintain glucose at 80–130 mg/dL.
15. Turn and deep-breathe client every 1–2 hr. ▶ **Rationale:** Hypothermia reduces carbon dioxide production with possible resultant hypoventilation.
16. Monitor client's skin condition and bony prominences every 2 hr. ▶ **Rationale:** Client is at risk for pressure ulcers when skin temperature is lowered.
17. Turn off unit when client's temperature is 1°–3°C above desired temperature. ▶ **Rationale:** Cooling will continue upon discontinuation of therapy.
18. Monitor vital signs every 15 minutes during rewarming.
19. Observe for edema. ▶ **Rationale:** Hypothermia causes fluid shift into the interstitium.
20. Clean and return reusable equipment to appropriate area and dispose of blanket.
21. Monitor client's vital signs frequently after discontinuation of treatment. ▶ **Rationale:** Overshoot hypothermia may occur.
22. Make client comfortable.
23. Perform hand hygiene.

Using a Hypothermia Garment (Body Wraps)

Equipment

- Water circulating vest and thigh wraps with temperature control console
- Distilled water
- Low-reading (below 34.4°C) thermometer: Rectal probe and lubricant, esophageal probe, urinary retention catheter, or pulmonary artery catheter with cable and module for continuous core temperature monitoring depending on thermometer used
- Glucometer
- Sequential compression devices (calf or foot)
- Four towels for hands, feet, scrotum (if indicated)
- Tape
- Lubricating eye drops

Preparation

1. Review physician's order for induced hypothermia and target temperature.
2. Determine that client has ice packs to axillae, neck, and groin before initiating therapy.
3. Determine that client has infusion of refrigerated normal saline at a rate of 1 L/hr before initiating therapy.
4. Determine client specific rationale for temperature management (e.g., traumatic brain injury; comatose cardiac arrest client will be intubated and sedated and should be cooled within 4 hr of return of spontaneous circulation).
5. Determine whether client is intubated and receiving moderate sedation (see Diagnostic Procedures, Chapter 21).

▲ Induced hypothermia system provides surface cooling to the torso and adjusts automatically to maintain client's target temperature. Medi-Therm MTA7900 and Repround system. Courtesy of Stryker Medical (Gaymar Team).

6. Determine that essential continuous monitoring systems (ECG, arterial BP) have been established. (See Cardiovascular Maintenance, Chapter 31, and Advanced Skills, Chapter 33.)
7. Identify medications client has received (e.g., insulin drip).
8. Review client's recent lab results: INR/PTT, D-Dimer, fibrinogen, CBC, and complete metabolic panel (CMA chemistries).
9. Reduce room temperature and remove all sources of heat.
10. Fill water reservoir of temperature control console according to manufacturer's instructions.

Procedure

For Cooling

1. Identify client, introduce yourself, and briefly explain procedure and rationale, whether or not client is responsive.
2. Apply chest and thigh garments directly to client, fitting securely. ► **Rationale:** To maximize body surface contact.
3. Connect chest garment tubing to console.
4. Interconnect leg wraps' tubing; connect to single tubing, then connect to console.
5. Apply towel wraps to client's hands and feet and secure with tape. ► **Rationale:** Skin counter-warming prevents stimulation of skin thermoreceptors that initiate shivering and need for sedation.
6. Connect core temperature monitoring thermometer to console. ► **Rationale:** A consistent body site must be used for temperature monitoring.
7. Plug console into outlet and turn machine ON.
8. Set target temperature to 33°C. ► **Rationale:** Target temperature should be reached in <4 hr. Cool time should be 24 hr from start of cooling.
9. Establish "AUTO" rapid mode of operation. ► **Rationale:** Garment system automatically adjusts to maintain client's target temperature. When client's temperature is within 1°C of set point, machine will change to a slower mode to reduce "overshoot."
10. Obtain BMP and CBC every 12 hr during hypothermia. ► **Rationale:** Potassium levels decrease as potassium moves into cells with induction; a level of 2.5 is usually acceptable.
11. Monitor client's glucose per agency protocol. ► **Rationale:** Insulin levels decrease with hypothermia, and glucose levels may rise with shivering.
12. Adjust *insulin drip* to maintain glucose at 80–130 mg/dL.
13. Monitor client's BP, EKG, and temperature every 30–60 minutes for 6 hr or until goal temperature is reached,

- then hourly. ► **Rationale:** BP may remain elevated due to vasoconstriction; bradycardia may occur; arrhythmias may occur as potassium moves into cells. Overshoot hypothermia may occur with cooling.
14. Assess client's neurologic status hourly. (For Glasgow Coma Scale, see Physical Assessment, Chapter 11; for the FOUR SCORE, see Neurological Management, Chapter 32.)
 15. Monitor client every 15 minutes for early signs of shivering. ► **Rationale:** Shivering raises core temperature, fights the cooling process, and increases oxygen consumption.
 16. Provide additional extremity and face counterwarming to help suppress shivering.
 17. If shivering continues, medicate according to protocol (meperidine or benzodiazepine) or notify physician.
 18. Monitor client's skin condition every 2 hr; skin should be kept dry. ► **Rationale:** Vasoconstriction increases risk for pressure ulcers.
 19. Obtain blood cultures ×2, 12 hr after initiating hypothermia. ► **Rationale:** Hypothermia may cause neutropenia and may increase risk for aspiration pneumonia.
 20. Provide frequent eye care using lubricating drops.
 21. Assess client for signs of bleeding. ► **Rationale:** Hypothermia can prolong clotting time and decrease platelet count.
 22. Monitor urine output hourly.

Hypothermia Toxicity: Related to Duration, Intensity of Therapy, and Rate of Rewarming

Cardiovascular – arrhythmias, bradycardia, reduced left ventricular function

Respiratory – hypoventilation with hypoxemia, atelectasis and pneumonia

Gastrointestinal – stress ulcer, ileus

Hematologic – platelet dysfunction, coagulopathy (prolonged PT/PTT)

Immunologic – impaired neutrophil function, risk for infection

Metabolic – hypokalemia, hyperglycemia due to decreased insulin release, possible systemic inflammatory response syndrome (SIRS) with rewarming.

For Rewarming

1. Stop all potassium administration 4 hr before rewarming. ► **Rationale:** Potassium level will increase with rewarming.
2. Enter target temperature to 36°C for rewarming.
3. Gradually rewarm client to normothermia over 12–24 hr or remove chest and leg garments and allow client to rewarm passively to normothermia. ► **Rationale:** Rewarming should be done slowly, no faster than 0.5°C/hr to prevent rewarming acidosis, shivering, or hypotension (due to vasodilation).
4. Continue to monitor client's temperature. ► **Rationale:** Rebound hyperthermia may occur with rewarming. Avoid temperature >37.5°C.
5. Monitor for hypoglycemia, especially if client has received continuous insulin infusion.
6. Obtain serum potassium level every 6 hr during rewarming. ► **Rationale:** Hyperkalemia may occur as potassium shifts out of cells with rewarming.
7. When client is stable, discontinue garment therapy and dispose of single-use body wraps.
8. Return reusable temperature control console to storage area.
9. Perform hand hygiene.

Clinical Alert

Fever should be aggressively controlled during the acute phase of brain injury. Fever occurs in 20%–50% of critically ill neurologic patients and is associated with increased morbidity and mortality after ischemic and hemorrhagic stroke and in subarachnoid hemorrhage. In traumatic brain injury patients, temperature elevation has been linked with increased intracranial pressure.

Mayer, S., Kowalksi, R., Presciutti, M., Ostapovich, N., McGann, E., Fitzsimmons, B., et al. (2004). Clinical trial of a novel surface cooling system for fever control in neurocritical care patients. *Critical Care Med*, 32(12) p2508-2514.

EVIDENCE-BASED PRACTICE

2005 American Heart Association Guidelines for CPR and ECC

Unconscious adult patients with return of spontaneous circulation (ROSC) after out-of-hospital cardiac arrest should be cooled to 32°C to 34°C for 12 to 24 hr when the initial rhythm was ventricular fibrillation. Similar therapy may be beneficial for patients with non-VF arrest out of hospital or for in-hospital arrest.

2005 AHA Guidelines for CPR and ECC. *Circulation* 2005 112: IV-84-IV-88.

DOCUMENTATION for Temperature Management Therapies

- Specific type of temperature management therapy used
- Target temperature settings established
- Application of compression wraps
- Application of insulating towel wraps to extremities and scrotum
- Time of initiation and duration of therapy
- Baseline and vital signs trends, including monitored cardiac rhythm
- Serum glucose determinations
- Medications administered
- Client's response to temperature management therapy and any adverse effects
- Physician notification of client's response (if indicated)

CRITICAL THINKING Application

Expected Outcomes

- Target core body temperature is achieved.
- Tissue oxygen demand is reduced.
- Secondary metabolic injury is minimized.
- Neurologic outcomes are optimized.
- Temperature management system functions properly.
- Client has no adverse responses to therapy (arrhythmias, bleeding, shivering, afterdrop or rebound hyperthermia).

Unexpected Outcomes

Client's core temperature decreases rapidly to desired level.

Cooling blanket does not function properly.

Shows early signs of shivering.

Hyperthermic client's core temperature is not reduced.

Rebound hyperthermia occurs after induced hypothermia cooling and rewarming.

Client shows early signs of skin breakdown with non-blanchable area noted.

Alternative Actions

- Turn off cooling blanket or discontinue tepid sponging.
- Monitor temperature every 15 minutes to detect additional temperature decrease.
- Check that plug is connected to the outlet.
- Check that the fluid level is sufficient and that unit freezing has not occurred.
- Check that the thermistor probe is properly connected.
- Check that the cool limit on the pad is not set too high.
- Adjust rate of cooling every 15 minutes to detect additional temperature decrease.
- Cover client's face for additional counterwarming.
- Contact physician for medication order (narcotic or sedative).
- Discuss need for cold water spray and warm air fan to reduce client's temperature.
- Consider that cutaneous vasoconstriction due to external cooling may be conserving core body heat.
- Discuss need for more aggressive internal cooling measures (e.g., endovascular cooling).
- Provide supplemental oxygen therapy.
- Leave the temperature management garment in place for up to 12 additional hr once goal temperature has been achieved. The garment can cool the client if rebound hyperthermia occurs.
- Loosen garment to remove direct cold and compression over area.
- Apply a clear adhesive dressing over the area to add a layer of protection and help prevent shearing.

GERONTOLOGIC Considerations

Elderly clients are more susceptible to injury from heat and cold therapy as a result of physiologic changes or medical conditions

- The epidermal cells are replaced more slowly in the elderly.
- Skin in the elderly is thin and contains less moisture.
- The elderly have a reduced sensitivity to pain and therefore may not feel untoward effects of heat and cold treatment.
- Temperature should be reduced when using heat therapy because the elderly client's skin burns more easily.

Vital signs and frequent assessment may be necessary during heat and cold therapy, as vasodilation from heat or vasoconstriction from cold can cause changes in cardiac function and blood pressure

- Peripheral circulation may be compromised due to chronic volume depletion, atherosclerosis, or microvascular disease.

- Sensation in distal extremities may be impaired in elderly clients with neuropathy due to diabetes.
- The elderly may take medications that decrease sweating (anticholinergics for Parkinson's) or increase heat production (CNS stimulants or lithium).
- Serious infections may not elicit a febrile response.
- Temperature threshold for sweating is higher in the elderly client and ability to mount a metabolic response to temperature loss is limited.
- Living conditions and financial limitations may not afford adequate environmental control.
- Hemodynamic responses to heat/cold therapies may be more unpredictable.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- RNs may assign LPN/LVNs to perform most of the skills covered in this chapter. For example, they may apply heat or ice to an extremity, set up a hypothermia blanket, or give a sitz bath.
- Assessment before delegation and evaluation of the client's response during and after therapy is required of licensed delegate.
- Systemic cooling or heating therapies are indicated for critically ill clients in special care settings who may be sedated. These clients are generally monitored and cared for exclusively by licensed personnel.

- CNAs and UAPs may be assigned to do many of the skills with supervision. They should not be assigned to use infant radiant warmers or cooling blankets without special guidance and supervision.

Communication Matrix

- Because many of the procedures in this chapter are performed by unlicensed personnel, there must be excellent reporting to the nurse responsible for client care. The treatment effect of these measures will influence client health, so outcomes of the procedures must be charted as well as orally reported to the nurse.
- Any adverse responses (local or systemic) should be reported to prescribing physician so that corrective measures can be provided.

CRITICAL THINKING Strategies

Scenario 1

Mrs. Moore is a 52-year-old client who has been admitted to your unit after a laparoscopic cholecystectomy. She has a peripheral IV infusion of 5% dextrose in 0.45% NS infusing at 120 mL/hr in the cephalic vein at the left wrist. She receives intermittent antibiotic therapy by IV piggyback.

One hour after the evening IV antibiotic administration, she calls the nurse and reports a discomfort in her left arm. Assessment findings include discomfort in the area, slight pallor, swelling (lower arm circumference 1.5 in. greater than contralateral arm), and coolness to touch.

1. Based on assessment findings, what is the probable complication and what are possible causes?
2. What should the nurse's first action be?
3. How should the area be treated?
4. When are heat or cold therapies indicated to manage IV complications?

Scenario 2

Mr. X, age 78, lives alone in a small urban dwelling. He has a history of heart failure and COPD, and was found unresponsive

in his back yard by his neighbor at 2:00 PM He has been admitted to the ED with a temperature of 40°C. Additional findings include confusion, lack of perspiration, dizziness, blurred vision, tachycardia, and hyperventilation. His laboratory tests reflect dehydration; insertion of a Foley catheter reveals minimal urine output.

His diagnosis is heatstroke.

1. What causes hyperthermia and how does it differ from fever?
2. Why are the elderly at great risk for developing heat-related illness?
3. What is the immediate goal of treatment for Mr. X?
4. Why are external cooling measures the treatment of choice rather than the use of antipyretics?
5. What are the principles involved with application of external cooling measures?
6. Why should cooling therapy be discontinued if shivering occurs?
7. What other ongoing assessments are essential during the cooling process?
8. How can heat-related injuries be prevented?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. Fever is an elevation of body temperature due to
 1. Cytokine influence on the hypothalamus.
 2. Injury to the hypothalamus.
 3. Dehydration.
 4. Environmental extremes.
2. The most effective method to reduce fever is the use of
 1. Tepid sponging.
 2. A cooling blanket.
 3. Antipyretic medication.
 4. Cool packs to axillae and groin.
3. The effect of shivering in response to external cryotherapy used in the febrile client is
 1. Enhanced body temperature cooling.
 2. Reduced metabolic rate.
 3. Increased heat production.
 4. Increased pyrogen production.
4. Most hospitals control facility water to be a maximum temperature of
 1. 95°F.
 2. 100°F.
 3. 110°F.
 4. 120°F.
5. The surgical client wears a head covering to prevent heat loss by
 1. Radiation.
 2. Evaporation.
 3. Convection.
 4. Conduction.
6. Which of the following fluids is preferred to rehydrate an over-heated dehydrated client?
 1. Water.
 2. Intravenous dextrose in water.
 3. Sport drink.
 4. Sugared cola.
7. Expected effects of local cold (cryo) therapy include **Select all that apply.**
 1. Pallor.
 2. Flushing.
 3. Blister formation.
 4. Anesthesia.
 5. Burning.
 6. Numbness.
8. After a sitz bath, the client should be monitored for possible
 1. Orthostatic hypotension.
 2. Perineal fungal infection.
 3. Increased vaginal bleeding.
 4. Exacerbation of hemorrhoid discomfort.
9. Cold applications to injured joints should be of short duration because
 1. Reactive vasodilation may occur.
 2. Joints become less flexible with cold application.
 3. Bleeding may be induced.
 4. Injury to superficial nerves can occur.
10. Heat therapies are contraindicated for areas with circulatory insufficiency because heat
 1. Increases tissue need for oxygen.
 2. Decreases metabolic rate thereby increasing ischemia.
 3. Promotes inflammation.
 4. Decreases sensation and increases risk for injury.

Wound Care and Dressings

LEARNING OBJECTIVES

1. Describe the three phases of wound healing.
2. Define the three types of wound healing.
3. Discuss three factors that affect wound healing.
4. State three complications associated with wound healing.
5. State criteria used to assess a wound.
6. Compare and contrast the four stages of pressure ulcers.
7. Write three nursing diagnoses for a client requiring wound care.
8. State three goals of wound care.
9. Discuss the effect of topical agents in wound healing.
10. Differentiate between clean, contaminated, and infected wounds.
11. Compare and contrast clean and sterile technique.
12. Describe dressing classification and indication for each type of dressing: gauze, transparent film, hydrogel, calcium alginate, foam, composite, hydrocolloid, and impregnated gauze.
13. Explain appropriate use of dressings: gauze, transparent adhesive film, hydrocolloid, and hydrogel.
14. Describe two methods to manage bacterial bioburden.
15. Outline the steps in irrigating a wound.
16. List steps to obtain a wound specimen for culture.
17. Perform the steps of a surgical hand scrub.
18. Prepare a sterile field for a dressing change.
19. Demonstrate the steps of putting on sterile gloves.
20. Describe the procedure for cleaning around a drain site.
21. List steps used to maintain a Hemovac or Jackson–Pratt suction drain.
22. Demonstrate changing a sterile dressing.
23. Outline the steps for removal of staples and sutures.
24. Outline the procedure for changing a wet-to-moist dressing.
25. Compare and contrast the three adjunctive wound care therapies.
26. Complete documentation on a wound assessment and wound care.
27. State five debridement methods.
28. Describe the term surgical site infection.

TERMINOLOGY

Adhesions formation of fibrous scar tissue around the incision as a result of surgical intervention. Adhesions can cause obstruction or malfunction by distorting the organ.

Adjunctive wound care therapy wound treatments other than dressings and cleansing agents.

Aerobe a microorganism that lives and grows in the presence of free oxygen.

Anaerobe an organism that lives and grows in the absence of molecular oxygen.

Antimicrobial an agent that prevents the multiplication of microorganisms.

Asepsis prevention of contact with microorganisms.

Bacterial bioburden the number of contaminating bacteria present on an object.

Collagen formation formation of the protein substance of the white fibers of skin, bone, and cartilage.

Cytokines one or more than 100 distinct proteins produced primarily by WBCs. They regulate immunological aspects of cell growth and function during inflammation and immune response.

Debridement the removal of damaged tissue and cellular debris from a wound or burn to prevent infection and promote healing.

Debris remains of damaged or broken-down tissue or cells.

Decubitus ulcer see pressure ulcer.

Dehiscence a bursting open, as a graafian follicle or wound, especially abdominal wounds.

Dermis synonym for corium; the skin layer beneath the epidermis; contains vascular connective tissues.

Edematous the presence of abnormally large amounts of fluid in the intercellular tissue spaces of the body.

Electrical stimulation of wound transfer of electrical current through contact with moist wound bed.

Epidemiology division of medical science concerned with defining and explaining the interrelationships of the host, agent, and environment in causing disease.

Epidermis superficial avascular layers of skin.

Epithelium outer covering of the body; top layer of skin.

Erythema redness of the skin due to congestion of capillaries.

Eschar scabs or dry crust that result from trauma or infection.

Evisceration protrusion of the viscera; removal of the viscera.

Exudate fluid that filters from the circulatory system into areas of the body that are inflamed.

Gangrene death and putrefaction of body tissue precipitated by poor or absent blood supply to the tissue. Occurs as a result of infection, injury, or disease processes.

Granulation formation of granules; fleshy projections formed on the surface of a gaping wound that is not healing by the normal joining together of skin edges.

Hyperbaric oxygen therapy 100% oxygen administered at greater than one atmosphere pressure absolute.

Incision a cut made with a knife.

Infection morbid state caused by multiplication of pathogenic microorganisms within the body.

Inflammatory process localized response when injury or destruction of tissue has occurred; destroys, wards off, or dilutes the causative agent or the injured tissue.

Irrigate to rinse or wash out with a fluid.

Isolation limitation of movement and social contacts of a client; especially those having communicable diseases.

Keloid scar-like growth of collagen that results in a rounded, hard, shiny, white benign tumor.

Macrophage a large monocyte that has left the circulation and settled and matured in tissue and serves as scavenger of the blood, cleaning it of old cells and cellular debris.

Macration the softening and whitening of skin that is kept constantly wet.

Microorganism minute living body not perceptible to the naked eye.

Monocyte phagocytic white blood cell that matures into a macrophage.

Monokine chemical mediator released by monocytes and macrophages during the immune response. They affect growth and activity of other white blood cells.

Myofibroblast an atypical fibroblast with features of a fibroblast and a smooth muscle cell.

Necrotic death of a portion of tissue.

Negative pressure wound therapy negative pressure applied to wound to promote healing using an electrical pump.

Neutrophil white blood cells responsible for body's protection against infection. Plays a large role in the inflammatory process.

Occlusion the closure or state of being closed, of a passage.

Organism a living thing, either plant or animal.

Pathogen disease-producing organism.

Peri wound area surrounding wound; healthy tissue around wound.

Phagocytosis ingestion and digestion of bacteria by phagocytes.

Pressure ulcer a break in the skin caused by pressure and restricted blood flow to the area. The ulcer generally occurs over bony prominences of the heels, sacrum, hip, and shoulder.

Primary intention healing minimal tissue loss and edges are closely approximated. Wound heals with minimal granulation tissue and scarring.

Purulent containing pus, or caused by pus.

Pus an inflammation containing leukocytes and exudate.

Secondary intention healing second stage in wound healing in which granulation occurs.

Semioclusive dressing create and maintain a moist environment by holding liquid drainage from wound and moisture vapor at the wound surface.

Slough to shed or cast off dead tissue.

Surgical site infections (SSIs) an infection related to an operative procedure.

Tertiary intention healing using open method of wound healing; allow granulation to occur.

Warm-Up therapy heat therapy used to stimulate healing process.

Wound dehiscence the separation of layers of a surgical wound.

Wound evisceration protrusion of the internal viscera or organs through an opened incision site.

Wound healing three phases involved: inflammatory, proliferative, remodeling.

WOUND HEALING

The three major phases of wound healing are inflammation (or reaction), proliferation (or regeneration), and maturation (or wound remodeling).

Inflammatory Phase (Reaction)

The onset of the first phase of wound healing occurs immediately after an injury and lasts 2–5 days. After the injury, small blood vessels dilate and become more permeable and serous fluid leaks into the traumatized tissue as a result of histamine and prostaglandin release. Plasma and electrolytes leak into the interstitial spaces, causing edema. The edema leads to a reddened, swollen, and tender wound. Neutrophils reach the site in about 6 hr. Through the process of phagocytosis, they assist in preventing infection by ingesting and digesting bacteria. Oxygen is necessary for the neutrophils to destroy the bacteria. They survive only several hours after ingesting bacteria and necrotic tissue before releasing their intracellular contents, which forms part of the wound exudate. By the fourth day, monocytes enter the wound and differentiate into macrophages, which digest necrotic tissue, remove debris, and inhibit microbial growth. They also play a role in creating collagen synthesis. If macrophages are depleted, deposition of wound collagen decreases significantly. Macrophages direct healing through the release of monokines.

Proliferative, or Granulation, Phase (Regeneration)

This phase begins between about 2 days to 3 weeks after the injury and ends 14–24 days later. During granulation there is rapid growth of epithelial cells to produce a protective covering for the wound. The granulation tissue is formed from a rebuilding of the vascular capillary network and collagen tissue. The collagen fibers increase the tensile strength of the wound and provide wound integrity. Collagen fibers fill in the gaps and form the scar. Wound scar tissue is very fragile and susceptible to reinjury. In 6 weeks, the scar is only 10% of the tensile strength of normal skin. Large wounds may take months to build enough granulation tissue to close the wound. Healthy granulation tissue has a healthy reddish-pink color. The color results from increased blood flow that delivers oxygen and nutrients to the newly formed tissue.

Maturation, or Wound-Remodeling, Phase

Wound contraction begins between 14 and 21 days after the injury and can last up to 2 years. During this phase, the scar shrinks and thins. It becomes less red as the capillaries regress. Contraction of the wound occurs as a result of myofibroblasts, which assist in moving the wound edges toward the center of

the wound. The skin and fascia of the healed wound achieve only about 70%–80% of the tensile strength of normal skin. Scar tissue has fewer melanocytes and thus has a lighter color than normal skin.

WOUND CLASSIFICATION

There are different wound classification systems used to describe wounds. These are useful when the nurse is planning for wound care management. The classification systems include categorizing the wound by cause: intentional or unintentional; cleanliness: clean, contaminated, or infected; depth: superficial, partial-thickness, or full-thickness; and by color. The RYB classification system has been used in wound care classification since the late 1980s. This system classifies open wounds that are healing by secondary or delayed primary intention in both acute and chronic wounds. It is used as an adjunct to other classification systems. It does not lend itself to an in-depth, comprehensive evaluation. It can be used to determine the state of healing. This system identifies what phase a wound is in on the continuum of the wound healing process. Red wounds (R) can be in the inflammatory, proliferative, or maturation phase of wound healing. Yellow wounds (Y) are infected or contain fibrinous slough and aren't ready to heal. Black wounds (B) contain necrotic tissue and aren't ready to heal. Treatment options are based on the color of the wound. Red wounds need to be kept clean and moist. Yellow wounds require the removal of slough or fibrinous tissue. Black wounds must have the eschar removed for healing to take place. If the wound has a combination of colors, the rule is that the most severe color treatment is completed.

Wounds are also classified in six main categories; surgical, trauma, diabetic, venous, arterial, and pressure. These categories can overlap.

TYPES OF WOUND HEALING

Primary Intention

This is the simplest form of healing. The skin is cleanly incised through a surgical incision or a traumatic laceration. The wound can be closed with sutures or staples, which approximate, or pull together, the wound edges. These wounds close rapidly because there are no gaps in the tissue. The top layer of cells migrate, or epithelize, within 72 hr. The wound surface is “sealed,” thus preventing bacteria from entering and fluid from escaping. The tensile strength of the wound is very weak at this stage of healing.

Secondary Intention

These wounds heal by granulation. As granulation tissue builds, it fills the gap under the skin and cells epithelize from the edge of the wound to create the closure. Burns, pressure ulcers, and wounds with large pieces of skin missing heal by this method. In these types of wounds, no edges are available to be approximated and sutured. These wounds are at risk for local and systemic infection due to the destruction of the dermis and the increased time necessary for healing to occur.

Tertiary Intention

Healing by tertiary intention is a method that leaves the wound open to heal. These wounds cannot be sutured or dehiscence occurs or the wounds are infected and need frequent irrigations and dressing changes to facilitate healing. Clients with peritonitis, a ruptured appendix, or diverticula frequently require this type of wound healing. After irrigations and dressing changes for approximately 10 days, the wound is sutured and allowed to heal by primary and secondary intention.

MAJOR FACTORS AFFECTING WOUND HEALING

In addition to proper wound care and generally good physical health, nutrition plays a major role in wound healing. Calories need to be increased to 30–35 cal/kg/day. Medication use may interfere with wound healing.

Nutrition

Low serum albumin levels slow the diffusion of oxygen and diminish the ability of neutrophils to kill bacteria. Low oxygen at the capillary level diminishes the proliferation of healthy granulation tissue. Zinc deficiency can slow the rate of epithelialization and decrease wound and collagen strength. Adequate amounts of vitamins A and C and of iron and copper are necessary for effective collagen formation. Collagen synthesis also depends on appropriate intake of protein, carbohydrates, and fats. Wound healing requires almost double the usual protein and carbohydrate requirements for age. For the scar to develop adequate tensile strength, the client's intake of vitamin C, iron, and zinc must be increased.

General Physical Health

The major obstacle to wound healing is infection. Infected wounds have friable tissue, bleed easily, and have delayed healing. Immunosuppressed clients have more difficulty healing wounds because the inflammatory phase is impaired. When the blood glucose level is consistently over 200 mg/dL or the hemoglobin is below 10 g/dL, wounds do not follow the usual phases of healing. Any condition that reduces the formation of adequate white blood cells, especially macrophages, adversely affects healing. Such conditions include diabetes mellitus, anemia, uremia, cancer, atherosclerosis, infection, and malnutrition. Older clients, clients who smoke or are obese, and those undergoing radiation or steroid therapy are also prone to delayed wound healing.

Medications

Any medication that reduces the inflammatory response, such as steroids and nonsteroidal medications used to treat arthritis or respiratory conditions, also impairs wound healing. Anti-inflammatories decrease epithelialization and wound contraction and may also affect fibroblast proliferation and collagen synthesis. Steroids decrease the tensile strength of a closed wound and cause inadequate deposits of collagen. Administration of vitamin A can reverse the processes associated with steroid use.

TABLE 25-1 Nutritional Support for Wound Healing

Nutrient	Food Sources
Protein	Meat, fish, poultry, milk, cheese, eggs, dried beans, peas, peanut butter
Carbohydrates	Legumes, fruits, vegetables, whole-grain cereal, bread, pasta
Vitamins	
Vitamin A	Dark green leafy vegetables, milk, eggs, carrots, liver, sweet potatoes
Vitamin C	Citrus fruits, vegetables, potatoes, tomatoes
Minerals	
Iron	Meat, eggs, cereal, vegetables
Copper	Seafood, nuts, seeds, organ meats
Zinc	Meat, liver, seafood, eggs, legumes
Calories	30–35 cal/kg/day

GOALS OF WOUND CARE

Wound assessment and measures to treat wounds have changed dramatically over the last 10 years. The major trend is to treat wounds using moisture-retentive dressing rather than drying the wound. Wound care specialists also diverge on the use of sterile versus clean technique during dressing changes.

Whatever plan is used in treating a wound, the goals remain the same:

- Remove necrotic tissue to promote wound healing.
- Prevent, eliminate, or control infection.
- Absorb drainage (exudate).
- Maintain a moist wound environment.
- Protect the wound from further injury.
- Protect the surrounding skin from infection and trauma.

To accomplish these goals, a moist wound environment must be maintained to allow tissue to granulate. A wound bed that is too moist or too dry kills healthy tissue and impairs healing. Drainage from the wound site needs to be contained to protect adjacent healthy skin from maceration. All wounds require a dressing that is dry on the air-exposed side to prevent bacterial invasion by downward capillary mobility of contaminants. The dressing should be secured over the wound and taped in place using the “window paning” method of taping if there is not an adhesive backing on the dressing. Using this method, the edges remain taped down and the dressing stays intact.

There are many types of wound care products available, including skin cleansers, skin barriers, irrigants, various types of dressings, gauze dressings, and enzymes. Physician and wound care specialist preferences, as well as type and extent of wound, determine wound care.

Complications Associated With Wound Healing

One complication that may occur after wound healing has seemed to progress satisfactorily is adhesions. Adhesions

TABLE 25-2 RYB Wound Dressing Guidelines*

Dressings Most Commonly Used to Treat RYB Wounds	
Red Wounds	Yellow Wounds (fibrinous slough)
Biologicals	Alginate
Foams	Exudate absorbers
Gauze	Foams
Hydrocolloids	Hypertonic gauze
Hydrogels	Hydrocolloid
Moist gauze	Hydrogel
Nonadherent gauze	Transparent film
Transparent film	
Yellow Wounds (infected)	Black Wounds
Alginates	Alginate
Impregnated dressings	Hydrocolloid
Exudate absorbers	Hydrogel
Foams	Gauze
Hypertonic gauze	Transparent film
Wound pouches	

*See *Assessing a Wound*, p. 905.

frequently form in the peritoneal cavity after abdominal surgery and can either constrict or fold around the intestines.

Frequently clients are admitted to the hospital with incisional strangulated internal hernias that may even be gangrenous. Other complications are surgical or incisional hernias that may occur when the intraperitoneal pressure pushes against the scar tissue, causing a hernia (or outpouching) through the incision.

Contractures, formed as a result of a shortening of scar tissue, can decrease mobility and joint movement. Contractures caused by incisional scars are far less common than those caused by scar tissue from burns.

Excessive collagen formation results in the formation of a keloid, a complication that does not present a serious problem with body function; however, it generally causes an altered self-image if the keloid is large or in a prominent place on the body.

WOUND INFECTIONS

Open wounds of any type provide an environment for bacterial invasion. All wounds may be considered contaminated but not necessarily infected. Wound care must include regular wound cleansing, the use of semioclusive dressings, using Standard Precautions when providing care to the client, maintaining proper hand hygiene technique, and following dressing change protocols. Semioclusive dressings in wound care have reduced the incidence of wound infections by more than 50% compared with gauze dressings. These dressings promote a moist environment, provide a mechanical barrier for bacterial invasion, and reduce airborne dispersal of bacteria during dressing changes.

The clinical symptoms of wound infection generally begin in 3–5 days postoperatively or after injury. When the client's temperature and pulse rate increase, an associated tachypnea occurs. As the inflammatory process occurs, the wound becomes progressively more tender, painful, and edematous. Erythema surrounds the edges of the wound unless the infection is in the deeper tissues. Abnormal firmness of the wound edge may be present. Usually, a persistent WBC count of 12,000/mm³ or greater, lasting longer than 72 hr, accompanies the infection. Foul-smelling, purulent drainage may occur. An absence of local signs of infection does not necessarily mean that deep wound infections are absent.

Several microorganisms are responsible for the majority of wound infections. *Staphylococcus aureus* is still a major cause of postoperative infection. *Escherichia coli*, *Streptococcus faecalis*, *Proteus vulgaris*, *Klebsiella*, *Enterobacter*, and *Pseudomonas aeruginosa* are also closely associated with wound infection. Antimicrobial agents themselves can promote infection by increasing the susceptibility of clients to colonization with nosocomial microflora; these agents also select and concentrate antibiotic-resistant organisms on or in the host.

Maintaining asepsis during dressing changes assists in preventing wound infections. Using sterile equipment, including gloves, is the first barrier against infection. A mask and gown should be worn during dressing changes to prevent the spread of microorganisms to other clients and to the healthcare worker.

When wounds become grossly infected or are extensive in nature, the physician may order wound irrigations. Normal saline or Ringer's solution are the usual irrigating solutions used for wounds. Most of the agents used in the past have been identified as toxic to the cells generated in the inflammatory phase of healing.

Each hospital has its own protocol for wound irrigation, and you should become familiar with the institution's procedure. This chapter presents one method of wound irrigation that is helpful in most clinical situations.

Wound Specimens for Culture

Exudate, or purulent drainage, from infected wounds can contain a variety of aerobic and anaerobic microorganisms. In the majority of wound infections, the causative agent is usually found in the upper respiratory tract, gastrointestinal tract, and genitourinary tract. When these organisms invade other body parts, they can cause severe infections and sometimes death.

Before a wound can be cultured, it should be irrigated with normal saline to remove the surface bacteria. The best method of obtaining a culture specimen is to rotate a swab along the granulation tissue. Refer to Chapter 20, Specimen Collection, for the skill. For the most accurate results, the physician should take a biopsy of the tissue.

Surgical Site Infections

Surgical Site Infections (SSIs) are best described as an infection related to the operative procedure that occurs at or near the surgical incision within 30 days of a procedure or within 1 year of an implant left in place.

At the time of the incision, every surgical site becomes contaminated with bacteria inward from the skin or outward from the organs undergoing surgical intervention. The client's endogenous flora at the incisional site leads to the contamination. In addition to the skin, the mucosal membrane or viscera are also involved in the contamination process. The contamination does not cause the infection themselves; the virulence of the bacteria and local blood flow and nutritional components lead to the infection. The amount of bacteria in the wound at the end of the surgery is the major cause of the SSI.

SSIs account for more than 40% of all hospital-associated infections among surgical clients and 22% of all hospital-associated infections. These clients are 60% more likely to be in an ICU, five times more likely to be readmitted to the hospital, and twice as likely to die as other postoperative clients. Seventy-five percent of surgical client deaths are related to a wound infection. As of October 2008, these SSI costs are not reimbursed by Medicare and Medicaid.

Wounds Caused by Vascular Insufficiency

There are three types of wounds caused by vascular insufficiency. These include venous insufficiency ulcers, arterial insufficiency ulcers, and pressure ulcers (capillary insufficiency ulcers). There are five major factors that contribute to ulcer formation in vascular insufficiency: poor nutrition and a lack of blood flow causing inability of nutrients to diffuse through the interstitial spaces; continuous pressure on certain areas of the body, such as bony prominences; mechanical, thermal, or chemical insults to limbs, resulting in lack of nutrients reaching the lower limbs; decreased sensation in the lower extremities; and excess moisture from incontinence.

Venous Ulcers

These are mistakenly termed venous stasis ulcers; however, they are not due to a lack of venous blood flow, but rather a diminished ability of nutrients to diffuse through the interstitial space from the capillaries. The usual etiology of this condition includes calf pump failure as a result of outflow tract obstruction, associated with pregnancy, obesity, tumor, or deep vein thrombosis. Insufficient valves, either deep venous valve incompetence or superficial vein incompetence (varicose veins), are causes as well. Peripheral neuropathy and musculoskeletal disorders may lead to venous ulcers as a result of calf muscle disuse.

Compression therapy is used to treat venous ulcers. This therapy includes the use of compression stockings, Unna's boot, or a compression dressing when wound care is included in the treatment. Compression therapy is contraindicated in clients with phlebitis, diminished sensation, and arterial insufficiency, as it will exacerbate the insufficiency.

Arterial Ulcers

Arterial ulcers are often seen in clients with diabetes mellitus and atherosclerosis. Clients with a history of smoking and who sustain mechanical trauma to the extremity are prone to

arterial ulcers. In these situations, there is diminished oxygenation and thus, nutrients, to the periphery. Drug therapy with vasodilators, anticoagulants, or thrombolytic agents are part of the treatment plan for these clients. Surgical treatment may be necessary if drug therapy is insufficient to treat the ulcer. Sympathectomy, endarterectomy, or bypass surgery may be necessary treatment modalities.

Pressure Ulcers

Pressure ulcers are defined by the National Pressure Ulcer Advisory Panel as any lesion caused by unrelieved pressure resulting in damage to underlying tissue. Four mechanical factors contribute to the development of pressure ulcers: pressure, friction, shearing, and moisture. Pressure ulcers are usually located over a bony prominence, where normal tissue is squeezed between the bone and pressure or friction caused by the bed or chair. External pressure that lasts long enough to result in decreased blood flow causes altered oxygenation and nutrition to the tissue, resulting in a pressure ulcer. Immobility, especially associated with the elderly, is the primary cause of pressure ulcer formation. In addition to mechanical factors and immobility, aging skin and malnutrition increase the risk of skin breakdown.

Each year 1.5 million hospitalized clients develop pressure ulcers, resulting in 60,000 deaths. Data suggest that 25% of these clients develop the pressure ulcer in the operating room, especially when the surgery is prolonged beyond 3 hr. Surgical clients experience periods of prolonged immobility, resulting in unrelieved pressure and decreased blood flow to the skin. In addition to the 9% of hospitalized clients, 23% of all nursing home clients develop pressure ulcers. Elderly clients are affected most often and account for the highest number of cases. A large percentage of the clients who develop pressure ulcers while in a nursing home die as a result. These statistics are appalling when one considers that ulcers are usually preventable and treatable.

Pressure ulcers are classified in stages by the degree of tissue damage observed. See Unit 5 for illustration and description.

Management of pressure ulcers is best accomplished using a team of healthcare providers, including physicians, nurses, an enterostomal therapist, dietitian, physical therapist, family members, and the client.

Client education should include:

- Discussion of options for pressure ulcer treatment.
- Discussion of client's active participation in his or her own care.
- Developing a plan of care that is consistent with the client's goals and desires.

Client treatment plan should include:

- Assessment of the pressure ulcer.
- Managing tissue loads.
- Ulcer care.
- Managing bacterial bioburden and infection.
- Operative repair of the pressure ulcer.

Management and prevention of pressure ulcers should begin on hospital admission with a thorough assessment of the client's skin, especially over bony prominences. Preventive steps for high-risk clients include the following:

- Ensure that skin is kept clean, and prevent it from getting too dry by using moisturizing lotions.
- Provide a balanced diet high in protein, vitamins, and minerals for tissue repair.
- Ensure a fluid intake of 2000 mL/day for adequate hydration.
- Place clients on a pressure-reducing mattress or chair cushion.
- Use turning sheets to reposition.
- Avoid massaging over bony prominences.
- Do not elevate head of the bed more than 30°.
- Positioning is the basic standard of ulcer prevention.
- Reposition a bedridden client at least every 2 hr; reposition a chair-bound client every hour.
- Complete a risk assessment for the client, evaluating factors for developing pressure ulcers.

ADJUNCTIVE WOUND CARE THERAPY

Three of the more common types of adjunctive wound therapy include electrical stimulation, noncontact normothermic wound therapy, and the vacuum-assisted closure system.

Electrical stimulation uses transfer of an electric current through a surface electrode pad that is in contact with external skin surface or the wound bed itself. It influences wound healing by attracting cells of repair, changing cell membrane permeability, enhancing cellular secretion through cell membranes, and orienting cell structure. A moist wound environment must be maintained for this therapy to be successful in healing. Electrical stimulation increases blood flow, oxygen uptake, and DNA and protein synthesis. It can be used in a variety of wound problems, including burns, pressure ulcers, vascular ulcers, and surgical wounds.

Warm-up therapy stimulates the healing process through application of infrared heat to the wound. This system uses warmth to help the body heal itself. It also maintains humidity and absorbs exudates, and its transparent window allows the nurse to assess the wound without disrupting wound tissue. Wound cover allows clients more freedom in their movements, as well as an increased comfort level. The heat increases blood flow and oxygen to the wound. It is commonly used for clients with venous ulcers and pressure ulcers. It can also be used for clients with surgical or traumatic wounds and diabetic ulcers.

Negative pressure wound therapy uses a foam dressing applied directly to the wound. This system stimulates growth of granulation tissue while promoting a moist environment. Negative pressure is applied to foam through the use of tubing connected to a canister where exudate and wound fluids

are collected. This system is used with infected wounds, as well as chronic wounds, acute and traumatic wounds, and dehiscence.

Hyperbaric oxygenation has been approved by Medicare and Medicaid for treatment of diabetic clients with leg ulcers. One hundred percent (100%) oxygen is delivered in a hyperbaric chamber. The oxygen is administered at greater than 1 atmospheric pressure absolute (ATA). This can only be accomplished in an environment of elevated atmospheric pressure, which is in the chamber.

The role of oxygen in wound healing takes on many roles. Disruption of microcirculation is the initial event leading to wound hypoxia. This hypoxia remains in chronic wound conditions. Cellular energy metabolism requires oxygen in the production of adenosine triphosphate (ATP). Without tissue oxygen at sufficient levels, acidosis occurs as a result of the hypoxia. Oxygen consumption is increased as leukocytes migrate to the wounded area, increasing the hypoxic state of the wound. An oxygen level of 40 mmHg is needed to sustain fibroblast activity that leads to collagen deposits for healing.

Hyperbaric oxygen wound therapy has proven to be very effective in healing diabetic ulcers.

HOME CARE

Before discharge from the hospital, a multidisciplinary team meeting should be held with the client to review the care at home. The team should include the following: home care RN, dietician, wound care specialist, and mental health CNS, if appropriate. A home care plan needs to include a discussion of the wound care and dressing change; mobility and exercise routine, if appropriate; diet to promote wound healing; and discussions with the healthcare workers and family regarding wound care techniques, signs and symptoms of infection, and when to notify the physician or healthcare provider.

Wound assessments and dressing changes are the same as that in the hospital. The more advanced adjunctive wound therapy modalities are usually not done in the home. If a complicated dressing change is required, a wound care specialist should be assigned to the home care client.

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to use on client care plans when the components are related to the client requiring wound care.

NURSING DIAGNOSIS	RELATED FACTORS
Infection, Risk for	Altered circulation, invasive procedures, trauma Exposure to nosocomial agents, surgical incision, open wound
Impaired Physical Mobility	Bedrest, wounds, or pressure ulcers
Chronic Pain	Tissue injury, extensive dressing changes, recent surgery, vascular ulcers
Skin Integrity	Mechanical factors (shearing force, pressure), altered circulation due to pressure on a bony prominence, immobility, poor nutritional intake
Impaired Tissue Integrity	Interrupted blood supply to site depleting oxygen and nutrients

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. *Remember to wash your hands or use antibacterial gel before and after each and every client contact.*

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Chapter 25

UNIT 1

Measures to Prevent Infection

Nursing Process Data

ASSESSMENT Data Base

- Identify clients at risk for infection (i.e., diabetics, elderly, malnourished, obese, smokers, immunosuppressed).
- Identify length of time client remained in surgery (the more hours in surgery, the greater the risk for infection).
- Assess incision three times a day.
- Identify the components necessary to prevent infection for individual clients.
- Assess need for sterile technique compliance in client care.
- Assess lab results for abnormal values (i.e., WBC, Hgb, Hct).

PLANNING Objectives

- To remove transient microorganisms from nails, hands, and forearms
- To prevent clients with impaired resistance from becoming infected
- To prevent microorganisms from entering the wound
- To provide a sterile working field for dressing changes

IMPLEMENTATION Procedures

- Completing Surgical Hand Antisepsis 893
- Donning Sterile Gloves 894
- Pouring From a Sterile Container 895
- Preparing a Sterile Field 896
 - *For Commercially Prepared Packages* 896
 - *For Hospital-Wrapped Packages* 896
- Preparing a Sterile Field Using Prepackaged Supplies . . 897
- Preparing for Dressing Change With Individual Supplies 897

EVALUATION Expected Outcomes

- Infection is prevented in clients with impaired resistance.
- Sterile field is maintained when preparing for dressing changes.
- Sterile technique is maintained throughout wound care.

- Critical Thinking Application** 898
- Expected Outcomes 898
 - Unexpected Outcomes 898
 - Alternative Actions 898

nursing.pearsonhighered.com

Prepare for success with NCLEX[®]-style practice questions
 and Skill Checklists

Completing Surgical Hand Antisepsis

Equipment

- Plastic or orangewood stick
- Antimicrobial solution (soap)
- Sterile towel

Procedure

1. Remove all jewelry: rings, watch, bracelets.
2. Turn on water using foot or knee pedal or hand lever. Water should be tepid. ► **Rationale:** Hot water dries skin and is uncomfortable. Cold water prevents soap from lathering and bacteria is not rinsed away.
3. Wet hands first with warm water. Apply 3–5 mL of antimicrobial soap to hands. Rub together for at least 15 seconds. Cover all surfaces of hands and fingers and 3 in. above wrists, keeping fingers pointing upward.
4. Scrub your hands for 10 strokes and nails for 15 strokes with an antimicrobial solution (time based on facility policy). Scrub each side of each finger for 2 minutes.
5. Scrub your hands using soap or alcohol-based hand rubs. When using antimicrobial soap, scrub hands and forearms up to 3 in. above elbows. This is done for

Research Studies

1950s It was thought that administering antibiotics after surgery would prevent wound infections. This did not happen.

1960s Confirmed giving antibiotics within 3 hr of the incision was more effective in preventing wound infections. Studies confirmed that giving antibiotics more than 24 hr after incision closure was not effective in preventing infections. Even with these statistics, many physicians continued to order the antibiotics after surgery for 7–10 days, in 25%–50% of surgeries in U.S. hospitals.

2010 The Recommendations from the Surgical Care Improvement Project (SCIP) will include the following changes in antibiotic administration to reduce the incidence of surgical complications by 25%.

- Administering the antibiotic 1 hr before the incision is completed, or within 2 hr before the incision, is required for prophylaxis. Vancomycin is used when client has a documented beta-lactam allergy or has colonization with methicillin-resistant *S. aureus*.
- Discontinue the antibiotic within 24 hr after surgery, except in cardiothoracic surgeries, in which case the antibiotic should be continued for 48 hr.

Source: Surgical Care Improvement Project (SCIP). www.qualitynet.org or www.premiervine.com. Chettle, C. (2008, April 21). Shockingly high rates. *NurseWeek*, California.

▲ Scrub hands with an antimicrobial solution.

length of time recommended by manufacturer (2–6 minutes) for each hand/arm. Most studies indicate this should be done for first OR scrub.

6. Rinse hands and arms by passing them through the water in one direction only, from finger tips to elbows. Do not move the hands and arms back and forth through the water.
7. When using alcohol solution, prewash hands and forearms with non-antimicrobial soap. Completely dry hands and forearms. Then use alcohol-based product according to manufacturer's directions, usually a vigorous 1-minute rub. Apply product to palm of one

Clinical Alert

Surgical site infection rates are the same in clients whose surgeon performed surgical hand antisepsis with either traditional antimicrobial scrub or an alcohol-based hand rub.

Decontaminating hands with alcohol-based hand rub:

- Apply 1.5–3 mL (size of a quarter) of alcohol gel or rinse to palm of one hand.
- Rub hands together, covering all surfaces of hands and fingers.
- Cover 3 in. above wrist with alcohol.
- Cover areas around and under fingernails.
- Continue to rub until alcohol dries (15–25 seconds).

Using soap and water for handwashing:

- Wet hand with water and place soap from dispenser on hands.
- Thoroughly spread soap on all surfaces of hands and fingers.
- Rub vigorously for 15 seconds, covering all surfaces.
- Rinse hands and dry thoroughly using single-use towel.
- Turn off faucet with towel if foot pedal not used.

Source: Baricenté, J. J., et al. (2002). *Journal of the American Medical Association*, 288. www.handhygiene.org.

hand and rub hands together covering all surfaces of hands and fingers until surfaces are dry.

8. Proceed to operative room and dry hands and arms thoroughly on sterile towel.
9. Dry hands and forearms thoroughly before donning sterile gloves.

Clinical Alert

Chlorhexidine added to alcohol-based preparations results in greater residual activity than alcohol alone. Minimal absorption, if any, occurs through the skin. Care should be taken to avoid contact with the eyes when using more than 1% chlorhexidine, as it causes conjunctivitis and severe corneal damage.

Donning Sterile Gloves

Equipment

Packaged sterile gloves

Procedure

1. Perform hand hygiene.
2. Place glove package on a clean, dry, firm surface that is at waist height (usually an overbed table). ► **Rationale:** Objects below waist level are considered to be out of the sterile field.
3. Remove outside wrapper of glove package by peeling the tabs apart where indicated on the wrapper. Pull edges laterally to expose glove package. Ensure that this step is accomplished over a firm surface. ► **Rationale:** This prevents the glove package from accidentally falling on a contaminated surface.
4. Place the glove package on the firm surface, maintaining sterility of gloves by touching only outside of wrapper.
5. Grasp two edges of wrapper and lift wrapper edges up and away from gloves, being careful to not touch gloves as you open the package. ► **Rationale:** Lifting the edges up and away as you open the package will prevent touching the gloves accidentally and causing contamination.
6. With your nondominant hand, pick up the opposite glove by grasping the section that has a folded edge (inside edge of the cuff). Lift the glove up and away from the wrapper. ► **Rationale:** This prevents accidental contamination of the glove or inside of glove package.
7. Holding your hands above waist level, insert your dominant hand into the glove opening. Gently pull the glove into place with your nondominant hand, touching only the inside of the cuff. Do not attempt to straighten out gloved fingers until both gloves have been put on. ► **Rationale:** It is easy to contaminate the glove when attempting to adjust the fingers in the glove.
8. With your dominant, gloved hand, remove the other glove from the package, making sure you touch only the inside of the folded cuff. Lift this glove up and away from the wrapper. ► **Rationale:** This prevents gloves from inadvertently touching wrapper and contaminating gloves.
9. Hold your gloved thumb away from your body to prevent touching your skin.
10. Place your ungloved fingers into the new glove opening. Gently pull the glove over your hand as before.
11. Keeping your hands above waist level, adjust both gloves by touching only your fingers, remembering to

▲ Grasp two upper edges of the glove package and pull laterally to open package.

▲ Place sterile glove wrapper on clean, flat surface and lift wrapper edges away from gloves.

▲ Grasp folded edge of glove with nondominant hand and lift glove away from wrapper.

▲ Slip dominant hand into glove opening without contaminating glove.

▲ Remove second glove from wrapper by placing gloved fingers under cuff.

▲ Continue to keep fingers under cuff of glove as the glove is pulled on.

touch sterile surfaces with sterile surfaces. ► **Rationale:** Fingers of gloves are considered sterile; cuff area is considered contaminated.

12. Keep both sterile gloves in front of you above your waist level. ► **Rationale:** Being able to see gloves at all times helps prevent potential contamination.

Pouring From a Sterile Container

Equipment

- Sterile container
- Nonsterile container
- Sterile solution

Procedure

1. Perform hand hygiene.
2. Gather equipment.
3. Open sterile container according to procedure.
4. Place container on firm surface.
5. Take cap off the bottle and invert the cap before laying on firm surface. ► **Rationale:** This keeps the cap sterile.
6. Hold the bottle with the label facing up.
7. Pour a small amount of liquid into a nonsterile container. ► **Rationale:** This action cleans the lip of the bottle.
8. Pour the liquid into the sterile container while keeping the label facing up and not touching the container with the bottle. Do not reach over a sterile field if the container has been placed on one. ► **Rationale:** Crossing over a sterile field can lead to contamination of the field.
9. Replace the cap if liquid remains in the bottle. If total contents have been used, dispose of bottle in trash.
10. Date and initial bottle if reusing.
11. Replace partially filled bottle to storage area if it is to be reused.

▲ First pour a small amount of liquid into nonsterile container.

▲ Pour liquid by placing container close to edge of sterile area.

Preparing a Sterile Field

Equipment

- Antiseptic cleansing solution, as ordered
- Two packages of sterile towels
- Number and type of dressings required for dressing change
- Tape
- Container for antiseptic solution
- Paper bag for disposal of soiled dressings
- Mask
- Sterile gloves

Preparation

1. Check physician's orders and client care plan.
2. Gather equipment from supply area.
3. Clean off overbed table.

Clinical Alert

Preparing a sterile field is commonly used for burn dressings or large wound dressings. It is not used routinely for other dressings.

Procedure

1. Perform hand hygiene, using aseptic technique.
2. Place sterile towel packages on overbed table or on another surface close to the table. Place packages so that first wrapper edge can be opened away from the sterile area. ► **Rationale:** This prevents contamination when crossing over a sterile field.
3. Grasp far edge of the wrapper and open away from you. ► **Rationale:** This exposes the sterile part of package.
4. Don sterile gloves and mask according to hospital policy. Gloves and mask are usually used when preparing burn sterile field. This procedure may be performed without gloves, maintaining sterility.
5. Using both hands, pick up the two side edges of the first wrapper and open them away from the middle of the sterile field. Unfold the last edge toward you, without touching the wrapper.
6. Pick up one edge of the sterile towel and move away from the table. Gently shake the towel open, keeping it away from the sterile area.
7. When the towel is open, use your other hand to pick up the two edges that are away from you. Be careful to not touch towel with clothing.
8. Lower the towel onto the tray or bedside stand so the towel is farthest away from you. Then lay the towel down on the tray by bringing it toward you, covering the entire tray. ► **Rationale:** This prevents crossing over the sterile field.
9. Repeat the same steps with a second sterile towel.
10. If solutions for cleansing the skin are required, place sterile medicine cups near one side of the sterile towel.
11. Take the cap off the antiseptic bottle.
12. Pour a small amount of solution into a container, not on the sterile field, keeping the label in uppermost position. ► **Rationale:** This action rinses contaminated particles from the lip of the bottle.
13. Pour the antiseptic solution, from the side of the sterile field, directly into the medicine cup. ► **Rationale:** Pouring solution from the side prevents crossing over the sterile field.
14. Open sterile packages of dressings, and place on sterile surface.

For Commercially Prepared Packages

- a. Open package at designated end by pulling edges apart and downward to expose contents.
- b. Grasp the edges of the two sides of the package and invert the package over the edge of the sterile field. Allow the contents to drop onto the sterile field.
- c. Repeat procedure for each item to be placed on the sterile field.

For Hospital-Wrapped Packages

- a. Hold package in your hand and securely grasp one edge.
- b. Open package wrapper by allowing edges to drop down, away from package.
- c. Grasp the edges of the wrapper with your free hand and pull them toward your wrist, thus exposing the sterile contents.
- d. Gently drop the contents on the sterile field. ► **Rationale:** Touching the sterile field with the wrapper contaminates it.
- e. Repeat procedure for each item to be placed on the sterile field.
15. If sterile supplies are not to be used immediately, cover with sterile towels.
 - a. Open sterile towel package by opening wrapper away from you so that you do not cross over a sterile field.

Guidelines for Sterile Field

- Never turn your back on a sterile field.
- Avoid talking, coughing, sneezing, or reaching across a sterile field.
- Keep sterile objects above waist level.
- Do not spill solutions on the sterile field.
- Open all sterile packages away from the sterile field to prevent crossover and contamination.
- One in. around edges is considered contaminated.

- b. Pick up one towel at the edge and open towel by moving yourself away from the sterile field and allowing towel to fall open.
- c. Grasp corner of towel opposite one you are holding. Keep towel from touching contaminated areas.
- d. Place towel over sterile field starting at edge nearest you. Lay the towel down without touching the tray with your hand. Move the towel across the tray toward the opposite edge.
- e. Repeat procedure with second sterile towel.

Preparing a Sterile Field Using Prepackaged Supplies

Equipment

Packaged supplies

Procedure

1. Perform hand hygiene.
2. Ensure working surface is clean and dry. Client's overbed table is frequently used as preparation area.
 - ▶ **Rationale:** This prevents contamination of sterile package.
3. Remove outer plastic wrap.
4. Place package in center of work area and position so that you first open package flap away from you.
 - ▶ **Rationale:** This prevents reaching across the sterile field as you continue to open package.
5. Grasp edge of the first flap of the wrapper, move it away from you, and place it on the working surface.
6. Grasp the first side flap, lift it up, grasp the second side flap, and together move both hands out toward the sides. Place the flaps down on the working surface.

7. Grasp the last flap of the wrapper and open it toward you, taking care not to touch the inside of the flap or any of the contents of the package. ▶ **Rationale:** This prevents contamination of the supplies.

▲ Grasp edge of top flap of wrapper and lift it away from you.

▲ Open last flap toward you—do not cross over sterile field.

Preparing for Dressing Change With Individual Supplies

Equipment

Antiseptic cleaner or cleaning solution
 Number and type of dressings needed (i.e., 4 × 4 gauze pads, ABD pads, application sticks, transparent dressings)
 Tape
 Clean gloves
 Sterile gloves
 Disposal receptacle
 Mask, if needed

Procedure

1. Perform hand hygiene.
2. Clean off bedside stand and wash thoroughly with antiseptic solution. Dry thoroughly.
3. Place supply packages on table in configuration that allows you to open packages without reaching over sterile field. ▶ **Rationale:** Reaching over sterile field will contaminate supplies.
4. Grasp cover of 4 × 4 pad plastic container and pull flap back and away from sterile area. Place cover in disposal bag.
5. Grasp edge of transparent dressings package, peel back top covering. Place open package on work surface. Do not cross over any open supply packages.
6. Continue to open all supplies using above steps.
7. Pour solution over pads in plastic container, if ordered.
8. Open sterile gloves. Place in position on table where you do not pass over a sterile field.

▲ Open sterile 4 × 4 pads container by pulling back on flap.

▲ Open transparent dressing packet.

▲ Pour cleaning solution over 4 × 4 pads.

▲ Open sterile glove packet on overbed table.

DOCUMENTATION for Measures to Prevent Infection

- Type and number of sterile dressings used
- Antiseptic solution used

CRITICAL THINKING Application

Expected Outcomes

- Infection is prevented in clients with impaired resistance.
- Sterile field is maintained when preparing for dressing change.
- Sterile field is maintained throughout wound care.

Unexpected Outcomes

Hole develops in glove while performing sterile technique.
Sterile field becomes wet or damp.

Alternative Actions

- Discard gloves and replace with sterile gloves.
- Examine hands for cuts if hole caused by sharp object.
- If hands are cut, scrub hands and replace sterile gloves.
- Discard supplies on sterile field.
- Set up new sterile field.

Dressing Change

Nursing Process Data

ASSESSMENT Data Base

- Identify type of dressing required.
- Determine if sutures or staples need to be removed.
- Assess incision for infection.
- Assess extent of healing.
- Assess nutritional status.

PLANNING Objectives

- To promote incision healing
- To prevent wound infection
- To maintain sterility during dressing change
- To remove sutures or staples using appropriate technique

IMPLEMENTATION Procedures

- Changing a Dry Sterile Dressing900
- Removing Sutures901
- Removing Staples902

EVALUATION Expected Outcomes

- Client's wounds do not become infected.
- Client's sutures and staples are removed intact.
- Client's wound remains intact after staple and/or suture removal.

Critical Thinking Application903

- Expected Outcomes903
- Unexpected Outcomes903
- Alternative Actions903

 and Skill Checklists

Changing a Dry Sterile Dressing

Equipment

- Sterile gloves
- Clean gloves
- Mask
- Gown
- Disposal receptacle for used dressings
- Dressing supplies, as needed
- Micropore tape
- Sterile normal saline, optional
- Package sterile cotton swabs, or 4 × 4 pads
- Bath blanket or sheet

Preparation

1. Check physician's orders and client care plan.
 2. Perform hand hygiene.
 3. Gather equipment.
 4. Identify the client and explain procedure.
 5. Provide privacy.
 6. Clean off overbed table.
 7. Place sterile supplies on overbed table.
 8. Raise bed to HIGH position and lower side rails, if appropriate.
 9. Place bag for soiled dressings near incision site.
 10. Fanfold linen to expose incision area.
11. Cover client with bath blanket or sheet, leaving incision area exposed.
 12. Open sterile packages and place on overbed table. Arrange packages to ensure you don't cross over the sterile field when reaching for dressings.
 - ▶ **Rationale:** Commercially prepared sterile packages can be opened and used for the sterile field because the inside of the package is sterile.
 13. Cut tape into appropriate length strips.

Procedure

1. Remove tape slowly by pulling tape toward the wound.
 - ▶ **Rationale:** Pulling toward the wound decreases the pain of tape removal by not putting pressure on the incision line.
2. Don clean gloves.
3. Remove soiled dressings and dispose of in the proper receptacle. Wet dressing with sterile normal saline if it adheres to the suture line.
4. Assess incision area for erythema, edema, or drainage.
 - ▶ **Rationale:** Persistent drainage, edema, or temperature above 100.4°F 2 days postop indicates a complication is occurring.
5. Assess color of incision. (A healing incision looks pink or red.)
 - ▶ **Rationale:** Redness that does not fade 48 hr after surgery may indicate impaired healing.

▲ Remove tape by gently lifting toward wound.

▲ Remove soiled dressing carefully.

▲ Dispose of dressing in appropriate container.

▲ Do not touch incision when applying dressing.

▲ Place abdominal pad over center of incision.

▲ Tape dressing securely to prevent slipping.

6. Remove clean gloves, and discard.
7. Move overbed table next to working area.
8. Don sterile gloves.
9. Cleanse incision area with sterile swabs or 4 × 4 pads soaked in normal saline, according to hospital policy. Cleanse from incision line outward, cleaning from top to bottom, using the swab only once. Discard swabs or 4 × 4 pads in disposal bag. ► **Rationale:** Cleaning outward from incision cleans from least to most contaminated area. Cleaning from top to bottom prevents contamination from secretions that accumulate at the bottom of the wound.
10. Place 4 × 4 gauze pads over incision area, being careful not to touch incision or client with your gloves. ► **Rationale:** Touching the incision or client contaminates the gloves. You need to reglove if this occurs.
11. Place abdominal pad over incision, being careful not to contaminate the gloves.
12. Remove gloves and discard.
13. Tape dressing securely.
14. Discard trash in appropriate receptacle.
15. Lower bed and raise side rails. Position client for comfort.
16. Perform hand hygiene.

Removing Sutures

Equipment

- Sterile suture removal set
- Antiseptic solution
- Tape
- Butterfly tape
- Paper bag for disposal of dressings
- Two pair clean gloves (one pair optional)

Procedure

1. Gather equipment.
2. Perform hand hygiene and don clean gloves.
3. Remove dressing and discard in disposal bag. (Discard gloves only if soiled.)
4. Open suture removal set, and don gloves if second pair needed.
5. Pick up forceps with nondominant hand.
6. Grasp suture at the knot with forceps and lift away from skin.

▲ Grasp suture at the knot with forceps and lift away from skin.

Topical Glue for Wound Closure

A new product to replace sutures and staples (estimated at 80–90 million procedures annually) was approved by the U.S. Food and Drug Administration after proving itself in clinical trials. This superglue is called *Dermabond*. It is a synthetic, noninvasive glue that mitigates trauma and post-procedure inflammation while providing a waterproof seal and protecting underlying tissue without the need for bandages. *Dermabond* is also painless, fast and simple to apply, and naturally sloughs off in 7–10 days.

7. Pick up suture scissors with dominant hand.
8. Place curved tip of suture scissors under suture, next to knot.
9. Cut suture, and with forceps, pull suture through skin with one movement.
10. Discard suture into disposal bag.
11. Check that entire suture is removed.

▲ After cutting suture, grasp suture at knot and pull through skin.

12. Continue to remove remaining sutures according to hospital policy. Some policies state that every other suture is removed and then remaining sutures are removed at a later time. ► **Rationale:** This prevents wound dehiscence.
13. Cleanse suture site with antiseptic solution.
14. Remove gloves and place in disposal bag.
15. Place dressing or butterfly tape over incision area, if ordered.
16. Discard disposal bag into contaminated waste container.
17. Perform hand hygiene.

Removing Staples

Equipment

- Sterile staple remover
- Disposal receptacle
- Two pair clean gloves (one pair optional)
- Dressings
- Tape or butterfly tape
- Antiseptic solution

Procedure

1. Gather equipment and open sterile staple remover.
2. Perform hand hygiene and don clean gloves.
3. Remove dressing and discard in disposal bag. (Discard gloves only if soiled.)
4. Don gloves if necessary.
5. Place lower tip of staple remover under staple.
6. Press handles together to depress center of staple.
7. Lift staple remover upward, away from incision site, when both ends of staple are visible.
8. Place staple removal device over disposal receptacle and release handles to release staple.
9. Remove all staples or as directed by hospital policy. Some policies indicate every other staple is removed

▲ Large abdominal wound with staples closing incision.

Clinical Alert

Steri-strips may be applied over incision to protect incision after staples are removed.

▲ Place lower tip of staple removal device under staple.

▲ Press handle together to depress center of staple.

▲ Lift staple remover device upward and away from incision.

with remaining staples done at a later time. ► **Rationale:**
To prevent wound dehiscence.

10. Cleanse incision area with antiseptic solution if ordered.
11. Remove gloves and place in disposal receptacle.

12. Place dressing over incision and secure with tape, or place butterfly tape over incision.
13. Perform hand hygiene.

Discharge Client Teaching

- Instruct client to eat foods high in protein, carbohydrates, vitamins, and minerals to promote wound healing.
- Splint wound when coughing or moving from chair or bed to prevent separation of wound edges.
- Provide list of signs and symptoms of wound infection or delayed healing. Include when to notify physician.
- Encourage use of daily showers; water may run over wound.
- Instruct not to use soap, lotions, or vitamin creams on incision.
- Instruct in dressing change procedure.
- Instruct to not lift heavy objects (anything over 10 lb).
- Instruct in measures to promote elimination.

DOCUMENTATION for Dressing Change, Removal of Sutures and Staples

- Conditions of suture line
- Presence of exudate or erythema
- Sutures removed
- Staples removed
- Dressing applied, if appropriate

CRITICAL THINKING Application

Expected Outcomes

- Client's wounds do not become infected.
- Client's staples or sutures are removed intact.
- Client's wound remains intact after staple and/or suture removal.

Unexpected Outcomes

Wound appears to be infected.

Client complains of fever, pain in incisional area.

Wound edges separate when suture or staple is removed.

Client complains of pain with dressing change.

Alternative Actions

- Obtain order for wound culture.
- Obtain order for different type of dressing.
- Document observations.
- Check incision for edema, erythema, or drainage; wound could be infected.
- Do not continue to remove sutures or staples.
- Place Steri-strip over edges.
- Notify physician.
- Lift small edge of tape or dressing.
- Use alcohol pad, wipe area next to dressing with pad.
- Remove dressing by wiping, with pad, each time the dressing is lifted up until entire dressing is removed.

Chapter 25

UNIT 3

Wound Care

Nursing Process Data

ASSESSMENT Data Base

- Identify type of dressing needed.
- Assess level of pain associated with wound care and dressing change.
- Assess wound for color, odor, drainage.
- Assess extent of wound.
- Assess type of wound.
- Assess for function of Hemovac or Jackson–Pratt suction.
- Assess for extent of wound healing.
- Assess wound.
- Assess for arterial insufficiency, claudication, pain, ischemic tissue loss, and functional limitations.
- Assess for suture site infections.

PLANNING Objectives

- To assess wound appropriately
- To assess for arterial sufficiency
- To promote wound healing by first or second intention
- To prevent microorganisms from entering the wound
- To decrease the presence of purulent wound drainage
- To maintain sterility during a dressing change
- To maintain patency of Hemovac or Jackson–Pratt suction
- To immobilize and support a wound
- To assist in removal of necrotic tissue
- To apply medication to wound
- To pack a wound to promote granulation of tissue
- To identify potential surgical site infections

IMPLEMENTATION Procedures

- Determining Surgical Site Infections (SSIs) 905
- Assessing a Wound 905
- Changing a Wound Dressing 908
- Packing a Wound 910
- Assessing a Venous Ulcer 910
- Changing a Dressing—Venous Ulcer 911
- Assessing Ankle–Brachial Index (ABI) 915
- Caring for a Wound With a Drain 915
- Applying an Abdominal Binder 917
- Maintaining Wound Drainage System 917
- Irrigating Wounds 919
- Teaching Wound Care for Clients 920

EVALUATION Expected Outcomes

- Wound care is provided for contaminated wound and healing occurs.
- Drainage system functions without obstructions.
- Wound irrigation is completed using sufficient pressure to cleanse wound bed.
- Abdominal binder supports client’s abdominal wound.
- Compression dressing applied to vascular ulcer site.

Critical Thinking Application 920

- Expected Outcomes 920
- Unexpected Outcomes 921
- Alternative Actions 921

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Determining Surgical Site Infections (SSIs)

Procedure

1. Before surgery assess client for risk factors associated with surgical site infections (SSIs).
 - a. Complete health history and physical assessment.
 - b. Obtain information on all medications currently taking.
 - c. Determine whether client is allergic to specific medications.
 - d. Review lab values.
2. Determine whether client has a preexisting viral or bacterial infection. ► **Rationale:** If the answer is yes, the client is at an increased risk for SSI.
 - a. Clients who must undergo surgery even with existing infections must be monitored closely postoperatively.
 - b. Clients scheduled for routine surgery should be treated first and then rescheduled for surgery once the infection is cleared.
3. Check that client does not have nasal bacterial colonization. ► **Rationale:** Clients with positive anterior nares cultures of *S. aureus* should receive a topical antibiotic ointment mupirocin before surgical intervention. (More research is needed before this becomes a standard of practice).
4. Complete a nutritional assessment and review lab findings for serum albumin, prealbumin, serum transferrin, and total lymphocyte levels. ► **Rationale:** Malnutrition in hospitalized adults is common and can prolong postoperative wound healing, increasing the risk of SSI. The client may need enteral or parenteral nutrition postoperatively.
5. Diabetic clients with an elevated fasting serum glucose are at higher risk than other diabetic clients for SSIs due to the high glucose levels. ► **Rationale:** High glucose levels impair phagocytosis, which affects the body's normal defense mechanisms. The client's serum glucose level must be kept below 200 mg/dL during and after surgery to prevent an SSI.
6. Clients with chronic illnesses such as hypertension and other uncontrolled conditions are at high risk for SSIs and must be monitored carefully after surgery. It is preferable to get the conditions under control before surgery is considered.
7. Determine whether client was instructed to perform a preoperative skin cleansing at home. ► **Rationale:** The CDC strongly recommends a preventative home cleansing be done for high-risk clients for SSIs. Chlorhexidine gluconate is the most effective cleaning agent in decreasing the microbial count.
8. Check that client has not shaved the surgical site. The CDC recommends that hair be left on client's skin unless it interferes with the surgical procedure. If clipping of the hair is required, the OR staff will complete the clipping. ► **Rationale:** Shaving can lead to nicks in the surgical site, predisposing it to an SSI.
9. Check that the client has an antibiotic order for 1 hr before surgery or, if vancomycin is ordered 2 hr before surgery.

Advancing age does increase the risk of SSI. One study showed that elderly clients who developed SSIs after orthopedic surgery were at increased risk for death within the first year postoperatively. Clients with COPD and obesity were at higher risk for SSIs after cardiothoracic and neurologic surgery. Clients who used (or use) nicotine exhibit slow wound healing, leading to SSIs. Obese clients are at higher risk for SSIs due to their inability to ambulate, move in bed, and complete postoperative exercises. Obesity can lead to a disruption of sutures due to increased stress on the adipose tissue.

It is imperative that these clients be monitored closely for signs and symptoms indicating an SSI could be occurring.

Assessing a Wound

Equipment

- Pliable disposable measuring device/grid
- Cotton-tipped applicator sticks
- Saline-filled syringe
- Plastic disposal bag or receptacle
- Clean gloves
- Sterile gloves if necessary

Preparation

1. Obtain health history, medical diagnosis, and physical examination data from chart or obtain missing information. The health history must include information on the following:
 - a. Initiating event and duration of wound.
 - b. Previous treatments, if any, and the outcome of treatments.
 - c. Current medical diagnosis, including all disease processes. ► **Rationale:** Diseases that affect circulation and perfusion of blood can interfere with nutrition and oxygenation of cells. Infection and wounds can result from this pathology.
 - d. Medications, both past and current, including anticoagulants, corticosteroids, immunosuppressives,

Nutrients for Wound Healing

- Protein
- Carbohydrates
- Fats
- Iron
- Zinc
- Copper
- Arginine
- Vitamin A
- Vitamin C
- Vitamin K
- Pyridoxine
- Riboflavin
- Thiamine
- Glutamine

and antineoplastics. ► **Rationale:** These drugs may adversely affect wound healing.

- e. Nutrition and hydration status: Check for signs of malnutrition and assess hydration status of client.
 - **Rationale:** Malnutrition leads to poor cell growth and repair. Both dehydration and overhydration lead to impaired oxygen and nutrient transportation.
 - f. Laboratory data evaluation: albumin, serum total protein, serum transferrin, and total lymphocyte count.
 - **Rationale:** These lab values are used to determine nutritional status and potential for wound healing.
2. Determine type of wound (acute or chronic) and cause of wound. ► **Rationale:** This information is used to evaluate healing process.
 3. Evaluate severity of pain.
 4. Perform hand hygiene and don gloves.

NOTE: Acute wounds progress through normal process of wound healing in about 1 month. Chronic wounds do not go through normal wound healing phases. Wounds that do not heal within 1 month should be considered chronic.

Procedure

1. Assess location of wound. ► **Rationale:** Location influences rate of healing. Lower body heals more slowly.
2. Assess size of wound: length, width, and depth.
3. Observe color of wound: if using this classification.
 - a. Black: necrotic tissue/black eschar (inhibits formation of granulation tissue)
 - b. Yellow: presence of exudate or slough; pus, fibrin, debris (will advance to eschar), requires cleaning
 - c. Red: indicates wound ready to heal (granulation tissue present)
4. Assess odor of wound.
 - a. Foul: infected (necrotic tissue has an odor even if not infected)
 - b. Sweet: *Pseudomonas* infection
5. Assess level of moisture in wound. (A moist environment allows wound to heal without forming a scab.)
6. Assess wound exudate.
 - a. Type: dry or moist
 - b. Amount: minimum, moderate, maximum (copious)
 - c. Color of drainage: clear (serous), brown-brown/yellow (slough), yellow-yellow/green (pus from strep, staph), blue-green (*Pseudomonas*)
7. Assess tissue viability.
 - a. Presence of granulation tissue; red, moist, beefy appearance.
 - b. Presence of epithelialized tissue; new pink, shiny epidermis.
 - c. Absence of necrotic tissue; slough of yellow, gray. Green and brown color or eschar of hard, black, leathery tissue.
8. Assess periwound condition.
 - a. Skin nutrition: loss of hair, thickening of nails, atrophy.
 - b. Edema of skin or scaly skin.
 - c. Skin hydration: skin turgor indicates hydration or dehydration.
 - d. Areas of inflammation surrounding wound.
 - e. Skin integrity: maceration, induration, crepitus, hematoma, blisters.
 - f. Color: red (inflammation), white (arterial insufficiency), blue (cyanosis, severe arterial insufficiency), black (necrosis), brown (venous insufficiency).
 - g. Skin temperature: cool, cold, warm, normal temperature.
9. Assess extent of pain, if present.
 - a. Determine whether pain is present during dressing change only or constant.
 - b. Use pain scale to determine severity of pain.
 - c. Observe for signs of infection.
 - d. Arterial insufficiency wounds are very painful.
 - e. Venous insufficiency wounds are relatively pain-free.
10. Measure the length and width of wound using a disposable measuring device/grid. Measure in centimeters (cm).
11. Measure depth of wound by placing a sterile cotton-tipped applicator stick into wound in several areas. Measure depth of each area using measuring device/grid. Measure in centimeters (cm).
12. Check for undermining and/or tunneling or sinus tracts by placing a sterile cotton-tipped applicator stick into

Clinical Alert

Cephalosporins are the drug of choice as prophylaxis for most wound infections. First- or second-generation drugs such as cefazolin or cefoxitin are used for colon surgery clients. Cephalosporins have a broad spectrum of activity against both gram-positive (gram +) and gram-negative (gram -) bacteria and a wide ratio of therapeutic to toxic dosages. Allergic reactions are rare to these drugs.

Clinical Alert

Moist wound environment is essential for healing without a scab. Epithelial tissue will not migrate into wounds with necrotic tissue or if deprived of oxygen.

suspected areas. Gently probe margins of lesion for extensions into surrounding tissue (undermining) and beyond wound base (sinus tract).

13. Evaluate laboratory values.
 - a. Increased white blood cell count indicates infection, usually before other signs and symptoms are evident.
 - b. Low hemoglobin and hematocrit indicates anemia, which can decrease oxygen transport to the wound.
- c. Altered serum glucose levels may indicate presence of diabetes mellitus, which interferes with normal wound healing.
14. Evaluate client's stress level. Increased stress leads to hypermetabolic states, which uses up oxygen and nutrients and affects wound healing.
15. Complete skill by following appropriate steps described in skill Changing a Wound Dressing.
16. Document findings and notify physician of any changes or unusual findings in the assessment.

TABLE 25-3 Moisture-Retentive Dressings

Advantages	Disadvantages	Clinical Use
<p>Transparent Adhesive Film</p> <ul style="list-style-type: none"> • Transparency allows wound visualization but is nonabsorptive • Conforms to area of application • Can reduce friction of area • Promotes autolysis of dry eschar • Semipermeable vapor can escape and environmental oxygen can enter to reduce chance of anaerobic bacterial growth • Barrier to bacterial invasion; can aspirate fluid and patch • Does not require secondary dressing 	<ul style="list-style-type: none"> • Does <i>not</i> absorb exudate • Exudate may macerate skin around wound • Edges will roll in friction area • May be difficult to apply • May be too tightly applied • Removal may tear underlying skin • May increase bacterial growth in infected wounds 	<ul style="list-style-type: none"> • Pressure ulcers, stage I and II • Donor sites • Abrasions • Partial-thickness wound with little or no exudate • Wound without necrotic tissue or slough • Extend edge to minimum 1¹/₄ in. beyond wound; skin around wound must be dry for adhesion; apply without tension • Change when fluid buildup and leaking occurs and when edges are loosening to potentially expose wound
<p>Hydrogel</p> <ul style="list-style-type: none"> • Comes in sheets or gel to conform to the wound • May have soothing and coating effect • Absorbs some exudate • Soften slough or eschar in necrotic wounds • Can be used when infection is present • Provides moist wound healing • Rehydrates dry wound beds 	<ul style="list-style-type: none"> • Expensive • Held in place with gauze dressing or transparent film • May have transparent film on both sides (film next to wound must be removed) 	<ul style="list-style-type: none"> • Wounds with necrosis and slough • Partial thickness (use sheets) • Gel can be used to fill wound cavity • Change every day or twice a day—based on wound exudate
<p>Hydrocolloids</p> <ul style="list-style-type: none"> • Use on acute and chronic wounds • Absorbs exudate in limited capacity • Conforms to area • Prevents bacterial invasion • Occlusive or semioclusive dressings 	<ul style="list-style-type: none"> • Not transparent • Melts down with exudate • Characteristic drainage and odor • Edges may need to be taped to prevent rolling • Most do <i>not</i> allow environmental oxygen, so growth of anaerobic bacteria may be a problem • Cannot be used for infected wounds 	<ul style="list-style-type: none"> • Noninfected dermal ulcers • May leave in place up to 7 days • Change if leaking • Change if clinical signs of infection • Cleanse wound before application • Roll dressing over wound • Do <i>not</i> stretch; press securely

Changing a Wound Dressing

Equipment

- Sterile, prepackaged dressing(s) as needed
- Tape; micropore, paper, or Montgomery tie tapes
- Clean gloves
- Sterile gloves
- Sterile normal saline irrigation solution or commercially prepared cleansing spray
- Wound culture media, as needed
- Plastic bag
- Bath blanket or sheet
- Emesis basin

Preparation

1. Complete steps in Assessing a Wound.
2. Check physician's orders and client care plan.
3. Perform hand hygiene.
4. Gather equipment.
5. Identify the client, using two forms of identification, and explain procedure.
6. Provide privacy.
7. Clean off overbed table.

▲ PYXIS supply station provides easy access for dressing supplies.

Clinical Alert

Gauze dressings do not support healing or prevent entry of exogenous bacteria.

Clinical Alert

Normal saline or Ringer's solution are widely advocated as fluids of choice for cleansing and irrigating wounds. Iodine and chlorhexidine are cytotoxic, particularly to fibroblasts. In severely infected wounds, antimicrobial irrigations may be used.

Povidone iodine, hydrogen peroxide, Dakin's solution, and other agents are not used on acute wounds. They are drying agents and as such, the wound bed is dried, and the exudate and all its beneficial cells are removed from the area. Wounds maintained in a moist environment have a lower infection rate than dry wounds.

8. Place sterile supplies on the over-bed table.
9. Raise bed to HIGH position, and lower side rails on working side of bed, if necessary.
10. Place bag for soiled dressings near wound site.
11. Open sterile packages and place on overbed table. Arrange packages to ensure that you don't cross over the sterile field when using dressings. ► **Rationale:** Commercially prepared sterile packages can be opened and used for the sterile field; the inside of the package is sterile.
12. Fanfold linens to expose wound site.
13. Cover client with bath blanket or sheet, leaving wound area exposed.
14. Cut tape into appropriate strips.

Procedure

1. Remove tape slowly by pulling tape toward the wound. ► **Rationale:** Pulling toward the wound decreases the pain of tape removal by not putting pressure on the incision line.
2. Don clean gloves.
3. Remove soiled dressings, and dispose of in bag. Soaking dressings that are dried to skin or incision with sterile normal saline prevents tissue damage and pain when dressings are removed.
4. Obtain wound specimen for culture if ordered.
5. Remove clean gloves and discard into plastic bag.
6. Bring overbed table close to working area.
7. Open sterile saline solution or commercially prepared cleansing spray and pour over wound. Place emesis basin next to skin surface to catch overflow.
8. Don sterile gloves.
9. Form a ball with gauze pads by tucking all four corners together. Use the center of gauze pads to cleanse the

How to Obtain a Wound Culture

- Rinse wound thoroughly with sterile saline.
- Use non-cotton-tipped swab.
- Rotate swab while obtaining specimen.
- Swab edges starting at top, crisscross wound to bottom.
- Do not take specimen from exudate or eschar.
- Place swab in culture medium and take to laboratory immediately.

▲ Montgomery straps are used to prevent skin irritation when frequent dressing changes are required.

wound. ► **Rationale:** This action prevents contamination of your hands during cleansing.

- Cleanse wound. When cleansing an area, always start at the cleanest area and work away from that area. Never return to an area you have previously cleaned. Usually start at top of wound and work toward bottom.
 - **Rationale:** Prevents contamination of area.
- Assess the wound, measure, identify type, and determine whether signs of infection are present.
 - **Rationale:** This allows nurse to determine most effective treatment and type of dressing to be used.
- Cleanse under the drain and around the site with a 4 × 4 gauze pad and cleansing solution if a drain is present. Do not use a cytotoxic or dangerous chemical.
 - **Rationale:** These agents may harm granulating tissue.
- Place several gauze pads under the drain.
- Place several 4 × 4 gauze pads by placing at wound center, extending at least 1 in. (2.5 cm) beyond wound. Loosely pack a tunneling area of wound if present before filling the base of the wound. Cover with an ABD pad if necessary; remove gloves, and tape securely. Montgomery straps (tie tapes) may be used if frequent dressing changes are required or the client has sensitive skin.
 - **Rationale:** Once a dressing has been placed over the wound, it is not to be moved and readjusted, as microorganisms from the skin could be introduced into the wound.
- Use skin sealants or moisture barrier ointments on intact skin and moisture-retentive dressing over 4 × 4 gauze pad and even over ABD, if used.
 - **Rationale:** Moisture-retentive dressings are flexible and water

Use of Antimicrobial Agents in Wound Care

Antiseptics and antibiotics are two types of antimicrobial agents used in wound care management. Antiseptics, unlike antibiotics, cannot be used exclusively to kill bacteria. Systemic antibiotics should be used only to treat wound infections; however, wounds that have impaired blood flow will not receive the systemic antibiotics. Topical antibiotics are used only for a limited time with infected wounds. These agents are not used as preventative measures; they are used when infection is present.

Antiseptics return the wound back to bacterial balance, promoting wound healing. Cadexomer iodine gel is used to absorb wound exudates and assists in autolytic debridement. Silver nitrate and sulfadiazine are used against many antibiotic-resistant strains of bacteria, as they reduce the number of viable bacteria.

resistant, which allows clients to move freely and take showers without disturbing the dressing.

- Cover client.
- Close the plastic bag and dispose of bag as isolation material.
- Remove gloves and perform hand hygiene thoroughly.
- Check with client to see that he or she is comfortable before leaving room.
- Lower the bed and raise the side rail, according to facility policy.

EVIDENCE-BASED PRACTICE

Maintaining a Moist Environment

Dressings that promote a moist wound environment stimulate rapid wound healing. Saline soaks are not as effective as moisture-retentive dressings. The type of dressing used is dependent on the type of wound, whether infected or if debris is present, amount of exudates, cost, and client comfort.

Source: The Joanna Briggs Institute. www.joannabriggs.edu.au.

Packing a Wound

Equipment

- Dressing pack, optional
- Sterile narrow packing gauze or 4 × 4 gauze pads
- Normal saline solution
- Alcohol wipe
- Dressings
- Forceps, optional
- Sterile scissors
- Paper tape
- Montgomery tapes
- Plastic bag or receptacle
- Clean gloves
- Sterile gloves

Procedure

1. Follow steps in Preparation for Changing a Wound Dressing.
2. Determine client's need for pain medication before beginning procedure. ► **Rationale:** Pain can be present particularly when removing old packing that may have become attached to the tissue.
3. Perform hand hygiene, don clean gloves, and place plastic bag near wound site.
4. Remove tape slowly by pulling tape toward wound.
5. Remove soiled dressings and dispose of dressings and packing into plastic bag. Moisten packing with sterile saline solution if dry.
6. Assess wound site.
 - a. Identify location of wound.
 - b. Observe wound bed and appearance.
 - c. Check wound size, shape, depth, and margins.
 - d. Observe exudates or drainage.
 - e. Evaluate presence of pain.
7. Remove clean gloves and discard.
8. Don sterile gloves.
9. Clean wound with saline solution and pat wound dry with 4 × 4 gauze pads.
10. Place packing material in wound; pack lightly, filling tunneling or undermined areas. Forceps can be used to place packing material into corners and wound areas hard to reach. ► **Rationale:** Pack lightly to prevent wound margins from contracting. Wound packing is used to facilitate healing by secondary intention. Type of packing

▲ Pack wound dressing in all tunneling and undermined areas.

material is dependent on type of wound and material available. Gauze pads should be moistened before packing.

11. Cut ribbon gauze with sterile scissors and leave small wick exposed, if used for packing.
12. Cover packing with dressing and tape securely.
13. Dispose of used packing and gloves.
14. Perform hand hygiene.
15. Position client for comfort.

EVIDENCE-BASED PRACTICE

Medieval Remedies

Medieval remedies, like maggots for bedsores, bee stings for MS, and leeches to improve blood flow after surgery, are enjoying a renaissance.

Leeches reemerged a while ago and now have a well-established role in plastic and reconstructive surgery. Maggots are being considered more often for treatment of chronic wounds that do not heal. Bee venom is also considered an alternative medicine.

Maggots do a better job than more conservative therapy for pressure ulcer treatment. Physicians who use maggots in their practice say they like them because they work.

Source: Graninger, M., Grassberger, M., Galehr, E., Huemer, F., Gruschina, E., Minar, E., & Graninger, W. (2002). Biosurgical debridement facilitates healing of chronic skin ulcers. (2002). *Archives of Internal Medicine*, 162(16), 1906–1907.

Assessing a Venous Ulcer

Equipment

- Blood pressure cuff and stethoscope
- Dressings
- Chux
- Clean gloves (two pair)
- Sterile normal saline
- Scissors, if needed

Procedure

1. Perform hand hygiene.
2. Don clean gloves.
3. Identify client using two forms of identification and explain procedure.
4. Place Chux under leg.
5. Remove dressings and discard into trash bag.
6. Cleanse site with normal saline as needed.
7. Remove gloves and don new gloves.
8. Observe lower leg. ► **Rationale:** The medial malleolus is the usual site for ulcer area.
9. Observe surrounding area of ulcer for:
 - a. Dilated veins.
 - b. Edema.
 - c. Maceration.
 - d. Hyperpigmentation.
 - e. Eczematous skin change: scaling, pruritic, erythema, and vesicle.
 - f. Atrophic blanch (white plaques with dot-like capillaries).
 - g. Scarring from prior healed ulcers (lipodermatosclerosis).
10. Complete a pain assessment. ► **Rationale:** Deep ulcers are most painful.
11. Check wound bed for “ruddy” or “beefy-red” granular appearance.
12. Observe for flat, irregular wound margins without undermining.
13. Assess amount of drainage and exudates (may be heavy to moderate).
14. Complete an ankle–brachial index (ABI) to check for arterial insufficiency. See p. 915 for skill.

TABLE 25-4 Comparison of Arterial and Venous Ulcers

Differentiation	Arterial	Venous
Predisposing factors	Peripheral vascular disease Atherosclerosis Diabetes mellitus Advanced age Raynaud’s syndrome	Valve incompetence in vein History of DVT Obesity Advanced age
Anatomic location	Between toes or tips of toes Over phalangeal heads Around lateral malleolus Area subjected to trauma	Medial distal lower leg and ankle Malleolar area
Wound characteristics	Even around margins Gangrene or necrosis Black eschar Deep, pale wound bed Blanched or purpuric periwound tissue Severe pain Cellulitis Minimal exudate	Irregular wound margins Superficial to deep wounds “Ruddy” granular tissue Minimal to moderate pain Minimal to moderate pain Moderate to heavy exudate

Changing a Dressing—Venous Ulcer**Equipment**

- Cleansing solution
- Normal saline solution
- Sterile 4 × 4 dressings
- Moisture-retentive dressings (hydrocolloid, transparent film or foam for light-to-moderate drainage)
- Absorbent dressings (foams, alginates, and absorptive dressings) for moderate to heavy exudate
- Compression dressing
- Clean gloves
- Sterile gloves
- Biohazard bag
- Scissors
- Absorbent pad

Preparation

1. Perform hand hygiene.
2. Gather equipment.
3. Explain procedure to client.
4. Provide privacy for client.
5. Raise bed to HIGH position and lower side rails.
6. Open sterile packages and arrange on overbed table.
7. Place absorbent pad under wound.

Procedure

1. Don clean gloves.
2. Remove compression bandage and old dressing and place in biohazard bag. Compression dressings may be left in place for 3–7 days depending on amount of drainage and type of dressing.

1 Obtain appropriate wound dressing kit, if available.

2 Remove compression dressing, being careful not to cut skin.

3 Assess wound healing and evaluate progress (stage II).

4 Pour normal saline solution over wound to clean off debris.

5 Don sterile gloves before cleaning wound with 4 × 4 gauze pads.

6 Dry with 4 × 4 gauze pad after cleansing.

3. Assess and measure wound. ► **Rationale:** This determines effectiveness of treatment.
4. Cleanse off debris by pouring cleansing solution over wound.
5. Rinse wound with sterile normal saline.

6. Debride wound, if ordered, using one of the following methods:
 - a. Autolytic: Applying occlusive dressings that assist in maintaining a moist wound environment, therefore promoting reepithelialization. ► **Rationale:** Autolytic

uses body's own enzymes and moisture to rehydrate, moisten, and slough tissue.

- b. Chemical: Apply enzyme debriding agents (Accuzyme, collagenase, papain, etc.).

NOTE: The major disadvantage of this method is that viable tissue is removed with necrotic tissue.

Clinical Alert

The wound bed should be kept moist to promote granulation and reepithelialization and to reduce pain. Ointments provide the most occlusive moisturizer because they contain oil and water.

- c. Mechanical: Apply wet-to-dry dressings, use hydrotherapy, irrigation.

7. Dry wound using sterile 4 × 4 dressings. Place in biohazard bag.
8. Remove gloves, and don sterile gloves.
9. Apply medicated moisturizer over wound, if ordered.
 - ▶ **Rationale:** This keeps wound area moist.

7 Measure wound to evaluate effectiveness of treatment.

8 Apply medicated moisturizer on wound, if ordered.

9 Apply moisture-retentive dressing over wound site.

10 Apply compression dressing for venous or lymphatic conditions.

▲ Cover entire area with compression dressing.

10. Remove backing on moisture-retentive dressing and place over open wound site. These dressings prevent entry of bacteria from surface of dressing.
11. Palpate arterial system; dorsalis pedis, posterior, or tibial pulse. If pulses are nonpalpable, obtain an Ankle-Brachial Index (ABI).
12. Apply compression dressing if ABI is greater than 0.6.
 - ▶ **Rationale:** Effective compression bandages generate 40–70 mmHg of pressure. If arterial insufficiency is present, another ulcer can occur.

NOTE: Medicinal maggots were originally used in the 1930s. In the past 10 years they have been reintroduced, now used to debride or eliminate necrotic tissue and remove pathogenic bacteria. There is evidence from recent studies that they may accelerate wound healing by promoting the formation of granulation tissue. The larvae feed on dead tissue, cellular debris, and exudates from necrotic wounds through extracorporeal digestion. This treatment has proven to be effective in clients with venous ulcer, diabetic ulcers, and arterial ulcers.

13. Reposition leg in elevated position. Leg should be elevated 18 cm above heart for 2 to 4 hr during the day and night. ▶ **Rationale:** This prevents edema and venous stasis and promotes healing.
14. Remove gloves and place in biohazard bag. Place all used supplies in bag.
15. Place biohazard bag in appropriate receptacle.

Clinical Alert

Use of semiocclusive dressings reduces incidence of wound infections by more than 50%. They maintain a moist environment, reduce airborne bacteria, and provide a mechanical barrier for bacterial entry.

Clinical Alert

Compression Therapy

Inelastic System

An Unna boot is frequently used to control edema in lower extremities. An inelastic bandaging system is applied to the lower extremity. As it dries it becomes rigid, and when calf muscles press against the rigid bandage, it pumps blood more effectively. This system can be used for both mobile and immobile clients. As edema subsides, the boot becomes less effective.

Elastic Therapy

Graduated compression and multilayer compression stockings and compression pumps are more effective in increasing venous return. Both mobile and immobile clients can use these stockings, although it is more difficult for the client who is mobile. The stockings are available in different pressures.

16. Perform hand hygiene.
17. Lower bed and raise side rails.
18. Assess peripheral circulation every 4 hr. ▶ **Rationale:** This ensures compression dressing is not too tight.

Arterial Ulcers

Assessment

- Assess arterial flow; dorsalis pedis, femoral, popliteal, or posterior tibial.
- Use Doppler to assess pulses if necessary.
- Assess Ankle–Brachial Index; below 0.5 indicates severe arterial insufficiency.
- Assess temperature of skin.
- Observe color of extremities.
- Assess for presence of pain when client resting.

Treatment

- Debridement
- Pain control
- Occlusive dressings: reduce pain, protect the wound from infection, control exudates, enhance autolytic debridement, maintain moist wound environment.
- Secure dressing with gauze; do not use tape as skin is fragile and tears easily.
- Management of disease process, i.e. BP, eliminate smoking, control blood glucose
- Surgical intervention to improve circulation
- Vacuum compression therapy
- Hyperbaric oxygen therapy

EVIDENCE-BASED PRACTICE

Treatment of Ambulatory Venous Ulcer Patients and Warming Therapy

This was a limited study, but other studies indicate the same type of findings. Five clients with a mean age of 65 and pressure ulcers for more than 8 months were treated with warm-up therapy along with zippered compression stockings for 2 weeks. These clients were monitored for 12 weeks. The therapy consisted of warm therapy three times a day for 1 hr each at a temperature of 38°C. The results indicated that four of five clients increased granulation tissue and decreased pain. Four of five clients were completely healed during the 12-week follow-up.

Source: Cherry, G. C., & Wilson, J. (1999, September). The treatment of ambulatory venous ulcer patients and warming therapy. *Ostomy/Wound Management* 45(9), 65–70.

Assessing Ankle–Brachial Index (ABI)

Equipment

- Sphygmomanometer (two cuffs, one arm and one leg)
- Stethoscope
- Doppler, handheld

Procedure

1. Review chart to determine whether client has diabetes.
 - ▶ **Rationale:** The ABI may not be reliable in these clients because arterial calcification causes false readings (high). The ABI is used to indirectly assess lower-extremity peripheral blood flow.
2. Explain procedure to client.
3. Place client in supine position. Instruct to lie quietly for 5 minutes.
4. Place cuff above right or left elbow, apply ultrasound gel to brachial pulse area.
5. Hold ultrasound probe at 90° angle on top of gel.
 - ▶ **Rationale:** This position opposes direction of brachial artery blood flow.
6. Inflate cuff pressure to the point that the “whooshing” sound of the brachial pulse stops and continue inflating at least 20 mmHg above that point.
7. Slowly deflate pressure until systolic pulse sound is heard (when “whooshing” sound restarts).
8. Obtain blood pressure readings in both arms. Use the higher systolic pressure as the brachial pressure for the ABI calculations.
9. Wrap leg cuff around leg 5 cm above ankle’s medial malleolus. Place conductivity gel over posterior tibial or dorsalis pedis artery.
10. Place Doppler probe at a 90° angle to dorsalis pedis or posterior tibial artery.
11. Inflate cuff until Doppler sound stops.
12. Deflate cuff slowly while maintaining Doppler probe in place over artery.
13. Obtain two readings of posterior tibial or dorsalis pedis measurements and select highest value to be used in ABI calculation.
14. Divide ankle systolic pressure by brachial systolic pressure to obtain Ankle–Brachial Index (ABI). Normally, ankle pressure is equal to or slightly higher than brachial pressure.
15. Review ABI guidelines to determine severity of arterial insufficiency.
16. Document findings in nurses’ notes and place note on chart for physician.

ABI Guidelines

1.0–1.2 ABI	Normal—No arterial insufficiency
0.8–1.0 ABI	Mild insufficiency
0.5–0.8 ABI	Moderate insufficiency
<0.5 ABI	Severe insufficiency
<0.3 ABI	Limb threatening

Caring for a Wound With a Drain

Equipment

- Same items as for Changing a Wound Dressing
- Sterile cotton applicators
- Sterile safety pin
- ABD dressings
- Gauze pads
- Sterile scissors
- Sterile gloves
- Clean gloves
- Cleansing solution

Preparation

1. Check physician’s orders.
2. Perform hand hygiene.
3. Gather equipment.
4. Provide privacy.
5. Identify client using two forms of identification and explain procedure.
6. Clean off overbed table.
7. Raise bed to HIGH position and lower side rails on working side of bed.

8. Place plastic bag for soiled dressings on bed near wound site.
9. Open sterile packages and place on overbed table.

Procedure

1. Remove tape from client's skin by pulling *toward* the incision. ► **Rationale:** This decreases pain and prevents damage to wound site by preventing a “pull” on the incision.
2. Don clean gloves.
3. Remove soiled dressing.
4. Discard gloves and dressings into plastic bag.
5. Observe wound closely for signs of infection or healing. Don sterile gloves.
6. If pin on the Penrose drain is crusted, replace it with a sterile pin. Be careful not to dislodge drain or suction tubing.
7. Using cotton applicators or gauze pads, cleanse drain site with cleansing solution and then saline.

▲ Use drainage pouches for wounds with drains.

▲ Cleanse the drain site, using a circular motion (unless using chlorhexidine) from the inside to the periphery of the wound. With chlorhexidine, use a back and forth motion.

▲ Place a precut sterile 4 × 4 gauze dressing around the drain site to prevent skin excoriation.

8. Start cleansing at drain site, moving in a circular motion toward the periphery, unless using chlorhexidine swab; then use back-and-forth motion. Hold drain erect while cleaning around it. ► **Rationale:** This prevents contamination of the drain site area.
9. Dry the surrounding skin with gauze swab.
10. Discard applicators in plastic bag.
11. Advance drain if ordered:
 - a. Using sterile forceps, pull drain out of wound the ordered number of centimeters. ► **Rationale:** To facilitate tissue healing.
 - b. Reposition the safety pin so it is at the level of the skin. ► **Rationale:** The pin prevents the drain from slipping back into the wound.
 - c. Cut off the excess tubing with sterile scissors. Leave at least 2 in. of tubing on the outside. ► **Rationale:** This prevents drain from being drawn up into the wound opening.

NOTE: Drains vary in length (25–35 cm or 10–14 in.) and width (1.2–4 cm or 0.5–1.5 in.).

12. Place several 4 × 4 dressings around the drain.
13. Apply gauze pad with a precut slit under the drain site.
14. Apply dry, sterile gauze pads over drain.
15. Apply ABD pads over sterile gauze.
16. Remove gloves and dispose of them in refuse bag.
17. Tape dressing or retie Montgomery straps (tie tapes).
18. Remove bag with soiled dressing from room.
19. Perform hand hygiene.
20. Position client for comfort.
21. Lower bed and raise side rail.

Drainage Pouches for Wounds

Apply a pouch to:

- Collect drainage
- Measure drainage
- Protect skin from drainage
- Contain drainage
- Contain microorganisms so spread is decreased
- Lessen frequency of care; dressing change is every 24–48 hr

Drainage Systems for Wounds

Open Drains: Discharge flows freely into an absorbent dressing or a drainage bag.

Closed Systems: Remove fluid and debris into a closed container (i.e., Hemovac or Jackson–Pratt). Fewer wound infections occur with this drainage system.

Applying an Abdominal Binder

Equipment

Abdominal binder: woven-cotton, synthetic, or elasticized material. Most facilities use commercial Velcro binders.
Safety pins for binders without Velcro closure

Procedure

1. Perform hand hygiene.
2. Explain use of binder to client.
3. Place client in supine position.
4. Ask client to raise hips, and then slide the binder under client's hips at level of gluteal fold. Place top of binder at client's waist.
5. Bring ends of binder around client, and secure by pressing Velcro surfaces together. If using non-Velcro

▲ Bring end of binder around client and secure Velcro surfaces.

binder, secure binder with safety pins placed vertically along edges. Start pinning at bottom of binder and pin toward waist. ► **Rationale:** Pinning binder from bottom to waist provides uplifting support for abdominal muscles.

6. Observe for wrinkles in binder. ► **Rationale:** Wrinkles can cause pressure areas, especially over iliac crest.
7. Assess client's ability to move freely, breathe deeply, and feel secure pressure over abdominal incision. ► **Rationale:** A binder that is too tight may compromise breathing or place pressure on incisional area.
8. Assess effectiveness of binder every 4 hr, and rewrap every 8 hr if non-Velcro binder is used. Many clients use this binder only when ambulating.

▲ Assess effectiveness of binder every 4 hr.

Maintaining Wound Drainage System

Equipment

Specimen cup for measuring drainage
I&O bedside record
Absorbent pad
Clean gloves
Hemovac suction or Jackson–Pratt suction drainage system

Preparation

1. Check physician's order and client care plan.
2. Bring specimen cup to bedside.
3. Identify client and explain procedure, giving client time to ask questions.
4. Provide for comfort and privacy.
5. Perform hand hygiene and don gloves.
6. Elevate bed to workable height.

Procedure

1. Expose catheter insertion site while keeping client draped. Place drainage system on absorbent pad.
2. Examine pump and catheter for patency, seal, and stability. If catheter is occluded, notify physician.
3. Remove Hemovac plug, which is labeled "Pouring Spout," or disconnect tubing from Jackson–Pratt system.
4. Pour drainage into specimen cup.
5. Compress the Hemovac by pushing the top and bottom together with your hands, or compress bulb on Jackson–Pratt.
6. Hold pump or bulb tightly compressed, and reinsert plug or connect tubing to Jackson–Pratt system. ► **Rationale:** This will reestablish closed drainage system.
7. Position suction devices on bed.
8. Measure and record amount of drainage.

▲ Jackson-Pratt drainage system in place.

▲ Empty, measure, and record drainage every shift.

▲ Squeeze bulb and reconnect to drainage tubing after emptying.

▲ Remove Hemovac plug from "Pouring Spout" for emptying.

▲ Compress Hemovac by pushing top and bottom together.

9. Examine drainage for color, consistency, and odor.
10. Discard drainage and container; remove gloves, and wash hands.
11. Send culture specimen to laboratory if ordered.
12. Make client comfortable, and lower bed.
13. Compress evacuator at least every 4 hr to provide suction. Measure drainage at least every 8 hr.

Irrigating Wounds

Equipment

- Sterile irrigation solution, preferably saline or Ringer's solution
- Commercial wound cleaner container with nozzle
- or
- Sterile irrigating set with 35-mL syringe and 19-gauge Angiocath tip or 19-gauge needle
- Absorbent pad
- Sterile gloves
- Equipment for dressing change

Preparation

1. Check physician's orders and client care plan.
2. Gather irrigation equipment and dressing material.
3. Identify client, using two identifiers.
4. Assemble equipment.
5. Explain procedure to client and answer any questions.
6. Raise bed and lower side rails.
7. Perform hand hygiene.
8. Open sterile packages on the overbed table as with dressing change.
9. Pour sterile irrigating solution into container.

Procedure

1. Place absorbent pads under the client. Place a bath blanket under absorbent pads when irrigating a large wound. ► **Rationale:** This will absorb any spilled irrigation solution.
2. Position client so that solution flows from wound to basin.
3. Don clean gloves.
4. Remove and discard used dressing.
5. Remove gloves and discard into plastic bag.
6. Place overbed table near working area with all packages open.
7. Don sterile gloves.
8. Inspect area surrounding wound for redness, tissue integrity, and signs of granulating tissue.
9. Place sterile basin under wound area.
10. Draw solution from sterile container into 35-mL syringe with syringe or Angiocath tip. Increasing syringe size decreases pressure of stream or increasing bore of catheter tip increases pressure.

NOTE: The goal of irrigation is to remove bacteria and debris without injury to normal tissue. Irrigation pressure of 5 to 15 pounds per square inch (psi) is required to accomplish the goal.

Clinical Alert

If wound has moderate to heavy drainage, alginate dressings should be used. Alginate forms a gel when it comes in contact with wound fluid. It absorbs up to 20 times its weight in fluid. It can be used in infected and noninfected wounds. It is not to be used in dry wounds, as it can dehydrate the wound.

11. Cleanse wound in the direction from least contaminated to most contaminated areas.
12. Open commercial cleaning solution package if using for irrigation.
 - a. Read directions on commercial wound cleaner container to determine appropriate distance nozzle is positioned from wound during irrigation.
 - b. If nozzle is too close to the wound, force may be higher than expected.
 - c. If nozzle is too far from the wound, force may be lower than needed.
 - d. If saline solution is used, deliver irrigant with 8 psi (pounds per square inch) pressure. The 35-mL syringe and 19-gauge Angiocath tip delivers this pressure. ► **Rationale:** Pressures effective in wound cleansing should be between 4 psi and 15 psi in order to effectively clean the wound surface by forcefully loosening foreign materials and nonattached bacteria.
 - e. Repeat until all irrigation solution has been used.
13. After the irrigation, cleanse client's skin around wound and dry.
14. Apply sterile dressing.
15. Dispose of equipment properly.
16. Remove gloves. Check to see that client is comfortable before leaving the room.
17. Lower bed and raise side rails.
18. Perform hand hygiene.

Debridement

Physical removal of affected tissue by debridement is the most effective method of cleaning the wound. Infected tissue is best removed by surgical debridement. Other methods of debridement include chemical or enzymatic, mechanical, or autolytic. Stage II ulcers can be debrided by gentle mechanical debridement using mesh gauze moistened with saline, hydrocolloid dressings, or enzymatic debriding. Stage IV and large stage III ulcers require surgical debridement. Surgical debridement uses sterile instruments and requires local anesthesia. Only a qualified clinician can use this technique.

Chemical debridement is slower than surgical debridement but is able to be used in home care and long-term care settings. Proteolytic enzymes such as collagenase or papain-urea are commonly used chemical agents. Mechanical debridement is accomplished through whirlpool treatments. Autolytic debridement uses moisture-retentive or moisture-donating dressings to facilitate digestion of tissue by the client's own enzymes and phagocytes.

Biologic or larval debridement is currently being used for wounds that are difficult to heal.

Teaching Wound Care to Clients

Procedure

1. Begin client teaching as soon as client is able to participate in activity. ► **Rationale:** Client will need to care for wound at home for a period of time before sutures are removed and/or wound is healed.
2. Assess wound daily for any changes in color, odor, drainage.
3. Keep wound dry and clean.
4. Instruct client that he/she can take a shower, unless contraindicated by wound condition (i.e., dressing on wound, splint, etc.).
5. Do not remove dressing unless it is wet or soiled. If soiled or wet, change dressing according to directions. Wound or dressing can be covered by plastic when taking shower.
6. Report any signs of infection to healthcare provider: erythema, edema around incision site, warmth and/or tenderness surrounding incision site, discharge or foul odor from site, streaks on the skin running from wound, chills or temperature above 100° F: ► **Rationale:** These are signs and symptoms of SSIs or wounds.
7. After sutures are removed, instruct client to:
 - a. Follow instructions from healthcare provider regarding activity level. ► **Rationale:** Even though sutures are removed, wound is not completely healed and will continue to strengthen over the next weeks.
 - b. Keep suture line clean, cleansing it using soft strokes, and pat dry.
 - c. Observe wound edges, they will appear red and slightly raised; this is normal.
 - d. Observe suture site; if site continues to be reddened and painful to pressure beyond 8 weeks, notify healthcare provider. ► **Rationale:** This could indicate excessive collagen formation.

DOCUMENTATION for Wound Care

- Observation of wound site, including amount, color, and odor of drainage, as well as appearance of suture site
- Document color of wound: serous—clear, watery, plasma; serosanguineous—plasma and red blood cells; sanguinous—bloody; purulent—thick drainage
- Observation of granulating necrotic or epithelial tissue
- Observations pertinent to client's tolerance of procedure
- Observation of skin condition around incision site; erythema, maceration, induration, edema
- Changes in vital signs that indicate possible infection
- Client's activity level, any incontinence
- Compliance with prescribed treatment
- Type of dressing applied
- Material used in wound packing
- Observations on wound irrigation
- Type and amount of irrigation solutions used
- Unusual tension on sutures if present
- Amount and color of Hemovac or Jackson–Pratt drainage
- Document undermining using clock orientation; measure in centimeters (i.e., 2 to 5 o'clock)
- Tissue viability; percent healthy and necrotic tissue relative to entire wound
- Signs and symptoms indicating potential SSI
- Teaching information provided to client

CRITICAL THINKING Application

Expected Outcomes

- Wound care is provided for contaminated wound and healing occurs.
- Drainage system functions without obstructions.
- Wound irrigation is completed using sufficient pressure to cleanse wound bed.
- Abdominal binder supports client's abdominal wound.
- Compression dressing applied to vascular ulcer site.

Unexpected Outcomes

Wound becomes infected with multiple microorganisms.

Alternative Actions

- Notify physician about changes in color or odor of drainage.
- Obtain culture and sensitivity if physician orders one.
- Wash your hands thoroughly after caring for client to prevent the spread of infection.
- Pay strict attention to changing dressings.

Wound does not heal.

- Evaluate use of dressing and perhaps choose a different type of dressing.
- Assess nutritional status. Increase protein and carbohydrates if not contraindicated.
- Determine availability of a vacuum-assisted closure machine.

Edges of wound split open (wound dehiscence).

- Place client in supine position. Apply butterfly tape to wound edges. Cover opening with sterile dressings.
- Apply binder for abdominal incisions after obtaining order.
- Notify physician if signs of infection are present.
- Obtain culture of drainage if physician orders one.
- Observe client for signs of shock. If client in shock, notify physician immediately.
- Encourage high-protein diet.

Evisceration occurs (protrusion of bowel contents).

- Institute emergency measures. Place the client in supine position. Cover bowel with sterile gauze moistened with sterile saline. Have IV-certified nurse insert IV catheter and infuse normal saline. Reassure client. Obtain vital signs, and treat for shock if present.
- After above measures are completed, notify physician, and prepare client for return to surgery.
- After surgical repair, notify dietician for diet change to increase protein and vitamin C in diet.
- Apply abdominal binder if ordered.

Wound hemorrhages.

- Outline area of blood on dressing with a pen and observe outline to see how quickly the bleeding spreads.
- If bleeding is excessive, notify the physician immediately.
- Apply pressure dressing to site if there is excessive bleeding.

Skin appears red and broken.

- Clean area with sterile saline and dry thoroughly with sterile 4 × 4 pads.
- Apply moisture-retentive dressing.

Wound is too extensive for application of drainage.

- Obtain Stomahesive or Hollihesive 8 × 8 sheets and cut on diagonal 1/8 to 1/4 in. larger than wound.

ABD pads cannot contain drainage.

- If larger barrier needed, Stomahesive may be pieced together to form larger barrier, reinforcing juncture points with Karaya paste.
- A superadhesive pouch may then be applied.
- If dressings are used, they may be secured with Montgomery straps (tie tapes).

Abdominal binder is not effective in supporting incisional area.

- Evaluate the effectiveness of the abdominal binder.
- Assess if the binder is properly positioned at the hip level and waist level to provide support.
- Assess if the binder is too loose.

Client is too large for the abdominal binder.

- Fold a drawsheet in half lengthwise and place under client. Position the edges at the waist and pubic area.
- Pull tightly on the drawsheet, and secure the edges with safety pins.

Drainage system expands quickly after being reconnected.

- Check all connections for an air leak because properly functioning reservoirs expand slowly.

Client is too large for bed.

- Request use of BariCare bed.

Client's assessment indicates he/she is at high risk for SSI

- Administer appropriate antibiotic 1 hr before surgery.
 - If client has a chronic illness, monitor carefully for signs and symptoms of SSIs postoperatively.
 - If client's surgery is not urgent, treat condition and then reschedule surgical intervention.
-

Promoting a Moist Environment

Nursing Process Data

ASSESSMENT Data Base

- Assess wound edges for presence of granulation tissue.
- Assess for changes in amount of drainage.
- Assess whether necrotic tissue is decreasing in amount.
- Identify whether appropriate dressing is used for wound care.

PLANNING Objectives

- To promote wound healing by secondary intention
- To maintain a moist environment conducive to wound healing
- To provide the most appropriate treatment for wound care
- To enhance local healing
- To maintain sterile technique throughout procedure
- To remove trapped exudate from wounds

IMPLEMENTATION Procedures

- Applying Wet-to-Moist Dressings924
- Using Hydrocolloid Dressing926
- Using a Hydrocolloid Wafer Dressing927
- Using a Foam Dressing928
- Applying a Transparent Film929

EVALUATION Expected Outcomes

- Wound heals without complications.
- Sterile technique is maintained throughout procedure.

Critical Thinking Application931

- Expected Outcomes931
- Unexpected Outcomes931
- Alternative Actions931

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
and Skill Checklists

Applying Wet-to-Moist Dressings

Equipment

- Sterile 4 × 8 noncotton gauze dressings
- Semiocclusive dressing, optional
- Sterile gloves
- Clean gloves
- Tape
- Plastic bag or receptacle for contaminated dressings
- Sterile normal saline solution
- Sterile receptacle (round basin or emesis basin) if dressing not in commercial pack
- Montgomery straps, if desired

Clinical Alert

Wet-to-dry dressings are used only to debride wounds, as they cause tissue damage. Maceration of healthy tissue can occur with dressings that are always wet. Dry dressings cause damage to granulating tissue if removed without first soaking the gauze.

Preparation

1. Check physician's orders.
2. Perform hand hygiene and gather equipment.
3. Identify client using two forms of identification.
4. Explain procedure to client.
5. Provide privacy.
6. Raise bed to HIGH position, and lower side rail nearest you.
7. Remove tape by pulling it toward the wound.
 - ▶ **Rationale:** This action prevents injury to newly formed tissue.
8. Don clean gloves.
9. Remove wound packing by gently grasping the gauze without touching the wound and tear it away at a right angle from the wound surface.
 - ▶ **Rationale:** Touching only the gauze prevents contamination of the wound.
10. Place soiled dressings in disposable bag.

11. Remove gloves, and dispose of them in bag.
12. Perform hand hygiene.

Clinical Alert

Heat lamps should not be used to treat pressure ulcers. Preferred wound care is to promote a clean, moist environment.

Procedure

1. Open packages of dressings making sure sterility is maintained.
2. Pour normal saline solution over dressings.
3. Don sterile gloves.
4. Pick up sterile gauze dressings one at a time.
5. Fluff each dressing, and place over wound.
 - ▶ **Rationale:** If packed tightly, dressing can prevent wound edges from contact with capillaries.
6. Place gauze in the wound, covering all exposed surfaces. Press gauze lightly into depressions or cracks.
 - ▶ **Rationale:** Necrotic tissue is more prevalent in these areas.
7. Unfold a moist, sterile, 4 × 8 (ABD pad) dressing into a single layer and place it on top of wet dressings covering the wound area (not on skin).
8. Place a dry 4 × 8 pad over the dressing to hold it in place. Some protocols call for semiocclusive dressing in place of pad.
9. Remove gloves, and place in plastic bag.
10. Tape only the edges of the dressing. Montgomery tapes may be used to prevent excessive skin irritation and damage due to frequent dressing changes.
11. Position client for comfort. Lower bed and raise side rail to UP position, if appropriate.

▲ Open sterile packages before beginning dressing change.

▲ Pour sterile saline solution over dressings to moisten.

▲ Fluff dressings and apply over wound, covering all exposed surfaces.

▲ Place moist ABD pad over dressings; then cover with dry pad.

12. Discard soiled material in appropriate container.
13. Perform hand hygiene.
14. Observe wound for excessive drainage or drying out of dressing between dressing changes. Remoisten dressing if dry. ► **Rationale:** Unless excessive drainage occurs, or dressing dries out, dressings are usually changed every 8 hr.

15. Provide client or family teaching regarding wound care, if appropriate.

NOTE: These dressings function as an osmotic dressing. Normal saline is isotonic. As water evaporates from saline dressing, it becomes hypertonic and fluid from wound tissue is drained into dressing.

TABLE 25-5 Additional Moist Wound Dressings

Type of Alternative Use		Outcome of Treatment	Considerations
Hydrogel Sheet	<ul style="list-style-type: none"> • Interacts with aqueous solutions • Used with minor wounds with light to moderate drainage • Absorbs minimal to heavy exudates • Cannot be used with infected wound • Nonadherent 	Softens necrotic tissue Creates moist environment	Use outer dressing to prevent wound from drying out Change dressing every 1–2 days
Impregnated Gauze Dressing	<ul style="list-style-type: none"> • Absorbs minimal to moderate exudates • Nonadherent 	Conforms to irregular surfaces Eliminates dead space Creates moist environment	Requires outer dressing Change daily Non-absorptive
Alginate*	<ul style="list-style-type: none"> • Absorbs heavy exudates • Converts to gel when comes in contact with wound drainage • Easily removed from wound • Nonadherent • Absorbs up to 20 times its weight in fluid • Can be used in infected and non-infected wounds 	Maintains moist environment Promotes fast healing of wound	Not to be used on dry wounds It dehydrates wound, delaying healing, eschar-covered wounds, third-degree burns or surgical wounds
Foams	<ul style="list-style-type: none"> • Absorbs minimal to heavy exudates • Highly absorbent • Used for deep cavity wounds 	Maintains moist environment Decreases tissue trauma when removed Increases time between dressing changes (3–4 days)	Requires external dressing Can cause drying effect on wound

*Alginates are made from acids that are obtained from brown seaweed. The calcium salts of alginic, mannuronic, and guluronic acids are processed into nonwoven, biodegradable fibers. When the fibers come into contact with fluids, sodium, and calcium ions, it results in the formation of a soluble sodium gel.

Continued

TABLE 25-5 Additional Moist Wound Dressings (Continued)

Type of Alternative Use		Outcome of Treatment	Considerations
Hydrophilic	<ul style="list-style-type: none"> Type of foam dressing Non-adherent Very absorbent 	Cushions wound Traps exudate	Used in wounds with moderate to heavy drainage
Hydrophobic	<ul style="list-style-type: none"> Non-adherent flexible dressing Minimal or no necrotic tissue Used with lightly-to-moderately exudating wounds 	Resists fluid penetration into wound Use on lightly draining wounds Provides cushion to irritated skin	
Medical Hydrolysate of Collagen	<ul style="list-style-type: none"> Soluble and degrades in wound site Absorbs wound exudates Is interactive with wound site to provide mechanical protection against physical and bacterial insult 	Absorbs up to 30 times own weight Used in stage I-IV pressure ulcers Accelerates tissue remodeling and reduces scarring	Cover with nonstick dressing Soak dressing in warm water before removing
Anticoat 7 Silver-coated contact dressing	<ul style="list-style-type: none"> Used for wounds with moderate to heavy exudates Has an antimicrobial barrier to protect against bacterial contamination and infection Calcium in the dressing provides antimicrobial to protect against bacterial contamination and infection Kills bacteria faster than any other forms of silver dressing 	Used for leg ulcers Pressure ulcers Diabetic foot ulcers Burns	Stays in place for up to 3 days to provide moist environment

EVIDENCE-BASED PRACTICE

Silver-Eluting Antimicrobial Dressings Don't Help Leg Ulcers

Silver-eluting antimicrobial dressings have not been found to help heal leg ulcers to any greater extent than other dressings. A study conducted in the United Kingdom compared these dressings with standard low-adhesive bandages in 213 elderly clients. The results in 6 months indicated the wounds of the clients in the control group had healed 77% and those of the clients in the pilot group had healed 85%. By 1 year, the wounds of clients in both groups had healed by 96%. The silver dressing cost five times as much as the standard dressing. The cost of treating the client with the silver dressing was 30% more than the standard dressing. The study found there was little to support the use of silver or any other antimicrobial dressings in the treatment of venous leg ulcers.

Source: (2010, January). *The American Journal of Nursing (News Caps)* 110(1), 20.

Using a Hydrocolloid Dressing

Equipment

- Sterile normal saline
- Hydrocolloid dressing (e.g., DuoDERM, Restore, Ultec, Comfeel Plus)
- Hydrogel if needed (ClearSite, Aquasorb)
- Sterile 4 × 4 gauze pads
- Hypoallergenic tape
- Clean gloves
- Skin prep, optional

NOTE: These dressings are a combination of adhesive and gelling polymers that are impermeable to oxygen, water, and water vapor. They promote a moist wound environment, aid in autolytic debridement, and have no toxic components. They are waterproof and bacteria proof. These dressings are best used in clients who have partial- to full-thickness wounds with minimal to moderate exudates such as for pressure ulcers, skin tears, surgical wounds, and burns.

Procedure

1. Select dressing size to ensure coverage 1¼ in. beyond ulcer margin. (Dressing available in 4 × 4 to 8 × 8 sizes.) ▶ **Rationale:** This ensures complete covering of wound. Use for small ulcers and in stage II and III ulcers.

NOTE: These dressings can be used for dry wounds as they contain 95% water. They are occlusive and do not allow water or bacteria into the wound. Hydrocolloid causes the pH of the wound surface to drop, and this acidic environment can inhibit bacterial growth.

2. Perform hand hygiene and don clean gloves.
3. Cleanse skin with gauze pad moistened with sterile normal saline and pat dry with gauze pad.
4. Measure wound using pliable device.
5. Apply skin prep to surrounding skin to protect, if ordered.

▲ Hydrocolloid dressing.

Clinical Alert

Hydrocolloids cannot be used if wound or surrounding skin is infected. The dressings are not used on wounds with heavy drainage or wounds with deep tunnels.

6. Fill ulcer area with Hydrogel if ordered—usually used with stage III or IV pressure ulcer of the hip when exudate is present. Do not overfill with gel.
 - ▶ **Rationale:** Facilitates autolytic debridement of devitalized tissue.
 7. Warm dressing by holding in hands. ▶ **Rationale:** To increase activity of adhesive, and it makes dressing more pliable.
 8. Remove silicone release paper backing from dressing. Minimize finger contact with adhesive surface.
 - ▶ **Rationale:** Dressing is sterile and contamination should be avoided.
 9. Center dressing over affected area and extend at least 1 in. onto periwound skin. Gently roll dressing over pressure ulcer—do not stretch dressing. ▶ **Rationale:** Stretching the dressing may cause wrinkling of dressing, which allows air to enter wound.
 10. Placing dressing one-third above wound and two-thirds below wound maximizes time between dressing changes.
 - ▶ **Rationale:** Increases absorption capacity of dressing.
 11. Mold the dressing gently to skin and hold down with hand for approximately 1 minute.
 12. Apply skin prep to area that is to be covered by tape if ordered. Allow to dry. Do not apply skin prep under hydrocolloid dressing. ▶ **Rationale:** Hydrocolloid dressings are placed over broken skin; skin prep may cause damage to skin.
 13. Picture-frame sides of hydrocolloid dressing with silk or hypoallergenic tape.
 14. Check dressing each shift for impaired integrity.
 15. Change dressing at first sign of impaired integrity. Dressings should not be left on longer than 7 days. Usually left in place for 3–4 days.
- NOTE:** DuoDERM is removed when exudate seeps from edges of dressing or white blister appears under dressing. Comfeel Plus is changed when dressing becomes transparent or there is leakage.
16. Remove dressing by pressing hand down on adjacent skin surface while carefully lifting edge of dressing from skin. Continue lifting dressing around periphery until all edges are released, then lift dressing carefully away from wound.
 17. Remove gloves and perform hand hygiene.
 18. Record stage, size, and appearance of ulcer; date; and reason for removal of hydrocolloid dressing.
- NOTE:** Although frequently listed as wound care alternatives, topical disinfectant agents such as iodine and silver sulfadiazine are very controversial in wound care. Iodine is cytotoxic to fibroblasts and can impair wound healing. Silver solutions are sometimes used to prevent bacterial colonization in infection-prone areas. They do not eliminate existing infections.

Using a Hydrocolloid Wafer Dressing

Procedure

1. Warm hydrocolloid sheet wafer between hands.
2. Apply wafer 1–2 in. larger than wound.
3. Monitor for periwound maceration.
4. Monitor dressing, as moisture from wound causes wafer to form a gel over wound.
5. Change every 3–7 days or as needed.
6. Secure edges with tape.
7. Remove dressing carefully. Residual may be noted on wound. Do not remove residual.

TABLE 25-6 Hydrocolloid Dressings

Dressing	Uses
Hydrocolloid dressing (2 mm thick) Exterior surface protects wound from contamination	On partial and full thickness wounds with exudate
Thin hydrocolloid dressing (less than 1 mm thick)	On superfluid wounds with minimal exudate and to protect areas at risk for skin breakdown
Hydrocolloid paste	To manage dermal wounds with light drainage
Hydrocolloid gel	On partial- and full-thickness wounds Fills dry wound cavities Promotes autolytic debridement

Hydrogel Dressings

- Hydrogel dressings contain 95% water; they are very absorbent and dehydrate easily when not covered with a secondary dressing.
- Dressings cannot absorb much exudate; they should be used for dry wounds such as skin tears, surgical wounds, and radiation therapy burns.
- Dressings are nonadhesive; can be transparent and conform to wound surfaces.
- Sterile aqueous hydrogen fiber is used to fill cavity with gel; also used to fill dead space in large wounds. Do not overfill wounds to prevent tissue damage.
- Hydrogel sheets are placed in direct contact with wound bed and margins; air bubbles and plastic covering on sheet must be removed. The unique cooling properties soothe painful wounds.

Applying a Foam Dressing

Equipment

- Adhesive foam dressing
- Receptacle for soiled dressing

Preparation

1. Identify client using two identifiers.
2. Perform hand hygiene.
3. Remove old dressing and discard in appropriate receptacle.
4. Clean wound according to policy.
5. Complete skin assessment and identify wounds that need dressings.
6. Measure wound and obtain dressing size: 1–2 in. larger than wound.

NOTE: Foam dressings are particularly useful for wounds with moderate to heavy exudate. The absorptive ability of the foam dressing must match the exudates property of the wound's exudate. Dry wounds with a scab or eschar are not candidates for foam dressing. They do not benefit from the foam dressing and the wound may dry out.

Procedure

1. Using foam dressing as primary dressing, measure wound and cut 1–2 in. larger than wound. ► **Rationale:** To protect periwound areas.
2. If wound is irregular, cut foam dressing to match shape of wound or specific part of body, such as toes.

3. If using foam under compression stockings, place foam in cavity of the wound. Leave space in cavity for expansion of dressing as exudates are absorbed.
4. Press down adhesive border to secure dressing.
5. Apply barrier cream to surrounding skin according to policy.
6. Perform hand hygiene.
7. Assess wound frequently if large volume of exudates in wound.
8. Change dressing every 3–5 days unless wet or soiled, then change as necessary

Foam dressings are useful in the following wounds:

- Wounds requiring negative pressure
- Minor burns
- Skin grafts and donor site
- Pressure ulcers
- Arterial and venous leg ulcers
- Sutured wounds

Foam can also be used around tracheostomy and gastrostomy tubes to absorb drainage and manage heavy exudate in wounds.

TABLE 25-7 Comparisons of Moisture-Retentive Dressings

	Transparent	Hydrocolloid
Common Brands	Tegaderm Op-Site Bioclusive	Tegasorb DuoDERM Comfeel Restore
Characteristics	Sterile Semipermeable membranes with hypoallergenic adhesive Permeable to oxygen and moisture vapor Allows oxygen exchange Impermeable to bacteria, prevents contamination	Impermeable to oxygen Dressing gel maintains moist environment that promotes autolysis Impermeable to external bacteria and contamination Minimally to moderately absorptive
Function	Provides moist environment Promotes autolysis and protects newly formed tissue Assists with debridement	Dressing contains hydroactive particles that absorb exudate to form a hydrated gel over wound When dressing removed, gel separates from dressing, which protects newly formed tissue
Use	Easy assessment of wound; dressing is transparent Nondraining or minimally draining wounds only, nonabsorbable Pressure ulcers, stage I and some stage II Minor burns, lacerations	Absorbs exudate while preserving moist environment needed for autolysis of slough Irrigate gel with saline to allow for assessing wound Pressure ulcers, some stage III and some clean stage IV Wounds with mild or moderate exudate Wounds with necrosis or slough
Contraindications	Infected wounds Wounds with fragile surrounding skin	Wounds that need frequent assessment, not transparent Wounds with heavy exudate

Applying a Transparent Film

Equipment

- Sterile normal saline
- Transparent dressing (e.g., Op-Site, Tegaderm, Bioclusive)
- Sterile 4 × 4 gauze pads
- Scissors
- Hypoallergenic tape
- Clean gloves
- Plasticizing agent (e.g., skin prep [optional])
- Syringe with 26 gauge needle, if needed

Preparation

1. Check physician's orders and client care plan.
2. Check type of dressing ordered. ► **Rationale:** These dressings are very important in preventing pressure ulcers; they prevent friction and shear over bony prominences when moving clients.
3. Gather supplies.
4. Obtain appropriately sized transparent dressing. Dressing can be applied to flat surface. (Coccyx area cannot be treated with this type of dressing.)
5. Perform hand hygiene.
6. Identify client using two types of identification and explain procedure to client.
7. Provide privacy.

Procedure

1. Raise bed to HIGH position, and lower side rail on working side of bed.
2. Don clean gloves.
3. Remove old dressing, “walk off” dressing from one edge to the other, and discard in appropriate receptacle.
4. Wash pressure ulcer with sterile gauze pads moistened with sterile normal saline.
5. Dry thoroughly with sterile gauze pad.
6. Measure wound using pliable device. ► **Rationale:** Comparison of measurement assists in determining effectiveness of treatment.
7. Apply plasticizing agent (skin prep, skin gel) over surrounding tissue if ordered. ► **Rationale:** Do not apply directly on ulcer area because the agent contains alcohol, which burns the ulcer area. *Alternate Treatment:* If skin is irritated, apply No Sting Barrier Film Spray to area surrounding tissue. ► **Rationale:** To protect/prevent skin breakdown.

▲ Dressing carts may be used to keep supplies closer to client area.

▲ Obtain specific dressing tray for ordered treatment.

▲ Assess size of wound to determine appropriate size of transparent dressing.

▲ Remove backing from Op-Site dressing before applying.

▲ Apply transparent adhesive dressing over wound.

Clinical Alert

Transparent film dressings remain in place for 5–7 days. These dressings are adhesive, permeable to moisture, vapor, and atmospheric gases. They are bacteria-proof and waterproof. It is imperative to observe the ulcer area daily to determine whether a large amount of secretions or serous fluid has accumulated under dressing. If fluid has increased, aspirate with a 26-gauge needle. These dressings are not used for infected areas.

8. Loosen transparent dressing from one side of backing paper.
9. “Walk on” dressing: Start at one edge of site and gently lay the dressing down, keeping it free of wrinkles. Allow at least a 1.5-in. margin of dressing beyond ulcer margin. ► **Rationale:** This ensures coverage of entire wound area.
10. Cut off tabs if using Op-Site after wound is completely covered.

11. Tape edges with hypoallergenic tape. ► **Rationale:** This assists in preventing frequent dressing changes due to loose dressings. These dressings can remain in place for 1 week.
12. Remove gloves and discard in appropriate receptacle.
13. Position client for comfort.
14. Lower bed and raise side rails.
15. Remove and discard equipment.
16. Perform hand hygiene.

DOCUMENTATION for Promoting a Moist Environment

- Condition of wound, location, size of wound
- Solution used
- Number and type of dressings used
- Signs and symptoms indicative of wound infection
- Color, consistency, presence of odor, amount of drainage on soiled dressings
- Presence of granular, necrotic, or epithelial tissue
- Condition of skin surrounding wound
- Client's reaction to procedure

CRITICAL THINKING Application

Expected Outcomes

- Wound heals without complications.

Unexpected Outcomes

Wound drainage increases.

Dressings dry between dressing changes.

- Sterile technique is maintained throughout procedure.

Alternative Actions

- Decrease time between dressing changes. Change every 4 hr.
- Obtain order for culture and sensitivity to determine whether different microorganisms are present or antibiotic medication is not sensitive to microorganism.
- Moisten dressing with sterile normal saline before removing to prevent debridement of granulation tissue.
- Ensure that dressing is moist when applied to wound and cover with moist dressing.
- Moisten and change dressing more frequently.
- Semioclusive dressing should be considered.

Chapter 25

UNIT 5

Pressure Ulcers

Nursing Process Data

ASSESSMENT Data Base

- Assess stage of ulcer.
- Assess size and depth of pressure ulcer.
- Assess presence and location of undermining, tunneling, and sinus tracts.
- Identify if infection is associated with pressure ulcer.
- Assess wound exudate.
- Evaluate effectiveness of ulcer treatment.
- Assess healing process of the ulcer.
- Assess other bony prominences for potential formation of pressure ulcers.
- Assess for presence of conditions that inhibit wound healing.
- Assess wound size for changes.

PLANNING Objectives

- To identify the stage of the ulcer
- To provide appropriate treatment for specific ulcer stage
- To promote healing of established ulcer
- To prevent new ulcer formation
- To prevent spread of pathogens from ulcerated area

IMPLEMENTATION Procedures

- Preventing Pressure Ulcers935
- Providing Care for Clients With Pressure Ulcers.....938

EVALUATION Expected Outcomes

- Stage of pressure ulcer is accurately assessed.
- Pressure ulcer is treated effectively according to stage of ulcer formation.
- Pressure ulcer is healing within usual time frame.
- Skin remains free of breakdown in surrounding areas of pressure ulcer.
- Absence of additional pressure ulcer formation.

Critical Thinking Application 939

- Expected Outcomes 939
- Unexpected Outcomes 939
- Alternative Actions 939

Pearson Nursing Student Resources

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Nursing Guide for Assessment of Clients at Risk for Pressure Ulcers

Factors that contribute to development of pressure ulcers:

- Pressure
- Friction
- Shearing
- Moisture

Identify at-risk individuals needing preventative measures:

- Bed- and chair-bound individuals
- Clients with impaired ability to reposition themselves
- Clients who are immobilized
- Clients who are incontinent
- Clients with nutritional deficits, such as inadequate dietary intake, malnutrition
- Clients with altered level of consciousness

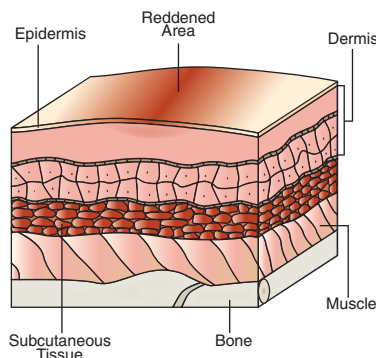

- Identification of stage I pressure ulcer may be difficult in a dark-skinned client.

A risk assessment tool should be used for all clients admitted to long-term care facilities, an acute care setting, or receiving home care (Braden scale or Norton scale). Systematic reassessments should be done at designated intervals.

- Nursing homes: Assess on admission and every week for 1 month, then every 3 months. Clients develop pressure ulcers within first month in nursing home.
- Home: Assess on admission and every visit. Instruct family to notify nurse if skin condition changes.
- Acute care: Assess on admission and every shift for at-risk clients in critical care units or daily to every other day for stable clients.

TABLE 25-8 Pressure Ulcer Staging and Treatment

Stage	Treatment Protocol for Pressure Ulcer Stages
<p><i>Stage I:</i> Intact skin with non-bleachable redness of a localized area usually over a bony prominence. Darkly pigmented skin may not have visible blanching; its color may differ from the surrounding area. The area may be painful, firm, soft, warmer or cooler as compared to adjacent tissue.</p>	<p>Unstageable Ulcers: Full thickness tissue loss in which the base of the ulcer is covered by slough (yellow, tan, gray, green, or brown) and/or eschar (tan, brown, or black) in the wound bed. Until enough slough and/or eschar is removed to expose the base of the wound, the true depth, and therefore stage, cannot be determined. National Pressure Ulcer Advisory Panel, February 2007</p>

Continued

TABLE 25-8 Pressure Ulcer Staging and Treatment (Continued)

Stage

Treatment Protocol for Pressure Ulcer Stages

Stage II: Partial thickness loss of dermis presenting as a shallow open ulcer with a red pink wound bed, without slough. May also present as an intact or open/ruptured

serum-filled blister. It presents as a shiny or dry shallow ulcer without slough or bruising. Bruising indicates suspected deep tissue injury.

Stage II pressure ulcer. ▶

Stage III: Full thickness tissue loss. Subcutaneous fat may be visible but bone tendon or muscle are not exposed. Slough may be present but does not obscure the depth of tissue loss. It may include undermining and tunneling. The depth of this

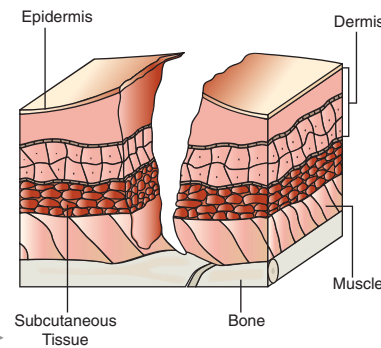

stage varies by the anatomical location. The bridge of the nose, ear, occiput and malleolus do not have subcutaneous tissue and therefore the ulcers can be shallow in contrast to areas of significant adipose tissue.

Stage III pressure ulcer. ▶

Stage IV: Full thickness tissue loss with exposed bone, tendon or muscle. Slough or eschar may be present on some parts of the wound bed. It often includes undermining and tunneling. The depth of this stage ulcer varies by anatomical location.

This stage can extend into muscle and/or supporting structures (fascia, tendon or joint capsule) making osteomyelitis possible. Other areas of the body without subcutaneous tissue will react the same as Stage III ulcers.

Stage IV pressure ulcer. ▶

Source: Wound Ostomy and Continence Nurses Society (WOLN) in the Standards of Care, 1992, the Agency for Healthcare Research and Quality (AHRQ), and the National Pressure Ulcer Advisory Panels (NPUAP). Guidelines published in *Advances in Wound Care* (1999, Nov.–Dec.), with update in revision of Stage I definitions by NPUAA.

Assessment for Dark-Skin-Tone Clients

Stage I. Ulcers appear with persistent red, blue, or purple hues. To assess darker skin tones that do not show erythema, shine a light at skin level to check for color change. Palpate area for induration or edema.

Stage II. Solid, smooth, dark pink tissue exposing basal membrane; exposed dermis epithelization.

TABLE 25-8 Pressure Ulcer Risk Assessment Scales

Norton Scale									
Physical Condition		Mental Condition		Activity		Mobility		Continence	
Good	-4	Alert	-4	Walks	-4	Full	-4	Good	-4
Fair	-3	Apathetic	-3	Walks with help	-3	Slightly limited	-3	Occasional incontinence	-3
Poor	-2	Confused	-2	Sits in chair	-2	Very limited	-2	Frequent incontinence	-2
Very poor	-1	Stuporous	-1	Remains in bed	-1	Immobile	-1	Urine and fecal incontinence	-1
Total ____		Total ____		Total ____		Total ____		Total ____	
Grand total = ____									

A score of 14 or less indicates risk of pressure ulcer; a score under 12 indicates high risk.

Braden Scale											
Sensory Perception		Moisture		Activity		Mobility		Nutrition		Friction and Shear	
No impairment	-4	Rarely moist	-4	Walks frequently	-4	No limitations	-4	Excellent	-4		
Slightly limited	-3	Occasionally moist	-3	Walks occasionally	-3	Slightly limited	-3	Adequate	-3	No apparent problems	-3
Very limited	-2	Very moist	-2	Chairfast	-2	Very limited	-2	Probably inadequate	-2	Potential problem	-2
Completely limited	-1	Constantly moist	-1	Bedfast	-1	Completely immobile	-1	Very poor	-1	Problem	-1
Total ____		Total ____		Total ____		Total ____		Total ____		Total ____	
Grand total = ____											

Assign a score of 1 to 4 in each category. Total the score; no risk: 19–23; at risk: 15–18; moderate risk: 13–14; high risk: 10–12; very high risk: 9 or below.

Norton Scale: Adapted from *Pressure Ulcers in Adults: Predictions and Prevention*. AHCPR Publication No. 92-0047 (May 1992), p. 15.

Braden Scale: Adapted from *Pressure Ulcers in Adults: Predictions and Prevention*. AHCPR Publication No. 92-0047 (May 1992), pp. 16–17.

Note: Refer to actual scales for detailed information about both scales.

Preventing Pressure Ulcers

Procedure

- Inspect skin at least on admission and once a shift, particularly over bony prominences. Heels and sacrum are most common areas for skin breakdown. Use Braden or Norton scale for assessment. Document assessment findings. **►Rationale:** If skin is red or skin breakdown is evident on admission, Medicare and other payers will reimburse for treatment. If not evident on admission, treatment costs will not be reimbursed.
- Individualize client’s bathing schedule. Daily baths are not essential. **►Rationale:** Daily cleansing can destroy the skin’s natural barrier, making it more susceptible to external irritants.
 - Avoid hot bath water. **►Rationale:** Tepid water prevents injury to skin.
 - Use mild cleansing agents to minimize dryness.
 - Cleanse skin immediately if urine, fecal incontinence, or wound drainage seeps onto skin.

- d. Provide humidity to prevent drying of skin.
- e. Use cream or thin layer of corn starch to protect skin.
3. Avoid massaging bony prominences. ▶ **Rationale:** Massaging can lead to deep tissue trauma.
 - a. Keep bony prominences from direct contact with one another.
 - b. Use pillow, foam wedges, or other positioning devices.
 - c. Use elbow pads and heel elevators.
4. Promote adequate dietary intake of protein, calories, and nutrients. Protein should be approximately 1.2 to 1.5 g/kg body weight daily. ▶ **Rationale:** Adequate protein intake in addition to vitamins and minerals help prevent pressure ulcer formation.

Clinical Alert

Be alert to altered skin integrity when pressure is reduced in one anatomical area by turning and repositioning, as the newer location may be placed at risk for pressure ulcer formation.

5. Ensure adequate fluid intake. ▶ **Rationale:** Prevent dehydration which is a risk factor for pressure ulcer formation.
6. Reposition bedridden client every 1–2 hr.
 - a. Do not position directly on trochanter.
 - b. Do not turn more than 30° angle.

NUTRITIONAL ASSESSMENT OF CLIENT WITH PRESSURE ULCER(S)

Client Name: _____ **Date:** _____ **Time:** _____
 To be filled out for all clients at risk on initial evaluation and every 12 weeks thereafter, as indicated. Trends will document the efficacy of nutritional support therapy.

Protein Compartments

Somatic:

Current Weight (kg) _____
 Previous Weight (kg) _____ (____ date)
 Percent Change in Weight _____
 Height (cm) _____
 Height/Weight _____
 Current Body Mass Index (BMI) _____ [wt/(ht)²]
 Previous BMI _____ (____ date)
 Percent Change in BMI _____

Visceral:

Serum Albumin _____
 (Normal ≥ 3.5 mg/dL)
 Total Lymphocyte Count (TLC) _____ (optional)
 (White Blood Cell count x percent Lymphocytes/100)
 Guide to TLC:
 • Immune competence ≥ 1,800 mm³
 • Immunity partly impaired < 1,800 but ≥ 900 mm³
 • Anergy < 900 mm³

State of Hydration

24-Hour Intake _____ mL 24-Hour Output _____ mL

Note: Thirst, tongue dryness in non-mouth-breathers, and tenting of cervical skin may indicate dehydration. Jugular vein distention may indicate overhydration.

Estimated Nutritional Requirement

Estimated Nonprotein Calories (NPC) _____/kg Estimated Protein _____ (g/kg)
 Actual NPC _____/kg Actual Protein _____ (g/kg)

Description of Ulcer(s): _____

Indicate Ulcer Sites:

(Attach a color photo of the pressure ulcer(s) (Optional))

^aClassification of pressure ulcers:

- Stage I:** Nonblanchable erythema of intact skin, the heralding lesion of skin ulceration. In individuals with darker skin, discoloration of the skin, warmth, edema, induration, or hardness may also be indicators.
- Stage II:** Partial thickness skin loss involving epidermis, dermis, or both.
- Stage III:** Full thickness skin loss involving damage to or necrosis of subcutaneous tissue that may extend down to, but not through, underlying fascia. The ulcer presents clinically as a deep crater with or without undermining adjacent tissue.
- Stage IV:** Full thickness skin loss with extensive destruction, tissue necrosis, or damage to muscle, bone, or supporting structures (e.g., tendon or joint capsule).

▲ Nutritional assessment of client with pressure ulcer(s).

Source: Pressure Ulcer Treatment: Quick Reference Guide for Clinicians, No. 15. U.S. Department of Health and Human Services, AHCPR.

- c. Raise heels off bed by placing pillows under legs; allow heels to hang over edges.
- d. Use trapeze or turning sheet to reposition client.
7. Encourage mobility or range-of-motion exercises.
 - ▶ **Rationale:** Range-of-motion exercises promote activity and reduce effects of pressure on tissue.
8. Minimize force and friction on skin when turning or moving client. Use turning sheets or Hoyer lift.
9. Maintain head of bed at lowest degree of elevation consistent with medical problem; below 30° if possible.
10. Place at-risk clients on pressure-reducing devices, in both bed and chair, such as foam, static-air, alternating gel, water mattress, or air-fluidized mattress.
11. Place client on specialty bed or mattress if highly at risk for pressure ulcer formation or has an ulcer.
12. Encourage chair-fast clients to shift position every 15 minutes.

▲ Stage I pressure ulcer.

▲ Stage II pressure ulcer.

▲ Stage III pressure ulcer.

▲ Stage IV pressure ulcer.

▲ Eschar must be removed by debridement before staging is done.

▲ Clinical signs of infection.

EVIDENCE-BASED PRACTICE

Pressure Relief in Surgical Clients

Pressure ulcers can begin in the operating room. The occurrence of ulcers can be as high as 45% of surgical clients. There are many risk factors leading to ulcer development in as few as 2.5 hr. Risk factors include position client is placed in during procedure and necessity of positioning devices that place pressure on bony prominences. Medications that constrict blood vessels or lower blood pressure can also lead to pressure ulcers.

Source: Armstrong, D., & Bortz, P. An integrative review of pressure relief in surgical patients. *American Organization of Operating Room Nurses Journal*, 74(3), 645-669 (2001).

EVIDENCE-BASED PRACTICE

Pressure Ulcer Formation

There is an unresolved and inadequately explained issue of how a pressure ulcer progresses. Some clinicians believe the ulcer forms from top down, and other theories have indicated that the pressure ulcer progresses from bottom up. There is limited research on this theory. Current literature indicates that the bottom-up theory is more appropriate, as the deeper tissues are involved in pressure ulcer formation. Latest opinion is that true pressure ulcers are an injury to soft tissue and muscle that occurs from pressure over bony prominences. It is recommended that further research be done.

Source: WOCN Society Response to NPUAP White Papers: Deep Tissue Injury, Stage I Pressure Ulcers, and Stage II Pressure Ulcers: 9th National NPUAP Conference, February 2005. Phyllis Bonham, PhD, MSN, RN, CWOCN, and Janet Ramundo, MSN, RN, FNP, CWOCN.

Clinical Alert

Air-fluidized beds and low-air-loss beds are recommended to manage pressure ulcers, especially in clients with large or multiple ulcers.

Air-Fluidized

Warm, pressurized air circulates through beads in the bed and creates support surface. Polyester sheet allows for moisture and air to pass through, keeping skin dry. Treatment can take several months. Use of this bed is very expensive.

Low-Air-Loss

Head and foot of bed can be elevated. Bed is a modified standard bed frame, lighter and more portable than air-fluidized bed. Bed circulates cool air. Urine and feces do not pass through fabric on the bed. Bed is portable and lighter.

See also section on *Special Beds* in Chapter 8.

Providing Care for Clients With Pressure Ulcers**Procedure**

1. Monitor client's overall condition daily. ► **Rationale:** Clients who are dying will have the tendency to develop new skin breakdown (skin failure) as other organs fail. Existing pressure ulcers of lesser staging (I and II) almost always worsen over time and become at least stage III.
2. Differentiate type of ulcer, pressure versus nonpressure.
3. Determine stage of ulcer.
4. Monitor and assess ulcer characteristics daily:
 - a. Observe dressing to determine whether dry, intact, and not leaking.
 - b. Observe ulcer bed, if appropriate, and document findings.
5. Assess pain level of client and provide adequate pain relief.
6. Photograph ulcer according to facility policy. ► **Rationale:** To determine progress of ulcer healing.
7. Monitor progress toward healing and for potential complications.
 - a. Measure pressure ulcer size weekly using a Pressure Ulcer Scale. Usual healing time is 2 to 4 weeks.
 - b. If healing is not progressing or has not healed in usual time frame, reevaluate treatment plan and client's condition.
8. Maintain turning and positioning schedule to promote healing and prevent additional ulcer formation.
9. Complete a nutritional assessment. Positive nitrogen balance and protein intake are necessary for healing.
10. Complete a psychosocial assessment to determine client's adherence to pressure ulcer treatment regimens.

Clinical Alert

Clients near the end of life have the right to refuse ulcer care. However, "Do Not Resuscitate" orders do not relieve the staff from providing quality pressure ulcer prevention or treatment.

11. Complete dressing change according to facility policy and type of dressing used. Follow manufacturer's guidelines for dressing change. ► **Rationale:** Dressing changes are based on a combination of factors, such as manufacturer suggested use, pressure ulcer characteristics, and goals for healing.

Clinical Alert

Centers for Medicare and Medicaid Services have indicated that long-term care facilities must implement evidence-based protocols of prevention and care for pressure ulcers.

DOCUMENTATION for Pressure Ulcers

- Client's general skin condition
- Periwound assessment
- Assessment of wound (i.e., size, presence of tunneling drainage, evidence of tissue granulation)
- Color, volume, type of exudate
- Type of ulcer care provided
- Type of pressure reducing/relieving device used
- Results of Braden or Norton pressure ulcer assessment scale
- Pressure ulcer record completed
- State the exact location of pressure ulcer; if bony prominence involved, use an anatomic name. Turning surface involved. (RI, LI, post., ant., medial, lateral)

- Size: Indicate size in centimeters
- Identify ulcers by number. Use chart
- Measure depth of ulcer
- Identify and measure undermining and tunneling location
- Stage: Write the number of the stage that corresponds to the description of the pressure ulcer (stage I–IV)
- Treatment: Chart treatment used (e.g., hydrocolloid dressing applied, transparent adhesive film applied, etc.)
- Position: Indicate time client's position was changed

CRITICAL THINKING Application

Expected Outcomes

- Stage of pressure ulcer is accurately assessed.
- Pressure ulcer is treated effectively according to stage of ulcer formation.
- Pressure ulcer is healing within usual time frame.

Unexpected Outcomes

Client does not have sufficient exercise; appetite decreased.

Client's wound does not heal with traditional types of treatments

Skin is exposed to moisture.

Nutritional or hydration deficit occurs.

Shearing and friction secondarily related to immobility or reduced activity.

- Skin remains free of breakdown in surrounding areas of pressure ulcer.
- Absence of additional pressure ulcer formation.

Alternative Actions

- Encourage small, frequent feedings.
- Offer high-calorie drinks like eggnog or Isocal.
- In client care conference discuss the following:
 - Is everyone following same treatment?
 - Are causative agents preventing healing?
 - Should treatment be adjusted or changed?
 - Would use of a support surface be effective?
 - Is surgical debridement and grafting necessary for healing?
- Establish bowel or bladder program and select absorbent products for wound care that wick the moisture from skin.
- Cleanse skin with pH-balanced cleansers, avoiding friction and dry skin after each incontinence and dry thoroughly.
- Apply skin barrier product.
- Consider use of fecal management system or urinary catheter.
- Monitor nutritional and fluid intake accurately.
- Obtain order for vitamin supplements if client is not already on vitamins.
- Increase protein intake by supplementing with high protein drinks.
- Keep head of bed in lowest position possible to prevent client from sliding down in bed.
- Use lifting devices to move client up in bed or out of bed to prevent friction on skin.
- Instruct client on use of trapeze to assist in repositioning.

Chapter 25

UNIT 6

Adjunctive Wound Care Therapy

Nursing Process Data

ASSESSMENT Data Base

- Identify why usual wound therapy treatments are ineffective.
- Identify most effective adjunctive treatment for client.
- Assess wound for baseline data before initiating treatment.
- Determine if wound is healing using adjunctive therapy.
- Assess if client is good candidate for adjunctive therapy.
- Assess client's nutritional status to ensure best results from V.A.C. therapy.
- Determine if wound is maintaining a moist environment with adjunctive therapy.
- Assess periwound area for signs of maceration.
- Assess for adverse reactions during hyperbaric oxygenation therapy (HBO).

PLANNING Objectives

- To assess if adjunctive therapy is providing adequate wound healing
- To place client on pressure relief surface if wound is over bony prominence
- To determine if client is able to participate in specific therapy
- To select appropriate type of dressing for adjunctive therapy
- To determine if client is a good candidate for HBO

IMPLEMENTATION Procedures

- Using Electrical Stimulation 941
- Using Noncontact Normothermic Wound Therapy . . . 942
 - For Using Warm-Up Therapy[®] System 942
 - For Changing Wound Cover 943
 - For Charging Batteries 944
- Using Negative Pressure Wound Therapy 944
 - For Removing Dressing 946
 - For Disconnecting V.A.C.[®] Unit 946
 - For Reconnecting V.A.C.[®] Unit 946
 - For Changing Canister 947
- Using Hyperbaric Oxygenation for Diabetic Ulcers . . . 947

EVALUATION Expected Outcomes

- Granulation tissue is evident using adjunctive therapy.
- Periwound area remains healthy without evidence of maceration.
- Moist wound environment is maintained.
- Pain is reduced with adjunctive therapy.
- Wound progresses through usual phases with electrical stimulation.
- Wound healing occurs faster with radiant heat dressing.
- Exudate is removed and wound healing occurs with negative pressure wound therapy.
- Hyperbaric oxygen therapy is effective in treating diabetic leg ulcers.

Critical Thinking Application 948

- Expected Outcomes 948
- Unexpected Outcomes 948
- Alternative Actions 948

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX[®]-style practice questions and Skill Checklists

Using Electrical Stimulation

Equipment

- Normal saline solution
- Bag for soiled dressings
- Gauze pads
- Two sterile basins
- Hydrogel sheets
- Electrode
- Bandage tape
- Alligator clip
- Stimulator
- Two pair clean gloves
- Sterile gloves

Preparation

1. Determine whether client is candidate for electrical stimulation.
2. Determine phase of wound healing. ► **Rationale:** This determines the correct treatment protocol.
3. Set the stimulator settings according to manufacturer's directions, based on client's phase in wound healing. The settings include polarity, pulse rate, intensity, duration, and frequency.
4. Explain procedure to client.
5. Gather equipment.
6. Perform hand hygiene.
7. Provide privacy.

Procedure

1. Raise bed to high position, lower side rails as needed.
2. Place client in position to enable staff to work with wound area and equipment. (Placement depends on wound site.)
3. Place supplies on overbed table, near working area.
4. Open all supply packages, maintaining sterility.
5. Pour sterile normal saline into one basin.
6. Don clean gloves.
7. Place disposal bag near wound. ► **Rationale:** For ease in disposing of soiled dressings.
8. Remove dressing carefully to avoid interfering with granulation tissue.
9. Remove clean gloves; place in disposal bag. Don sterile gloves.
10. Place sterile basin next to wound to catch irrigation solution as wound is cleansed.
11. Pour sterile normal saline into wound to cleanse wound. ► **Rationale:** To remove exudates, slough, and petrolatum products. Current will not be conducted into wound tissue if petrolatum products remain in the wound.

12. Remove excess irrigation solution using sterile gauze pads.
13. Place fluffed gauze pads into normal saline solution, squeeze out excess liquid.
14. Fill wound cavity with gauze, including any undermined/tunneled spaces. Pack gently.
15. Place surface (active) electrode in wound bed, over gauze packing. ► **Rationale:** This transfers electrical energy into wound bed, producing positive effects on necessary components for wound healing (i.e., blood flow, oxygen uptake, DNA, and protein synthesis).
16. Cover with dry gauze pad.
17. Tape dry pad securely.
18. Connect alligator clip to foil.
19. Connect to stimulator lead.
20. Place a wet washcloth over area where dispersive electrode will be placed.
21. Select a dispersive pad that is larger than the sum of areas of active electrodes and wound packing.
22. Place dispersive electrode proximal to wound, over soft tissue, avoiding bony prominences.

NOTE: The greater the separation between two electrodes, the deeper the current path. Larger separation space is used to treat deep and undermined wounds. Closer separation space is used for shallow or partial thickness wounds. Ensure electrodes do not touch.
23. Ensure all edges of electrode are in good contact with skin. Hold electrode in place with nylon elasticized strap.
24. Place client in position of comfort. Electrical stimulation treatments usually last 60 minutes.
25. Remove gloves and discard.
26. Perform hand hygiene.
27. Don clean gloves.
28. Remove electrode from wound after treatment.
29. Remove saline-soaked gauze and cover wound with occlusive dressing.

NOTE: Hydrogel sheets or amorphous hydrogel-impregnated gauze can be used to conduct current. If hydrogel gauze is the conductor, it is changed BID.

Candidates for Electrical Stimulation

- Pressure ulcers, stage I–IV.
- Diabetic ulcers
- Venous ulcers, ischemic ulcer
- Traumatic wounds
- Surgical wounds
- Wound flap
- Donor site, burn wound

Using Noncontact Normothermic Wound Therapy

Equipment

- Warming cover (latex free)
- Warming card
- Temperature control unit (TCU)
- AC adapter
- Wound measuring guide
- Sterile normal saline solution
- Skin sealant
- Carrying pouch
- Sterile normal saline
- Gauze pads
- Moisture-proof pad
- Sterile basin and irrigating syringe
- Sterile gloves
- Clean gloves
- Disposable bag

Preparation

1. Check physician's orders and client care plan.
2. Gather equipment. Select appropriate-size wound cover and warming card after measuring wound.
3. Check that temperature control unit's battery is charged; if not, recharge with battery pack or wall outlet power source.
4. Explain procedure to client.
5. Provide privacy for client.
6. Perform hand hygiene.

Procedure

1. Place equipment on overbed table.
2. Open sterile normal saline bottle, gauze pads, and basin with irrigating syringe.
3. Place disposable bag near wound site.
4. Position client for easy access to wound.
5. Remove compression stockings, if used.
6. Don clean gloves.
7. Remove old dressing and place in disposal bag.
8. Remove clean gloves and discard into disposal bag. Don sterile gloves.
9. Fill irrigating syringe with normal saline. ► **Rationale:** Using the syringe will increase pressure in wound to assist with removing debris and slough.
10. Place moisture-proof pad or sterile basin under wound site.
11. Irrigate wound using the prescribed amount of irrigating solution.
12. Cleanse the surrounding skin with normal saline.
13. Dry periwound skin area.
14. Apply sealant to periwound area. ► **Rationale:** This protects periwound area from exudates.

The wound cover is sterile and protects wound from contamination and trauma. The cover maintains a moist and warm wound, which creates a healing environment. The cover is a thin shell with a window and a foam frame. The shell has an adhesive border, is water resistant, and can be cleaned. It is flexible and moves with the client. The foam cover absorbs excess exudates to protect periwound area from maceration. The foam frame keeps the pocket above the wound surface, so warming card is not in contact with the wound. The window is in the center of the cover and contains a pocket for the warming card.

15. Select wound cover size that is appropriate size for wound. ► **Rationale:** To ensure that there is adequate healthy periwound skin between edge of foam and wound.
16. Hold wound cover near edges only. Pull away half of wound cover liner.
17. Place wound cover over wound, so wound can be seen through window. Do not stretch wound cover over skin while applying. ► **Rationale:** Damage can occur to skin.
18. Check for holes in wound cover, wrinkling, and folding of its edges. ► **Rationale:** Wound cover will not be a barrier if this occurs.
19. Press adhesive portion of cover to skin.
20. Pull away other half of wound cover liner and press adhesive portion to skin.
21. Gently smooth adhesive portion of wound cover with your finger tips to ensure adhesive sticks to skin.
22. Instruct the client that wound cover is worn 24 hr per day and requires no additional dressing.
23. Attach wound cover to Warm-Up therapy system.
24. Remove gloves and discard into disposal bag.
25. Perform hand hygiene.

For Using Warm-Up Therapy® System

1. Select appropriate-size warming card based on size of wound cover.
2. Plug warming card into gray socket on temperature control unit (TCU).

Clinical Alert

This warming treatment is done three times a day for 1 hr each treatment. Ensure that there is at least 1 hr between treatments. You can expect a significant increase in exudate for at least 7–10 days. This is considered a normal consequence of wound healing process.

TABLE 25-9 Adjunctive Therapies in Wound Care

Therapy	Outcomes
Hydrotherapy	Promotes debridement and cleans wound.
Electrical Stimulation	Increases oxygen and nutrients to tissues, reduces pain and edema, improves scar tissue elasticity.
Ultrasound	Increases collagen elasticity, decreases pain and muscle spasms. Increases oxygen, decreases edema, and accelerates wound recovery.
Hyperbaric Oxygen	Increases tissue oxygenation and promotes wound healing.
Compression	Promotes venous blood return, prevents pooling of blood and edema formation.
Nutritional Support	Decreases susceptibility of soft tissue breakdown.
Support Surfaces	Distributes body weight and reduces tissue pressure. Controls shear forces on skin surfaces and provides stability for client's torso.
Biological Products	Increases wound healing by increasing wound strength, increasing cellular content, and controlling collagen deposition.

3. Insert warming card into wound cover pocket. (Warming card is used throughout warming therapy and is only for one client; it can be cleaned with damp cloth and clean water, if needed.) Do not apply the warming card directly to the periwound area. Always cover the card with the wound cover. ► **Rationale:** Thermal injury can occur.
4. Turn off TCU.
5. Select mode of power (can use battery or AC adapter wall outlet).
6. Check that battery has sufficient charge for therapy session, usually 1 hr.
 - a. If battery needs charging; plug AC adapter into TCU, then plug the AC adapter into wall outlet.
 - b. Charge TCU until amber light on AC adapter flashes rapidly. It takes up to 2 hr to fully charge battery.
7. Plug AC adapter into black socket on the TCU if using the TUC with the AC adapter. Plug AC adapter into wall outlet.
8. Position TCU and warming card cable to allow client some movement. Instruct client not to lie on any electronic component, cable, cord, or wound cover.
9. Press the ON button to begin therapy. Follow physician orders for length of time for therapy. The unit will automatically turn off after 2 hr of continuous use.
10. Shut off TCU and remove warming card by grasping edge of card and sliding it out of wound cover pocket.

- Place card in plastic pouch for storage between treatments. **DO NOT REMOVE WOUND COVER.**
- **Rationale:** Wound cover is replaced if drainage occurs, the cover comes loose, the periwound area becomes macerated, or it has been in place 72 hr.
11. Replace compression therapy if ordered.

For Changing Wound Cover

1. Check wound cover to ensure it needs to be changed.
2. Gather equipment for new wound cover.
3. Explain procedure to client.
4. Perform hand hygiene.

▲ Warm-Up Therapy® unit. (Courtesy of Augustine Medical, Inc., Eden Prairie, MN.)

Clinical Alert

Do not use compression therapy while warming card and TCU are in place. Client injury could occur.

5. Follow steps in skill Using Noncontact Normothermic Wound Therapy, Preparation.
6. Don clean gloves.
7. Place disposal bag near wound.
8. Gently press down on skin along one edge of wound cover.
9. Carefully lift edge of wound cover.
10. Slowly peel away wound cover until all edges are loose.
11. Discard wound cover in disposal bag.
12. Remove gloves, discard, and wash hands.
13. Reapply new wound cover following steps in skill Using Noncontact Normothermic Wound Therapy.

EVIDENCE-BASED PRACTICE

Radiant Heat Therapy and Chronic Wound Healing

A prospective, randomized, controlled study of 41 clients with stage III or IV pressure ulcers on the trunk explored effects of radiant heat therapy (RHT) versus a hydrocolloid dressing on full-thickness pressure ulcers in various settings, including clinics, long-term care, and a rehabilitation center. The clients were managed for up to 12 weeks or healing, whichever came first.

The results indicated that eight clients healed in the RHT group, and seven clients healed in the hydrocolloid dressing group. Therefore, no statistical significance was found between the two groups.

Source: Thomas, D. R., Diebold, M. R., & Eggemeyer, L. M. (2005). A controlled, randomized, comparative study of a radiant heat bandage on the healing of stage 3–4 pressure ulcers: A pilot study. *Journal of American Medical Directors Association*, 6(1), 46–49.

For Charging Batteries

1. Plug AC adapter connector into black socket on temperature control unit.
2. Plug AC adapter power cord into AC adapter inlet.
3. Plug AC adapter power cord into properly grounded wall outlet.
4. Observe that green light and a steady amber light on AC adapter panel are on.
5. Charge until amber light is flashing rapidly on AC adapter. Full charge takes 2 hr.

EVIDENCE-BASED PRACTICE

Effects of a Normothermic Dressing on Pressure Ulcer Healing

Twenty clients with stage III and IV ulcers were studied to determine the effects of wound healing when heat was applied. Three groups were treated using three different methods; one group used heating therapy for 4.5 hr each day Monday–Friday for 4 weeks. One group had wounds warmed for two 60-minute periods daily. One group received no heat therapy. Results of the study indicated that the clients who received the most heat therapy healed significantly faster than the others. There were no adverse affects from the heat therapy.

Source: Kloth, L. C., Berman, J. E., Dumit-Minkel, S., Sutton, C. H., Papanek, P. E., & Wurzel, J. (2000, March/April). Effects of a normothermic dressing on pressure ulcer healing. *Advances in Skin & Wound Care*, 13(2), 69–74.

Using Negative Pressure Wound Therapy

Equipment

Foam, Black or White V.A.C.[®] kit
 Gauze pads
 Sterile normal saline
 Irrigating syringe
 Moisture proof pad or sterile basin
 Skin prep agent, optional

Razor, optional
 Clean gloves
 Sterile gloves
 V.A.C. device
 Disposal bag
 Sterile scissor

1 V.A.C.[®] unit.

2 V.A.C.[®] foam cut to fit shape and wound cavity, with tubing attached to vacuum pump.

▲ Remove adhesive drape by gently pulling away from skin.

Preparation

1. Evaluate whether client is candidate for V.A.C. therapy: nutritionally stable, able to use device 22 hr each day, uses a pressure support surface if wound is over bony prominence. ► **Rationale:** If therapy turned off longer than 2 hr, dressing must be removed and replaced with traditional dressing.
2. Assess wound to determine whether therapy can be implemented.
 - a. Wound surrounded by at least 2 cm of intact periwound tissue to maintain airtight seal.
 - b. Wound open enough to insert foam dressing that touches all edges.
 - c. Wound debrided.
 - d. Sufficient circulation to assist in healing process.
3. Select correct foam dressing according to size and type of wound. Black foam has larger pores and is used to stimulate granulation tissue and wound contraction. White (soft) foam is used when granulation tissue needs to be restricted or client cannot tolerate pain associated with black foam. White foam is used with superficial wounds, shallow chronic ulcers, and tunneling or undermining wounds.
4. Gather equipment and supplies.
5. Provide privacy.
6. Explain procedure to client and determine his willingness to use this therapy.
7. Perform hand hygiene.
6. Clean wound using aggressive irrigation. If debridement is to be done, only a trained professional can perform the skill. Notify the appropriate person. ► **Rationale:** Devitalized tissue should be removed as areas of soft or stringy slough delays the healing process.
7. Remove gloves and place in disposal bag.
8. Don sterile gloves.
9. Dry wound and prepare periwound tissue with skin preparation agent if necessary. ► **Rationale:** To promote an airtight seal.
10. Cut the V.A.C. foam to fit the shape and entire wound cavity, including tunneling or undermined areas. White foam is used for tunneled wounds.
11. Size and trim drape to cover foam dressing, leaving a 3.5-cm border per wound area.
12. Gently place the foam into wound, ensuring entire wound is covered.
13. Apply tubing to foam. Tubing can be laid on top of foam or placed inside foam dressing. Keep tubing away from bony prominences.
14. Cover foam and 3.5 cm per wound area with drape. Do not stretch drape or compress foam with drape. ► **Rationale:** This ensures a tight seal without causing tension or a shearing force on periwound tissue.
15. Lift tubing and place on drape that has been bunched up to protect skin from pressure of tube.

Procedure

1. Place disposal bag near wound.
2. Open supplies and place on overbed table. Open kit maintaining sterility.
3. Draw up normal saline irrigating solution in syringe.
4. Don clean gloves.
5. Place moisture-proof pad or sterile basin under wound. ► **Rationale:** Protects skin and bed during irrigation.

Negative Pressure Wound Therapy

Uses	Contraindications
Acute and chronic wounds	Malignancy in wound
Traumatic	Untreated osteomyelitis
Partial-thickness burns	Nonenteric and unexplored fistula
Dehisced wounds	Necrotic tissue with presence of diabetic ulcers eschar
Pressure ulcers	Directly over exposed blood flaps vessel or organ
Grafts	When using hydrogen peroxide and alcohol-based solutions Clients who cannot tolerate temperature of fluid

Clinical Alert

Do not pack foam into any areas of the wound. Forcing foam dressings in a compressed manner into any wound may lead to risk of adverse health issues.

16. Secure tubing with additional piece of drape or tape several centimeters away from dressing. ► **Rationale:** This prevents pulling on the dressing, leading to a leak.
17. Remove gloves and discard.
18. Remove canister from sterile package and push it into the V.A.C. unit until you hear it click in place. Alarm will sound if canister is not properly inserted into unit.
19. Connect dressing tubing to canister tubing.
20. Open both clamps, one on dressing tubing and one on canister tubing.
21. Place V.A.C. unit on level surface or hang from footboard.
22. Press power button ON.
23. Adjust V.A.C. unit settings according to physician's orders or Guidelines for Treating Wound Types in the Reference Manual. Target pressure should be set for 5 minutes on and 2 minutes off (intermittent therapies on machine). Intensity of setting sets the negative pressure.
24. Assess dressing in 1 minute. ► **Rationale:** The dressing should collapse unless air leak is present.
25. Dressing changes must be completed every 48 hr unless wound is infected, then change every 12–24 hr.

For Removing Dressing

1. Perform hand hygiene.
2. Don clean gloves.
3. Raise tube connector above level of pump unit.
4. Tighten clamp on dressing tube.
5. Separate canister tube and dressing tubes by disconnecting the connector.
6. Allow pump unit to pull exudates in canister tube into canister; then tighten clamps on canister tube.

V.A.C.[®] GranuFoam Silver

- Provides continuous delivery of silver directly to wound bed.
- Provides a protective barrier to reduce aerobic, gram-negative, and gram-positive bacteria, yeast, and fungi, and it may reduce infections in wounds.
- Indicated for client with chronic, acute, traumatic, and dehisced wounds, partial thickness burns, and pressure ulcers.

Clinical Alert

For deep wound, reposition tubing to minimize pressure on wound edges every 2 hr. Excess foam can be used to cushion skin under tubing.

EVIDENCE-BASED PRACTICE

Vacuum-Assisted Closure (V.A.C.[®]) for Sternal Wounds: A First-Line Therapeutic Management Approach

A retrospective review of 103 clients was completed at one institution. The clients underwent vacuum-assisted closure therapy after median sternotomy between June 1999 and March 2004. The clients' wounds were classified as sterile wounds, superficial sternal infections, and mediastinitis. The wound closure device was applied sterilely to all wounds over a layer of Acticoat. The results indicated that vacuum-assisted closure was utilized in the treatment of 103 clients with sternal wounds (67 males and 36 females). The median age was 52 years (3 months to 91 years). Client comorbidities included diabetes, chronic obstructive pulmonary disease, end-stage renal disease, immunosuppression, and other conditions. The therapy was utilized for 11 days per client. Sixty-eight of the clients had definitive chest closure with open reduction internal fixation and/or flap closure. The remaining 32% of the clients had no definitive closure method. The overall mortality rate was 28%, although none of the four deaths were directly related to the use of the therapy. The conclusion indicated that vacuum-assisted closure therapy has been shown to decrease wound edema, decrease time to definitive closure, and reduce wound bacterial colony counts.

Source: Agarwal, J. P., Ogilvie, M., Wu, L. C., Lohman, R. F., Gottlieb, L. J., Franczyk, M., & Song, D. H. (2005). Vacuum-assisted closure for sternal wounds: A first-line therapeutic management approach. *Plastic Reconstructive Surgery*, 116(4), 1035–1040.

7. Press Therapy ON/OFF to deactivate pump.
8. Stretch drape horizontally and slowly pull up from skin. Gently remove it from skin. Do not peel it off skin.
9. Discard disposable equipment including gloves in appropriate bag or container.
10. Perform hand hygiene.

NOTE: Dressing changes are completed every 48 hr; if infected, every 12 hr.

For Disconnecting V.A.C.[®] Unit

1. Turn the unit to OFF.
2. Clamp both clamps on tubing.
3. Press quick-release connector to separate dressing tubing from canister tubing.
4. Cover ends of tubing with gauze and secure.

For Reconnecting V.A.C.[®] Unit

1. Remove gauze from ends of tubing.
2. Connect tubing.
3. Unclamp clamps
4. Press V.A.C. green power button to ON.
5. Select NO at new client prompt. Unit will resume previous settings.
6. Press therapy to ON.

Safety Tips for Negative Pressure Therapy

- Maintain therapy 22 hr per day.
- Perform wound cleansing and dressing changes every 48 hr unless wound infected, then change to every 12 hr.
- Monitor wound and dressing at least every 4 hr to ensure foam is collapsed and for signs of infection or other complications.
- Change type of wound system or medicate if client complains of pain or discomfort during treatment.
- Use continuous therapy (24 hr) to minimize movement and help stabilize wound bed over unstable body structures such as chest wall.
- Change canister when full or at least weekly. Use Standard Precautions.

For Changing Canister

1. Don clean gloves.
2. Assess that canister unit is full. Unit will alarm when full.
3. Tighten clamps on canister tubing from dressing tubing.
4. Pull back on release knob on V.A.C. unit at same time as you pull canister from slot.
5. Put canister in biohazard disposable bag and place in designated area for disposal.
6. Dispose of gloves.
7. Perform hand hygiene.

NOTE: Average length of treatment is 4–6 weeks. Home systems are available as well.

Using Hyperbaric Oxygenation for Diabetic Ulcers

Equipment

- Hyperbaric chamber
- Compressed air mask (optional)

Preparation

1. Identify client using two forms of identification. Introduce yourself.
2. Explain the procedure to client.

Procedure

1. Perform hand hygiene.
2. Ensure client is wearing 100% cotton fabrics only.
 - ▶ **Rationale:** to prevent spark potential.
3. Ensure client does not have petroleum-based and alcohol-based products on hair or cosmetics.
 - ▶ **Rationale:** Vapors from sprays, cosmetics, and

Vaseline can spontaneously combust in an increased atmospheric environment of 100% oxygen.

4. Check that topical wound and skin care products with petroleum base are not present on client.
5. Take client to treatment area.
6. Once client is placed in chamber, the following observations must be observed constantly during compression and during entire treatment.
 - a. Assess client for ability to equalize pressure changes in ear. Client will complain of ear pain. Instruct client to yawn, swallow, or perform Valsalva maneuver.
 - b. Determine if client has sensation of warmth as the pressure increases, temperature increases, and decreasing rate of compression of the chamber.
 - c. Check for confinement anxiety. Minimize this potential adverse effect through orientation to the

HBO Therapy

Two types of chambers are used in HBO therapy: multiplace chamber and monoplace chamber.

Multiplace chamber

- Compressed with 100% oxygen administered through direct piped-in gas.
- Multiple clients treated at one time (1–12 clients can be done at the same time).
- Nurse is in chamber to provide care.
- Critically ill client can be more readily treated.

Monoplace chamber

- Single client therapy.
- Uses 100% O₂ to compress chamber.
- Client can breathe compressed air by mask during treatment.
- For clients with claustrophobia or who can't tolerate mask, alterations in treatment protocols may be required.

Risk to nurse is minimized by strict adherence to diving protocols that allows for period of decompression of the nerve. See also Chapter 30, page 1187.

- process of decompression. Anxiolytic therapy using benzodiazepines may be ordered.
- d. Determine potential for hypoglycemia with diabetic client. Assess client during decompression for loss of consciousness, disorientation, and seizures. Preventive measures include maintaining blood glucose levels by adequate nutrition and timing of insulin injections in

relationship to treatment. Peak insulin levels should not occur during treatment.

7. Observe client continuously while in chamber and when decompression is reversed.
8. Evaluate client for signs of oxygen toxicity or other potential adverse reactions. Report adverse findings to physician.

DOCUMENTATION for Adjunctive Wound Care Therapy

- Wound assessment including location, measurement of wound, presence of tunneling or undermining
- Color of wound, presence of exudates, color, and odor
- Wound stage, if appropriate
- Eschar description if present
- Presence of pain in periwound area
- Type, frequency, and duration of adjunctive therapy
- Date and time of wound cover change in Warm-Up Therapy
- Client's response to therapy
- Length of time negative pressure therapy treatment is off
- Client's reaction to HBO and any adverse effects

Legal Alert

Wound care practitioners are at risk for litigation. Clients who experience wounds frequently believe it is because of neglect by healthcare workers. Wound care practitioners may face liability for:

- Negligence
- Violations of Medicare and Medicaid fraud and abuse prohibitions
- Abandonment for terminating services to clients

To prove negligence, a client must show that the provider owed the client a duty and breached the duty owed the client, and the breach of duty must result in injury or damage to the client. Owing a duty of reasonable care to a client incorporates the standards of wound care. Breaching a duty occurs when the healthcare practitioner does something that should not have been done. To be charged with causing injury, the client would need to prove that injuries occurred as a result of practitioner error.

CRITICAL THINKING Application

Expected Outcomes

- Granulation tissue is evident using adjunctive therapy.
- Periwound area remains healthy without evidence of maceration.
- Moist wound environment is maintained.
- Pain is reduced with adjunctive therapy.

- Wound progresses through usual phases with electrical stimulation.
- Wound healing occurs faster with radiant heat dressing.
- Exudate is removed and wound healing occurs using negative pressure wound therapy.
- Client's diabetic wound heals with hyperbaric oxygen therapy.

Unexpected Outcomes

Warm-Up Therapy[®] system shows heat light is on and low battery light is flashing.

Fault light is flashing and an alarm is sounding on TCU.

Alternative Actions

- Charge battery.
- Use TCU and AC adapter together.
- Reconnect warming card, it may be disconnected.
- Warming card or cable could be bent or damaged. Replace warming card.
- TCU is broken. Turn TCU on and off. If light continues and alarm continues, turn off TCU and obtain new unit.
- TCU is not on or battery is low. Turn unit ON or charge battery.

Nothing lights up on TCU panel.

Wound is too large for V.A.C.[®] kit.

Periwound skin is fragile.

Dressing does not collapse following V.A.C.[®] application.

Foam is not collapsed in wound bed.

Audible alarm sounds on V.A.C.[®] system and therapy is stopped.

Dressing adheres to wound with negative pressure system.

Client exhibits signs of anxiety when providing education regarding use of hyperbaric chamber.

- Use more than one foam piece.
- Place pieces so they touch each other.
- Use only one tubing to one of the pieces.
- Use skin prep before applying drape.
- Frame wound with skin barrier or DuoDERM.
- Cut drape large enough to enclose foam dressing and skin barrier layer.
- Listen for whistling sound indicating a leak in the system.
- Gently press around tubing, check for wrinkles or drape not covering correctly.
- Most leaks occur around tubing.
- Use excess drape to patch over leak.
- Ensure therapy is ON. Ensure clamps are open and tubing is not kinked.
- Check for leaks and patch.
- Check for blockage in tubing and replace as needed.
- If problem continues after tubing is replaced, notify company that produces the system.
- Instill sterile water or normal saline into dressing, let sit for 15–20 minutes, then gently remove dressing from wound.
- Place client in multichamber where a nurse is present to assist client with anxiety-reducing interventions.

GERONTOLOGIC Considerations

As clients grow older, the usual function of the skin declines, leading to major complications. Nearly 40% of clients aged 65–75 have at least one significant problem related to the skin.

- Dry skin is present in 77% of clients over 64.
- Vitamin D deficiency.
- Decrease in sebum production.
- Decrease in sweat production.
- Decrease in thermoregulation.
- Basal cell carcinoma is most common skin malignancy.
- Decrease in sensory perception.
- Decrease in adequate oxygen or nutrition occurs when issue is subjected to excessive pressure.

The inflammatory and proliferation phases of wound healing are often defective with elderly clients who have chronic diseases.

- A hemoglobin below 10 g/dL increases susceptibility.
- Uncontrolled diabetes mellitus or a blood glucose level that exceeds 200 mg/dL presents a risk.
- Hyperglycemia retards neutrophil production.
- T and B cells diminish in function and number, indicating a reduced inflammatory response. Elderly clients are at risk for cutaneous viral and fungal infections.
- Clients with rheumatoid arthritis who take steroids or non-steroidal anti-inflammatory medications are at risk for

decreased wound healing. There is a slower rate of epithelialization and severely inhibited contraction.

- Ischemia, anemia, and edema from vascular insufficiency or pressure leads to lack of blood flow to a wound area. Lower oxygen-carrying capacity results from anemia. Edema makes it difficult to transport oxygen and cellular wastes to and from cells. Ischemia leads to diminished oxygen necessary for wound healing.

Nursing actions to counteract risks against wound healing

- All at-risk elderly clients should have a pressure ulcer risk assessment completed at the time of admission and at regular intervals thereafter.
- Use of compression stockings assists in treating both the edema and ultimately the ischemia, therefore increasing blood flow to wound area.
- Turning frequently, at least every 2 hr, for clients free of pressure ulcers and every 1 hr for those at high risk, should be a priority.
- Use of pressure-relieving mattresses decreases risk potential.
- Wound care, including irrigation, use of appropriate dressings, and maintaining aseptic technique with dressing changes, should be priority care for clients with any type of wound.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility. Nurses working in a hyperbaric chamber must be trained in how to work with the clients and how to protect themselves when in the chamber. Before being assigned to this activity, ensure they have had the education necessary to work in this environment.

Delegation

- Assessment and evaluation of wounds and their management modalities are only RN functions and may not be delegated to other healthcare workers. The RN in collaboration with the physician develops a plan of care for clients requiring wound management.
- An LVN/LPN may be assigned to complete a sterile dressing change following instructions from the RN and in accordance with the wound care protocol established for the individual client.
- An LVN/LPN may remove staples and sutures after instruction and return demonstrations have been documented. (Most nursing programs include this information in the curriculum.)

- A CNA may apply a dry dressing, but may not perform a sterile procedure.

Communication Matrix

- Information regarding assessment of the wound should be reported to all staff caring for the client. This can be accomplished during report or documented on the nurses' notes and on client care plans or clinical (critical) pathway documents, or electronic forms.
- Wound care procedures (i.e., dressing changes) should be outlined or special wound care steps inserted into computer record. Specific instructions regarding type and amount of dressing material needed and specific directions in the application of the dressings must be written clearly so all nurses may follow appropriate directions.
- Specific directions for wound management and use of specialized equipment must be given to the nurse during report from the RN team leader or manager.
- Reports outlining specifics of the wound, such as color, odor, and amount of drainage, must be provided to the RN manager after the dressing change has been completed.
- Any change in wound appearance must be immediately reported to the RN team leader or manager before the dressing change has been completed.

CRITICAL THINKING Strategies

Scenario 1

Mrs. Johnson is an 84-year-old retired school teacher who was widowed 10 years ago and now lives alone. She developed diabetes mellitus at the age of 58. She has been in failing health for the last 3 years and has been at home with the assistance of home health aides and weekly visits by the RN. Her coccyx area has had frequent skin breakdown. The Homecare RN determined she now has a stage III pressure ulcer as a result of her being on bedrest the past week. She is being admitted to the hospital for treatment of the ulcer.

1. Identify risk factors for Mrs. Johnson developing pressure ulcers.
2. Describe the stage III pressure ulcer.
3. Identify the most effective treatment for the stage III pressure ulcer.
4. Compare and contrast the two Pressure Ulcer Assessment Scales and identify the score indicating that Mrs. Johnson is a high risk for pressure ulcer formation on one of the scales.
5. In addition to dressing changes, identify a preventative therapy that should be used for clients at high risk for pressure ulcers.
6. Explain why massaging bony prominences should be avoided for clients at risk for pressure ulcer formation.
7. Briefly describe the application of a hydrocolloid dressing.

8. Identify and briefly explain the use of one new advance in the treatment of pressure ulcers.

Scenario 2

A young client was in a motor vehicle accident and has numerous wounds on his buttocks, back, and both legs. He is in extreme pain and is on a PCA pump with morphine sulfate for pain control. He is able to respond to questions. His vital signs are BP 140/88, P. 110, R. 26, O₂ Sat 96% on room air.

1. When assessing the client's wounds, what questions will you need to ask to determine the client's history and physical findings that contribute to his treatment?
2. Describe how you would determine the extent of the wounds.
3. The physician has determined that the negative pressure wound therapy protocol would be the most beneficial treatment for the leg wounds. This decision is based on what criteria?
4. Compare and contrast the use of white foam and black foam for the leg wounds.
5. Describe the method you will use to prepare the wound for the V.A.C. system.
6. Provide the rationale for using GranuFoam silver dressings for wound care.

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. The phase of wound healing which begins about 2 days to 3 weeks after injury is termed
 1. Maturation.
 2. Inflammatory.
 3. Regeneration.
 4. Wound remodeling.
2. Tertiary intention in wound healing is described as
 1. A wound that heals by granulation.
 2. The simplest form of wound healing.
 3. The skin is cleanly incised through a surgical incision.
 4. A wound that heals by leaving it open.
3. Instructing clients in measures to increase wound healing should include increasing the client's daily intake of calories to
 1. 20–25 Cal/kg/day.
 2. 30–35 Cal/kg/day.
 3. 35–45 Cal/kg/day.
 4. 45–50 Cal/kg/day.
4. Instructing student nurses in the use of alcohol-based hand rub to decontaminate hands includes instructions to
 1. Apply 1.5–3 mL of alcohol in palm of hand and begin to rub hands together.
 2. Vigorously rub hands for 10 seconds, covering all hand surfaces.
 3. Scrub hands for 3 minutes.
 4. Rinse hands and dry using a single-use towel.
5. To maintain a sterile field, the nurse needs to
 1. Place the sterile package near the edge of the overbed table on the opposite side of the bed.
 2. Open the package by placing it directly in front of you and grasping the wrapper.
 3. Open the last flap of the wrapper toward you.
 4. Move the sterile dressing tray toward you after opening the last flap of the wrapper.
6. The physician asks you to remove the sutures on a client with an abdominal incision. Which one of the following steps is appropriate to carry out?
 1. Don sterile gloves before removing sutures.
 2. Grasp suture at knot with forceps and lift away from skin.
 3. Place straight tip of suture scissors over knot and cut knot.
 4. Begin to remove sutures in the middle of the incision to ensure it is healed.
7. Advantages to using transparent adhesive film dressing for wound care include

Select all that apply.

 1. Allows visualization of wound.
 2. Promotes autolysis of dry eschar.
 3. Does not require secondary dressing.
 4. May be soothing by having a cooling effect.
8. A wound culture has been ordered for a client with a leg wound. You remember that the appropriate method for obtaining the culture includes
 1. Cleaning the wound area with hydrogen peroxide before swabbing the wound.
 2. Swabbing the wound using a single straight motion with the swab down the middle of the wound.
 3. Swabbing the edges of the wound starting at the top and crisscrossing the wound to the bottom.
 4. Cleaning the edge of the wound with saline and then swabbing inner aspects of wound.
9. The client requires a wet-to-moist dressing change daily. When placing the dressing in the wound, the most appropriate method is to
 1. Pack several flat sterile 4 × 4 dressings into the wound bed.
 2. Fluff each sterile dressing and place over the wound.
 3. Place a moist dressing on top of the sterile dry dressings in the wound.
 4. Unfold a dry dressing and place on top of moistened dressings in the wound.
10. The physician has ordered negative pressure wound therapy. The nurse needs to evaluate the wound before this therapy can be initiated to ensure it can be effective. If the wound can accommodate the therapy, it will

Select all that apply.

 1. Be surrounded by at least 2 cm of intact periwound tissue.
 2. Open enough to insert the foam dressing that must touch all edges.
 3. Be debrided.
 4. Be on the extremities.

Perioperative Care

LEARNING OBJECTIVES

1. Define the word *perioperative*.
2. Discuss the nursing care focus in each of the three stages of the perioperative period.
3. Identify at least three factors that influence the surgical client's degree of stress.
4. Explain why postoperative complications are reduced by decreasing the stress level.
5. Describe at least one potential problem and the suggested solution for clients demonstrating high stress levels in the preoperative period.
6. State the primary purpose of providing preoperative care for clients.
7. Discuss how preoperative teaching can reduce the surgical client's stress.
8. Describe the information contained in the surgical permit.
9. Outline the essential steps in physically preparing a client for surgery.
10. Describe information contained in the surgical safety checklist.
11. Explain the purpose for administering the three classifications of drugs used for preoperative medications.
12. Describe the nurses' role in caring for a client with moderate (conscious) sedation.
13. Outline the essential postoperative nursing interventions completed in the surgical unit.
14. Summarize the major categories of postoperative pain medications and describe the general side effects of each category.
15. Discuss at least three major postoperative complications and the nursing interventions to prevent and treat the complications.
16. Describe the process of "Hand Off" communication.
17. Discuss the differences in procedure when a client is discharged to home after outpatient surgery.

TERMINOLOGY

Adaptation ability of an organism to adjust to a change in environment.

Analgesia absence of the sense of pain.

Analgesic a drug that relieves pain without altering the conscious state.

Anesthesia partial or complete loss of sensation by administration of a drug or gas.

Anxiety experiencing a sense of dread or fear without a known stimulus. A condition associated with physiologic changes.

Arthrogram a diagnostic radiological test involving use of dye, which is injected into a joint to visualize tears in ligaments and surrounding tissue.

Arthroscopy using a scope to visualize, diagnose, or treat problems inside a joint.

Asepsis sterile; a condition free from germs.

Atelectasis a collapsed or airless section of the lungs.

Bronchitis inflammation of the bronchial mucous membrane.

Bronchoscopy examination of the bronchi with a scope.

Capnography indicator of respiratory depression because it measures ET_{CO₂} (end-tidal carbon dioxide).

Conscious (Moderate) Sedation a medically controlled state of depressed consciousness that allows protective reflexes to be maintained.

Contamination the introduction of disease, germs, or infectious materials into or on normally sterile objects.

Dehydration loss of water to the body or tissues due to low intake or high output of fluid.

Diplopia double vision.

Egophony a nasal sound heard while auscultating the lungs of a person as he speaks; a sound heard in pleural effusion.

Emesis vomiting.

Emphysema a condition in which the alveoli of the lungs become distended or ruptured.

Enema injection of water or fluid into rectum and colon to empty the lower intestine or to introduce medicine or food for therapeutic purposes.

Euphoria an exaggerated feeling of well-being.

Exudate fluid, cells, or other substances that have been slowly discharged from cells or blood vessels through small pores or breaks in cell membranes.

“Hand Off” communication method of reporting off from one nursing staff to another nursing staff or between nursing units.

Hernia the protrusion or projection of an organ or part of an organ through the wall of the cavity that normally contains it.

Hypertension higher blood pressure than normal; usually above 140 mmHg/90 mmHg.

Hypnotic drugs that cause insensibility to pain or partial to complete unconsciousness; includes sedatives, analgesics, anesthetics, and intoxicants.

Hypothermia the state of low body temperature.

Hypovolemia diminished intravascular volume.

Immunosuppressive acting to suppress the body’s natural immune response to an antigen.

Induction the process of causing or producing; in anesthesia, the period from the initial inhalation or injection until

optimum level of anesthesia is reached, including airway competency intubation.

Intervention the act of coming in or between so as to modify.

Laparoscopy a scope is inserted into the abdominal cavity to perform diagnostic and/or surgical procedures.

Laser surgery procedure used to divide or cause adhesions or to destroy or fix tissues in place.

Lethargy a condition of sluggishness; stupor.

Lithotripsy procedure for eliminating a calculus in the renal pelvis, ureter, bladder, or gall bladder.

Magnetic resonance imaging (MRI) use of electromagnetic energy in radiography to provide soft tissue images, especially of the musculoskeletal and central nervous system.

Maladaptive poorly adjusted; inability to adapt.

Mesentery a peritoneal fold connecting the intestine with the back of the abdominal (postabdominal) wall.

Narcotic producing stupor or sleep; a drug that depresses the central nervous system.

Neurohormonal concerning the interaction between nerves and hormones.

Orthopedic concerning the prevention or correction of deformities of the musculoskeletal system, especially bones, tendons, and ligaments.

Palpitation rapid, violent, or throbbing pulsation, as an abnormally rapid, throbbing, or fluttering heart.

Perioperative refers to the three phases of the surgical experience: preoperative, intraoperative, and postoperative.

Peritonitis inflammation of the peritoneum.

Pneumonia inflammation of the lungs caused primarily by bacteria, viruses, and chemical agents; can be characterized by chills, high fever, pain in the chest, cough, and purulent and often bloody sputum.

Stress a mentally or emotionally disruptive or disquieting influence; distress.

Surgical site infection (SSI) the infections that result from the surgical procedure.

Therapeutic having medicinal or healing properties.

Thrombophlebitis inflammation of a vein associated with thrombus.

Topical pertinent to a particular area; local.

Trauma a physical injury or wound caused by external force or violence; an emotional or psychologic shock that may produce disordered feelings or behavior.

Vasoconstriction constriction of a blood vessel.

THE SURGICAL EXPERIENCE

Just a few years ago, the surgical experience involved 3 to 10 days in a hospital setting; now it is often a short hospital stay or an outpatient experience. Many procedures are now performed safely in an outpatient setting and may consist of a same-day surgical procedure lasting a few hours. The short-stay procedure involves an observation period during an overnight stay in the facility, usually less than 24 hr. In these situations, much of the postoperative period is managed at home. Depending on the protocol, if necessary a home health nurse may visit, or some outpatient facilities provide a postoperative follow-up visit by the nursing staff. In all cases where outpatient procedures are performed, the nurse does phone follow-up within the first 1 to 3 postoperative days.

Surgical procedures are classified as either emergency or elective procedures. Elective procedures can be scheduled in advance. This allows the client time to plan for child care arrangements and employment responsibilities, as well as prepare psychologically for the experience. Emergency procedures usually are a result of a life-threatening situation such as hemorrhage, obstruction, malignancy, or body system disruption. Procedures are also termed major or minor according to the degree of risk to the client. Major surgical procedures involve a risk of bleeding and loss of organs or bodily parts. Minor surgical procedures usually involve less risk of bleeding and fewer complications. Examples of these procedures include arthroscopic procedures of the knee, rhinoplasty, and eye surgeries.

Nurse's Role Nurses take an active role in the psychologic and physiologic preparation of the surgical client. Nurses instruct the preoperative client in stress-reduction techniques, explanations of the operating room experience, expectations for the postoperative period, and use of special postoperative

equipment. In fact, many hospitals provide time for the operating room nurse to make postoperative visits to clients to assess the client's evaluation of the surgical intervention.

PERIOPERATIVE CARE

Perioperative Areas There are specific physical areas of the hospital where client care takes place during the operative experience.

Personnel working in these areas must adhere to regulations regarding appropriate attire with personal protective equipment identified for each specific area. Personnel must also follow standard precautions and are not permitted to work if they have open lesions on the hands or arms, eye infections, diarrhea, or respiratory infections.

Preoperative Area Preoperative care can take place in a holding area for invasive procedures and/or the preoperative area of the operating room. Care can also take place in a central testing area, an inpatient room, or clinic examination or treatment room. During this stage the client must be identified by at least two identifiers (i.e., medical record number, birth date, name, charge number).

The operative site needs to be verified, both to site and side, and then marked by two parties (ideally the client and the physician).

If a female client is of childbearing age, a pregnancy test is usually done. The potassium levels are checked if the client is on diuretics.

Intraoperative Area This includes the operating room suite or a procedure room where invasive surgical procedures

occur. The intraoperative area of the operating room suite includes the area surrounding the operating room and the actual operating room suite. Intraoperative care begins when the client enters the invasive procedure area or the operating room suite.

Postoperative Area Care can commence in the operating room suite, the procedure room, a recovery room/postoperative area, a client room (ICU), or a treatment room. The postoperative care begins immediately after the completion of the surgical procedure.

Preoperative Stage The first stage of the perioperative period is the *preoperative stage*. During this stage, a health history, including identification of all allergies (including latex allergies and Betadine/prep solutions), medical concerns in other systems, identification of side and site of procedure, and verification of a client's understanding of the procedure including side and site, a thorough physical assessment, and review of all laboratory tests ordered is completed. Some clients will require an ECG, chest x-ray, pregnancy test, or blood type and screen. The registered nurse completes the operative check list and notifies the surgeon and anesthesiologist of any abnormal findings according to facility policy and procedures. Infections such as urinary tract infections must be treated before any surgical procedure is done. Not all infections such as urinary tract or respiratory are obliterated before surgery, but must be identified and reported to the surgeon and anesthesiologist to determine whether surgery can proceed. Some clients receive preoperative IV antibiotic therapy before surgery. The nurse must ensure that these orders have been completed before surgery. If clients are to receive preoperative antibiotics, they should be administered before the beginning of surgery to maximize the effects. The antibiotics are frequently administered in the holding area.

Admission to the hospital or outpatient surgery facility and anticipation of surgery result in some degree of anxiety and stress. Stress is a physiologic and psychologic response to a stressor. Anxiety is one of the manifestations of stress. The degree of anxiety and stress depends on many factors:

- The client's likelihood of reacting to anticipated stressors with high anxiety
- The number of stress-producing events that have occurred recently in the client's life or within the client's family
- The client's perceptions of the hospitalization and surgical experience
- The significance of the surgery to the client and how life will be altered
- The number of unknowns that confront the client on admission
- The client's degree of self-esteem and self-image and perception of how surgery will impact body image
- The client's belief system and religious conviction

The body responds physiologically to an actual or perceived threat. The hypothalamus controls a neurohormonal response. The heart rate is increased, and the heart contracts more forcefully. Blood volume is redistributed by vasoconstriction of the vessels in the skin, stomach, mesentery, and kidneys. Increased

blood volume increases cardiac output. Increased blood flow to the skeletal muscles results in the muscles becoming tensed for action. The bronchi dilate, and the increased respiratory rate increases oxygenation. Mechanisms that provide energy include increased glucose release and decreased insulin production. The effects of these mechanisms make it important to know the blood glucose status of a diabetic client; a higher blood glucose level immediately preceding the procedure is better than one that is too low.

Behavioral responses to stress or anxiety can be adaptive or maladaptive (Table 26-1). Adaptive behaviors are purposeful. The client adapts to a stressful situation by preparing to face it or by removing the threat. Maladaptive behaviors result from the inability to adapt to a stressful situation.

One of the objectives of providing preoperative care is to identify the level of stress present in the client. If nursing interventions can be planned that reduce high anxiety levels, the result is a safer intraoperative period. High levels of anxiety can prevent successful preoperative adaptation and can negatively influence postoperative recovery. Mild anxiety, on the other hand, increases alertness, increases the ability to learn, and increases the ability to assess and to adjust to one's environment. Mild anxiety also increases the ability to adjust to several simultaneous stressors. In the preoperative client this level of anxiety is adaptive in nature, while a high level is maladaptive. When levels of anxiety or stress become intolerably high, defense mechanisms are unconsciously implemented to reduce the distress by concealing, falsifying, or distorting reality.

Preoperative anxiety is increased by ambiguity, conflicting perceptions, misconceptions, fears of the unknown, and bombardment by many simultaneous stressors. Ambiguity occurs from uncertainty or vagueness concerning the hospital environment, preoperative procedures, intraoperative procedures, or postoperative events.

Conflicting perceptions occur when preconceived notions about the operative experience are different from those actually encountered. A client may not have comprehended the pertinent facts about the procedure (i.e., incision site and how the procedure is going to be done). The client who thought that a herniorrhaphy would be a quick, safe cure can become quite anxious after the anesthesiologist informs him or her of potential complications.

Misconceptions arise when inaccurate information is given, or accurate information is misinterpreted, when terminology is not understood, and when events are not explained clearly. A client who is scheduled for a bronchoscopy in the morning, and whose nurse silently places an NPO sign over the bed, may believe that he is destined for the same hospital regimen as his roommate, who had a gastrectomy.

Stress responses are cumulative. An increasing number of stressors can eventually drain adaptive energy. The newly admitted surgical client who has been confronted with many stressors before admission is more likely to respond with a higher level of stress as each new stressor is encountered.

Preoperative teaching is essential for clients undergoing any surgical procedure. Research studies have repeatedly identified the positive outcomes of client teaching as decreased perception of pain, increased compliance with treatments, decreased

TABLE 26-1 Responses to Anxiety States

Low Anxiety	High Anxiety
Less likely to react with high anxiety to stressors	Likely to react with high anxiety to stressors
Few changes in personal situation in recent past	Many changes in personal situation in recent past
Perceives hospital and surgical experience as beneficial	Perceives hospital and surgical experience as threatening
Believes surgery will end chronic problem	Fears that surgery may lead to pain, disability, and possibly death
Regards admission procedures as friendly and supportive	Regards admission procedures as strange and frightening
Finds hospital conditions comfortable and the nursing staff supportive and informative	Finds hospital conditions unbearable and the nursing staff nonsupportive

See also Chapter 17, Alternative Therapies and Stress Management.

TABLE 26-2 Managing Surgical Clients

Conscientious Preoperative Care of Clients Prevents Postoperative Complications

- Preparing the client psychologically reduces the client's stress level and helps to prevent postoperative complications.
- Teaching coughing and deep breathing exercises, procedures for getting out of bed, and uses of specialized equipment enhances the client's cooperation and prevents postoperative complications.

Scrupulous Asepsis Throughout the Perioperative Period Reduces Complications

- Maintaining strict asepsis reduces cross-contamination.
- Completing the surgical scrub reduces microorganisms on the body surface and the possibility of wound infections postoperatively.
- Identifying breaks in sterile technique and taking appropriate actions decrease the risk of postoperative complications.

Accurate Identification of Client and Surgical Site Prevents Surgical Errors

- Marking of correct site and side by client, nurse, and surgeon reduces errors.
- Time to reconfirm client identifiers and correct procedure should involve the entire surgical team.

postoperative complications, and decreased duration of hospitalization. Of course, fear and anxiety are greatly reduced when explanations are complete and time is allowed during the teaching session to answer questions by both the client and family. The client has the right to know what to expect during the surgical procedure and the postoperative period as set forth in The Client's Bill of Rights. Informing the client to expect postoperative presence of a urinary catheter, drainage tubes, central/arterial IV lines, cast, etc., while awake before anesthesia, promotes postoperative cooperation.

The teaching plan needs to include the preoperative preparation, time of surgery, and postoperative activities. A tour of the postoperative unit is also an important aspect of the teaching, particularly if the client will be going to a critical care or special care unit. Clients should also know what to expect about invasive tubes (i.e., Foley catheter, drains, chest tube) and monitoring lines (i.e., arterial and central venous pressure), which will help to decrease their anxiety postoperatively. A demonstration of specific equipment such as incentive spirometer, PCA pumps, cardiac monitors, and immobilizers should be presented to increase compliance with the equipment postoperatively. Information regarding time of arrival to the hospital and fluid and food restrictions should be provided before hospitalization, whether it is for outpatient or inpatient surgery.

Other areas covered in the preoperative stage are the type of anesthesia (usually described by the anesthesiologist) and the physical preparation of the client, which includes preoperative skin preparation, identifying the correct client in the operating room, and in some cases, the preoperative scrub. This may include the surgical cleansing prep and hair removal. Cutting excessive hair has replaced shaving, which produces minute dermal cuts and increased risk of infection. If it must be completed in the intraoperative area, a method that controls aerosolization of hair and epithelium is utilized.

Intraoperative Stage

This stage includes the time the client arrives in the preinduction or holding room until he or she arrives in the recovery room. The client may well complain of being cold. The operating room is kept cool, so offering a warm blanket will make the client more comfortable. The use of the Bair Paws Warming System provides heat more effectively than a blanket. Nurses complete an assessment, and may insert IVs and Foley catheters.

Once the client is moved to the operating room itself, a "Time Out" is called before anything transpires. The Time Out is a formal verbalization and checking of "Correct Client, Correct Procedure, Correct Site." All members of the OR team must participate in the process, including surgeon, anesthesiologist,

surgical assistant, circulating RN, surgical scrub nurse, or technician. The process includes verification of antibiotic administration, allergies, presence of appropriate prosthesis/implants, and correct client positioning. The process is an Association of Perioperative Registered Nurses (AORN) Standard of Practice and a mandate of The Joint Commission. The anesthesiologist prepares the client for and administers the anesthesia while monitoring the client throughout the procedure. The operating room nurses, circulating and scrub, prepare the operating room and provide for client safety. Operating room technicians are used in many facilities in place of scrub nurses.

AORN has developed a position statement regarding the role of the scrub nurse to achieve optimal client outcomes (AORN, Inc., 2004, “Perioperative Patient-focused Model: Standards Recommendations, Practices, and Guidelines”). An RN must be assigned to the operating room when an OR technician is used as a member of the team. In this case, the OR nurse functions as the circulating nurse. The circulating nurse must always be an RN. The nurse assists in the preparation of the client, positions the client on the operating room table, and ensures that a grounding pad (if electrocautery is used) is securely attached to the client. To maintain client safety, the role of the circulating nurse is highly complex due to the mandates, technical innovations, client advocacy issues, interactions with physicians, operating room personnel, and scheduling/timing of cases. Critical responsibilities of the circulating RN include ensuring sterile technique, correct counts of instruments and sponges, and availability of correct instrumentation. The circulating nurse must be an RN as he/she supports the anesthesiologist during the procedure. The assistance includes starting and monitoring venous lines, administering IV medications when necessary, verifying and hanging blood, and assisting in monitoring the condition of the client. The circulating nurse also assists the team in gowning and gloving for the procedure.

Moderate (Conscious) Sedation Conscious sedation is used for some surgical procedures and for invasive procedures or tests. Procedures once performed only in an operating room can now be safely done in outpatient settings and special procedures rooms. Conscious sedation may be used in critical care units when clients are restless and anxious and this proves detrimental to treatment. Conscious sedation requires a signed permit, the same as when using general anesthesia. Conscious sedation is the administration of an IV sedative, opioid, or hypnotic drug that

produces sedation, analgesia, and amnesia. Clients receiving conscious sedation can respond to commands and maintain their own airway. Clients under light sedation are able to maintain normal respiration, eye movements, and protective reflexes. They usually do not remember the procedure or even the environment. After the use of conscious sedation, the client may have slurred speech and nystagmus at the end point of the sedation.

Moderate sedation occurs on a continuum from the state of being alert to being in deep sedation. When the client is in a minimum sedation state, he or she can still be anxious. In deep sedation, the client is in a controlled state of depressed consciousness or unconsciousness and is not easily aroused and does not respond to command. Moderate sedation is considered to be safer than general anesthesia; however, there are risks involved with the use of conscious sedation. As the level of sedation increases, the risk of complications increases as well. Clients can become too deeply sedated and require intervention to maintain a patent airway and breathing. Unlike general anesthesia, conscious sedation allows clients to maintain a patent airway and respond appropriately to physical stimulation and verbal commands. Another benefit of conscious sedation includes a quicker return to baseline neurologic status.

A qualified anesthesia provider must give orders for administration of conscious sedation. Some states and institutional guidelines allow qualified registered nurses to administer sedating drugs. The American Nurses Association (ANA) and other nursing organizations have written position papers relative to the practice of administering and monitoring clients undergoing conscious sedation. Nurses must be familiar with the state nurse practice act as well as the institutional policies regarding their role in this procedure. Nurses allowed to administer conscious sedation must meet additional criteria and demonstrate proficiency in the skill. The nurses are working under *standard procedures* in this situation. Nursing students are not allowed to administer conscious sedation or monitor clients while they are receiving conscious sedation.

During the entire procedure the safety of the client is the priority goal for the entire staff assigned to the procedure. All staff assist in monitoring the client, ensure that sterile technique is maintained throughout the procedure, and maintain accurate and complete documentation, including sponge and instrument counts. OSHA guidelines are followed by the staff to protect both the client and the staff from exposure to bloodborne pathogens.

Surgical Safety Checklist

The surgical safety checklist was established in 2008 as a result of the World Health Organization (WHO) published guidelines, with recommended practices to ensure the safety of surgical clients worldwide. The guidelines were developed to reduce the rate of major surgical complications. A worldwide study was completed to determine whether complications could be reduced by following the surgical checklist before each surgical procedure. There are an estimated 234 million surgical procedures performed annually.

Perioperative death rate in inpatient surgery is 0.4%–0.8%, and there is a 3%–17% rate of major complications. Data have suggested that at least half of all surgical complications are avoidable. The checklist was used to collect data on 500 consecutively enrolled clients in eight cities throughout the world. Clients were followed from surgery to 30 days postoperative. A 20% reduction in complications occurred in study participants after the checklist was implemented.

Surgical Safety Checklist

Before Induction of Anesthesia

(with at least nurse and anesthetist)

Has the patient confirmed his/her identity, site, procedure, and consent?

Yes

Is the site marked?

Yes

Not applicable

Is the anesthesia machine and medication check complete?

Yes

Is the pulse oximeter on the patient and functioning?

Yes

Does the patient have a: Known allergy?

No

Yes

Difficult airway or aspiration risk?

No

Yes, and equipment/assistance available

Risk of >500 mL blood loss (7 mL/kg in children)?

No

Yes, and two IVs/central access and fluids planned

Risk of hypothermia (operation >1 hr)?

No

Yes, and warmer in place

BEFORE INDUCTION check complete

Before Skin Incision

(with nurse, anesthetist, and surgeon)

Confirm all team members have introduced themselves by name and role.

Yes

To surgeon, anesthetist and nurse:

What is this patient's name?

What procedure is planned?

Where will the incision be made?

Has the antibiotic prophylaxis been given within the last 60 minutes?

Yes

Not applicable

Is venous thromboembolism prophylaxis needed?

Yes, and boots/anticoagulants in place

Not applicable

Anticipated Critical Events to Surgeon:

What are the critical or non-routine steps?

How long will the case take?

What is the anticipated blood loss?

What implants/equipment issues or any concerns?

To Anesthetist:

Are there any patient-specific concerns?

To Nursing Team:

Has sterility (including indicator results) been confirmed?

Are there equipment issues or any concerns?

Is essential imaging displayed?

Yes

Not applicable

BEFORE SKIN INCISION check complete

Before Patient Leaves Operating Room

(nurse or anesthetist reads out load)

Nurse verbally requests from the team:

How shall I record the name of the procedure?

Are the instrument, sponge, and needle counts complete?

How shall I label the specimens (including patient name)?

Are there any equipment problems to be addressed?

To Surgeon, Anesthetist, and Nurse:

What are the key concerns for recovery and management of this patient?

BEFORE LEAVING ROOM check complete

Source: World Health Organization. (2008). Based on the WHO Surgical Safety Checklist. Available at: http://whqlibdoc.who.int/publications/2009/9789241598590_eng_Checklist.pdf.

After the procedure the client is transferred to the postanesthesia room by the anesthesiologist and/or surgeon and, in some facilities, the circulating nurse. A complete report of the client's status is provided to the postanesthesia staff.

Postoperative Stage The *postoperative stage* can be divided into three segments. The immediate postoperative period includes the care given to the client in the postanesthesia room

and in the first few hours on the surgical floor. The intermediate period usually involves the care given during the course of surgical convalescence to the time of discharge. The third segment in the postoperative stage is discharge planning, teaching, and referral. Discharge planning and teaching begin during the preoperative period and are reinforced and continued in the postoperative period.

Universal Protocol for Preventing Wrong Site, Wrong Procedure, Wrong Person Surgery

The implementation of the universal protocol is required by all hospitals accredited by The Joint Commission. The protocol is based on the consensus of experts from clinical specialties and professional disciplines and more than 40 professional medical associations and organizations (The Joint Commission: Effective July 1, 2004).

The protocol identifies the principles necessary to eliminate a surgical client's injury from a wrong procedure, wrong site, wrong person. It includes the method of marking the operative site and active communication amongst all surgical team members to ensure that procedures are carried out to prevent these tragedies. Markings are required whenever there is a procedure involving right/left distinction, multiple structures such as toes and fingers, or levels such as spinal procedures. These markings are placed at the operative site indicating the exact surgical site. This is critical when it involves limbs to ensure the surgical procedure is performed on the correct limb. The person performing the surgical procedure should do the marking. If the surgeon is unable to perform the markings, a surgical team member can be designated to mark the site. In most states, nurses on the surgical team may be delegated to mark the surgical site.

Source: The Joint Commission. <http://www.thejointcommission.org>.

Besides nursing care, nursing management during the postoperative period centers on assessing the client's postoperative condition and monitoring for complications. It also includes client teaching, pain control, and psychologic support of both the client and family.

When the client is deemed stable, he or she is transferred to the nursing unit, critical care unit, and in the case of an outpatient client, to home. The nursing care provided in the postoperative period is well described in the chapter.

CULTURAL AWARENESS

Most religions and cultures allow the administration of blood and blood products. The exception is Jehovah's Witnesses, who forbid the use of blood and blood products. Christian Science followers ordinarily do not allow blood and blood products either. Surgical procedures are accepted by all religions and cultures with some modification. Buddhists permit surgery, but will avoid extremes in surgical procedures. Roman Catholics do not allow abortion or sterilization procedures.

NURSING DIAGNOSES

The following nursing diagnoses are appropriate to include in a client care plan when the components are related to a surgical experience.

NURSING DIAGNOSIS	RELATED FACTORS
Ineffective Airway Clearance	Pulmonary secretions, allergic response, medications, suppressed cough reflex, decreased oxygen intake, pain, mechanical obstruction
Anxiety	Actual or perceived threat to body image, ability to maintain independence, long-term effects of surgical procedure
Ineffective Coping	Inadequate support system, change in body integrity, unrealistic expectations regarding surgical outcome, stress from surgery
Infection, Risk for	Impaired wound healing, nutritional deficits, inadequate acquired immunity
Deficient Knowledge	Inadequate understanding of surgical procedure, language barrier, incomplete client teaching, lack of motivation, cognitive limitation
Latex Allergy Response, Risk for	Clients at risk have allergies to bananas, tropical fruit, poinsettia plants; clients with multiple surgical procedures who have repeated contact with natural latex rubber
Acute Pain	Tissue damage resulting from surgical intervention, ineffective pain relief, psychological factors
Perioperative Positioning Injury, Risk for	Joints and extremities malpositioned or maintained in one position for long period of time
Impaired Skin Integrity, Risk for	Excessive hours on operating table, operative table drapes wrinkled, excessive fluid accumulation on drapes
Delayed Surgical Recovery	Evidence of interrupted healing of surgical area; difficulty in ambulation, pain, fatigue

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. Remember to wash your hands or use antibacterial gel before and after each and every client contact.

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Chapter 26

UNIT 1

Stress in Preoperative Clients

Nursing Process Data

ASSESSMENT Data Base

- Identify if high level of stress exists.
- Assess exaggerated anxiety or stress behaviors.
- Assess client's use of defensive behaviors.
- Assess client's vulnerability to number and significance of changes in life before admission.
- Assess client's level of knowledge and perceptions of the impending surgery and perioperative period.

PLANNING Objectives

- To identify the level of stress and anxiety present in preoperative clients
- To provide interventions that decrease stress levels and promote optimal preoperative behavioral and physiologic responses
- To observe for use of defensive behaviors that mask a failure to adapt appropriately in stressful situations
- To prepare the client for a smooth preoperative and postoperative period
- To prevent postoperative complications

IMPLEMENTATION Procedures

- Preventing Anxiety and Stress 961
- Reducing Anxiety and Stress 961
- Assisting the Client Who Uses Denial 962

EVALUATION Expected Outcomes

- Client's level of stress and anxiety is identified.
- Nursing interventions are provided that decrease stress levels and promote optimal preoperative responses.
- Denial, as a defense mechanism, is identified in the client and therapeutic interventions are made.
- Client identifies stressors and own stress response.
- Client demonstrates coping strategies to control stress and anxiety.
- Client and family state expectations for perioperative experience.
- Client demonstrates activities that will be performed postoperatively.

Critical Thinking Application 963

- Expected Outcomes 963
- Unexpected Outcomes 963
- Alternative Actions 963

Prepare for success with NCLEX®-style practice questions
and Skill Checklists

Preventing Anxiety and Stress

Procedure

1. Establish a trusting relationship.
2. Encourage verbalization of feelings.
3. Listen attentively.
4. Communicate acceptance of the client as an individual.
5. Identify the client's needs (Table 26-3) and keep the charge nurse informed of them.
6. Give adequate information regarding hospital procedures.
 - a. Hospital environment, including sights, sounds, and equipment.
 - b. Hospital personnel and routine procedures: mealtimes, telephone usage, call light.
 - c. Ordered preoperative procedures: lab tests, diagnostic procedures (explain the sensory experiences that will be encountered).
 - d. Scheduled time of surgery.
 - e. Hospital regulations: visiting hours, children's age for visiting.
 - f. Preoperative procedures: skin preparation, NPO, medications, side rails, dentures, nail polish.
 - g. Anticipated intraoperative events: monitors, oxygen mask, intravenous line, etc.
 - h. Anticipated postoperative events: recovery room, pain and pain medications, coughing and deep breathing exercises, dressings, IVs, Foley catheter.

TABLE 26-3 Preoperative Stress Assessment

Physiologic Responses	Emotional and Defensive Responses	Anxiety and Activity Responses
Heart rate: rate increases 10 beats/min over baseline during three observations	Withdrawal: daydreaming, increased time in sleep, unwillingness to talk, disinterest	Hyperactivity: pacing, hand-wringing, lip or nail biting, finger-tapping, impatience, irritability, insomnia
Presence of palpitations	Anger: resentment, aggressiveness, noncompliance, swearing, boasting, attempts to gain control, and independence	Disorganization of thought: repetitive speech, constant conversation, difficulty concentrating
Blood pressure: increases more than 10 mmHg over baseline during three observations	Denial: joking, carefree attitude, inappropriate laughter, refusal to discuss impending surgery	Increased sensitivity to environmental noise, light, temperature, activity
Respiratory rate: increases more than five per minute over baseline during three observations		Increased muscle tensing: furrowed eyebrows, facial tics, clenched jaws, loud or high-pitched voice, stammering, rapid speech, elevated shoulders, clenched fists, urinary frequency, tension, or inability to relax
Vasoconstriction of blood vessels near the skin: cool, pale fingers and toes; increased capillary filling time of more than 3 seconds		Increased energy and preparedness: restlessness, easily startled, increased activity level
Vasoconstriction of renal vessels: decreased urine output compared with baseline and fluid intake		
Vasoconstriction of gastric and mesenteric vessels: anorexia, nausea, vomiting, abdominal distention with flatus, decreased bowel sounds, hyperactivity, diarrhea		

Reducing Anxiety and Stress

Equipment

- CD player or Ipod
- Appropriate relaxation tape

Procedure

1. Establish a trusting relationship.
2. Encourage verbalization of feelings.
3. Use touch to communicate caring and genuine interest, if culturally appropriate.
4. Avoid false reassurance.
5. Use realistic outcomes.
6. Assist client in exploring effective coping methods to reduce anxiety and/or stress.
 - a. Ask the client or the family what method the client normally uses to successfully reduce stress.
 - b. Provide activity: walking, range of motion.
- c. Provide a back rub to loosen tense muscles.
 - **Rationale:** Physical relaxation will often lead to mental relaxation.
- d. Teach client relaxation techniques. One technique is to ask the client to picture a blue sky that is clear except for one white, fluffy cloud. Tell client to concentrate on this scene for 10 minutes. This often relaxes the mind and body.
- e. An alternative is to ask the client to picture a favorite place (e.g., a warm, sunny beach with sand and a clear, blue lake).
7. As the client begins to relax, reinforce success. Assist client in recognizing his or her strengths.
8. Encourage self-awareness of increasing tension and immediate reversal of escalation.

Assisting the Client Who Uses Denial

Procedure

1. Establish a trusting relationship.
2. Encourage verbalization of feelings and use an interpreter if necessary.
3. Use touch to communicate caring and genuine interest if acceptable to client (i.e., some cultures prefer not to be touched).
4. Do not attempt to enforce reality. The client is denying reality to prevent outright panic. Allow use of this defense.
5. Use techniques to reduce anxiety and stress to manageable proportions.
6. Attempt to determine the cause of the need for denial.
7. Listen for cues that indicate readiness to discuss the stressors causing the need for denial.
8. Notify physician of your findings.

DOCUMENTATION for Preoperative Stress

- Objective and subjective indications of anxiety or stress levels
- Nursing interventions used to decrease stress and the results of the intervention
- Changes that occurred as a result of the nursing interventions
- Specific fears verbalized by the client
- Nonverbal indications of stress or anxiety

CRITICAL THINKING Application

Expected Outcomes

- Client's level of stress and anxiety is identified.
- Nursing interventions are provided that decrease stress levels and promote optimal preoperative responses.
- Denial, as a defense mechanism, is identified in the client and therapeutic interventions are made.
- Client identifies stressors and own stress response.
- Client demonstrates coping strategies to control stress anxiety.
- Client and family state expectations for perioperative experience.
- Client demonstrates activities that will be performed postoperatively.

Unexpected Outcomes

Anxiety level increases rapidly.

Alternative Actions

- Maintain calm composure and speak in a soft, caring manner.
- Use touch to communicate caring and peacefulness, if culturally appropriate.
- Reinforce client self-acceptance as an individual.
- If unable to achieve success with stress-reducing techniques, notify physician.

Client becomes angry or hostile.

- Maintain calm composure.
- Accept anger, but place limits on how it may be expressed (e.g., no destructive behavior). Understand that anger is usually the result of feeling helpless and powerless to change an intolerable situation.
- Do not reward this behavior, but explore other means of meeting client's needs.
- Do not isolate client, but continue to respond to needs.
- Notify physician of client's behaviors and the actions you used to decrease anger or hostility.

Client becomes depressed because of overwhelming anxiety and feelings of helplessness or hopelessness.

- Convey respect and belief that the client is worthwhile. Question the client's appraisal of reality and provide support while the client works through his or her feelings.
- Provide positive feedback and recognition of strengths, progress, and improved self-esteem.
- Spend additional time with the client to allow time to verbalize fears.

Chapter 26

UNIT 2

Preoperative Teaching

Nursing Process Data

ASSESSMENT Data Base

- Identify type of surgical procedure planned.
- Determine whether client understands type of anesthesia planned.
- Assess client’s sociocultural needs.
- Assess client’s learning needs.
- Determine most appropriate method of client teaching.
- Assess client’s willingness and ability to learn.
- Determine availability of prepared audiovisual material or printed information regarding surgical procedure.

PLANNING Objectives

- To reinforce physician’s explanation of surgical procedure and answer questions regarding treatment
- To identify client’s readiness to learn about surgical treatment
- To select appropriate time and place for client instruction regarding surgery
- To provide instruction in measures to prevent postoperative complications
- To provide a time for client to ask questions regarding surgical procedure
- To instruct client in use of special equipment required during the postoperative period
- To provide tour of specialty units, such as critical care unit, lithotripsy, or laser rooms

IMPLEMENTATION Procedures

- Providing Surgical Information965
 - For the Preoperative Client in the Hospital965
 - For the Preoperative Client in an Outpatient Setting . . .965
 - For the Intraoperative Client965
 - For the Postoperative Client966
- Providing Client Teaching966

- Providing Family Teaching967
- Teaching for Laser Therapy967
- Teaching for Lithotripsy968
- Teaching for Laparoscopy969
- Teaching for Arthroscopy970
- Instructing in Deep Breathing Exercises971
- Instructing in Coughing Exercises972
- Providing Instruction to Turn in Bed972
- Instructing in Leg Exercises972

EVALUATION Expected Outcomes

- Client is psychologically and physically prepared for surgery.
- Client demonstrates deep breathing, coughing, turning, and leg exercises accurately.
- Client verbalizes knowledge of operative procedure, potential problems, and expected nursing actions postoperatively.
- Client’s family states what they expect during perioperative period.
- Client uses appropriate audiovisual and written materials to increase understanding of perioperative experience.
- Client reports decreased fear regarding special equipment used during perioperative experience.
- Client states safety precautions used with laser and lithotripsy surgery.

Critical Thinking Application973

- Expected Outcomes973
- Unexpected Outcomes973
- Alternative Actions973

Pearson Nursing Student Resources

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Providing Surgical Information

Equipment

Quiet room for client and family where there will be no interruptions during the teaching program

Equipment that may be used postoperatively by the client (e.g., IV solution, drainage tubes, nasogastric tube, suction equipment, cardiac monitor, and electrodes)

Procedure

For the Preoperative Client in the Hospital

1. Explain necessity for blood work, ECG, urinalysis, chest x-ray.
 2. Describe preoperative skin preparation.
 3. Discuss placement of nasogastric tube, Foley catheter, as indicated.
 4. Describe enema or special bowel preparation as ordered.
 5. Explain use of ongoing medications preoperatively and postoperatively.
 6. Demonstrate deep breathing and coughing exercises (use of incentive spirometer if indicated).
 7. Assess alcohol use and smoking habits. Emphasize smoking cessation techniques.
 8. Assess and document medications used at home, including prescribed, OTC, and herbal remedies; verify that medications related to clotting have been discontinued for an adequate amount of time, usually 1 week before surgery.
 9. Demonstrate leg exercises, antiembolic stockings, and sequential compression device.
 10. Demonstrate turning and moving in bed.
 11. Explain use of postoperative medications for pain control; PCA.
 12. Discuss reason for NPO, when it begins, and medication schedule.
 13. Explain alterations in diet preoperatively or postoperatively.
 14. Describe activities and preparation the morning of surgery, including their participation in the “Time Out” process.
 15. State need for quiet environment after medications have been given.
 16. State time of surgery to client and family.
 17. Describe and reinforce information usually provided by anesthesiologist and surgeon.
 18. Offer tour of procedure room, PACU, or ICU that would be used with client and explain monitoring devices and special equipment used there.
3. Call the client several days in advance if long-duration surgical preparations need to be completed before the procedure. If short-duration preparations are required, call the client in the afternoon before the procedure. It is best if the nurse who will care for the client during the surgery calls the client. ► **Rationale:** The call begins the nurse–client relationship and helps decrease anxiety.
 4. Assess client’s ability to understand instructions. If necessary, ask to speak to someone else in the home. ► **Rationale:** If instructions are not followed, it could result in unsafe canceled surgery.
 5. Review any lab work that needs to be completed before the scheduled surgery. Explain where the lab work is to be done.
 6. Answer the client’s questions regarding the surgery and the procedures carried out by the staff during the surgery, including “Time Out” process.
 7. Arrange for preadmission as needed.
 8. Discuss the procedure for admission to the facility; when to check in at the facility (usually 1.5–2 hr before the scheduled surgery), and what documents need to be available at the time of registration (e.g., insurance card and possibly deductible payment).
 9. Determine whether client has an advance directive available or explain what it is and how to obtain a temporary advance directive.
 10. Discuss procedure-appropriate clothing to be worn to the setting. For example, clients having knee surgery should wear loose-fitting sweatpants or shorts.
 11. Explain that all jewelry and valuables should be left at home for safekeeping.
 12. Explain that someone needs to be with the client to take him/her home.
 13. Instruct client to not shave surgical site at home. ► **Rationale:** Skin nicks increase the risk of infection.

For the Intraoperative Client

1. Describe mode of transportation to operating room.
2. Discuss procedure in preinduction room or operating room suite in relationship to anesthesia.
3. Reinforce physician’s explanation of surgery.
4. Describe dressings, tubes, or equipment that will be used postoperatively.
5. Verify side of body and site involved. See pages for “Time Out” process.

Clinical Alert

All herbal medications must be stopped at least 2 weeks before surgery. Side effects vary depending on type of herbal remedy, ranging from sympathomimetic effects, tachycardia, and hypertension to inhibition of platelet activity.

For the Preoperative Client in an Outpatient Setting

1. Check two forms of client ID.
2. Verify accurate consent form has been signed by the client.

6. Describe postanesthesia room physical environment and procedures.
7. Explain administration of oxygen.
8. Explain administration of medications.

For the Postoperative Client

1. Describe assessment procedures.
2. Provide overview of routine procedures of vital signs.
3. Demonstrate deep breathing, turning, and coughing exercises.

4. Describe IV therapy if indicated.
5. Explain irrigation of tubes when indicated.
6. Discuss Foley catheter care if indicated.
7. Review dietary alterations.
8. Describe observation and changes of dressing.
9. State ambulation or restrictions in ambulation.
10. Define type of medications used postoperatively.
11. Provide anticipated discharge and plans for assisted care if needed.

Providing Client Teaching

Equipment

Prepare teaching aids when available: audiovisual, videos, interactive computer programs, pamphlets, pictures, posters, programmed learning modules, cassette tapes, overhead transparencies, equipment used with client.

NOTE: Ask client about the best way they learn (auditory, kinesthetic, visual). This will determine the best method for teaching.

Procedure

1. Assess client's knowledge base and readiness to learn.
 - ▶ **Rationale:** This provides framework for client education at the level client can understand.
 - a. Determine the information provided to client by physician by reading physician's progress notes and asking client specific questions.
 - b. Identify client's psychosocial and cultural background and ability to listen to teaching by

▲ Demonstrate use of special equipment in prospective teaching plan.

- a. Communicating with client and asking direct questions.
 - b. Be alert for cultural or religious beliefs that may influence client's surgical experience.
 - c. Identify client's perceptions of expected surgical experience and preferences for learning.
2. Develop individualized teaching plan based on client's needs.
 - a. Choose appropriate equipment for teaching, based on client's level of understanding, knowledge base, and language of preference.
 - b. Review information previously provided.
 - ▶ **Rationale:** To determine retention of information and needless repetition of information already mastered.
 - c. Choose a quiet environment, and provide for sufficient time to allow client to ask questions.
 - ▶ **Rationale:** To ensure client understands planned surgical experience.
 - d. Be alert for clues indicating client confusion or misunderstanding of information. Clients may be nodding "yes" even though they do not understand, especially non-English-speaking clients. ▶ **Rationale:** Misunderstanding information can be detrimental to the client's sense of well-being.
 3. Select appropriate audiovisual materials to assist with teaching.
 4. Demonstrate use of special equipment or devices (e.g., incentive spirometer, chest tubes, suction equipment).
 5. Evaluate client teaching by assessing client's ability to return demonstration of exercises and verbally answer specific questions. Reinforce information or provide additional data as needed.

Providing Family Teaching

Procedure

1. Include family in teaching provided to client.
2. Instructions to family members should include:
 - a. Visiting hours.
 - b. Where to wait during surgery.
 - c. Where the surgeon will meet with them and when.
 - d. Where they can find bathrooms, telephones, and food and beverage service.
 - e. When they can see the client after surgery.
 - f. How to contact a spiritual or religious resource person.
 - g. How they can best get information regarding the client's condition while they are at home or in the hospital.
 - h. Whether they will be called if there is a change in the client's condition.
 - i. What to expect: client's behavior, which may be regressive; attitude, which may be depressed or angry; physical condition, which may appear worse than it is; and postrecovery period. ▶ **Rationale:** Some medications may impair client's memory of events.
 - j. If parents are allowed in recovery room, remind them child will still be under effects of anesthesia. Child may cry, be combative, or agitated. Child may be held down by nurses to prevent injury.
 - k. Instruct parent they should touch and speak to child to promote reassurance until medications and anesthesia effects are diminished.

Teaching for Laser Therapy

Procedure

1. Determine type of laser (Table 26-4) to be used for surgery.
2. Check two forms of client ID and introduce yourself.
3. Determine client's willingness to accept instruction.
4. Determine most appropriate time and place for instruction.
5. Identify client's level of understanding of surgical procedure and what information physician has provided (Table 26-5).
6. Reinforce explanation of surgical procedure by physician as needed.
7. Describe operating room setting or outpatient setting, including the environment.
8. Explain that client and operating room staff will wear goggles. ▶ **Rationale:** Goggles protect eyes from the laser beam.
9. Explain the use of wet drapes placed over client's skin if required. ▶ **Rationale:** Wet drapes protect skin from burns when some types of laser therapy are used.
10. Describe that laser machine may be very noisy.
11. Describe physician's actions during laser therapy. Physician will discharge laser by using a foot pedal while at the same time issuing instructions to nurses using terms such as *fire*, *watt seconds*, and *standby*. ▶ **Rationale:** Describing these words to client allays fear of unfamiliar terms or actual fire. It also describes nurses' role of regulating power and duration of laser beam use.
12. Caution client, if under local anesthesia, he or she may feel heat and smell smoke and a burning odor from tissue being lased.
13. Instruct client to tell physician if pain occurs. ▶ **Rationale:** Additional anesthetic may need to be administered as client should not feel pain.

TABLE 26-4 Types of Laser *

Types	Uses
Carbon dioxide	High-precision cutting instrument used in areas where function must be preserved (e.g., vocal cords, brain, GYN procedures). Also used to treat snoring and for dermatology procedures (e.g., removal of scars and skin cancers).
Holmium	Combines the cutting properties of the CO ₂ laser with the coagulation properties of the YAG laser. It is used in targeted tissue affecting adjacent, healthy tissue. Can be used with dense or hard tissue. Used in urology procedures (e.g., laser ablation of the prostate [TLAP, HOLAP], stone fragmentation [lithotripsy], strictures, obstructions, condylomata, bladder and ureteral tumors and contractures)
Nd: YAG	Laser made of a neodymium alloy, yttrium, aluminum, and garnet crystals. Beam penetrates deeply; can be passed through flexible fibers for cardiovascular laser therapy and scopes (e.g., cystoscope, bronchoscope, and endoscope to treat bladder, prostate, and lung tumors and coagulate esophageal varices; also used for eye surgery)
Argon	Used for ophthalmic and dermatologic procedures (e.g., treating glaucoma, cataract, retinal detachment, and removing birthmarks, hemangiomas)
Liquid dye	Used for diagnostic procedures and in conjunction with drugs for photodynamic treatment (e.g., lithotripsy)

*Light amplification by the stimulated emission of radiation. Choice of laser type is determined by procedure required for treatment.

TABLE 26-5 Common Types of Laser Surgical Procedures and Complications

Procedure	Client Teaching	Assessment Findings for Potential Complications
Pulmonary	Gag reflex returns in 2–4 hr Begin taking fluids when gag reflex returns Expect hoarseness, dyspnea, sore throat, difficulty swallowing for 48–72 hr	Bright red blood expectorated related to hemorrhage Fever, shortness of breath Use of accessory muscles for breathing related to tracheal edema Wheezing related to airway obstruction Pneumonia and respiratory insufficiency related to aspiration of secretions Altered arterial blood gases and sudden pain causing altered vital signs related to pneumothorax
Upper GI	May experience burning sensation in esophagus May experience difficulty swallowing Heartburn present for 3 days	Poor skin turgor and decreased urine output related to dehydration that may be caused by dysphagia Vomiting bright red blood related to perforation Abdominal pain related to perforated bowel Vomiting and abdominal distention related to obstruction of GI tract due to edema
Urology	May experience traces of blood, small blood clots, or traces of tissue in urine for 24 hr Catheter may be left in place temporarily for up to 1 week Urinary frequency and urgency may occur for 1 week	Bright red urine related to hemorrhage Abdominal pain related to perforated bladder Fever, increased pulse, malaise related to infection Inability to void related to blood clots
Cardiovascular	May experience slight burning or chest pain over coronary vessels	Arrhythmias related to hypoxia or laser treatment Bleeding at site of percutaneous laser angioplasty; related to catheter insertion Intake and output values altered related to osmotic contrast media used for laser treatment Changes in vital signs (i.e., may become hypotensive with cardiac tamponade)
Eye	Most clients feel no pain because local or topical anesthesia is used Need to remain quiet during procedure	Corneal injury can occur if eye is rubbed or bumped Increased intraocular pressure is unusual but can occur

- Instruct client to maintain NPO status 6–8 hr before surgery.
- Instruct client in postoperative care specific to procedure performed.

- Instruct client to notify physician if temperature is above 100°F for more than 24 hr after laser therapy. ► **Rationale:** Infections are unlikely but can occur; therefore, client needs to monitor for presence of symptoms.

Teaching for Lithotripsy

Preparation

- Identify type of extracorporeal shock wave lithotripsy (ESWL) used for kidney stones and occasionally for gallstones.
- Identify type of anesthesia that will be used: local, epidural, spinal, or general. General anesthesia is usually used to prevent pain as stones are fragmented.
- Identify whether client will have a ureteral stent or Foley catheter inserted after the procedure. A string may be visible at the end of the penis and is attached to a stent; this will aid in the removal of the stent at a later time.

Procedure

- Check two forms of client ID and introduce yourself.
- Determine client's knowledge base and information provided by physician.

- Reinforce physician's description of procedure, as needed.
- Answer client's questions regarding procedure.
- Explain that lithotripter discharges a series of shock waves through water or water-filled cushion.
- Describe to client that he or she may feel fluttering or mild blows where shock waves are beamed. From 500 to 2,400 shocks are required to disintegrate stones.
- Discuss use of specialized equipment that will be used. Client may sit in tank of water or lie with water-filled cushion pressed against area of back or abdomen where stones are present.
- Describe use of monitoring equipment throughout procedure. ► **Rationale:** The heart rate and rhythm are monitored throughout procedure and shocks may be synchronized with the rhythm to prevent arrhythmias.

9. Explain that the procedure takes 20 minutes to 2 hr, depending on type of procedure.
10. Describe postlithotripsy care.
 - a. After procedure, client is removed from tub, covered with warm blanket, and taken to recovery room.
 - b. Vital signs are monitored as with any surgical client.
 - c. Urine output is monitored for hematuria.
 - ▶ **Rationale:** To determine kidney damage from procedure.
 - d. Strain all urine at the facility and at home.
 - ▶ **Rationale:** To obtain fragments of the stones in order to send them for analysis. Knowing composition of the stone is essential for altering dietary habits in some cases.
 - e. Liver function studies are performed after lithotripsy for gallstones. ▶ **Rationale:** To assess whether shock waves have damaged liver.
 - f. Pain management is monitored and maintained as gravel is passed after disintegration of stones.
 - g. Medication is provided for nausea and vomiting.
 - ▶ **Rationale:** Nausea and vomiting often accompany pain and postanesthesia.
 - h. Intake and output measurements are taken.
 - ▶ **Rationale:** Fluids are encouraged to hydrate clients with kidney stones to assist in the excretion of gravel.
 - i. Catheter care is provided for clients having kidney procedure requiring indwelling catheters. If a stent is used, it may cause urgency, dysuria, frequency, and bleeding. ▶ **Rationale:** Indwelling catheters and ureteral stents, if used, are left in place for 24 hr to assist with passage of gravel or if second ESWL treatment is required.
 - j. Exercise is encouraged to assist with passing of gravel.
 - k. Ecchymoses and discomfort may be felt over area of the body that experienced shock waves.
11. Provide tour of lithotripter room, if possible.

Teaching for Laparoscopy

Preparation

1. Identify purpose of laparoscopy.
2. Identify type of anesthesia that will be used. Usually, it is done under general anesthesia.
3. Determine whether ultrasound, CT scan, and/or MRI was done; if so, have results available for physician.
4. Obtain results of standard blood tests and urine tests if done.

Procedure

1. Check two forms of client ID and introduce yourself.
2. Determine client's knowledge base and information provided by physician.
3. Reinforce physician's description of procedure: as needed.
4. Describe equipment used for procedure: instrument used in procedure is a medical telescope with a light and high-resolution television camera so physician can see what is in the abdomen.
5. Describe procedure to client: incision is made into umbilicus; CO₂ gas is infused into abdomen to insert a small air pocket; a small camera and instruments are inserted through incision.
6. Instruct client that procedure is usually done in a same-day surgery setting. Client will go home the same day. More major procedures require overnight stay for observation and pain management.
7. Instruct client to not eat or drink for 6–8 hr before procedure.
8. Explain that client should shower evening before or day of surgery with chlorhexidine or agent prescribed by

physician. The umbilicus is cleaned with soap, water, and a Q-tip. ▶ **Rationale:** Chlorhexidine is well tolerated and does not leave discoloration on skin as a povidone-iodine preparation does.

9. Instruct client to be at the hospital 1–2 hr before the scheduled surgery, according to hospital policy. Tell client to bring someone to drive home.
10. Have client discuss with the surgeon whether to take routine medications the morning of surgery. If medications are taken, only a sip of water is used to swallow pills. Medications causing increased risk for bleeding need to be discontinued before surgery, such as

Therapeutic procedures commonly include:

- Cholecystectomy
- Bowel resection
- Nephrectomy
- Adrenalectomy
- Radical prostatectomy
- Tubal ligation
- Hysterectomy
- Repair of pelvic prolapsed
- Appendectomy
- Hernia repair
- Pulmonary resection
- Nissen procedure
- Urethral repair

A diagnostic laparoscopy is used for the following purposes:

- Diagnose causes of abdominal pain
- Obtain tissue from an abdominal mass to determine diagnosis
- Determine cause of ascites
- Obtain liver tissue for diagnosis
- Assist in cancer staging or for a “second look” procedure

those prescribed for arthritis, anticoagulants, OTC (i.e., aspirin), or certain alternative herbal medications, according to physician’s orders.

11. Instruct client to follow specific orders from physician’s office regarding other preoperative directions.
12. Explain setting where surgery will be performed. If possible, allow client to visit the area if he or she is anxious.
13. Describe postlaparoscopy care to client:
 - a. After surgery, client will go to the recovery room.
 - b. Vital signs are monitored, dressing will be observed for signs of bleeding, and medication for pain may be administered. IV fluids will be infused and monitored until effects of anesthesia have dissipated.

- c. Client is discharged home as soon as he or she is fully awake and able to get out of bed unassisted. Many facilities require the client to urinate and manage nausea without emesis after light intake of crackers and soda or juice before discharge.

Client must be accompanied by someone who can drive him or her home. ► **Rationale:** The effects of anesthesia may persist for several hours or as long as a day, even if the client feels fully awake.

- d. Instruct client that some soreness around incision is normal. Take pain medications as prescribed by physician. It is important to take pain medication on time or at the beginning of pain cycle for first 24–48 hr.
- e. Notify physician if chills, vomiting, redness at incision site, or worsening pain is not controlled by medication, or if unable to urinate. ► **Rationale:** These are signs of infection.
- f. Instruct client there may be a sharp pain under the scapula up to 24–48 hr postop and that changing positions may relocate “gas” bubble. ► **Rationale:** Retained carbon dioxide irritates the phrenic nerve in the diaphragm, causing referred pain. Carbon dioxide is used to distend the abdominal cavity to aid in visualization and provide working space during a laparoscopy.
- g. Instruct client to schedule a follow-up appointment with physician within 2 weeks.

Teaching for Arthroscopy

Preparation

1. Determine joint on which arthroscopy will be performed. Most common joints: knee, shoulder, elbow, ankle, hip, and wrist.
2. Identify type of anesthesia that will be used. General, spinal, or local anesthetic is used, depending on specific joint involved and suspected problem.
3. Determine whether diagnostic tests were done, i.e., MRI, x-rays, or arthrogram. Obtain results for physician.

Procedure

1. Check two forms of client ID and introduce yourself.
2. Determine client’s knowledge base and information provided by physician.
3. Reinforce physician’s description of procedure, as needed.
4. Describe equipment used for the procedure: pencil-sized instruments (arthroscope) that contain small lens and lighting system to magnify and illuminate structures inside the joint are inserted through incision.
5. Describe procedure to client: a small incision is made in client’s skin to allow instruments to be inserted into the

joint so that physician can see the interior of the joint. Several small incisions may be made to see other parts of the joint if needed. The image is projected on a television screen. The surgeon can then determine the amount or type of injury and repair or correct the problem.

6. Instruct client that procedure is done in an outpatient setting and he or she will go home the same day.

Conditions usually found and corrected by arthroscopy include:

- **Inflammation:** Synovitis
- **Injury:** acute and chronic:
 - Shoulder—rotator cuff tendon tears, dislocation, and impingement syndrome
 - Knee—meniscal tears, chondromalacia, and anterior cruciate ligament (ACL) tears and instability
 - Wrist—carpal tunnel syndrome
- **Loose bodies of bone and/or cartilage:** knee, shoulder, elbow, ankle, or wrist

7. Explain preoperative preparation that is completed before the day of surgery:
 - a. Diagnostic tests completed.
 - b. Operative permit signed.
 - c. Physical examination and health history completed.
 - d. Physician informed of routine medications and any allergies.
 - e. Procedure discussed with physician and anesthesiologist.
 - f. Client meets with physical therapist to be fitted with crutches and/or knee brace, if lower extremity affected.
8. Instruct client to not eat or drink anything after midnight unless otherwise instructed by physician.
9. Explain skin prep that is to be completed the night before surgery. A 5-minute scrub with an antiseptic is usually ordered. Follow facility policy for specifics—some physicians order a full shower and some concentrate on the surgical site.
10. Instruct client to follow surgeon or anesthesiologist instructions regarding taking routine medications.
11. Instructions to client before admission:
 - a. Remove all nail polish and make-up according to hospital policy. (This may not be necessary as newer oxygen saturation monitors use laser light that are not affected by nail polish.) ► **Rationale:** Capillary refill and skin coloration is assessed on all clients receiving anesthesia.
 - b. Do not bring jewelry, money, or other valuables to facility. ► **Rationale:** Facility is not responsible for client's valuables.
 - c. Wear comfortable, loose-fitting clothes such as loose-fitting button-down shirts or blouses, drawstring shorts, sweatpants, and boxer-style shorts. ► **Rationale:** This is to make it easier to dress after surgery, especially if a brace or sling has been applied.
 - d. Bring crutches, brace, sling, or immobilizer to facility, if available.
 - e. An adult must accompany client to facility to provide transportation home. ► **Rationale:** Even if client feels alert and awake, effects of anesthesia can last up to a day or two.
 - f. Arrive at the facility 1.5 to 2 hr before scheduled surgery, according to facility policy.
12. Describe post-arthroscopy care to client:
 - a. After surgery he/she will go to recovery room.
 - b. Vital signs, circulatory assessments, pain management, IV fluid infusion will continue until client is fully awake and ready for discharge.
 - c. A pressure dressing, brace, and/or ice may be applied to joint.
 - d. Discharge instructions are based on joint involved with arthroscopy. Most common joint is knee. Client is to use crutches for short time. Weight bearing is allowed according to physician orders. Brace is worn when walking. Physical therapy will begin within a day or two of surgery.
13. Repeat instructions for home care.
 - a. Explain to client that wound and dressing is to be kept clean and dry and changed if it becomes soiled.
 - b. Instruct client to place a plastic bag over brace and tape it securely when showering.
 - c. Instruct client to apply ice to joint for 24–48 hr after surgery. ► **Rationale:** To reduce pain and edema.
 - d. Demonstrate how to elevate joint (leg, ankle, wrist) to reduce pain and edema.
 - e. Explain how pain medication is to be taken: 30 minutes before exercises; tell client to not drink alcohol when on medications.
 - f. Discuss symptoms that indicate complications and should be reported immediately to physician: swelling; tingling; pain or numbness in extremities; drainage that is yellow, green, or foul-smelling; chills or temperature above 38.5°C (101.3°F).

Instructing in Deep Breathing Exercises

Procedure

1. Check two forms of client ID and introduce yourself.
2. Explain procedure and purpose of exercises. ► **Rationale:** Deep breathing and coughing exercises promote lung expansion; lower the risk of pneumonia, atelectasis, and pulmonary emboli.
3. Instruct and have client demonstrate deep breathing exercises. ► **Rationale:** Encouraging the client to practice and return the demonstration before surgery assists him or her to deep breathe more effectively after surgery.
4. Have client sit in upright position.
5. Place client's hands along lower borders of rib cage. Client should feel rib cage expand when breathing in. ► **Rationale:** This assists client to feel adequate chest movement.
6. Instruct client to breathe through nose slowly, take a deep breath, hold 1–2 seconds, then exhale through mouth. ► **Rationale:** This expands alveoli and prevents hyperventilation if client is breathing too quickly.
7. Repeat exercise sequence 3–4 times, at least every 2 hr when awake.

NOTE: Incentive spirometry is preferred by most facilities. Refer to respiratory chapter for incentive spirometry instructions.

Instructing in Coughing Exercises

Procedure

1. Check two forms of client ID and introduce yourself.
2. Explain procedure and purpose of exercises.
3. Instruct and have client demonstrate coughing exercises.
4. Have client sit in upright position.
5. Instruct client to splint incision when deep breathing and coughing.
6. Demonstrate placement of hands on either side of incision. Instruct client to press hands firmly toward incision during exercises. ► **Rationale:** This prevents tension on the suture line and diminishes pain.
7. Instruct in use of cough pillow. Place folded bath towel in pillowcase. Hold pillow directly over incision and press on pillow when performing exercises. ► **Rationale:** This prevents pain and discomfort by splinting the incision and reducing stress on suture line.
8. Demonstrate technique for inhaling deeply and holding breath for 1–2 seconds.
9. Instruct client to take 2–3 breaths slowly and exhale passively; on third breath, hold for 2–3 seconds.
10. Encourage client to cough forcefully 2–3 times by using abdominal and other respiratory muscles to assist with coughing. ► **Rationale:** This extra force provides a more effective cough.

▲ Instruct client in coughing exercises using cough pillow or demonstrate placement of hands on either side of incision for support during coughing.

11. Have client cough a second time.
12. Instruct client to do coughing exercises after deep breathing exercises at least every 2 hr when awake.
13. Have tissue available for secretions if client has a productive cough.

Providing Instruction to Turn in Bed

Procedure

1. Check two forms of client ID and introduce yourself.
2. Explain turning procedure and purpose. ► **Rationale:** Turning assists in the prevention of thrombophlebitis, pressure ulcer formation, and respiratory complications.
3. Instruct and demonstrate turning procedure.
4. Instruct client to splint incision whenever turning.
5. Have client move to far side of bed with side rails up. ► **Rationale:** This position allows client to turn without rolling to edge of bed.
6. Instruct client to splint incision with hand on side toward which he or she will be turning. ► **Rationale:**

This leaves the uppermost hand available to grasp side rail or trapeze to assist with turning.

7. Instruct client to keep leg straight on side to which he or she will turn.
8. Flex other leg over straight lower leg. ► **Rationale:** Flexing the leg assists in shifting the weight when turning to opposite side.
9. Instruct client to turn on side and grasp side rail.
10. Instruct client to move pillow into comfortable position under head or place pillow under top leg and place arm into comfortable position.

Instructing in Leg Exercises

Procedure

1. Check two forms of client ID and introduce yourself.
2. Explain exercise and purpose. ► **Rationale:** These exercises assist in preventing stasis of blood in lower extremities and thus thrombophlebitis.
3. Place client in supine or semi-Fowler's position.
4. Instruct client to bend knee, raise foot in air, and hold this position for 2–3 seconds.
5. Have client extend the leg and lower it to bed.
6. Repeat procedure with other leg.

NOTE: Inhale when extending leg and exhale slowly when lowering leg. This prevents back strain and strengthens abdominal muscles.

7. Complete sequence 5–10 times each hour while awake.
8. Have client extend toes (plantar flexion) toward bottom of bed, then flex (dorsiflexion) toward head of bed.
9. Repeat foot extension and flexion with other side.

10. Repeat sequence five times each hour while awake.
11. Instruct client to make circles with the ankle moving first to the left and then to the right.
12. Repeat sequence five times each hour while awake.

NOTE: Sequential compression devices are more commonly used during the postoperative period.

DOCUMENTATION for Preoperative Teaching

- Type of instruction provided
- Amount of time provided for instruction
- Type of audiovisual materials or written information used
- Client's response to teaching
- Accuracy and participation in return demonstration exercises
- Areas of instruction that need to be reinforced
- Psychological response to preoperative teaching and impending surgery
- Preop teaching form if available

CRITICAL THINKING Application

Expected Outcomes

- Client is psychologically and physically prepared for surgery.
- Client demonstrates deep breathing, coughing, turning, and leg exercises accurately.
- Client verbalizes knowledge of operative procedure, potential problems, and expected nursing actions postoperatively.
- Client's family states what they expect during perioperative period.
- Client uses appropriate audiovisual and written materials to increase understanding of perioperative experience.
- Client reports decreased fear regarding special equipment used during perioperative experience.
- Client states safety precautions used with laser and lithotripsy surgery.

Unexpected Outcomes

Client refuses to participate in preoperative teaching.

Client unable to understand directions.

Alternative Actions

- Encourage client to state reasons for refusal.
- Encourage client to discuss knowledge of surgery.
- Assess whether client is experiencing fear or denial regarding impending surgery.
- Ask client to provide a time frame more acceptable for teaching.
- Notify physician of client's refusal if facility policy.
- Identify client's learning capabilities.
- Determine whether a language barrier exists. If so, find person who speaks client's primary language and ask for assistance with teaching.
- Use different words to explain information.
- Determine a different teaching strategy that the client can understand, or involve family members who can assist with explanations to client.
- Evaluate client's stress level to determine whether it is interfering with learning.
- Establish a new time for teaching when client may be able to concentrate on teaching.
- Develop a slower pace for instruction and present less information at one time.

Client not adequately prepared for surgery.

- Ascertain where data are insufficient or unclear and provide additional instruction in that area.
- Use a different approach or teaching style to provide information.
- Select different teaching materials that may explain information in a more useful way.

Client becomes angry or hostile.

- Maintain calm composure.
- Acknowledge anger, but place limits on how it may be expressed (e.g., destructive behavior). Understand that anger is usually the result of feeling helpless and powerless to change an intolerable situation.
- Do not reward this behavior, but explore other means of meeting client's needs.
- Do not isolate client; continue to respond to needs.
- Try to defuse anger, but if safety is threatened, call for assistance.

Client becomes depressed because of overwhelming anxiety and feelings of helplessness or hopelessness.

- Convey respect and belief that client is worthwhile. Question client's appraisal of reality; provide support while client works through feelings.
 - Provide positive feedback and recognition of strengths, progress, and improved self-esteem.
 - Spend additional time with the client to allow time to verbalize fears.
-

Preoperative Care

Nursing Process Data

ASSESSMENT Data Base

- Assess type of surgical procedure to be carried out and extent of data base needed.
- Evaluate the client’s ability to provide accurate information.
- Assess level of anxiety present that may interfere in the transmission of information at that moment.
- Identify the appropriate physical care needed for the specific surgical intervention.
- Assess special needs for the surgical shave.
- Check hospital protocol for shaving surgical site or if a special permit is needed for shaving, such as the head for neurosurgical clients, extremities for orthopedic clients, or children.
- Check for need for special soap or antiseptic scrub before shave.
- Check if a policy exists in the hospital for disposing or handling of scalp hair.
- Assess surgical site before preparing; observe for unusual cuts, abrasions, or markings, and report findings to charge nurse.
- Assess client’s knowledge of side and site of surgical procedure.

PLANNING Objectives

- To assist with monitoring the client’s progress through the operative experience
- To assist in identifying deviations from the client’s baseline data that may occur as a result of anxiety or stress of admission, preoperative events, diagnostic procedures, the surgical trauma, postoperative complications, responses to and side effects of drugs
- To provide appropriate preoperative physical care to enable the client to have a safe intraoperative and postoperative period
- To report client’s statements about allergies or chronic problems that could affect postoperative nursing care
- To complete a surgical prep correctly

IMPLEMENTATION Procedures

- Obtaining Baseline Data 976
- Preparing the Surgical Site 976
- Preparing the Client for Surgery 978
- Administering Preoperative Medications 980

EVALUATION Expected Outcomes

- Client’s physical or emotional deviations from normal are identified preoperatively.
- Preoperative baseline data are obtained.
- Surgical site is marked and prepared correctly.
- Client states expectations regarding intraoperative and postoperative course.

Critical Thinking Application 981

- Expected Outcomes 981
- Unexpected Outcomes 981
- Alternative Actions 981

Pearson Nursing Student Resources

Find additional review materials at nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Obtaining Baseline Data

Equipment

Thermometer
 Sphygmomanometer and stethoscope
 O₂ saturation probe
 Chart or computer for documenting findings

Procedure

1. Check two forms of client ID and introduce yourself.
2. Ask about allergies to drugs, food, or latex.
3. Assess for surgical risk: nutritional status, fluid and electrolyte balance, use of prescribed medications, over-the-counter complementary medications (i.e., herbs), and illicit drugs. **► Rationale:** Medications such as anticoagulants, tranquilizers, or CNS depressants can adversely affect surgical experience.
4. Assess for alcohol use and smoking habits. **► Rationale:** Complications can arise in clients using these substances, particularly with anesthesia.
5. Take and record vital signs and weight of client. Obtain oxygen saturation levels.
6. Check if client wears dentures, hearing aid, glasses, has an artificial eye, or body piercing jewelry. Check for toe rings. If body piercing jewelry cannot be removed, cover with tape to protect skin from electrical arcing from the electrical surgical unit, which could cause skin burns.
7. Assess mental attitude; record any unusual stress or anxiety exhibited by the client.
8. Complete a physical assessment and health history. Report unusual findings to physician, OR staff, and anesthesiologist if client has history of MRSA, VRE, hepatitis B or C, or history of TBC.
9. Evaluate lab values for abnormalities (ECG, x-rays, blood work, urinalysis) and pregnancy test on age-appropriate client if she has an intact uterus. **► Rationale:** To detect potential sources for complications (e.g., low Hct, Hgb, urine glucose, lung or cardiac abnormalities).
10. Determine whether skin preparation was completed either evening before or morning of surgery. Check if shower or bath with designated antiseptic was completed.
11. Assess for fall potential (unsteady gait, use of assistive devices).
12. Identify topics requiring client teaching.
13. Identify discharge plans.
14. Determine religious or cultural beliefs that may affect surgical experience.

Clinical Alert

It is imperative that nurses on the surgical floor check documentation carefully to find any abnormalities in the H&P, lab results, or assessment indicating potential complications during procedure. This information must be reported to the anesthesiologist and OR staff.

Preparing the Surgical Site

Equipment

Washcloth and towels
 Absorbent pad
 Bath blanket or drape
 Scissors or electric clippers (optional)
 Disposable prep kit (for shaving)
 If kit not available:
 Disposable razor (number according to area to be shaved)
 Two sterile bowls
 4 × 4 gauze pads
 Emesis basin
 Applicator sticks
 Cleansing solution
 Sterile water
 Clean gloves
 Depilatory
 Antiseptic solution

Tongue blade
 4 × 4 gauze pad

Procedure

1. Refer to physician's orders for specific operative site or area to be prepared. If orders do not state preference for site, refer to procedure manual for appropriate area to be prepared, based on surgical procedure.

NOTE: Many surgeons do not require hair to be shaved for a surgical site unless it interferes with the surgical procedure or wound closure. Based on clinical research, it has been found that shaving the hair does not prevent surgical site infections, but it does interfere with the client's psychological status. Client's body image can be impaired and he or she senses a loss of control with shaving of the hair, particularly of the head or pubic area.

2. Determine type of preparation to be done: clipping of hair, shaving site, or hair removal using depilatory. Gather equipment.
3. Check two forms of client ID and introduce yourself.

4. Explain procedure to client and provide privacy.
5. Adjust light to ensure good visualization.
6. Perform hand hygiene.
7. Position client for maximum comfort and site exposure.
8. Drape client for comfort and to prevent undue exposure.
9. Protect bed with absorbent pad.
10. Arrange equipment for your convenience.
11. Put on clean gloves.
12. Assess surgical site before skin preparation for moles, warts, rash, and other skin conditions. ► **Rationale:** Inadvertent removal of lesions traumatizes skin and may contribute to infection.

NOTE: CDC standards indicate that clients are to shower or bathe with an antiseptic agent at least the night before surgery. The FDA has also shown that antimicrobial activity of the antiseptic agent prevents skin infections.

13. Prepare site using scissors or clippers according to facility policy/procedures.
 - a. Use scissors or electric clippers and cut hair 1 cm above surgical site or according to facility policies.
 - b. Clip small amount of hair each time.
 - c. Cut in direction hair grows.
 - d. Remove all hair from site and discard.
14. Prepare site using depilatory.
 - a. Clip hair before applying cream.
 - b. Apply cream to designated area using tongue blade or gloved hand.
 - c. Leave on skin for designated time, according to directions on package, usually 10 minutes.
 - d. Remove cream by rubbing off with tongue blade or moistened 4 × 4 gauze pads.
 - e. Wash skin with antiseptic soap; dry area thoroughly.
 - f. Remove all hair with washing. ► **Rationale:** This provides clean, smooth skin, free of abrasions and cuts.
15. Prepare site using razor.
 - a. Lather skin with antiseptic soap and 4 × 4 gauze pads. ► **Rationale:** Wet shave results in fewer

EVIDENCE-BASED PRACTICE

Surgical Site Infection (SSI)

A preoperative antiseptic shower or bath decreases skin microbial colony count. In a study of more than 700 clients who received two preoperative antiseptic showers, chlorhexidine reduced bacterial colony counts nine fold. Iodine or triclocarban-medicated soap reduced colony counts 1.3- to 1.9-fold, respectively.

Chlorhexidine gluconate-containing products require several applications to obtain maximum antimicrobial benefit, so repeated antiseptic showers are indicated. Even though these showers reduce the colony count, they have not definitively shown a reduction in SSI rate.

Source: Mangram, A. J., Horan, T. C., Pearson, M. L., Silver, L. C., & Jarvis, W. R. (1999). Guideline for prevention of surgical site infection, 1999. The Hospital Infection Control Practices Advisory Committee. *Infection Control and Hospital Epidemiology*, 20(4), 250–278.

Clinical Alert

If hair must be removed, scissors or clippers should be used and procedure completed before the client reaches the operating room suite. Many hospitals use the minimal shave and scrub preparation approach. The shaved area may be as small as 2 cm surrounding the surgical incision site. Refer to the policy and procedure manual and physician's orders before beginning the surgical prep.

- microabrasions to the skin. Shaving should be done in direction of hair growth.
- b. Discard soiled sponges frequently.
- c. Using sharp razor, shave hair moving away from incision site. With free hand, stretch skin taut and shave, following the hair growth pattern and using firm, steady strokes. Shave small area at one time. ► **Rationale:** Shave is closer and nicks are prevented.
- d. Change razor as often as necessary. Avoid nicking the skin. Report if skin is nicked. ► **Rationale:** Nicks, if severe, can cause infection by bacteria normally found on the skin.
- e. Wash all hair off site with 4 × 4 gauze pads or use sticky mitt or tape to remove hair.
- f. The shave should be completed close to the time of surgery. The shave prep is completed before the client enters the operating room. ► **Rationale:** Shaving and clipping hair immediately before surgery is associated with a lower risk of infection than if done the night before.
16. After removing hair, apply antiseptic solution with 4 × 4 pads or use disposable prep kit.

Clinical Alert

Electric or battery-powered clippers are preferred to razors to prevent skin irritation and microscopic cuts to the skin. Clippers must have a disposable head that is changed between clients. Handles should be disinfected.

EVIDENCE-BASED PRACTICE

Skin Preparation and Surgical Site Infections

Many studies show that hair removal with a razor or clippers can cause skin abrasion or even nicks in the skin. This can lead to subsequent surgical site infections (SSIs). In a study discussed in the *CDC Guideline for Prevention of Surgical Site Infection*, it was identified that SSIs occurred in 5.6% of clients who had their hair removed by razor shave, compared with an 0.6% rate among those who had hair removed by depilatory or had no hair removed at all. The CDC advises that if hair is to be removed, it should be done so immediately before surgery, and preferably with electric hair clippers.

Source: Mangram, A. J., Horan, T. C., Pearson, M. L., Silver, L. C., & Jarvis, W. R. (1999). Guideline for prevention of surgical site infection, 1999. The Hospital Infection Control Practices Advisory Committee. *Infection Control and Hospital Epidemiology*, 20(4), 250–278.

17. Begin at incision site and, with light friction, make ever-widening circles, moving outward from the center to the most distant line of area. ► **Rationale:** Working from most clean to least clean area prevents contamination. Scrub area for 2–3 minutes.
18. Rinse area with warm water and blot dry with 4 × 4 gauze pads.

19. Remove and dispose of equipment; scissors and razors are disposed of in sharps container.
20. Remove gloves and discard.
21. Perform hand hygiene.
22. Assist client to put on clean gown.
23. Position the client for comfort.

Preparing the Client for Surgery

Equipment

- Preoperative checklist
- Operative permit
- Specific equipment needed to provide physical care as ordered, such as enema equipment, nasogastric tube, Foley catheter
- Antiseptic agent for shower

Procedure

1. Check two forms of client ID and introduce yourself.
2. Obtain client’s signature on surgical consent form and check agency policy. Ensure all preoperative forms are complete, with no blank areas.
3. Assist client to complete anesthesia questionnaire if required.

4. Assess whether bowel prep was completed at home. ► **Rationale:** Most clients complete bowel prep before admission to facility. Administer an enema if ordered.
5. Assist client to shower if not completed at home. Instruct on how to shower and specific time guidelines according to facility guidelines.
6. Complete skin prep, if ordered. Follow facility guidelines for skin prep.
7. Assess for latex allergy. If present, ensure allergy band is applied, physician is notified, and OR staff are notified. ► **Rationale:** All latex products must be removed from OR and client must be scheduled for first case in morning.

Client Information

AUTHORIZATION FOR AND CONSENT TO SURGERY, ADMINISTRATION OF ANESTHETICS, SPECIAL DIAGNOSTIC OR THERAPEUTIC PROCEDURES

Date _____ Time _____

Your admitting physician is _____, M. D.
Your surgeon is _____, M. D.

1. The hospital staff and facilities assist your physicians and surgeons in the performance of various surgical operations and other diagnostic and therapeutic procedures. These surgical operations and special diagnostic or therapeutic procedures all may involve calculated risks of complications, injury or even death, from both known and unknown causes and no warranty or guarantee has been made as to result or cure. Except in a case of emergency or exceptional circumstances, these operations and procedures are not performed upon a client unless and until the client has had an opportunity to discuss them with his/her physician. Each client has the right to consent to or refuse any proposed operation or special procedure (based upon the description or explanation received).
2. Your physicians and surgeons have determined that the operations or special procedures listed below may be beneficial in the diagnosis or treatment of your condition. Upon your authorization and consent, the operations or special procedures will be performed by your physicians and surgeons and their staff. The persons in attendance for the purpose of administering anesthesia or performing other specialized professional services, such as radiology, pathology and the like, are not the agents, servants or employees of the hospital or your physician or surgeon, but are independent contractors performing specialized services on your behalf and, as such, are your agents, servants, or employees. Any tissue or member severed in any operation will be disposed of in the discretion of the pathologist, except _____ and those body parts specified as donor organs.
3. Your signature opposite the operations or special procedures listed below constitutes your acknowledgement (a) that you have read and agreed to the foregoing, (b) that the operations or special procedures have been adequately explained to you by your attending physicians or surgeons and that you have all of the information that you desire, and (c) that you authorize and consent to the performance of the operations or special procedures.

Clinical Alert

The Association of PeriOperative Registered Nurses (AORN) recommends preop skin prep should be an antimicrobial agent that has a broad germicidal range and is nontoxic.

The most common antiseptic agents used for preoperative skin preparation and surgical scrubs include alcohol, chlorhexidine, iodine/iodophors, and Triclosan.

Alcohol has the most rapid microbial action, which denatures proteins and is effective against both gram-positive (gram +) and gram-negative (gram –) bacteria, viruses, and fungi.

Chlorhexidine has an intermediate rapidity of action, disrupting the cell membrane. It should not be used on mucous membranes, eyes, or brain tissue (neurotoxic). It works well against gram-positive bacteria, and less well against gram-negative bacteria.

Iodine/iodophors has an intermediate action and is acceptable for use against a wide range of bacteria, fungi, and viruses.

Triclosan disrupts the cell wall and has an acceptable kill rate against bacteria. Even though alcohol has microbial action, it is not often used as a surgical skin prep because it does not stay on the skin.

- Enquire for symptoms and observe for signs of cold or upper respiratory infection.
- Explain need for client to be NPO for 8–10 hr preoperatively.
- Remove lipstick and nail polish if required by hospital policy.
- Insert Foley catheter if ordered.
- Take and record vital signs.
- Remove earrings, necklaces, medals, watch, rings (ring may be taped to finger or toe in some facilities). If possible, remove body piercing jewelry. Cover with tape if not possible to remove. ► **Rationale:** Protect skin from possible burns from electrical arcing generated by electrical cautery machines.
- Remove contact lenses, glasses, hairpieces, and dentures. Some hospitals/anesthesiologists allow full dentures to remain if using a mask.
- Assist client to void if catheter not inserted, and record time and amount.
- Check Ident-A-Band, blood band, and allergy bracelet. During this stage the client must be identified by at least two identifiers (i.e., medical record number, birth date, name, charge number).
- Put antiembolic stockings on client as ordered.
- Administer preoperative medications.
- The operative site needs to be verified and marked, both site and side, by the physician while the client is awake.
- Place side rails in UP position and bed in low position after administration of medications.
- Darken room and provide quiet environment after administration of medications.
- Check client 15 minutes after medication administered to observe for possible side effects.

EVIDENCE-BASED PRACTICE

Surgical Checklist May Improve Outcomes for Noncardiac Surgery

Surgical procedures are estimated at 234 million operations performed yearly throughout the world. A longitudinal study over 1 year utilizing eight participating hospitals representing a diverse group of socioeconomic environments within the World Health Organization regions from Amman, Jordan, to Seattle, Washington, and Toronto, Canada, were utilized in the study of 3,733 consecutive inpatient noncardiac surgery clients 16 years or older. The objective of the study was to evaluate the effect on rates of mortality and major complications with implementing the surgical checklist in inpatient surgical units. Data were first prospectively collected regarding clinical processes and outcomes. Then after implementing the Surgical Safety Checklist, data were collected from 3,955 consecutive inpatient noncardiac surgery clients.

Death rates during hospitalization decreased from 1.5% in the initial cohort to 0.8% after implementation of the checklist. This represents a decline in the rate of inpatient complications from 11.0% to 7.0%.

Source: Barclay, L. (2009). Surgical Checklist May Improve Outcomes for Noncardiac Surgery. *New England Journal of Medicine*, 360, 491–499.

Administering Preoperative Medications

Equipment

- Preoperative checklist
- Preoperative medications

Procedure

1. Check two forms of client ID and introduce yourself.
2. Complete preoperative checklist.
3. Check orders for medication, dosage, route, and time.
4. Verify that surgical consent is accurate, understood by client, and properly signed before giving any preop sedation.
5. Check history for allergy to ordered medication.
6. Explain purpose of medication to client.
7. Warn client that injection may sting or burn.
8. Follow procedure for administration of injections.
9. Administer medications 30 minutes before beginning of surgery.
10. Raise side rails to UP position and put bed in low position.
11. Explain why client should not get out of bed after medications have been given. ► **Rationale:** Medication makes client drowsy and affects equilibrium.

Preoperative Medications: Type and Action

Hypnotic or Antianxiolytic—Given Night Before Surgery

- Decreases anxiety
- Promotes good night's sleep

Hypnotic or Opiate—Preoperative Medication

- Decreases anxiety
- Allows smooth anesthetic induction
- Provides amnesia for immediate perioperative period

Anticholinergic—Preoperative Medication

- Decreases secretions
- Counteracts vagal effects during anesthesia

12. Place call light within reach and encourage client to use it.
13. Ask if there are any questions or assistance you can offer before leaving the room. Darken room or close curtains.
14. Inform client of the estimated time he or she will be going to surgery.

Clinical Alert

Universal Protocol for Preventing Wrong Site, Wrong Procedure, and Wrong Person Surgery

- Preoperative validation of the right client, procedure, and site should occur when the client is awake, aware, and before he/she leaves the preoperative area or enters the surgical suite.
- Person performing the procedure must do the marking.
- Incision site must be marked, using a marker that is not easily removed, at or near the incision site.
- **DO NOT MARK** any nonoperative site(s) unless necessary for some other aspect of care.
- Use initials, word “yes,” or a line indicating proposed incision site to prevent ambiguous marks.
- Mark must be visible after client is prepped and draped.
- Final verification of site mark must take place in the location where the procedure will take place. This time is identified as the “Time Out” period. Nothing happens until this has occurred. The entire team must be present during this check.
- Verification must include:
 - a. Correct client identity.
 - b. Correct site and side.
 - c. Agreement on procedure to be done.
 - d. Correct client position.
 - e. Availability of any special equipment or implants needed for procedure.

Exemptions From the Marking Procedure

- Single organ cases (e.g., C-section, cardiac surgery).
- Interventional cases: insertion site of instrument/catheter not predetermined.
- Premature infants: for whom the mark may cause permanent mark.

Source: The Joint Commission. <http://www.jointcommission.org/PatientSafety/UniversalProtocol/>.

DOCUMENTATION for Preoperative Care

- Safety measures carried out preoperatively
- Completion of preoperative site preparation and area involved
- Antiseptic solution used and length of time of scrub
- Operative checklist completed
- Review physician's explanation of potential surgical complications
- Physical care completed before surgery

- Surgical site marking procedure (site, individual who marked site, persons present during “Time Out” step in procedure)

- Preoperative medications given and effects of medications
- Time and method of transportation to operating room
- Preoperative teaching completed

Legal Alert

In 2001, The Joint Commission reported surgical mistakes were on the rise. After this report a study was completed. The study analyzed 126 cases involving surgical mistakes and found that 76% of the cases

involved operating on the wrong body part, 13% involved the wrong client, and 11% involved the wrong surgical procedure.

Source: <http://MedicalMalpracticeLawyers.us>.

CRITICAL THINKING Application

Expected Outcomes

- Client’s physical or emotional deviations from normal are identified preoperatively.
- Preoperative baseline data are obtained.

- Surgical site is marked and prepared correctly.
- Client states expectations regarding intraoperative and postoperative course.

Unexpected Outcomes

Factors that can affect the postoperative course are identified during the preoperative care (e.g., arthritic changes in client’s back, history of thrombophlebitis).

Alternative Actions

- Place information in client’s care plan and inform charge nurse and surgeon about findings.
- Write a note in client’s chart and alert the operating room and recovery room staff of the findings so that they can assess for the problems.
- Explain to client that dentures are likely to be lost, broken, or inadvertently pushed to back of mouth if not removed.
- If client refuses to remove dentures, alert anesthesiologist that dentures are in place.
- Notify MD and OR staff of client’s condition.
- Follow specific directions; surgery may be canceled as infection could occur as result of break in skin integrity.
- Run water so client can hear trickling sound to stimulate voiding.
- Run warm water over perineum.
- Place ammonia or oil of wintergreen on a cotton ball in urinal or bedpan.
- Help male to stand or sit at edge of bed with urinal positioned.
- Help female to commode if urinating into bedpan is difficult.
- Notify MD and OR staff. Record in chart.
- Explore feelings and reasons for client’s or family’s stressed behaviors.
- Explore more effective methods to reduce stress for client and family.
- Provide additional stress reduction exercises.
- Clarify misconceptions and inappropriate perceptions.
- Introduce client to another client who has had similar surgery.
- Have physician speak to client and answer questions.

Client refuses to go to operating room without dentures.

Client’s skin is cut during shave.

Client unable to void before surgery.

Client appears to be abnormally stressed.

Client's preoperative laboratory findings are abnormal.

- Check with laboratory to have them reevaluate if lab results are accurate.
- Have laboratory redo tests if extremely abnormal.
- Notify physician of abnormal findings.
- Notify surgeon and anesthesiologist.

Client is unable to participate in marking surgical site.

- If client is comatose, non-English speaking, or incompetent, follow protocol as with informed consent.
- Guardian or individual with power of attorney should be involved with marking, if possible.

Client refuses site marking.

- Client has right to refuse; document client refusal on appropriate forms.
 - Procedure may be performed without marking.
 - Provide client with information regarding safety aspects for marking procedure.
 - Discuss rationale for client's refusal to determine whether insufficient information was provided regarding marking procedure.
-

Moderate (Conscious) Sedation

Nursing Process Data

ASSESSMENT Data Base

- Assess type of procedure to be done and determine whether moderate (conscious) sedation is appropriate.
- Assess type of sedation to be used for procedure.
- Determine whether medication can be administered by nurse or only by physician.
- Check whether physician has ordered medication for moderate (conscious) sedation and whether nurse is approved to administer medication.
- Determine whether history and physical is in client's chart.
- Check that signed consent form is in chart.
- Assess client according to American Society of Anesthesiologists (ASA) Classification of Physical Status.

PLANNING Objectives

- To determine whether client is to receive moderate (conscious) sedation from nurse or physician
- To establish venous access before sedation administration
- To monitor vital signs throughout procedure
- To continuously assess for changes in client's condition and/or untoward responses or effects of medication
- To immediately notify physician of changes in client's condition

IMPLEMENTATION Procedures

- Preparing Client for Moderate (Conscious) Sedation 984
- Monitoring Client During Procedure 985
- Caring for Client After Moderate (Conscious) Sedation 986

EVALUATION Expected Outcomes

- Client maintains airway and respiratory status throughout procedure.
- Client does not experience anxiety or pain during procedure.

Critical Thinking Application 987

- Expected Outcomes 987
- Unexpected Outcomes 987
- Alternative Actions 987

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Preparing Client for Moderate (Conscious) Sedation

Equipment

- Consent form
- History and physical
- Lab test results, if necessary
- Sedation Scale

Procedure

- Ensure that client is candidate for conscious sedation. Use ASA Classification of Physical Status. **Rationale:** Clients in ASA categories 1 and 2 may receive conscious sedation by qualified physicians and nurses. Clients in category 3 or 4 are referred to anesthesia provider for further evaluation because their condition puts them at risk for complications. Further evaluation of elderly, pregnant, or obese clients, and those with a history of substance abuse, sleep apnea, or severe cardiac, respiratory, hepatic, renal or central nervous system diseases is necessary because these clients are placed at higher risk during the use of conscious sedation.
- Determine whether client has any contraindications for conscious sedation:
 - Recent ingestion of large food or fluid volumes (in past 2 hr).
 - Physical status IV or greater.
 - Lack of support staff or monitoring equipment.
 - Lack of experience on part of clinician.
- Determine whether nurse or physician will administer medication.
- Check that qualified anesthesia provider has written order for conscious sedation.
- Check two forms of client ID and introduce yourself.
- Check that client has been informed about procedure and use of conscious sedation.
- Ensure that history and physical has been completed and on client's chart.
- Obtain height and weight. **Rationale:** To use for drug calculation when administering conscious sedation.
- Ask about allergies, particularly sedatives.
- Ensure client has been NPO for at least 2 hr.

ASA Classification of Physical Status

Class	Definition
P1	A normal healthy client
P2	A client with mild systemic disease
P3	A client with severe systemic disease
P4	A client with severe systemic disease that is a constant threat to life
P5	A moribund client who is not expected to survive without surgery
P6	A declared brain-dead client whose organs are being removed for donor

Source: Adapted from the American Society of Anesthesiologists. (1999). ASA Physical Classification System. Available at: <http://www.asahq.org/clinical/physi-classstatus.htm>

The image shows two forms from Community Hospital. The top form is the 'PHYSICIAN PROCEDURAL SEDATION EVALUATION' which includes patient demographics, vital signs table (Time, Pre Procedure, Pre Sedation, Intra Procedure, Post Procedure, Discharge Home), and various assessment criteria like Activity, Respiration, Circulation, Consciousness, and ASA Score. The bottom form is the 'NURSING PROCEDURAL SEDATION RECORD' which includes patient information, pre-procedure assessment, medication administration table, and discharge instructions.

▲ Moderate (Conscious) sedation record samples.

- Explain that the medication will relax him or her during procedure, client will feel sleepy but will not be asleep, and will be able to communicate during procedure. **Rationale:** This is necessary to determine comfort and level of sedation during procedure.
- Discuss the possibility of unpleasant sensations of pain, nausea, vertigo.
- Determine gestures that will be used during procedure to indicate whether client is having pain.
- Ensure that someone is with the client to take him or her home if discharge is anticipated after the procedure. **Rationale:** Residual effects of sedation can last for several hours. Driving can be impaired and thus it is unsafe for the client to drive home.

NOTE: The American Nurses Association and other nursing organizations allow nurses to administer sedating drugs, assess client responses, and monitor vital signs during the use of conscious sedation. Nurses who administer conscious sedation must function within the standard of practice and be allowed to administer conscious sedation according to the nurse practice act in the state in which they are practicing. They must also administer conscious sedation according to policies and procedures of the facility in which they are working. At no time will student nurses be allowed to administer conscious sedation.

Capnography

Capnography has been shown to be effective in detecting hypoventilation during procedural sedation. The traditional PCA pump now has built in sensors that monitor ventilation and oxygenation. It is also used to monitor clients on PCA pumps using narcotics.

A capnography monitor is a device that measures carbon dioxide. The monitor is attached to tubing at

the end of the tracheostomy or endotracheal tube. The Alaris PCA pump with capnography/pulse oximetry has a module that measures CO₂. CO₂ can also be measured by attaching a tube to an oxygen mask or nasal cannula. The mask or nasal cannula contains a sensor that measures the CO₂. The results are reported on a hand-held device rather than the monitor.

Monitoring Client During Procedure

Equipment

Crash cart or following list of equipment:

- Suction equipment; machine, tubing, and suction catheter (tonsil tip)
- Oxygen supply and appropriate delivery system
- Laryngoscope handle and blades of appropriate size
- Endotracheal tubes and stylets in various sizes
- Oral and nasal cannulas
- 3-mL and 10-mL syringes
- Needles, if not using needless system
- IV solution bags
- Reversal drug agents (i.e., Narcan, Romazicon)
- Pulse oximeter (optional with capnography)
- ECG machine and defibrillator, cardiac monitor
- Intubation tray and bag–valve–mask device
- Vital sign portable machine
- Client's chart
- Procedural sedation record
- Conscious sedation medications; usually benzodiazepines and opioids
- Emergency cardiac drugs, naloxone, flumazenil

Procedure

1. Ensure that backup personnel skilled in ACLS are available if needed.
2. Verify correct client by using two identifiers.
3. Evaluate ASA Classification of Physical Status again.
4. Check that chart contains appropriate documents.
5. Check that preprocedural assessment is completed on sedation record.
6. Check that consent form was signed.
7. Gather emergency equipment and place near client.
8. Determine whether premedication was ordered and given.
9. Obtain vital signs and document findings on procedural sedation record.
10. Start peripheral IV with ordered solution.
11. Determine gesture to be used for communication regarding pain and sedation.
12. Place ECG leads on, if appropriate.
13. Administer oxygen via nasal cannula at 2 L/min.
14. Monitor end-tidal CO₂ with capnography.
15. Begin administration of medication as ordered.
16. Monitor vital signs, oxygen saturation, sedation level, pain level, ECG rate, and rhythm every 1 to 5 minutes according to facility policy and client condition.
 - ▶ **Rationale:** Close monitoring of these values identifies potential complication such as respiratory depression, oversedation, hypoxia, and hypotension.
17. Continue to monitor client every 15 minutes until stable after completion of procedure using conscious sedation.

TABLE 26-6 Levels of Sedation/Analgesia

Minimal (Anxiolysis)	Client is relaxed but able to respond to verbal commands. Cognitive function and coordination may be impaired; ventilatory and cardiovascular functions are not affected.
Moderate (Conscious Sedation)	Client is drowsy and may sleep throughout procedure, responds purposefully to verbal commands. Airway remains patent with spontaneous ventilation and cardiovascular status is maintained.
Deep	Client will sleep through procedure with little or no memory of the procedure. Airway intervention may be required (supplemental oxygen or ventilatory support); cardiovascular status is maintained.

TABLE 26-7 Moderate (Conscious) Sedation Medications

	Benzodiazepines	Opioids
Drugs	Midazolam (Versed), diazepam, lorazepam*	Fentanyl, morphine, meperidine
Action	Produce anxiolysis and amnesia	Produce sedation, euphoria, pain relief
Disadvantages	Lack of analgesic properties	Can cause respiratory depression and decreased level of consciousness
Side Effects	Decreased blood pressure Increased heart rate	Apnea, hypotension, vertigo, nausea
Reversal Agent	Flumazenil	Naloxone

Note: The most common drugs used for conscious sedation are the benzodiazepines and opioids.

*Frequently administered with narcotics.

Clinical Alert

The sedation assessment parameters that need to be observed during the procedure include responsiveness, speech, facial expressions, and eyes. Scales available that provide a scoring system are the Ramsay Sedation Scale and the Riker Sedation–Agitation Scale.

EVIDENCE-BASED PRACTICE

Over- and Under-Sedation

A survey of critical care nurses and physicians revealed they felt that their critically ill clients were receiving adequate sedation only 50% of the time. Interestingly enough, physicians felt their clients were over-sedated and nurses felt clients were under-sedated.

Source: McGaffigan, P. A. (2000, February). Advancing sedation assessment to promote patient comfort. *Critical Care Nurse Supplement*, 29–36.

Caring for Client After Moderate (Conscious) Sedation

Equipment

- Electronic vital sign machine
- Oxygen supply
- Oxygen nasal cannula
- Procedural sedation record
- Aldrete scale
- Pulse oximeter
- ECG monitor and leads
- Emergency equipment
- Naloxone

Procedure

1. Check two forms of client ID and introduce yourself.
2. Observe vital signs, oxygen saturation, respiratory rate and rhythm, and ECG rate and rhythm every 15 minutes unless more frequent monitoring is required according to client condition. ► **Rationale:** Major complications during the use of conscious sedation and immediately after include respiratory depression,

oversedation, hypoxia, and hypotension. Assess need for naloxone, an antagonist of the opioids, to reverse narcotic analgesic (rarely needed).

3. Observe client for patent airway if he or she was intubated during procedure and ensure oxygen cannula is in place immediately after extubation.
4. Assess client for pain and medicate accordingly.
5. Monitor client and obtain sedation scale score in preparation for discharge. Client must attain specified score within 1 hour of completion of procedure.
 - **Rationale:** If using Aldrete Scale, client must attain Aldrete score of ± 1 point of preprocedure score before discharge. This score should be achieved within 1 hour of the procedure. A potential complication is occurring if this score is not attained within the specified time.
6. Provide instructions as needed before client is discharged.
7. Ensure client has someone with him or her if discharged to home.
8. Complete documentation on Procedural Sedation Record.

DOCUMENTATION for Moderate (Conscious) Sedation

- Preprocedural assessment: past medical history, drug allergies, anesthetic history
- Consent form signed
- Baseline vital signs, particularly respiratory and cardiac findings, ECG findings
- Height and weight

- Teaching provided regarding medication and procedure
- ASA rating
- Continuous documentation of level of consciousness, speech, facial expression, agitation level, pupils, respiratory rate and rhythm, ECG findings if appropriate during procedure
- Score on a sedation scale (Aldrete, Ramsay, or Riker)
- Oxygen saturation levels during and after procedure
- Amount and type of medication administered
- Supplemental oxygen, liter flow, and system used
- Aldrete score before discharge
- Complications that occurred during the procedure and actions taken
- Complete Procedural Sedation Record

CRITICAL THINKING Application

Expected Outcomes

- Client maintains airway and respiratory status throughout procedure.

Unexpected Outcomes

Client is scheduled to have conscious sedation for procedure but scores above P2 on ASA scale.

Client does not respond to verbal commands during procedure when using minimal or moderate sedation.

Client experiences airway obstruction or respiratory depression.

Client experiences hypoxemia.

Client experiences a 20% drop in blood pressure during procedure.

Client experiences pain during procedure.

- Client does not experience anxiety or pain during procedure.

Alternative Actions

- Notify anesthesiologist and physician; nurses may not administer conscious sedation if the client scores above P2 on the scale.
- Client is physically compromised and could be unstable during use of conscious sedation medications.
- Notify physician of change in client's status.
- Notify anesthesiologist immediately and prepare for intubation.
- Have reversal drug available to administer if directed by physician.
- Continue to monitor client every 1 minute for changes in status.
- Administer oxygen via nasal cannula if not already in place.
- Reposition client's head, lifting jaw and tipping back the head.
- Suction client or insert oral airway.
- Be prepared to bag client with bag–valve–mask device.
- Ensure pulse oximeter is on client.
- Check respiratory rate, pattern, and effort.
- Increase amount of oxygen delivered. May need to change delivery system to oxygen mask.
- Use Capnography to evaluate CO₂ level.
- Inform physician.
- Assess client for potential complications leading to decrease in blood pressure.
- Check for presence of hypovolemia. Administer 200 mL bolus of fluid and monitor for response.
- Dosage of amnesia or analgesic agents needs to be reviewed.
- Ensure client's weight was calculated correctly.
- Allow sufficient time for agents to work.
- Allow time to titrate effect of medication.

Chapter 26

UNIT 5

Postanesthesia Care Unit (PACU) and Discharge

Nursing Process Data

ASSESSMENT Data Base

- Assess for patent airway.
- Assess for order and type of oxygen administration set.
- Check gag reflex and remove endotracheal tube as ordered.
- Assess vital signs and appropriate pulses.
- Assess body temperature.
- Check all IVs for type, amount of fluid, and infusion rate.
- Observe all dressings, tubes, and drains.
- Monitor urine output, color, and consistency.
- Assess color, skin temperature, and condition.
- Assess monitor findings if ordered.
- Assess neurologic status if necessary.
- Assess heart and lung sounds.
- Assess bowel sounds.
- Assess residual anesthetic effect.
- Assess for postoperative bleeding.

PLANNING Objectives

- To provide safe, effective nursing care during the immediate postoperative period for clients in the recovery room
- To promote and maintain adequate airway function
- To monitor and maintain adequate circulatory status
- To identify potential postanesthesia complications and initiate nursing interventions to prevent complications
- To identify client's readiness to return to nursing unit or to be discharged if an outpatient
- To use "Hand Off" communication process when discharging client to surgical unit

IMPLEMENTATION Procedures

- Providing Postanesthesia Care989
- Discharging Client From Postanesthesia Unit to Nursing Unit990
- Discharging Client From Phase II Unit to Home.....991

EVALUATION Expected Outcomes

- Client has an uneventful experience in the recovery period.
- Potential postoperative complications are identified early and corrective interventions prevent occurrence of complications.
- Client is discharged to home or nursing unit within prescribed time frame.
- Client reports pain: < 4 on a scale of 0–10.
- Client does not experience nausea or vomiting.

Critical Thinking Application 992

- Expected Outcomes 992
- Unexpected Outcomes 992
- Alternative Actions 992

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

“Hand Off” Communication

- Report focuses on client safety.
- Report is coordinated effort among healthcare professionals involved in changeover of client.
- Communication must be accurate, clear, specific, and allow time for questions and concerns.
- Communication occurs in all areas of surgical care.

SBAR—Approach to “Hand Off” Communication

S – Situation—Identify yourself and the client. State what is happening with the client.

B – Background—Review chart. Provide the client’s background. Anticipate other caregiver’s questions.

A – Assessment—Provide your observations and evaluation of client’s current state. Be accurate and complete.

R – Recommendations—Make informal suggestions based on correct information for continued care of client.

Source: Standardized Approach to Hand-Off Communications is part of National Patient Safety Goals from The Joint Commission.

Providing Postanesthesia Care

Equipment

- Blood pressure cuff and stethoscope
- Pulse oximeter
- Oxygen administration device: nasal cannula or mask
- Cardiac monitor and leads
- IV pole
- Suction catheters
- Gloves
- Special equipment needed—based on surgical procedure

Procedure

1. Check two forms of client ID, introduce yourself, and determine surgical procedure performed.
2. Complete Hand-Off Communication process.
3. Connect client to monitoring systems.
4. Assess for patent airway. Leave airway in place until gag reflex returns and client attempts to remove it.
 - ▶ **Rationale:** This promotes adequate airway exchange and prevents tongue from falling back and occluding airway.
5. Administer humidified SpO₂ by mask or nasal cannula at 6 L/min or as ordered. ▶ **Rationale:** Humidified oxygen prevents drying of the tracheobronchial tree and liquifies secretions to facilitate expectoration.
6. Monitor oxygen saturation using pulse oximetry (SpO₂).
7. Monitor carbon dioxide levels in client’s expiration, using capnography.
8. Encourage client to cough and deep breathe when awake.
9. Suction client as needed.
10. Position client to ensure adequate ventilation. Side-lying position is best if not contraindicated. Turn every hour if not contraindicated. ▶ **Rationale:** This prevents pooling of secretions in lungs and assists with ventilation.

11. Monitor vital signs every 5–15 minutes as condition warrants. Vital signs are sometimes difficult to obtain due to hypothermia and movement from operating room to postanesthesia care unit.
 - a. Check pulse rate, quality, and rhythm; include pulse distal to surgical site.
 - b. Check blood pressure, pulse pressure, and quality.
 - c. Check respiratory rate, rhythm, depth, and pattern.
 - d. Assess pain level, determine cause, and medicate as needed.

Clinical Alert

- Ineffective communication is the most frequently cited root cause of sentinel events.
 - Adverse events occur more often for surgical clients than clients in other clinical specialties.
12. Maintain body temperature by applying warm blankets or use Bair Paws Warming System. ▶ **Rationale:** Operating rooms are cold, which promotes vasoconstriction and increases risk of infection.
 13. Observe for adverse signs of general or spinal anesthesia:
 - a. Level of consciousness.
 - b. Movement of extremities.

▲ Recovery room is usually an open space for easy observation of all clients.

▲ Clients are connected to monitoring system for cardiac surveillance.

14. Monitor IV fluids.
 - a. Verify correct type and amount of solution being administered.
 - b. Set appropriate flow rate using IV pump or controller if needed.
 - c. Observe IV site for signs of infiltration.
 - d. Maintain accurate IV intake record.
15. Monitor blood or blood component infusions.
 - a. Identify appropriate replacement fluid.
 - b. Check client's name and identification number with fluid.
 - c. Check blood type, blood bank number, and expiration date.
 - d. Check time infusion initiated.
16. Monitor and measure urine output hourly if indwelling catheter is in place or before client leaves recovery room.
17. Observe surgical dressings and drains hourly.
 - a. Follow hospital policy for marking drainage on dressings.
 - b. Note color and amount of drainage on dressings and from drains or tubes.
 - c. Check that dressings are secure.
 - d. Reinforce dressings as needed.
 - e. Empty drainage collection device as needed.
 - f. Report unusual amount or type of drainage to physician before client leaves recovery room.
18. Monitor skin for warmth, color, and moisture.
19. Check nail beds and mucous membranes for color and blanching. Report unusual findings or signs of cyanosis to physician immediately.
20. Orient client to surroundings and relieve anxiety and fear.
21. Observe for return of movement, especially if client received spinal or epidural anesthesia.
22. Monitor for muscle strength/movement.
23. Administer all STAT drugs.
24. Provide pain medication as needed.
25. Complete PAR record.
26. Assess parameters for discharge from postanesthesia room.
 - e. Observe and record amount of fluid remaining in bag when admitted to recovery room.
 - f. Determine time frame for completion of fluid.

Discharging Client From Postanesthesia Unit to Nursing Unit

Procedure

1. Assess that lung sounds are clear to auscultation and airway is maintained without artificial measures (unless client is to remain on mechanical assistance).
2. Assess that vital signs are within normal range for at least 1 hr and appropriate for client's condition.
3. Observe that client is awake, alert, and responds to commands.
4. Assess that reflexes are present (including gag, swallowing) and that client can move all extremities.
5. Assess skin color and nail beds for signs of cyanosis.
6. Ensure IVs are patent, infusing with correct solution and at prescribed rate. Record total amount of IV fluid infused and amount remaining in bags. Ensure all IVs and irrigating solutions are in sufficient quantity for transfer and immediate continuity of care.
7. Check that all dressings are intact, and there is no excessive drainage from drains or tubes. Reinforce dressings if needed and empty all drainage collection receptacles before returning to nursing unit.
8. Ensure urinary output is adequate. Record all urine output and empty drainage bag before transporting to nursing unit.
9. Record all medications administered in recovery room.
10. Medicate client one half hour before transport if vital signs are stable and client requires pain medication.
 - **Rationale:** Transporting clients from postanesthesia room can increase pain due to moving and transfer from gurney to bed.
11. Call anesthesiologist for discharge orders or use Aldrete Postanesthesia Recovery Scoring System if used by facility.
12. Call for transport assistance if available. Postanesthesia room nurse accompanies client to nursing unit.
13. Call nursing unit and provide information on equipment needs for client (e.g., oxygen, IVs).
14. Document all findings in computer or in chart before discharge.
15. Prepare data for "Hand Off" communication with Surgical floor RN.

Data to Include In “Hand Off” Communication Process (SBAR)

- Situation.
 1. Client’s name and date of birth.
 2. Procedure completed with site identified.
- Background.
 1. Type of anesthesia and name of anesthesia care provider.
 2. Intraoperative PACU medications; dose and time.
 3. IV fluids administered in OR and PACU.
 4. Estimated blood loss.
 5. Data regarding dressings, tubes, drains, or packing.
 6. Significant OR events and PACU events.
- Assessment.
 1. Hemodynamic stability.
 2. Airway and oxygenation status.
 3. Temperature.
 4. Urine output.
 5. Surgical complications if present.
 6. Pain level.
 7. Type of pain management.
- Recommendations.
 1. Ensure PACU MD orders were completed.
 2. Surgeon’s plan of care has been implemented.
 3. Identify educational needs for client and family.
 4. Provide discharge instructions.
 5. Discharge within 2 hr or when stable.

Source: Amato-Vealey, E. J., Barba, M. P., & Vealey, R. J. (2008, November). Hand-off communication: A requisite for perioperative patient safety. *AORN Journal*, 88(5), 763–770. http://www.aorn-greaterhouston.org/files/Nov_08_handoff.pdf.

TABLE 26-8 Aldrete Postanesthesia Recovery Scoring System

Activity
2 = moves all four extremities voluntarily or on command
1 = moves two extremities voluntarily or on command
0 = unable to move any extremity voluntarily or on command
Respiration
2 = able to breathe, cough freely
1 = requires assistance, shallow or limited breathing
0 = apneic
Circulation
2 = BP+20 mmHg of preanesthetic level
1 = BP+20 to +50 mmHg of preanesthetic level
0 = BP+50 mmHg of preanesthetic level
Consciousness
2 = fully awake
1 = arousable on calling
0 = not responding
Oxygen saturation
2 = SpO ₂ >92% on room air
1 = Supplemental O ₂ required to maintain SpO ₂ >90%
0 = SpO ₂ supplementation
10 = Total score >9 for PACU discharge

This is one method for determining whether postanesthesia room discharge criteria have been met. In addition to stable vital signs, a total score of 10 for the five assessed areas must be achieved for nurses to discharge clients without a physician’s order.

Discharging Client From Phase II Unit to Home

Procedure

1. Follow all actions for Discharging a Client From Postanesthesia Unit to Nursing Unit.
2. Assess for nausea or light-headedness. ▶ **Rationale:** These symptoms may be a result of anesthesia or hypovolemia. The client is not discharged until these symptoms have abated or are medically treated.
3. Provide discharge teaching regarding medications, activity, dressing changes, physician office visit, etc. If client is unable to understand instructions, provide information to person taking client home. Send written instructions home with client as well.
4. Assist client to side of bed, feet on floor, and allow to sit for a few minutes. ▶ **Rationale:** To prevent a fall when standing as a result of postural hypotension.
5. Assess client’s ability to dress self or identify what assistance is needed.
6. Ensure client has urinated, ambulated to bathroom, and is not vomiting before discharge.
7. Obtain prescriptions from pharmacy if needed.
8. Place client’s equipment, supplies, and medications in a plastic bag and hand to person taking client home.
9. Transfer client to wheelchair.
10. Take client to car and assist with transfer.
11. Document all activity related to discharge, including person taking client home and method of transport.

DOCUMENTATION for Postanesthesia Care

For Nursing Unit

- Assessment findings—follow SBAR
- Effects of anesthesia
- Status of airway management
- Need for oxygen administration
- Status of neurologic signs and reflexes
- Fluid replacement—type and amount
- Blood and blood product replacement
- Medications administered
- Condition of dressings, drains, and tubes
- Intake and output from all sources: urine, drains, tubes, IVs
- Vital signs: T, P, R, BP, and pain

- Description of pain and interventions for relief of pain
- Response to postanesthesia room activities
- Discharged to room (number) and transporter
- “Hand Off” Communication Data

For Discharge Home

- Additional charting includes ability to stand or transfer to wheelchair and having urinated
- Discharge teaching completed
- Signs or symptoms of nausea, light-headedness
- Discharged to care at home
- Discharged via automobile or other means of transportation.

Legal Alert

Operating Room Negligence

The nurse’s responsibility is to accurately count and monitor the sponge count and equipment. A common litigation against operating room nurses involves sponges or instruments left in a client after a surgical procedure.

After a hysterectomy, three different sponge counts were completed (before, during, and after the

procedure) and confirmed by the nurse. Two years later, when the client had a second surgery for bowel obstruction, a sponge was found in the site. A suit was filed against the physician and the hospital (which included the nurse) for negligent acts by the nurse who had made an inaccurate sponge count. Both were found negligent by the jury.

Source: *Truhitte v. French Hospital* (1982).

CRITICAL THINKING Application

Expected Outcomes

- Client experiences no untoward effects during recovery period.
- Potential postanesthesia complications are identified early, and appropriate nursing actions are taken to prevent occurrence of complications.
- Client is discharged from postanesthesia unit at appropriate time.

Unexpected Outcomes

Client experiences untoward effects in postanesthesia room.

Alternative Actions

- Contact physician for additional orders.
- Complete physical assessment.
- Identify and initiate appropriate nursing interventions within allowed guidelines and parameters of the facility.

Client does not awaken easily.

- Retain client in postanesthesia room; check Glasgow scale.
- Continue to provide oxygen.
- Arouse every 15 minutes.
- Check pain medication (may need Narcan).

Client has postoperative hemorrhage.

- Apply direct pressure.
- Notify physician immediately.
- Assess for signs of hypovolemia.
- Assess for signs of overt bleeding (i.e., saturated dressings, large amount of drainage in drainage collection devices, increase in girth of affected surgical area).
- Check lab values for hematocrit, hemoglobin, and coagulation levels.
- Check records for estimated blood loss during surgery.

Postoperative Care

Nursing Process Data

ASSESSMENT Data Base

- Assess for patent airway.
- Check if oxygen is ordered.
- Auscultate lungs.
- Observe for adverse signs of general anesthesia or spinal anesthesia.
- Take vital signs (T, P, R, BP, and pain).
- Check client's temperature for heat control.
- Observe dressings and surgical drains.
- Check IVs for type and amount of fluid to be infused.
- Observe color and amount of urine.
- Auscultate bowel sounds and verify bowel movement and flatus.
- Observe client's overall condition.

PLANNING Objectives

- To ensure that the client experiences an uneventful postoperative course
- To provide safe, effective nursing care in the immediate postoperative period
- To ensure that postoperative pain is relieved promptly
- To be aware of the common postoperative drugs for pain control

IMPLEMENTATION Procedures

- Providing Postoperative Care 994
- Administering Postoperative Medications 995
- Postoperative Complication Table 996

EVALUATION Expected Outcomes

- Client experiences an uneventful postoperative course.
- Postoperative nursing interventions are carried out effectively and in a timely manner.
- Client reports pain levels: <4 on scale of 0–10.
- Client is free of nausea and vomiting.

Critical Thinking Application 999

- Expected Outcomes 999
- Unexpected Outcomes 999
- Alternative Actions 999

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Providing Postoperative Care

Equipment

Absorbent pads
 Warm blankets or Bair Paws Warming System
 IV pole
 Oxygen source, tubing, and equipment
 Emesis basin and tissues
 Sphygmomanometer and stethoscope
 Thermometer (tympanic, oral, or rectal)
 Nurses' notes
 Intake and output record
 Special equipment depending on type of surgery
 Pulse oximeter
 Sterile dressings

Procedure

1. Perform hand hygiene before each client contact.
2. Check two forms of client ID and introduce self to client.
3. Orient client to time, person, and place. Reorient as needed.
4. Assess for patent airway and level of consciousness; administer oxygen if ordered. Attach pulse oximeter if ordered.
5. Assess for effects of anesthesia including general, regional, or local.
6. Take vital signs, including pain assessment: usual orders are every 15 minutes until stable; then every half hour for 2 hr; every hour for 4 hr; then every 4 hr for 24–48 hr, or according to hospital policy.
7. Check pulse oximetry every hour for 4 hr, then every 4 hr. ► **Rationale:** To detect early signs of hypoxemia.
8. Check ETCO₂ using capnography monitoring, if available.
9. Check for nausea and vomiting.
10. Check IV site and patency frequently.
11. Observe, and record urine output, amount, and color.
12. Measure intake and output.
13. Observe skin color and moisture and nail beds.
 - **Rationale:** To determine adequacy of tissue perfusion.
14. Position client for comfort and maximum airway ventilation according to orders.
15. Turn every 2 hr and PRN.
16. Give back care at least every 4 hr.
17. Encourage coughing and deep breathing every 2 hr (may use spirometer or Tri-flow if ordered).
18. Keep client comfortable with medications.
19. Monitor for side effects of medications.
20. Check dressings and drainage tubes every 2–4 hr; if abnormal amount of drainage, check more frequently. Empty drainage system when needed
21. Assess for signs and symptoms of Surgical Site infections (SSIs).
 - a. Superficial incisional:
 - Purulent drainage with or without elevated white blood cell count
 - Pain or tenderness at the site
 - Localized swelling, heat, or redness
 - Positive wound culture
 - b. Deep incisional:
 - Purulent drainage
 - Temperature above 100.4°F (38°C)
 - Leukocytosis
 - Localized pain or tenderness
 - c. Organ/space:
 - Purulent drainage from a drain placed in an organ or space
 - Positive culture from fluid or tissue in the organ or space

▲ Recovery room documentation is accomplished using computerized system.

- Temperature above 100.4°F
- Leukocytosis
- Pain
- Abscess formation or other evidence of infection in the organ or space

NOTE: See Wound Care, *Chapter 25*, for further information.

22. Provide oral hygiene at least every 4 hr; if nasogastric tube or nasal oxygen is inserted, give oral hygiene every 2 hr. ► **Rationale:** To decrease risk of infection from presence of oral bacteria.
23. Bathe client when temperature can be maintained. ► **Rationale:** Bathing removes the antiseptic solution and stimulates circulation.
24. Keep client warm and avoid chilling, but do not increase temperature above normal. Use of Bair Paws Warming System allows client to maintain warmth and provides comfort. (See Chapter 24.) ► **Rationale:** Increased temperature increases metabolic rate and need for oxygen. Excessive perspiration causes fluid and electrolyte loss.
25. Irrigate nasogastric tube every 4 hr and PRN, as ordered, with normal saline to keep patent and to prevent electrolyte imbalance.
26. Maintain dietary intake: type of diet depends on type and extent of surgical procedure.
 - a. Minor surgical conditions: Client may drink or eat as soon as he or she is awake, desires food or drink, and has gag reflex present.
 - b. Major surgical conditions: NPO until bowel sounds return. Clear liquid advanced to full diet as tolerated.

Use of Spirometry for High-Risk Clients After Coronary Artery Bypass Surgery

A study was conducted to determine whether the addition of incentive spirometry to postoperative pulmonary physical therapy is more effective than physical therapy alone in reducing postoperative pulmonary complications in high-risk clients after coronary artery bypass grafting. One group received pulmonary physical therapy combined with the spirometry and the other did not receive the spirometry. The results indicated that no difference was found between the two groups in atelectasis, oxygen saturation, or pulmonary infection. Use of the spirometer was not monitored; therefore, the effectiveness of the spirometer could not be fully evaluated.

Source: Crowe, I.M. (1997). *Physical Therapy*, 77(3), 260–268.

Conditions That Place Clients at Risk for Postoperative Infection

- Uncontrolled diabetes
 - Renal failure
 - Obesity; advanced age
 - Receiving corticosteroids
 - Receiving immunosuppressive agents or are immunosuppressed
 - Prolonged antibiotic therapy
 - Protein or ascorbic acid deficiencies
 - Marked dehydration and hypovolemia
 - Decreased cardiac output
 - Edema and fluid and electrolyte imbalances
 - Anemia
 - Preoperative infection
27. Place client on bedpan 2–4 hr postoperatively if catheter not inserted.
 28. Check physician's orders when to begin the client's postoperative activity. Most clients are ambulated within first 24 hr.
 29. Observe for signs and symptoms of possible postoperative complications, particularly postoperative bleeding and infection.
 30. Dangle or position client in chair as ordered.

Surgical Site Infections

Prevention

- Appropriate use of prophylactic antibiotics
- Appropriate hair removal
- Maintenance of perioperative glucose control
- Maintenance of perioperative normothermia

Bacterial Causes of SSIs

Common bacteria

- *Staphylococcus*
- *Enterococcus*
- *Pseudomonas*
- *Streptococcus*

Newer causes (due to antibiotic resistance)

- *Escherichia coli*
- Methicillin-resistance *staphylococcus aureus*
- *Candida*

Administering Postoperative Medications*

Equipment

- Medication as ordered
- Appropriate syringe and needle for parenteral medications

Procedure

1. Check two forms of client ID and introduce self to client.

*See Chapter 16, Pain Management, for PCA and epidural.

TABLE 26-9 Postoperative Complications

Potential Complication	Clients at Risk	Indicative Findings	Prevention	Intervention	Drug Therapy
<p>Atelectasis: Collapse of alveoli; may be diffuse and involve a segment, lobe, or entire lung</p> <p><i>Potential Onset:</i> First 48 hours</p>	<p>All with general anesthesia</p> <p><i>Special risk clients:</i></p> <ul style="list-style-type: none"> Smokers Chronic bronchitis Emphysema Obesity Elderly Upper abdominal surgery Chest surgery Abdominal distention 	<ul style="list-style-type: none"> Fever to 102°F Tachycardia Restlessness Tachypnea 24–30 minutes Altered breath sounds Dullness to percussion Diminished or absent breath sounds Crackles ABGs: decreased PaO₂ 	<p><i>Preoperative:</i> Have client practice turning, coughing, and deep breathing</p> <p>Discuss importance of exercises</p> <p><i>Postoperative clients at risk:</i></p> <ul style="list-style-type: none"> Turn every 30 minutes Deep breathe and cough <p><i>Other clients:</i></p> <ul style="list-style-type: none"> Initiate turning and deep breathing exercises every 1–2 hr <p>Ambulate as soon as possible</p> <p>Medicate to reduce pain, splinting, and resistance to treatment</p>	<ul style="list-style-type: none"> Deep breathing and incentive spirometry Administer supplemental oxygen as ordered Monitor response to treatment Monitor for onset of pneumonia If entire lobe of lung is involved, prepare for bronchoscopy to remove plug Change position every 2 hr 	<ul style="list-style-type: none"> Analgesics: pain control Bronchodilators (nebulized through IPPB); liquefy secretions Water or saline (nebulized through IPPB); liquefy secretions
<p>Pneumonia:</p> <p>Inflammatory process in which alveoli are filled with exudate</p> <p><i>Potential onset:</i> First 36–48 hr</p>	<ul style="list-style-type: none"> Clients with unresolved atelectasis Following aspiration Smokers Elderly Chronic bronchitis Emphysema Heart failure Debililitated Alcoholic Immobile Cough suppressant medications Respiratory depressant medications 	<ul style="list-style-type: none"> Client complains of dyspnea, tachycardia, increasing temperature, productive cough, and increasing amount of sputum becoming tenacious, rusty, or purulent Tactile fremitus Dullness to percussion Bronchial breath sounds Increased crackles or rhonchi Voice sounds present ABGs: decreased PaO₂ 	<ul style="list-style-type: none"> Provide vigorous treatment of atelectasis Prevent aspiration Ambulate as soon as possible 	<ul style="list-style-type: none"> Turn, cough, and deep breathe every 1 hr May need to stimulate cough with nasotracheal suctioning Send sputum for culture and sensitivity Frequent mouth care for comfort Administer oxygen as ordered Increase fluid intake Monitor for response to treatment 	<ul style="list-style-type: none"> Antibiotics: Cephalosporin or ampicillin prophylactically for 48 hr for high-risk clients Cephalosporin IV or parenteral for infections Antipyretics: decrease temperature
<p>Pulmonary embolism:</p> <p>Foreign object has migrated to branch of pulmonary artery</p> <p><i>Potential onset:</i> Seventh to tenth day</p>	<ul style="list-style-type: none"> Superficial vein thrombosis: rare Deep vein thrombosis: 40% to 60% Air emboli: intraperitoneal surgery Fat emboli: long bone fracture, split sternum 	<ul style="list-style-type: none"> Only 10% recognized clinically Pain sharp and stabbing, occurs with breathing, localized (right lower lobe most frequent) Marked shortness of breath Increased heart rate—tachycardia Restlessness and other symptoms of hypoxia (severe anxiety) 	<ul style="list-style-type: none"> Provide range of motion Encourage early ambulation Prevent thrombophlebitis Do not massage an area with potential for or suspected thrombus Elastic stockings or leg compression devices 	<ul style="list-style-type: none"> Administer oxygen to relieve hypoxia Reduce anxiety Position client on left side with head dependent to prevent air embolus Prevent recurrent embolization; prepare for fibrinolysis; prepare for anticoagulation 	<ul style="list-style-type: none"> Anticoagulation therapy: IV heparin to maintain therapeutic APTT Sodium prophylactically for high-risk clients Urokinase, t-PA, streptokinase: thrombolytic effect (24 hr) Analgesics: pleuritic pain control Prepare for x-ray or scan Adequate hydration

<p>Thrombophlebitis: Inflammation of vein with clot formation</p> <p><i>Potential onset:</i> Seventh to fourteenth day</p>	<p><i>Abnormal vein walls:</i> Varicose veins Previous thrombophlebitis Trauma to vein wall Tight strap on operating room table Surgery on hips or in pelvis Age over 60 years (arteriosclerosis)</p> <p><i>Venous stasis:</i> Immobility, long duration surgery Casts, restrictive dressings Constant Fowler's position Prolonged dependent lower extremities Knee gatch elevated Pillows under knees, calves Obesity Abdominal distention Shock Heart failure</p> <p><i>Hypercoagulability:</i> Surgical stress response Anesthesia Decreased circulation Hypovolemia, dehydration Malignant neoplasms Postpartum Oral contraceptives Insert rectal tube</p>	<p><i>Superficial vein thrombophlebitis:</i> Pain, redness, tenderness, and induration along course of vein Palpable "cord" corresponding to course of vein History of trauma including IV site</p> <p><i>Deep small vein thrombophlebitis:</i> Increased muscle turgor and tenderness over affected vein Deep muscle tenderness Most frequent site: vessels at call Affected limb warm to touch with occasional swelling Client complains of tightness or stiffness in affected leg Positive Homan's sign (dorsiflexion of foot leads to calf pain) Fever rarely more than 101°F</p> <p><i>Major deep vein thrombophlebitis:</i> No superficial signs of inflammation Homan's sign unreliable</p> <p><i>Femoral vein thrombosis:</i> Pain and tenderness in distal thigh and popliteal region Swelling extends to level of knee</p>	<p><i>Avoid injury to vein wall:</i> Use care when strapping to operating room table Avoid IVs in lower extremities Pad siderails for restless, convulsive, and/or combative client Avoid restraints</p> <p><i>Avoid venous stasis:</i> Encourage early ambulation Provide feet and leg exercises Elastic stockings; sequential-compression devices Increase frequency of exercise for client at risk Prevent client's sitting with legs in dependent position Place pillow between legs while client is lying on side to prevent pressure from upper leg on lower leg Provide deep breathing exercises Provide range of motion Increase velocity of blood flow: No standing Steady IV flow Antiemetic stockings (controversial)</p> <p>Decrease hypercoagulability: Provide adequate hydration Prevent infections Maintain circulation Decrease stress/anxiety</p>	<p><i>Superficial vein thrombophlebitis:</i> Treat symptoms Continue ambulation unless accompanied by deep venous involvement Monitor for progression toward saphenofemoral junction (may need ligation)</p> <p><i>Deep vein thrombophlebitis:</i> Provide adequate bedrest Elastic stockings Sequential-compression devices Elevate foot of bed with 6–8-in. blocks Administer warm moist compresses to relieve venospasm and help resolve inflammation Monitor for pulmonary embolism</p>	<p>Streptokinase: thrombolytic effect (24 hr) Heparin IV or subcutaneous: decrease clotting time (short-term) Nonorthopedic surgery—low-dose subcutaneous heparin (or low molecular-weight heparin) Coumadin PO: decrease clotting time (long term) Analgesics: pain control Low-molecular-weight dextran IV on operative day and 2 days postoperative Aspirin 1.2 g/day in divided doses</p>
<p>Ileus: Failure of peristalsis</p> <p><i>Potential onset:</i> First 24–36 hr</p>	<p>All surgical clients Stress response to surgical trauma</p>	<p>No bowel sounds or fewer than 5/min (normal; 5–35 clicks or gurgles/min) Vomiting Abdominal distention</p>	<p>Do not feed until bowel sounds return Offer only sips of water until return of bowel sounds Maintain normal serum potassium level</p>	<p>Monitor for return of normal bowel sounds (enteral feeding following non-GI surgeries will resolve ileus faster) Monitor for distention Monitor for passage of flatus signaling return of peristalsis Monitor signs of hypokalemia</p>	<p>Switch to nonopioid analgesic (opioids slow GI motility), NSAIDs, and acetaminophen</p>

Continued

TABLE 26-9 Postoperative Complications (Continued)

Potential Complication	Clients at Risk	Indicative Findings	Prevention	Intervention	Drug Therapy
Paralytic ileus: Paralysis of intestinal peristalsis <i>Potential onset:</i> First 3–4 days	Intraperitoneal surgery Peritonitis Kidney surgery Decreased cardiac output Pneumonia Electrolyte imbalance Wound infection	No bowel sounds Abdominal distention No passage of flatus or feces Nasogastric drainage green to yellow, 1–2 L in 24 hr Anorexia, nausea Complaints of fullness and diffuse pain	Maintain electrolyte balance, especially potassium Maintain cardiac output Prevent pneumonia Provide early ambulation	Treat cause Maintain nasogastric suction until peristalsis returns Monitor for intestinal obstruction	Potassium chloride if serum level is low Dexpantenol (Ilopan) to stimulate return of peristalsis total parenteral nutrition (TPN) if indicated
Urinary tract infection <i>Potential onset:</i> Third to fifth day or 48 hr after removal of catheter	<i>Decreased resistance:</i> History of bladder distention History of urinary retention Previous urinary tract infection History of prostatic hypertrophy History of catheterization Diabetic Debilitated Immobile	Dysuria Frequency Urgency High fever: up to 104°F with fewer systemic toxic symptoms than would be expected Change in urine odor Pus in urine Sediment May be asymptomatic	Maintain sterile technique with catheterization and catheter removal Provide competent indwelling catheter care Encourage early ambulation to decrease retention and stasis	Encourage fluid intake; cranberry juice to decrease urine pH Increase activity to enhance bladder emptying Encourage voiding every 2 hr while awake Send specimen for culture and sensitivity Monitor for residual urine of more than 100 mL	Urinary antiseptics (sulfonamides); bacterial suppression Antibiotics (ampicillin, tetracycline); bacterial suppression Anticholinergics; antispasmodic Topical urinary analgesic; pain relief
Wound infection <i>Potential onset</i> Streptococcal: 24–48 hr after contamination Staphylococcus gram-negative rods, etc.: 5–7 days postoperatively	<i>Slow to heal:</i> Obese Diabetic <i>Poor nutrition:</i> Debilitated Elderly <i>Poor circulation:</i> Elderly Hypovolemic Heart failure <i>Lack of oxygen to wound:</i> Vasoconstriction Severe anemia Depressed immunity Cancer Renal failure Preoperative steroid therapy Prolonged complex surgery (stress response leading to increased ACTH) Malnutrition Elderly <i>At risk for transmission</i> Proximity of another client with infection Transmission by hands of personnel	Initial inflammation: 36–48 hr Wound tender, swollen, warm, increased redness Increasing heart rate Increasing temperature (100.4°F or more) Increasing or recurring serous drainage; drainage becomes purulent, foul odor There may be no local signs if infection is deep Elevated WBC Malaise	Practice meticulous hand hygiene and gloving Practice aseptic technique in wound care Separate from infected clients Use special caution for a new wound, easily contaminated Maintain nutrition Provide frequent turning Ambulate as soon as possible Maintain PaO ₂ Increase attention to prevention for clients with depressed immunity Operative site: clip excess hair and cleanse with chlorhexidine (reduces bacterial counts)	Maintain nutrition Maintain oxygenation Maintain circulation and blood volume Maintain pulmonary toilet Cleanse wound or irrigate as ordered Apply wet-to-moist dressings Monitor for systemic response to infection, fever, malaise, headache, anorexia, nausea Treat symptoms	Administer antibiotics as ordered New cyanoacrylate adhesives (Dermabond, Indermil) close wounds and promote healing Send wound drainage specimen for culture and sensitivity

2. Evaluate client's need for pain relief.
3. Provide nonmedication measures for relief of pain, such as relaxation techniques, back care, positioning.
4. Identify the pharmacologic action of the ordered medication.
5. Review the general side effects of the medication.
 - a. Drowsiness
 - b. Euphoria
 - c. Sleep
 - d. Respiratory depression
 - e. Nausea and vomiting
6. Administer medications as ordered, usually at 3- to 4-hr intervals for first 24–48 hr for better action and pain relief. Assess for pain relief.
7. Instruct in use of PCA pump, if ordered.
8. Know the action of the following drugs:
 - a. Opiates.
 - b. Synthetic opiate-like drugs.
 - c. Nonnarcotic pain relievers.
 - d. Narcotic antagonists.
 - e. Antiemetics.

DOCUMENTATION for Postoperative Care

- Postoperative nursing interventions
- Fluid replacement—type and amount of solution
- Condition of dressings and drains
- Urine output, fluid intake
- Orientation to place, person, time
- Vital signs
- Signs and symptoms of potential complications
- Preventive nursing measures
- Client's activity level
- Clinical manifestations indicating pain
- Type, time, and amount of pain medication administered
- Site of injection
- Any side effects of medications observed
- Effectiveness of pain medication

CRITICAL THINKING Application

Expected Outcomes

- Client has an uneventful experience in the recovery period.
- Potential postoperative complications are identified early and corrective interventions prevent occurrence of complications.
- Client is discharged to home or nursing unit within prescribed time frame.
- Client reports pain: < 4 on scale of 1–10.
- Client does not experience nausea or vomiting.

Unexpected Outcomes

Client develops abnormal breath sounds.

Bowel sounds are absent.

Alternative Actions

- Increase deep breathing and coughing exercises to every 2 hr.
- Medicate for pain before coughing or ambulating.
- Encourage use of incentive spirometer.
- Turn every 1–2 hr and ambulate if allowed.
- Place client in Fowler's position to expand lungs.
- Increase fluid intake to liquify secretions if not contraindicated.
- Obtain physician's order for nebulizer treatments if indicated.
- Do not give ice chips or fluids; keep on NPO status until discussed with physician.
- Notify physician if client is experiencing nausea and vomiting or if abdomen is distended and bowel sounds remain absent. It may be necessary to insert an NG tube.
- Auscultate bowel sounds every 4 hr.
- Encourage frequent turning and ambulation, if allowed.

Deep vein thrombosis (DVT) occurs.

- Place on bedrest.
- Remove antiembolic stockings or compression devices on affected leg.
- Check for calf pain, discoloration, or Homan's sign.
- Do not massage legs.
- Monitor clotting times and titrate anticoagulants if using heparin, according to physician's orders.
- Measure circumference of both legs each shift to determine effectiveness of treatment.
- Encourage leg exercises on unaffected leg.

Temperature increases.

- Day of surgery—check for dehydration.
- Days 1 and 2—check breath sounds for potential atelectasis.
- Fever in first 24 hr is most commonly from atelectasis.
- Days 2—check for urinary tract infection.
- Days 3–10—check for possible wound infection or pneumonia.
- Check breath sounds for adventitious sounds or diminished breath sounds.
- Increase fluids if not contraindicated.
- Monitor temperature frequently until it returns to normal.

Blood pressure decreases; pulse and respirations increase.

- Check for IV access.
- Check skin turgor and urine output and hypovolemia.
- Observe dressings and drains for signs of bleeding.
- Check intake and output values to determine hydration status.

Urinary retention occurs.

- Check bladder using bladder scanner.
- Assist to commode or bathroom if possible.
- Increase fluid intake if appropriate.
- Review I&O record to determine findings.
- Assess for signs and symptoms of dehydration.
- Obtain order for catheter if necessary.

GERONTOLOGIC Considerations

Statistics for elderly clients requiring surgery are important to consider when providing care.

- Fifty percent of clients over 60 years of age require surgery before they die.
- Forty percent of elderly clients admitted to hospitals undergo a surgical procedure before discharge.
- The most common surgical procedures for elderly clients involve tissue biopsy and pacemaker insertion. Fractures comprise a large percentage of surgical interventions, particularly hip fractures.

Elderly clients are more prone to fluid and electrolyte imbalance.

- Dehydration is the most common cause of fluid and electrolyte imbalance.
- Check IV fluid type and amount to ensure adequate hydration.
- Elderly clients require 1.5–2.5 L of fluid every 24 hr.
- Monitor intake and output carefully to ensure adequate hydration.

- Monitor neurologic status for possible electrolyte imbalance.
- Fluid loss occurs with nasogastric tube placement and preop bowel preparation; clients requiring either of these interventions should be observed for dehydration.
- Evaluate electrolyte lab values for abnormal levels. (Hyperkalemia is common as a response to age-related alterations in the renin–aldosterone system.)

Elderly clients are at risk for complications associated with immobility after surgical interventions.

- Turn client frequently, at least every 2 hr.
- Ambulate as soon as possible postoperatively.
- Evaluate skin for early signs of breakdown (nonblanching erythema).
- Encourage deep breathing and coughing exercises every 1–2 hr. Instruct in use of incentive spirometer if ordered.
- Encourage leg exercises every hour when awake.

Preoperative teaching should be individualized, keeping in mind the following:

- Elderly clients may have chronic conditions that make movement difficult, altering preventative measures such as turning.
- Clients may have visual or auditory alterations requiring a quiet environment for teaching.
- Larger print or brochures with photos and large print should be used when teaching elderly clients.

Chronic conditions may alter normal vital signs, which may be misinterpreted during the perioperative phases.

- Document abnormalities in vital signs on client care plan so that all healthcare workers are alerted to client's usual values. Blood pressure and pulse alterations can be different for this age group.
- Monitor peripheral pulses to ensure adequate circulation.

Altered physiologic states need to be communicated to all healthcare workers.

- Document if client has an artificial eye or other prosthesis.
- Document client's visual or auditory alterations. If hearing aid is necessary for client to hear, indicate clearly on care plan.
- Identify if client has any condition that can interfere with postoperative care.

Elderly clients may not be candidates for conscious sedation.

- Many elderly clients have an ASA reading above 3. This would be considered a contraindication for this sedation.
- Anesthesiologists would most likely have to administer the medication.

Consent forms must be signed by legally competent client.

- Signing of consent form can only be done if client is considered competent to understand directions given and explanation of procedure.
- Signing of consent form must be voluntary.
- Client must be informed about procedure and must understand what he or she is signing.
- A court-appointed conservator may need to be obtained for clients not considered mentally competent to sign for themselves.
- Family members may not sign for client unless they are legally considered the client's guardian or advance directive provides instructions.
- In emergency situations, permission may be obtained from family members, but not for routine procedures.
- Two physicians can sign for emergency surgery; however, the surgeon performing the surgery should not sign the permit.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- RNs and LVN/LPNs can complete routine preoperative teaching and care. Anything out of the ordinary would be the responsibility of the RN.
- Postanesthesia room staff are usually RNs because they need to make quick decisions and use nursing judgment in times of crisis.
- Postoperative care of clients may be provided by both RNs and LVN/LPNs.
- Clients undergoing conscious sedation may be monitored by RNs if their State Nurse Practice Act and hospital policy allows it and the clients are in ASA categories 1 and 2 (see section on conscious sedation).
- CNAs can be delegated to take vital signs and do routine hygienic care for clients once they are stable.
- Many facilities use "scrub techs" or OR techs to perform routine duties such as the preoperative scrub. OR techs are also assigned to assist the physician during surgery.

Communication Matrix

- It is very important that all preoperative forms be completed in a timely manner. If data are missing, the client's surgery may be delayed while laboratory tests are taken, history and physical examination reports are found and placed in the chart, or chest x-ray results are placed in the chart. History and physical provide information to ensure continuity of care.
- Notify OR staff and physician if client indicates he or she has a known latex allergy or does not know of a latex allergy. All latex supplies and equipment must be removed from the OR suite before surgery can commence.
- When the phone call is received from the operating room indicating the nurse should give the preoperative medications or that the OR is ready for the client, ensure the message is relayed immediately to the staff caring for the client. This will allow the nurse to give the medication or complete any last-minute charting and have the client ready for the transporter.
- If there are any client issues or problems that directly affect the surgical procedure, contact the operating room or physician immediately. Surgery may need to be delayed or canceled. Examples of issues that could impact the surgery include an overly anxious client, if the client has a temperature, symptoms indicating an upper respiratory or

urinary tract infection, labs that are abnormal (bleeding time, cardiac enzymes, electrolytes), or new abnormal ECG changes.

- Specific report regarding the client's condition will be completed upon admission to the postanesthesia room and again when the client is returned to the nursing unit. The

report is given by the RN in the operating room to the RN in the postanesthesia room. The postanesthesia room nurse accompanies the client to the nursing unit and gives report to the RN. The report is outlined as Step 15 of the skill Discharging Client From Postanesthesia Room to Nursing Unit.

CRITICAL THINKING Strategies

Scenario 1

You are assigned to the postanesthesia room on the day shift. You have just arrived on the unit to begin the shift. There are two clients assigned to your care:

- Mrs. Cohen, a 54-year-old client, had an exploratory laparoscopy with general anesthesia and is just arriving in the recovery room.
- Mr. Brewer is a 24-year-old client who had local anesthesia for an arthroscopy of the right knee. He has been in the recovery room for 1 hr.

1. Which client will you see first? Provide rationale for your response.
2. Identify the first action you will take when first seeing each of the two clients. Provide rationale for your response.
3. Identify the priority assessment for Mrs. Cohen and state your rationale.
4. Identify the priority assessment for Mr. Brewer and state your rationale.
5. State nursing interventions that will be provided for all clients in the postanesthesia room.
6. Before discharge from the recovery room, you assess Mr. Brewer on the Aldrete Recovery Scoring System and his score is 7. What is your next action?

7. Mr. Brewer is being discharged home. He tells you he is concerned about going home because he has a dry mouth and is thirsty. What would be an appropriate response to him?
8. Write the SBAR "Hand Off" communication you will prepare for transfer of Mr. Brown to the surgical floor.

Scenario 2

You assess that Mr. Marconi is very anxious while you are admitting him for a surgical procedure.

1. List four priority components of baseline data you need to obtain before surgery. Provide a rationale to support this data.
2. What factors might contribute to preoperative stress?
3. Identify a priority intervention to use after assessing that Mr. Marconi is in high-level stress.
4. Mr. Marconi becomes angry and hostile when you attempt to provide preoperative teaching. Describe three possible actions you could take, and state the priority intervention and the rationale for selecting this intervention.

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. During the preoperative stage, the client activity not completed is
 1. Obtaining a health history.
 2. Identifying a client's allergies.
 3. Beginning the infusion of a moderate sedative drug.
 4. Identifying the side and site of the surgical procedure.
2. The role of the circulating nurse in the operating room is to
 1. Mark the operative site with a felt pen.
 2. Insert the IV and begin infusing fluids.
 3. Assist the physician during the operative procedure.
 4. Position the client on the operative table and attach grounding pad.
3. The most common malpractice action against operating room nurses is
 1. Sponges and instruments left in the surgical site accidentally.
 2. Surgical procedure performed on wrong site or side.
 3. Burns from electrical grounding pad not placed correctly on client.
 4. Infection at surgical site after surgical procedure.
4. The student's client assignment includes a preoperative client scheduled for surgery in 3 hours. The initial

intervention is to reduce anxiety and stress for this client. This can best be accomplished by _____.

Select all that apply.

1. Discussing realistic outcomes with the client.
 2. Avoiding promoting false reassurances.
 3. Using touch to communicate caring.
 4. Encouraging range of motion and walking activities.
5. As a student nurse working in the outpatient setting, you are asked to provide postoperative instructions to a client after a laparoscopy. The most appropriate instructions should be to
1. Instruct the client that he/she may experience a sharp pain under the scapula up to 24–48 hr after surgery.
 2. Inform the client he/she will be hospitalized for a minimum of 24 hr to monitor for pain.
 3. Inform the client that this type of surgery usually requires very little pain medication; Tylenol is sufficient to control the pain.
 4. Explain that the client can return to work the next day, as long as they do not lift anything over 50 pounds.
6. While you are working on a surgical unit, you are preparing the client for a surgical procedure. Your responsibilities in this preparation include
1. Asking the client if he/she has made arrangements for home care after discharge.
 2. Instructing the client to sign the surgical consent form at the time the OR transporter arrives in the room.
 3. Administering the preoperative medication at least 2 hr before the surgery is scheduled.
 4. Checking for allergies to latex, food, and medications.
7. The Joint Commission standards regarding Universal Protocols for preventing wrong site, wrong procedure, and wrong person surgery includes _____.
- Select all that apply.**
1. Marking the surgical site by the preoperative nurse.
 2. Validating the correct surgical site by the surgeon before beginning the procedure.
 3. Writing the word “yes” on the surgical check list line indicating the correct incision site.
 4. Completing a final verification of the site in the location where the procedure takes place.
8. You are caring for a client after a procedure where moderate (conscious) sedation was used. You understand the client will not be discharged until the
1. Ramsay Sedation Scale is normal.
 2. Riker Sedation-Agitation Scale is –1 to +1.
 3. Aldrete score is ± 1 point of preprocedure score.
 4. Glasgow Coma scale is more than 9.
9. A client is returning to the nursing unit after an abdominal surgical procedure. The priority nursing intervention is to
1. Take and record vital signs.
 2. Assess type of IV solution and amount of IV solution remaining in bag.
 3. Check pulse oximeter reading.
 4. Assess for patent airway.
10. Pneumonia is a major postoperative complication related to inactivity and decreased pulmonary ventilation. As you are assessing the client postoperatively, you recall the usual onset of signs and symptoms is _____
1. Within 24 hr.
 2. 24–36 hr.
 3. 36–48 hr.
 4. More than 72 hr.

Orthopedic Interventions

LEARNING OBJECTIVES

1. Identify nursing diagnoses that apply to care of clients with orthopedic conditions.
2. Outline emergency measures for an injured extremity.
3. Describe different ways to classify fractures.
4. Assess circulation, motion, and sensation in an injured limb.
5. Recognize indicators of circulatory compromise in an injured or immobilized extremity.
6. Apply a variety of immobilizing devices (sling, bandage, splint, brace).
7. Describe differences between plaster of Paris and synthetic casts.
8. Explain the purpose for skin versus skeletal traction.
9. Identify types of skin and skeletal traction.
10. Develop a teaching plan for the client with a cast.
11. Outline the nursing care needs of the client in traction.
12. Outline the teaching needs of a client with an amputation.
13. Develop a teaching plan for a client undergoing joint replacement (arthroplasty).
14. Discuss the advantages of autologous reinfusion after joint replacement surgery.

TERMINOLOGY

Abduction movement away from the midline of the body or body part, as in raising the arm or spreading the fingers.

Adduction movement toward the midline of the body.

AKA above-the-knee amputation.

Alignment arranged in a straight line.

Amputation traumatic or surgical removal of a diseased limb or part.

Arthroplasty repair/replacement of a joint.

Autologous reinfusion involves collection of shed blood through suction into a reservoir and reinfusion through the client's venous access.

Balanced suspension use of a sling or splint to elevate and support an extremity that is in traction.

BKA below-the-knee amputation.

Bryant's traction a type of skin traction used to treat fracture of the femur in a small child.

Buck's traction a type of skin traction applied to the lower leg to reduce muscle spasm and immobilize hip fracture.

Callus fibrous matrix of protein that bonds a fracture site, but has not ossified and cannot support weight bearing.

Cast circumferential immobilizer generally reserved for short-term fracture management.

Comminuted broken in pieces; usually occurs in spongy bone areas.

Contusion soft tissue injury.

Diaphysis the part of the long bone between the ends, also known as the shaft.

Edema excess fluid in the interstitial space.

Epiphysis the wide spongy end of a long bone.

Extension a movement that increases the angle between two bones, straightening a joint.

External fixation device a metal frame of telescoping rods with attached metal percutaneous pins inserted into or through a bone to maintain alignment.

External rotation turning an extremity away from the midline.

Exudate inflammatory response: migration of plasma fluid and circulating components to an injury site.

Flexion a movement that decreases a joint angle.

Hyperextension continuation of extension beyond the anatomic position, as in bending the neck backward.

Internal rotation turning an extremity toward the midline.

Intracapsular within the joint capsule (e.g., head and neck of the femur).

Metaphysis wide part of bone at end of shaft adjacent to the epiphysis.

Mobility state or quality of being mobile; facility of movement.

Musculoskeletal pertaining to the muscles and bones.

Osteoblasts immature cell, which on maturation plays a role in bone production.

Orthostatic concerning an erect or standing position.

Orthostatic hypotension drop in blood pressure upon standing.

Osteoclast cell that resorbs bone.

Paralysis loss of voluntary motion.

Paresthesia abnormal sensation of tingling or numbness.

Pearson attachment an attachment to Thomas splint that supports lower leg. Used in balanced suspension traction. Allows continuous traction in line with the femur by the use of cords and weights.

Periosteum connective tissue that covers the bone; contains proliferating cells.

Prosthesis artificial replacement for a body part.

Prosthetist specialist who provides preoperative training, prosthetic fabrication, prosthetic training, and follow-up assessments of fit, alignment, and appearance of prostheses.

Restorative promoting a return to health.

Russell's traction type of skin traction used to treat fracture of the shaft of the femur.

Shrinker A rigid or sock device suspended by a strap; worn to reduce edema and protect the stump of an amputated extremity.

Spica figure-eight bandage with one of the two loops larger than the other (used for ankle or stump).

Spiral bandage used to cover a cylindrical part.

Splint Noncircumferential immobilizer used for management of a variety of musculoskeletal conditions in which swelling is anticipated (sprain, acute fracture period).

Sprain injury caused by wrenching or twisting of a joint that results in tearing or stretching of the associated ligaments.

Strain injury caused by excessive force or stretching of muscles or tendons around the joint.

Stryker frame a special bed used to treat clients with spinal cord injuries.

Syncope a transient loss of consciousness due to inadequate blood flow to the brain.

Thomas splint used for balanced suspension along with skeletal traction for fracture of the femur.

Torque a rotary force.

Traction application of a mechanical pulling force applied to soft tissue.

RESTORING FUNCTION

Orthopedic nursing involves the prevention and correction of alterations in the musculoskeletal system. To help clients achieve and maintain optimal mobility, nurses use preventative, restorative, and rehabilitative methods. Preventative and restorative measures include the use of bandages, positioning, splints, casts, and traction.

The most common cause of injury to the musculoskeletal system is trauma, which results in soft tissue injuries, fractures, and dislocations. Injuries occurring from falls in the home account for many admissions to healthcare facilities.

Sprains and strains are common musculoskeletal injuries. The usual initial treatment is “RICE.” “R” stands for resting the injured part, “I” refers to application of ice, “C” stands for compression such as with a bandage, and “E” stands for elevating the part 6 in. above the heart. These early interventions help to minimize pain, muscle spasm, edema formation, and secondary injury (review Inflammatory Response in Chapter 24).

Bandages are used for applying pressure over an area, immobilizing a body part, preventing or reducing edema formation, correcting a deformity, and securing splints in place. Several types of material are used as bandages: woven cotton, elastic webbing, and gauze.

Fractures

A fracture is a break in the continuity of a bone that occurs when the bone is subjected to stress forces greater than ordinary. No two fractures are alike since forces occur from different directions and in different amounts and muscle pulls differ in response to injury.

Long bones, most commonly involved in fractures, are composed of the shaft, or diaphysis, and the flared end of the bone, termed the metaphysis. In children the metaphysis consists of two segments: the growth plate, and the epiphysis, which is directly adjacent to joints. The epiphysis fuses to the metaphysis when long bone growth has ceased. Mid-shaft injuries to long bones in childhood can result in excessive growth of the extremity, while intra-articular fractures involving the growth plate can cause retardation or arrest in the longitudinal growth of the limb.

Bone healing is similar to soft tissue healing except that bones heal by limited regeneration rather than by scar formation. When a bone is fractured, a specific repair process takes place, beginning with formation of a blood clot at the fracture site. Osteoblasts and fibroblasts then converge on the site and start laying down an organic matrix or “callus,” which bonds the fracture site and is similar to cartilage. Immobilization is an important factor during these critical phases. This callus is then mineralized by calcium deposition and thus converted into bone. In the final stage of the repair, osteoblasts and

osteoclasts remodel the bone so that it is suited to perform its intended function (Wolff’s Law).

When a fracture occurs, deformity is noted because bone fragments override due to spasm of surrounding muscles. In order to align (“reduce”) fracture components, muscle spasm must be overcome. This can be accomplished by closed reduction (without surgery) or by open reduction (with surgery). Open reduction (ORIF) incorporates a form of internal fixation of fracture fragments with screws, plates, nails, etc. External immobilization with a cast or splint may be used along with either method of fracture reduction. An external fixator apparatus is used to reduce and immobilize fractures often associated with soft tissue injury. The fixator stabilizes fractured parts by the use of percutaneous pins.

Fractures are classified in a variety of ways. One classification is by fracture configuration. Examples include a transverse fracture, which breaks directly across the bone; an oblique fracture, which breaks at an angle across the bone; and a comminuted

▲ Types of fractures.

Classification of Fractures

Greenstick

- A crack; the bending of a bone with incomplete fracture. Only affects one side of the periosteum.
- Common in children when bones are pliable.

Comminuted

- Bone broken into several fragments.
- Common in long bone ends (spongy bone).

Open (Compound)

- Bone is exposed to the external environment through a break in the skin.
- Can be associated with soft tissue injury.
- Infection is common complication.

Closed (Simple)

- Skin remains intact.
- Has reduced risk for infection.

Compression

- Frequently seen with vertebral fractures.
- Fractured bone has been compressed by other bones.

Impacted

- One part of fractured bone is driven into another.

Depressed

- Usually seen in skull or facial fractures.
- Bone or fragments of bone are driven inward.

Pathologic

- Break associated with a disease process (e.g., osteoporosis, cancer).

fracture, which results in more than two fragments of bone. Fractures can also be classified as open or closed. A closed fracture occurs with no break in the skin and is usually reduced without surgery, then immobilized with a cast. An open fracture is one in which the skin has been broken due to penetration of a bone fragment or external trauma. An open fracture requires additional treatment to prevent infection as a result of tissue exposure to the external environment. Surgical debridement and irrigation must be completed within hours of the fracture.

Casts and Splints

Casts are rigid cylinders applied to maintain the reduced (realigned) fracture in proper alignment and usually include the joint adjacent to the fracture. Casts are made from plaster of Paris or synthetic materials, such as polyester, polyurethane, fiberglass, or plastic. Synthetic casts dry faster, weigh less, and can get wet without fear of cracking or disintegration. Splints are not circumferential or as constrictive as casts and may be applied temporarily until swelling in the injured extremity has resolved. Frequent ongoing assessment of circulation, motion, and sensation in parts distal to the cast is essential for early recognition of neurovascular complications. Splitting or windowing the cast may be necessary to release pressure over a specific area, particularly a bony prominence.

Traction

Skin Traction Traction is the application of a mechanical pulling force. Skin traction can be applied to immobilize an injured site and to relieve pain. A rope, pulley, and weight system (5–10 lb) is attached to the device to provide pulling force to skin and soft tissues.

There are many types of skin traction. Buck's traction consists of a foam boot with Velcro straps applied to the lower leg to help immobilize and may relieve pain in clients with fractured hip before surgery. Superficial peroneal nerve compression can

result if the straps are too tight. Frequent release of the straps prevents this complication. Bryant's traction, another type of skin traction, is used primarily for children under 3 years of age who have sustained a fractured femur. The cervical halter and pelvic girdle are also used in skin traction.

Skin traction for acute muscle spasm (fracture of the femur) should be continuous, but skin traction for chronic problems such as muscle strain is *intermittent*, removed and reapplied as specified by the physician. Complications of skin traction relate to skin integrity and neurovascular impairment.

Skeletal Traction Skeletal traction is applied directly to bone to reduce a fracture or to maintain a surgically manipulated bone alignment. Significantly greater weight is used with this mode of traction. Pins or wires are inserted through the skin and soft tissue and into bone, then the desired weight is applied to maintain bone alignment. This type of traction is *continuous*; removing or lifting weights displaces fragments and can cause neurovascular damage. Balanced suspension uses splints and slings to support the extremity and weights applied for countertraction (e.g., Thomas splint with Pearson attachment). Suspended support allows greater mobility for the client with skeletal traction.

External Fixation Device External fixation devices have a rigid metal frame of telescoping rods with attached percutaneous pins or wires. They are used to align and immobilize complex fractures with extensive soft tissue injury or may be used to stabilize a closed fracture that will not remain in position otherwise. These self-contained devices provide traction without the use of ropes and weights and therefore allow client mobility. Similarly, a client with fracture or dislocation of cervical or high thoracic vertebrae can mobilize with a halo ring and vest.

Complications include neurovascular compromise, inadequate bone alignment, skin or soft tissue injury, pin tract infection, and osteomyelitis. Neurovascular function must be

assessed every 4 hr because clients requiring these devices usually have extensive soft tissue, nerve, and vessel damage. Extensive client teaching is necessary since these clients go home with the devices in place.

To be effective, any mode of traction must include *countertraction*. This might be provided by the client's body weight, by the pull of weights in the opposite direction, or by elevating the bed under the part in traction. The line of pull must be maintained, weights must hang freely, ropes must be intact and glide freely in the pulley, and knots must be secure. Weights and knots should hang far from the pulleys. The system should be free of any impingement such as linens. It is essential that the nurse have a clear understanding of the traction type and purpose, prescribed amount of weight, and client positioning.

Acute Compartment Syndrome

Since muscle groups are bound in a nonyielding fascia and injury causes swelling due to bleeding, edema, and the like, increased pressure within the “compartment” can compromise circulation to involved tissues. Similarly, external pressure (e.g., a cast) can compromise circulation and cause muscle ischemia and necrosis. As pressure increases within the site, venous return is compressed, leading to increased interstitial fluid (edema), then compression of arterioles and eventual ischemic myositis (necrosis) and contracture formation. The client can nevertheless have intact distal pulses.

To prevent this complication and ultimate loss of limb, immediate fasciotomy is necessary to release the unyielding fascial boundaries. The nurse must be vigilant to early signs and symptoms of acute compartment syndrome:

- Pain on *passive* stretching of the muscle (or distal digits)
- Pain out of proportion to the injury
- Pain that is unrelieved by pain medication
- Pain that increases with *elevation* of the part
- Pain when pressure is applied over the compartment
- Weak active movement of distal digits

Diminished or absent pulses, coolness, and pallor are late signs and unreliable indicators of acute compartment syndrome.

Joint Replacement (Arthroplasty)

Degenerative joint disease of the hip and knee is the number one cause of disability among the elderly. This chronic disease, sometimes called osteoarthritis, has an insidious onset that may progress to pain and stiffness, which impact the client's activities of daily living and role functioning. Elective total joint replacement (arthroplasty) has become increasingly popular because it restores mobility and relieves pain for clients who cannot be managed by medication or physical therapy.

Total hip arthroplasty includes replacement of both the femoral and acetabular components of the hip joint. The components are usually implanted with cement. Cementless components are also available and are preferred for younger clients who may require implant revision over time. These are textured prostheses that “cement” themselves by bony ingrowth.

After total hip arthroplasty or hemiarthroplasty (femoral prosthesis only), the client must adhere to precautions to prevent prosthesis dislocation and infection in remote sites that may spread by blood to the implanted component's site. Additionally, clients may be on long-term anticoagulant therapy and must understand the need for follow-up laboratory appointments.

Discharge planning begins before admission for elective joint arthroplasty. The client receives education about the perioperative process and “clinical path” expectations, including essentials of self-care rehabilitation. The home is typically equipped with adaptive and safety features before the planned surgery. Prepared clients experience less anxiety, fewer postoperative complications, shorter length of hospital stay, and reduced incidence of hospital readmissions.

Hip Fracture

Hip surgery for the fracture client presents a different challenge. The fracture client is not undergoing *elective* surgery, has had no preoperative preparation, and is frequently ill prepared for hospitalization. The emergent hip fracture client may not have the physical health enjoyed by the elective client. The trauma client is more apt to experience serious adverse consequences of emergent hospitalization and surgery, including delirium, and requires vigilant monitoring. Care and teaching for the client with prosthetic replacement for intracapsular hip fracture is identical to care and teaching for the client with total hip replacement.

Hip fracture involving the head or neck of the femur is classified as *intracapsular* (within the joint capsule). Since intracapsular bone lacks periosteum, fracture healing is limited. A hemiarthroplasty is performed whereby the head and neck of the femur are surgically removed and replaced with a *prosthesis*. The client is weight bearing with an assistive device soon after surgery. Because the joint capsule has been surgically disrupted, the hip prosthesis is at risk for dislocation until healing is complete. Specific rehabilitative adherence promotes healing and prevents dislocation of the prosthesis. If the fracture is *extracapsular* (involving the intertrochanteric region), internal fixation with nail, plate, and screws is performed. There is no disruption of the joint capsule, no prosthetic implant, and therefore no risk of femoral head dislocation, and dislocation precautions are not necessary. On the other hand, a repaired fracture site must heal, so total weight bearing is usually delayed.

Amputation

Amputation of a limb may be due to trauma, in which case the psychological ramifications can be very complex, or it can be a planned reconstructive procedure and a welcome source of relief for the client who has suffered painful vascular insufficiency and tissue necrosis (80% of cases). Regardless, the client who has lost a limb must regain psychological equilibrium and learn new skills. A supportive nurse–client relationship can assist the client to cope with grieving and body image reintegration. A rehabilitation team approach addresses goals to reduce stump edema, promote healing, prevent contractures, increase strength, and facilitate adjustment to loss by maximizing fractional independence.

It is normal for amputees to experience *phantom sensation*, a feeling that the amputated part is still there. This occurs early postamputation and goes away over time. Clients should be informed of this before amputation, if possible. *Phantom pain*, however, appears later (after 2–3 months) and is more likely to occur in above-the-knee amputees. The client experiences knife-like pain, squeezing, or burning sensations triggered by a number of stimuli (urination, defecation, cigarette smoking, and others). This complication is thought to be due to signals generated by intact nerves previously associated with the amputated part and relayed to the cerebral cortex as originating in the phantom limb, or there may be a response by the central nervous system to a stimulus that seems to come from an intact body or a response to stored pain sensations from the previously intact limb. Analgesics are effective in managing postoperative stump pain, but have no effect on phantom pain. Unfortunately,

there is no treatment that is consistently effective. Interventions to reduce phantom pain include:

- Intense preoperative pain management
- Use of opioids, ketamine
- Use of anticonvulsants, antidepressants, TENS
- Stump desensitization with massage and transdermal anesthetics
- Early prosthetic use

Orthopedic Assessment

All orthopedic clients must be vigilantly monitored for skin and neurovascular status (circulation, motion, and sensation) of the affected part. Assessments should be conducted before, during, and frequently after application of any immobilizing modality. The contralateral extremity and documented baseline findings should be used for comparison.

TABLE 27-1 Neurologic Assessment

	Motion	Sensation
Upper Extremity		
Radial nerve	Hyperextends wrist Hyperextends thumb and four fingers	Web space between thumb and index finger
Ulnar nerve	Abducts (spreads) fingers	Lateral aspect of hand and distal end of little finger
Median nerve	Flexes wrist Opposes thumb and little finger	Distal end of index finger
Lower Extremity		
Peroneal nerve	Dorsiflexes ankle Flexes toes	Web space between great and second toe
Tibial nerve	Plantar flexes ankle and toes	Medial and lateral surfaces on sole of foot

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to include in a client care plan when the components are related to a client who requires special orthopedic procedures.

NURSING DIAGNOSIS	RELATED FACTORS
Disturbed Body Image	Trauma or injury, illness, chronic pain, situational crisis, treatments
Acute Confusion	Delirium
Ineffective Health Maintenance	Motor impairment
Injury, Risk for	Altered mobility, risk for falls or trauma, physical environmental factors, impaired balance, gait difficulties
Impaired Physical Mobility	Loss of integrity of bone structures, musculoskeletal impairment, neuromuscular impairment, pain, prescribed movement restrictions
Acute Pain	Physical injury
Chronic Pain	Arthritis, neurologic injury
Disturbed Sensory Perception	Amputation, nerve impingement
Impaired Tissue Integrity	Altered circulation, impaired physical mobility, mechanical factors
Ineffective Peripheral Tissue Perfusion	Interruption of arterial flow, interruption of venous flow, mechanical reduction of venous or arterial blood flow

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. Remember to wash your hands or use antibacterial gel before and after each and every client contact.

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Chapter 27

UNIT 1

Application of Immobilizing Devices

Nursing Process Data

ASSESSMENT Data Base

- Recognize need for site immobilization.
- Determine type of immobilization required.
- Select appropriate immobilizing equipment.
- Assess status of surrounding tissue.
- Assess affected extremity for circulation, motion, and sensation (CMS) before and after applying modality.

PLANNING Objectives

- To immobilize an extremity or body part
- To maintain functional alignment
- To limit harmful movement
- To reduce or prevent pain
- To prevent further soft tissue injury and complications
- To preserve neurovascular function
- To promote healing

IMPLEMENTATION Procedures

- Applying a Sling1011
- Applying a Spiral Bandage1011
- Applying a Figure-Eight Bandage1012
- Applying a Splint1013
- Applying a Cervical Collar1014
- Applying a Jewett–Taylor Back Brace1014

EVALUATION Expected Outcomes

- Treated part is effectively immobilized.
- Pain is reduced.
- Edema and bleeding are controlled.
- Further injury is prevented.

- **Critical Thinking Application** 1015
 - Expected Outcomes1015
 - Unexpected Outcomes1015
 - Alternative Actions1015

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
and Skill Checklists

Applying a Sling

Equipment

- Commercial sling or
- Triangular cloth or bandage
- Safety pins

Clinical Alert

Never move an extremity yourself to see if it is fractured. Ask if the client is able to move the limb instead. Always splint the extremity as found.

Preparation

1. Check physician's orders for a sling.
2. Do not remove clothing or shoes.
3. Assess injured extremity circulation, motion, and sensation (CMS) before sling application.
4. Explain procedure and purpose of immobilization.
5. Remove any circumferential jewelry (ring, bracelet).
6. Have client sit or stand with forearm across chest.

Procedure

1. Place one end of triangular cloth against the chest on the affected side and over the shoulder of the unaffected arm.
2. Place the apex (point) of the triangle toward the elbow of the affected extremity.

▲ Bring strap over shoulder and pull strap through metal hoops on sling.

▲ Hand should be supported at a level slightly higher than the elbow to prevent edema.

3. Bring the opposite end of the triangle over the affected arm and over the affected shoulder.
4. Tie the sling at the side of the neck.
5. Fold the apex of the triangle over the elbow in the front, and secure with a safety pin or twist end and tie a square knot.
6. Assess client for comfort and for support of the affected arm.
7. Assess for neck pressure and peripheral CMS after 30 minutes and then every 2 to 4 hr.

NOTE: If using commercial sling, check directions on package for proper application.

Clinical Alert

If greater immobilization is indicated (e.g., for shoulder dislocation or fracture), a swathe can be applied over the sling, circling and securing the upper arm to the thorax.

8. Check that hand is supported at a level higher than elbow to prevent dependent edema.
9. Teach client to support the arm higher than heart level and to perform external rotation shoulder exercises to prevent shoulder joint stiffness.

Applying a Spiral Bandage

Equipment

- Elastic or gauze roller bandages (width and number required to treat site)
- Safety pins or tape
- Supplies for wound care if indicated

Preparation

1. Check physician's orders, identify client, and explain procedure and purpose of immobilization.
2. Assess CMS of extremity before bandage application.
3. Remove any circumferential jewelry (ring, bracelet).
4. Have client sit or lie with part elevated.

Procedure

1. Remove existing elastic bandage or use bandage scissors to remove previously applied gauze bandage.
 - ▶ **Rationale:** To prevent further injury and allow direct observation of site and wound care if indicated.
2. Remove dressing and redress wound if indicated (see Chapter 25).
3. Place part to be bandaged in an elevated position.
 - ▶ **Rationale:** This promotes venous return and facilitates bandage compression to control edema and bleeding.
4. If area is functional or to be exercised, apply bandage with muscle in full contraction. ▶ **Rationale:** This prevents bandage constriction with future muscle activity.
5. Hold gauze or elastic roll with loose end of outer part of bandage facing client's skin several inches below the site of injury.
6. Unroll bandage twice around extremity to anchor bandage.
7. Continue wrapping extremity upward, using a moderate amount of tension to stretch and apply bandage uniformly. ▶ **Rationale:** Unequal pressure can adversely affect circulation.
8. Wrap the extremity *proximally* with spiral or angled turns. ▶ **Rationale:** Circular turns create a tourniquet effect. Proximal wrapping promotes venous return.
9. Make bandage turns that overlap by at least one half the previous wrap to prevent bandage separation. ▶ **Rationale:** Bandage turn separation tends to pinch the skin.

▲ Spiral bandage may be used to secure a wound dressing.

10. Finish wrap with a couple of wraps directly overlying each other.
11. Secure the bandage by tying or using tape or safety pin.
12. Observe that bandage is snug but not tight, is free of wrinkles, and is not occluding distal circulation.
13. Assess distal digits for CMS in 30 minutes and every 2–4 hr initially.
14. Maintain elevation of involved extremity and encourage active motion of digits. ▶ **Rationale:** This helps reduce edema and maintain function.
15. Rewrap bandage at least every 8 hr.

Cryotherapy Limits Injury

Application of ice (cryotherapy) causes vasoconstriction, reduces capillary permeability, and decreases tissue metabolism. The decreased metabolism results in decreased secondary metabolic injury and thus less tissue debris (free tissue protein). Cryotherapy used as soon as possible limits the extent of the injury, but once secondary metabolic injury has occurred, cryotherapy has no value in removing edema that has formed. The only way to relieve the edema is by removing excess free protein in the tissue by way of the lymphatic system. This generally requires intermittent compression as occurs with active exercise. (see Chapter 24, Heat and Cold Therapies).

EVIDENCE-BASED PRACTICE**Rest vs. Early Mobilization**

Rest seems to be overused as a treatment. Forty-nine trials of immobilization for soft tissue injuries and fractures of both upper and lower extremities were reviewed (3,366 clients). All the studies reported either no difference between rest and early mobilization or found in favor of early mobilization. Benefits of earlier mobilization included return to work; decreased pain, swelling, and stiffness; and more preserved range of joint motion. Early mobilization caused no increased complications, deformity, or residual symptoms.

Source: Nash, C., Mickan, S. M., Del Mar, C. B., & Glasziou, P. P. (2004). Resting injured limbs delays recovery: A systematic review. *The Journal of Family Practice*, 53(9), 706–712.

Applying a Figure-Eight Bandage**Equipment**

- Roller bandage
- Safety pin or tape

Preparation

1. Identify client and explain procedure and rationale.
2. Provide privacy.
3. Position ankle in neutral alignment, neither overflexed nor overextended.

Procedure

1. Gather necessary bandages. The number and width of the bandage depends on the extent and area of the extremity to be bandaged.
2. Hold roll with outer part next to client's skin over instep.
3. Anchor bandage by making an angled turn around instep.
4. Make a circular turn around heel and return to starting point.

5. Make a spiral turn down over the ankle and around the foot.
6. Continue to make alternate turns around the ankle and foot. Overlap the preceding turn by at least two-thirds over the preceding layer.
7. Wrap the entire area below and above the involved joint. ► **Rationale:** This immobilizes the affected area.

▲ Make an angled turn around instep.

8. Assess extremity (exposed digits) for CMS and evenness of pressure as well as comfort of client.
9. Assess extremity after 20 minutes and then every 2 to 4 hr, and rewrap every 8 hr.
10. Maintain elevation of extremity.

NOTE: Edema can result if the heel is not enclosed within bandage.

▲ A figure-eight turn is used to support and limit joint movement.

Applying a Splint

Equipment

Splint materials: pieces of wood or pillows, magazines, blankets

Padding materials: pieces of cloth or towel

Wrapping materials: strips of cloth, rope, tape, elastic bandage

Preparation

1. Assess involved extremity for deformity or soft tissue injury.
2. Do not remove clothing or shoes (except with scissors).
 - **Rationale:** To prevent excessive manipulation of the injured part.
3. Remove any jewelry from extremity to prevent circulatory compromise with swelling.
4. Assess neurovascular status of distal digits.
5. Explain need for and purpose of splint to client.

Procedure

1. Gather needed supplies.
2. Control bleeding by applying direct pressure and by using pressure dressings; apply clean covering to any wound.
3. Explain the rationale for the intervention to client.
4. Move injured extremity as little as possible and splint as it lies.

Clinical Alert

Never straighten an injured extremity or push bone or tissue back into place. Splint a deformed extremity in its deformed shape using a soft support such as a pillow.

5. Pad joints, bony prominences, and between digits.
 - **Rationale:** This prevents skin damage. Also make sure that the padding does not affect the client's circulation (e.g., don't put padding in axilla).
6. If splint material is not available, use the client's body for support.
 - a. Splint the legs together.
 - b. Splint an arm to the torso.
 - c. Splint toes or fingers together.
7. Use a spiral (not circular) technique to wrap splint.
8. Strap the splint and extremity together securely so that the extremity is immobile. Try to include the proximal and distal points in the splint.
9. Check the client's distal circulation by assessing pulse, capillary refill, color, and temperature.
10. Elevate part to reduce edema formation.
11. Arrange to transport client to medical facility as soon as possible.
12. Report specifics to transport personnel.

Applying a Cervical Collar

Equipment

- Sizing chart
- Two collars of appropriate size (a spare for alternate use), each with an additional removable pad
- Assistant, if client has known or suspected cervical injury

Preparation

1. Explain procedure to the client.
2. Place client flat supine.
3. Select appropriate size collar based on length of neck from client's mandible to the clavicle (the longer the neck, the larger the collar).

NOTE: Some collars allow for anterior and posterior vertical height adjustment.

4. Select appropriate size collar.

Procedure

1. Perform hand hygiene.
2. Obtain assistance if client has known or suspected cervical injury. One maintains neck alignment while the collar is applied.
3. Follow manufacturer's instructions to apply collar. Save instructions and container for later use.
4. Place back half of collar on client's neck, centering with the spine, arrow pointing up.
5. Center front half of collar on front of client's neck, using a scooping motion upward from the chest, so that chin fits into the indentation. ► **Rationale:** This ensures neutral alignment.
6. Lap back half over front half of collar.

7. Adjust velcro straps, to ensure a secure fit. ► **Rationale:** Collar should be snug enough to prevent movement, but not interfere with client's ability to breathe, swallow, or speak.
8. Inspect skin under collar regularly, and cleanse with soap and water.
9. Assess neurovascular status of upper and lower extremities every 4–8 hr, if indicated.
10. Clean collar and removable pads as needed with soap and water and allow to dry naturally; do not use a hair dryer.
11. Maintain collar use 24 hr/day or as ordered, using alternate collar when necessary.
12. Caution the ambulatory client that without neck flexion, visibility of stairs or objects on the floor is limited.

▲ Ensure side straps of collar are properly adjusted for a secure fit.

Applying a Jewett–Taylor Back Brace

Equipment

- Front and back brace with Velcro straps
- T-shirt

Preparation

1. Check physician's order and determine rationale for brace application.
2. Determine that client's brace has been fitted by an orthotist (brace fitter).
3. Identify client, explain procedure, or supervise client's application and reinforce previous teaching.
4. Provide privacy.
5. Change wound dressing, if indicated, before applying brace.

▲ Jewett-Taylor brace is applied to client while lying supine. This photo is for demonstration.

Procedure

1. Perform hand hygiene.
2. Put T-shirt on client. ▶ **Rationale:** This protects the skin from the brace rubbing on bare skin.
3. Place bed in a flat position. Keep side rail in UP position on side of bed opposite from you.
4. Log-roll or ask client to roll to side away from you.
 - ▶ **Rationale:** This position prevents torque on the spine.
5. Position brace on back so that struts fit on either side of spine and it fits the natural contour of the back.
 - ▶ **Rationale:** Struts provide an open space along the spine so pressure is not exerted on a surgical site or on vertebrae.
6. Log-roll the client back onto brace to a supine position.
7. Place front section of brace over the iliac crest and position iliac wings (made of plastic material). Adjust triangular sternum piece; metal struts will fall into place.
8. Secure brace with Velcro straps.
9. Check under brace for pressure areas. If pressure areas are present, report to orthotist.
10. Provide client with adaptive aids (i.e., reacher).
 - ▶ **Rationale:** Client cannot bend forward while wearing brace.

DOCUMENTATION for Applying Immobilizing Modalities

- Time of application
- Site involved
- Skin integrity or wound status
- Type of immobilizing modality applied
- Circulatory and neurologic status of distal parts before and after modality application
- Site positioning or alignment
- Subjective statements of client

CRITICAL THINKING Application**Expected Outcomes**

- Treated part is effectively immobilized.
- Pain is reduced.

Unexpected Outcomes

Bandage securing wound dressing continues to fall off.

Client with back brace refuses to eat.

Client with brace expresses feelings of “being trapped.”

Elevation of extremity and passive stretching of digits increase pain, pain medications are ineffective, and pressure applied to injured site produces severe pain.

Client experiences pain while wearing back brace.

- Edema and bleeding are controlled.
- Further injury is prevented.

Alternative Actions

- Avoid tape if skin is fragile or area has impaired circulation.
- Use expanding “turkey skin” wrap to secure dressing.
- Consult wound care specialist for alternative suggestions.
- Loosen brace before and for a while after meals.
- Encourage small, frequent meals.
- Reduce intake of gas-forming foods (cabbage, beans, corn).
- Suggest intake of liquid nutritional supplement.
- Allow client to voice concerns and explore options for self-control, such as access to telephone, call bell.
- Suspect acute compartment syndrome and notify physician immediately. Fasciotomy may be indicated if tissue swelling compromises circulation within a muscle compartment.
- Loosen external immobilizing device.
- Maintain extremity in *dependent* position.
- Encourage the client to not sit for longer than 30 minutes after back surgery. This increases pain due to spinal alignment in this position.

Distal edema is noted in bandaged extremity and client is unable to move digits and states sensation is altered.

- Remove bandage and check distal circulation, motion, and sensation.
- Keep extremity elevated.
- Rewrap bandage with extremity in elevated position.
- If edema persists, notify physician for possible addition of cold therapy, anti-inflammatory medication, or further evaluation.

Toes become edematous after ankle bandaging.

- Do *not* apply ice to extremity since this reduces blood flow to area.
- Elevate extremity and encourage active exercise of toes to promote venous return.
- If area feels warm to touch, consider application of ice to help reduce inflammation.
- Loosen bandage.

Client with neck brace expresses fear of falling.

- Suggest removal of scatter rugs, other obstacles that might cause tripping.
 - Have client view environment from a distance before advancing into it.
 - Suggest use of a “blind” cane to scan or tap the area in front of client to warn of potential obstacles or steps.
-

Nursing Process Data

ASSESSMENT Data Base

- Identify type of cast applied and rationale for application.
- Note condition for which the cast was applied.
- Observe condition of the cast.
- Assess neurovascular status of involved extremity.
- Assess client's understanding of and adherence to care instructions.

PLANNING Objectives

- To immobilize a fracture site
- To maintain normal sensation, movement, and circulation in a casted extremity
- To improve muscle tone and joint flexibility
- To promote bone healing
- To facilitate self-care after cast application and removal

IMPLEMENTATION Procedures

- Caring for a Wet Cast 1018
- Assessing a Casted Extremity 1019
- Instructing Client in Self-Care 1020

EVALUATION Expected Outcomes

- Cast integrity is maintained to provide adequate site immobilization.
- Client experiences minimal swelling.
- Neurovascular complications do not occur.

- **Critical Thinking Application** 1021
- Expected Outcomes 1021
- Unexpected Outcomes 1021
- Alternative Actions 1021

and Skill Checklists

TABLE 27-2 Comparison of Cast Types

	Plaster	Synthetic
Material	Plaster of Paris, comprised of powdered calcium sulfate crystals impregnated into the bandages	Polyester and cotton, fiberglass, or plastic. Polyester and cotton are impregnated with water-activated polyurethane resin.
Drying time	24–48 hr No weight bearing until dry, 48–72 hr	7–15 minutes for setting 60 minutes for weight bearing
Advantages	Less costly More effective for immobilizing fracture site Smooth surface Doesn't require expensive equipment for application	Less likely to indent into skin Lighter in weight Less restrictive Doesn't crumble Nonabsorbent

Caring for a Wet Cast

Equipment

- Pillows for support
- Pen to mark drainage

Preparation

- Note physician's orders for any client-specific instructions about positioning or cast handling.
- Identify client and explain all procedures.
- Recruit assistant(s) to help turn client.
- Consider client's need for an analgesic.

Procedure

- Explain that the cast feels warm as plaster dries, but urge client to report undue warmth or a burning sensation.
 - **Rationale:** Cast burns can cause serious tissue injury.
- Until the cast is dry, use *only* the palms of your hands to handle cast when turning and positioning.

▲ Position extremity above heart level to reduce edema formation. Check cast for tightness. The nurse should be able to insert one or two fingers between cast and skin.

► **Rationale:** Fingers can indent cast and create pressure areas on underlying tissue.

- Avoid handling over joints where nerves and blood vessels are superficial.
- Support cast with pillows, with extremity elevated above heart level. ► **Rationale:** This promotes venous return and reduces edema formation.
- Maintain contours built into the cast; support leg so that heel is free of pressure. ► **Rationale:** To prevent flattening.
- Keep wet cast uncovered and turn client to both sides, prone, and supine to expose all surfaces, allowing cast to dry by natural evaporation from the inside out.

NOTE: The wet plaster of Paris cast is dry when musty odor is gone, the cast is white and shiny, and it sounds resonant when tapped.

- Do not try to hasten drying by using artificial measures such as a hair dryer. ► **Rationale:** Outer layer may dry before inner aspect, resulting in cast weakening.

▲ Plaster casts are still being used, especially in disaster situations. Position casted extremity above level of heart to reduce edema formation.

8. If ice pack is ordered to reduce edema, place it alongside of cast, not on cast. ► **Rationale:** Placing ice pack on the cast can cause flattening.
9. If cast edges are rough or crumbly, pull inner stockinette out and over the edge and secure with tape.

Clinical Alert

Injured tissues swell, but encircling therapies do not expand. For any encircling modality, assess distal digits for circulation, motion, and sensation. Assessment is ongoing and continues after discharge.

Assessing a Casted Extremity

Equipment

Pen to mark drainage on cast

Procedure

1. Explain rationale for the procedure to client.
2. Encourage client to notify you of any change in sensation, mobility, or color/temperature in the casted extremity.
 - a. Circulation
 - Report if digits are swollen despite elevation and active exercise.
 - Report if digits are pale, blue, or cold to touch.
 - Report delayed (>2 seconds) capillary refill (pinch finger to blanch and determine length of time required for color to return)
 - b. Motion
 - *Immediately* report pain on passive movement of digits.
 - Report inability to actively move digits (see Table 27-1).
 - Compare strength of action with uninvolved extremity.
 - c. Sensation
 - *Immediately* report increasing or unrelieved pain, pain with passive motion of digits, or pain that increases when the extremity is elevated.
 - Report numbness or paresthesia (pins-and-needles feeling).
 - Assess involved nerve sites for sensation (see Table 27-1).

3. Emphasize that a fine margin exists between reversible and irreversible damage to neurovascular structures.

Clinical Alert

Do not use abductor bars (incorporated into cast) for moving the client. Move the client as a unit instead.

Clinical Alert

When casting material inhibits palpation of peripheral pulses, assess capillary refill, assess for edema, comfort level, and other parameters of CMS as an indication of neurovascular status.

4. Assess for capillary refill by applying pressure to one of the client's digits. After you stop the pressure, observe the area to see how rapidly the color returns.
5. Ask the client to move the fingers or toes distal to the cast. The client should be able to move them without difficulty.
6. Check for any drainage on cast. Note color and size of drainage and mark cast with time.

Clinical Alert

Casted extremity should be assessed every half hour for 4 hr, then every 4 hr.

▲ Check fingers or toes for color, temperature, capillary refill, sensation, and motion.

▲ Observe casted extremity frequently to monitor and mark drainage. Assess dependent area for drainage as well.

7. Report any unusual odor or increase in drainage.
 - ▶ **Rationale:** Active bleeding should cease. Stain should turn brown after 24 hr.
8. Check for redness around casted area.
9. Cover rough edges of cast with stockinette or smooth tape “petals.” ▶ **Rationale:** Prevent skin irritation, which can lead to skin breakdown.
10. Massage area under cast, but avoid lotions and powders.
11. Remind client to not stick objects inside the cast to scratch skin. ▶ **Rationale:** Skin breakdown can occur, leading to infection.
12. Suggest use of an aseptic syringe or hair dryer (cool setting) to blow under cast to relieve itching or to apply pressure over the area.

Clinical Alert

If the client has had open reduction, wound drainage will be absorbed and spread rapidly or seep down to back of cast. The visible drainage does not necessarily indicate the amount of actual drainage.

Inspect all cast surfaces and mark drainage regularly if it is increasing. Bleeding should not persist after 24 hr.

Clinical Alert

Diminished or absent pulses, coolness, and pallor are late signs and unreliable indicators of acute compartment syndrome. Always assess active extension, flexion, adduction, and abduction of the fingers, flexion and extension of the toes, and inversion and dorsiflexion of the foot. Pain on passive stretching of the muscle or distal digits is an *early* indicator of circulatory compromise.

Instructing Client in Self-Care

Equipment

- Instructions pamphlet
- Relevant telephone numbers

Preparation

1. Review client’s chart for type of reduction performed (open or closed).
2. Identify client and explain importance of self-care to prevent complications.
3. Provide written instructions that reinforce teaching.
4. Provide telephone number of patient care coordinator if relevant for follow-up concerns.

Procedure

1. Demonstrate and teach importance of regular neurovascular checks, comparing with contralateral extremity. (See Assessing a Casted Extremity.)
2. Teach client to keep casted extremity elevated and to actively exercise digits. ▶ **Rationale:** This reduces edema formation, pain, and stiffness; stimulates lymph flow; and reduces risk of thrombus formation.
3. Report any unusual odor, new drainage, or fever.
 - ▶ **Rationale:** These are signs of possible infection, especially if client has had open reduction or an object has been placed or fallen into the cast.
4. Remind client to not stick objects into the cast to scratch the skin. Encourage client to blow cool air (hair dryer on cool setting or Asepto bulb syringe) or to apply pressure over the area to relieve itching. ▶ **Rationale:** Scratching the area abrades the skin and can cause infection.
5. Teach cast protection.

- a. Remove stains with nonabrasive powder cleanser and damp cloth.
- b. Do not shellac or varnish to waterproof the cast. It must “breathe.”
- c. Use plastic covering (garbage bag) for showering. Do not cover for prolonged periods as this will cause condensation and weaken the cast.
- d. Report any cracking or softening of cast and redness of skin at cast edges.
- e. Protect cast from urine or stool by covering edge with plastic wrap as odor can’t be removed.
- f. Sleep with casted lower extremity next to wall, if possible. ▶ **Rationale:** If the casted extremity falls off the bed, the client will go with it.
6. Cast removal.
 - a. Inform client that cast saw blade is safe. It does not cut through material, but vibrates.

▲ Cast is split with a vibrating blade. Underlying padding is cut with bandage scissors.

- b. Prepare client that muscle will have atrophied with disuse, joints will be stiff, and bone is vulnerable to refracture.
- c. Teach client to continue to protect, support, and elevate the extremity after cast removal.
- d. Teach client that skin will be caked with adherent exudate and not to forcibly remove this. Soften

exudate with olive oil or use full-strength cold water wash (e.g., Woolite, Delicare), leave on 20 minutes, then rinse in warm water. ► **Rationale:** Aggressive removal of exudate can cause bleeding. Enzymes in special cleansers will loosen dead cells and fatty or crusty lesions without injuring underlying cells.

DOCUMENTATION for Cast Care

- Type of cast applied
- Positioning of cast
- Client's complaints and nursing responses
- Color, warmth, movement, and sensation in casted extremity
- Presence, location, and amount of drainage from wound
- Client's acceptance of the cast

Legal Considerations

Collins v. Westlake Community Hospital (1974)

In this case a client treated for a fractured leg developed ischemia within 3 days, necessitating amputation. The physician had written an order for the nurses to monitor peripheral CMS, and although the standard of nursing care required frequent monitoring of the client's circulation, the nurses' notes failed to show that the client's circulation had been monitored at any time during

the crucial 7-hr period when the client's condition became critical. Nursing negligence was upheld by the court.

Standard nursing practice dictates that clients with casts be monitored frequently to detect and prevent complications. Additionally, clients discharged post-cast application must receive discharge instructions including self-care, cast care, and adverse signs/symptoms to be reported.

NOTE: Monitoring the client's condition and reporting changes are primary nursing responsibilities. Nurses who fail to record their observations run the risk of being unable to convince a jury that such observations actually were made. Failure to report the client's worsening condition is also another source of litigation.

Source: Bernzweig, E. (1996). *The Nurse's Liability for Malpractice* (6th ed.). St. Louis: Mosby.

CRITICAL THINKING Application

Expected Outcomes

- Cast integrity is maintained to provide adequate site immobilization.
- Client experiences minimal swelling.
- Neurovascular complications do not occur.

Unexpected Outcomes

Cast cracks from improper drying or stress.

Alternative Actions

- Notify physician immediately.
- Reassure client.
- Do not reposition client until physician assesses.

Synthetic cast has rough edges.

- Smooth edges by filing with nail file if necessary.
- Make sure furniture and clothing are protected from scratches and snags by covering cast with stockinette.

Cast edges begin to crumble.

- "Petal" edges of cast with 1- to 2-in. strips of tape.
- Place half of tape inside cast, pull tape over cast, and anchor on outside of cast.
- Continue to petal cast until all edges are covered.

Client develops itching and burning under synthetic cast after swimming.

- Immersion should be avoided.
- Flush skin under cast with plain water if it has been exposed to chlorine.
- Dry skin under cast thoroughly with hair dryer on LOW. This may require several hours!

Fingers swell after application of arm cast.

- Assess that there is room for two fingers to be slipped under cast.
- Apply ice along side of cast and maintain elevation after cast application.
- Maintain arm positioning with hand higher than elbow.
- Encourage client to exercise fingers to help reduce edema.
- Monitor neurovascular status frequently.

Client develops pain not relieved by analgesics, pain that worsens with extremity elevation and passive stretching of digits.

- Maintain extremity in dependent position.
 - Notify orthopedic technician immediately: windowing or bivalving cast may be indicated.
 - Suspect acute compartment syndrome and notify physician immediately to obtain measurement of compartment pressure.
 - Fasciotomy may be indicated if tissue swelling or external device compromises circulation within a muscle compartment.
-

Nursing Process Data

ASSESSMENT Data Base

- Determine type and purpose of traction used.
- Note the amount of weight ordered.
- Note any conditions requiring special treatment (i.e., continuous or intermittent traction).
- Assess circulation, motion, and sensation of affected extremity.
- Assess pin site for drainage and signs of infection.
- Assess neurovascular status of clients with external fixation devices.

PLANNING Objectives

- To relieve muscle spasm
- To maintain alignment of fracture site
- To prevent unnecessary injury to soft tissue
- To prevent neurovascular complications
- To use for temporary management of fractures in adults
- To maintain pin site free of infection

IMPLEMENTATION Procedures

- Maintaining Skin Traction 1024
- Maintaining Skeletal Traction 1025
- Maintaining an External Fixator Device 1027
- Maintaining Halo Traction 1028

EVALUATION Expected Outcomes

- Extremity is maintained in correct alignment.
- Neurovascular status is within normal limits.
- Pin site remains free of infection.

- Critical Thinking Application** 1029
 - Expected Outcomes 1029
 - Unexpected Outcomes 1029
 - Alternative Actions 1029

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX[®]-style practice questions
and Skill Checklists

Maintaining Skin Traction

Preparation

1. Determine whether client is preoperative. If so, do not manipulate the extremity.
2. Determine whether client has condition (diabetes, peripheral vascular disease) that predisposes to skin damage with traction.
3. Determine whether traction is continuous or intermittent.
4. Recruit an assistant to apply manual traction when removing and replacing traction.
5. Explain purpose of traction to client and family.

Procedure

1. Examine type of traction used that attaches weights to the extremity.
 - a. Material should be held firmly in place.
 - b. Material should fit comfortably, neither too loose nor too tight.
 - c. Client should be in functional alignment.
2. Examine all bony prominences of the involved extremity for abrasions or pressure areas.
 - a. Traction should be released at least every 8 hr for skin inspection.
 - b. Have an assistant apply manual traction when discontinuing for assessment.
 - c. Check for redness, which, if present, indicates excessive pressure on site.
3. Examine extremity distal to the traction.
 - a. Note any presence of edema.
 - b. Palpate peripheral pulses.

Clinical Alert

Unless ordered otherwise, the client with Buck's extension should have the knee gatch of the bed elevated 20°–30° to flex the hip in a neutral position.

▲ Remove straps on Buck's traction every 8 hr to maintain function and allow inspection.

EVIDENCE-BASED PRACTICE

Traction vs. No Traction for Hip Fracture

Trials of traction versus no traction for patients with hip fracture have found no significant differences in pain, operative blood loss, ease of fracture reduction, or length of hospitalization. It seems that providing adequate intravenous analgesia and placing the extremity in a comfortable position are the best measures for reducing preoperative pain.

Source: Gregory W. Hendy, MD, FACEP (2005). 7 myths of orthopedic emergencies. *Emergency Medicine* 7: 38–43.

Clinical Alert

Do not apply Buck's traction over or under a calf compression device. Foot pumps (only around the foot) are acceptable for deep-vein thrombosis prophylaxis.

- c. Check temperature and color contralaterally to see if both extremities are normal.
 - d. Check capillary refill time.
4. Assess for possible neurologic impediment from traction slings encroaching on popliteal space, peroneal nerve, or axilla. ► **Rationale:** Numbness or tingling, if present, indicates possible neurologic involvement.

Principles of Traction Maintenance

- Maintain traction pull by ensuring weights are hanging freely, off the floor or bed frame.
- Ensure knots are secure in all ropes.
- Maintain ropes in pulley system and ensure rope moves freely through system and knots do not interfere with movement.
- Maintain prescribed amount of traction (5–10 lb for adult clients).
- Maintain countertraction, with client aligned in center of bed.
- Maintain traction, either continuous or intermittent, according to physician's orders.

▲ Maintain traction by ensuring that weights hang freely.

▲ Bryant's traction is used to reduce fractured femur or treat hip dislocation in a small child.

▲ Ensure client is positioned correctly in bed.

5. Examine traction system to see that the pull aligns with the long axis of the fractured bone.
6. Check the traction mechanism.
 - a. Weights should hang freely, off the floor and bed.
 - b. Weights are 5–10 lb for adult clients.

- c. Knots should be secure in all ropes.
- d. Ropes should move freely through pulleys.
- e. Pulleys should not be constrained by knots.
7. Position correctly in bed: The client should be positioned in the center of the bed. Affected leg or arm should be aligned with trunk of body. ► **Rationale:** Misalignment is the leading cause of pain for traction clients. The client should not migrate or be pulled down to the end of the bed because this negates the traction.

TABLE 27-3 Skin Traction

Type	Purpose	Bed Position
Buck's extension	Short-term immobilization of a hip fracture before surgical intervention	Head elevated 10°–20° for ADLs, knee flexed 20°–30°
Cervical	Degenerative or arthritic conditions of cervical vertebrae, neck strain	Flat in bed or head can be elevated 15°–20°
Dunlop	Either skin or skeletal, used for fractured humerus	Flat in bed; arm suspended and flexed
Pelvic girdle	Low back pain, muscle spasm, or herniated disc	Head of bed and knee gatch raised so hips flexed 45° angle (William's position)
Russell's	Used for fractured shaft of femur or lower leg and some knee injuries	Head of bed elevated 30°–45°
Bryant's	Used specifically for child weighing less than 30 lb for fractured femur or hip dysplasia	Flat in bed with both hips flexed at 45°–90°, legs extended and buttocks raised 1 in. from mattress

Maintaining Skeletal Traction

Equipment

- Sterile cotton-tipped applicators
- Prescribed cleansing agent
- Sterile cup for solution
- Sterile gloves
- Sterile gauze sponges (as ordered)

Preparation

1. Check physician's orders regarding pin site care and client positioning.

2. Check client using two forms of ID.
3. Gather necessary equipment.
4. Perform hand hygiene.
5. Provide privacy and explain procedure to client.

Procedure

1. Check pin and site surrounding the pin.
 - a. Pin should be immobile.
 - b. Pin site should be clean and dry.

2. Assess for infection at the pin site. Note any local pain, redness, heat, or drainage.
3. Provide pin site care if ordered.
 - a. Open applicator sticks and gauze package.
 - b. Open prescribed cleansing agent and pour into cup.
 - c. Don sterile gloves.
 - d. Clean area with prescribed cleansing agent. Soak cotton-tipped applicators. Dip stick into solution bottle, or pour solution over sticks.
 - e. Clean pin site starting at insertion area and working outward (away from pin site). ► **Rationale:** To cleanse site from cleanest to dirtiest area.
 - f. Use new applicator stick for cleaning each pin site.
 - **Rationale:** This prevents cross-contamination of sites.
 - g. Loosely dress site with separate gauze sponge.
 - h. Remove gloves and discard sticks.
 - i. Perform hand hygiene.
4. Examine all bony prominences for signs of pressure areas or abrasions.
5. Check for circulation, motion, and sensation in the affected extremity.
6. Assess distal extremity for color and edema.
7. Check ropes and weights to make sure pull goes directly through long axis of the fractured bone. ► **Rationale:** This pull maintains fracture in alignment.
8. Check traction mechanism.
 - a. Weights should hang freely, off the floor and bed.
 - b. Knots should be secure in all ropes.
 - c. Rope should move freely through pulleys.
 - d. Pulleys should not be constrained by knots.

▲ A Thomas splint supports the thigh. It is used for balanced suspension along with skeletal traction for fracture of the femur. A Pearson attachment supports the lower leg.

9. Instruct client to use trapeze correctly to assist in moving in bed and during linen change and back care.
 - **Rationale:** Use of the heel of the unaffected foot for repositioning can cause pressure ulceration. The foot should be placed flat on the bed for assistance in using the trapeze.
10. Make sure client is positioned correctly in bed.
 - **Rationale:** If the client is pulled down to the foot of bed, the traction is negated.
11. Check placement of the foot rest. The client's foot should be correctly positioned to prevent footdrop.
12. Check if client has migrated to foot of bed—pull client up using turn sheet. Do *not* release traction during repositioning.
13. Change bed linen in a top-to-bottom manner while client uses trapeze to lift buttocks.

TABLE 27-4 Skeletal Traction

Type	Purpose	Bed Position
External fixation devices Hoffman Synthes	Manage complex fractures with soft tissue damage; provide stability for severe comminuted fractures	Allows client mobility and active exercise of uninvolved joints
Cervical tongs Crutchfield Gardner–Wells Vinke	Used to immobilize and reduce cervical fractures Tongs maintain alignment of cervical spine	Bedrest, supine position; may be log-rolled
Balanced suspension with Thomas splint and Pearson attachment	Align bone and promote effective line of pull	Bedrest in supine position; may turn side to side for care; knee is flexed

EVIDENCE-BASED PRACTICE

This study examined six randomized controlled trials (349 participants) to assess the effect on infection of different methods of cleansing and dressing pin sites. Three trials compared a cleansing regimen with no cleansing, two trials compared cleansing solutions, one trial compared identical pin site care performed daily or weekly, and four trials compared dressings. One trial reported infection rates were lower (9%) with a regimen that included cleansing with 1/2 strength hydrogen peroxide and application of Xeroform dressing when compared with other regimens (rates >26%). There was no evidence of a difference between groups in any of the other trials.

Authors concluded that there is insufficient evidence for a particular strategy of pin site care that minimizes infection rates.

▲ A trapeze attached to an overhead frame facilitates client mobility and nursing care. Client uses both hands for repositioning to avoid twisting and back strain.

Clinical Alert

Skeletal traction is never released without a physician's order.

Stages of Pin-Site Reaction

	Findings	Treatment
Stage I	Copious serous drainage in first 72 hr	Absorbent dressing
Stage II	Superficial cellulitis: erythema, tenderness, swelling around pin	Oral antibiotics
Stage III	Deep infection: purulent drainage, swelling erythema over several pins, loose pins	IV antibiotics Pin removal
Stage IV	Osteomyelitis: loose pin, ring sequestrum on x-ray, persistent drainage	Debridement Long-term IV antibiotics

Source: Patterson, M. (2005). Multicenter pin care study. *Orthopaedic Nursing*, 24(5), 349–360.

Maintaining an External Fixator Device

Equipment

- Sterile cotton-tipped applicators
- Prescribed cleansing solution
- Sterile gloves
- Sterile gauze sponges (as ordered)

Procedure

1. Follow steps 1–5 of previous skill.
2. Assess neurovascular status of affected part every 4 hr.
 - ▶ **Rationale:** Clients with external fixation devices usually have extensive soft tissue, nerve, and vessel damage.
3. Provide client teaching before discharge.
 - a. Instruct client on the importance of, and how to perform, neurovascular checks and when to call the physician.
 - b. Demonstrate pin site care. Have client return the demonstration. ▶ **Rationale:** To ensure he or she is using appropriate technique.

Clinical Alert

The fixator–fat tissue interface may show fatty drainage that appears with movement of the tissue at the pin site. This should not be confused with purulent drainage.

▲ Hoffman frame, external fixator is used for complex fractures and to allow early mobility.

▲ Pin site care for external fixator.

NOTE: Clean technique is used after discharge.

- c. Reinforce physician's instructions regarding activity level. Discuss weight bearing on affected limb, if appropriate.
- d. Explain that fixator device is not to be used as a handle.

4. Demonstrate range-of-motion exercises, if appropriate, and have client perform return demonstration.
 - ▶ **Rationale:** To ensure appropriate exercises are being performed correctly.
5. Instruct client to continue to elevate extremity if edema occurs in affected limb.
6. Teach appropriate use of assistive devices as necessary.
 - ▶ **Rationale:** To prevent falls or inappropriate use of the device, which could cause accidents. Lower-extremity fixators particularly alter the client's balance.

Clinical Alert

The extremity and the external fixator should be moved as a unit, supporting the joint above and below the frame. Repeated lifting and manipulation of the frame itself can lead to pin loosening and fracture malalignment.

Maintaining Halo Traction

Equipment

Allen wrench
 Emergency tracheostomy set (available)
 Bag–valve–mask (available)
 Bright nail polish
 Equipment for pin site care, as ordered
 Prescribed cleansing solution, as ordered
 Sterile cup for solution
 Sterile cotton-tipped applicators
 Clean gloves

Preparation

1. Review client's history to determine level and type of spinal injury and purpose of halo brace immobilization.

▲ Halo brace traction provides immobilization after cervical or upper thoracic vertebral injury.

2. Determine specific assessment required for the particular client (depends on the level of client's spinal injury).
 Cervical injury at C3–C5 may compromise ventilation.
3. Gather necessary equipment.
4. Perform hand hygiene.

▲ The halo ring is attached to the vest by vertical bars (two in front and two in back). The ring is attached to the skull by two anterior and two posterior pins. Wrench on vest is for emergency release.

Procedure

1. Evaluate client's understanding of halo traction and its purpose.
2. Assess client's respiratory status regularly.
3. Perform complete neurologic assessment (peripheral nerves, motion, and sensation). **Rationale:** Because of their location, these nerves are prone to injury or excessive stretching with halo traction.
4. Check alignment of traction–brace system. Client's neck should not be flexed or extended.
5. Discuss safety issues. Halo alters client's center of gravity and balance.
 - a. Client has a limited view of the surrounding environment. Pathways for walking must be clear of obstacles.
 - b. Consult PT and OT for adaptive aids and tips for ADLs. ► **Rationale:** Client should anticipate situations and problems that may occur at home such as sleeping position, bathing, and getting in and out of a car.
 - c. Keep Allen wrench taped to front of vest. Mark anterior screws that attach vertical bars to brace with bright nail polish. ► **Rationale:** When marked they are easy to locate. The anterior vest is removed for emergency measures such as CPR.

Clinical Alert

Never use the bars of a halo brace to move the client.

Clinical Alert

If skull pins are loose, apply manual traction and keep client immobilized. Notify physician immediately.

6. Have emergency equipment available for establishing an airway and maintaining ventilation.
7. Suggest that client cover bolts/screws with moleskin or tape to protect clothing.
8. Inspect anterior (above eyebrows) and posterior (above and behind ears) pin sites for signs of drainage, crusting, or inflammation.
9. Provide skin care under vest:
 - a. Open vest at both sides during bath.
 - b. Check skin at vest edges and where vest overlaps.
 - c. Wash and dry skin thoroughly.
 - d. Do not use lotion or powder under brace.
 - **Rationale:** They combine with perspiration and irritate the skin.
 - e. Replace vest liner if it becomes wet or dirty.
10. Provide pin site care as prescribed. See steps in previous skill for skeletal traction.

DOCUMENTATION for Traction

- Type and location of traction, intermittent, or continuous
- Alignment of traction, client's positioning
- Integrity of the skin
- Circulation, motion, and sensation in extremity
- Specific client concerns and nursing actions taken to solve problems
- Client's comfort and overall feelings
- Pin site, assessment, and care
- Client and family teaching including written materials provided
- Client's progress in self-care

CRITICAL THINKING Application

Expected Outcomes

- Extremity is maintained in correct alignment.
- Neurovascular status is within normal limits.

Unexpected Outcomes

Client in skeletal traction keeps migrating to foot of bed.

Bone in skeletal traction has migrated to end of Kirschner wire.

- Pin site remains free of infection.

Alternative Actions

- Without releasing traction, use pull sheet and an assistant to reposition client up in bed.
- Elevate lower part of bed to provide countertraction.
- Increase weight of countertraction at head of bed.
- Notify orthopedic surgeon.
- Pin will be sterilized and moved so that bone centers on wire.
- Review ordered mobility restrictions with client.

Client experiences “tightness” in thigh after fracture of the femur.

- Measure thigh circumference and compare with contralateral thigh.
- Assess for presence of ecchymosis.
- Monitor vital signs closely for hypovolemia (several units of blood may be sequestered in the thigh after fracture of the femur)
- Notify physician for significant changes.

Client in Buck’s traction is unable to dorsiflex the foot.

- Release proximal strap as it may be compressing peroneal nerve over head of fibula.
- Assess sensation over dorsum of foot and between big and second toes.
- Notify physician.

Halo pin site appears to be infected.

- Notify physician.
 - Obtain culture of drainage for antibiotic sensitivity studies.
 - Cleanse pin site as prescribed, using aseptic technique, separate applicator for each site.
 - Remove crusts to allow drainage.
 - Monitor for systemic signs of infection.
-

Client With Joint Replacement

Nursing Process Data

ASSESSMENT Data Base

- Determine type of joint replacement performed (hemiarthroplasty, total joint arthroplasty).
- Determine surgical approach to total hip arthroplasty (anterolateral or posterolateral)
- Determine whether client has had elective surgery with preoperative preparation.
- Review client's understanding of protective and preventive self-care measures.
- Assess client's progress with clinical path (pain management, activity, client's understanding of expected progress toward discharge).
- Assess that leg position is abducted with pillows or splint.
- Determine whether client uses assistive devices appropriately.

PLANNING Objectives

- To assist the client to progress with self-care after elective joint replacement surgery
- To promote activities that prevent hip dislocation
- To determine that client understands joint motions that could cause joint dislocation
- To encourage use of safety and assistive devices in performing activities of daily living

IMPLEMENTATION Procedures

- Providing Wound Suction/Autologous Reinfusion1032
 - For Reinfusion/Establishing New Collection System1032
 - For Reinfusion1032
 - For Continued Wound Drainage1032
- Caring for a Client With Posterolateral Approach Hip Arthroplasty1033
 - For Bed Positioning1033
 - For Strengthening Exercises1033
 - For Mobility and Dislocation Prevention1034
 - For Assistive Devices and Adaptive Aids1034
- Caring for a Client With Knee Arthroplasty1035
 - For Continuous Passive Motion1035
 - For Postoperative Exercises1035
 - For Getting Out of Bed1035

EVALUATION Expected Outcomes

- Client benefits from autologous reinfusion of wound drainage.
- Client actively participates in elective arthroplasty experience.
- Client describes positions and activities to avoid in order to prevent hip prosthesis dislocation.
- Client voices understanding and demonstrates correct use of assistive devices for ADLs.

Critical Thinking Application1036

- Expected Outcomes1036
- Unexpected Outcomes1036
- Alternative Actions1036

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Providing Wound Suction/Autologous Reinfusion

Equipment

- Auto-transfusion reservoir ready for second collection/reinfusion
- Standard blood transfusion tube set with 40- or 20-micron filter
- 200 mL of normal saline for IV tubing and filter prime and flush post reinfusion
- Blood (IV therapy) transfusion documentation form
- Clean gloves

NOTE: A complete collection reinfusion and wound drainage system accompanies the client from PACU, consisting of a drain tube leading from the client's wound to a suction system (e.g., Hemovac). The suction collection unit is attached to the wound drainage evacuator to produce a vacuum.

Preparation

Upon client's return from PACU

1. Review physician's order for reinfusion.
2. Identify time reinfusion system was activated in the OR.
3. Mark time reinfusion should be completed.
4. Identify client using two forms of ID.
5. Ensure that collection reservoir is connected to the wound tubing (done in OR).
6. Ensure that evacuator suction tubing is connected to drainage reservoir and evacuator is compressed for suction.
7. Monitor drainage collection, allowing 4 hr to drain, then 2 hr for reinfusion. ► **Rationale:** Total reinfusion of blood should be completed within 6 hr of system activation in the OR.

Procedure

For Reinfusion/Establishing New Collection System

NOTE: If physician has ordered to reinfuse a second time, check the reservoir 4 hr after the first reinfusion was started. If greater than 100 mL has been collected, repeat the above Preparation.

1. Don clean gloves.
2. Place new (empty) collection system in a convenient location.
3. Detach the Hemovac evacuator (secured by clip or Velcro) and remove it from the wound drainage collection reservoir.
4. Close both drain clamps on the evacuator tubing.
5. Unscrew the wound drainage tubing clamps on the evacuator tube.
6. Cap the full wound drainage collection reservoir and set it aside.
7. Connect the evacuator tube to new (empty) reinfusion reservoir.
8. Unscrew tubing connecting Hemovac evacuator to full reservoir to be reinfused.

▲ Auto-reinfusion system with filter provides gravity infusion of autologous blood obtained within 6 hr of wound suction activation in the OR.

9. Connect Hemovac evacuator tube onto new (empty) collection reservoir.
10. Uncap the Hemovac attachment spout and activate the evacuator, then open the client's wound drain clamp.
11. Mark start time on new collection system.
12. Hang new collection unit on client's bed frame.

For Reinfusion

1. Remove the spike port cap on full reservoir.
2. Insert the filter spike and begin reinfusion.
3. Gravity reinfuse autologous blood within 6 hr of system activation (in OR).
4. Dispose of equipment in biohazard receptacle.
5. Remove gloves and perform hand hygiene.

For Continued Wound Drainage

1. Connect client's wound drainage tubing to Hemovac evacuator and activate to initiate suction.
2. Empty evacuator every 8 hr.
3. Remove gloves and perform hand hygiene.

Caring for a Client With Posterolateral Approach Hip Arthroplasty

Equipment

- Abductor pillow (“wedge”) or pillows (posterolateral approach)
- Non-rotation boot (if ordered)
- Bath blanket
- Poster reminder for exercises
- Walker
- Toilet seat extender
- Adaptive aids

Preparation

1. Identify client and assess client’s understanding of postoperative expectations.
2. Determine what instructions client has received.
 - ▶ **Rationale:** To reinforce and not contradict previous teaching. The client may be included in an acute care group exercise program.

Procedure

For Bed Positioning

1. Maintain body in alignment using abductor pillow or wedge. ▶ **Rationale:** The abductor serves as a reminder to keep legs in abduction to prevent dislocation of the prosthesis.
 - a. Place narrow end of wedge between the thighs, above the knees, as high as possible.
 - b. Place legs flush with sides of wedge and strap into place above the knee and above the ankle.
 - ▶ **Rationale:** Avoid pressure over joints where nerves and vessels are superficial.

▲ The abduction wedge or pillow prevents hip adduction and internal rotation to prevent dislocation after hemiarthroplasty or posterolateral approach total hip arthroplasty.

- c. If abductor has separate leg straps, the *unoperated* side may be loosened for comfort and to allow range of motion while client is supine.
2. Place rolled soft blanket or towel under ankles to free heels from the mattress. ▶ **Rationale:** To prevent skin breakdown.
3. Turn client every 2 hr, keeping legs abducted with both legs strapped. *Although not generally contraindicated, review surgeon’s orders before turning client to operated side.*
4. Maintain non-rotation boot (if indicated) while client is supine, but remove when client is turned.
 - ▶ **Rationale:** This boot with bar prevents hip rotation.
5. Encourage standard postoperative preventive measures such as deep breathing, foot pumps, and ankle rotations.
6. Encourage strengthening exercises such as gluteal sets and quadriceps sets.
7. Assess CMS and skin integrity at least every 4 hr.

For Strengthening Exercises

1. Place an exercise reminder sign at foot of bed. Have client hold muscle contraction for a count of 5 and repeat 10 times, then increase hold and number of repetitions each day (may do during commercials if watching TV).
2. Quadriceps strengthening:
 - Have client push back of the knee into bed.
 - ▶ **Rationale:** This contracts muscle on top of the thigh. The quadriceps muscle is used to rise to a standing position, to climb stairs, and to walk.
3. Gluteal strengthening:
 - a. Have client squeeze buttocks together tightly and hold for a count of 5 and repeat 10 times.
 - ▶ **Rationale:** These exercises help strengthen muscles surrounding the hip.
 - b. While standing, move operated leg backward, placing one hand on lower back to prevent arching, then return leg to starting position.
 - c. While standing, move operated leg laterally (out to the side), keeping foot and knee pointing straight forward, then return to starting position.

EVIDENCE-BASED PRACTICE

Preparing for Total Hip/Knee Arthroplasty

Preoperative exercise has been shown to reduce postoperative complications and length of stay for cardiac and abdominal surgery patients. This review of research literature from 1998–2008 (three studies met inclusion) found that evidence is inconclusive regarding preoperative exercise benefits for patients having THA or TKA. This was due to lack of functional measurements and small sample size in two of the studies. One of the studies did show that the exercise group had more patients discharged to home rather than to a rehabilitation unit. Additional research is needed.

Barbay, K. (2009). Research evidence for the use of preoperative exercise in patients preparing for total hip or total knee arthroplasty. *Orthopaedic Nursing*, 28(3), 127–133.

For Mobility and Dislocation Prevention

1. Assist client to get out of bed.

NOTE: A physical therapist usually supervises and assists with the first time out of bed.

- a. Raise bed to high position. ▶ **Rationale:** This allows client to exit bed without acute hip flexion.
- b. Elevate head of bed and instruct client to exit bed from unoperated side. ▶ **Rationale:** The stronger side should lead a transfer.
- c. Have client pivot on hips, while keeping legs abducted, and sit on edge of bed with operated leg out in front. Do not allow client to bend forward and push down to stand. ▶ **Rationale:** Bending forward may cause prosthesis dislocation.
- d. Assist client by supporting operative leg.
- e. Have client push down with hands on mattress to rise to a standing position. Walker should not be used for support when rising to a standing position.
- f. Walk client first postoperative day (as ordered) with an assistant and a walker with weight bearing as tolerated.

2. Instruct client about positions to avoid.

NOTE: Gluteal isometrics strengthen muscles that surround the joint capsule and decrease the risk of dislocation.

- a. Do not cross the legs at ankle or knee. Keep knees apart at all times. ▶ **Rationale:** Adduction can cause prosthesis dislocation.
- b. Do not stand with toes turned in. ▶ **Rationale:** Internal rotation can cause prosthesis dislocation.
- c. Do not flex hips greater than 90°. Always sit with knees lower than hips. Avoid low chairs and do not bend over. Use toilet seat extender (elevator).
▶ **Rationale:** Flexion beyond 90° can cause prosthesis dislocation.
- d. Do not sit in bathtub. Use a standing shower or shower/tub chair.
- e. When standing and turning is necessary, turn toward unoperated side. ▶ **Rationale:** Turning toward operated hip can cause hip dislocation due to internal rotation.

For Assistive Devices and Adaptive Aids

1. Consult physical therapy and occupational therapist to obtain a walker, client instruction, and supervised ambulation and activity precautions.

Clinical Alert

Hip prosthesis dislocation usually requires a simultaneous combination of contraindicated hip positions, such as crossing the legs and acutely flexing at the same time. Dislocation precautions are continued until the joint capsule has healed. Only the orthopedic surgeon should advise clients when and if precautions are no longer necessary.

▲ Adaptive aids, such as a reacher, facilitate independence in ADLs.

TABLE 27-5 Total Hip Arthroplasty Precautions Differ with Surgical Approach

Posterolateral Approach	Anterolateral Approach
Keep leg in abduction and extension (pillow or wedge often used).	Sitting at 90° is allowed. Avoid active abduction.
Avoid flexion of the hip beyond 90° angle. If while sitting you can put your hands on your legs below your knees, that's too much flexion.	Keep legs side by side without a wedge or pillow between them.
Do not bend at the waist to put on shoes.	Avoid turning toes and knee outward. Do not extend the leg backward.
Keep needed items on the nonoperative side. Use a toilet elevator (21 in.) and shower chair. Do not cross the operative leg past the body's midline. Do not inwardly rotate the operative leg.	Place needed items on operative side.
To turn while standing, turn away from the operative side.	To turn while standing, turn toward the operative side.

2. Consult occupational therapy for provision and instruction in use of adaptive aids such as toilet seat extender, reachers, sock aid, long-handled sponge, and shoehorn. Instruct client to avoid wearing shoes with laces that must be tied.

Clinical Alert

The client undergoing hemiarthroplasty (replacement of the femoral head and neck) for fracture of the femur must adhere to the same precautions as the elective total hip replacement client to prevent prosthesis dislocation.

3. Discuss home safety adaptations which client may have already installed in preparation for *elective* surgery: toilet extender (21 in.), elevated chair seats, shower or tub chair, safety rails, removal of loose rugs and electrical cords, placement of frequently used items within easy reach.

Clinical Alert

Because of changes in the skin that occur with aging, older clients are at increased risk for blistering and accidental removal of the epidermis by mechanical means such as tape removal. Tape should be applied vertically only, and without tension.

Caring for a Client With Knee Arthroplasty

Equipment

- Knee splint immobilizer
- CPM device or rocking glider chair

Preparation

See *previous skill*.

Procedure

For Continuous Passive Motion

1. Assist client to comfortable position. Client may turn from side to side and may have head of bed up or down. There is little risk of dislocation of knee prosthesis.
2. Place pillows lengthwise under lower leg, but not under knee.
3. Apply soft foam knee immobilizer or brace (if ordered).
 - a. Place wide strap over knee.
 - b. Allow client to direct tightness of fit.
 - c. Monitor surgical wound drainage output frequently for the first 48 hr postoperatively.

▲ CPM (continuous passive motion) device may be used to increase joint mobility after knee surgery.

- d. Assess CMS and skin integrity at least every 4 hr while splint is in place.

For Postoperative Exercises

1. Maintain accurate positioning of continuous *passive* motion device, if ordered, to gently flex knee by adjusted increments. Settings start at 10°–30° and are gradually increased until 90° of flexion is achieved.
 - ▶ **Rationale:** CPM may prevent adhesion formation and improve range of joint motion during early postoperative period.
2. *Alternate:* Client may use a rocking glider chair.
 - ▶ **Rationale:** This encourages independent *active knee flexion and extension*, which has added benefit of getting the client out of bed, improving venous return, reducing edema formation, and preventing clot formation and other complications of bedrest.
3. Encourage foot pumps, straight leg raising, ankle rotations, quadriceps, and gluteal sets as for client with a total hip replacement.

For Getting Out of Bed

1. Assist client to pivot and sit on side of the bed, supporting the leg.
2. Unless brace is worn, encourage client to alternate bending and straightening the knee. Flex unaffected leg to support weight to a standing position while keeping operative leg extended.
3. Weight bearing as tolerated with an assistant and use of a walker is usually allowed first postoperative day.
4. A raised seat will assist client to get in and out of a chair.

Clinical Alert

There may be an increase in wound bleeding when initiating knee flexion exercises (CPM or mobilizing client).

Clinical Alert

Infection is a grave complication with joint replacement surgery. It may occur during the first 3 months postoperatively or even after a year. Late infection is usually due to hematogenous spread from a distant site (teeth, GI, or urinary tract).

Clients should remind their physicians and dentists about their prosthesis; antibiotics may be prescribed before dental work or other invasive procedure to prevent infection.

EVIDENCE-BASED PRACTICE**Continuous Passive Motion**

Studies on the use of continuous passive motion (CPM) have not clearly identified its use as best practice. There are no differences in range of motion, edema, drainage, and the amount of pain experienced in clients who use and those who do not use CPM. Differences may relate to initiation of therapy, hours of use, length of time used, use of a knee immobilizer.

Source: Roberts, D. (2002). Degenerative disorders. In A.B. Maher, S. W. Salmond, & T.A. Pellino (Eds), *Orthopaedic Nursing*. Philadelphia: Saunders.

**DOCUMENTATION for Client With Joint Replacement**

- Character and amount of wound drainage
- Auto-reinfusion times and amounts on I&O record as output from a drainage system and intake as a blood product
- Wound assessment findings
- Character and amount of wound drainage
- Client positioning and frequency of turning
- Neurovascular and skin status of involved extremity
- Placement of abductor splint or brace
- Use of continuous passive motion or rocking glider chair
- Exercises performed: type, duration, and client's tolerance
- Client and family teaching and teaching materials aids provided
- Client's understanding of teaching (return demonstration of preventive measures), use of assistive devices and other aids

CRITICAL THINKING Application**Expected Outcomes**

- Client benefits from autologous reinfusion of wound drainage.
- Client actively participates in elective arthroplasty experience.

Unexpected Outcomes

Client's hemoglobin lab result remains less than 10 g/dL after reinfusion.

Client with knee arthroplasty is fearful of dislocation.

Client is unable to remember instructions for hip precautions.

- Client describes positions and activities to avoid in order to prevent hip prosthesis dislocation.
- Client voices understanding and demonstrates correct use of assistive devices for ADLs.

Alternative Actions

- Notify physician of lab results.
- Obtain order for type and cross and type for possible allogenic blood transfusion.
- Assure client that, in contrast to hip arthroplasty, knee dislocation rarely occurs.
- Encourage client to continue quadriceps and gluteal setting and knee flexion/extension exercises.
- Consult with physical therapist regarding client's concerns/need for reassurance and encouragement.
- Provide written instructions with pictures of positions to avoid.
- Request occupational therapist to work with client and caregiver to reinforce instructions/precautions.
- Request Social Service consult for postoperative rehabilitation living needs.
- Request OT consult for individualized assessment and recommendations/teaching.

Client with hip arthroplasty asks about adapting ADLs to accommodate hip precautions.

- Suggest purchasing a raised toilet seat before leaving hospital (many agencies sell these).
 - Use a standing shower or tub with shower chair for bathing.
 - Wear lace-up shoes with elastic laces so tying is not required and the foot can be slipped in with a long-handled shoe horn.
 - Purchase reachers or long barbecue tongs to retrieve things from the floor.
 - Place frequently used items at arm level so bending is not required.
 - Remove scatter rugs, electric cords, and small objects from the floor.
 - Move car seat back as far as possible. Keep operated leg out in front, slide back into seat, then semi-recline and pivot to face front of car.
-

Chapter 27

UNIT 5

Client With an Amputation

Nursing Process Data

ASSESSMENT Data Base

- Determine whether amputation was therapeutic or traumatic.
- Determine rationale for therapeutic amputation (tumor, peripheral vascular disease, diabetes).
- Assess status of stump wound.
- Assess stump positioning.
- Inspect stump for presence of edema.
- Assess for phantom sensation or phantom pain.
- Assess client's acceptance of amputation.

PLANNING Objectives

- To promote wound healing
- To reduce edema and discomfort
- To prevent contracture development
- To mold and prepare stump for prosthesis use
- To assist the client in acceptance and self-care

IMPLEMENTATION Procedures

- Positioning and Exercising the Stump1039
 - For Preoperative Care1039
 - For Postoperative Care1039
- Shrinking/Molding the Stump1040

EVALUATION Expected Outcomes

- Stump wound heals without complication.
- Stump maintains functional alignment.
- Stump is prepared for prosthesis use.

Critical Thinking Application	1041
• Expected Outcomes	1041
• Unexpected Outcomes	1041
• Alternative Actions	1041

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Positioning and Exercising the Stump

Equipment

Pillows

Preparation

1. Check chart for physician's orders.
2. Identify client and explain purpose of positioning and exercising.
3. Provide privacy.
4. Perform hand hygiene.

Procedure

For Preoperative Care

1. Evaluate nutritional status and request nutritional consult if indicated. ► **Rationale:** Adequate protein is necessary to promote wound healing.
2. Recruit assistance of OT, PT, and social worker for early multidisciplinary care planning. A prosthetist explains future prosthetic care to the client and possibly organizes amputee peer visit, as this helps lessen anxiety about living with an amputation.
3. Explain importance of exercises to client. Tell client that because flexor muscles are stronger than extensors, stump will be permanently flexed and abducted unless the client practices extension and adduction exercises. ► **Rationale:** Exercises increase muscle strength and improve mobility of amputated extremity. Both are necessary for optimal ambulation with a prosthesis.
4. Teach client quadriceps-setting exercises with a below-the-knee amputation.
 - a. Extend leg and try to push back of knee into bed; try to move patella proximally.
 - b. Contract quadriceps and hold contraction for 10 seconds.
 - c. Repeat this procedure four or five times.
 - d. Repeat the exercise at least four times a day.
5. Teach use of ambulatory aids. ► **Rationale:** Prepares client for post-surgery mobility.
6. Explain phantom limb sensation; the client may continue to "feel" the lost limb after surgery.

Clinical Alert

Adequate pain management in the preoperative period can reduce the occurrence of phantom limb pain postoperatively.

Clinical Alert

Keep a tourniquet nearby in the event of excessive stump incision bleeding.

7. Counsel families, for they also mourn the loss of a visible body part. ► **Rationale:** They too need psychological support and education about rehabilitation and necessary skills for self-care.

For Postoperative Care

1. Monitor for complications: hemorrhage, infection, unrelieved pain, wound that will not heal.
2. Assess for excessive wound drainage. Keep tourniquet at bedside. ► **Rationale:** If excessive bleeding occurs, tourniquet must be applied, as hemorrhage is a potentially life-threatening complication.
3. Administer ordered pain medication and continually assess to determine whether pain is controlled.
4. Do not place stump on pillow, but elevate foot of bed for first 24 hr ONLY to reduce stump edema and pain. ► **Rationale:** Elevation on a pillow can promote flexion contracture of stump.
5. Turn client to prone or supine position for at least 1 hr every 4 hr. ► **Rationale:** This promotes hip extension and helps counteract possible flexion contracture formation.
6. Avoid dependent positioning of stump. ► **Rationale:** To prevent edema and discomfort. Edema may be present for up to 4 months after amputation.
7. While washing the stump, tap and massage the stump skin toward the incision line. ► **Rationale:** To prevent development of painful adhesions.
8. Teach stump extension exercises.
 - a. Lie in a prone position with foot hanging over the end of the bed.
 - b. Keep stump next to intact leg to extend stump and to contract gluteal muscles.
 - c. Hold the contraction for 10 seconds.
 - d. Repeat this exercise at least four times a day.
9. Teach adduction exercise.
 - a. Place a pillow between the client's thighs.
 - b. Squeeze the pillow for 10 seconds and then relax for 10 seconds.
 - c. Repeat this exercise at least four times a day.
10. Have the client keep track of time spent with the stump flexed and then spend an equal amount of time with the stump extended.
11. Encourage appropriate use of trapeze: Use both hands to pull up with trapeze; place foot flat on mattress to lift body. Do not use heel to push in the mattress. ► **Rationale:** Pushing with the heel can lead to pressure ulcers.
12. After stump incision heals, have client begin to bear weight on stump, initially pressing into padded surface (pillow on chair seat). ► **Rationale:** To reduce pain and help prepare the stump for prosthesis.

Shrinking/Molding the Stump

Equipment

- Two elastic bandages: 4 in. for below-the-knee amputation (BKA), 6 in. for above-the-knee amputation (AKA)
- Tape or safety pins
- Commercial stump shrinker (sheath)

Preparation

1. Review client's chart to determine date and type of amputation.
2. Gather equipment.
3. Identify client using two forms of ID and explain rationale for procedure.
4. Perform hand hygiene.
5. Provide privacy.

Procedure

1. Wash stump with soap and water and allow to dry for at least 10 minutes before bandaging. Do not use lotions, powders, or alcohol.
2. Inspect and encourage client to assess stump for circulatory status, pressure areas, wound healing, and edema.
3. Explain that purpose of wrap is to form a conical AKA stump to prepare for prosthesis use.
4. Explain that wrap is to be worn at all times except during bathing or when wearing a prosthesis.

▲ “Commercial shrinkers” may be used for above-the-knee amputations (AKA).

5. Start by placing bandage end outer surface on distal stump. ▶ **Rationale:** The pressure gradient of the bandage should be greatest at the distal stump.
6. Wrap bandage medially and diagonally around stump. Have client assist by holding turns. Stretch bandages to two-thirds of the limit of the elastic.
7. Continue to wrap smoothly up the stump with medially directed spirals or figure eight turns (not circular). Progress up the stump and well into groin area. ▶ **Rationale:** Circular turns constrict circulation. Medial turns help correct stump tendency toward abduction.
8. Finish bandaging with a “spica” turn over and around the client’s pelvis, then back down to stump. ▶ **Rationale:** Large “spica” turn prevents bandage slipping.
9. Secure the bandage with tape or (*cautiously*) with safety pins. Do not use bandage clips. ▶ **Rationale:** Clips can pierce the skin or easily come loose.
10. Reapply elastic bandage every 4–6 hr or when loose. ▶ **Rationale:** It must never be in place for more than 12 hr without being rewrapped.
11. If client has a stump “shrinker sheath,” roll down and stretch the sheath using plastic ring. Fit onto stump end and apply, making sure there are no wrinkles.
12. Teach client home care of residual limb and prosthesis (washing; assessing for redness, pressure points, irritation, swelling skin breakdown; socket, stump, socks, liners, mechanical parts, etc.).

Clinical Alert

Amputees use more energy in ambulation than nonamputees. The elderly with an AKA must put forth an effort 100% above normal to walk at a slow rate. The longer the residual limb, the less energy the client must expend for ambulation.

▲ Compression bandage may be used after amputation to mold and shrink stump in preparation for prosthesis.

DOCUMENTATION for Client With an Amputation

- Time, type, and site of bandage application
- Stump positioning
- Stump and wound assessment
- Exercises performed
- Client teaching
- Client's response to stump and participation in self-care

CRITICAL THINKING Application

Expected Outcomes

- Stump wound heals without complications.
- Stump maintains functional alignment.
- Stump is prepared for prosthesis use.

Unexpected Problems

Client sits in chair most of the day and keeps stump elevated on a pillow while in bed.

Stump edema occurs in spite of compression bandage application.

Client expresses fear of losing other leg.

Alternative Actions

- Discuss hip and knee contracture complications that occur with prolonged flexion positioning of the stump.
- Review and reinforce exercises that promote stump adduction and extension to prevent contractures and facilitate prosthesis use.
- Evaluate wrapping procedure.
- Ensure that wraps are applied with pressure greater at distal stump and reapplied several times a day.
- Instruct client to avoid prolonged dependent positioning of stump.
- Consult prosthetist for possible rigid shrinker use.
- Apply shrinker before client gets out of bed.
- Teach client to care for the remaining extremity.
- Inspect for lesions; wash and dry daily; use lotion for dry skin (not between toes); keep nails trimmed straight across; avoid mechanical, chemical, or thermal injury; wear shoes that are wide and deep enough for toes.
- Avoid smoking; exercise daily.
- Consult podiatrist for individual foot care or shoe orthotic adaptations, especially if diabetic.
- Consult physician for management of diabetes or atherosclerosis.

Chapter 27

UNIT 6

Stryker Frame

Nursing Process Data

ASSESSMENT Data Base

- Determine client’s musculoskeletal and neurologic status.
- Evaluate client’s understanding of turning procedure.
- Assess client alignment and security of device.
- Evaluate client’s ability to assist with turning.

PLANNING Objectives

- To turn client horizontally from supine to prone to supine positions
- To provide optimal skin care for immobilized clients
- To prevent pressure areas and pressure ulcers
- To provide optimal nursing care to clients with skin grafts or other conditions that require minimum client movement

IMPLEMENTATION Procedures

- Using a Stryker Wedge Turning Frame1043
- Turning From Supine to Prone1043
- Using a Stryker Parallel Frame.....1043
- Assisting Client With Bedpan1044

EVALUATION Expected Outcomes

- Client turns horizontally without torsion or abnormal flexion/extension of the spine.
- Client receives optimal skin care without developing pressure ulcers.
- Client receives optimal nursing care for skin grafts or neurologic condition.

Critical Thinking Application 1044

- Expected Outcomes1044
- Unexpected Outcomes1044
- Alternative Actions1044

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Using a Stryker Wedge Turning Frame

Equipment

- Stryker wedge turning frame
- Armrests and footboard
- Software: mattress, canvases, linen, straps
- Safety straps
- Pillows and sheepskin (if used)

Procedure

1. Explain procedure to client.
2. Show client the Stryker frame before placing on the frame.
3. Position the posterior frame at the bottom of the turning circle.
4. Place client supine on the posterior frame (using the three-man carry transfer method, if necessary).
5. If client is on a backboard, place client and board on the posterior frame.
6. Attach the anterior frame.
7. Turn client and remove the backboard.
8. Reverse the procedure, and turn client to his or her back.

NOTE: The Stryker frame has been infrequently used for the past 10 years. However, due to increased numbers of spinal instrumentation procedures, the new Stryker wedge turning frame is again being used after surgery in many parts of the country.

▲ Stryker wedge turning frame.

Turning From Supine to Prone

Procedure

1. Explain procedure to client. This procedure requires only one person; however, it is advisable to have two people when possible.
2. Position sheepskin, pillows, or comfort aids on top of client.
3. With client on posterior frame, open the turning circle and put head end of anterior frame on the securing bolt and fasten it with the nut.
4. Fasten the foot end of the anterior frame with the nut, making sure that client's legs and feet are correctly positioned.
5. Have client clasp hands around anterior frame. If client is unable to do this, put a safety strap around the whole frame at elbow level to keep arms contained.
6. Close the turning circle until it locks.
7. Move the armrests down out of the way of the turn.
8. Pull out the bed-turning lock.
9. Turn the frame toward the client's right until it locks automatically. The narrow side of the wedge (at the client's right) always turns down. The frame automatically locks when the bottom frame is horizontal.
10. Open the turning circle, unscrew the nuts, and remove the upper posterior frame. Relock the turning circle for safety.
11. To turn the client on the Stryker wedge from prone to supine, reverse procedure for turning from supine to prone. Remember that the narrow side of the wedge (on client's right) always turns down so client cannot slip out.

Using a Stryker Parallel Frame

Equipment

- Stryker parallel frame
- Armrests and footboard
- Software: mattress, canvases, linen, straps
- Safety straps
- Pillows and sheepskins

Procedure

1. Place a pillow lengthwise over the client's legs to prevent moving during turning.
2. Attach the anterior frame to the main frame using the two nuts on the turning circle. Make sure the client is held firmly between the frames.

3. Put three safety straps around the frame at level of knees, waist, and elbows. Tighten securely.
4. With a person at each end of the frame, pull out the locking pins at the center of each end, turn the frame slightly to hold the lock open, and then quickly finish turning the client. The bed automatically locks when the bottom frame is horizontal.
5. Remove the top frame and reposition the client for comfort.

Assisting Client With Bedpan

Equipment

- Special bedpan
- Plastic drape
- Towels
- Clean gloves

Procedure

1. Explain procedure to client.
2. Place client in a supine position.
3. Don clean gloves.
4. Drop the center section of the posterior frame by releasing the hooks or rubber bands from the sides of the frame.
5. Protect the linen by putting plastic or towels around the edges.
6. Insert the bedpan into the opening and hold securely with hands or with the arm supports.
7. Remove the bedpan, clean the client, and reattach the center section of the frame.
8. Clean bedpan and replace in storage area.
9. Remove gloves and discard.
10. Perform hand hygiene.

DOCUMENTATION for Stryker Frame

- Time and frequency of turning
- How client tolerates turning procedure
- Neuro assessment findings
- Neurovascular status
- Status of the traction apparatus, if indicated
- Vital signs
- Skin assessment

CRITICAL THINKING Application

Expected Outcomes

- Client turns horizontally without torsion or abnormal flexion/extension of the spine.
- Client receives optimal skin care without developing pressure ulcers.
- Client receives optimal nursing care for skin grafts or neurologic condition.

Unexpected Outcomes

The client expresses fear of being turned.

Alternative Actions

- Encourage client to be on frame and be turned before surgery.
- Explain each step of the turning process and the use of each piece of equipment.
- Allow client to express fears and concerns.
- Carefully answer all questions in a way that the client can understand.

The client experiences unusual pain or discomfort when turned.

- Have the client describe details of pain.
- Assess the client's neurologic status and compare it with the client's status before turning.
- Ensure that the traction apparatus is intact.
- Notify physician if pain persists or if there is a change in neurologic status.

GERONTOLOGIC Considerations

Musculoskeletal integrity can be enhanced and therapeutic goals reached if the aging effect on the musculoskeletal system is appreciated and incorporated into individualized care planning.

Elderly clients generally experience:

- Decreased height
- More brittle bones, decreased density
- Reduced muscle mass
- Diminished strength
- Joint stiffening
- Weakness and slowed movement
- Thinning of the dermis and structures supporting the junction of the epidermis and dermis weaken. Older clients are at increased risk for blistering and epidermal stripping.
- Slower and less effective healing, which may result in greater incidence of malunion and nonunion after fracture

Elderly clients are at high risk for falls and musculoskeletal injury as a result of:

- Weakness and being easily fatigued
- Unsteady balance, gait, and alterations in posture
- Poor eyesight
- Altered mobility resulting from medications or use of assistive device
- Increased time on bedrest, leading to muscle weakness
- Presence of chronic disease

Active elderly clients may seek joint replacement surgery to:

- Decrease pain
- Increase mobility
- Continue an active life

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- All healthcare workers can be assigned to clients with orthopedic conditions for nursing tasks associated with activities of daily living. Occupational and Physical Therapists are assigned to the more complex tasks of ambulating and teaching clients with hip replacements, clients requiring assistive devices to ambulate, etc.
- Some facilities employ orthopedic technicians who set up and monitor traction, assist with cast application, bivalve or removal and help with transfer.

Communication Matrix

- The RN needs to assess the skill level of all staff assigned to clients requiring assistive devices or special equipment. Documentation of the skill level for the staff should be available on the unit. This is a major safety factor for all staff assigned to orthopedic clients.
- When new equipment is purchased, and before it is put into service, the manufacturer should provide in-service education to all staff to prevent damage to the equipment and promote safety in client care.

- Most orthopedic clients are followed by a multidisciplinary care team, which includes physicians, nurses, physical and occupational therapists, and social workers. The team use the client's DRG related "clinical path" as an action plan for coordinating hospital, discharge, and subacute setting or home care services. Variances can be identified as the client moves through the sequences of specific interventions that promote timely discharge. Such collaboration requires open and ongoing communication among all members of the team. Special documentation forms may be used to facilitate this process.
- The nurse "Patient Care Coordinator" oversees the client's progress and brings multidisciplinary issues to the physician's attention so that the "path" can be individualized to reflect the client's unique needs.
- Assistive personnel (aides, orthopedic technicians) must be informed of any restriction in client positioning or mobility. They should report any noted changes in the client's condition or problem with any immobilizing device or equipment to the RN so that further assessment and problem solving can be conducted.
- On-coming staff should receive information about the client's progress toward satisfaction of expected outcomes, any unexpected variance that impedes the client's progress toward discharge, and any change in the medical plan of care.

CRITICAL THINKING Strategies

Scenario 1

Your orthopedic unit has just admitted an 84-year-old female, Nora James. She was brought to the ED after a fall in the grocery store. Her admitting diagnosis is “intertrochanteric fracture of the left hip.” She is scheduled for hip “nailing” surgery as soon as she is cleared by her primary physician, cardiologist, and anesthesiologist.

1. What behaviors would you expect to see upon initial assessment of Miss James?
2. What are the priorities of care in the preoperative period?
3. How will this client’s care plan differ from that of the client with hemiarthroplasty replacement of the femoral head and neck?

Scenario 2

Mrs. Jacobson, a 73-year-old retired school teacher, has been admitted to the hospital for a right total hip replacement as a result of osteoarthritis. She has been very active her entire

life, playing golf three times a week, bowling on a team, hiking, and gardening. She is very concerned that she will be unable to continue with these activities if she doesn’t have surgery. Her lab work was completed before her admission. She did give 2 units of autologous blood in case she needs it for surgery. Her vital signs are: BP 148/80, P 88, R 26. She uses a cane, which she says is “for balance.”

1. Identify the priority preoperative intervention for Mrs. Jacobson. Provide a rationale for your choice.
2. Develop a client care plan: identify short- and long-term goals, state three nursing diagnoses in priority order, and provide the rationale for your choices. Describe at least two priority nursing interventions for each nursing diagnosis.
3. Identify two safety issues related to Mrs. Jacobson’s care.
4. Describe at least three procedures that need to be discussed before her discharge.

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. Appropriate application of a sling to the upper arm includes
 1. Positioning so that hand is higher than elbow.
 2. Positioning so that hand is lower than elbow.
 3. Teaching client to avoid any shoulder joint motion.
 4. Teaching client to avoid any movement of distal digits.
2. Wet plaster casts are best dried by
 1. Using a hair dryer.
 2. Covering with blankets.
 3. Using a heat lamp.
 4. Natural evaporation.
3. A synthetic cast, compared with a plaster cast

Select all that apply.

 1. Is more expensive.
 2. Dries more quickly.
 3. Is heavier.
 4. Provides greater stability.
 5. Will not cause skin burns.
 6. Is nonabsorbent.
4. The following are early indications of acute compartment syndrome in a casted extremity

Select all that apply.

 1. Weak or absent distal pulses.
 2. Pain with passive extension of distal digits.
 3. Pain relieved with extremity elevation.
 4. Pain worsens with extremity elevation.
 5. Pain worsens when extremity is dependent.
 6. Pain unrelieved by analgesics.
5. Injury to the peroneal nerve can result in permanent
 1. Urinary incontinence.
 2. Inability to plantarflex the foot.
 3. Inability to dorsiflex the foot.
 4. Anesthesia on sole of the foot.
6. The client with posterolateral approach total hip replacement surgery should be kept in this position postoperatively
 1. Legs adducted.
 2. Legs abducted.
 3. Operative leg in external rotation.
 4. Operative leg in internal rotation.
7. Adaptive aids for the client with total hip replacement primarily help the client avoid
 1. Hip flexion.
 2. Falls.
 3. Hip extension.
 4. Pain.
8. Studies show that clients receiving CPM (continuous passive motion) versus those who do not receive CPM after total knee replacement surgery have
 1. Better joint range of motion.

2. Less venous thrombosis.
 3. Less edema.
 4. Less wound drainage.
 5. None of the above.
9. Phantom pain in the amputated extremity is most apt to occur in clients with
1. Drug dependency.
 2. Inadequate stump shrinkage/shaping.
 3. Traumatic limb amputation.
 4. Limb pain preoperatively.
10. The client with above-the-knee amputation should be encouraged to perform exercises that promote stump
1. Adduction and hip flexion.
 2. Abduction and hip flexion.
 3. Adduction and hip extension.
 4. Abduction and hip extension.
-

Intravenous Therapy

LEARNING OBJECTIVES

1. Describe the role the kidneys play in maintaining fluid and electrolyte balance.
2. Discuss the two hormonal regulatory systems that influence urinary excretion by the kidneys.
3. State the major cations and anions in the body.
4. Identify the assessment data to determine a client's fluid status.
5. Compare and contrast the client assessment data associated with fluid volume excess or deficit.
6. Describe the steps for performing venipuncture using a winged needle or over-the-needle catheter.
7. State at least two potential problems that can occur with venipuncture and one suggested solution for each problem.
8. Describe the steps for performing vein cannulation.
9. Outline the steps in preparing the IV bag for fluid administration.
10. Describe the steps for hanging a secondary IV bag.
11. Calculate an IV flow rate using a standard formula.
12. Describe the procedure for administering an intravenous push medication.
13. Discuss client safety and the use of infusion control pumps.
14. Describe the proper use of chlorhexidine gluconate as a skin preparation for intravenous access.
15. Discuss the nursing interventions required for each type of venous access connectors.
16. Describe safety checks utilized to ensure proper blood administration.
17. Differentiate signs and symptoms of hemolytic and allergic blood transfusion reactions.

TERMINOLOGY

Anaphylaxis a hypersensitive state of the body to a foreign protein or drug.

Antiarrhythmic an agent used to regulate heart rhythm.

Antidiuretic hormone that decreases urine production.

Antimicrobial preventing the development or pathogenic action of microbes.

Ascites the excessive accumulation of serous fluid in the peritoneal cavity.

Aspirate to remove material by suction.

Autologous blood transfusion client’s own blood is collected before a surgical procedure or future need for transfusion.

Bolus direct injection of a medication intravenously in order to achieve rapid serum concentrations.

BSI bloodstream infection.

Cardio pertaining to the heart.

Cardiovascular pertaining to the heart and blood vessels.

Catheter-related bloodstream infection the same organism is found in the blood and catheter segment with clinical symptoms of BSI and no other sources of infection present.

Central line bundle a bundle is a collection of interventions delivered as a group to improve outcomes for catheter-related bloodstream infections.

Colonization growth of an organism from the proximal or distal catheter segment or catheter lumen in conjunction with signs of infection at catheter site.

Cyanosis slightly bluish, grayish, slate-like, or dark purple discoloration of the skin/mucous membranes.

Diarrhea frequent passage of watery stool.

Diffusion passive movement of molecules from an area of high concentration to one of lower concentration.

Directed donation of blood friends or relatives donate blood for a specific client.

Diuretic a chemical agent that increases the production of urine.

Dyspnea a subjective feeling of difficulty breathing.

Edema an excessive amount of extracellular fluid.

Electrolyte substance that develops an electrical charge when dissolved in water.

Evaporation change from liquid to vapor.

Extracellular outside the cell.

Girth the distance around something; circumference, as in measuring abdominal circumference.

Granulocytes a granular leukocyte (e.g., neutrophil).

Hematoma a collection of blood confined in a space.

Hematuria blood in the urine.

Hemo- prefix meaning blood.

Hemolytic pertinent to the breaking down of red blood cells.

Homeostasis state of equilibrium of the internal environment.

Homologous blood transfusion blood from another individual is used for transfusion.

Hydration the chemical combination of a substance with water.

Hydrostatic pressure the pressure of liquids during equilibrium.

Hypersecretion abnormally large amount of secretion.

Hypertonic solution having greater than 340 mOsm, increased amount of solutes in relationship to plasma.

Hypotonic solution having less than 240 mOsm, decreased amount of solutes in relationship to plasma.

Hypovolemia diminished circulating blood volume.

Infiltration blood leaks into surrounding tissue when IV fluids are infusing.

Infusion-related bloodstream infection the same organism found in the infusion and separate percutaneous blood cultures without an identified source of infection.

Infusion introduction of a liquid into a vein or other body part.

Interstitial extracellular fluid found between the cells.

Intracellular inside the cell.

Intravascular within blood vessels.

Isotonic having the same tonicity as plasma, 240–340 mOsm.

Local-catheter-related infection growth of an organism from the proximal or distal catheter or lumen with accompanying signs of inflammation at the catheter site.

Metabolism the sum of all physical and chemical changes that take place within an organism.

Nephro prefix meaning kidney.

Nephrotoxic damaging to renal cells.

Osmolality concentration of osmotically active particles per Kg of body water (tonicity).

Osmosis transmission of water across a semipermeable membrane from an area of low solute concentration to one of higher solute concentration.

Osmotic pressure pressure exerted on a semipermeable membrane separating a solution from a solvent, the membrane being impermeable to solutes in solution and permeable only to solvent.

Palpate to examine by touch; to feel.

Pruritus severe itching.

Purulent containing pus.

Skin turgor elastic property of the skin reflecting body fluid status.

Smart pumps computerized IV pumps.

Specific gravity weight of a substance compared with an equal volume of water.

Transfusion injection of blood or a blood component of one person into the blood vessels of another.

Urticaria a vascular reaction of the skin characterized by the eruption of pale raised wheals, which are associated with severe itching.

Valsalva's maneuver attempt to forcibly exhale against a closed glottis.

Venipuncture puncture of a vein with a needle.

Vesicant blistering; causing or forming blisters, irritant to blood vessels.

Viscosity resistance offered by a fluid; property of a substance that is dependent on the friction of its component molecules as they slide by each other.

FLUID AND ELECTROLYTE BALANCE

The body's internal environment is made up of fluids and dissolved substances including electrolytes. Fluids and electrolytes are in a constant state of dynamic equilibrium in order to maintain the delicate balance essential for all the physiologic processes that support life.

Fluids

Body fluid is primarily water. Depending on the amount of body fat, a person's total body weight is usually 50%–70% water. Since fat is essentially water-free, an obese adult's body weight is 50% water. In a leaner individual, the percentage of body weight due to body water is closer to 70%. With aging, there is a decrease in lean body mass; therefore, the elderly may have only 46%–52% of body weight as water.

Body water is divided into two main compartments: intracellular and extracellular. The majority of body water (64%) is located inside the cells. The remaining 36% of body fluid is extracellular. Three-fourths of this extracellular fluid is interstitial (surrounding cells), and the remaining one-fourth is intravascular plasma.

Communication between these fluid compartments varies. Intracellular water does not move readily out of the cell. In contrast, in the capillary beds there is constant movement of fluids between the extracellular fluid (interstitial and intravascular) compartments. The movement of body fluid between the intravascular and interstitial space is controlled by two opposing forces: *osmotic pressure* (holding fluid in the vessels) and *hydrostatic pressure* (forcing fluid into tissue spaces). Interstitial and intravascular fluid are similar in composition except for the presence of plasma proteins (which provide osmotic pressure) in the intravascular space.

Body water balance is the result of physiologic homeostatic responses to the fluid gains (intake) and losses (output) that occur on a daily basis. The major sources of intake and output are shown in Table 28-1.

The primary organ of fluid balance is the kidney. The kidneys excrete the end products of cellular metabolism, as well as eliminate excess fluids. In order to clear the blood of wastes, they must produce a minimum of 500–600 mL of urine every 24 hr. To balance a typical amount of fluid intake, however, the usual amount of urine produced on a daily basis varies from 1 to 2 L.

Regulation of the volume, composition, and osmolality of body fluid is controlled by homeostatic mechanisms. A major regulator of intake is thirst. Thirst is stimulated by receptors in the central nervous system. Under normal circumstances, an individual ingests fluids when these receptors are activated. During illness or an altered level of consciousness, and in the aged, the thirst response may be depressed, resulting in hypovolemia and increased tonicity or concentration of the extracellular fluids (Deficient Fluid Volume).

Urine production by the kidneys is influenced by two hormonal regulatory systems, one of which is the antidiuretic hormone (ADH). When extracellular body fluids become concentrated, osmoreceptors located in the hypothalamus stimulate the release of ADH, which stimulates the kidneys to retain more water. As this retained water circulates through the extracellular fluid compartment, the concentration of body fluid is reduced. The osmoreceptors sense this change, slow the secretion of ADH, and the kidneys stop retaining water (negative feedback).

TABLE 28-1 Average Daily Fluid Gain and Loss

Intake (mL)		Output (mL)	
Oral intake (liquid and food)	2300	Urine	1500
Cellular catabolism of proteins, carbohydrates, and fats	300	Skin	600 (insensible loss by evaporation)
		Lung	300 (insensible loss by vapor)
		Feces	200
	<u>2600</u>		<u>2600</u>

Other conditions that can stimulate the secretion of ADH and lead to increased water retention by the kidneys include hemorrhage, decreased cardiac output, trauma, pain, fear, surgery, and dehydration. Drugs such as morphine, barbiturates, nicotine, and some anesthetics and tranquilizers also increase the secretion of ADH. The secretion of ADH can be inhibited by alcohol, decreased concentration of body fluids, and hypervolemic states.

Another major regulatory hormone is aldosterone, which is secreted by the adrenal cortex. Aldosterone regulates fluid volume by stimulating the kidneys to reabsorb sodium and water (an isotonic gain). During this process, sodium is exchanged for potassium or hydrogen; therefore, aldosterone also affects levels of these electrolytes. Secretion of aldosterone is increased in response to several stimuli, which include decreased sodium and increased extracellular potassium, hypovolemia, and stress states.

When blood flow to the kidneys is decreased, a receptor-like area in the glomerulus of the nephron releases an enzyme called renin. As renin circulates in the body, it converts a plasma protein in the liver into a vasoconstrictor substance called angiotensin I. When this substance enters the lungs, it is converted into angiotensin II. Angiotensin II acts directly on the adrenal cortex to increase aldosterone secretion. This then leads to extracellular volume expansion and even possible fluid volume excess if the cause of decreased renal blood flow was due to heart or liver failure.

Electrolytes

In partnership with body fluids are substances called electrolytes. These substances, mostly minerals, contribute to body function in many ways and are essential to life (Table 28-2). Electrolytes are important components of intracellular and extracellular fluids. The major intracellular electrolytes are potassium, magnesium, phosphate, and sulfate. Major extracellular electrolytes are sodium, chloride, and bicarbonate.

Electrolytes are distributed throughout the body, both intracellularly and extracellularly. In the extracellular compartment, the main electrolytes are sodium, chloride, and bicarbonate. Intracellular electrolytes are potassium, magnesium, phosphate, and sulfate.

Electrolytes develop an electric charge when dissolved in water. Electrolytes with a positive charge are called cations. Negatively charged electrolytes are called anions. Positive cations and negative anions are attracted to each other because of their opposite electric charges. When they combine with each other, they form neutral compounds that either remain in

body fluids or dissociate and regain their electric charges. When they dissociate, or ionize, they are referred to as ions.

FLUID AND ELECTROLYTE IMBALANCE

Alterations in fluid and electrolytes may occur as a primary event or as a secondary response to a preexisting disease state or to a sudden, unexpected traumatic event. When alterations of fluid and electrolytes exceed the narrow limits consistent with health, the body needs to adjust quickly.

Changes in the composition of body fluid and electrolytes may be relative or absolute. Relative losses or gains can occur when fluids or electrolytes shift from one body space to another. Absolute losses or gains occur when fluids and electrolytes are lost outside the body or added to the overall body stores by IV fluid.

The kidney has an obligatory urine output, and the body has an insensible water loss. A minimum fluid intake of 1500 mL is essential to balance these losses. If the loss of body water is greater than fluid intake (fluid volume deficit), weight loss results. If the gain of body water is greater than output, weight gain results. One kilogram of body weight gain or loss is equal to 1000 mL (1 L) of fluid.

In addition to methods of assessing fluid balance, this chapter discusses interventions for providing fluid and electrolytes to clients who have experienced alterations in their homeostasis. The rationale for interventions associated with alterations in either fluids or electrolytes is to maintain homeostasis.

Clients undergoing major surgery or trauma may be subjected to blood loss necessitating fluid replacement therapy. Clients requiring prolonged intravenous therapy may have associated nutritional losses. Support for these clients must be considered.

IV ADMINISTRATION

Initiating, monitoring, and providing care for clients with IV therapy consumes a large portion of the nurses' time each shift, and requires safe nursing practice to protect the client from complications. Up to 90% of hospitalized clients require some form of IV therapy. *Source: (Hanchett, 2004).*

Administering IV drugs can lead to medication errors, even if the nurse does not mix the medication, but hangs and monitors the IV. Whenever the nurse administers an IV, both the hospital and federal guidelines must be followed. Guidelines include being properly educated in the use of IV equipment, understanding venous anatomy to ensure proper IV selection sites, and knowing the appropriate catheter gauge and length for the vein selected. In addition, it is imperative that the nurse is knowledgeable about drugs and solutions being administered, the side effects, and treatment if a side effect occurs.

Frequent monitoring of IV infusions is a requisite for safe nursing practice. Knowing the solution infusing, medications added to the solution, and rate of infusion promotes safe care. Maintaining the IV site and following guidelines established by the Intravenous Nurses Society, The Joint Commission, and the CDC are critical to prevent complications associated with the IV site and cannula.

TABLE 28-2 Major Electrolytes

Cations		Anions	
Na ⁺	Sodium	Cl ⁻	Chloride
K ⁺	Potassium	HCO ₃ ⁻	Bicarbonate
Ca ²⁺	Calcium	HPO ₄ ²⁻	Phosphate
Mg ²⁺	Magnesium		

The CDC Guidelines for Prevention of Catheter-Related Infections state that skin should be disinfected before catheter placement and that chlorhexidine gluconate is preferred. Use of chlorhexidine gluconate has demonstrated superiority to povidone–iodine in decreasing infections at the site of IV catheter insertion. In addition to the use of chlorhexidine gluconate, the CDC recommends the use of a sterile catheter securement device such as the Statlock. This device protects the client’s skin from damage and prevents movement of the IV catheter. Movement can damage the vessel and lead to infection. Another recommendation is the use of semipermeable transparent film dressings to prevent the passage of liquids, bacteria, and viruses to the IV site. The use of this type of dressing allows easy observation and monitoring of the IV site without removing the dressing. It is recommended that tape not be used to secure the IV site. Tape used to stabilize IVs has historically been unsterile, leading to infections at the IV site. In addition, tape not only allows movement of the catheter, but also has been shown to be the cause of infiltration, phlebitis, occlusion/thrombosis, and other device-related complications. If the tape is necessary, it is highly recommended that sterile tape be utilized to prevent infection.

Intravenous devices are an important part of hospital practice for the administration of fluid, nutrients, medications, blood products, and to hemodynamically monitor unstable clients. These devices are not without problems. Catheter-related bloodstream infections can be associated with increased hospital stays, even life-threatening events or death. Peripheral venous catheters are usually not associated with these infections, whereas central vascular devices are the most problematic devices. Phlebitis and infiltration are the most common complications associated with peripheral vein catheters. The risk of phlebitis differs between sites. It is much higher if the lower limb is used as the IV site. Catheters inserted in the hand carry a lower risk of phlebitis than those inserted higher up on the wrist and arm. Providing intravenous therapy for clients is one of the main skills provided by nurses.

Most medication errors resulting in client deaths occurred with IV infusions. To meet the need for improved medication safety at the point of care, “smart technology” was developed to standardize IV infusion administration, reduce IV programming errors, and streamline IV administration processes. The infusion pumps are programmed with a database of information about medications and parameters for correct dosage and infusion rate. The pump can alert the nurse if it is not programmed correctly for a given drug. The pharmacy alters the provided database from the company to meet the specifications of the hospital and formulary that goes into the pump. There are two levels of alerts in the pump: a soft stop and a hard stop. When a minor error is detected, the pump warns the user, but will allow the user to override the alert. When a more serious problem occurs, the pump shuts down and does not allow an override.

A point-of-care “smart pump” consists of the computer (brain) that programs the infusions and contains the safety software. Lightweight, large-volume infusion modules, as well as a syringe, client-controlled analgesia (PCA), capnography

(EtCO₂), and pulse oximetry (SpO₂) modules, can be attached to or removed from the “smart pump” (brain) as needed for each client.

The safety software can also be added to some traditional infusion pumps. The hospital can configure up to 10 profiles for specific client care areas such as ICU and Medical–Surgical units. These profiles include customized operating parameters and drug libraries. Each drug library contains institution-specific parameters for up to 1000 drugs, all of which can be customized. The drug library provides the best-practice guidelines for each medication. If programmed parameters are outside of pre-established limits, the software provides an alert that must be addressed before the infusion can begin.

An IV Medication Harm Index monitors the number of potential errors that were avoided through the use of the system. Potential errors that can be detected are overdose of drugs and adverse events. Having these data available allows the hospital to identify practice issues that were difficult to identify with earlier IV pumps. Several studies have been conducted to determine the extent of the error prevention when using the “smart technology.” One of the studies indicated a 350-bed hospital averted potentially life-threatening IV programming overdoses every 2.6 days and additional potentially significant IV errors every 3.6 days (Cardinal Health, 2003). Examples of potentially significant IV administration errors included morphine sulfate reprogrammed from 100 mg to 5 mg; heparin errors with extra zeros; and 705 units insulin reprogrammed to 7.5 units (Brigham and Women’s Case Report, 2004).

This chapter presents skills for providing fluids and electrolytes, blood, and blood components, as well as pharmacologic therapy through the intravenous route. Methods for assessing baseline data and evaluating fluid and electrolyte gains or losses are included in this chapter.

CULTURAL AWARENESS

Religion and Use of Blood and Blood Products

It is important to know clients’ religious beliefs about the use of blood and blood products in order to understand their preferences in choosing to allow or not allow transfusions.

- Clients who practice Christian Science (Church of Christ, Scientist) usually do not accept use of blood or blood products in their medical care.
- Clients who are Jehovah’s Witnesses believe blood in any form and agents in which blood is an ingredient are not acceptable. Blood volume expanders are acceptable if they are not derived from blood. Mechanical devices for circulating blood are acceptable as long as they are not primed with blood initially. Their religious belief is based on scripture references and precedents in the history of Christianity. There are times when court orders are obtained for children in life-threatening situations so they may receive blood or blood products.

NURSING DIAGNOSES

The following nursing diagnoses are appropriate to include in a client care plan when the components are related to intravenous therapy.

Nursing Diagnosis	Related Factors
Deficient Fluid Volume	Excess fluid loss secondary to vomiting, increased temperature, blood loss, drainage sites or tubes, diarrhea, and diuretics
Excess Fluid Volume	Excessive fluid accumulation secondary to excess sodium intake, medications, renal or cardiac failure; inaccurate IV infusion rate
Infection, Risk for	Chronic diseases, invasive procedures, immunodeficiency, tissue destruction and increased environmental exposure
Noncompliance	Inaccurate I&O records, denial, lack of instruction regarding I&O, fluid restriction, care of IV site
Impaired Skin Integrity	Alterations in skin turgor, edema, tissue damage, IV infiltration, infection, immobilization
Ineffective Peripheral Tissue Perfusion	Loss of blood related to hemorrhage or loss related to hemodialysis

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. *Remember to wash your hands or use antibacterial gel before and after each and every client contact.*

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Chapter 28

UNIT 1

Initiating Intravenous Therapy

Nursing Process Data

ASSESSMENT Data Base

- Validate physician's order for IV therapy.
- Assess need for client teaching about IV therapy.
- Evaluate client for IV site selection.
- Select appropriate vessel for venipuncture.
- Determine appropriate type and size of cannulation device for client.
- Determine IV equipment needed.

PLANNING Objectives

- To maintain fluid and electrolyte balance
- To aseptically prepare infusion system
- To identify and prepare the appropriate site for venipuncture
- To perform successful venipuncture using appropriate equipment

IMPLEMENTATION Procedures

- Preparing the Infusion System1055
- Adding Extension Tubing1057
- Preparing the Venipuncture Site1057
- Using a Vascular Imaging Device1059
- Inserting a Winged Needle1060
- Inserting an Over-the-Needle Catheter1062

EVALUATION Expected Outcomes

- Fluid and electrolyte needs are met.
- Appropriate IV site is selected and IV inserted without difficulty.
- IV fluids infuse at prescribed rate without complications.
- IV equipment is appropriate for client.
- IV site is maintained using sterile technique.

Critical Thinking Application1067

- Expected Outcomes 1067
- Unexpected Outcomes 1067
- Alternative Actions 1067

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Preparing the Infusion System

Equipment

IV solution in bag

NOTE: The only glass bottles used today are for infusions of certain medications (e.g., nitroglycerin, amiodarone, and lipids). Check facility procedures for correct infusion of these medications using the glass bottle.

Primary administration tubing set (compatible with infusion pump)

Add-on particulate filter (according to agency policy) compatible with infusion pump psi

Electronic infusion device or free pole for bag suspension and gravity infusion

Clinical Alert

Take IV solutions out of refrigerator (if stored in refrigerator) and allow to warm to room temperature. This will reduce the number of air bubbles in the IV solution.

It is difficult to detect air bubbles because gas is well assimilated into liquid at low temperatures; thus air bubbles are fully assimilated into the IV solution when kept in refrigerator. Once solution warms to room temperature, air bubbles appear.

Preparation

1. Verify the type and amount of solution with physician's order.
2. Perform hand hygiene.
3. Check pharmacy label for client's identification, solution type, additives, and expiration date.

Except when infusing TPN, TPN with lipids, or certain IV medications, PCAs, continuous epidurals, and blood products, in-line filters are not recommended. There is no evidence to suggest that in-line filters prevent infections associated with intravascular devices and infusion systems. Some studies do suggest that they may reduce the incidence of infusion-related phlebitis; however, it has not been proven. Because studies do not justify the cost of the in-line filters, the CDC does not recommend them for infection control purposes. Before hanging drugs, check the drug formulary to determine the need for an in-line filter.

4. Select IV tubing appropriate for infusion device.
5. Select add-on filter if indicated.

Procedure

1. Remove outer wrap around IV bag if necessary. (It may be wet due to condensation.)
2. Inspect bag carefully for tears or leaks by applying gentle pressure to bag.
3. Hold bag up against both a dark and light background to examine for discoloration, cloudiness, or particulate matter. ► **Rationale:** Any evidence of change may indicate contamination, and bag should be discarded.
4. Hang the IV bag on the IV pole. Close tubing roller clamp. (Affix time strip on bag according to facility policy.)
5. Remove plastic protector from tubing spike (end of tubing with drip chamber).

1 Most hospitals require a "Red Label" if potassium or other drugs are pre-added to the solution.

2 Clamp tubing before spiking IV fluid bag.

3 Pull to remove port cap on IV bag.

4 Squeeze drip chamber while spiking bag port, maintaining sterility.

5 Squeeze and release drip chamber to fill.

6 Fill drip chamber one-half full of fluid.

7 Close tubing clamp when priming is complete.

6. Squeeze drip chamber while inserting tubing spike into bag port, holding port securely to prevent contamination. ► **Rationale:** Squeezing chamber during insertion prevents air entry into bag.
7. Release pressure on the drip chamber until chamber is partially full.
8. Attach add-on terminal filter (if indicated).
9. Remove protective cap at end of tubing.
10. Open clamp on line to prime tubing and filter.
11. Hold tubing tip higher than tubing-dependent loop while priming. ► **Rationale:** Air rises and passes out as fluid primes tubing.
12. Invert and tap Y injection sites to remove air as tubing primes.
13. Hold filter (if attached) pointing downward so proximal (closest to client) half of filter fills with fluid first, then invert to complete filter priming, tapping air out as filter primes.
14. Close tubing clamp when primed.
15. Load administration set into electronic pump according to manufacturer's instructions. Most pumps require dedicated tubing and specific loading format.

Clinical Alert

Do not use felt-tip pens to mark directly on IV plastic bag. ► **Rationale:** The ink may leach through the plastic and contaminate the solution.

Adding Extension Tubing

Equipment

- Extension tubing
- 2% Chlorhexidine gluconate
- Injection cap with Luer-Lok adapter, if necessary
- Syringe cannula
- Two syringes of 0.9% preservative-free normal saline (NS) in volume at least twice the volume capacity of the catheter and any add-on devices

Procedure

1. Gather equipment and determine type of cap, if needed. Extension tubing may be attached directly to IV catheter.
2. Swab tubing's terminal injection cap and insert syringe cannula.
3. Remove protector at opposite end and prime extension tubing with 1 mL of NS solution.
4. Add needless IV access device to tubing or use Luer-Lok with attached extension tubing.

Clinical Alert

Peripheral IVs should be started using aseptic technique. IVs started without proper asepsis, for example, in an emergency or outside the hospital, should be replaced at the earliest opportunity, and within 24 hr.

▲ Swab injection cap and insert syringe cannula.

5. Swab client's established IV cannula resealable cap and connect extension tubing or insert primed extension tubing directly into client's IV catheter.
6. Flush with 0.9% NS at twice the volume (capacity) of the catheter and any add-on devices.

NOTE: INS standards discourage the use of additional routine extension tubing. ► **Rationale:** This adds additional potential source of IV contamination.

Preparing the Venipuncture Site

Equipment

- Prepared IV administration setup or sterile needless access device
- Single-use, latex-free tourniquet (constricting band)
- Chlorhexidine gluconate swab (not used on infants under 1000 grams)
- Sterile needle or catheter for venipuncture
- Half-inch wide sterile tape
- Transparent semipermeable dressing
- Securement device
- Gloves (clean or sterile depending on facility policy)
- Electronic infusion pump

Preparation

1. Check physician's orders and MAR.
2. Identify client using two forms of identification.
3. Assemble equipment.

Procedure

1. Explain procedure.
2. Provide privacy.

3. Hang solution bag and primed administration set within easy reach.
4. Position client and adjust lighting as necessary. Explain procedure to client.
5. Perform hand hygiene and don gloves.
6. Select appropriate IV device. Catheter gauge should be smallest size that allows greatest flow, without occluding vessel lumen.

NOTE: Over-the-needle catheters are used most commonly for IV fluid/blood administration. A smaller catheter (22 gauge) may be used for routine antibiotics or maintenance fluids, but a larger catheter (20 gauge) is needed for blood products. For irritating medications, a small-bore catheter is preferable.

7. If possible, select a vein on client's nondominant arm. Also consider client's activity level and expected duration of IV therapy.
 - a. Inspect both of client's arms, palpating and visualizing the course of the veins.
 - b. Vein should be superficial, easily palpated, and large enough for needle insertion and advancement.
 - c. Area should be free of lesions or scars and away from joints and areas of frequent motion. ► **Rationale:**

▲ Explain procedure to client.

Motion frequency increases the risk of mechanical phlebitis.

- d. Do not use the antecubital fossa except in atypical circumstances.
- e. Do not use the same vein below a site where infiltration or phlebitis has occurred.
- f. Select shortest and smallest cannula that will be sufficient to deliver fluids/medications. ► **Rationale:** The longer the catheter, the greater the risk of infiltration, infection, and thrombus formation. A catheter that is too large does not allow for adequate blood flow around catheter, and this can lead to phlebitis.
- g. Distal end of vein should be selected first, reserving more proximal sites for future IV therapy.
- h. Select larger veins for hypertonic solutions, blood, and viscous fluids.

Clinical Alert

Do not shave the venipuncture site. Shaving can facilitate the development of infection through the multiplication of organisms in resulting microabrasions. Hairy sites can be clipped with scissors.

▲ Equipment for IV start for over-the-needle.

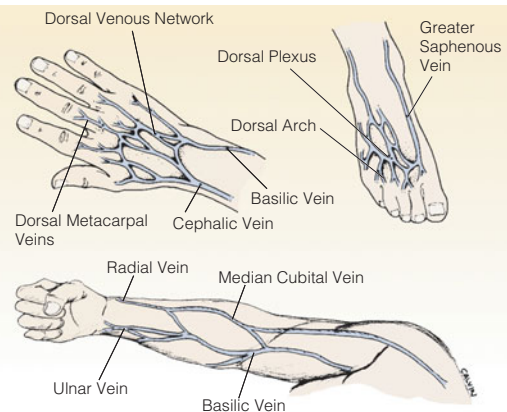

▲ Hang IV bag and primed administration set within easy reach.

- i. Avoid using veins in affected arm after mastectomy.
 - j. Lower extremity sites are associated with complications (e.g., thrombosis) and should be used ONLY if necessary. The legs and feet of diabetic clients and those with peripheral vascular disease should never be used. Check the facility policies to determine if a physician's order is needed when using lower extremity for IV site.
8. Apply tourniquet 6 in. above the selected site to distend vein. Overlap ends of tourniquet, lift and stretch, then tuck top end under bottom; keep ends pointing away from puncture site. ► **Rationale:** Tourniquet traps blood and engorges vein for better visibility.
 9. Prepare vein for venipuncture.

Clinical Alert

Some agencies allow only certified IV therapists to perform venipuncture.

- a. Place arm in dependent position. ► **Rationale:** This position increases capillary refill and venous distension to increase chance of successful venipuncture.
- b. Lightly tap vein. ► **Rationale:** To distend vein in preparation for venipuncture.

▲ Anatomical sites used for venipuncture.

▲ Apply tourniquet 6 in. above insertion site.

- c. Ask client to open and close fist several times to help distend selected vein.
 - d. If vein is difficult to palpate, release tourniquet and apply warm, moist compresses to arm for 10–20 minutes before reapplying tourniquet.
10. Prep site with chlorhexidine gluconate swab. Cleanse area using back-and-forth motion, 2–4 in. in diameter.
 ► **Rationale:** Vigorous skin preparation decreases organisms at the venipuncture site.

Clinical Alert

Latex-free tourniquets should be used and disposed of after each use.

▲ Use back-and-forth-movement to cleanse site with chlorhexidine gluconate.

11. Let prep solution air dry for a minimum of 30 seconds or until skin is dry. ► **Rationale:** Area must be dry for antimicrobial action before continuing with venipuncture. Do not fan to dry skin.
12. Do not touch selected insertion site after prepping.
13. Proceed to appropriate procedure for inserting the needle.

Clinical Alert

When repetitive peripheral IV access fails and IV medication doses and fluids are missed, many facilities are now inserting PICC lines or implantable ports. Use of PICC lines decreases incidence of phlebitis as little as 2% to 22%.

Using a Vascular Imaging Device

Equipment

- Infrared or transillumination device
- Specific type of IV equipment

NOTE: The infrared device projects invisible infrared or near-infrared light waves onto the client's skin. The light is reflected off tissue surrounding vein, but not off blood inside the veins so it can differentiate between tissue and veins. The transillumination device is applied to the client's skin by focusing bright visible light onto the skin; it illuminates the tissue under the skin and helps locate superficial veins.

Procedure

1. Obtain all IV equipment necessary for specific type of infusion and IV infrared machine.
2. Identify client using two identifiers.
3. Explain procedure to client. The vascular imaging device can highlight vein location. It determines sites for placement of IV. Identifying sites can minimize pain and provide more options where sites may be secured. It will not come in contact with client, nor will they experience heat at the site.
4. Instruct client to take off all jewelry in the area that will be assessed. ► **Rationale:** Metal reflects light and can interfere with the projected image, causing blank or distorted images in some instances.
5. Plug in device and lock wheels.
6. Turn on device and calibrate. Place the calibration card on a horizontal surface and position the device head perpendicular over it, approximately 2 feet away. Check the card to ensure the device was successfully calibrated. It will indicate when it is calibrated.
7. Place the device head perpendicular to the area and 2 feet from where the IV is to be inserted.
 ► **Rationale:** An inaccurate focus can cause a shift from the projected image away from the vein location, cast shadows, and decrease image quality.
8. Check the focus by making sure the text around the image border is clean and legible.
9. Using the projected image, identify a vein site suitable for IV access.

10. Move the imaging modes and contrast levels to determine the view that is most useful to assist with the venipuncture.

NOTE: If the site has excessive hair, select the Hair Reduction Mode. ► **Rationale:** This mode highlights the veins and minimizes the shadowing caused by the hair.

11. Perform the venipuncture. Insert the needle just outside the lighted area to prevent reflection from the metal of the light. Another option is to turn off the light after marking the IV site with a surgical skin marker and access the vein at the mark.

Inserting a Winged Needle

Equipment

- Prescribed solution, infusion administration set, and electronic infusion pump
- Protective resealable injection cap (if indicated)
- Syringe with 0.9% preservative free NS, 2–3 times the volume of catheter and all connecting devices, for locking resealable injection cap
- Tourniquet or blood pressure cuff
- Sterile winged (small vein) needle (typical hub replaced by two flexible wings) with attached tubing and resealable injection cap or short tubing to affix to infusion administration tubing. (Used for IV push medication lasting only 24 hr.)

NOTE: Winged needles are available as steel needles or flexible over-the-needle catheter types. The hub is replaced by flexible wings for easier insertion and taping.

Scalp vein needle: Stainless steel—gauge 17–25; or Siliconized—gauge 18–25 if using scalp site (usually for infants).

- Chlorhexidine gluconate swab
- Sterile tape
- Transparent dressing
- Gloves

Procedure

1. Follow steps in Preparing the Venipuncture Site.
2. Select a winged needle for adults and for children, infants, and elderly clients who have small or fragile veins. Winged-needle access is only used for intermittent infusion access or access needed for less than 24 hr.

▲ Select site at distal end of vein to preserve future proximal IV sites.

▲ Remove protective cap from winged needle.

▲ Insert needle at 30° angle through skin below selected vein.

▲ Attach sterile resealable injection cap to end of winged needle tubing.

3. Carefully affix end of IV infusion tubing to end of winged needle tubing. Remove sterile cover from needle and run fluid through needle to prime tubing, then clamp it, and replace needle cover.
4. Apply tourniquet to distend selected vein.

▲ Use chevron method to secure winged small vein needle; then apply occlusive transparent dressing over infusion site.

▲ After chevron method secure needle, loop, and tape tubing.

5. Prep the selected site with chlorhexidine gluconate; it should be applied with back-and-forth motion for a minimum of 30 seconds. Allow to air dry.
6. Remove protective cap from winged needle and hold needle by its wings, anchor vein by placing thumb below client's vein.
7. Place thumb of nondominant hand below selected site and pull skin taut. With needle bevel up, enter client's skin at a 30° angle. You may use either of these methods:
 - a. Enter skin next to or alongside vein. Flatten angle to 15° once needle is under skin and then enter vein from side.
 - b. Insert needle through skin below intended puncture site, then enter vein. ► **Rationale:** Inserting needle through skin and into small vein with one thrust will result in hematoma formation.
8. Follow course of vein. Sudden "pop" and lack of resistance is felt when vein is entered.
9. Observe for flashback of blood in needle tubing.
10. Carefully advance needle up course of the vein until it reaches hub.

▲ Bring sterile tape over needle and secure needle and wings with chevron method.

▲ Cover site with transparent dressing: date, time, initials, and size of catheter.

11. Release tourniquet.
12. Inject normal saline for lock, or affix IV tubing, open clamp, and observe drip chamber. ► **Rationale:** Fluid should flow easily, and there should be no sudden swelling at the IV site.
13. Reduce flow rate to keep open until you have secured needle in place.

General Time Frame for Tubing Changes

- Primary and secondary tubing— 72 hr
- Primary intermittent tubing—24 hr
- Extension tubing—replace when vascular device is replaced (it is considered part of the IV system)
- TPN and lipids—every 24 hr
- Blood or blood products tubing—every 4 hr or after 2 units of blood
- Always check facility policies and procedures and follow their regulations.

IV Insertion Sites**Select**

Use vein in nondominant arm
 Use smallest catheter for site
 Use most distal sites first. Save antecubital site for emergencies.
 Assess client's condition; vein condition, size, location; type and duration of therapy

Avoid

Antecubital fossa
 Lower extremities
 Previously used veins and injured or sclerotic veins
 Veins in affected arm with dialysis fistula or axillary dissection

EVIDENCE-BASED PRACTICE**Needle Sticks Related to IV Devices**

In a 2002 study of 47 facilities, 1,693 needle-stick injuries were reported. One-half of all documented injuries were caused by devices used by nurses throughout their daily practice. The number one injury was the disposable syringe (35%). The second most common injury was the use of a winged steel needle (7%). Most injuries occurred after use, when the devices were being discarded. Most facilities have converted to needleless IV systems for connecting IV lines.

Source: Perry, I., & Metules, T. (2004, November). How to avoid needlesticks. *RN*, 28ns2–28ns7 (supplement).

14. Secure needle with half-inch wide sterile tape and place over the hub or attach a securement device according to manufacturers' directions.
15. Loop and tape IV tubing a short distance from needle.
16. Apply occlusive transparent dressing over infusion site. Gently smooth dressing from center to edges.

► **Rationale:** Excessive tension can cause skin shearing. Do not seal dressing's edges with tape and do not cover dressing with roller gauge.

17. Remove gloves.
18. Label dressing with date, time, and initials, and size of catheter inserted.
19. Establish prescribed infusion rate by pump or calculated gravity flow drops per minute.
20. Change site every 48 hr or if it becomes soiled.

► **Rationale:** According to studies, an increased risk of thrombophlebitis and bacterial colonization of catheters occurs after 72 hr.

Clinical Alert

Meticulous care must be used to insert the winged-tipped needle because these needles lead to the majority of reported needle-stick injuries.

Clinical Alert

All tape placed under transparent dressings should be sterile. Check facility policy before securing IV site. Some hospitals do not allow tape under the transparent dressing.

Source: Intravenous Nurses Society, Standard 49, 2006.

Clinical Alert

The CDC has not established a recommendation for hang time of IV fluids. Follow hospital policy and change fluids accordingly.

Inserting an Over-the-Needle Catheter**Equipment**

Tourniquet (constrictive band)
 2% Chlorhexidine swab
 Sterile over-the-needle catheter sizes 12–24 gauge, ½–2 in. long

NOTE: Some winged devices are over-the-needle catheters.

Optional: EMLA cream (lidocaine and prilocaine) cream or syringe with local anesthetic (lidocaine) and 25–26-gauge needle (check agency policy or physician's orders and client sensitivity before using)

Prepared administration set and infusion solution if ordered
 Electronic infusion device
 Protective needleless cap if required
 Syringe with at least 2–3 times the volume capacity of the catheter and add-on devices with preservative-free normal saline for lock (if indicated)
 Sterile half-inch tape
 Sterile gloves

Procedure

1. Prepare IV system and follow steps in Preparing the Venipuncture Site.
2. Select appropriate size over-the-needle catheter.
3. Perform hand hygiene and don gloves.
4. Position extremity for venipuncture.

NOTE: Apply EMLA cream or inject site (intradermally) with small wheel of local anesthetic, according to hospital policy. (Allow 60 minutes for cream and 90 seconds for anesthetic to take effect.)

5. Place extremity flat on bed or place in a dependent position. ► **Rationale:** Gravity will slow venous return and thus dilate the vein. If vein is not distended sufficiently for easy venipuncture, ask client to make a fist or lightly tap on the vein with your fingertips.
6. Hold catheter with bevel up and examine the integrity of end of catheter.
7. Apply traction to stabilize vein.

8. With bevel of needle up, insert needle/catheter unit at a 45° angle into client's skin either:
 - a. Alongside of vein, or
 - b. About a half-inch distal to selected puncture site.
9. Revisualize vein; reduce angle of cannula to 30°, pierce vein. A “pop” will frequently be felt. Observe for backflow of blood in plastic hub. Slide needle into vein about 1/4 in. after backflow observed. Continue to apply

traction. ► **Rationale:** This indicates you are in the vein. If vein is hard to find, use the vascular imaging device if the facility has one.

10. Hold needle and gently advance plastic catheter hub over needle and up vein no more than halfway.

NOTE: Maintain aseptic technique throughout procedure and prevent trauma to site and vein. These catheters are associated with a very high rate of phlebitis—80% in one study.

1 Inspect integrity of needle tip.

2 Attach saline-filled syringe to extension tubing.

3 Insert needle, with bevel up, at 30° angle.

4 Check for blood return or check the flashback.

5 Pick up protective covering.

6 Separate, but do not completely remove, the stylette.

11. Stop and separate, but do not completely remove, the stylet from catheter.
12. Advance only the catheter until catheter hub meets the skin. The catheter moves over the stylet. If the hub is against the vein valve, you will need to initiate the infusion of IV fluids in order to float catheter to the middle of the vein.
13. Release tourniquet. Leave stylet in catheter while you tape catheter to the skin. ► **Rationale:** Stylet acts like a plug, and leaving it partially in place you don't have to hurry to tape catheter to the skin.
14. Tape catheter under hub of needle, without touching puncture site, and without touching hub/catheter juncture. Securement device may be used in place of taping procedure.
15. Place digital pressure above distal end of catheter and carefully remove stylet. Maintaining aseptic technique, connect catheter to IV tubing or place a saline lock on catheter.
16. Connect catheter to needleless cap or insert IV tubing into catheter.

Clinical Alert

If no blood is observed and you did not feel the catheter enter the vein, pull back on entire catheter apparatus without exiting skin. Reassess vein position, then reattempt venipuncture. If you are not successful, remove catheter and look for a different site. Remember the catheter is now contaminated and cannot be used again. Most facilities allow the nurse to attempt two venipunctures; if unsuccessful, they must notify another professional to attempt venipuncture.

EVIDENCE-BASED PRACTICE

Flushing With Low-Dose Heparin

There are many conflicting studies indicating outcomes that are both pro and con for using low-dose heparin with peripheral venous catheters. In one study, low-dose heparin infused continuously through peripheral venous catheters required further study to determine effectiveness in prolonging catheter life. Studies have proven that using heparin in arterial catheters is of benefit. Using intermittent heparin flushes for peripheral IV catheters also requires further validation, as it seems to be no more effective than using NS flushes.

Source: Randolph, A., Cook, D. J., Gonzales, C. A., & Andrew, M. (1998, March 28). Benefit of heparin in peripheral venous and arterial catheters: Systematic review and meta-analysis of randomized controlled trials. *British Medical Journal*, 316(7136), 969–975.

Flushing Using Saline or Heparin

In a second study completed at the Mayo Clinic, Rochester, MN, a prospective, randomized, and double-blind study was completed on 73 hospitalized pregnant women between 24 and 42 weeks gestation. The clients were randomly assigned to receive a peripheral intermittent IV lock flush of either saline or heparin after each medication administration, or at least every 24 hr. The IV sites were assessed every 12 hr for signs of phlebitis. The results of the study indicated there were no statistically significant differences in IV lock patency or in phlebitis between heparin or normal saline flushes. The conclusion was that the study provides support for both normal saline and heparin in the doses studied as being equally effective in the maintenance of peripheral IV locks. With the small number of participants, the authors suggest additional studies are needed to determine optimal therapy over time.

Source: Niesen, K. M., Harris, D. Y., Parkin, I. S., & Henn, L. T. (2003). The effects of heparin versus normal saline for maintenance of peripheral intravenous locks in pregnant women. *Journal of Obstetric, Gynecologic, Neonatal Nursing*, 32(4), 503–508.

Evaluation Criteria

Catheter sites are evaluated at least each shift for both phlebitis and infiltration using evaluation criteria established by the Intravenous Nurses' Society (standards were revised in 2000).

Phlebitis

- 0 = no clinical symptoms
- 1+ = erythema at access site with or without pain
- 2+ = pain at access site with erythema and/or edema
- 3+ = pain at access site with erythema and/or edema, streak formation
- 4+ = pain at access site with erythema and/or edema, streak formation, palpable venous cord >1 in. in length, purulent discharge

Note: No catheter should remain in place with signs of phlebitis, even with good blood flow and IV infusion rate.

Infiltrations

- 0 = no symptoms
- 1 = skin blanched, edema

- 2 = skin blanched, edema 1–6 in. in any direction, cool to touch, with or without pain
- 3 = skin blanched, translucent, gross edema >6 in. in any direction, cool to touch, mild-moderate pain, possible numbness
- 4 = skin blanched, translucent, skin tight, leading, gross edema >6 in. in any direction, deep pitting tissue edema, skin discolored, bruised, swollen, circulatory impairment moderate-severe pain, infiltration of any amount of blood product, irritant, or vesicant.

Note: Infiltrations should be diagnosed well before obvious swelling occurs. Most infiltrations should be warm packed to promote reabsorption of fluid into vascular bed and out of tissues, except in case of infiltration by a vesicant drug, then follow facility policy or drug manufacturer's directions.

EVIDENCE BASED PRACTICE

Heparin Flush vs. Saline Flush for Maintaining CVC

Two studies completed at the University of Pennsylvania and Seattle's Children's Hospital suggested there was insufficient evidence to conclude that a heparin flush is more effective than a saline flush. Flushing CVCs with heparin poses a risk of heparin induced thrombophlebitis. In the University of Pennsylvania study, the evidence for using heparin to flush CVCs is small, and the published studies reviewed by the committee were of low quality, therefore the nursing policy for maintaining CVCs was changed to flushing catheters with saline only.

In the first 18 months after the change in policy there was a reduction in catheter-assisted blood stream infections, no increase in catheter or vein occlusion, and a reduction in nursing workload without compromising patient safety.

In a study conducted at Seattle's Children Hospital and reported in *Nursing Times*, February 12, 2010, there was no evidence to support a difference between normal saline and heparin for patency of locked peripheral IVs. Seattle elected to conform to the Infusion Nurses Society (INS) standards published in late 2008. It recommends the use of NS for flushing peripheral IVs.

Source: Anderson, Barbara: Abstract (2010, February 12). A comparison of heparin and saline flush to maintain patency in central venous catheters. *Nursing Times*.

Source: Seattle Children's Clinical Effectiveness Program. Executive Summary NS Flush PIV. December 12, 2009. www.seattlechildrens.org/doc/executive-summary.

17. Open clamp and observe drip chamber for fluid flow (or preserve patency of system by injecting 2–3 times the amount of volume of the catheter and connecting devices using 0.9% preservative free normal saline through access site). There should not be any sudden swelling at IV site.
18. Observe for signs of infiltration.
19. Reduce flow and proceed with stabilizing the catheter.
 - ▶ **Rationale:** Stabilizing the catheter reduces the need for unscheduled restarts and risks for health workers from unnecessary exposure to needles.
20. Prep site with skin protectant and place catheter in securement device.
21. If using sterile tape, do not tape over connectors.
 - ▶ **Rationale:** Taping impedes access to the IV site in emergencies. Cover insertion site with sterile transparent dressing.
22. Loop IV tubing only once to prevent decreasing length of tubing.
 - ▶ **Rationale:** Too many loops in tubing reduce distance from IV solution container to client's IV site.

7 Attach extension tubing.

8 Backflush and instill 3 mL of normal saline.

9 Prep site with skin protective for Statlock device.

10 Place Statlock under cannula with arrows pointing up.

▲ 11 Remove cover carefully and press down on skin.

▲ 12 Anchor tubing with tape.

▲ 13 Place date, initials, and size of catheter on dressing tab.

▲ 14 Place transparent dressing over site.

▲ 15 Secure dressing and place tab on dressing.

This can put excess pressure on IV site and potentially cause catheter to dislodge from vein or infiltration to occur.

23. Loop and tape tubing to client's arm a short distance from site.
24. Set drip rate according to physician's order.

25. Label IV site with date, time, initials, and size of catheter.
26. Remove gloves and perform hand hygiene.
27. Change cannula and infusion site every 72 hr unless infiltrated, site shows evidence of phlebitis, or cannula compromised.

IV catheter stabilization devices should include manufactured catheter stabilization devices, sterile tape, and surgical strips. The INS promotes the use of manufactured catheter stabilization devices such as the StatLock IV catheter securement device.

Source: (2006). Catheter stabilization. In *Infusion nursing: Standards of practice* (chapter 43). Hagerstown, MD: Lippincott Williams & Wilkins.

Clinical Alert

If using needleshielded Angiocath system, once the "flash" is noted and catheter is advanced, the retract button is pushed and the needle automatically shielded.

DOCUMENTATION for IV Therapy

- Time and date of insertion
- Location of insertion site, name of vein cannulated
- Gauge length and type of needle/catheter inserted
- Number of attempts (if more than one)
- Type of dressing applied
- Flush administered for cannula patency
- Type, amount, and rate of solution infused
- Status of IV site
- Client response to procedure

CRITICAL THINKING Application

Expected Outcomes

- Fluid and electrolyte needs are met.
- Appropriate IV site is selected and IV inserted without difficulty.

Unexpected Outcomes

Venipuncture is unsuccessful for needle/catheter insertion.

- IV fluids infuse at prescribed rate without complications.
- Appropriate IV equipment for client.
- IV site is maintained using sterile technique.

Alternative Actions

- Remove needle/catheter, apply pressure at insertion site until bleeding stops. (This prevents ecchymosis at site.) Apply Band-Aid.
- Apply small pressure dressing if client on anticoagulant therapy.
- Select another site more proximal in vein or use another extremity.
- Avoid the one-step entry method since this frequently results in a through-and-through vein puncture.
- After two failed attempts, seek a more experienced person to perform venipuncture.
- Place extremity in dependent position before placing tourniquet. Allows vein to fill.
- Place warm compress on extremity to increase vasodilation before placing tourniquet.

Vein rolls and is difficult to enter.

- Apply traction with thumb and index finger to stabilize skin and vein; maintain traction until venipuncture complete.
- Select a smaller gauge catheter.
- Advance catheter slowly.

Vein is fragile and “balloons” around needle on vein entry.

- Release tourniquet as soon as vein entry is evident.
- Avoid use of tourniquet if veins are very fragile or client is taking an anticoagulant.
- Enter vein with needle bevel down.

Infiltration occurs.

- Place warm moist pack, using warm towel, enclose area from fingertips to elbow. Place extremity in plastic bag with open end at elbow. Leave in place no more than 10 minutes.

Vesicant drug infuses into tissue.

- Clamp IV tubing.
- Infuse antidote for specific medication, according to physician orders.

Chapter 28

UNIT 2

Intravenous Management

Nursing Process Data

ASSESSMENT Data Base

- Assess site for erythema, swelling, or pain.
- Assess infusion for correct solution, amount, and flow rate.
- Assess need to change IV to saline lock.
- Assess need to change client's gown while IV is infusing.
- Assess need to change IV solution/administration set and infusion site.

PLANNING Objectives

- To maintain the IV site free from erythema, swelling, or pain
- To monitor the IV infusion rate accurately
- To change a gown while maintaining the IV site
- To discontinue IV therapy without complication
- To convert IV to saline lock

IMPLEMENTATION Procedures

- Regulating Infusion Flow Rate1069
- Using an Electronic Flow-Control Device1070
- Using a “Smart” Pump1072
- Using a Syringe Pump1074
- Managing the IV Site1075
 - For IV Administration Sets1076
 - For Converting from Continuous IV to a “Lock”1076
 - For Applying a Securement Device1076
 - For Applying a Transparent Dressing1076
- Converting IV to Saline Lock1077
- Changing Gown for Client With IV1078
- Discontinuing an IV1078

EVALUATION Expected Outcomes

- Fluids are administered without adverse effects.
- IV site remains clean without signs of infection or filtration.
- IV is converted to a saline lock and is functioning properly.
- Client's gown is changed while maintaining IV placement.
- IV is discontinued intact; site remains free of infection or bleeding.

Critical Thinking Application1080

- Expected Outcomes 1080
- Unexpected Outcomes 1080
- Alternative Actions 1080

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Regulating Infusion Flow Rate

Procedure

1. Check manufacturer's drip-rate calibration on administration set package. Macro drip sets vary from 10 to 15 gtt per 1 mL. Microdrip factor is 60 drops/mL.
2. Check physician's order for amount of fluid to be delivered per unit of time (e.g., 1 L every 8 hr, or hourly flow rate such as 100 mL/hr).
3. Calculate flow rate.
 - a. To find the number of milliliters to be given per hour:

$$\frac{\text{Total solution}}{\text{No. of hours to run}} = \text{mL/hour}$$

- b. To find drops per minute:

$$\frac{\text{mL/hr} \times \text{drop factor}}{60 \text{ minutes}} = \text{gtts/minute}$$

IV Calorie Calculation

- 1000 mL of D₅W provides 50 g of dextrose.
- 50 g of dextrose provides 4 Cal/g; therefore, multiply 50 g × 4 Cal.
- 1000 of mL D₅W provides 200 Cal.
- Usual IV fluid maintenance is 2000–3000 mL/day (400–600 Cal/day).
- 4 cal/g is used in calculation; however, it is actually 3.4 cal/g.

▲ Count drops per minute to check accuracy of drip rate.

4. Note drip chamber; count the drops in 1 minute (or in 15 seconds and multiply by 4).
5. Adjust tubing clamp until the chamber drips the desired number of drops per minute (or 15-second increment).
6. Monitor flow rate frequently—adjustments to maintain desired delivery are often necessary.

Factors That Influence IV Flow Rates When Using Gravity for Infusion

- Warm fluids drip faster than cold fluids.
- The higher the bag is above insertion site, the faster the infusion.
- The more IV administration is tilted, the larger each drop from drip chamber.
- The larger the catheter diameter, the faster the flow rate.
- The longer the catheter, the slower the flow rate because of resistance.
- Increased blood pressure or coughing will slow the flow rate (this is a temporary situation usually).

Note: Because of these variables, manual control of IVs is not recommended. IV pumps are the most predictable method of infusing fluids.

Using an Electronic Flow-Control Device

Equipment

- Electronic infusion device (pump)
- Device-compatible IV administration set
- Needleless access device
- Gloves

Preparation

1. Verify client using two identifiers.
2. Attach controller to IV pole.
 - a. Attach controller to the IV pole so it is below and in-line with IV container.
 - b. Plug machine into electric outlet (unless using battery-operated).

NOTE: Batteries last up to 6 hours. Keep device plugged into electric outlet unless it is necessary to move device.

Procedure

1. Explain procedure to client and discuss the various sounds that can be heard during the use of the equipment.
2. Perform hand hygiene.

Clinical Alert

Observe IV site frequently when pumps are used. IV pumps do not normally detect infiltration at the IV site. Infiltration does not produce enough pressure to trigger an alarm. Check for edema, cool skin, discomfort, and tenderness at the IV site.

IF Alarm Sounds, Check the Following

Most devices have a message system that specifies the exact problem. You should be prepared to troubleshoot various components of the system.

- **Infusion Complete:** When the exact volume to be delivered is set and the volume limit has been reached, an alarm sounds and the machine goes to a KVO “keep-open” mode. Establish if the total volume of the container has been delivered; change the solution container if needed, and reset the volume to be infused.
- **Occlusion:** All devices sound an alarm when they cannot maintain delivery in the face of increasing resistance. In this instance, check the insertion site for infiltration and look for position problems, pinched tubing, closed clamp, turned stopcock, or clogged filter.
- **Other Problems:** Other messages may indicate “air in the line,” “low battery,” “cassette” (improperly loaded), or “free flow.”
- **Nursing Action:** Check trouble spot carefully, readjust, and restart the infusion.

▲ Baxter: Multiple Channel Pump.

3. Close regulating clamp on the set tubing before hanging bag.
 4. Spike IV solution bag.
 5. Fill drip chamber to minimum one-third full. ► **Rationale:** This amount allows sufficient air space in drip chamber.
 6. Prime tubing by opening regulating clamp slowly and allowing tubing to fill with IV solution. If using a cassette-type tubing, follow package instructions to correctly prime the cassette portion of the tubing that engages into the control device.
- NOTE:** Check if tubing has anti-free-flow device that must be opened before primary tubing.
7. Follow manufacturer’s instructions to load administration set into device, taking care to fit tubing and cassette into appropriate receptor sites. (One type of pump is a multiple-channel pump that can infuse three different IV solutions at one time.)
 8. Close device door and latch.
 9. Perform hand hygiene and don gloves.
 10. Check that client’s venipuncture site is free from signs of vein irritation or infiltration.
 11. Connect administration set tubing to established infusion site.
 12. Open regulating clamp on administration set.
 13. Turn device ON.

14. Set device parameters for operation, again following manufacturer's instructions or machine's setup prompts. Parameters may include:
 - a. Infusion (e.g., primary)
 - b. Volume to be infused
 - c. Rate (mL/hr)
 - d. Pressure (measure can vary; e.g., mmHg, cm H₂O, or psi)
15. START device when parameters are set.
16. Observe that infusion is running properly.
17. Remove gloves and perform hand hygiene.
18. Check client's infusion site frequently.

Infusion Pump

In contrast to gravity flow devices, positive-pressure infusion pumps are more accurate in the preselected volume delivery by adding pressure to overcome resistance to fluid flow produced by tubing diameter, filter, viscosity of infusing fluid, cannula, etc. Pumps usually require use of specially designed administration sets. When the system is working with normal resistance, delivery pressure is minimal. When resistance (5 psi over baseline) develops in the catheter or tubing, the pump adds pressure (within limits) to maintain infusion. Changes in resistance at an insertion site due to infiltration or thrombosis may not set off the system's alarm, and site problems could become serious. When the pump's maximum pressure limit is reached, an occlusion pressure alarm sounds. The nurse must become familiar with infusion devices by reading the manufacturer's literature and adhering to all instructions to ensure safe, efficient operation.

Smart IV Pumps

- Smart pumps have a "brain" (computer).
- Nurses are alerted when a pump setting does not match the facility's drug administration guidelines.
- Data is logged from pump to pharmacy computer: time, date, drug that was infused, concentration, programmed rate, and volume infused are recorded.
- Individual facility pharmacists create the data base of information for their own facility, and then the information is programmed into the pump.
- Facilities program pumps with specific data sets or "profiles." Each area of the facility develops their own drug library, i.e., OB, Peds, ICU.
- Manufacturers of smart pumps offer different features:
 - Add-on syringe pumps for small-volume IV push or bolus infusions.
 - Multiple infusions through one pump.
 - Administration of patient-controlled analgesia (PCA).

Using a “Smart” Pump

Equipment

- Point-of-care computer specific to nursing unit
- IV tubing
- IV fluids and/or IV medications

Procedure

1. Identify client using two identifiers and explain pump’s function.
2. Assemble equipment and bring to client’s bedside.

▲ Hang IV on pole. Prime tubing and insert into pump module cassette.

▲ Place top of IV tubing into top of cassette and listen for click indicating it is seated.

▲ Insert white slide clamp into cassette and listen for click.

▲ Close pump module door and lower locking level.

3. Perform hand hygiene.
4. Verify IV site is patent and without signs of infiltration.
5. Plug pump into electrical outlet.
6. Insert the pump module into the point-of-care computer (“brain”).
7. Spike IV fluid bag.
8. Prime IV tubing with appropriate solution.
9. Insert the IV tubing into the pump module and close the door to the pump. (Follow photos for inserting tubing into cassette.)
10. View screen will ask which client care area is being used. ► **Rationale:** The pump automatically configures itself to provide the infusion parameters for that area.
11. Choose the intended drug and concentration from the list outlined on the screen.
12. Enter the ordered dose and infusion rate; the pump checks this information against the drug library. If what was programmed matches the pump’s drug library, the pump allows the infusion to begin. Follow manufacturer’s directions on how to program the pump. Each manufacturer’s equipment is somewhat different.

▲ Select medication to be infused.

▲ Check screen for drug name and infusion rate.

▲ Check screen when “soft alert” sounds to determine problem.

Using a Bar Code Medication Administration System

- If the facility uses a bar code medication administration (BCMA) system, a computerized prescriber order entry (CPOE), automatic medication dispensing, and electronic medication records, smart pumps can provide a very high level of client safety. The system will tell you which IV medications were ordered via a CPOE for your client and when the medication is due.
- When the nurse enters the client’s room with the scanning device, she/he scans the bar-code labels on the medication, the client’s ID band, and the nurse’s ID badge. The information from the bar-code label attached to the medication IV bag will be transmitted wirelessly to and programmed into the infusion pump.
- The pump will begin infusing only when scanning of all pieces of information is completed.
- The pump automatically communicates with a computer in the pharmacy, providing the status of the infusion.

13. If an audible and visual alert occurs, the programmed data are outside the specified limits. The alert informs you about which parameter is out of the recommended range.
14. Depending on the medication or client care area, the pump will sound a “soft” alarm or a “hard” alarm. Some facilities allow a “soft” alarm to be overridden. If you override the alarm, the infusion will begin. This alarm is considered a minor error.
15. When “hard” alarm occurs, the pump shuts down. It cannot be overridden. Reprogram the pump with settings that are within your facility’s specified limits to begin infusing when a “hard” alarm sounds.

NOTE: The smart pump’s software logs and tracks all alerts, recording the time, date, drug, concentration, and infusion rate, as well as any action taken, whether the pump is overridden or not.

Clinical Alert

Check the facility’s policies and procedures to determine whether the pump can be run with the override or whether a verbal verification of the order with a physician or pharmacist must be obtained before proceeding.

16. Observe the screen to ensure medication is infusing at prescribed rate.

EVIDENCE-BASED PRACTICE

Smart Pump Technology Reduces Errors

There has been little IV error-prevention data published that documents the actual frequency of IV medication errors with infusion devices.

In a study conducted in the intensive care unit and operating room areas at Massachusetts General Hospital where use of an electronic drug library was implemented, a 50% reduction in the number of drug administration errors involving syringe pumps occurred over a 3-month period using the smart pump. The study indicated that logs from the 135 smart pumps showed:

- 40,644 infusion starts (potential for error)
- 693 alert messages (1.7% of start-ups)
- 158 programming changes (0.4% of start-ups, 22.8% of alert messages).

Source: Reves, J. (2003). “Smart pump” technology reduces errors. Anesthesia Patient Safety Foundation: (2003). 18: 1–10. www.apsf.org/resource_center, 2003. Information was based on a study by Ellen Kinnealey, BSN, Infusion pumps with “drug libraries” at the point of care: A solution for safer drug delivery.

Using a Syringe Pump

Equipment

- Battery or electronic operated syringe infusion pump
- Pharmacy-prepared and labeled syringe with prescribed medication
- Microbore tubing with needleless access device
- Chlorhexidine gluconate

Procedure

1. Check syringe label with physician’s order for drug, dosage, and amount of drug to be delivered over specified time.
2. Assure that medication is compatible with primary infusing solution.
3. Calculate amount of medication to be delivered per minute.
4. Attach microbore tubing to syringe, and holding syringe upright, expel air from medication syringe before priming tubing.
5. Holding syringe downward, carefully prime microbore tubing with medication (about 0.5 mL).
6. Insert syringe into cradle of pump, squeezing clamp around designated parts of syringe; attach pusher to plunger.
7. Verify that IV site is free from infiltration or vein irritation.
8. Swab primary IV tubing port closest to client.
9. Insert microbore cannula into port.
10. Set rate for drug delivery according to pharmacy specifications on syringe label, or as prescribed. Drug

will be infused *independent* of the primary infusion rate.

11. Start syringe pump.
12. Check infusion indicator to verify pump is infusing.
13. Monitor site and pump function frequently.
14. For subsequent doses, pharmacy dispenses a new syringe, but microbore tubing may be reused for 48–72 hr (according to agency policy). A sterile cap is used each time client’s primary tubing is accessed.

NOTE: For other brands of syringe pumps, follow directions for setup and delivery of meds with their product.

▲ Smart Pumps have syringe modules available to be attached to the point-of-care computers. To attach module, follow manufacturer’s directions.

Managing the IV Site

Equipment

- Appropriate tubing for IV site
- IV cap (according to hospital policy)
- Clean gloves
- Transparent dressing
- Sterile tape
- Stabilizing device

2. Identify client using two forms of ID and perform hand hygiene.
3. Include gentle palpation through an intact transparent dressing.
4. Remove IV cannula in the periphery, and change to a new more proximal site every 72–96 hr. (CDC recommends 72–96 hr; INS Standards of Practice recommend 72 hr.)

Clinical Alert

Clients receiving hypertonic, acidic, or irritating agents; geriatric clients with fragile veins; and pediatric clients who are active are at particular risk for IV site problems.

Clinical Alert

To check for extravasation, place constrictive band proximal to infusion site tight enough to restrict blood flow through the vein. Set tubing roller clamp to a “keep open” (or slow) rate, and remove tubing from infusion pump. If the infusion continues to drip, fluid is extravasating into the surrounding tissue.

Procedure

1. Evaluate every 2 hr for site-related complications (Table 28-3).

TABLE 28-3 Complications of IV Therapy

Assessment: Signs and Symptoms	Implementation: Nursing Action
<p><i>Phlebitis</i></p> <p>Pain along the vein, tenderness</p> <p>Erythema—red streak at vein site</p> <p>Edema at insertion site</p> <p>Sluggish flow rate</p> <p>Area is warm to touch</p>	<p>Discontinue infusion, and remove needle</p> <p>Apply warm compresses</p> <p>Start IV at another site</p> <p>Select a large vein when administering irritating agents</p> <p>Anchor cannula to prevent movement in vein</p> <p>Do not use positive irrigation with sluggish flow rate—there may be a clot at the end of the needle and it could be flushed into bloodstream</p> <p>Reposition extremity. Note where the IV catheter is in relationship to joint, such as wrist, antecubital</p> <p>Document description and location of site</p>
<p><i>Infiltration of fluid</i></p> <p>Edema around insertion site—swelling of cannulated extremity</p> <p>Blanching of infusion site</p> <p>Coolness of skin around site</p> <p>No backflow of blood when tubing is pinched or fluid container lowered below IV site (tubing must be removed from infusion device)</p>	<p>Discontinue infusion and remove needle</p> <p>Apply warm compresses to encourage absorption</p> <p>Notify physician if solution contains potassium or other irritating component (e.g., 10% dextrose)</p> <p>Do not rely on backflash of blood to determine location of catheter/needle in vein</p> <p>Lower container below IV site—if blood returns, needle is in vein, <i>but</i> fluid may be leaking into tissue if bevel has pierced posterior wall of vein</p> <p>Restart IV at another site</p>
<p><i>Extravasation of medication</i></p> <p>Pain, stinging, or burning at site</p> <p>Redness and swelling</p>	<p>Discontinue infusion; attempt to aspirate the drug</p> <p>Apply ice compress to area</p> <p>Research the medication—some agents have specific antidotes for extravasation injury</p> <p>Notify physician</p> <p>Administer irritating or vesicant medications through a central venous device</p>

▲ Flush site, then attach needleless cannula into needleless cap.

5. Assess IV site every 4 hr if client's status prohibits changing IV site.

For IV Administration Sets

1. Change administration sets, including all stopcocks, access devices, and extension tubings, every 72 hr (according to agency policy). This can be done routinely at the same time a new container of IV solution is started.
2. Change IV tubing according to use.
 - a. Primary intermittent tubing, every 24 hr.
 - b. Hyperalimentation, every 24 hr.
 - c. Secondary infusion tubing, every 24 hr. ► **Rationale:** Once a secondary tubing is disconnected, it must be treated as a primary tubing according to INS Standard 54.
 - d. Blood and blood component tubing, every 4 hr or after 2 units of blood.
 - e. Hemodynamic and arterial pressure monitoring tubing, every 96 hr.
3. Use separate secondary tubing for each "piggy-backed" agent if agents are incompatible.

For Converting From Continuous IV to a "Lock"

1. Ensure site is patent and functional.
2. Perform hand hygiene and don clean gloves.
3. Clamp infusion tubing.
4. Disconnect IV tubing from catheter.
5. Attach needleless injection cap or primed T connector extension tubing with needleless injection cap to catheter hub.
6. Prep, then inject port with 1 mL of sterile normal saline to maintain patency.

Clinical Alert

Some facilities use a single secondary tubing for all agents. The tubing is back-flushed with the primary solution before administering a new agent, providing the agents are compatible.

▲ Using the needleless cannula reduces risk of needle sticks during IV procedures.

For Applying a Securement Device

1. Prepare skin area according to facility policy—chlorhexidine recommended.
2. Apply skin prep provided with device. ► **Rationale:** To increase adhesion of device and protect skin.
3. Place IV catheter into device before adhering anchor pad to skin.
4. Assess site daily. ► **Rationale:** To ensure placement of device on skin.
5. Assess skin under device for skin tears.
6. Change device every 7 days by gently stroking under device surface with alcohol swab while continuing to lift pad off skin.

For Applying a Transparent Dressing

1. Cover IV insertion site with transparent dressing.
 - a. Line up slit in the frame with the catheter hub.
 - b. Apply the dressing over insertion site just to top edge of the hub.
 - c. Do not stretch the dressing during application.
 - d. Firmly smooth down the dressing edges as the frame is slowly removed.
 - e. Gently pinch and seal the dressing around the catheter hub.
 - f. Smooth down the entire dressing from the center out to the edges, using firm pressure to enhance adhesion.
 - g. Label dressing with date of insertion, date of change, gauge used and initials of nurse.
2. Document catheter insertion and dressing information.

Clinical Alert

Regard IV systems as closed sterile systems and maintain as such. All entries into the tubing should be made through injection ports that are disinfected just before entry.

Needleless IV Access Devices

Split Septum Technology-Needleless Access System

The system consists of a pre-split injection cap that requires a blunt cannula to access the fluid path. One new version of the split septum is accessed with a standard male Luer syringe or administration set.

Luer Access Mechanical Valve

A needleless access device that consists of a valve that is opened by the insertion of a standard male Luer syringe or administration set to access the fluid path. There are two types:

1. Compression seal that is depressed by male Luer, opening the fluid path.

2. Open Luer that houses a valve that is activated by the male Luer; it requires a new cap on the Luer after each use.

Luer Access Mechanical Valve With Positive Displacement-Needleless Access Device

The system consists of a valve and a fluid reservoir. The valve is opened by the insertion of a standard male Luer syringe tip or administration, accessing the fluid path. When the male Luer is disconnected, the compression seal reseats, causing the reservoir to empty and creating positive displacement of fluid into the catheter lumen.

Source: Hadaway, Lynn, RN, RNC. (2006). Principles of flushing vascular access devices. In: *Becton Dickinson (BD) Medical Clinical Resource*, Service Department CD, Franklin Lakes, NJ.

Converting IV to Saline Lock

Equipment

- Extension tubing with needleless connector
- Needleless syringe
- Clean gloves
- Saline flush syringes with 0.9% preservative-free normal saline
- 2 × 2 sterile gauze

Procedure

1. Gather equipment and perform hand hygiene.
2. Assess that IV is infusing and there are no signs of phlebitis or infiltration.
3. Don gloves.
4. Prime extension tubing with normal saline syringes
5. Turn off IV and disconnect from pump if necessary.
6. Disconnect IV tubing and attach extension tubing. A 2 × 2 gauze can be placed under IV site to catch drops from IV tubing disconnect.

7. Redress IV site.
8. Discard equipment.
9. Remove gloves and perform hand hygiene.

▲ Attach extension tubing to IV catheter.

▲ Prime extension tubing.

▲ Attach IV tubing to threaded lock cannula.

Changing Gown for Client With IV

Equipment

- Clean gown
- Bathing supplies, if needed

Procedure

1. Check client care plan for infusion drip rate, type of solution, and any special considerations.
2. Perform hand hygiene.
3. Identify client using two descriptors.
4. Take equipment to client's room and explain procedure to client.
5. Untie back of gown and remove gown from unaffected arm.
6. Support arm with IV and slip gown down arm to IV tubing.
7. Place clean gown over client's chest and abdomen.
8. Use tubing clamp to slow infusion to "keep open" rate and remove tubing from infusion pump if in use.
9. Remove IV bag from hook and slip sleeve over bag, keeping bag above client's arm. **► Rationale:** This prevents backflow of blood into tubing. Do not jar or

pull tubing. **► Rationale:** IV tubing may become dislodged and infiltrate into surrounding tissue.

10. Place your hand up through distal end of clean gown sleeve and grasp IV bag. Pull bag and tubing out through clean gown sleeve.
11. Rehang bag on hook and check to see that infusion is running according to ordered drip rate.
12. Replace tubing into infusion pump, unclamp, and reestablish prescribed infusion flow rate.
13. Guide sleeve of gown up client's arm to shoulder.
14. Assist client to put other arm through remaining sleeve.
15. Tie gown at the back.
16. Check IV infusion rate and IV tubing to determine that solution is flowing unimpeded into client's vein. **► Rationale:** Kinks in tubing impede solution flow.
17. Return bed to comfortable position for client.
18. Remove dirty linen from room.
19. Perform hand hygiene.

NOTE: Most facilities provide "IV gowns" that snap from the shoulder down the sleeve of the gown for ease in removal without disturbing the IV.

Discontinuing an IV

Equipment

- Sterile 2 × 2 gauze pads (3–4)
- Sterile tape
- Clean gloves

Procedure

1. Gather equipment.
2. Perform hand hygiene and don gloves.
3. Identify client using two descriptors and explain procedure to client.
4. Turn off infusion.
5. Loosen transparent dressing and securement device. Alcohol swabs can be used to loosen dressing and devices to prevent skin tears.
6. Stabilize catheter while removing dressing and securement device. **► Rationale:** Stabilizing site prevents unnecessary movement that could injure the vein.
7. Hold sterile gauze over site and remove catheter carefully and smoothly, keeping it almost flush with skin. Observe catheter for breakage and ensure it is intact.
8. Quickly press sterile pad over venipuncture site and hold firmly until bleeding stops.
9. Hold pressure for several minutes if client's drug therapy prolongs bleeding.
10. Apply sterile pad and tape in place.

Clinical Alert

Assess whether client has been receiving antithrombotic (aspirin) or anticoagulant (Coumadin, heparin) therapy. Hold pressure for several minutes if client has prolonged bleeding caused by drug therapy.

11. Elevate arm to reduce venous pressure and help collapse vein to facilitate clot formation. Do not bend arm at elbow. **► Rationale:** Bending elbow causes hematoma formation.

▲ Remove tape carefully from tubing site.

2 Remove occlusive dressing, starting at top and pulling down toward IV site.

3 Holding cannula in place, continue to pull dressing toward IV site.

4 Lift dressing off skin.

5 Remove IV cannula carefully.

6 Place sterile gauze directly over IV site and press firmly until bleeding stops.

7 Tape gauze dressing in place.

12. Observe venipuncture site for redness, swelling, or hematoma.
13. Dispose of equipment and gloves.
14. Perform hand hygiene.

15. Check site again in 15 minutes.
16. Record volume infused on I&O sheet.

NOTE: If there are signs of infection or inflammation at catheter site or client complains of symptoms related to infection, cut tip of catheter with sterile scissors, place in sterile container, and send to lab for culture.

DOCUMENTATION for Intravenous Management

IV Insertion

- Date and time
- Location of insertion site
- Gauge and length of catheter inserted
- IV solution and flow rate
- Site care given
- Condition of site
- Client response to procedure

IV Discontinued

- Date and time
- Note condition of the catheter—“intact”
- Assess catheter length
- Condition of site
- Client response to procedure
- Catheter tip to lab if appropriate

Legal Alert

By 2006, the FDA mandated that all drug manufacturers must label most prescription medications and certain over-the-counter drugs with machine-readable bar codes, using the National Drug Code number that uniquely identifies each drug, its dosage form, and strength. The FDA predicts that using bar codes will prevent up to 500,000 adverse drug events and transfusion errors over the next 20 years.

Source: U.S. Food and Drug Administration. (2005, September). *FDA issues bar code regulation, 2004*. www.fda.gov/oc/initiatives/barcode.

▲ Example of Intake and Output Record.

CRITICAL THINKING Application

Excepted Outcomes

- Fluids are administered without adverse effects.
- IV site remains clean, without signs of infection or infiltration.
- IV is converted to a saline lock and is functioning properly.

Unexpected Outcomes

Client develops unexplained fever with chills and rising pulse rate.

- Client's gown is changed while maintaining IV placement.
- IV is discontinued intact and site remains free of infection or bleeding.

Alternative Actions

- Unexplained fever may be associated with catheter-related sepsis. Report to physician.
- Assess IV site for signs of infection.
- Ensure that IV solutions hang for no more than 24 hr.
- Check client's vital signs: temperature usually above 100°F when caused by IV-related sepsis.
- Check for other symptoms of pyrogenic reactions (e.g., backache, headache, malaise, nausea, and vomiting).
- Stop the infusion.
- Obtain blood specimens, if ordered.

IV solution does not flow properly.

- Ensure that the control clamp is open.
- Check that blood pressure readings are not taken on arm in which IV is running, as flow is impeded and a clot can form on the end of the catheter.
- Ensure that IV administration set is properly loaded. Check pump for flow problem indicator (e.g., cassette seating, air in line).
- Check IV tubing from insertion site to IV solution for kinks/obstructions.
- Check for extremity causing positional obstruction to flow (e.g., elbow bent, arm rotated).

IV solution appears to be infiltrating, resulting in tissue swelling.

- Decrease the flow rate. (Remove from pump for “keep open” rate.)
- Lower bag of IV solution; if blood returns, cannula may be in the vein but fluid may be leaking into surrounding tissue via existing puncture in vein wall.
- Discontinue infusion and establish a new site.

Phlebitis is suspected at infusion site (tenderness, warmth, erythema, and pain).

- Check infusion solution and medications being administered. (Potassium chloride and hypertonic solutions are particularly irritating to veins.)
- Discontinue IV.
- Apply warm compress per hospital policy.

Postinfusion phlebitis may also occur after the IV has been discontinued in response to either chemical or mechanical factors of the preexisting IV.

- Check IV solution; hypertonic solution causes irritation necessitating use of large veins and changing IV sites more frequently.
- Follow hospital policy for treatment. Warm compresses to the site are generally recommended.
- Elevate extremity.

Chapter 28

UNIT 3

Monitoring Fluid Balance

Nursing Process Data

ASSESSMENT Data Base

- Assess client's need for intake and output recording.
- Assess client's ability to keep intake and output fluid records.
- Evaluate client for any factors that might affect his or her intake and output (e.g., preexisting disease states, concurrent disease, drug therapies, and current physical status).
- Determine all measurable sources of fluid intake: fluids with and between meals, tube feeding, liquid medications, IV fluids, and IV medications.
- Determine all measurable sources of fluid output: urine, emesis, diarrhea, and drainage sites.
- Determine alterations in nonmeasurable sources of fluid intake and loss: food, increased metabolism (e.g., fever), rapid respirations, and perspiration.
- Determine balance of daily intake and output.

PLANNING Objectives

- To establish a written record of the client's total fluid intake (oral, parenteral, and feeding tubes) and fluid output (urine, wound/tube drainage, diarrhea, and vomiting)
- To plan fluid replacement or appropriate therapy by assessing deficits or excesses of fluid and electrolytes
- To ensure a fluid intake of at least 2000–2600 mL unless contraindicated by diagnosis
- To monitor the client's fluid status, vital signs, and mental state to determine homeostasis

IMPLEMENTATION Procedures

- Monitoring Intake and Output1083
- Monitoring IV Intake1085

EVALUATION Expected Outcomes

- Client's intake and output are maintained within expected parameters of 200–300 mL of each other.
- Fluid intake is at least 2600 mL unless contraindicated by diagnosis.
- Client's fluid status, vital signs, and mental status are within normal range.
- Output is maintained at more than 30 mL/hr.
- IV flow rate is maintained at prescribed rate.

- **Critical Thinking Application**1086
- Expected Outcomes 1086
- Unexpected Outcomes 1086
- Alternative Actions 1086

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Monitoring Intake and Output

Equipment

- Graduated container in client's bathroom
- I&O bedside record sheet and PDA for recording in computer
- Urinal or bedpan; bedside commode or underseat basin for toilet
- Hourly in-line urine measurement device for clients requiring frequent monitoring
- Posted measurement standards for commonly used drinking and eating utensils (e.g., glasses, mugs, bowls)
- Posted signs, dietary slips, and other communication devices to notify hospital personnel about how client's I&O is to be measured

Procedure

1. Determine whether client needs I&O measurements by checking client's chart or care plan. All clients with an IV need I&O measurement.
2. Instruct client and/or family about the need to measure all intake and output. Keep I&O sheet at bedside for the family to record I&O.
3. Measure intake from all sources.
 - a. Oral fluids.
 - b. IV fluids.
 - c. Fluid medications (oral, enteral, or IV).
 - d. Tube feedings and water used to clear tubing.

▲ The trend in most facilities is to eliminate paper records. Electronic recording through Palm Pilots is now frequently utilized.

Clinical Alert

Measurement of all fluids is done in milliliters (mLs).

TABLE 28-4 Body Sites for Assessment of Fluid Status

Site	Fluid Excess	Fluid Deficit
<i>Head and Neck</i>		
Face	Eyeballs firm or protruding Edema, especially around eyes	Eyeballs soft or sunken Decreased skin turgor over forehead
Mucous Membranes	Excessive salivation Swollen tongue	Dry or sticky mucosa with thick mucous secretions Shrunken tongue with multiple longitudinal furrows Crusted lips
Neck	Jugular vein distention	
<i>Trunk</i>		
Chest	Crackles in lung bases	Decreased skin turgor over sternum Dry, flaking skin
Abdomen	Ascites (measure girth at umbilicus)	
Sacrum	Edema	
<i>Extremities</i>		
Arms	Distended veins Edema, particularly of the hands Delayed capillary refill Pulse bounding	Flattened veins Delayed capillary refill Dry, flaking skin Pulse weak and thready
Legs	Edema Taut shiny skin Peripheral cyanosis	Poor skin turgor, especially across shins Dry, flaky skin, especially on feet Weak pedal pulse or decreased capillary refill

TABLE 28-5 Objective Data Associated With Fluid Status

Data	Fluid Excess	Fluid Deficit
<i>Vital Signs</i>		
Blood Pressure	Increased*	Decreased (especially on standing)
Pulse	Increased rate	Increased rate
Temperature	Unchanged	Elevated
Respirations	Increased rate	Unchanged or increased
<i>Laboratory Findings</i>		
Urine-Specific Gravity	Decreased, approaching 1.003	Increased, approaching 1.025 or greater
Blood Hematocrit	Less than three times the hemoglobin	Greater than three times the hemoglobin
Serum Sodium (Na)	Less than 135 mEq/L or normal	Greater than 145 mEq/L or normal
Blood Urea Nitrogen (BUN)	Decreased (except in heart or renal failure)	Proportionately greater than the serum creatinine
<i>Hourly Urine Output</i>	More than 60 mL/hr	Less than 30–60 mL/hr
<i>Weight</i>	A 5% or greater gain	Mild: 2% loss Moderate: 3%–5% loss Severe: 6% or greater loss

*If the heart is unable to pump the increased blood volume, the blood pressure (reflecting cardiac output) may decrease. Polyuria can also be seen with fluid volume deficit (FVD) as in diabetic states.

4. Measure output from all sources to establish a record and plan fluid therapy.
 - a. Urinary catheters
 - b. Bedpans and urinals
 - c. Nasogastric drainage
 - d. Drainage tubing (e.g., T-tubes, wound, or chest tube)
 - e. Diarrheal stools
 - f. Draining wounds
 - g. Emesis
5. Record I&O on bedside record each time you check on client's intake or measure output, or enter data into computer.
6. Correlate intake and output with daily weight. Weight is measured in kilograms (1 kg = 2.2 lb).
7. Record 24-hr totals of I&O on bedside record and place in client's chart, or enter data into computer.
8. Notify physician of any significant imbalance; more intensive monitoring may be indicated. ► **Rationale:** Hourly urine output less than 25–30 mL/hr for 2 consecutive hours or 24-hr urine output less than 500 mL can indicate dehydration or internal bleeding and can result in acute renal failure.

Clinical Alert

Check all drainage receptacles such as Foley bag and NG canister at the beginning of each shift to ensure they were emptied from the previous shift and that there has not been excessive drainage.

Fluid Replacement Solutions

Hypertonic Solutions—a solution with higher osmolality than blood serum

- Solution causes cells to shrink
- Used in severe salt depletion (very rare)
- Used as nutrient source (10% dextrose)
- Examples of solutions: 5% dextrose in 0.45% normal saline; 10% dextrose in water; 3% normal saline

Hypotonic Solutions—a solution with lower osmolality than blood serum

- Hydrates cells, causes them to expand
- Used to correct dehydration
- Examples of solutions: 0.45% normal saline; 0.2% normal saline; 2.5% dextrose

Isotonic Solutions—a solution with the same osmolality as blood serum

- Cells remain unchanged
- Used for replacement or maintenance (expands extracellular volume). Especially used to expand circulating (intravascular) volume.
- Examples of solutions: 5% dextrose in water; 0.9% normal saline (NS); Lactated Ringer's

NOTE: One liter of normal saline (0.9% NaCl) meets the usual daily requirement of these electrolytes in an adult.

TABLE 28-6 Intake and Output Flow Sheet (Sample)

Intake									
Date	Time	IV No.	IV Started	Description	IV Intake	Oral Intake	Urine Output	Other	N/G
1/9/12	9 A			Full liquid breakfast		620			
	9:45 A			Vomitus				400	
	10:30 A	#1	1000						
	12 N						500		
	2:30 P						400		
				7–3 Total	600	620	900	400	100
	6:30 P	#2	1000						
	9 P						500		
				3–11 Total	1000	NPO	500		350
1/10/12	2:30 A	#3	1000		450				
	5 A				550		350		
				11–7 Total	1000	NPO	350		375
				24-hr Total	2600	620	1750	400	825

Monitoring IV Intake

Equipment

- Electronic infusion device
- I&O record
- Graphic sheet
- IV container marked with timed intervals
- IV flow sheet or PDA

Procedure

- Place I&O worksheet at bedside unless using PDA to record I&O.
- Determine time interval required for monitoring IV intake.
- Mark time intervals on IV container according to facility policy (use tape to mark, or use preprinted time strips).
- Set IV drip rate according to physician's orders.
- Observe IV container and read IV solution level.
- Record amount of IV solution infused at prescribed time (e.g., every hour, every shift).
- If using electronic infusion device, push "total volume infused" for shift amount, then "clear."
- Record total IV intake on I&O record at end of each shift or record in electronic PDA.
- Record 24-hr IV total at midnight. Take into account all sources of IV fluid (all IV sites, IV medications).

DOCUMENTATION for Monitoring Fluid Balance

- Amount and description of all measurable I&O
- Approximate volume of loss when unable to measure contents (e.g., incontinent of urine in bed)
- Dietary intake (food that liquefies at room temperature, as well as liquids)
- 8-hr and 24-hr totals
- Signs and symptoms of client's fluid status, including vital signs, mucous membranes, daily weight, etc.

NOTE: I&O records are frequently inaccurate due to numerous possibilities for error, estimation being a common source of inaccuracy. It is important to maintain these records accurately.

CRITICAL THINKING Application

Expected Outcomes

- Client's intake and output are maintained within expected parameters of 200–300 mL of each other.
- Fluid intake is at least 2600 mL unless contraindicated by diagnosis.

Unexpected Outcomes

Recorded I&O do not balance.

Client unable to maintain an intake of at least 1500 mL/day.

IV flow not maintained at appropriate rate.

- Client's fluid status, vital signs, and mental status are within normal range.
- Output is maintained at more than 30 mL/hr.
- IV flow rate is maintained at prescribed rate.

Alternative Actions

- Correlate I&O imbalance with weight changes.
- Emphasize importance of accurate measures to client and family.
- Check that entries into computer are accurate (i.e., entering 100 mL instead of 1000 mL).
- Identify possible nonmeasurable sources of I or O.
- Report to charge nurse so she can ensure that all nurses are keeping accurate records.
- Check if client or family can help with keeping the I&O record.
- Check the addition on the I&O record to see if an error was made.
- Ensure that fluid restriction is not ordered.
- Offer fluids in small amounts more frequently.
- Determine client's fluid preferences.
- Determine client preference for fluid to be hot, cold, or room temperature.
- Consider "other" fluids such as Jell-O, Popsicles.
- Assess client's ability to use a straw (hemiplegic client is often unable to suck through a straw).
- Check if client is able to drink fluids independently or if assistance is needed.
- Ensure that adequate fluids are accessible at the bedside for the client.
- Do not administer fluids with a bulb syringe.
- Address client's toileting needs every 2 hr—some clients restrict their fluid intake for fear of incontinence.
- Use a thickening additive to liquids to facilitate swallowing for the client with aspiration precautions.
- Monitor IV fluid intake hourly.
- Observe IV site for complications.
- Restart IV immediately when infiltrated to ensure continuous IV fluid intake.
- Document IV fluid intake every shift.
- Account for interruption of primary infusion and the delivery of intermittent infusions of medications.
- Check accuracy of IV administration equipment: electronic device, dial-a-flow, etc.
- Inform physician of alterations in fluid received from what was ordered.

IV Medication Administration

Nursing Process Data

ASSESSMENT Data Base

- Note client’s allergies.
- Note any drug or solution incompatibilities.
- Assess amount and type of diluent needed to prepare medications.
- Assess client’s general status to establish a baseline.
- Assess patency of infusion set and condition of IV insertion site.
- Assess physical parameters as indicated such as blood pressure, heart rate.

PLANNING Objectives

- To maintain a therapeutic level of medication in the client’s bloodstream
- To administer medication safely over a specific period of time
- To prevent complications associated with medication administration

IMPLEMENTATION Procedures

- Adding Medication to IV Solution1088
- Using a Secondary (“Piggyback”) Bag1088
- Using a Volume Control Set1090
- Using a Peripheral Saline Lock1091
- Flushing a Peripheral Saline Lock1092
- Administering Medications by Peripheral IV Line Injection “Push”1093

EVALUATION Expected Outcomes

- Solutions from secondary IV bags infuse without difficulty.
- Therapeutic blood levels of medication are maintained.
- Complications of medication administration are prevented.
- Medication is infused over appropriate time span using volume control set.
- Saline lock inserted for medication administration without complications.

Critical Thinking Application1094

- Expected Outcomes1094
- Unexpected Outcomes1094
- Alternative Actions1094

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Adding Medication to IV Solution

Equipment

- IV solution bag
- Syringe with medication
- Antimicrobial swab
- Label with medication dosage, date, time, and initials

Clinical Alert

Only under unusual circumstances will the nurse be asked to add medications to parenteral solution. Refer to the facility's policy and procedure manual to determine which medications can be added by the nurse.

Procedure

1. Check physician's orders, MAR, and agency policy.

NOTE: The addition (admixture) of medication to an IV solution for continuous administration is usually performed by the pharmacist, according to standards established by the American Society of Health System Pharmacists (ASHP) and Occupational Safety and Health Administration (OSHA). Special precautions for this procedure include preparation in a laminar airflow environment, strict adherence to requirements of asepsis, safety regarding components' stability and compatibility, proper dilution of agents, and control of extraneous particle addition to the admixture.

2. Perform hand hygiene.

3. Gather equipment.
4. Check to ensure that prescribed drug is compatible with IV solution.
5. Draw up medication into syringe according to directions on medication insert (or PDR).
6. Check all medications to be added to IV solutions with a second RN before injecting into the IV solution.
7. Wipe injection port on IV bag with antimicrobial swab.
8. Inject medication into bag while maintaining aseptic technique.
9. Mix IV solution and medication by gently agitating bag to mix thoroughly.
10. Affix medication label to IV bag.
11. Hold bag against both dark and light backgrounds to inspect for any precipitate.
12. Insert IV tubing into bag, and proceed with appropriate method of administration as ordered.

Clinical Alert

Some drugs are incompatible with saline solution; these include diazepam (Valium), chlorthalidone hydrochloride (Librium), and amphotericin B. Check compatibility of all IV drugs with solutions infusing.

Using a Secondary ("Piggyback") Bag

Equipment

- Primary IV set, consisting of compatible IV solution bag and IV administration set with injection port
- Short secondary administration set with needleless cannula and extension hook or lowering hanger for primary bag (if indicated)
- Pharmacy-prepared medication bag with label, including name of medication, date, time, rate for infusion, and client's name
- 2% Chlorhexidine gluconate swab

Preparation

1. Check medication with physician's orders and MAR.
2. Perform hand hygiene.
3. Gather equipment.
4. Identify client using two forms of identification.

Procedure

1. Ensure medication compatibility with primary infusing solution.

NOTE: If medication is incompatible with primary IV solution, temporarily discontinue primary infusion. Flush client's injection

port, initiate a normal saline (or other compatible) solution as the primary, then proceed with "piggyback" into the "new" compatible primary. When complete, restart original primary solution (use new needleless cannula to access client's injection site).

2. Spike bag with secondary administration set.
 3. Cleanse injection port of primary tubing with chlorhexidine gluconate swab.
 4. Insert needleless connector of secondary "piggyback" tubing into primary tubing port (port above pump).
- NOTE:** If using the same tubing from a previous administration, change needleless connector before inserting into primary tubing.
5. Hang the secondary bag on the IV pole.
 6. Use extension hook to lower primary bag below secondary bag if indicated (some infusion devices do not require this). ► **Rationale:** Primary solution ceases flow because of increased hydrostatic pressure in higher secondary bag.
 7. Clear tubing of medication bag by opening clamp, temporarily placing secondary bag lower than the primary solution bag, and allowing primary solution to flow retrograde into secondary bag tubing (back-priming).
 8. Backfill until secondary tubing chamber is one-third full. Clamp secondary tubing. ► **Rationale:** This ensures that no medication is lost during priming.

▲ Insert needleless cannula of secondary tubing into distal primary tubing port.

▲ Hang secondary bag on IV pole; lower primary bag.

9. Program secondary settings into infusion device if used.
10. Open clamp on secondary bag tubing. The secondary solution should begin to flow.
11. Check that primary infusion resumes at its “set” rate when secondary volume has been infused.

NOTE: Some infusion devices control secondary infusions without necessitating bag height differentials.

12. When secondary bag is empty, readjust rate of administration in primary solution to desired flow (unless infusion device controls this).
13. To add a new secondary bag, ensure that medication is the same as previously administered since some drug

▲ Lower medication bag to clear tubing and back-prime tubing.

▲ Unclamp secondary tubing.

- remains in the secondary tubing. A *different* medication requires its own secondary tubing. ► **Rationale:** This prevents admixture of potentially incompatible drugs.
14. Remove old secondary bag, and spike new “piggyback” medication bag.

15. Lower partial-fill bag below injection port of primary IV.
16. Open clamp on secondary tubing and allow solution from primary IV set to enter tubing, backfilling the tubing to drip chamber. ► **Rationale:** This procedure displaces air in the secondary tubing.
17. Replace new secondary bag on IV pole and proceed with administration.
18. Change secondary tubing every 24 hr.

Clinical Alert

Always document all fluids as intake used for administering medications in piggyback or volume control sets.

Using a Mini-Infuser Pump

A mini-infuser pump is a tandem device that allows a small amount of medication to be given (5–60 mL) as a controlled infusion.

- The prefilled syringe is added to the battery-operated mini-infuser and connected to the main IV line.
- A needleless system is connected to the primary IV line.
- The infusion pump is hung with the primary IV bag and activated by an ON button.
- After infusion of medication, the primary infusion automatically begins to flow as the pump stops.
- The primary infusion should be checked and the flow regulated when the mini-infusion pump stops.

Using a Volume Control Set

Equipment

- Primary IV set (IV solution bag and IV administration set)
- Calibrated volume control set
- Medication prepared in syringe
- 2% Chlorhexidine gluconate swab
- Label with medication, date, time, and nurse's initials

▲ Add extension tubing, if necessary.

Preparation

1. Check physician's orders and MAR.
2. Identify client using two descriptors.
3. Determine compatibility of medication with primary infusion.
4. Perform hand hygiene.

Procedure

1. Add extension tubing to volume control set if needed and close clamps on volume control set, both above and below volume chamber.
2. Open air vent by turning clamp located on top of volume chamber.
3. Spike IV bag with volume control set and then hang bag. Attach IV tubing to volume control set.
4. Open upper clamp (between the bag and volume chamber) and fill chamber with IV solution so that chamber is one-third full.
5. Close upper clamp.
6. Open lower clamp and squeeze drip chamber (located underneath the volume chamber) until it is one-half full.
7. Allow solution to flow down tubing.
8. Prime tubing and cannula affixed to end of tubing. If volume control set has membrane filter instead of floating valve filter, follow manufacturer's instructions for priming so that you do not damage the filter.

Clinical Alert

New guidelines from The Joint Commission require that all syringes with medication must be labeled with client's name, drug, and time syringe was prepared.

▲ Swab injection port before infusing medication.

9. Close clamp.
10. Swab off injection port (located on top of the volume chamber) with antimicrobial swab.

▲ After instilling medication, gently mix with solution in volume control chamber.

11. Inject prepared medication into chamber and agitate gently to mix medication with solution in chamber.
12. Dilute medication, if necessary, by opening upper clamp and adding additional fluid from the IV bag.
13. Open clamp on volume control set and adjust drip rate to desired rate of administration.
14. Place medication label on volume control set. Include client's name, medication, dose, and time medication infusion began.

Using a Peripheral Saline Lock

Equipment

- Needless injection cap with primed extension tubing and port (if one is not in place)
- Needless access device
- Syringe for medication and diluent (if indicated)
- Two 0.9% preservative-free normal saline prefilled syringes (3–5 mL each) (preferred method)
- 2% Chlorhexidine gluconate swab
- Clean gloves
- Stethoscope and sphygmomanometer (if indicated)

Preparation

1. Check physician's orders and MAR.
2. Gather equipment.
3. Perform hand hygiene and don gloves.
4. Identify client using two descriptors.
5. If client does not have peripheral lock in place, proceed with venipuncture, selecting veins that are both large

enough to receive the medication and away from areas of movement (e.g., the elbows and wrists).

Procedure

1. Prepare medication with appropriate diluent according to manufacturer's instruction for IV injection and draw it up into syringe. (See drug insert or PDR.)
2. Fill two syringes, each with 1 mL of 0.9% preservative-free normal saline.
3. Explain procedure to client.
4. Check client's vital signs if agent to be given has hemodynamic effects.
5. Prep needless injection port with antimicrobial swab.
6. Insert *first* saline syringe into port, briefly aspirate to check patency, then flush system and observe for site swelling. ► **Rationale:** Presence of blood and absence of swelling at site indicate that needle is probably in vein, not in surrounding tissue.

7. Insert medication syringe into port and inject medication into vein, timing injection administration rate according to drug manufacturer's instruction (see insert or PDR).
8. Observe client for any adverse reactions.
9. Remove medication syringe.
10. Flush with *second* saline syringe to clear line and maintain patency of lock. Administration of saline should take same time period as the medication administration. ► **Rationale:** This prevents a bolus of medication or "speed shock" when fluid is administered.
11. Dispose of equipment and gloves and perform hand hygiene.
12. Recheck client's vital signs if indicated.

Clinical Alert

Studies indicate that there is no significant difference in the use of saline or heparin to maintain catheter patency, maintain dwell time, and avoid phlebitis. Some hospitals still use a small amount of dilute heparin for flushing peripheral locks; it is usually prepared with 1 mL of heparin (1000 units/mL) added to 9 mL of normal saline to produce 100 units/mL solution. Prefilled syringes of heparin and saline for infusion come in 10 units of heparin/mL. Caution should be exercised because heparin-induced thrombocytopenia can occur with as little as 500 units of heparin/day.

Flushing a Peripheral Saline Lock

Equipment

- Two prefilled syringes with 0.9% preservative-free normal saline
- 2% Chlorhexidine gluconate swab
- Clean gloves

Preparation

1. Check physician's order and MAR including allergies.
2. Gather equipment.
3. Perform hand hygiene.
4. Identify client using two descriptors.

Procedure

1. Explain procedure to the client.
2. Don clean gloves.
3. Prep injection port with chlorhexidine gluconate swab. ► **Rationale:** When prepping with an antimicrobial swab, it is the pressure and friction applied that produce the antimicrobial effect.

4. Insert/connect first saline syringe into injection port and gently aspirate for blood.
5. Observe for blood in syringe. ► **Rationale:** Blood will indicate catheter is not occluded (see Clinical Alert).
6. Remove and discard used syringe in appropriate trash/sharps container. Be careful not to contaminate

▲ After checking for blood return, discard syringe and attach second syringe with saline into port and gently irrigate lock.

▲ After swabbing injection port, attach syringe with normal saline.

▲ Remove syringe and discard in sharps container.

the injection port. If the port is contaminated, prep again with an antimicrobial swab.

7. Insert/connect second syringe into injection port and gently flush with saline. Assess IV insertion site for tissue swelling or pain when injecting saline.
 - ▶ **Rationale:** This could be a sign of infiltration.
8. Disconnect syringe and discard in appropriate trash/sharps container.
9. Remove and discard gloves.
10. Perform hand hygiene.
11. Document flush on MAR.

Clinical Alert

If the gauge of the catheter is small, i.e., 22 gauge or smaller, it is possible that you may not get a blood return. This can be due to the collapse of the tip of the catheter as negative pressure is applied when attempting to aspirate blood. This does not always mean that the catheter is occluded. You may attempt to gently inject the saline while feeling for resistance. If any resistance is felt, it is possible that the catheter is occluded and needs to be removed and a new catheter inserted.

Administering Medications by Peripheral IV Line Injection “Push”

Equipment

- Medication prepared in syringe with needleless access device, according to pharmaceutical instruction for IV administration
- 2% Chlorhexidine gluconate swab
- Clean gloves
- Stethoscope and sphygmomanometer (if indicated by drug action)
- Two prefilled 0.9% normal saline solution syringes

Preparation

1. Check physician’s orders and MAR.
2. Gather equipment.
3. Perform hand hygiene.
4. Prepare medication according to pharmaceutical company’s instructions for IV administration according to drug insert or PDR.
5. Check package insert or other references for drug’s compatibility with primary infusing solution.
 - ▶ **Rationale:** Flushing the primary infusion tubing will be necessary both before and after administering the drug if incompatibility exists. Alternatively, a secondary “piggyback” bag of normal saline can be hung and used for flushing the primary line during the drug injection.
6. Check medication according to the *Six Rights*.
7. Take medication to client’s bedside.
8. Check that client is not allergic to the drug.
9. Don clean gloves.

Procedure

1. Identify client using two descriptors.
2. Obtain vital signs if agent to be given has hemodynamic effects.
3. Don gloves.
4. Validate placement using first prefilled syringe.

5. Prep primary tubing injection port closest to client.
6. Insert medication syringe cannula into line port.
7. Pinch primary tubing between port and infusion bag while injecting medication slowly in calculated increments (e.g., inject one-fourth of medication over a 20-second period). Always check literature to determine injection times for specific medication.
8. After injecting small increments, unpinch primary tubing to allow flushing of medication.
9. Observe client for any adverse effects.
10. Deliver next increment, using your watch and timing drug injection according to the drug insert instructions.
11. Withdraw syringe when medication injection is complete.
12. Prep primary tubing injection port again.
13. Insert second saline syringe to flush all medication from IV tubing. Use same time rate as medication administration. ▶ **Rationale:** To prevent adverse reactions.
14. Discard equipment.
15. Remove gloves and perform hand hygiene.
16. Recheck client’s vital signs and document if indicated.

Clinical Alert

Before any IV push or if drug is irritating, validate intravenous line placement. Place a tourniquet proximal to primary infusion; slow drip rate and remove tubing from pump. Ensure that infusion slows or stops before injecting the IV medication. This action validates intravenous status of infusion. Blood flashback is not a reliable indicator of such.

Clinical Alert

In contrast to IV “push,” an IV bolus of a drug is rapidly injected in order to achieve an immediate desired drug level—usually for emergency situations. Always refer to pharmaceutical company’s instructions for *IV drug injection* before administering.

DOCUMENTATION for IV Medications

- Amount of medication administered
- Method of drug administration
- Flush (e.g., NS) if indicated for compatibility
- Document flush solutions on I&O flow sheet
- IV site status
- Client's response to medication
- Parameters such as vital signs, as indicated

Legal Alert

Up to 90% of all clients receiving healthcare services require some form of IV therapy. As a nurse, you will most likely be involved in starting, monitoring, and discontinuing IV therapy.

Administering drugs is a major problem related to IV therapy. Medication errors account for 2 in 1,000 hospital deaths and are frequent causes of malpractice actions. The most frequent errors are incorrect dose, wrong drug, and improper technique (such as infusing the medication too quickly).

Ensure that you administer IV therapy according to the acceptable nursing standards established by your facility, as well as state and federal guidelines. Keeping up with new standards and reading journal articles will assist you in keeping current. In order to accomplish this, you will need to update your skills yearly.

Documentation must be appropriate, accurate, and concise in case of lawsuits regarding client injuries.

Documentation: "Do and Don't"

- Document only what you observed firsthand, what the client stated, and what was done. Do not offer opinions.

- Use the word "observed," not "noted." This could mean something was written in the medical record.
- Do write "no IV-related complications observed." If you document only parts of the assessment, such as "no redness noted," it could be taken that you didn't observe for any other signs of infection.
- Document details about complications: nursing interventions, physician orders, client's comments regarding complications or responses to treatments.
- Document catheter length when removing a peripheral venous access device or PICC line.
- Do not write "client tolerated procedure well." Provide statement from client as to how he/she felt.
- DO NOT rely solely on charting by exception or check-off flow sheets to document. They do not prove proper client assessment and may or may not hold up in court.

Source: Satarawala, R. (2000, August). Confronting the legal perils of i.v. therapy. *Nursing*, 30(8), 44–47.

CRITICAL THINKING Application

Expected Outcomes

- IV solutions from secondary IV bags infused without difficulty.
- Therapeutic blood levels of medication are maintained.
- Complications of medication administration are prevented.
- Medication is infused over appropriate time span using volume control set.
- Saline lock inserted for medication administration without complications.

Unexpected Outcomes

Secondary bag solution does not infuse adequately.

Alternative Actions

- Check that primary IV bag is lower than secondary bag (if infusion device requires).
- Ensure that secondary needleless connector is properly attached in the primary injection port and secondary bag is sufficiently spiked.
- Check that the roller clamp of the secondary tubing is open fully.

Solution in primary IV tubing is incompatible with medication to be administered via secondary “piggyback.”

- Turn primary infusion off.
- Before administering medication, flush primary tubing with solution compatible with medication (e.g., normal saline, 5% D/W).
- Hang a separate solution compatible with medication and run through line to flush during drug administration.

Solution does not infuse through peripheral lock.

- Gently turn lock to establish flow.
 - Reposition client’s extremity.
 - Initiate a new IV site.
-

Chapter 28

UNIT 5

Blood Transfusions

Nursing Process Data

ASSESSMENT Data Base

- Assess that client has signed informed consent for transfusion.
- Assess if client has an established IV site.
- Assess client's vital signs, especially temperature, for baseline data.
- Ensure that client's number and blood type on unit match client's blood ID bracelet name and number before administration to ensure compatibility. (Validate consistency with another nurse.)

PLANNING Objectives

- To provide blood or blood components (e.g., platelets, fresh-frozen plasma) for clients with a demonstrated deficiency
- To ensure compatibility between client's blood and the blood or blood component to be transfused
- To prevent the infusion of microaggregates or leukocytes
- To prevent febrile reaction to the transfusion
- To monitor and ensure a timely transfusion
- To monitor for potential complications during and after the blood transfusion

IMPLEMENTATION Procedures

- Administering Blood Through a Y-Set1097
- Administering Blood Through a Straight Line1099
- Administering Blood Components1100
- Monitoring for Potential Complications1100

EVALUATION Expected Outcomes

- Transfusion of blood is performed in a timely manner.
- Client's blood deficiency is corrected.
- Transfusion reaction does not occur.

- Critical Thinking Application**1103
- Expected Outcomes 1103
 - Unexpected Outcomes 1103
 - Alternative Actions 1103

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Administering Blood Through a Y-Set

Equipment

Blood unit (packed RBCs)

NOTE: Few conditions require the transfusion of whole blood. Most whole blood is used to prepare separate components to meet specific client needs (e.g., RBCs, plasma, platelets).

250-mL bag of normal saline

Y-set blood tubing with filter

Venipuncture supplies if client does not have established site, at least an 18- or 20-gauge needle or catheter

Needleless injection cap (if not in place)

2% Chlorhexidine gluconate swabs

Tape

Clean gloves

Clinical Alert

In emergency situations, when time does not allow ABO determination, group O red blood cells may be given. Whole blood, however, *must* be administered ABO identical.

Preparation

1. Check physician's order for number and type of transfusion units (order must dictate "transfusion").
2. Identify client using two descriptors.
3. Explain procedure to client and confirm that client has signed consent form for transfusion.
4. Check that type and crossmatch have been completed and that blood is ready in blood bank.
5. Determine patency of client's IV and needle or catheter gauge. Begin infusion of NS with appropriate blood tubing.
6. Obtain client's pretransfusion vital signs. ► **Rationale:** If client has temperature above 100°F (37.8°C), physician must be notified before proceeding.
7. Obtain ordered typed and matched blood component bag from blood bank, or notify blood bank to deliver unit (according to agency policy). Both nurse and lab tech check transfusion number and sign transfusion form.

If transfusion requires electronic monitoring device to control blood flow, only pumps designed for the infusion of whole blood and RBCs may be used. These pumps require the use of special tubing and filter. Other types of pumps may cause hemolysis of RBCs.

▲ Obtain ordered typed and matched blood/component bag from blood bank.

Clinical Alert

Always determine patency of the IV line before obtaining blood from the blood bank.

8. With another nurse, validate that client's ID bracelet number matches blood bank number on unit of blood to be transfused.
9. Validate client's name, ID number, blood group/Rh, blood product, unit number, and expiration date.
10. Take and record client's vital signs on transfusion record 5 minutes before starting, 5 minutes after starting infusion, 15 minutes, and then every 30 minutes until transfusion is completed (1–1.5 hr), and immediately after the transfusion.
11. Remember that blood cannot be returned to the blood bank after it has been checked out for 20 minutes.

▲ Ascertain that client's name, ID number, blood group, number/Rh, unit expiration date, and hospital number match number on record on the blood bag.

Warming Blood for Transfusion

Routine transfusions are not usually warmed. Warming is required in massive transfusions or, more commonly, may be ordered in maternity or the postanesthesia care unit. A blood warming device is used. Never warm blood bag in hot water or microwave. Once blood is warmed, it must be used or disposed of, as it cannot be returned to the blood bank. Hemolysis of the blood occurs at temperatures above 104°F.

Clinical Alert

Most clients can tolerate a flow rate of one unit of packed cells in 1.5–2 hr. For elderly clients or those with respiratory or cardiac conditions, nurse may need to adjust flow rate according to client's status.

12. Check blood bag for bubbles, cloudiness, dark color, or sediment. ► **Rationale:** These signs indicate bacterial contamination.
13. Perform hand hygiene and don clean gloves.

Procedure

1. Close all clamps on the Y-set tubing.
2. Spike bag of normal saline with one arm of the Y-tubing.
3. Open clamps on both arms of the Y-tubing to flush.
4. Close clamp on free arm of Y-set (blood side) and open clamp below tubing filter to prime main tubing.
5. Close main clamp when tubing is primed.
6. Close clamps.
7. Gently agitate blood unit bag. ► **Rationale:** Agitation suspends the red cells in the anticoagulant.
8. Pull back tabs on blood unit bag, and expose port.
9. Spike blood bag port with free arm of Y-tubing, then hang unit.
10. Prep client's injection port.
11. Connect blood tubing via needleless connection.
12. Open clamp to blood bag.
13. Start blood infusion, administering slowly at 5 mL/min for first 15 minutes. ► **Rationale:** Slow administration allows time to observe for adverse reactions. Most reactions occur in the first 15 minutes.

▲ Prime blood administration Y-set tubing with sterile normal saline before starting infusion.

Clinical Alert

Blood must be hung within 30 minutes after taking it from blood bank. Usually only 1 unit of blood is dispensed at a time.

NOTE: According to American Association of Blood Banking (AABB) Technical Manual, 14th ed., 2002.

14. Take vital signs 5 minutes *before*, and 5 minutes, 15 minutes, and every 30 minutes *after* starting transfusion and record on Transfusion Record. Check hospital policy and procedures.
15. Observe client closely for adverse signs: chilling, backache, headache, nausea or vomiting, tachycardia, tachypnea, respiratory distress, skin rash, itching, or hypotension.
16. Agitate blood bag each time the client is checked.
17. If venous spasm occurs with cold blood infusion, apply warm pack to site to improve flow rate.
18. Complete the blood transfusion in less than 4 hr.
 - ▶ **Rationale:** Blood deteriorates rapidly after a 2-hr exposure to room temperature and increases risk of bacterial infection.
19. Check that transfusion is completed, then flush line with normal saline.
20. Obtain posttransfusion vital signs.
21. Report a 1°C (2°F) rise in temperature to the physician.
 - ▶ **Rationale:** This could be indicative of a transfusion reaction.
22. Complete documentation on the Transfusion Record: place one copy on client's chart and send remaining copy of the Transfusion Record to the Blood Bank as soon as transfusion is completed.
23. Discard administration set within 4 hr of use.

▲ Observe client carefully for first 15 minutes and frequently throughout the blood transfusion.

24. Place all transfusion-related equipment in a biohazard waste receptacle.
25. Remove gloves and perform hand hygiene.
26. Continue to observe client.

Administering Blood Through a Straight Line

Equipment

- Blood unit
- Blood administration straight-line set with 170-micron filter microaggregate or leukocyte-depleting filter
- Needleless cannula
- Electronic infusion device (optional)
- Clean gloves

Procedure

1. Obtain and check blood as stated in Preparation for Administering Blood through a Y-Set.
2. Perform hand hygiene and don gloves.
3. Spike blood bag port carefully and hang unit.
4. Gently agitate unit, and suspend on IV pole.
5. Open clamp and fill drip chamber, making sure filter is totally submerged in the blood.
6. Open clamp on tubing and run blood through tubing, then clamp.
7. Load tubing into infusion pump if used.
8. Carefully connect blood tubing to client's IV site catheter or lock.
9. Begin blood transfusion.
10. Observe client closely and obtain vital signs 5 minutes before, 5 minutes after start, then after 15 minutes, then every 30 minutes or per hospital policy and procedures.

Blood Transfusion Protocol

The nurse is responsible for early assessment of possible transfusion reactions by completing the following interventions.

- Identify client and blood bag.
 - Ident-A-Band number matches transfusion record number.
 - Name spelled correctly on transfusion record.
 - Blood bag number and pilot tube number are the same.
 - Blood type matches on transfusion record and blood bag.
- Double-check blood with another RN before infusing; record on transfusion record.

- Determine client allergy history and previous blood reactions.
- Establish baseline vital sign data.
- Start transfusion slowly to observe for severe reactions.
- Maintain aseptic technique during procedure.
- Observe time rules for administering blood. (Hang no longer than 4 hr.)
- Observe blood bag for bubbles, cloudiness, dark color, or black sediment, which is indicative of bacterial invasion.

11. When blood bag is empty, close all clamps and remove blood tubing cannula from IV site.
12. Dispose of equipment in biohazard waste receptacle.

13. Remove gloves and perform hand hygiene.
14. Continue to observe client.

Administering Blood Components

Equipment

Blood component
 Appropriate IV administration set
 Filter, if indicated
 Clean gloves

Procedure

1. Check physician's orders and client's signed consent for transfusion.
2. Obtain blood component from blood bank.
3. Obtain appropriate administration set.
4. Perform hand hygiene and don gloves.
5. Read directions for proper administration of the solution.
6. Identify rate at which blood component should infuse.
7. Check Table 28-8 for appropriate rate, risk factors, and possible complications.

Modified Blood Products

In addition to the usual blood components such as platelets and cryoprecipitate, modified blood products are becoming more popular. Washed, irradiated, or leukocyte-removed blood is being used for clients at risk because of multiple transfusions or a weakened immune system. Testing for cytomegalovirus and matching RBC or human leukocyte antigens is also done to ensure safe transfusions.

Clinical Alert

When infusing a blood product that has undergone leukocyte reduction, it still must be filtered again through a standard blood administration set in order to trap cellular debris that may have accumulated since the original filtration.

Monitoring for Potential Complications

Equipment

Sphygmomanometer
 Stethoscope
 Thermometer

Procedure

1. Check temperature, blood pressure, pulse, and respiration before transfusion is started.

2. Check vital signs 5 minutes before, then 5 and 15 minutes and every 30 minutes for the first 100 mL after transfusion has started. ► **Rationale:** Most blood transfusion reactions occur during this time.
3. Maintain vital sign assessment throughout blood infusion according to hospital policy.
4. Monitor client for possible transfusion reactions.
 - a. Hemolytic or incompatibility reaction—most severe reaction
 - b. Bacterial contamination
 - c. Allergic reaction
5. If any severe untoward sign occurs (increase in temperature, pain in kidney region), STOP transfusion immediately.
6. Remove blood and any blood-filled tubing and replace with saline bag and new tubing to keep line open. Return blood bag and administration set to blood bank or laboratory.
7. Notify physician immediately after stopping IV for signs of transfusion reaction. Also notify physician if any unusual sign (itching or hives) occurs.

TABLE 28-7 Transfusion Reactions

Type	Clinical Manifestations	Nursing Interventions
Bacterial	Sudden increase in temperature Hypotension Dry, flushed skin Abdominal pain Headache Lumbar pain Sudden chill	Stop transfusion immediately and remove blood tubing. Maintain IV site; change tubing and start infusion of normal saline. Observe for shock. Monitor vital signs every 5 minutes. Insert Foley catheter and monitor urine output hourly. Notify physician and obtain order for antibiotic and steroids/shock management. Draw blood cultures before antibiotic administration. Send remaining blood and tubing to laboratory for culture and sensitivity.
Allergic	Mild: urticaria and hives, pruritus Severe: respiratory distress, wheezing Anaphylactic reaction: shock, loss of consciousness	Stop transfusion immediately if symptoms are severe—immediate resuscitation may be necessary. Monitor vital signs for possible anaphylactic shock. If symptoms are mild, stop transfusion or follow hospital policy and obtain physician’s orders. Monitor for signs of progressive allergic reaction as transfusion continues.
Hemolytic	Severe pain in kidney region and chest Pain at needle insertion site Fever (may reach 105°F), chills, flushing Dyspnea and cyanosis Oozing of blood at IV site Headache Hypotension Hematuria Nausea	Stop transfusion immediately and remove blood tubing. Start normal saline infusion at “keep open” rate with a new IV tubing. Obtain vital signs. Notify blood bank STAT. Administer oxygen. Notify physician. Obtain orders for IV volume expansion and diuretic or vasopressor to dilate renal blood vessels to prevent acute renal tubular necrosis. Complete transfusion reaction form. Send two blood samples (from different sites), urine specimen, remaining blood and tubing, and transfusion record to laboratory. Monitor vital signs every 15 minutes for shock. Monitor urine output hourly for possible acute renal failure.

TABLE 28-8 Blood Component Therapy

Type	Use	Alerts	Administration Equipment
Fresh plasma	To replace deficient coagulation factors To increase intravascular compartment	Hepatitis is a risk Administer as rapidly as possible Use within 6 hr	Any straight-line administration set
Platelets	To prevent or treat bleeding problems, especially in surgical clients To replace platelets in clients with acquired or inherited deficiencies (thrombocytopenia, aplastic anemia) To replace when platelets drop below 20,000 mL/mm (normal 150,000–350,000 mL/mm)	Administer at rate of 10 minutes a unit (usually comes in multiple platelet packs)	Platelet transfusion set with special filter to allow platelets to infuse through filter
Granulocytes	To treat oncology clients with severe bone marrow depression and progressive infections To treat granulocytopenic clients with infections that are unresponsive to antibiotics To treat clients with gram-negative bacteremia or infections where marrow recovery does not develop	Administer slowly, over 2–4 hr Give one transfusion daily until granulocytes increase or infection clears Use within 48 hr after drawn Observe for shaking, fever, chills Observe for hives and laryngeal edema (treat with antihistamines)	Use Y-type blood filters and prime with physiologic saline. A microaggregate filter is not used as it filters out platelets
Serum albumin	To treat shock To treat hypoproteinemia	Available as 5% or 25% solution Infuse 25% solution slowly 1 mL/minute to prevent circulatory overload Administer 100–200 mL (25% solution) for shock clients and 200–300 mL for hypoproteinemia	Special tubing accompanies albumin solution in individual boxes
Gamma globulin	To treat agammaglobulinemia To act as a prophylaxis for hepatitis exposure	Pooled plasma contains antibodies to infectious agents Administer 0.25–0.50 mL of immune serum globulin/kg of body weight every 2–4 weeks	Given IM
Coagulation factors	To treat clients with von Willebrand's disease	Made from fresh-frozen plasma	Standard syringe or component drip set only
Factor VIII (cryoprecipitate)	To treat clients with factor VIII, hemophilia A	Administer one unit cryoprecipitate for each 6 kg of body weight initially, followed by 1 unit/3 kg of body weight at 6–12-hr intervals until treatment discontinued Administer 1 unit/5 minutes Observe for febrile reactions	

TABLE 28-8 Blood Component Therapy (Continued)

Type	Use	Alerts	Administration Equipment
Factor IX	To treat clients with factor IX, hemophilia B	<p>Administer in 12–24-hr cycle</p> <p>Preparation for administration is 400–500 units/vial. Must reconstitute in 10–20 mL diluent</p> <p>One unit/pound of body weight increases the circulating factor activity by 5%</p> <p>Serum hepatitis can be transmitted</p>	Any straight-line set—drip or by IV push—not to exceed 10 mL/min

DOCUMENTATION for Blood Transfusions

- Type, unit number, and amount of blood product administered
- Name of healthcare provider who verified information with nurse
- Amount of normal saline used
- Type and gauge of catheter or needleless access device
- Time transfusion began and ended
- Vital signs 5 minutes before transfusion begins; 5, 15, 30, and 60 minutes after infusion begins; and then hourly until infusion completed (check hospital blood administration policy and procedure for vital sign frequency)
- Document on I&O record
- Transfusion tag may have space for vital sign information as well
- Client's response to procedure
- Any unusual clinical manifestations; any nursing interventions
- Warning device if used
- Infusion device used and flow rate setting
- Filter if used

CRITICAL THINKING Application

Expected Outcomes

- Transfusion of blood is performed in a timely manner.
- Client's blood deficiency is corrected.
- Transfusion reaction does not occur

Unexpected Outcomes

Transfusion reaction occurs.

Blood does not flow through tubing.

Alternative Actions

- Stop blood administration and begin infusion of normal saline or ordered solution to keep IV open.
- Check transfusion reaction form for appropriate nursing intervention.
- Complete all relevant nursing actions.
- Check client's IV site and gauge of needle or catheter (at least 18 or 20 gauge).
- Gently agitate blood bag to mix blood cells with the anticoagulant.
- Raise blood bag higher on IV pole. Squeeze flexible tubing to promote blood flow.
- Adjust clamp on tubing. As the blood passes over the filter, more blood microaggregates clog the filter and slow drip rate.
- Replace tubing.
- Utilize an infusion pump, especially if administering blood through a small catheter or lock.
- Consider using blood warmer.

Blood has been hanging for more than 4 hr.

- Take down blood bag and send to laboratory.
- Document amount of blood administered.
- Maintain IV with normal saline or ordered IV solution.
- Monitor vital signs for complications.
- Notify physician.

Potential circulatory overload occurs.

- Monitor symptoms: sudden dyspnea, tachypnea, tachycardia, chest discomfort, distended neck veins, moist crackles and rales, restlessness, sudden increase in blood pressure.
- Stop transfusion and place client in Fowler's position.
- Start oxygen at 2 L/min per nasal cannula.
- Be prepared for ECG and chest x-ray.
- Be prepared to administer Lasix and morphine sulfate.

GERONTOLOGIC Considerations

Elderly Clients' Veins Are Fragile and Roll Easily, and Frequently the Needle Punctures the Wall of the Vessel

- Insert small-gauge winged catheter in distal vein first to preserve proximal vessel.
- Tourniquet (constricting band) may not be necessary for venipuncture. If used, it should be applied loosely.
- If used, release tourniquet as soon as venipuncture yields blood return to prevent excessive pressure in vein.
- Maintain close assessment of IV sites to promote long-term use of vessel.

Elderly Clients Are Prone to Fluid and Electrolyte Disorders as a Result of the Normal Aging Process

- Thirst mechanism is decreased.
- Renal threshold is altered.
- Total body fluid is less due to decreased lean muscle mass.
- Fluid replacement therapy requires close monitoring to prevent fluid overload, leading to pulmonary edema and electrolyte imbalance.
- Dehydration is a common reason for IV therapy.
- When infusing IV fluids, monitor closely for signs of fluid volume overload.
- Monitor BUN and electrolytes regularly for signs of overload.

- Use IV pump whenever infusing fluids into elderly clients. If dextrose solution is being infused, IV pumps *must* be used. Dextrose overload can lead to cerebral edema if infused too rapidly.

Stabilizing IV Catheter and Dressing Is Problematic Due to Client's Fragile Skin

- Avoid excessive use of tape.
- Apply skin protector solution before dressing site.
- Use stretch mesh gauze to cover site and tubing to prevent catching on bed (avoid roll-type gauze).

Protect Fragile Skin That Is More Susceptible to Injury, Infiltration, and Discomfort From Irritating Drugs

- Observe IV site carefully for signs of infiltration. Because of skin's loose folds and decreased tactile sensation, a large amount of fluid can sequester in subcutaneous tissue and go unnoticed before client complains of pain.
- Check IV site frequently when client is receiving drugs that can cause irritation and even necrosis if they infiltrate.
- At first sign of phlebitis or infiltration, remove IV and restart in a new site.
- If client complains of discomfort during IV therapy, apply a moist and warm pack to site, decrease rate of fluid infusion.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- Each state identifies the scope of practice for RNs and LPN/LVNs. Several states have identified that the

LPN/LVN has a specific role in IV therapy, but the scope of practice is always dictated by each agency (e.g., initiating, regulating, discontinuing IVs).

- Daily weighing of clients is usually assigned to the CNA or UAP. The RN should verify that weights are taken in the morning before breakfast, using the same scale each time. The client should urinate before weighing for accuracy. Since a client's weight changes are frequently taken into consideration for prescribing fluid allowances or

medication adjustments, accuracy in measurement and documentation is imperative.

- All care providers must be aware of clients whose intake and output are monitored and must conscientiously participate in accurate measurement.
- All care providers must be aware of clients for whom fluid restriction is ordered and carefully adhere to designated allowances.
- CNAs and UAPs report vital data to the professional nurse by monitoring vital signs. This skill can be delegated for the pre-, intra-, and post-blood transfusion, and results should be given immediately to the nurse. The professional nurse then validates and acts upon any abnormal findings accordingly.
- The CNA/UAP providing personal hygiene must understand that the IV system is a closed one and must be able to give care without disrupting this system. The components of the system must never be disconnected for the convenience of care (e.g., changing gown). The CNA/UAP should receive training in changing the client's gown without disrupting the IV system.
- It is the nurse's responsibility to monitor and document intravenous fluid volume administered.
- It is the nurse's responsibility to evaluate the client's total balance of intake and output and to investigate significant imbalances for further decision making.

- While the professional nurse monitors the IV infusion site regularly, the CNA/UAP must communicate observations of swelling, client reports of concern (e.g., pain), and infusion device signals that prompt the professional to further assess the client.

Communication Matrix

- All care providers participate in accurate recording of the client's intake and output. Records are usually kept at the bedside. All must be familiar with the standard capacities for frequently used vessels (bowls, cups) to facilitate accurate recording of intake.
- Likewise, careful recording of measurable output and best estimation of unmeasurable losses (e.g., incontinence) will facilitate care decisions.
- The nurse must ensure that CNA/UAPs know to report any unusual fluid loss the client is experiencing (e.g., vomiting). It is the nurse's responsibility to evaluate alterations in fluid loss (e.g., vomiting, scant urine output) and act upon these findings accordingly. Knowledge and judgment cannot be delegated.
- It is the nurse's responsibility to document vital client information on the Transfusion Record, which is placed into the client's hospital chart.

CRITICAL THINKING Strategies

Scenario 1

Mrs. Beatty is a 40-year-old client, 5'1" tall and weighing 300 lb. She had emergency abdominal surgery for lysis of adhesions. You are assigned to care for her on her first postoperative day. As you begin your assessment, you note she has an NG tube that is draining bile-colored return. Her IV is D5% in 0.45NS infusing at 125 mL/hr. The IV is on a pump. As you observe the IV site, you find it difficult to determine whether the site is edematous or it is just her normal appearance. It seems like the area surrounding the site is cooler to the touch than the remaining part of the arm. Mrs. Beatty states the IV area is sore. A gauze dressing is placed directly over the IV site, making it difficult to visualize it. The IV fluid seems to be infusing at the prescribed amount and the IV pump alarm is not ringing.

1. What is your priority action in this situation?
2. After completing the first priority, what is your second priority?
3. While assessing the IV site, what would you look for if you suspect phlebitis or infiltration? With the initial information provided in the scenario, which of these potential complications do you suspect? Provide rationale for your answer.

4. How will you check the IV to determine whether the client does have an infiltration?
5. Indicate your priority intervention if you determine the client has an IV that has infiltrated.
6. Indicate your priority intervention if you determine the client has beginning signs of phlebitis.

Scenario 2

The head nurse comes to you, a new RN, and tells you that Mr. Jones' physician has ordered whole blood for his client, to be given immediately, and hands you a unit of blood.

1. What is your first action after this interaction with the head nurse?
2. What additional data should be collected before implementing this order?
3. After starting the transfusion, the client develops urticaria, hives, and slight respiratory distress. From these symptoms, what would you conclude about the client's status and what intervention would you make?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. In-line filters are not recommended for which one of the following IV infusions?
 1. Ringer's Lactate.
 2. TPN.
 3. PCA.
 4. Blood platelets.
2. The nurse begins to assess the client's arms to determine the most appropriate site for the venipuncture. Which of the following principles should be kept in mind when determining this site?
 1. The veins that are deeper in the forearm should be assessed first.
 2. The antecubital fossa is a primary site.
 3. The most appropriate site is below an infiltrated area to save the vein.
 4. The distal end of the vein should be selected first.
3. Nursing actions that are completed when preparing for a venipuncture include
Select all that apply.
 1. Lightly tap the vein to distend it.
 2. Instruct the client to open and close fist to distend vein.
 3. Apply cool cloth to arm for 10 minutes before attempting venipuncture.
 4. Position arm on pillow to increase blood flow to area.
4. It is recommended that the skin prep used before attempting the venipuncture is
 1. Alcohol swab.
 2. Betadine swab.
 3. Iodine swab.
 4. Chlorhexidine gluconate swab.
5. You are preparing to change IV tubing as required during your shift. You recall that
 1. Primary and secondary tubing is changed every 24 hr.
 2. Primary intermittent tubing is changed every 96 hr.
 3. TPN and lipids are changed with each bottle.
 4. Blood or blood products tubing is changed every 4 hr or 2 units.
6. As you review the steps of inserting an over-the-needle catheter, you recall that the steps include the following
 1. Check catheter with the bevel in a "downward" position to examine the integrity of the end of the catheter.
 2. Place the bevel of the needle in the "up" position and insert the catheter at the 45° angle into the skin.
 3. Insert the needle into the anterior surface of the vein.
 4. After hearing the "pop" sound in the vein, remove the plastic catheter hub.
7. The client's IV order is: Administer 2500 mL of normal saline in 24 hr. The administration set delivers 10 gtt/mL. The IV will deliver ____ mL/hr
 1. 10.
 2. 15.
 3. 60.
 4. 104.
8. You walk into the room of a client whose Smart Pump is sounding a "hard" alarm. Your initial action is to
 1. Reset the pump after checking for possible air in tubing.
 2. Reset the rate of the medication infusion on the pump.
 3. Notify the client's nurse.
 4. Reprogram the pump after scanning your badge into the system.
9. The client has an isotonic IV solution ordered for the next 24 hr. The faculty asks you to explain the rationale for this solution. Your answer is that it
 1. Hydrates the cells, causing them to expand.
 2. Corrects dehydration.
 3. Is used as a nutrient source.
 4. Is used to expand intravascular volume.
10. One of your clients has a medication ordered to be infused through the primary tubing injection port. Which of the following safety issues must be considered when administering IV drugs through this method?
 1. Administer the medication over 20 seconds.
 2. Flush the primary infusion tubing before and after administering any drug.
 3. After injecting a small amount of drug, unpinch primary tubing and flush medication.
 4. Administer IV drugs using only a dextrose solution to ensure drug compatibility.

Central Vascular Access Devices

LEARNING OBJECTIVES

1. Identify the common types of central vascular access devices (CVADs).
2. Discuss the rationale for using central vascular catheters for long-term IV therapy.
3. Discuss the special needs of clients with central vascular catheters (prevention of infection, air embolism).
4. Describe the role of the nurse in the insertion of CVADs.
5. Explain the nurse's responsibility for assisting the physician with a percutaneous central vascular catheter insertion.
6. Compare and contrast features of various central vascular access devices.
7. Describe initiation and discontinuation of infusions via CVADs.
8. Differentiate protocols for maintaining patency of intermittently used CVADs.
9. Outline steps for dressing and protecting the CVAD insertion site.
10. Discuss the advantage of using a BIOPATCH at the catheter insertion site.
11. Outline the steps in changing an access cap.
12. Discuss the data that is included in client education for the care and maintenance of vascular access devices.

TERMINOLOGY

Antimicrobial preventing the development of pathogenic action of microbes.

Aspirate application of negative pressure to check for blood return.

Calorie the amount of heat necessary to raise the temperature of 1 kilogram of water 1°C. One thousand (1 kcal) of these calories equals 1 dietary calorie (or calorie).

Carbohydrates a group of chemical substances, including sugars, glycogen, starches, dextrans, and cellulose, that contain only carbon, oxygen, and hydrogen.

Cardio word part that pertains to the heart.

Cardiovascular term that pertains to the heart and blood vessels, as cardiovascular system.

Central vascular access device (CVAD) catheter, centrally placed in the superior vena cava, to provide medication, fluid, and nutrition.

Central venous pressure (CVP) measurement monitors central venous return (volume) and right ventricular function.

Catheter-related bloodstream infection (CRBSI) fourth most common hospital-acquired infection with central line catheter placement.

Cyanosis slightly bluish, grayish, slate-like, or dark purple discoloration due to desaturation of hemoglobin.

Digestion the process by which food is broken down mechanically and chemically in the gastrointestinal tract.

Dyspnea a subjective feeling of difficulty breathing.

Electrolyte substance that develops an electrical charge when dissolved in water.

Erythema redness of the skin produced by capillary congestion as in a sunburn.

Extracellular fluid outside the cell (interstitial and intravascular fluid).

Fat substance made up of carbon, hydrogen, and oxygen, occurring naturally in most foods but especially in meats and dairy products.

Gastrointestinal term that pertains to the stomach and intestines.

Hemo prefix meaning blood.

Hemodynamic study of circulation of blood.

Hemolytic pertinent to the breaking down of red blood cells.

Huber needle a right-angled (90°) or straight, noncoring needle.

Hydrostatic the pressure exerted on liquids.

Hyperalimentation the process of nourishing the body through parenteral means.

Hyperglycemia condition characterized by an increase in blood glucose levels.

Hypertonic solution having a higher osmotic pressure or tonicity than a solution with which it is compared.

Hypovolemia diminished circulating fluid volume.

Implanted inserted under the skin.

Implanted infusion port device placed in subcutaneous tissue with a tunneled catheter that goes into the central venous system.

Infusion a liquid substance introduced into the body via a vein for therapeutic purposes.

Intracellular fluid inside the cell.

Intravascular within blood vessels.

Irrigate to rinse or wash out with a fluid.

Isotonic a solution that has the same concentration of salts, or tonicity, as another solution with which it is compared.

Lipids emulsion containing fats used to correct fatty acid deficiencies via parenteral nutrition.

Lumen the inner open space of a tube or blood vessel.

Malnutrition a condition characterized by a lack of essential food substances or improper absorption and distribution of food substances in the body.

Minerals inorganic elements or compounds.

Nutrient nourishing food item that supplies the body with necessary elements.

Obstruction blocking of a structure that prevents it from functioning normally; obstacle.

Osmosis transmission of water across a semipermeable membrane from an area of low solute concentration to one of higher solute concentration.

Palpate to examine by touch; to feel.

Peripherally inserted central catheter (PICC) long, soft, flexible catheter placed through an arm vein to the superior vena cava.

Phlebitis inflammation of a vein.

Polyunsaturate a long chain of carbon compounds with more than one double bond between the carbons; especially refers to fats.

Port subcutaneously implanted plastic or metal case that provides access to the venous system.

Protein substance that contains amino acids essential for growth and repair of tissues.

Sepsis pathologic state, usually febrile, resulting from the presence of microorganisms or their poisonous products in the bloodstream.

Thrombo a clot of blood; a thrombus.

Thrombophlebitis an inflammation of a vein due to the presence of a thrombus.

Transfusion injection of blood or blood component of one person into the blood vessels of another.

Tunneled catheter a long single or multi-lumen catheter inserted into a central vein, the remainder tunneled subcutaneously to a distant exit site on the chest or abdomen.

Valsalva's maneuver attempt to forcibly exhale with the glottis closed.

Venipuncture puncture of a vein with a needle.

Viscosity resistance offered by a fluid; property of a substance that is dependent on the friction of its component molecules as they slide by each other.

Vitamins a group of organic substances essential for life.

VENOUS ACCESS DEVICES

Peripheral Catheters

Intravenous therapy is administered through a variety of catheters and devices. Several factors are considered when selecting the proper catheter: duration of therapy, pH, and osmolarity of solution to be infused. The most common type of venous access device is the peripheral catheter, inserted into veins of the hands, arms, and antecubital area. These are short catheters, less than 3 in. length, (7.5 cm), intended for short-term IV therapy, usually no more than 7 days. The insertion site needs to be changed frequently, usually every 48–72 hr, according to facility policy. Therapies not appropriate for short catheters include continuous solutions with pH less than 5 or greater than 9, and osmolarity greater than 600 mOsm/L. Medication that cannot be infused in short catheters include vancomycin, penicillin, ganciclovir, dilantin, and Phenergan due to their pH.

Short catheters are used for one-time infusions of less than 7 days. They are used frequently in emergency situations where medications must be administered quickly. They are not recommended for blood draws. If used, they should only be in place for 48 hr.

Site selection is based on four factors: condition of selected vein, type of infusate, rate of infusion, and duration of infusion. When considering the vein, keep in mind that if it has been used previously, you must select a site above the previously used site, especially if there was an infection. It is best to place the first catheter at the lowest point on the upper extremity; this allows for further catheter placement, if needed.

Areas above the flexion of a joint, such as wrist and elbow, should be avoided. These sites can result in mobility problems and catheter dislodgement due to movement of the extremity.

Lower extremities are used only if necessary and require a physician's order in most facilities due to the risk of deep

vein thrombosis and pulmonary embolism. (See Chapter 28 for more details on these IV devices.)

Midline Catheters

Midline catheters are 3 to 8 in. (7.5–20 cm) in length and are inserted 1.5 in. (2.5–3.8 cm) above or below the antecubital fossa and terminate in one of the client's arms in a proximal vein. The basilic, cephalic, or median antecubital sites are also used. They are similar to the peripherally inserted central catheter (PICC) but shorter in length. Both catheters are used for long-term IV therapy. Midline catheters are used only for administering nonirritating, normal pH solutions or medications, whereas the PICC can be used to infuse vesicants, hyperosmolar solutions, and TPN. Clients with midline catheters should not receive any medications or IV fluids where the pH is below 5 or above 10, and osmolarity greater than 600 mOsm/L. Damage to the vessel walls can lead to phlebitis or thrombosis.

Midline catheters, because they are placed in larger veins, can be left in place for up to 2–4 weeks. Because of the longer dwell time as compared with the peripheral catheter, complications such as thrombosis at the catheter site can occur. Phlebitis, infection, occlusion, clotting, breakage, and leakage at the insertion site of the catheter are also associated with use of the midline catheter. Unfortunately, complications are not as easy to assess in clients with midline catheters, as opposed to clients with peripheral lines. For example, it takes longer for symptoms of phlebitis to occur in the client with a midline catheter. The short peripheral or midline catheters are not checked by x-ray for placement because they do not enter the superior vena cava as do the central vascular catheters.

Central Vascular Access Devices

Long-term intravascular therapy is best accomplished through use of medically placed central vascular access devices

(CVADs), which include subcutaneous ports and catheters as well as central venous catheters. The specific type of device used depends on the type and duration of treatment, as well as client variables. CVADs are placed in clients who are actively involved and at home, as well as critically ill hospitalized clients. Clients requiring chemotherapy, nutritional supplements, blood products, and fluids can benefit from CVADs. These devices allow repeated access to the vascular system without venipuncture.

Central vascular catheters are categorized into three types: central catheters, PICC lines, and subcutaneously implanted ports. Central catheters are further classified as tunneled or nontunneled catheters. Nontunneled catheters are large-bore catheters that vary in length from 6 to 8 in. (15 to 20 cm) and have one to four lumens. The catheters are made of soft silicone or a polyurethane material. Some of the newer catheters are impregnated with heparin, chlorhexidine, or an antibiotic. In most cases, physicians insert these catheters. Inaccurate placement of any central vascular catheter that is threaded to the superior vena cava can present a potential life-threatening arrhythmia if the catheter lodges against the myocardium.

Central Venous Catheters Central venous catheters are medically placed percutaneously through the chest wall into the jugular or subclavian vein and are used for fluid or blood administration, obtaining blood specimens, and administering medications and parenteral nutrition. Catheter extension into the superior vena cava minimizes vessel irritation and sclerosis of the vessel due to infusion. Because of the high volume of blood that normally flows through this portion of the superior vena cava (2000 mL/min) the risk of complications is lessened. Central catheters can be single or multi-lumen catheters.

Tunneled Catheters Hickman, Broviac, and Groshong catheters are tunneled catheters. The closed-ended or Groshong-type catheter is designed to prevent backflow into the catheter when it is not in use. The Groshong catheter is used when low flow rates will be infused. In the Groshong, fluids infuse through a slit valve on the side of the tip; when there is not an infusion of fluids into the catheter, the slit valve remains in a closed position. These catheters are never clamped due to this design factor. Pressure related to clamping the catheter or extension tubing can force the slit valve to open, allowing a blood leak back into the lumen. Heparin flushing is not routinely done because of the design of the catheter tip.

The Hickman catheter is open-ended with a silver ion impregnated cuff in the subcutaneous tract. This promotes growth of a connective tissue seal, reducing the risk of microbial immigration from the exit site along the catheter tract. The catheter has a reinforced sleeve of silicone on which the catheter clamp is used.

Hickman catheters are flushed with heparin. The client may shower and swim once the exit site has healed, but the hub of the catheter must be covered.

Tunneled catheters are used for long-term replacement therapy, medication administration, nutritional supplementation, and blood specimen withdrawal. These catheters can

remain in place from months to years. The catheter's tip is inserted into a central vein (e.g., subclavian or internal jugular vein) and advanced to the distal area of the superior vena cava. The remaining portion of the catheter is threaded subcutaneously to exit at a convenient distal site (chest, abdomen). A Dacron cuff on the catheter promotes scar formation to seal the tract to prevent ascending tract infection. Only physicians may discontinue a tunneled catheter.

Client Selection for CVADS

- Long-term intravenous therapy
- Need for frequent venous access
- CVP monitoring
- Administration of total parenteral nutrition (TPN)
- Self-administration of intravenous therapies
- Sclerosed peripheral veins
- Limited peripheral venous access
- Irritating IV solutions

Subcutaneously Implanted Ports

These implanted ports are surgically placed under the skin in a subcutaneous pocket in the chest, arm, abdomen, and occasionally, the back. The newer ports are MRI compatible and available as a titanium port or titanium dome. Implanted ports are used for long-term and complex IV therapy such as chemotherapy. The septum of the port is made of silicon or polyurethane rubber latex, allowing more than 2,000 punctures with a 19-gauge noncoring needle. The attached catheter enters the superior vena cava. Single and dual septal ports are available with open end or closed catheter endings.

Access to the port is by placement of a noncoring needle through the skin, into the self-sealing injection port housed in a plastic or metal case. This needle can remain in place for 7 days, then be replaced. Since the entire unit is implanted subcutaneously, risk for infection and maintenance requirements are greatly reduced.

Peripheral Insertion of a Central Catheter (PICC)

Peripheral (antecubital) insertion of a central vascular catheter (PICC) to the superior vena cava is easier and less risky than entering the central vein through the chest wall or neck. The basilic vein is the usual choice for catheter insertion due to the blood flow rate of 95 mL/min. and it provides the straightest pathway to the superior vena cava. The tip of the catheter resides in the lower third of the superior vena cava, not in the right atrium. The usual length of the catheter is 40–60 cm. The PICC lines result in fewer problems than other types of access devices; however, common problems associated with PICC lines include phlebitis and infection. One common problem is that they tend to occlude frequently due to their small diameter. They need to be assessed thoroughly for breakage and phlebitis. Using a PICC line is the most appropriate method for infusing vesicants

such as dopamine HCL, hyperosmolar solutions such as TPN or blood products, and antibiotics that are potentially irritating drugs. These drugs and solutions can be infused through the PICC line because the superior vena cava is large and has a large volume of blood by which these medications are diluted before they enter the systemic circulation. Studies have indicated that PICC lines have been in place for up to 1 year. Current research is looking at the exact time frame for PICC line placement, so this time frame may change. These access devices may be inserted by specially trained nurses who complete a certification process. The PICC line is inserted at the bedside using a bedside ultrasound, which makes it possible to accurately visualize and access the veins in the upper arm. The PICC line is inserted in the upper arm 95% of the time. Upper arm insertion has a lower rate of thrombosis, phlebitis, and catheter migration. A small gauge (21–22 gauge) needle can be used that reduces the incidence of hematomas and damage to the vein. Most facilities use PICC-certified nurses to insert the line. As with all centrally placed catheters, a chest x-ray is taken to verify placement of the radiopaque catheter to validate that the tip is in the superior vena cava. The catheter must not be used until IV placement is verified. Trained healthcare workers may discontinue the line when no longer needed.

StatLock securement devices are routinely used to prevent complications and restarts in hospitalized clients. Documentation indicates there is a 45% decrease in these problems since the securement device has been instituted. When compared with suture securement, these devices have eliminated the sharps injuries when securing the central catheter lines. Arterial catheter restarts have been decreased by 49%. Using the StatLock device has lowered the rate of total IV complications by approximately 67%, decreased IV total complications from 48% to 16%, decreased phlebitis rate by approximately 80%, and decreased the rate of tape-related skin damage, which is documented to be as high as 54%. *Source:* www.bardaccess.com.

Sterile technique must be maintained throughout all procedures associated with CVADs and PICC lines. Infection may occur if contamination results from poor technique in maintaining insertion sites, flushing catheters, or inserting the noncoring needle. Transparent dressings are placed over the insertion site for better stabilization and easy assessment and monitoring.

Catheter-Related Bloodstream Infections

Catheter-related bloodstream infections (CRBSIs) are the fourth most common hospital-acquired infections with central line catheter placement. Approximately 80,000 CRBSIs occur yearly in U.S. ICUs with central lines, with 25% of the cases resulting in death. As of October 2008, the Center for Medicare and Medicaid Services (CMS) stopped reimbursing hospitals for these costs. Hospitals have been developing central line bundle procedures to reduce the rates of infection, usually following the Institute for Healthcare Improvement (IHI) guidelines.

Source: Martin, Walter MD, Harnage, Sophie RN. (May-June 2008.) A new bundle of preventing CRBSIs. Patient safety and quality healthcare. www.psqh.com.

Use of Antimicrobial Central Venous Catheters

Antimicrobial central venous catheters (CVCs) have been recommended for clients at risk for CRBSIs and for whom the expected duration of use is between 1 and 3 weeks. There are several types of antimicrobial CVCs. There is concern that the use of these catheters may encourage the emergence of resistant microorganisms; however, there is no evidence to support this at this time.

The most common type of antimicrobial CVC is coated with chlorhexidine and silver sulfadiazine. The newest available catheter has three times the concentration of chlorhexidine, with silver sulfadiazine on the external CVC surface. It has a coating of chlorhexidine on the internal surface of the CVC lumen. The results of a meta-analysis have demonstrated that the earlier type of CVC shows a significant reduction in CVC colonization and a trend toward a reduction in CRBSIs. There have been insufficient numbers of studies to form a conclusion on their effectiveness.

Total Parenteral Nutrition

Parenteral nutrition is a method whereby nutrients are introduced intravenously. Bypassing the normal gastrointestinal system, this route provides a nitrogen source for those with a nonfunctional gastrointestinal tract (enteral starvation) or those with high caloric requirements (burn client), or acute hypoalbuminemia.

Balanced blends of nutrients, including vitamins and minerals, can be administered both by central line and peripherally using isotonic concentrations of glucose (no greater than 10% dextrose). In contrast, hypertonic solutions that are irritating to veins are administered through a central, high-flow vein. Rapid dilution of the solution decreases risk of phlebitis, clot formation, and hemolysis. This technique requires special handling and management, presents greater risk for complications, and is the most expensive method of feeding.

Central Line Bundle

These are groupings of best practices that individually improve care, but when used together, greatly increase the outcome or prevention of CRBSIs. The central line bundle has five key components (www.ih1/IH1program):

- Hand hygiene
- Maximal barrier precautions
- Chlorhexidine gluconate skin antisepsis
- Optimal catheter site selection, with preferred site, the subclavian vein for nontunneled catheters
- Daily assessment of skin and lines

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to include in a client care plan when the components are related to intravascular therapy.

NURSING DIAGNOSIS	RELATED FACTORS
Activity Intolerance	Change in setting—intensive care, catabolic state Compromised cardiac reserve
Anxiety	Lifestyle modification, pain, chronic condition Uncertainty related to illness and diagnosis, placement of a CVAD
Decreased Cardiac Output	Impaired myocardial function, hypovolemia
Excess Fluid Volume	Excess fluid replacement, medications, renal and cardiac dysfunction
Infection, Risk for	Invasive procedures, inadequate site care, use of hypertonic glucose solutions
Deficient Knowledge	Ability to care for intravenous catheter or administer TPN
Imbalanced Nutrition: Less Than Body Requirements	Chronic fatigue states, nausea and vomiting, inadequate absorption, faulty metabolism, eating disorders, side effects of chemotherapy
Ineffective Peripheral Tissue Perfusion	Altered blood supply, arterial or venous, impaired myocardial contractility, hypovolemia

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. Remember to wash your hands or use antibacterial gel before and after each and every client contact.

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Percutaneous Central Vascular Catheters

Nursing Process Data

ASSESSMENT Data Base

- Determine client's level of consciousness so explanation of procedure can be done to allay anxiety.
- Assess level of anxiety to determine need for possible premedication.
- Assess skin and surrounding tissue for erythema, edema, and warmth.
- Assess circulating volume status and right heart function.
- Assess StatLock[®] site for potential complications.

PLANNING Objectives

- To assist the licensed practitioner with percutaneous central vascular catheter insertion
- To maintain patency of central vascular catheter
- To change central venous catheter dressing without complications
- To maintain the insertion site free of infection
- To prevent air embolism
- To monitor central venous pressure

IMPLEMENTATION Procedures

- Assisting With Percutaneous Central Vascular Catheterization 1114
- Changing a Central Line Catheter Dressing 1116
- Infusing IV Fluids Through a Central Line 1117
- Drawing Blood From Central Venous Access Device 1119
 - *Using the Vacutainer Method* 1119
 - *Using the Syringe Method* 1120
- Applying a BIOPATCH 1121
- Applying a StatLock[®] Securement Device 1122
- Removing a StatLock[®] Securement Device 1122
- Changing an Access Cap 1123
- Measuring and Monitoring Central Venous Pressure (CVP) 1123

EVALUATION Expected Outcomes

- Central vascular line is properly placed without complication.
- Central vascular line remains patent and free of infection.
- CVP monitoring guides fluid management.
- Central vascular catheter dressing is changed without complications.
- BIOPATCH is applied and potential infection prevented.
- Access cap replaced, maintaining sterile technique.
- StatLock[®] prevents catheter displacement.

Critical Thinking Application 1125

- Expected Outcomes 1125
- Unexpected Outcomes 1126
- Alternative Actions 1126

nursing.pearsonhighered.com

Prepare for success with NCLEX[®]-style practice questions and Skill Checklists

Assisting With Percutaneous Central Vascular Catheterization

Equipment

Specific nontunneled catheter
 Routine IV setup (tubing and solution)
 Through-the-needle radiopaque central catheter
 Local anesthetic, syringes, and needles
 Sterile gloves, sterile gown, masks, drapes, and sutures
 Antimicrobial 2% chlorhexidine gluconate swabs
 Intermittent infusion caps or positive pressure device
 Prefilled syringes with preservative-free normal saline
 Transparent semipermeable dressing
 Securement device

Procedure

1. Identify client using two descriptors and validate signed consent for catheter insertion.
2. Perform hand hygiene and explain procedure to client, including rationale for mask, positioning, and Valsalva's maneuver.
3. Place client in Trendelenburg position. ► **Rationale:** This position prevents air embolism and helps distend subclavian and jugular veins.
4. According to licensed practitioner's preference, extend client's neck and upper chest by placing a rolled pillow or blanket between shoulder blades. ► **Rationale:** Usual insertion sites are either subclavian or right jugular vein.
5. Place mask on client and turn client's head away from side of venipuncture. ► **Rationale:** This facilitates filling the vessel with blood and prevents contamination.
6. Maintain sterility while opening glove packet and sterile drape pack.
7. Open antimicrobial prep pads.
8. Don mask and gloves and assist with central catheter insertion.
 - a. Licensed provider dons mask, gown, and sterile gloves for this procedure.
 - b. Licensed provider prepares the client's skin, drapes area, and, using a sterile syringe and needle, draws up anesthetic to infiltrate the site.
 - c. As licensed provider inserts catheter, client is instructed to perform Valsalva's maneuver to prevent air embolism.
 - (1) Instruct client to exhale against a closed glottis or to hum.
 - (2) If client is unable to do this, compress client's abdomen. ► **Rationale:** Both these procedures help to decrease chances of air embolism.

NOTE: A 14-gauge needle is inserted into the subclavian vein, using the clavicle as a guide. When blood returns in syringe, the syringe is removed from the needle and a wire is threaded through the needle into the subclavian vein. The needle is removed and the catheter is fed over the wire into the subclavian and brachiocephalic vein. The wire is removed when the tip of the catheter rests in superior vena cava.

9. When catheterization is complete, insert injection cap, flush with 5 mL of normal saline, and then heparinize with 3 mL of dilute heparin (according to agency policy).
10. Apply securement device to skin and place catheter in clamp.
11. Cover securement device and catheter with sterile transparent dressing (according to hospital policy).
12. Label insertion site dressing with date, nurse's initials, and time of insertion.
13. Obtain x-ray for validation of placement into superior vena cava before initiating infusion (unless emergency placement performed).
14. Monitor client's vital signs. ► **Rationale:** Bleeding or pneumothorax may occur.

NOTE: New guidelines to prevent catheter-related bloodstream infection recommend that licensed provider dons cap and sterile gown in addition to mask and sterile gloves (Institute for Healthcare Improvement).

▲ Central line “Blue Guard.” Triple lumen catheter—subclavian vein.

Clinical Alert

Required drying time needed in order to prevent skin breakdown as a result of chemical reaction between solutions and dressings is as follows:

Solutions	Required Drying Time
Chlorhexidine gluconate 2% with alcohol	30 seconds
Chlorhexidine gluconate without alcohol	2 minutes
Povidone-iodine	2 minutes
70% isopropyl alcohol	Dries quickly, kills bacteria only when first applied. No lasting bactericidal effect; can excessively dry the skin.

Source: Hadaway, L. C. (2002). I.V. infiltration: Not just a peripheral problem. *Nursing*, 32(9), 36–48; Hadaway, L. C. (2003). Skin flora and infection. *Journal of Infusion Nursing*, 26(1), 44–48.

Guidelines to Prevent Catheter-Related Blood Stream Infections

Hand Hygiene

- Decontaminate hands with alcohol-based hand cleaner; if hands are visibly contaminated with blood or body fluids, use antimicrobial soap and water.
- Use hospital-provided hand lotions compatible with antiseptic agents to maintain integrity of skin. Home lotions may neutralize antibacterial agents in antiseptic agents used in hospitals.
- Decontaminate hands before and after putting on or removing gloves, providing direct client care, assisting with insertion of central venous catheter, inserting peripheral catheter, changing central venous dressing, or accessing catheter to administer medication or flush.
- Do not use artificial nails when working in the healthcare facility.

Barrier Precautions

- Use maximum barrier precautions when inserting or assisting with insertion of central venous catheters, including PICC lines. Include: cap that covers all hair, mask covering mouth and nose, sterile gown, and sterile gloves.
- Cover client from head to toe with large sterile drape leaving small opening for insertion of catheter.
- Place mask on client when PICC insertion is done, and cover face if subclavian or jugular vein placement site for central venous catheters.
- Keep all supplies together on nursing unit to prevent need to look for additional supplies after CVC insertion is begun.

Site Preparation Using Chlorhexidine Gluconate

- Prepare site using 2% chlorhexidine gluconate.

- Pinch wings on chlorhexidine applicator to break open ampule. Hold applicator down to allow solution to saturate pad.
- Press sponge against skin.
- Swab with applicator using a gentle back-and-forth motion. This motion creates friction and lets solution more effectively penetrate epidermal layers.
- Swab site for 30 seconds and then allow to dry thoroughly, approximately 2 minutes. Do not wipe or blot area.

Catheter Site Selection

- Use central venous catheters (CVCs) impregnated with antimicrobial agents, if available.
- Nontunneled percutaneously inserted CVCs are available with three different agents: chlorhexidine/silver sulfadiazine; rifampin/minocycline; and silver/platinum ionic metals. PICC brand uses rifampin/minocycline agents.
- Catheter should be inserted in the subclavian vein for nontunneled catheter.
- These catheters should be used for clients with dwell time of more than 5 days and in healthcare facilities where catheter-related bloodstream infection rates are high.
- There is inconclusive evidence that multiple-lumen catheters should not be used; even though they have higher infection rates, they also have fewer mechanical complications than single-lumen catheters.

Daily Assessment

- Evaluate need to determine when lines are no longer necessary and should be removed.
- Provide site care when needed.

EVIDENCE-BASED PRACTICE

Antimicrobial Swabs

Studies have shown that 2% chlorhexidine gluconate solution significantly lowers catheter-related bloodstream infection rates when compared with 70% povidone-iodine and 70% isopropyl alcohol.

Sources: LeBlanc, A., & Cobbett, S. (2000). Clinical Alert

To decrease pressure in the catheter, use a 10-mL syringe.

Clinical Alert

All continuous IV infusions administered via a central line must have an electric infusion controller device in place.

EVIDENCE-BASED PRACTICE**Chlorhexidine gluconate-impregnated sponges reduced rate of catheter-related infections in ICU**

Using chlorhexidine-impregnated sponge dressings with intravascular catheters reduced the risk for major catheter-related infections by 60% among patients treated in the ICU. Changing unsoiled, adherent dressings weekly was not inferior to a three-day changing schedule, according to data from the randomized controlled trial.

A randomly assigned study consisted of 1,636 patients over the age of 18 in an ICU setting. The patients were expected to need an arterial catheter, central vein catheter, or both for 48 hours or longer. Some of the patients received chlorhexidine-impregnated sponges and some the standard dressings, scheduled for change either once every seven days or once every three days. The rate for major catheter-related infection decreased from 1.40 per 1,000 catheter days to 0.60 per 1,000 catheter days with the use of the chlorhexidine-impregnated sponge. The three-day group had a 7.8% rate of catheter colonization vs. 8.6% for the seven-day group, which proves noninferiority for the seven-day dressing schedule compared with the three-day dressing schedule. Use of chlorhexidine gluconate-impregnated dressings decreases the rate of major catheter-related infection when the baseline rate is lower than two per 1,000 catheter days.

Source: Timsit, J F (2009: April 14). Chlorhexidine gluconate-impregnated sponges reduced rate of catheter-related infections in ICU, JAMA 2009;301: 1231-1241.

Changing a Central Line Catheter Dressing**Equipment**

- 2% chlorhexidine gluconate or according to facility policy
- Antimicrobial hand soap
- Tape or transparent dressing
- Needleless access caps
- Receptacle for soiled dressing
- Clean gloves
- Sterile gloves
- Mask
- Sterile long-sleeved gown, according to facility policy

Preparation

1. Review facility policy and procedure manual to determine protocol for skin prep.
2. Check Medication Administration Record and client chart for last dressing change (usually changed every 96 hr or per agency protocol), unless site is oozing.
3. Gather equipment.
4. Identify client using two descriptors and explain procedure to client.
5. Perform hand hygiene.
6. Position client flat on back. ► **Rationale:** Reduces risk of air embolism.
7. Turn client's head away from the insertion site and mask the client's nose and mouth. ► **Rationale:** Decreases exposure to microorganisms at site.
8. Make sure that all personnel don masks and/or gloves according to hospital policy.

Procedure

1. Don clean gloves and gown, according to facility policy.
2. Carefully remove old dressing or tape without pulling on catheter. Remove edges toward insertion site.
 - **Rationale:** This prevents stress on insertion site.

3. Discard old dressing and gloves in proper receptacle.
4. Inspect site for loose sutures, signs of infection, inflammation, or infiltration, and check length of exposed catheter.
5. Remove clean gloves, perform hand hygiene and don sterile gloves.
6. Cleanse insertion site, sutures, and catheter with 2% chlorhexidine in 70% alcohol or according to facility policy.
7. Cleanse site using back-and-forth scrubbing motion for 30 seconds.
8. Cover site with a sterile transparent dressing.
9. Change IV tubing according to hospital policy.
 - a. Clamp central catheter using on-line slide or squeeze clamp.
 - b. Use aseptic technique to change needleless access cap.
 - c. Prepare cap with antimicrobial swab.
 - d. Insert new tubing with needleless connector.

▲ Gauze dressings are used only if the catheter insertion site is oozing. The dressing should be changed every 48 hr or if soiled.

10. Label dressing and tubing with date and your initials.
11. Change dressing if it becomes loose, wet, or soiled or according to facility policy. ► **Rationale:** If it is wet, soiled, or loose, it is considered contaminated.
12. Discard equipment, gown, and gloves, and perform hand hygiene.

Clinical Alert

All primary and secondary continuous IV administration sets should be replaced at least every 96 hr (according to facility policy) or immediately if signs/symptoms of infection are present.

Intermittent sets should be changed every 24 hr.

TABLE 29-1 Administration Set Change According to Solution Type

Solution Type	Set Change Frequency
Parenteral Nutrition (Amino Acids)	q 72 hr or when integrity compromised
Lipids, Parenteral Nutrition Solutions containing Lipids	q 24 hr or when integrity compromised
Whole blood and components (platelets, red blood cell concentrate, plasma, cryoprecipitate)	4 hr or 2 units or immediately upon suspected contamination
Fractionated products (IVIG, Clotting factors, Albumin)	Upon completion of infusion

Source: U.S. Centers for Disease Control and Prevention, 2002.

Prevention of Air Embolism in Clients With Central Lines

1. Clear central line of air before insertion.
2. Use IV pumps with in-line air detectors.
3. Use the head-down position and Valsalva’s maneuver during both insertion and removal.
4. Use screw-on connections and secure with tape. ► **Rationale:** Hemostats or other clamps can crack hub and open system.
5. Use transparent dressing during the time the catheter is in place and after removal of a central catheter. Leave in place for at least 24 hr.

TABLE 29-2 Infusion Site Complications

Signs and Symptoms	Possible Indications
<ul style="list-style-type: none"> • Redness, swelling at CVAD infusion site • Crepitus on chest 	<ul style="list-style-type: none"> • Infiltration, hematoma, or sepsis • Subcutaneous emphysema that can lead to respiratory distress
<ul style="list-style-type: none"> • Respiratory distress with recent placement of a central line 	<ul style="list-style-type: none"> • Pneumothorax
<ul style="list-style-type: none"> • Arm, shoulder, or neck pain 	<ul style="list-style-type: none"> • Infiltration or thrombosis
<ul style="list-style-type: none"> • Temperature elevation • Fluid leaks from IV site 	<ul style="list-style-type: none"> • Catheter-related infection • Hole or break in catheter

Infusing IV Fluids Through a Central Line

Equipment

- Primed IV fluid administration set with needleless Luer-Lok connector
- Infusion delivery pump
- Antimicrobial swabs
- 10-mL needleless syringe with 5 mL of preservative-free 0.9% normal saline solution
- CLC 2000 Positive Pressure Cap (or another brand)
- Clean gloves

Preparation

1. Check physician’s order sheet and client’s Medication Record for IV order.
2. Check IV order with IV solution bag.
3. Take equipment to client’s room.
4. Identify client using two descriptors.
5. Explain procedure to client and provide privacy.

Procedure

1. Perform hand hygiene and don gloves.
2. Hang IV solution on IV stand.
3. Wipe access port with antimicrobial swab and allow to dry.
4. Insert needleless cannula from saline flush syringe and unclamp lumen. (Clamp is not found on PICC lines or Groshong valve catheter.)
5. Aspirate for blood return, using very little force, to check for lumen patency and placement.
6. Instill saline solution slowly. The CVD and tubing has a volume of 1–3 mL; therefore, about 5 mL solution in 10 mL syringe should be used to thoroughly flush the catheter. ► **Rationale:** To clear lumen of in-line dilute heparin.
7. Maintain positive pressure when withdrawing syringe by clamping catheter before removing syringe or by maintaining pressure on syringe plunger before you

▲ Hang IV solution on IV stand.

▲ Ensure clamp is open before attaching syringe.

▲ Attach 10-mL needleless syringe with saline to pressure valve.

▲ Attach point-of-care module and program.

▲ Aspirate and check for blood return before infusing saline solution.

▲ Wipe access cap or positive pressure clamp with antimicrobial swab and allow to dry.

▲ After connecting IV to catheter, turn on electronic device to prescribed rate.

clamp or use the CLC 2000 Positive Pressure Cap.

► **Rationale:** This prevents aspiration of blood into lumen and decreases risk of catheter occlusion.

8. Swab access port again with antimicrobial swabs.
9. Insert IV tubing with Luer-Lok connector into access port. Unclamp lumen.
10. Set electronic device to prescribed rate and begin infusing IV fluids.
11. Ensure central line dressing is clean and intact.
12. Remove gloves and perform hand hygiene.

Clinical Alert

To minimize pressure on the catheter during injection NEVER use less than a 10-mL syringe for central lines. Smaller syringes increase pressure within the catheter.

Clinical Alert

Nontunneled central vascular access devices have the highest infection rate of all types of CVADs; therefore, it is crucial that aseptic techniques be used in all aspects of catheter care.

Positive fluid displacement and positive end-pressure prevent blood reflux into catheter lumen. The device provides the saline flush to prevent clotting of catheter. (See Skill, Using a Positive Pressure Device, page 1141.)

Drawing Blood From Central Venous Access Device

Equipment

- 2 × 10-mL Luer-Lok syringes filled with sterile preservative-free normal saline
- 3-mL Luer-Lok syringe with 3 mL of heparinized saline (10 units/mL heparin) **ONLY** if policy of facility
- Two 10-mL syringes (or larger if needed)
- Antimicrobial swabs
- Blood tubes appropriate for tests ordered
- Sterile injection cap
- Clean gloves

Preparation

1. Check physician's orders and MAR.
2. Identify client using two descriptors.

Procedure

1. Explain procedure to client.

Clinical Alert

Some facilities do not allow Vacutainers to be used for blood draws from central lines because of increased pressure buildup in catheter.

2. Perform hand hygiene and don gloves and mask.
3. If fluids are infusing through catheter, turn off infusion for at least 1 minute before drawing blood specimen.
4. Swab cap and hub with antimicrobial swabs for 30 seconds and allow to dry. Use most distal lumen of catheter for blood draw. ► **Rationale:** Proximal port specimen will not be contaminated if fluids are infusing distally.
5. Remove cap from syringe, insert 10-mL saline-filled syringe, and unclamp catheter.
6. Flush catheter with 3–5 mL of normal saline.
 - **Rationale:** To determine patency of catheter.

Using the Vacutainer Method

- a. Clamp catheter
- b. Attach needleless connector to Vacutainer barrel holder.
- c. Place blood tube into Vacutainer holder.
- d. Disinfect injection or access cap with alcohol.
- e. Remove needle cover and insert Vacutainer needleless connector into injection or access cap.
- f. Unclamp catheter.
- g. Advance blood tube inside Vacutainer holder to activate retrograde blood flow.

- h. Hold tube in place until blood flow ceases; this is considered the “discard.” The volume should be 1.5–2 times the fill volume of the CVAD.
 - i. Clamp catheter and remove blood tube from Vacutainer holder, leaving needles and holder connected to injection or access cap.
 - j. Discard blood tube immediately into appropriate container.
 - k. Insert another blood tube, unclamp catheter, and obtain blood specimens as ordered.
 - l. After all specimens are collected, clamp catheter.
 - m. Remove Vacutainer holder and needleless connector from injection or access cap.
 - n. Disinfect injection or access cap with alcohol.
 - o. Flush catheter using 5 to 10 mL of preservative-free 0.9% sodium chloride.
 - p. Change injection or access cap and extension set, if needed.
- c. Disinfect catheter hub with alcohol.
 - d. Attach empty 10-mL syringe to catheter hub.
 - e. Unclamp catheter.
 - f. Withdraw 1.5–2 times the fill volume of the CVAD of blood and discard.
 - g. Reclamp catheter.
 - h. Remove and discard syringe into biohazard container.
 - i. Attach second syringe to catheter hub and unclamp catheter. Withdraw blood into syringe.
 - j. Reclamp catheter. Remove syringe.
 - k. Cleanse catheter hub with alcohol.
 - l. Attach prefilled injection or access cap attached to 10mL syringe with 5–10mL of preservative-free 0.9% sodium chloride.
 - m. Unclamp catheter and flush with sodium chloride solution.
 - n. Transfer blood from syringe into collection tube using needleless transfer device.

Source: Alexander, M., Corrigan, A., Gorski, L., et al. (2010). *Infusion nursing: An evidenced-based approach*. 3rd ed. St. Louis, MO: Saunders/Elsevier, Chapter 25, p. 503.

Source: Alexander, M., Corrigan, A., Gorski, L., et al. (2010). *Infusion nursing: An evidenced-based approach*. 3rd ed. St. Louis, MO: Saunders/Elsevier.

Using the Syringe Method

- a. Clamp catheter.
- b. Remove injection or access cap and discard.

▲ Unclamp catheter; clean cap and hub with antimicrobial swab, and allow to dry.

▲ Insert 10-mL needleless syringe into cap and unclamp catheter.

▲ Withdraw 5 mL of blood for discard before drawing blood sample unless specimen is for culture.

▲ Dispose of blood waste in biohazard container.

7. Clamp catheter, remove syringe and attach new 10-mL empty syringe. Unclamp catheter.

8. Withdraw 1.5–2 times fill volume of the CVAD; discard volume of blood from catheter slowly and then clamp catheter. Discard syringe. ► **Rationale:** To clear the catheter of fluids or medications, particularly heparin, before blood samples are obtained.

NOTE: Withdraw 8–10 mL of blood if coagulation studies have been ordered.

Clinical Alert

Do not discard any blood if drawing blood for cultures. Blood from the first draw is always used for blood cultures.

9. Discard syringe in biohazard box.
10. Remove gloves and discard.
11. Perform hand hygiene.

Clinical Alert

Specimens obtained from central catheter lines have been reported as inaccurate in some studies, especially coagulation studies. Heparin molecules can bind within the catheter to cause abnormal results. If lab values are significantly different from earlier values or from the normal range, assess client to determine whether additional lab tests need to be drawn. In this case, draw specimens from a direct vein, if possible.

Applying a BIOPATCH

Equipment

- BIOPATCH Antimicrobial Dressing with Chlorhexidine Gluconate
- BIOCLUSIVE Transparent Dressing or other similar dressings
- Sterile gloves
- Clean gloves
- Mask

Procedure

1. Check the client chart to determine last dressing change.
2. Gather equipment.
3. Identify client using two descriptors and explain procedure to client.
4. Remove dressing using clean gloves.
5. Perform hand hygiene and don sterile gloves.
6. Prepare skin surrounding percutaneous device according to hospital protocol. Ensure sufficient space is left between hub of catheter and insertion site for placement of dressing.
7. Remove dressing from sterile package using aseptic technique.
8. Place the BIOPATCH dressing around catheter so catheter rests on slit portion of patch. Ensure GRID side of patch is facing upward. The smooth foam side of patch is next to the skin.
9. Ensure edges of slit approximate each other to ensure efficacy of patch.

Clinical Alert

The patch is made of a hydrophilic polyurethane absorptive foam with chlorhexidine gluconate (CHG). The patch absorbs up to eight times its own weight in fluid and the CHG inhibits bacterial growth under dressing.

▲ BIOPATCH with transparent dressing over insertion site.

10. Apply transparent dressing over patch and catheter insertion site. Ensure complete contact between skin and transparent dressing.
11. Discard equipment packages.
12. Remove gloves and place in receptacle.
13. Perform hand hygiene.
14. Change BIOPATCH as necessary. Follow facility policy; however, dressing change should be at a minimum of every 7 days.
 - a. Don clean gloves.
 - b. Remove patch by picking up corner of dressing and stretching dressing away from catheter while holding catheter in place. Dressing should partially lift off skin when stretching dressing.
 - c. Peel back dressing until resistance is felt.
 - d. Repeat stretch and peel action until dressing is removed. Both the dressing and the patch will be removed together with this action.
 - e. Discard old dressing in biohazard container.
 - f. Discard gloves in appropriate receptacle and perform hand hygiene.

EVIDENCE-BASED PRACTICE**Evaluation of BIOPATCH Antimicrobial Dressing**

A controlled, randomized study of 687 clients with 1,699 central venous or arterial catheter insertion sites was conducted in two centers. Results indicated a 44% reduction in local infections and a 60% reduction in catheter-related bloodstream infections. There were no serious device-related adverse events during the study. Data regarding use of patch on children under 16 is limited. Patch should not be used on premature infants as hypersensitivity reactions and necrosis of the skin have occurred.

Source: Maki, D. G., Genihner, D., Hua, S., Chiacchierini, R. P. (2000). An evaluation of Biopatch Antimicrobial Dressing compared to routine standard of care in the prevention of catheter-related bloodstream infection. www.ethicon.com. Johnson & Johnson Medical Division of ETHICON, Inc.

Applying a StatLock® Securement Device**Equipment**

- Securement device
- Sterile gloves
- Antimicrobial skin prep, according to facility policy
- Transparent dressing

Procedure

1. Identify client using two identifiers.
2. Introduce yourself to client and explain procedure.
3. Open device package, sterile skin prep, and gloves.
4. Perform hand hygiene and don gloves.
5. Cleanse insertion and securement site with antimicrobial skin prep according to directions. Allow to completely dry.
6. Apply protectant (in package) to securement site. Allow to dry completely, about 10–15 seconds.
7. Align anchor pad so directional arrow points toward insertion site.

- a. *Using Post Version:* Place suture hole in catheter wing over first post, then slide catheter to capture second post.
- b. *Using Fixed Version:* Place suture holes in catheter wings over fixed posts.
8. Support undersurface of anchor pad and catheter while closing retainer doors.
9. Peel away paper backing from anchor pad, one side at a time, then place on skin.
10. Apply transparent dressing per facility policy.
11. Apply both provided dressing change labels.
12. Discard equipment in appropriate receptacle.
13. Perform hand hygiene.

NOTE: Monitor the device daily, and replace when clinically indicated, at least every 7 days. Treat insertion site according to facility policy. This device is sterile and latex-free; however, clients with known adhesive allergies should not use the device.

Removing a StatLock® Securement Device**Equipment**

- Sterile gloves
- New StatLock device
- 3–4 alcohol pads

Procedure

1. Open new device package.
2. Don gloves.
3. Remove transparent dressing using the “stretch technique.” Lift edge of anchor pad using three to four alcohol pads. Fold alcohol pad to squeeze out alcohol.
 - ▶ **Rationale:** This will dissolve undersurface of pad away from skin. Do not pull or force pad to remove.
4. Fold adhesive anchor pad underneath.
5. Stabilize catheter while holding the StatLock device.
6. Use thumb of opposite hand to gently lift retainer door from behind, while pressing down with index finger.

7. Reposition hands and repeat process to open second door.
8. Remove PICC from retainer and carefully reapply new device or discontinue line.

EVIDENCE-BASED PRACTICE**Peripheral Intravenous Catheter Dwell Times**

This prospective, sequential clinical trial evaluated the survival time of IV catheters using three methods: nonsterile tape, StatLock, and the Hub-Guard. The use of nonsterile tape securement resulted in an 8% peripheral IV catheter (PVI) survival rate, the Hub-Guard result was 9%, and the StatLock had a survival rate of 52%. The study was completed in an effort to determine the best method to assist in prolonging the 96-hr PIV change protocol. This study strongly suggests that a mechanical catheter securement device allows the implementation of the 96-hr IV change protocol that was sanctioned by the CDC.

Source: Smith, B. (2006). Peripheral intravenous catheter dwell times: A comparison of 3 securement methods for implementation of a 96-hour scheduled change protocol. *Journal of Infusion Nursing*, 29(1), 14–17.

Changing an Access Cap

Equipment

- Antimicrobial swabs
- Sterile resealable injection cap
- 10-mL syringe with 5–10 mL of preservative-free 9% normal saline for flush
- 10-mL syringe with 2–3 mL of heparin solution for maintenance according to agency policy
- Clean gloves

Procedure

1. Check client’s chart to determine time of last access cap change.
2. Identify client using two descriptors.
3. Explain procedure to client, and provide privacy.

Clinical Alert

The exact time interval is not scientifically known at this time, but it is suggested that the access cap be changed at least every 7 days, when the cap has been accessed more than the manufacturer’s recommendations, if the integrity of the port is compromised, if residual blood remains within the port, or after blood draw or blood administration. Positive Pressure Caps (such as the CLC 2000) are changed after blood draws.

4. Gather equipment.
5. Perform hand hygiene and don gloves.
6. Open access cap package maintaining sterility and place near working area.
7. Assess access cap to determine whether cap should be changed even if time frame is not met.
8. Place client in supine position. Clamp catheter using on-line slide or squeeze clamp. ► **Rationale:** To prevent air embolism during cap change. Client can be instructed to perform Valsalva’s maneuver during cap change as an alternative to lying supine.
9. Stop any IV infusion and disconnect IV tubing from access cap.
10. Remove existing cap using aseptic technique.
11. Take new access cap out of package, flush access cap with saline to prime, maintaining sterility, and place on catheter hub.
12. Cleanse injection cap with antimicrobial swab.
13. Flush catheter using 10-mL syringe with normal saline or insert new IV fluid tubing and begin infusion at prescribed rate.
14. Infuse heparin solution if central line is used for intermittent infusions ONLY if agency policy.
15. Remove gloves and perform hand hygiene.

TABLE 29-3 Maintaining CVADS: General Guidelines

CVAD	Frequency of Irrigation	Flush Solution
Single or multi-lumen	q 12 hr to daily, after each use	10–20 mL of normal saline
Percutaneous Catheter		
short-term		
long-term	daily to weekly and after each use	2–5 mL of dilute heparin (10 units) per lumen
Implanted Port	weekly and after each use	10 mL of normal saline after each infusion 3–5 mL of dilute heparin in 10-mL syringe monthly (100 units/mL)
Groshong Valve Device	weekly and after each use	10–20 mL of normal saline ONLY in 10-mL syringe
PICC	q 4–12 hr and after each use	Normal saline (twice the normal volume of the catheter and access device) followed by 5 mL of dilute heparin (10 units/mL)

Note: Check frequency and flush solutions according to agency protocols.

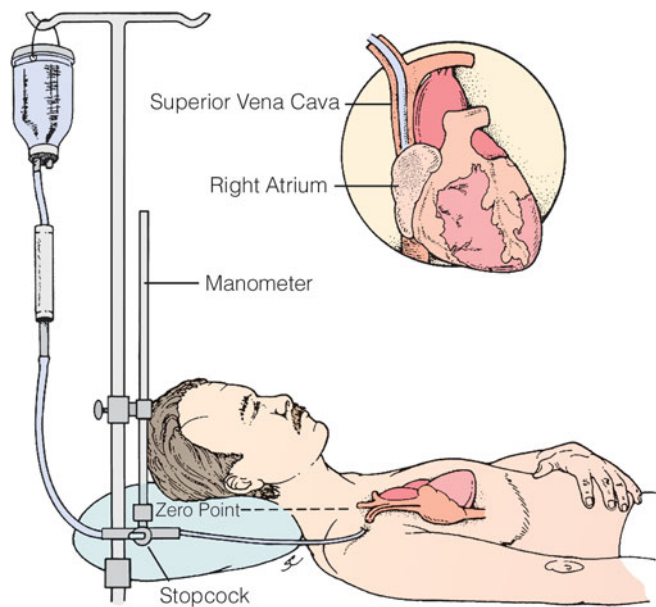

Measuring and Monitoring Central Venous Pressure (CVP)

Equipment

- Disposable CVP manometer with stopcock
- IV solution according to facility policy.
- Extension tubing with needleless Luer connector
- IV pole
- Carpenter’s level, laser
- Antimicrobial swabs
- Prefilled 10-mL syringe with 5 mL of preservative-free 9% normal saline
- Marker

Preparation

1. Check physician’s order.
2. Identify client using two descriptors.
3. Explain procedure to client.
4. Provide privacy.
5. Determine client’s previous CVP parameters. ► **Rationale:** Trends are more relevant than isolated pressure readings.

▲ When a CVP reading is taken, the zero of the manometer must be level with client's right atrium, regardless of his position.

Procedure

1. Perform hand hygiene.
2. Spike IV solution bag with IV administration set using sterile technique.
3. Prime tubing with solution.
4. Close clamp on tubing.
5. If you are using a one-piece disposable manometer and stopcock, affix unit to IV pole.
6. Push male end of IV administration set into female end of stopcock, connecting the IV set to stopcock.
7. Turning stopcock so that manometer and IV solution are open to each other, open clamp on IV tubing and fill manometer with IV solution to between 18 and 20 cm. ► **Rationale:** Overfilling the manometer may expose the client to contamination resulting from overflow.
8. Close clamp and rotate stopcock so that IV solution is open to client.
9. Prime the rest of IV tubing that extends from stopcock to client's central line.
10. Place client flat in bed, without a pillow, if client can tolerate this position. If not, place client in position of comfort (e.g., head of bed at 15°–30°).
11. Record position so that same position can be used each time a CVP reading is made. ► **Rationale:** This allows accurate CVP trending.
12. Locate client's right atrium (midaxillary at fourth intercostal space). Mark this location on client's skin using marking pen.
13. Adjust level of CVP manometer (using carpenter's level) so that zero on manometer is at the same level as client's right atrium, 5 cm on manometer level to sternal notch. ► **Rationale:** Using level at right atrium reflects blood volume and cardiac function of client.
14. Turn stopcock to open position for manometer, filling manometer with additional solution if needed.
15. Turn stopcock to the manometer→client position and watch level of the solution in the manometer fall to the pressure level existing in the right atrium. ► **Rationale:** Normally this pressure should be between 5 and 10 cm. Remember, however, there are no absolute values and trends—the rise and fall of CVP readings are more important than one isolated pressure reading.
16. Observe meniscus at eye level and watch rise (with exhalation) and fall (with inhalation) of fluid column in response to client's breathing. ► **Rationale:** Fluctuations reflect changes in intrathoracic pressures during respiratory cycle and indicate that manometer is functioning properly.
17. Take reading at end of exhalation (rise of fluid in manometer).
18. Turn off stopcock to manometer, and adjust rate of infusion to reestablish IV solution flow to client.
19. Return client to desired position and record CVP reading.

▲ Left stopcock: Fill the manometer by turning stopcock OFF to the client. This allows solution to flow from the container to the manometer. Middle stopcock: Measure CVP by turning stopcock OFF to the IV solution, allowing fluid to flow from manometer to client. Right stopcock: Reinstigate flow from IV container to the client by turning stopcock OFF to the manometer.

Clinical Alert

Central venous pressure (CVP) is a measure of venous return or the pressure of blood in the right atrium. Used to guide fluid administration, it is measured in centimeters of water pressure (normal is 5–10 cm H₂O).

▲ Take CVP reading.

▲ CVP reading is taken with manometer zeroed at client's maxillary fourth space.

▲ Solution to manometer.

▲ Manometer to client.

▲ Solution to client.

DOCUMENTATION for Central Vascular Catheterization

- Location of insertion site
- Type and size of cannula used for insertion
- Time of insertion
- Assessment of site and dressing every 8 hr
- Name of physician performing catheterization
- Types of solutions infused
- Amount of solution infused
- Time x-ray was performed to check position of catheter
- Time, initials, date dressing and tubing changed
- Date and time of CVP reading (record subsequent CVP readings on appropriate flow sheets)
- Client's response to treatment
- Any unusual conditions or reactions

CRITICAL THINKING Application

Expected Outcomes

- Central vascular line is properly placed without complication.
- Central vascular line remains patent and free of infection.
- CVP monitoring guides fluid management.
- Central vascular catheter dressing is changed without complications.
- BIOPATCH is applied and potential infection prevented.
- Access cap replaced, maintaining sterile technique.
- StatLock prevents catheter displacement.

Unexpected Outcomes

Air enters central vein, producing air embolism from system being open to atmosphere.

Alternative Actions

- Immediately clamp catheter and place client in Trendelenburg's position (turned to the left so right ventricle is uppermost).
- Immediately inform physician and monitor until physician arrives. Assess vital signs and breath sounds.
- Administer high-flow O₂ as necessary.
- Prevent air embolism by having client perform Valsalva's maneuver any time catheter is open to air, or use in-line catheter clamp.
- Ensure client has a patent peripheral IV line.

Infection at insertion site.

- Prepare for catheter removal and possible reinsertion at another site.
- If catheter is removed, cut off catheter tip with sterile scissors and place in sterile container; send tip to laboratory for culture.
- Administer antibiotics as ordered.
- Observe client carefully for signs of systemic infection.

Dysrhythmia detected.

- Change client's position.
- Notify physician.
- Verify catheter position on chest x-ray (right atrium placement causes dysrhythmias).
- Prepare for catheter repositioning or removal of catheter by physician.

Catheter becomes dislodged.

- Check the exact length of catheter to determine extent of problem.
- Secure catheter and extension tubing with securement device to prevent further migration of tube.
- Notify physician immediately.

Catheter appears to be or becomes occluded.

- Reposition client.
- Ask client to raise arms overhead.
- Follow facility policy and procedure
- Assess mechanical problem: tubing, pumps, catheter, clamps, insertion site, or securement device.
- Assess nonthrombotic problem: medications infused, fluids, or withdrawal of blood. Use of precipitate clearance agent is established by individual facility policies and procedures.
- Assess thrombotic problem: use of thrombolytic clearance agents is established by individual facility policy and procedures.
- Perform Valsalva's maneuver. Turn head to one side.
- Attempt to flush catheter with normal saline, using gentle pressure.
- Notify physician for order to administer fibrinolytic agent or other agents.

CVP system does not infuse.

- Check line for kinks. Change client's position. Check to make sure the manometer stopcock is in the IV→ client position.
- Obtain order for placing heparin in IV bag to maintain patency.
- Notify physician and prepare for possible reinsertion.

CVP readings vary greatly.

- Assess patency of setup.
 - Assess client's level of pain; pain increases the CVP reading.
 - Assess if position of client has been changed; raising the head of the bed alters the reading unless setup is adjusted.
 - Check that the marked area at midaxillary level is at the level of the client's right atrium (4th ICS).
 - If client has COPD, heart failure, or hypovolemia, expect readings to differ from normal range. However, once baseline is established for individual client, trends should be watched and evaluated against goals of therapy.
-

Chapter 29

UNIT 2

Total Parenteral Nutrition/Total Nutrient Admixture

Nursing Process Data

ASSESSMENT Data Base

- Complete a physical assessment and client history.
- Assess client’s nutrition status.
- Identify any condition that would affect TPN (renal or cardiac disease).
- Assess nutritional needs of clients who are unable to process nutrients normally (gastrointestinally).
- Observe for correct additives in each hyperalimentation bag or container.
- Check rate of infusion on physician’s orders.
- Monitor catheter insertion site for signs of infection or possible infiltration.
- Monitor regularly client’s blood sugar response to hyperalimentation.

PLANNING Objectives

- To provide a nutrition source for clients unable to process nutrients normally
- To provide nutrients for clients requiring bypass of the gastrointestinal tract (bowel rest)
- To provide increased calories for clients in a catabolic state
- To prevent or correct a deficiency of essential fatty acids
- To provide a contamination-free mode of delivering parenteral nutrition
- To regularly administer sliding scale insulin according to client’s glucose level

IMPLEMENTATION Procedures

- Assisting With Catheter Insertion.....1129
- Maintaining Total Parenteral Nutrition (TPN) Infusions1131
- Changing Total Parenteral Nutrition (TPN) Infusion Dressing and Tubing1132
- Maintaining Total Parenteral Nutrition (TPN) Infusions for Children1133

EVALUATION Expected Outcomes

- Catheter is placed correctly.
- Dressing remains dry and intact.
- Catheter insertion site remains free of infection and inflammation; sepsis does not occur.
- TPN infuses at prescribed rate and client receives nutrients necessary for tissue repair.
- Client’s blood glucose is maintained within normal parameters.
- Client’s electrolytes, protein, renal, and liver function maintained within normal parameters.

NOTE: Total Nutrient Admixture (TNA) is being used more frequently in healthcare facilities. Skills are the same as for TPN, only the solution composition is different.

Critical Thinking Application 1134

- Expected Outcomes1134
- Unexpected Outcomes.....1134
- Alternative Actions1134

Pearson Nursing Student Resources

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Assisting With Catheter Insertion

Equipment

Multi-lumen catheter
 Antimicrobial swabs, 2% chlorhexidine gluconate
 Transparent dressing
 Sterile 4 × 4 gauze pads
 Sterile gloves
 Sterile drapes
 Sterile gown
 Two masks
 3-mL syringe with 25-gauge needle
 Lidocaine (Xylocaine—local anesthetic agent)
 Suture material, only if securement device not used
 Syringe with 5 mL of normal saline
 Syringe with 2 mL of dilute heparin
 IV administration set with appropriate filter
 Hyperalimentation solution
 Blanket or pillow to provide roll under shoulders

Preparation

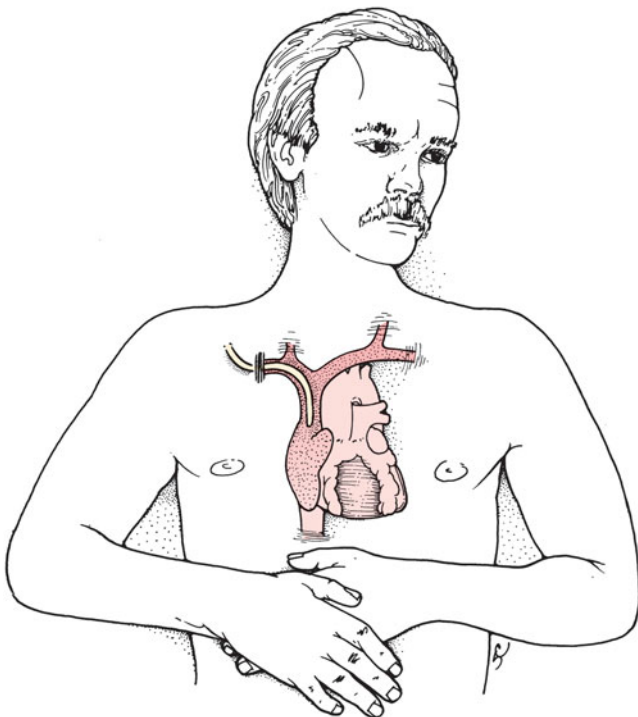

1. Identify client using two descriptors and validate signed consent for catheter insertion.
2. Reinforce procedure explanation to client to allay anxiety.
3. Teach Valsalva's maneuver for use during catheter insertion procedure. ► **Rationale:** This maneuver prevents air from entering the catheter during catheter insertion or tubing changes.

Composition of TPN Solutions

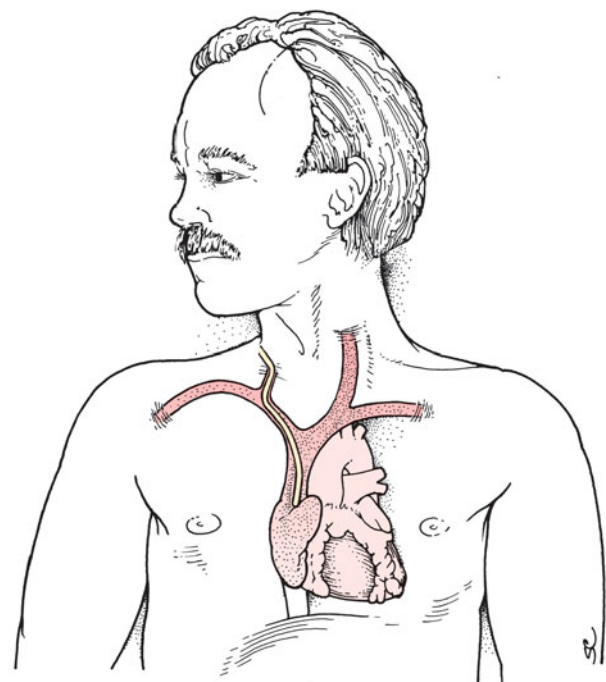

- Amino acid
- Carbohydrates—10%–35% glucose
- Vitamins (become inactive when exposed to light)
- Minerals and trace elements
- Electrolytes (individualized)
- Water
- Hyperalimentation solution is prepared aseptically in the pharmacy under a laminar flow hood

- a. Ask client to take a deep breath and bear down without exhaling.
 - b. This action produces increased intrathoracic pressure.
4. Review physician's orders for correct hyperalimentation solution.
 5. Inspect TPN container for layering, turbidity, or precipitates. If there are layers, return to pharmacy.
 6. Assemble IV system with in-line filter. Tubing with a 1.2 micron filter is used for TPN with lipids; a 0.2 micron filter is used for TPN without lipids.

NOTE: Many facilities use interventional radiology to insert central venous catheters.

▲ Right subclavian vein is preferred access to right atrium.

▲ Central venous catheter inserted via right jugular vein.

7. Perform hand hygiene.
8. Prime IV tubing and filter with solution.
9. Insert IV tubing into infusion pump.

Procedure

1. Position client in head-down position with head turned to opposite direction of catheter insertion site. Place a small roll between client's shoulders to expose insertion site. ► **Rationale:** This position increases intrathoracic venous pressure and reduces risk of air embolism.
2. Assist physician to put on gown, mask, and gloves before beginning procedure.
3. Don mask and sterile gloves.
4. Cleanse insertion area with antimicrobial swab.
 - a. Cleanse a large area around insertion site.
 - b. Use a scrubbing back-and-forth motion.
 - c. Scrub for 30 seconds.
5. Assist physician as needed during catheter insertion.
6. Instruct client in Valsalva's maneuver when stylet is removed from catheter and injection cap is connected to catheter.
 - a. Instruct client to exhale against a closed glottis.
 - b. If client is unable to do this, compress client's abdomen. ► **Rationale:** Both these procedures help decrease possibility of air embolism.

Clinical Alert

TPN and lipids are frequently infused together in the same bottle to prevent microorganism growth from lipid emulsion.

7. After cap is connected, instruct client to breathe normally.
8. Flush catheter with saline, then heparinize with dilute heparin according to agency policy.
9. Apply transparent dressing over insertion site.
10. Obtain portable chest x-ray to verify correct catheter placement.
11. After confirmation of catheter placement, initiate hyperalimentation solution and adjust flow rate as ordered.
12. Observe for signs of complications.
13. Take vital signs every 4 hr. ► **Rationale:** If signs change or temperature rises significantly, the client may be developing complications.

Monitoring Guidelines for TPN

- Monitor for signs of infection or sepsis at the insertion site—the most common complication of TPN.
- Weigh client daily—observe for fluid gain or loss (0.5–1.5 kilograms or 1–3 pounds per week). Weight gain may indicate fluid overload rather than nutritional gain.
- Monitor electrolyte and protein levels. Electrolyte imbalances may occur.
- Regularly monitor blood glucose levels observing for hyperglycemia (thirst, polyuria).
- Assess blood urea nitrogen and creatinine levels—increases may indicate excess amino acid intake.
- Check liver function test results—abnormal values may indicate an excess of lipids or problems in protein or glucose metabolism.

TABLE 29-4 Complications With Total Parenteral Nutrition

Implementation			
Complication	Symptoms	Prevention	Nursing Action
Air embolism Air enters catheter during catheter insertion or tubing changes	Potentially fatal Respiratory distress, apprehension Chest pain, dyspnea Hypotension Pulse weak and rapid Churning heart murmur (classic sign)	Instruct client in Valsalva's maneuver for tubing and cap changes Check all catheter connections Place client in head-down position with head turned opposite direction of insertion site (increases intrathoracic venous pressure)	Clamp catheter Place client in left Trendelenburg position (to trap air in right side of heart) Notify physician Administer oxygen as ordered
Catheter-related infection (sepsis) Because the TPN solution is high-concentrate glucose, it is a medium for bacterial growth	Fever (early sign), chills Insertion site—erythema or drainage Elevated white blood cell count Septic shock	Use strict aseptic technique Change solution every 12 hr Change tubing as ordered (every 24 hr using aseptic technique) Change dressing every 48 hr	Remove tip of catheter, send to laboratory for culture Administer antibiotics as ordered

TABLE 29-4 Complications With Total Parenteral Nutrition (Continued)

Complication	Symptoms	Implementation	
		Prevention	Nursing Action
Hypoglycemia Increased blood glucose level due to infusion, stress, medications, diabetes	Elevated glucose levels (more than 200 mg/dL) Excessive thirst, fatigue, restlessness, confusion, weakness, diuresis When severe—coma	Check history for glucose intolerance; frequent glucose monitoring—check medications (e.g., steroids) Begin infusion at slow rate (usually 40 mL/hour) Increase proportion of calories as lipids Do not “catch-up” if infusion rate falls behind	Start sliding-scale insulin therapy as ordered Monitor blood glucose levels every 4–6 hr Maintain blood glucose <200 mg/dL
Hypoglycemia TPN is discontinued abruptly or client is receiving too much insulin	Client is shaky, weak, anxious, diaphoretic May be hungry Decreased blood glucose (less than 70 mg/dL)	Continue blood glucose monitoring Gradually decrease infusion when discontinuing TPN Use infusion pump	Infuse 10% dextrose in water (50% may be needed) (Restart IV if necessary) Assess blood glucose 1 hr after discontinuing TPN

Maintaining Total Parenteral Nutrition (TPN) Infusions

Equipment

- Parenteral nutrition solution (TPN) (refrigerated)
- IV tubing, filter, and infusion pump
- Extension tubing
- Glucometer
- I&O record
- Securement device

Procedure

- Store TPN solution in refrigerator until 30 minutes before use. (Some pharmacies deliver the solution before each infusion.) ► **Rationale:** Solution is refrigerated to prevent growth of organisms, but should be left at room temperature 1 hr before use.
- Ensure central line is patent when infusing TPN. Check for patency according to facility policy.
- Change IV tubing and filter every 24 hr. This is completed when entire system is changed. ► **Rationale:** This is recommended for TPN infusions to prevent infection.
- Maintain IV flow rate as prescribed. Use infusion pump for infusion.
 - If rate is too rapid, hyperosmolar diuresis occurs (excess glucose and water is excreted); if severe enough, intractable seizures, coma, and death can occur.
 - If rate is too slow, little benefit is derived from the calories and nitrogen.

▲ Total parenteral nutrition.

▲ Nontunneled catheter used to deliver parenteral nutrition.

Clinical Alert

Do not “catch up” a deficit in infused volume, as doing so could result in complications for the client. To ensure constant flow rate, check rate every 2 hr.

5. Change solution every 24 hr. ► **Rationale:** Changing the solution prevents growth of bacterial organisms that proliferate in glucose solution.
6. Monitor client’s blood glucose regularly (e.g., every 6 hr).
7. If necessary, administer Regular insulin according to prescribed “sliding scale.”

▲ In-line filter used when administering TPN solution.

8. Maintain accurate I&O.
9. Observe for complications, such as air embolus, hyperglycemia, osmotic diuresis, infiltration, or sepsis.

Clinical Alert

No medication or blood products are to be added or piggybacked into TPN line. No blood specimen should be withdrawn from an IV line infusing TPN. TPN is never stopped abruptly. It should be tapered off.

Changing Total Parenteral Nutrition (TPN) Dressing and Tubing

Equipment

- Clean and sterile gloves
- Mask
- IV tubing and filter (0.22 micron)
- TPN solution
- 2 × 2 sterile gauze pads and tape
- Antimicrobial swabs, 2% chlorhexidine gluconate
- Transparent semipermeable dressing
- Securement device

Preparation

1. Check to determine when tubing was last changed.
2. Gather equipment and perform hand hygiene.
3. Verify client ID using two descriptors and explain procedure to client.
4. Connect IV tubing and filter to parenteral hyperalimentation (TPN) solution container.

5. Flush tubing to clear air.
6. Place IV tubing through infusion pump.
7. Prepare dressing: antimicrobial swabs, sterile 2 × 2 gauze pads and tape, or sterile transparent dressing.
8. Place client supine with head turned in opposite direction of insertion site. Instruct client not to talk or cough. (Place mask on client if client cannot cooperate.) ► **Rationale:** These instructions reduce risk of contamination.

Procedure

1. Don mask (according to institutional policy) and clean gloves.
2. Remove old dressing and discard both dressing and gloves in appropriate receptacle.
3. Don sterile gloves.
4. Observe insertion site for signs of erythema, drainage, or swelling.

Clinical Alert

When central-line dressings are loose, wet, or soiled, they are considered contaminated and must be changed. Dressings are routinely changed every 72 hr.

5. Cleanse insertion site with antimicrobial swabs, using back-and-forth motion for 30 seconds.
6. Allow 30 seconds for drying.
7. Apply securement device following package instructions and according to agency policy.
8. Place sterile transparent dressing over insertion site.
9. Change IV tubing.

- a. Clamp catheter using slide clamp.
 - b. Loosen tubing in catheter hub.
 - c. Insert new primed tubing *or*
 - d. Cap catheter and insert new IV tubing using needleless connector or use positive pressure device.
10. Remove gloves and perform hand hygiene.
 11. Label dressing with date and your initials.

Clinical Alert

Transparent dressings are changed every 72–96 hr. Transparent dressings are preferred unless site is draining.

Maintaining Total Parenteral Nutrition (TPN) for Children**Equipment**

Same as for adult Parenteral Nutrition with these additions:

- Intracath, 22-gauge needle
- Microdrip IV tubing administration set
- 0.22 micron in-line filter
- Restraints, only if necessary and ordered

Preparation

1. Identify client using two descriptors.
2. Gather equipment for blood glucose monitoring and dressing change.
3. Perform hand hygiene.

Procedure

1. Verify solution with physician's orders.
2. Examine solution. Generally, there is a higher concentration of calcium, phosphorus, magnesium, and vitamins. Either a 10% dextrose/2% amino acids or 5% dextrose/4% amino acids solution can be infused peripherally. Higher concentrations are infused centrally, as is long-term therapy.
3. Monitor patency of catheter. Stopcocks are never used. Monitor infusion pump and filter.

4. Obtain finger stick or urine glucose samples every 8 hr. Glucose level rises, but usually exogenous insulin is not required as the pancreas adapts to high glucose loads.
5. Monitor intake and output and daily weight.
6. Change the dressing every 96 hr and the tubing every 24 hr using aseptic technique. Stockinette can be used to keep scalp dressing secure. Tight-fitting T-shirt can keep chest site secure.
7. Monitor for accurate rate of infusion. Do not “catch up” if infusion is behind. Pumps can be used to maintain infusion rates, particularly when small amounts of solution are being infused.
8. Observe the child when ambulating for twisting or kinking of tubing, getting the tubing caught in the crib, or stepping on it.
9. Instruct parents on rationale for treatment and methods to prevent accidental dislodging of the tubing.
10. Provide play therapy and sources of stimulation to distract the child from the catheter.
11. If discontinuing TPN, taper infusion for 1 hr (decrease rate every 30 min). ► **Rationale:** Abrupt discontinuation may cause a hypoglycemic reaction since insulin production is increased.

DOCUMENTATION for Total Parenteral Nutrition

- Special TPN sheet may be used; if so, charting is done directly on the sheet or computer
- Catheter type, insertion site, physician's name
- X-ray, following insertion
- Type of parenteral nutrition solution and flow rate
- Results of blood glucose monitoring
- If insulin administered, type, amount, and site
- Date and time of dressing and tubing change with name or initials of person who did the change
- Condition of insertion site
- Client's tolerance of procedure
- Daily weights
- Intake and output

CRITICAL THINKING Application

Expected Outcomes

- Catheter is placed correctly.
- TPN infuses at prescribed rate and client receives necessary nutrients for tissue repair.
- Dressing remains clean, dry, and intact.
- Catheter insertion site remains free of infection and inflammation; sepsis does not occur.
- Client's blood glucose remains within normal parameters.
- Client's electrolytes, protein, renal, and liver function maintained within normal parameters.

Unexpected Outcomes

Parenteral nutrition solution is not infused at the prescribed rate.

Alternative Actions

- Observe filter to ensure patency. A plugged filter is the most common cause of infusion failure. Change the filter and tubing.
- Ensure that the next parenteral nutrition bag is ready to be superimposed.
- Observe for signs of hypoglycemia caused by sudden change in dextrose concentration—weakness, trembling, sweating, hunger. Check blood glucose.
- Adjust flow rate to that which was ordered. Do not attempt to “catch up” the amount not infused as this action could lead to osmotic diuresis from hyperglycemia.

Catheter insertion site becomes inflamed.

- Notify physician immediately so catheter can be discontinued if catheter-related sepsis is suspected.
- Cut tip of catheter off with sterile scissors and place in sterile container. Send to laboratory for culture and sensitivity for specific causative organism.
- Cleanse site of catheter insertion with antimicrobial swab and place sterile dressing over site.
- Obtain order for and administer antibiotics as needed.

The dressing becomes wet or loose.

- Change the dressing as soon as moisture is observed, using aseptic technique.
- If the dressing is exposed to moisture or secretions, cover with transparent dressing (e.g., showering).

TPN solution temporarily unavailable.

- Infuse D10W IV solution at prescribed rate until TPN solution is available.

Lipid Emulsion Therapy

Nursing Process Data

ASSESSMENT Data Base

- Observe for signs of essential fatty acid deficits: rash; eczema; dry, scaly skin; poor wound healing; sparse hair.
- Assess pancreatic function.
- Assess client for predisposing factors that could promote fat emboli, such as anemia, coagulation disorders, abnormal liver or pulmonary function.
- Check IV site for patency, erythema, and edema before infusing solution.
- Assess vital signs to establish baseline.

PLANNING Objectives

- To spare protein in critically ill client
- To provide a source of energy for clients with deficient protein intake
- To provide essential fatty acids

IMPLEMENTATION Procedures

- Infusing IV Lipids1136

EVALUATION Expected Outcomes

- Lipids infused within time frame.
- Adequate calories and essential fatty acids are provided to clients unable to ingest orally.
- Parenteral nutrients are provided without complications or adverse effects.
- Normal pancreatic function is maintained.

Critical Thinking Application1138

- Expected Outcomes1138
- Unexpected Outcomes1138
- Alternative Actions1138

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX[®]-style practice questions and Skill Checklists

Infusing IV Lipids

Equipment

- IV lipid solution in container
- Non-phthalate vented IV tubing infusion set (to prevent pooling of fat in IV tubing)
- Needleless cannula
- 2% chlorhexidine gluconate swabs
- Volume control device

NOTE: Many facilities do not infuse lipids alone but combine with TPN.

Preparation

1. Review physician's orders and MAR.
2. Obtain lipid emulsion (refrigerated) from the pharmacy and allow to warm to room temperature (may take 1 to 2 hr).
3. Examine solution for separation of emulsion into layers or fat globules or for accumulation of froth. Do not use if any of these appear.
4. Label bottle/bag with client name, medical record number, room number, date, time, flow rate, bottle number, and start and stop times.
5. Identify client using two forms of identification.
6. Explain procedure to client.

Procedure

1. Take vital signs for baseline assessment. ► **Rationale:** Baseline information is needed because an immediate reaction can occur.
2. Perform hand hygiene and then swab stopper on IV bottle with antimicrobial swab and allow to dry.
3. Attach vented non-PVC infusion set to bottle, twisting the spike to prevent particles from stopper falling into the emulsion, or spike bag with regular IV tubing.
4. Hang IV bottle at least 30 in. above IV site.
 - **Rationale:** Due to solution viscosity, lipid emulsion needs to be at this height to prevent backing up into infusion tubing.
5. Fill drip chamber two-thirds full, slightly open clamp on the tubing, and prime the tubing slowly. ► **Rationale:** Priming more slowly reduces chance of air bubbles with this solution.
6. Attach the tubing to the IV site.
7. If piggybacking lipids into hyperalimentation, use port closest to client, below tubing filter.

Clinical Alert

Administration sets that contain di-(2-ethylhexyl)phthalate (DEHP) plasticizers extract lipids from infusion set. It is recommended to use a separate administration set, glass infusate containers, or special non-polyvinyl chloride (non-PVC) IV bags.

Clinical Alert

Lipid emulsions alone promote growth of specific bacteria and yeasts as soon as 6 hr after the infusion. When lipids are combined with TPN (solution of amino acids, lipid emulsion, and glucose) in the same bag, it doesn't appear to support any greater microbial growth than non-lipid-containing TPN fluids. Thus TPN solution can hang safely for 24 hr.

Clinical Alert

In-line filters are not recommended by CDC as a routine infection control measure; however, the Infusion Nurses Society favors the filters. Always check hospital policies and procedures to determine use of filters.

8. Infuse lipid solutions initially at 1 mL/min for adults and 0.1 mL/min for children for first 15–30 minutes. Then increase rate to 2 mL/min for adults and 0.2 mL/min for children.
9. Monitor vital signs according to facility policy and observe for side effects during first 30 minutes of the infusion. If side effects occur, stop the infusion and notify the physician.

▲ Lipids are administered from glass container or non-PVC infusion sets.

▲ Vented tubing is required for lipid infusion.

▲ Check facility policy regarding use of in-line filters for lipid administration. Filters are not recommended by CDC but Infusion Nurses use them.

10. Adjust flow to prescribed IV rate if no adverse reactions occur.
11. Monitor and maintain the infusion at the ordered rate.

Guidelines for IV Lipid Infusion

- IV lipid solutions are isotonic and provide 1.1 kcal/mL of solution in a 10% solution or 2.0 kcal/mL in a 20% solution.
- Do not put additives into IV lipid bottle.
- Do not use an IV filter because the particles are large and cannot pass through.

For Adults

- Lipid 10%: Up to 500 mL 4–6 hr on first day to maximum of 2.5 g/kg body weight per day. Do not exceed 60% of client's total caloric intake per day.
- Liposyn 10%: No more than 500 mL/day in 4–6 hr.

For Children

- Lipid 10%: Up to 1 g/kg in 4 hr. Do not exceed 60% of total caloric intake.

12. Monitor serum lipids 4 hr after discontinuing infusion.
 - ▶ **Rationale:** If you draw blood too soon after infusion is completed, incorrect blood values result.
13. Monitor liver function tests for evidence of impaired liver function. ▶ **Rationale:** These tests indicate the liver's ability to metabolize the lipids.
14. Discard partially used bottles/bags. ▶ **Rationale:** This action prevents contamination.
15. Discard administration set after each unit unless additional units are administered consecutively.
16. Continue to monitor vital signs and observe client for adverse reactions during the entire process of infusion.
17. Answer any questions the client may have about the procedure and make client comfortable before leaving room.

Clinical Alert

Observe for IV lipid side effects after starting lipid infusion:

chills	chest and back pain
fever	nausea and vomiting
flushing	headache
diaphoresis	pressure over the eyes
dyspnea	vertigo
cyanosis	sleepiness
allergic reactions	thrombophlebitis

DOCUMENTATION for Lipid Emulsion Therapy

- Type of solution infused
- Rate of infusion
- Site of infusion
- Vital signs monitored
- Adverse clinical manifestations and appropriate nursing intervention

CRITICAL THINKING Application
Expected Outcomes

- Lipids infuse within time frame.
- Adequate calories and essential fatty acids are provided to clients unable to ingest orally.

Unexpected Outcomes

Client experiences side effects and cannot continue with lipid infusion.

Client develops dyspnea, cyanosis, or allergic reaction, such as nausea, vomiting, increased temperature, or headache.

Client's serum triglyceride and liver function test results remain elevated.

Client develops hyperlipemia or hypercoagulability.

- Parenteral nutrients provided without complications or adverse effects.
- Normal pancreatic function is maintained.

Alternative Actions

- Reassess client's ability to tolerate fat solution.
- Notify physician for order to discontinue fat solution, and administer hyperalimentation solution.
- Monitor liver function test results.
- Stop infusion immediately and notify physician.
- Continue IV lipid infusion.
- Begin the feeding with a weaker concentration of formula and increase the concentration slowly as ordered.
- Repeat lab values.
- Monitor laboratory results, particularly liver function tests, and notify physician when any abnormality occurs.

Tunneled Central Vascular Access Devices (CVADs)

Nursing Process Data

ASSESSMENT Data Base

- Assess patency of catheter.
- Assess insertion site for signs of infection.
- Assess the tubing for accidental breaks.
- Assess injection cap at the end of catheter to ensure tightness.

PLANNING Objectives

- To provide a patent catheter
- To clear a nonpatent catheter
- To provide an access for blood drawing
- To provide an access for infusions

IMPLEMENTATION Procedures

- Maintaining the Hickman or Broviac CV Catheter . . .1140
 - For Flushing Intermittently Used Line1140
 - For Irrigating a Nonpatent Catheter1140
- Using a Positive Pressure Device1141
- Changing the Hickman or Broviac CV Catheter Dressing1142
- Maintaining the CV Catheter With Groshong Valve .1143
- Drawing Blood From the CV Catheter With Groshong Valve1144

EVALUATION Expected Outcomes

- IV catheter remains patent using CLC 2000 device.
- The catheter site remains infection-free.
- Blood samples are obtained without difficulty.
- Infusions of medications or fluids are accomplished without difficulty.

Critical Thinking Application1145

- Expected Outcomes1145
- Unexpected Outcomes1145
- Alternative Actions1145

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Maintaining the Hickman or Broviac CV Catheter

Equipment

- 10-mL Luer-Lok syringe with 3 mL of dilute heparin (100 units/mL solution or 10 units/mL) or tissue plasminogen activator (t-PA) 2 mg/2 mL (Alteplase).
- 2% chlorhexidine gluconate swab
- Clean gloves
- Syringes (size per facility policy)
- 10-mL syringe prefilled with preservative-free 9% sodium chloride
- CLC 2000 (or other brand) positive pressure device

Preparation

1. Check client care plan.
2. Identify client using two forms of identification and explain procedure to client.
3. Provide privacy for client.
4. Perform hand hygiene and don gloves.

Procedure

For Flushing Intermittently Used Line

1. Wipe catheter cap with antimicrobial swab.
2. Insert syringe cannula into needleless access cap or CLC 2000 device and unsnap catheter squeeze clamp.
3. Inject heparin solution slowly through catheter until almost empty.
4. Remove syringe while still moving plunger forward or clamp catheter before removing syringe if not using positive pressure device (see page 1141 for skill).
 - ▶ **Rationale:** This maintains positive pressure in the catheter and prevents clotting by preventing backflow of blood into catheter.

▲ The tunneled Broviac catheter (single, double, or triple lumen) is commonly used for children.

5. Withdraw syringe.
6. Flush nonused capped lines daily.

For Irrigating a Nonpatent Catheter

1. Follow facility policy for irrigating catheter.
2. Prepare 10-mL syringes with dilute heparin.
 - ▶ **Rationale:** The size of this syringe decreases pressure exerted in the system.
3. Swab catheter cap with antimicrobial swab.
4. Insert syringe with Luer-Lok and unclamp catheter.
5. Inject heparin from syringes, 1 mL at a time or per facility policy.
6. Leave heparin in catheter tubing for prescribed time.
7. Check that dwell time is completed, then use a 10-mL syringe to aspirate solution from catheter by gently pulling back on plunger.
8. Follow with an irrigation of 5–10 mL of heparinized solution if aspiration is successful. Use same solution for irrigation as with maintenance solution.
9. Repeat procedure once. If unsuccessful, notify physician and be prepared to instill thrombolytic agent, t-PA (t-PA is infused at 2 mg/2 mL). Alteplase is the only approved thrombolytic agent for treatment of catheter occlusion.
10. Discard equipment and gloves and perform hand hygiene.

Tunneled Central Vascular Access Devices (CVADS)

- Tunneled central vascular access devices (CVADs) provide long-term access to a central vein for the purpose of drawing blood, administering drugs (chemotherapy, antibiotics), administering total parenteral nutrition (TPN), or administering blood and blood products.
- Catheters are soft, silicone elastomers, thermoplastic polyurethane, or PVC. Used because of tensile strength and biocompatibility.
- Long-term catheters have one, two, or three lumens.
- The tip is inserted into a central vein and advanced to the superior vena cava. The remainder of the catheter passes through a subcutaneous track and exits on the chest wall or abdomen for easy access. A Dacron cuff on the catheter elicits scar formation that prevents ascending tract infection.
- Three common tunneled CVADs are the Hickman, Broviac, and Groshong.
- Clients with tunneled CVADs are advised to display medical-alert information.

Using a Positive Pressure Device

Equipment

- Positive Pressure Device; CLC2000 or FloStar, or SmartSite
- Antimicrobial swab
- Gloves
- 10-mL prefilled saline syringe

Procedure

1. Assess peripheral or central venous access site for signs of infection.
2. Perform hand hygiene and don gloves.
3. Use aseptic technique to open package, remove device, and remove cap without contaminating.
4. Prepare positive pressure device by attaching prefilled saline syringe and priming through device with saline. Leave syringe attached.
5. Attach the syringe to the female Luer and prime the CLC2000 device according to facility policies and procedures. Invert the device to expel air.
6. Attach the male spin lock to the venous access device. Push and twist the male spin lock of the CLC2000 into the VAD until it is tight.
7. Cleanse the female Luer vigorously with an antimicrobial swab for 5–10 seconds.
8. Attach the prefilled saline syringe; push and twist the Luer into the CLC2000 until there is a tight fit; unclamp catheter.
9. Irrigate with saline as ordered.
10. Remove the syringe and dispose of it in the sharps container.
11. Remove gloves and discard.
12. Perform hand hygiene.

NOTE: If using device for IV fluid infusion, cleanse female Luer and attach IV tubing. Open clamp on catheter and begin IV flow.

The positive pressure device (CLC2000) creates positive pressure within the central venous access device, preventing blood from being drawn back into the catheter when the flush syringe is removed. The CLC2000 is a Luer-Lok that replaces the other needleless caps and should be used when a CVAD cannot be flushed with heparin. The device is only flushed with saline, and the line must not be clamped, nor should extension sets be added as these actions negate the antireflux action of the device.

▲ CLC2000 devices are applied to PICC line.

Attach Positive Pressure Device

▲ Clamp catheter and remove cap from line, maintaining sterility of device.

▲ Cleanse proximal adapter tip with chlorhexidine before attaching device.

▲ Attach male spin lock to venous access device by screwing device into catheter.

Irrigating Catheter Using Positive Pressure Device

▲ Cleanse female Luer vigorously.

▲ Attach 10-mL prefilled saline syringe, infuse saline, and aspirate for blood return.

▲ Remove syringe from device and cleanse Luer.

▲ Attach IV tubing to device.

Changing the Hickman or Broviac CV Catheter Dressing

Equipment

- Antimicrobial swabs, 2% chlorhexidine gluconate
- Transparent, semipermeable dressing
- Clean gloves
- Sterile gloves
- Mask (if client is neutropenic and per agency policy)

Procedure

1. Identify client using two descriptors.
2. Apply mask as needed.
3. Perform hand hygiene and don gloves.
4. Remove old dressing and place in appropriate receptacle.
5. Observe for signs and symptoms of infection and crepitus at insertion site. ► **Rationale:** Signs most frequently observed are erythema, edema, and drainage for infection; crackling under the skin denotes crepitus due to air in the subcutaneous tissue—this finding should be reported to physician.

6. Remove and discard gloves.
7. Set up supplies on a sterile field and don sterile gloves.
8. Clean exit site using antimicrobial swabs. Swab with back-and-forth movement for 30 seconds.
9. Clean catheter tubing at exit site. Allow to dry.
10. Apply sterile transparent dressing; change weekly or if soiled. When cuff heals into place, dressings are not necessary.
11. Remove gloves and discard.
12. Sign and date dressing.
13. Secure catheter to prevent dislodging; tape to chest.
14. Perform hand hygiene.

NOTE: Nonhospitalized clients who are not immunosuppressed may protect exit site with a Band-Aid or leave the site undressed. They should cleanse daily with antibacterial soap and water, palpate site daily to check for signs of infection, and tape catheter to chest to prevent accidental dislodgement.

▲ Hickman catheter.

▲ The tunneled CV catheter with Groshong valve is ideal for long-term therapy.

Clinical Alert

To prevent a potentially life-threatening mistake, never use scissors near central venous catheters.

Flushing Tunneled Catheters

Flush catheter with 3–5 mL of heparin (10 units/mL) daily when catheter is not used and before and after each use. The SASH protocol is used (saline, administer drug or withdraw blood, saline, and heparin). This type of flushing is not done with a closed-ended (Groshong) catheter, as its internal valve is designed to prevent blood reflux into the catheter.

Irrigation Protocols

Using 10 mL of Saline

- Irrigate catheter weekly when not in use.
- Irrigate catheter after every use.

Using 20 mL of Saline

- Irrigate catheter before and after any aspiration of blood, after transfusion of blood, or when blood is seen in the catheter (client straining or lifting may cause blood to back up into catheter).
- Irrigate catheter after infusion of lipids or hyperalimentation solutions.

NOTE: Regardless of the volume of saline used, ALWAYS irrigate in a stop–start action. ► **Rationale:** This creates a swirling effect at the distal end of the catheter.

Maintaining the CV Catheter With Groshong Valve

NOTE: The Groshong valve is available in a variety of CVADs, including ports and PICCs. The Groshong allows infusion, but prevents backflow of blood unless negative pressure is applied. There is no need for heparin flush, and external clamps are not used. Clamping could force the slit valve open, allowing blood to leak into the lumen.

Equipment

- Normal saline, preservative-free
- Antimicrobial swab, 2% chlorhexidine gluconate
- Sterile injection cap
- Appropriate syringe: 10 mL or 20 mL
- Clean gloves
- Sterile gloves
- Positive pressure device

Preparation

1. Check physician's orders.
2. Gather equipment.
3. Identify client using two descriptors.
4. Perform hand hygiene and don gloves.

Procedure

1. For non–positive pressure device, wipe injection cap and catheter connection with antimicrobial swab.
2. While holding catheter, remove catheter cap and attach hub of syringe directly to catheter hub.
3. Inject normal saline rapidly into lumen.
4. Maintain positive pressure on syringe plunger as last 0.5 mL is injected and syringe is withdrawn. ► **Rationale:** Keeping pressure on the plunger prevents backup of blood into catheter.

5. Remove cap by holding catheter connector between thumb and forefinger of one hand and grasping barrel of cap with other hand.
6. Twist and pull counterclockwise to separate cap from connector.
7. Continue to hold connector with one hand.
 - **Rationale:** Holding connector prevents inadvertent contamination by placing connector on dirty surface.
8. Discard old cap.
9. Clean liberally around connector using antimicrobial swab.
10. Holding new sterile injection cap, twist clockwise and insert into connector.

For 10- or 20-mL Irrigation

1. Remove syringe from package.
2. Remove injection cap carefully from connector and discard.
3. Clean connector with chlorhexidine gluconate wipe. DO NOT let go of connector. ► **Rationale:** Holding connector prevents inadvertent contamination.
4. Insert syringe barrel directly into catheter connector, twisting slightly to ensure good connection.
5. Irrigate lumen with preservative-free normal saline using stop–start action. ► **Rationale:** Heparin is not used

Clinical Alert

Nursing attention to the catheter during dressing change is important to ensure catheter is not pinched, kinked, occluded, cut, or dislodged. It is recommended that the external portion of catheter be coiled and taped to avoid a straight pull on catheter insertion site.

because clotting is not a factor with catheter tip design of the Groshong.

6. Maintain positive pressure on syringe barrel as syringe is removed from connector. DO NOT clamp the catheter after irrigation. ► **Rationale:** The Groshong CV catheter does not require clamping to keep blood from entering the lumen. Clamping the catheter damages it.
7. Change injection cap.
8. Remove gloves and perform hand hygiene.

▲ The tunneled CV catheter with Groshong valve is ideal for long-term therapy.

The Groshong Catheter

The Groshong catheter offers an alternative to the Hickman and Broviac catheters. It is distinguished by a rounded, blunt catheter tip with a three-way pressure-sensitive valve that remains closed at normal vena caval pressure. When closed, it restricts air from entering the venous system or a backflow of blood from the catheter. When a syringe is inserted to create a vacuum, it allows the valve to open inward for blood aspiration. Positive pressure into the catheter by infusion forces the valve to open outward. The primary advantages of this type of catheter are:

- Decreased risk of air emboli or bleeding
- Elimination of heparin to flush the catheter
- Elimination of catheter clamping
- Reduced flushing protocols between use

NOTE: It is recommended that a positive pressure device be used for irrigating CVADs. See page 1141 for skill.

Drawing Blood From the CV Catheter With Groshong Valve

Equipment

- Sterile injection cap.
- Three 10-mL Luer-Lok syringes for drawing blood
- One 20-mL Luer-Lok syringe filled with preservative-free normal saline
- Blood tubes appropriate for tests ordered
- Antimicrobial swabs, 2% chlorhexidine gluconate
- Clean gloves
- NOTE:** Vacuum tubes should not be used with the Groshong valve.

Procedure

1. Perform hand hygiene and don gloves.
2. Clean cap and outside of connector with swabs and allow to dry.
3. Remove and discard injection cap while holding connector so that it does not make contact with any surface.
4. Insert first 10-mL syringe with saline directly into catheter, twisting slightly to ensure connection.
5. Irrigate with stop-start action. Groshong catheter must be irrigated with stop-start action with at least 10 mL of normal saline before blood sample removal.
6. Pull back plunger 0.5 mL, pause 2 seconds, and then continue aspirating until 5 mL of blood is in syringe.
7. Remove syringe, set aside; continue to hold connector.
8. Connect second 10-mL syringe directly to catheter connector, twisting slightly to ensure connection.
9. Proceed to aspirate blood volume needed for sample after same aspiration procedure of pulling 0.5 mL and waiting for 2 seconds.
10. Remove syringe and continue to hold connector.
11. Flush catheter briskly with 20 mL of preservative-free normal saline and attach new sterile injection cap.
12. Transfer blood sample from second syringe into appropriate tube(s), and label. Do not hold receiving tube during transfer.
13. Discard syringe containing first aspirated blood into biohazard container.
14. Remove gloves and perform hand hygiene.

DOCUMENTATION for CVADs

- Flush frequency and solution used
- Dressing changes and type applied
- Site condition
- Condition and patency of catheter
- Medications or solutions administered through catheter
- Amount of blood withdrawn for testing and the amount discarded.
- Infusion cap change
- Positive pressure device in place

CRITICAL THINKING Application

Expected Outcomes

- IV catheter maintains patency with use of CLC2000 device.
- Catheter site remains free of infection.

Unexpected Outcomes

CV Catheter:

Unable to aspirate blood even though solution flows through the catheter.

Clotting of catheter occurs (client develops arm or neck swelling on catheter side of body).

Catheter breaks or is pierced by clamp.

Air enters catheter when open to atmosphere; client experiences chest pain, shortness of breath, or coughing.

Signs of infection develop at exit site (redness, pain, fever, chills).

- Blood samples are obtained without difficulty.
- Infusions of medications or fluids are accomplished without difficulty.

Alternative Actions

- Use less negative pressure on syringe when aspirating blood. Tip of catheter may be sucking against wall of vessel.
- Have client raise arms above head. This can alter position of catheter.
- Have client perform Valsalva's maneuver.
- Change client's position.
- Do not force plunger with Groshong; this may rupture catheter.
- Make sure clamps are open and tubing is not kinked.
- Use irrigating procedure for catheter with a recently developed clot. Instill 1 mL of normal saline.
- Allow 15 minutes before aspirating to see if declotting occurs. Repeat if necessary.
- Prevent occlusion due to drug sludge by flushing carefully after administration.
- Thrombolytic agent is required for fibrinous clot.
- FDA approved use of t-PA (tissue plasminogen activator) for thrombolytic protocol. Follow facility policy regarding instillation of drug.
- Instill 2 mg of t-PA in a 10-mL syringe. Wait 60 minutes. Aspirate; if unable to obtain blood flow, instill a second dose of t-PA. If this does not produce blood flow, notify physician.
- Immediately clamp catheter proximal to break site, if necessary (Groshong may be clamped using rubber band).
- Obtain repair kit for catheter.
- Clamp catheter (use rubber band if Groshong device).
- Turn client on left side with head lower than rest of body to trap air in right heart.
- Notify physician immediately.
- Administer oxygen.
- Notify physician immediately.
- Catheter will have to be removed and cultures taken.

Chapter 29

UNIT 5

Implanted Subcutaneous Port

Nursing Process Data

ASSESSMENT Data Base

- Assess site.
- Assess patency of port.

PLANNING Objectives

- To provide an access for blood withdrawal
- To provide an access for drug or blood/fluid administration

IMPLEMENTATION Procedures

- Accessing and Flushing an Implanted Port Using a Huber Needle1147
- Administering Drugs via a Subcutaneous Implanted Port1148
- Administering Infusions via a Subcutaneous Port1149
- Drawing Blood From an Implanted Subcutaneous Port1149

EVALUATION Expected Outcomes

- Subcutaneous implanted port remains patent to facilitate medication administration.
- Implantation site remains infection-free.
- Blood samples are obtained without difficulty.

Critical Thinking Application1150

- Expected Outcomes 1150
- Unexpected Outcomes..... 1150
- Alternative Actions 1150

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Accessing and Flushing an Implanted Port Using a Huber Needle

NOTE: Implanted venous access ports, such as Port-a-Cath, are usually placed in a subcutaneous pocket on the chest wall, require minimal maintenance, and may be used for months to years before the maximum 2,000 punctures are achieved. Ports are best utilized for cyclic therapies like chemotherapy or antibiotic therapy. They are well suited for care of clients with cancer or others with long-term illnesses requiring IV medications. Ports can be used for either bolus or continuous infusions.

Equipment

Noncoring needle (Huber) with attached extension tubing and clamp
 Intermittent infusion cap or CLC 2000
 Two 10-mL Luer-Lok syringes
 Preservative-free normal saline or prefilled syringes
 Heparin (100 or 10 units/mL) according to facility policy
 Antimicrobial swabs, 2% chlorhexidine gluconate
 Sterile gloves
 Clean gloves
 Mask

Preparation

1. Check physician's orders and client care plan. Review specific hospital policy and procedure for care of implanted port.
2. Gather equipment.
3. Perform hand hygiene.
4. Draw up 10 mL of normal saline into 10-mL syringe, or use prefilled syringes.
5. Draw up 5 mL of dilute heparin (10 mL or 100 units/mL according to facility policy) into 10-mL syringe.
6. Identify client using two forms of identification.
7. Explain procedure to client.
8. Don clean gloves.

Procedure

1. Palpate skin over subcutaneous infusion port. ► **Rationale:** This identifies location and contours of the device.

- Noncoring needles, such as the Huber needle, are the only ones used to access the port.
- Huber needle and tubing are changed every 7 days.
- This specially designed needles (bent at 90° angle to its hub or wings) has a sharp-angled bevel and attached extension tubing with clamp and needleless cap. Huber needles can also be straight.
- Inserted through skin and into rubber septum for central venous access.
- Prevents coring of the port.
- Produces insertion tract that seals itself when it is removed.

▲ Implanted subcutaneous port.

▲ Huber needle.

▲ Placement of Huber needle.

2. Place thumb and forefinger of left hand on port (right hand if left-handed) and feel for septum with right hand. ► **Rationale:** This position stabilizes the port.
3. Numb the area with a topical anesthetic cream or ice, according to facility policy. Depending on the product used, the time for effective anesthesia may vary from a few minutes to 1 hr.
4. Clean skin with antimicrobial swab using a back-and-forth movement. Scrub for 30 seconds.
5. Allow site to air dry for 30 seconds. ► **Rationale:** Drying permits solution to work best against bacteria, fungi, and spores.
6. Affix syringe with 10 mL of normal saline into Huber needle extension tubing cap and prime tubing; leave syringe attached.
7. Remove clean gloves and dispose in appropriate container.
8. Apply mask according to facility policy, perform hand hygiene, and don sterile gloves.

9. Stabilize port using thumb and index finger or index finger and middle finger.
10. Insert needle into port at a 90° angle until it meets resistance from the stainless steel back of the port.
11. Check for correct placement by aspirating for blood return.
 - a. Withdraw flash of blood to check needle position. If no blood is obtained, try repositioning client (sit up, raise arms, cough.)
 - b. If still unable to obtain blood, try flushing port with small amount (2–3 mL) of normal saline.
 - c. If no blood return, remove noncoring needle and reaccess port.
 - d. If still unable to obtain blood, call the physician (x-ray for placement may be required.)
12. If placement is correct, stabilize needle and inject remaining normal saline. There should be no sign of infiltration into surrounding tissue.
13. Close clamp of needle extension tubing.
14. Exchange syringe of normal saline for syringe filled with dilute heparin flush, then open clamp.
15. Instill 5 mL (in 10 mL syringe) of heparin flush (100 units/mL).
16. Clamp extension tubing before removing syringe.
17. Remove needle by pulling straight out from port while stabilizing port with free hand.
18. If needle is to be left in place for intermittent use, secure wings with tape for hub (chevron style) and apply sterile transparent dressing over all.
19. Dispose of equipment.
20. Remove gloves and perform hand hygiene.

NOTE: If CLC2000 device is used, follow directions for use on page 1141.

Clinical Alert

Implanted ports have the lowest risk of infection of all chest-accessed central lines.

Administering Drugs via a Subcutaneous Implanted Port

Equipment

- Syringe filled with medication
- Equipment as listed in previous skill
- Syringe filled with 10 mL of saline
- Syringe with 10 mL of dilute heparin solution

Procedure

1. Follow procedure listed in previous skill. (Using sterile gloves, access port verifying correct placement, i.e., blood return on aspiration, ability to infuse normal saline flush, and no infiltration.)
2. Clamp short needle extension tubing.
3. Exchange saline syringe for syringe filled with ordered medication.
4. Unclamp tubing.
5. Administer medication at prescribed rate.
6. Flush port between drugs with 5 mL of saline if giving more than one drug. ► **Rationale:** This prevents the possibility of drug–drug interactions.
7. Flush system with saline, then with dilute heparin.
8. Inject last 0.5 mL of heparin flush while simultaneously withdrawing needle and stabilizing port.
9. Wipe skin gently with dry swab to remove any solution.
10. If client is to receive intermittent IV drugs or solution, the Huber needle may remain in place for 1 week. After intermittent administration, clamp tubing, insert new sterile protective cap into extension tubing, open clamp to flush and heparinize, then reclamp tubing.
11. Flush used port with 5 mL heparin (100 units/mL) daily; if unused, flush monthly.
12. Dispose of equipment (including gloves) and perform hand hygiene.

NOTE: Change port dressing weekly or when wet or soiled.

▲ Check for blood flashback when flushing CVAD (unless Groshong valve present).

▲ Always have CVAD clamped when changing infusion cap (Groshong valve does not require).

Administering Infusions via a Subcutaneous Port

Equipment

Huber needle with attached extension tubing and in-line clamp
 Intermittent infusion cap
 5-mL syringe with needleless cannula
 Two 10-mL syringes with needleless connector
 Normal saline
 Heparin (10 units/mL or 100 units/mL according to facility policy) or normal saline
 Antimicrobial swabs, 2% chlorhexidine gluconate
 Sterile and clean gloves
 Mask
 Sterile gauze squares
 Transparent dressing
 Sterile tape
 Prescribed IV solutions, drugs, or blood products

Preparation

1. Check physician's orders.
2. Gather equipment.
3. Identify client using two descriptors.
4. Explain procedure to client.
5. Provide privacy.
6. Raise bed to comfortable working position.
7. Perform hand hygiene.
8. Don clean gloves.

Procedure

1. Remove dressing, prepare site, and access port using sterile technique (sterile gloves and mask) as previously described.
2. Secure needle hub with sterile tape, or wings with tape or Steri-strips.
3. Place transparent dressing over insertion site, needle, and proximal IV tubing; date and initial.
4. Flush port with 10 mL of saline solution.
5. Proceed with administration of ordered solution, drug, or blood.
6. Upon completion, flush with 10 mL of normal saline, followed by 5 mL of dilute heparin flush.
7. Clamp tubing before removing syringe to maintain positive pressure; cap tubing.
8. For continuous infusion, change tubing daily and dressing every 96 hr.
9. Dispose of equipment (including gloves) and perform hand hygiene.

NOTE: If using CLC2000 device, refer to page 1141 for directions.

Clinical Alert

Electrical controller device (pump) should be used for continuous IV infusion via CVAD.

Drawing Blood From an Implanted Subcutaneous Port

Equipment

Huber 19-gauge needle with short extension tubing
 Needleless injection cap or CLC2000 device
 Two 10-mL syringes
 Blood collection tubes
 Heparin 3-mL and normal saline 10-mL flush solutions
 Antimicrobial swabs, chlorhexidine gluconate
 Sterile tape
 Sterile gloves

Procedure

1. Gather equipment.
2. Check physician's orders for type of blood test.
3. Identify client using two descriptors and explain procedure to client.
4. Perform hand hygiene and don sterile gloves.
5. Access implanted port using Huber needle with capped extension tubing as discussed previously.

- a. Prep tubing cap or CLC2000 device with antimicrobial swab.
 - b. Clean around junction of cap and hub with antimicrobial swab before removing cap or before inserting syringe into CLC2000 device.
6. Insert syringe into hub of extension tubing.
 7. Unclamp tubing.
 8. Withdraw 5–10 mL blood, remove syringe, and discard.
 - **Rationale:** This discards the filling volume of the catheter.
 9. Maintain aseptic technique—attach new syringe to hub of extension tubing or insert into CLC2000 device.

Clinical Alert

When drawing blood, attach syringe directly to hub of extension tubing. Never draw through an older type cap as hemolysis can occur. Always place a new cap on extension tubing after withdrawing blood samples. Check the newer caps to determine if blood can be drawn through the cap.

- Withdraw appropriate amount of blood for tests and remove syringe.
10. Fill appropriate type of blood tubes with specified amount of blood according to tests ordered.
 11. Flush catheter with 10 mL of saline solution after obtaining blood specimens.
 12. Place new cap on extension tubing. CLC2000 device is changed every 24 hr.
 13. Discard equipment.
 14. Remove gloves and perform hand hygiene.

DOCUMENTATION for Implanted Subcutaneous Port

- Condition of port implantation site
- Frequency and type of flushes
- Name and dosage of drugs or solutions administered
- Presence of Huber needle, if left in place
- Document gauge and length of Huber needle
- Dressing type
- Amount of blood withdrawn
- CLC2000 device if used

CRITICAL THINKING Application

Expected Outcomes

- Subcutaneous implanted port remains patent to facilitate medication administration.
- Client's subcutaneous port implantation site remains infection-free.
- Blood samples are obtained without difficulty.

Unexpected Outcomes

Needle entry is painful.

Alternative Actions

- Use topical anesthetic or apply ice before accessing.
- Use local anesthetic injected intradermally before inserting needle (check client sensitivity and agency policy).
- Change needle. If no improvement, suspect occluded catheter.
- Try gentle aspiration to dislodge clot.
- Never try to forcefully flush system—clot may mobilize; catheter may rupture.
- Thrombolytic agent may be required to lyse fibrin clot (specialty nurse skill).
- Transfuse packed red blood cells along with continuous infusion of normal saline; use an infusion pump; flush catheter well with 20 mL of normal saline after infusion to prevent occluded catheter.

Occluded catheter.

Inability to aspirate blood when checking placement.

- Needle may not be in port reservoir.
- Tip of catheter may be against vessel wall. Try changing client's position from sitting up to lying or ask client to raise one or both arms. If appropriate, have client bear down or cough using Valsalva's maneuver while irrigating with normal saline.
- Heparinize catheter and return in 40 minutes to aspirate.
- Removal of a fibrin clot, thrombolysis, is done by a certified IV nurse (according to agency policy).

Pain, swelling at site.

- Suspect catheter rupture. Report to physician.
- Suspect port migration and infusion infiltrating subcutaneously.

Port becomes movable.

- Port may not be anchored securely. Port could be flipped under skin.
- Silicone tubing has separated from port.
- Always check for blood return to ensure accurate needle placement, before injecting medications.
- Notify physician and prepare for removing port.

Peripherally Inserted Central Catheter (PICC)

Nursing Process Data

ASSESSMENT Data Base

- Assess length of exposed catheter.
- Assess that catheter is secure.
- Assess insertion site.
- Assess catheter patency.

PLANNING Objectives

- To provide access for infusion, parenteral nutrition, or drugs
- To provide access for blood sampling
- To provide patent access

IMPLEMENTATION Procedures

- Maintaining the PICC1152
- Changing the PICC Dressing1154
- Drawing Blood From the PICC1155
- Removing the PICC.....1156

EVALUATION Expected Outcomes

- PICC remains patent without sign of infection.
- Catheter is irrigated at designated time frames.
- Transparent dressing remains intact for 7 days.

Critical Thinking Application 1157

- Expected Outcomes.....1157
- Unexpected Outcomes.....1157
- Alternative Actions1157

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Maintaining the PICC

Equipment

- Pre-filled syringe with 10 mL of preservative-free normal saline (0.9%)
- Pre-filled syringe with 20 mL of preservative-free normal saline
- Pre-filled syringe with 3–5 mL of dilute heparin (10 units/mL) solution (per hospital policy)
- Optional CLC2000
- Sterile gloves
- Antimicrobial swabs, 2% chlorhexidine gluconate
- Transparent dressing
- StatLock Securement device

For Medication Administration

- Medication IV bag
- Two 10-mL syringes pre-filled with preservative-free 0.9% normal saline
- Heparin flush according to facility policy
- 2% Chlorhexidine gluconate swabs

NOTE: Midline catheters are very similar to PICC lines, except they are shorter. The same policy and procedures apply to the care and maintenance of these lines.

Preparation

1. Check client care plan and MAR.
2. Identify client using two descriptors.
3. Explain procedure to client.
4. Provide privacy for client.

Procedure

1. Perform hand hygiene and don gloves.
2. Assess IV site and surrounding area for signs of infection (i.e., erythema, tenderness, edema, and drainage).
3. Assess securement device site for stability, cleanliness, and intact dressing.

Clinical Alert

If catheter tip is resting in the right atrium or pericardium instead of the superior vena cava, the tip can move across the muscle to the sinoatrial node (SA node) and can cause cardiac arrhythmias, cardiac rupture, or other associated conditions. The PICC catheter must be withdrawn 1 in. (2.5 cm) and a repeat x-ray taken to check for catheter placement.

Clinical Alert

All continuous infusions using a PICC line should be connected to an electric infusion device to maintain infusion and patency of line.

4. Swab catheter port with chlorhexidine swab. Allow to dry for 30 seconds.
5. Inject pre-filled syringe with preservative-free 0.9% normal saline into catheter hub and aspirate.
 - ▶ **Rationale:** Check for patency.
6. Inject solution of 0.9% preservative-free sodium chloride (twice the internal volume of the CVD and injection cap) slowly; flush with minimal force using a pulsatile motion until syringe is almost empty.
 - ▶ **Rationale:** This action creates turbulence for catheter cleansing.
7. Continue to inject flush while removing syringe from catheter port.
8. For medication administration:
 - a. Perform hand hygiene.
 - b. Check client using two identifiers.
 - c. Don gloves, if facility policy.
 - d. Remove protective tab from both the PICC tubing and the IV bag. (The tabs are usually in bright colors so you can easily identify them.)
 - e. Push the pointed end of the tubing into the opening on the IV bag. Hold the bag up high and squeeze the drip chamber until it is half full.

▲ Maintain PICC line with cleaning and irrigation.

▲ Double-lumen PICC with CLC 2000 positive pressure device.

- f. Open roller clamp and observe fluid run through tubing until all air is removed from tubing. Close roller clamp.
 - g. Flush PICC line using saline solution and a push–pause technique.
 - h. Attach needleless connector on PICC tubing to rubber cap of IV catheter. Unclamp catheter and adjust the roller clamp to prescribed rate.
 - i. When IV bag is empty, clamp PICC tubing and remove tubing from rubber cap.
 - j. Clean lumen with 2% chlorhexidine gluconate swab by vigorously rubbing port.
 - k. Flush PICC line with saline using push–pause technique. ► **Rationale:** Avoids buildup of precipitates, which can occur in catheter occlusions.
 - l. Flush PICC line with heparin according to facility policy.
 - m. Clamp IV catheter.
9. Flush nonused catheter at least every 12 hr using push–pause technique.
 10. Place discarded equipment in appropriate receptacle. Place syringe in sharps container.
 11. Remove gloves and perform hand hygiene.

NOTE: The use of positive pressure devices is now suggested for catheter care.

Recommendations for Use of Catheter Securement Devices

Infusion Nurses Society

The Infusion Nurses Society has published major guidelines that state a preference for using a securement device such as the StatLock for stabilizing catheters.

Centers for Disease Control and Prevention (CDC)

The CDC states that sutureless securement devices are an advantage over sutures in preventing bloodstream infections and complications.

The Joint Commission and National Patient Safety Foundation

The Joint Commission and the National Patient Safety Foundation identify securement devices as a major contributor to client safety because they reduce catheter-related infections and overall complications. This is in addition to improving safety for healthcare providers.

Occupational Safety and Health Administration (OSHA)

OSHA has issued directives that instruct healthcare employers to consider using securement devices to reduce needle-stick injuries in healthcare providers.

Flushing Procedure

Frequency

1. Check facility policy and follow protocol.
2. Suggested recommendations:
 - a. Every 4–6 hr for no. 2 French or smaller catheters and after each use.
 - b. Every 8–12 hr for larger size catheters and after each use.

Other Times

1. When LOCK is applied.
2. After blood draws.
3. After intermittent medication administration.
4. After blood or blood component administration.
5. After administration of TPN.

Pulsatile (Push–Pause) Flushing

Use a rapid succession of push–pause–push–pause movements exerted on the plunger of the syringe barrel. This motion creates a turbulence within the catheter lumen causing a swirling effect to move fibrin, lipids, medications, or other adherents attached to catheter lumen and prevents occlusions to the catheter.

Peripherally Inserted Central Catheter

PICCs are long, soft, flexible, single or multi-lumen catheters placed in basilic, cephalic, or brachial vein and advanced into the superior vena cava for central venous access. The length of catheter is documented. Placement is less invasive and less expensive than other CVADs since they can be inserted by specially educated certified IV nurses. As with tunneled catheters, exit site below heart level decreases risk of air embolism when system is open to the atmosphere. PICC lines need to be checked by x-ray to verify tip placement if inserted into a proximal arm. Clients receiving TPN or vesicants should have tip inserted into SVC, and x-ray should be done to confirm position. Research has shown that PICC lines inserted into SVC have fewer complications such as inflammation or thrombosis.

Securement devices are now recommended to prevent catheter migration. These catheters may be used for long-term therapy if changed every 6 weeks. PICC lines can be left in place for at least 1 year.

Preservative-free 0.9% saline is recommended for flushing. Heparin is usually not recommended. You will need to check facility policy regarding heparin usage and dosage.

Prevention of Catheter-Related Bloodstream Infections

- Hand hygiene
- 2% chlorhexidine gluconate skin antisepsis
- Optimal catheter site selection; subclavian vein preferred route
- Maximal barrier protection
- Daily monitoring of IV site
- Dressing change every 7 days unless soiled or loose.

Source: 100,000 Lives Campaign. (2006). How-to guide: Preventing catheter-related bloodstream infections—Five components of care. Retrieved June 14, 2006, from www.ihl.org/IHI/Programs/campaign.

EVIDENCE-BASED PRACTICE

Complication Rates for Valved Versus Nonvalved PICCs

In a randomized study, 362 clients (233 men, 129 women; mean age, 44) were given PICC catheters; half of the clients received clamped catheters and half received valved catheters. The complication rate for the clamped PICC clients was double that of clients with valved catheters as a result of occlusions or infections (26 for clamped and 12 for valved catheters).

Source: Hoffer, E. K., J. Borsa, P. Santulli, R. Bloch, A. B. Fontaine. (2005). Comparisons of valved versus nonvalved PICC catheters. <http://www.ajronline.org/cgi/content>

EVIDENCE-BASED PRACTICE

Peripheral Intravenous Catheter Dwell Times

This prospective, sequential clinical trial evaluated the survival time of IV catheters using three methods: nonsterile tape, StatLock, and the Hub-Guard. The use of nonsterile tape securement resulted in an 8% peripheral IV catheter (PVI) survival rate, the Hub-Guard result was 9%, and the StatLock had a survival rate of 52%. The study was completed in an effort to determine the best method to assist in prolonging the 96-hr PIV change protocol. This study strongly suggests that a mechanical catheter securement device allows the implementation of the 96-hr IV change protocol that was sanctioned by the CDC.

Source: Smith, B. (2006). Peripheral intravenous catheter dwell times: A comparison of 3 securement methods for implementation of a 96-hour scheduled change protocol. *Journal of Infusion Nursing*, 29(1), 14–17.

EVIDENCE-BASED PRACTICE

It has been found that the use of a single-lumen CVC is recommended to reduce the risk of catheter-related bloodstream infections. Studies evaluating this issue have produced variable results, with some studies indicating multi-lumen CVCs are significantly more at risk to develop infections, whereas other studies indicated no increased risks with multi-lumen CVCs. It is well recognized that intraluminal migration from hubs and ports is a major source of microorganisms; therefore, keeping the number of ports or lumen to a minimum is preferred.

(O'Grady, et al. 2002, DH 2007, Pratt 2007, Zurcher) (Dezfulian, et al. 2003).

Changing the PICC Dressing

Equipment

- Antimicrobial swabs, 2% chlorhexidine gluconate
- Securement device
- Transparent semipermeable dressing
- BioPatch disc (optional)
- Clean gloves
- Sterile gloves
- Mask

Procedure

1. Identify client using two descriptors and check electronic medical record and client care plan for last dressing change (review facility policy and procedure).
2. Explain procedure to client.
3. Perform hand hygiene and don mask and clean gloves.
4. Remove old transparent dressing by gently pulling in an upward direction. ► **Rationale:** Prevents dislodgement of catheter.
5. Check site for bleeding, infection, or signs of phlebitis. ► **Rationale:** Bleeding may occur with arm use. Phlebitis is the most common complication.
6. Discard old dressing and gloves. Perform hand hygiene.

Clinical Alert

Unless absolutely necessary, avoid blood pressure measurement in the arm with a PICC and avoid venipunctures on the extremity with a PICC line.

7. Prepare sterile supplies.
8. Don sterile gloves.
9. Clean exit site and catheter with antimicrobial swabs using back-and-forth movement.

NOTE: The catheter is anchored by a securement device, which does not require suturing of PICC line. Approximately 1 in. of catheter extends from the insertion site.

10. Allow time for antimicrobial solution to dry. Do not blow on arm or wave hand to hasten drying. ► **Rationale:** Waving hand or blowing may contaminate site—antibacterial action does not take effect until solution is dry.
11. Place securement device over catheter. ► **Rationale:** Catheter is not sutured in place, so securement device is used to prevent catheter migration. (Refer to skill in Unit 1, page 1122, Applying a StatLock Securement Device.)

▲ Cleanse site with chlorhexidine gluconate swab using back-and-forth motion.

▲ Allow site to dry before applying dressing. Place transparent dressing over site.

▲ StatLock device, the only evidence-based catheter stabilization device that meets national standards. (Courtesy of Venetec, Intl.)

12. Cover exit site with transparent semipermeable dressing. Avoid stretching the dressing. Press down on dressing to seal catheter site. No part of actual catheter should be outside transparent dressing.

NOTE: Transparent dressings are not occlusive; they allow air to circulate through the semipermeable dressing and thus prevent perspiration from collecting under the dressing.

▲ Remove dressing by gently pulling in an upward direction.

13. Remove gloves, mask, and perform hand hygiene.
14. Initial and date dressing.
15. Change initial transparent dressing in 24 hr and then every 7 days or whenever it is soiled or loose.
 - **Rationale:** First dressing change is done to check insertion site.

Drawing Blood From the PICC

Equipment

- Antimicrobial swabs—2% chlorhexidine gluconate
- Two 10-mL syringes with needleless connector
- 20-mL syringe with needleless connector filled with saline
- Syringe with 3–5 mL of dilute heparin (per hospital policy) and needleless connector
- Clean gloves

Preparation

1. Check physician orders.
2. Identify client using two descriptors.
3. Perform hand hygiene and don gloves.
4. Explain procedure to client.

Procedure

1. Stop all infusing fluids for at least 1 minute before drawing a specimen.
2. Swab catheter cap with antimicrobial swab and allow to dry.
3. Use 10-mL syringe and withdraw 5 mL of blood and discard appropriately in biohazard container. Check facility policy and procedure for amount to discard.
4. Use 10-mL syringe with needleless connector and withdraw required amount of blood for laboratory tests. Do not use Vacutainer. ► **Rationale:** Catheter will collapse with intense vacuum.
5. Change cap after all blood draws and transfusions. Flush with 20 mL of saline solution to clear catheter.

6. Complete procedure with dilute heparin flush (unless Groshong valve present).
7. Discard equipment and gloves; perform hand hygiene.
8. Handle blood sample appropriately. Transfer to collection tube.

Removing the PICC

Equipment

- Gloves
- 10-mL syringe pre-filled with 0.9% preservative-free sodium chloride
- Sterile 2 × 2 gauze
- Tape

Procedure

1. Check physician's order.
2. Identify client using two descriptors.
3. Explain the procedure to the client. Client may be in bed or sitting in a chair.
4. Perform hand hygiene and don gloves.
5. Flush catheter with 0.9% sodium chloride.
6. Carefully remove dressing, loosening edges toward insertion site. Remove Steri-strip on securement device.
7. Grasp catheter at insertion site.
8. Gradually pull catheter parallel to skin 1 in. at a time.
9. Continue inching catheter out—if resistance is felt, stop and reposition arm, wait 15 seconds.
10. After removal, measure length of catheter and compare to documented length on chart.
11. Culture tip according to facility policy. Cut tip with sterile scissor and place in sterile container. Be careful not to contaminate tip when withdrawing blood from vein.
12. Hold gauze at exit site for hemostasis.
13. Apply tape to gauze securely. Leave in place for 24 hr.
14. Dispose of catheter in biohazard container.
15. Document length of catheter removed.

NOTE: Certified infusion nurses only remove the PICC.

Clinical Alert

NEVER FORCE catheter removal (apply warm moist pack to upper arm to relax vein for approximately 15 minutes).

Notify Physician or IV Therapist if There Is:

- Infusion leaking from insertion site
- Inconsistent flow rates
- Inability to infuse fluids
- Excessive bleeding or drainage at insertion site
- Chest, neck, ear pain, numbness, tingling of affected arm
- Swelling, pain, redness, palpable cord at or above insertion site

DOCUMENTATION for the Peripherally Inserted Central Catheter

- Label site “PICC” to ensure proper use of line
- Frequency of flush and type of solution
- Type of dressing applied. Label date, time, initials, and “PICC.”
- Site assessment
- Length of exposed catheter
- Amount of blood withdrawn for specimen
- Solutions or drugs administered including flow rate
- Electronic infusion device utilized

For Discontinuing PICC

- Note condition and length of catheter
- Document site assessment
- Client's response to treatment and procedure
- Catheter tip sent to lab for culture, if appropriate

CRITICAL THINKING Application

Expected Outcomes

- PICC remains patent without signs of infection or migration
- Catheter is irrigated at designated time.
- StatLock remains in place.
- Transparent dressing remains intact for 7 days.

Unexpected Outcomes

Mechanical phlebitis (pain, redness spreading to surrounding tissue).

Bleeding occurs at insertion site.

Exudate occurs at insertion site.

Solution does not infuse.

Pain in shoulder or neck occurs during infusion—or client hears gurgling sound with flush.

Sepsis occurs (rare).

Alternative Actions

- Apply warm moist compresses for 20 minutes 4 times a day.
- Elevate the arm and encourage mild exercise.
- Report problem—antiinflammatory drugs may correct problem and prevent PICC removal.
- Apply direct pressure on insertion site.
- Check client's coagulation profile (bleeding time, platelet count, PT, PTT) for coagulation problem.
- Consider removal if excessive bleeding persists after using pressure.
- Notify physician or IV therapist.
- Send specimen to lab for culture.
- Maintain aseptic technique during site care.
- Increase volume of flush solution.
- Utilize infusion pump or elevate infusion bag for gravity pressure.
- Flush with a push–pull motion and clamp catheter before removing syringe.
- Report problem—thrombolytic de clotting may be necessary.
- Report so x-ray can validate catheter placement (catheter may have migrated with client maneuvers).
- Monitor client for fever and assess insertion site for drainage, tenderness, redness.
- PICC may be removed—send tip to lab for culture.

GERONTOLOGIC Considerations

Elderly Clients Requiring Chemotherapy or Parenteral Nutrition Are Good Candidates for Implanted Vascular Access Devices.

- Decreased amounts of fluids can be administered to prevent fluid overload.
- Risk of infection is decreased, and in the elderly infection is a concern. Frequency and severity of infection tend to increase with age due to a decline in the immune response.

- Repeated IV punctures are not necessary so veins are preserved and discomfort minimized.
- Greater client mobility is achieved.

With Aging, Epidermal Turnover Decreases and Skin Fragility Increases. Even Minimal Trauma May Result in Serious Erosion.

Healthcare Providers or Family Members Can Be Instructed to Provide Medication Administration, Fluid Therapy, or Parenteral Nutrition at Home.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- Each state identifies the scope of practice for RNs and LVN/LPNs. Several states have identified that the LVN/LPN has a specific role in IV therapy, but the scope of practice is always dictated by each agency (e.g., initiating, regulating, discontinuing IVs). The LPN/LVN educated in IV therapy is the minimum level practitioner to assist in tasks delegated by the RN for the delivery of IV therapy. The RN may be assisted by an LVN/LPN educated in IV therapy, but the RN remains responsible for the care given.
- Policies outlining the responsibility of the IV nurse vary significantly among agencies. A written policy should clearly outline all aspects of this role, and all staff should be familiar with its scope. Policies and procedures should follow national guidelines and standards of practice established by the Centers for Disease Control and Prevention, the American Association of Blood Banks, and the IV Nurses Society. All nurses must be aware of the many physical hazards associated with IV therapy and related OSHA rules to be observed.
- Central line catheter management must be done by an RN.
- The nurse who delivers IV therapy must be qualified by specific knowledge and experience to perform such highly specialized skills. Many agencies utilize a team of specialty educated and experienced certified IV nurses who focus their attention solely on aspects of IV therapy (initiation, drug preparation, fluid/blood/drug administration, regular client assessment and site care, as well as monitoring product integrity). While these nurses are freed from other care responsibilities, the professional nurse must provide for ongoing client care and ensure client safety.
- TPN and lipids may be administered only by an RN according to specific physician orders.

- The CNA/UAP providing personal hygiene must understand that the IV system is a closed one and must be able to give care without disrupting the system. The components of the CVAD system must never be disconnected. Doing so places the client at risk for infection and air embolism. The CNA/UAP should receive training in changing the client's gown without disrupting the CVAD system.
- For the client with a CVAD allowed to shower, the RN should disconnect infusion lines, place a dry sterile gauze (4 × 4) over the dressed site and exposed tubing(s), then cover all with a large transparent dressing for waterproofing. Post-shower removal of the covering and inspection of the dressing should also be performed by the RN.

Communication Matrix

While the professional monitors the IV infusion site regularly, the CNA/UAP provides vital data to the professional nurse by immediately reporting:

- Observations of redness or swelling around the CVAD insertion site (signs of possible infiltration, hematoma, sepsis).
- Presence of crepitus (bubble-wrap feeling) on the client's chest (sign of possible subcutaneous emphysema that can lead to respiratory distress).
- Observations of respiratory distress in any client with recent (24 hr) placement of a central line (symptoms of possible pneumothorax).
- Any client complaint of arm, shoulder, or neck pain (symptom of possible thrombosis or infiltration).
- Temperature elevation (fever—sign of possible catheter-related infection if otherwise unexplainable).
- Infusion device alarms to prompt the professional to further assess the client.
- Presence of blood backup in the catheter.
- A loose or soiled/wet dressing.

CRITICAL THINKING Strategies

Scenario 1

Mr. John Baker is a 68-year-old retired pharmacist who has just returned from surgery after placement of a tunneled CVAD with a Groshong valve. He will be started on a long-term intermittent chemotherapy regimen for acute lymphocytic leukemia. His wife is a retired RN who worked in the operating room for many years.

1. Identify at least three advantages for inserting the tunneled catheter for his treatment.
2. His wife is very concerned about the initial care of the catheter. What explanation will you give her?
3. After the explanation regarding the care of the catheter, Mrs. Baker asks you how they can prevent an infection of the catheter.
4. The client needs to be instructed on how to flush the catheter. What are the most important directions you should provide to him?

5. Mrs. Baker asks you to describe what symptoms require reporting to the physician. What is your best response to this question?

Scenario 2

Seth Eley, age 24, has been admitted to your unit with the diagnosis of inflammatory bowel disease (Crohn's disease) with exacerbation of fever, severe diarrhea, right lower quadrant pain, weight loss, and anemia. Short-term total parenteral nutrition and bowel rest are planned. A triple-lumen central venous catheter has been placed for these purposes.

1. Based on these data, what generalizations can you make about the purpose of hyperalimentation for this client?
2. Why is central venous access necessary?
3. Develop several scenarios about the most common complications of central catheter placement.
4. How does TPN affect fluid and electrolyte balance?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. The best device for long-term IV therapy is a
 1. Peripherally inserted central vascular catheter.
 2. Midline catheter placed in the basilic vein.
 3. Peripheral catheter placed in the antecubital vein.
 4. Long-line catheter threaded into the right atrium.
2. Guidelines to prevent catheter-related bloodstream infections include
Select all that apply.
 1. Using good hygiene principles.
 2. Using a catheter impregnated with an antibiotic agent.
 3. Preparing the IV site with Betadine or alcohol swabs.
 4. Placing a mask on the client when inserting a PICC line.
3. You are preparing the site for an IV insertion of a PICC line. Which one of the following drying times is required when using chlorhexidine gluconate 2% with alcohol?
 1. 30 seconds.
 2. 1 minute.
 3. 2 minutes.
 4. 3 minutes.
4. Primary and secondary continuous IV administration sets should be replaced at least every _____ hours, or immediately if signs and symptoms of infection occur.
 1. 24.
 2. 48.
 3. 72.
 4. 96.
5. When assessing the client's IV that is infusing a parenteral nutrition solution, you find it not infusing at the prescribed rate. Your priority intervention is to
 1. Recalculate the amount of solution and time remaining for the infusion and set the flow rate at that newly calculated rate.
 2. Notify the physician immediately and have a new IV catheter available for insertion by the physician.
 3. Change the dressing to ensure it was not too tight, causing the change in IV flow rate.
 4. Observe the filter because a plugged filter is the most common cause of infusion failure.
6. Place in sequence the steps in obtaining a central venous pressure reading.
 1. Turn stopcock so manometer and IV solution are open to each other.
 2. Close clamp and rotate stopcock so IV solution is open to client.
 3. Open clamp on IV tubing and fill manometer to 18–20 cm.
 4. Turn stopcock to the manometer-client position and obtain reading.
7. A client is admitted to the healthcare facility and has an implanted port in place for chemotherapy. Instructions for care of the port include irrigating the port
 1. Weekly with heparin.
 2. Daily with normal saline.
 3. Monthly and after each use.
 4. Every 12 hr.

8. The physician has ordered a blood sample using a central line catheter. Which one of the following steps will be implemented after turning off the IV flush infusion for one minute?
 1. Flush the catheter with normal saline.
 2. Swab cap and hub with antimicrobial swabs.
 3. Remove cap from syringe.
 4. Flush catheter with 10 mL of normal saline.
 9. The client has a medication order to be administered through a subcutaneous implanted port. Which one of the steps is appropriate for this procedure?
 1. Scrub the site over the port using a Betadine solution for 1 minute.
 2. Insert a 10-mL syringe with a large-bore needle and withdraw 10 mL of blood and discard the sample.
 3. Insert a Huber needle into the port at a 90-degree angle until it meets resistance.
 4. After infusion is completed, irrigate port with normal saline and remove needle by pulling it out at a 60-degree angle.
 10. The major advantage of using a positive pressure device, such as a CLC2000, is to
 1. Ensure ease of obtaining blood samples from the IV site.
 2. Maintain an accurate IV solution at the prescribed rate.
 3. Maintain sterility at the junction of the IV tubing and the cap.
 4. Prevent blood from being drawn back into the catheter when the flush syringe is removed.
-

Respiratory Care

LEARNING OBJECTIVES

1. Outline the three processes of respiration.
2. Identify three nursing diagnoses for clients with ventilatory dysfunction.
3. Describe the steps for teaching a client deep breathing and coughing exercises.
4. Discuss the purpose of using an incentive spirometer.
5. Describe the steps for peak flow measurement.
6. Describe positions for postural drainage and chest percussion and vibration.
7. Differentiate modes of oxygen delivery and describe nursing care relevant to each mode.
8. Differentiate various modes of airway maintenance.
9. Outline the care needs of the intubated client.
10. Describe the nursing actions included in tracheostomy care.
11. Explain the procedure for inflating a tracheal tube cuff.
12. Describe safety measures used when suctioning clients.
13. List measures to promote safe, effective care for clients with chest tubes.

TERMINOLOGY

Acidosis accumulation of acids (metabolic or respiratory), potentially disturbing acid–base balance and causing acidemia (low pH).

Adventitious abnormal extra sounds (crackles, wheezes) superimposed on breath sounds.

Alkalosis condition in which the alkalinity of the body tends to increase beyond normal, potentially resulting in alkalemia (high blood pH).

Apnea cessation of breathing, usually of a temporary nature.

Atelectasis collapse of alveoli, which may lead to hypoxemia, increased PCO₂, and pneumonia.

Auscultation process of listening for sounds produced by body organs.

Bradycardia slow heart rate (below 60 beats/min).

Bronchiectasis dilation of a bronchus or bronchi with production of large amounts of malodorous secretions.

Crackles discontinuous popping (opening) sounds indicative of hypoventilation of alveoli, usually auscultated at end of inspiration in dependent lung areas.

Cyanosis bluish or grayish discoloration of the skin resulting from significant reduction of oxygen saturation of hemoglobin.

Diaphoresis profuse sweating.

Dyspnea a subjective feeling of having difficulty breathing.

Expectorant an agent that facilitates the removal of airway secretions.

Hemothorax blood in the pleural space resulting in compression of normal lung tissue.

Hyperventilation abnormally deep breathing that results in a decrease in PCO₂ (respiratory alkalosis).

Hypoventilation reduced rate and depth of breathing resulting in retention of carbon dioxide (respiratory acidosis).

Hypoxemia insufficient oxygenation of the blood (decreased PO₂).

Hypoxia lack of adequate amount of oxygen transported to the tissues.

Intubation insertion of a tube into a body opening, as into the trachea.

Narcosis unconscious state due to narcotics or other depressing agent (e.g., elevated PCO₂).

Nares the nostrils.

PEP An abbreviation that means positive expiratory pressure.

Percussion rhythmic striking of the thorax to loosen pulmonary secretions.

Pneumothorax presence of air in the intrapleural space resulting in lung collapse.

Polycythemia excess number of red blood cells.

Postural drainage the use of gravity to drain secretions from the airways.

Spirometer device used for measuring inhalation and exhalation volumes.

Sputum substance expelled by coughing.

Tachypnea increased rate of breathing (over 24 breaths/min).

Tension pneumothorax lung collapse with potential contralateral shift of mediastinal structures resulting from accumulation of air or fluid in the intrapleural space.

Tracheostomy surgical opening into the trachea, usually for insertion of a tube to provide airway patency.

Ventilation the acts of inspiration and exhalation for the exchange of oxygen and carbon dioxide between the lungs and the atmosphere.

Vibration therapeutic high-frequency shaking of a body part.

Wheezes musical adventitious sounds heard on inspiration and/or expiration due to airway spasm, retained secretions, or other obstruction.

THE RESPIRATORY SYSTEM

The respiratory system provides for the exchange of gases between the blood and the external environment so that cellular respiration can occur. The respiratory structures involved include the nose, pharynx, larynx, trachea, bronchi, lungs, diaphragm, intercostal muscles, and ribs.

The upper respiratory tract includes the nose, pharynx, and larynx. These structures filter, warm, and humidify the air before it passes into the lower airways. When the upper respiratory tract is bypassed by intubation or tracheostomy, these protective processes are lost.

The lower respiratory tract is considered a sterile environment. It begins below the larynx. The trachea is composed of smooth muscle reinforced by C-shaped rings of cartilage lined with a membranous sheath. It branches into the right and left mainstream bronchi. The right bronchus extends vertically from the trachea, whereas the left bronchus branches from the trachea at an angle. The right and left bronchi divide further and further into terminal bronchioles and finally into respiratory bronchioles, alveolar ducts, and alveoli.

Because of the anatomical difference of the bronchi, migration of an endotracheal tube (ET) into the right bronchus occurs more frequently. Such a migration would result in ventilation of only the right lung. Chest x-rays are taken to ensure proper placement of ET tubes in the trachea. Auscultation of *bilateral* breath sounds also helps to verify optimal ventilation of intubated clients.

Protective processes of the lower airway include mucus secretion and the presence of special hairlike cells (cilia). This “mucociliary escalator” continuously traps and moves inhaled irritants up toward the pharynx to be removed by swallowing or

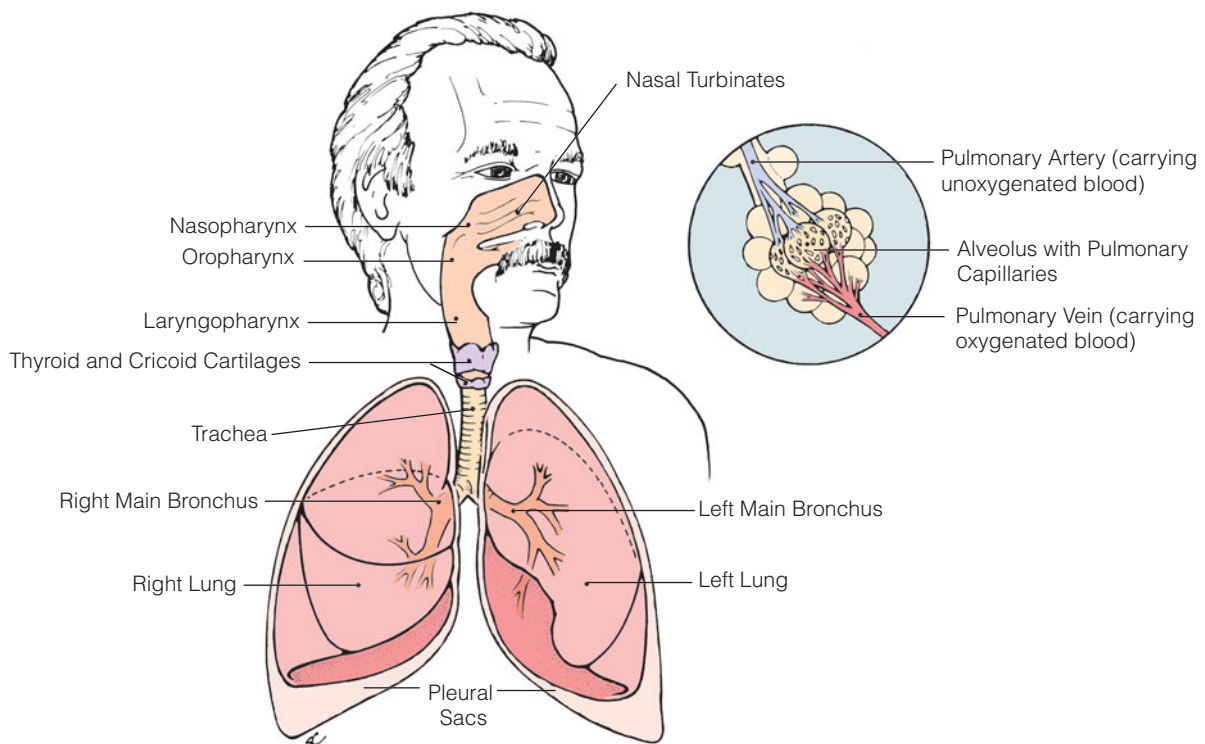

coughing. Drying pharmacologic agents and pathophysiologic states (e.g., immobility) interfere with these protective processes and place the client at risk for pulmonary complications.

PROCESSES OF RESPIRATION

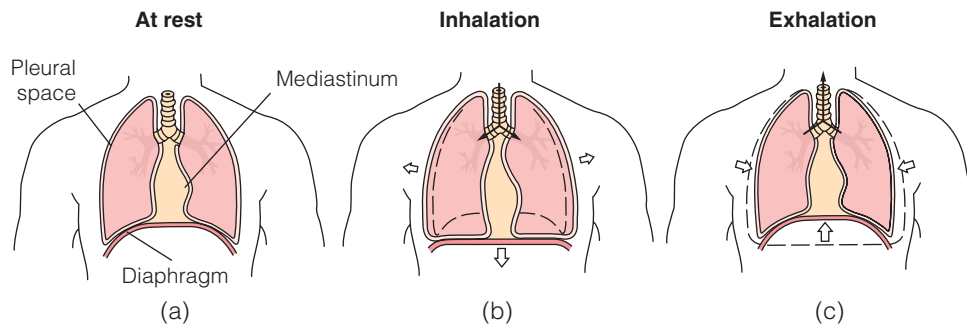

Cellular respiration occurs when oxygen is transported from the atmosphere to tissue cells, and carbon dioxide is removed and carried from the cells to the atmosphere. RBC hemoglobin is the carrier for these gases. Three processes—ventilation, diffusion, and perfusion—are essential for this to occur.

Ventilation is the mechanical exchange of air between the lungs and the atmosphere. *Inspiration* is the *active* phase of ventilation. It requires contraction of the diaphragm and external intercostal muscles to expand the thorax. When thoracic expansion occurs, intrapulmonic pressure becomes negative compared with atmospheric pressure, and air flows into the lungs. *Exhalation* is the *passive* phase of ventilation. It occurs when alveolar pressure increases due to elastic recoil of lung tissue and relaxation of the respiratory muscles, and air flows out of the lungs back into the atmosphere.

Ventilation is controlled by the brainstem, which responds to a rise in blood carbon dioxide level (PCO_2). As breathing eliminates CO_2 , there is a negative feedback to the brain. Through exhalation of carbon dioxide (which with water forms the volatile acid carbonic acid in the bloodstream) the lungs play a vital role in maintaining the normal alkaline pH of the blood (7.35–7.45). Conditions that result in metabolic acidosis (e.g., diabetic ketoacidosis) make the blood more acidic, also stimulating the brainstem to increase the rate and depth of breathing. The resultant lowering of PCO_2 (exhalation of volatile acid or respiratory alkalosis) helps return the

▲ Anatomy of the respiratory system.

▲ Diaphragm contracts and descends on inspiration. Diaphragm relaxes and ascends on expiration.

blood pH to an alkaline state. This process is called respiratory compensation for metabolic acidosis.

Although CO_2 is the major stimulus for breathing, high sustained levels of carbonic acid depress the respiratory center, and respiratory arrest can occur. Individuals who have chronically elevated PCO_2 levels due to chronic obstructive pulmonary disease (COPD) may become insensitive to PCO_2 as a stimulus for breathing. Instead, their brain responds to a lower than normal PO_2 (less than 60 mmHg) to stimulate breathing. The administration of high flows of oxygen to such “hypoxic-dependent breathers” can eliminate their stimulus to breathe. Such individuals are at high risk for CO_2 narcosis.

Diffusion is the process of gas exchange between the alveolar air and the blood. The respiratory unit (respiratory bronchiole, alveolar ducts, and alveoli) is surrounded by capillaries, which allow for this exchange of oxygen and carbon dioxide. Alveoli must be ventilated and must remain diffusible for gas exchange to prevent respiratory failure. Oxygen tension in blood flowing through alveolar capillaries is *lower* than the oxygen tension in the alveoli. This pressure gradient causes oxygen to pass from the alveoli to the blood, thus increasing the PO_2 and “arterializing” the blood. Conversely, carbon dioxide tension is *higher* in the capillary blood than it is in the alveoli, thus promoting its diffusion into alveoli and the elimination of carbon dioxide on exhalation.

Perfusion is the process of circulating oxygen and carbon dioxide between the lungs and tissue cells. Without this blood transport and exchange of gases at both the pulmonary and tissue capillary levels, survival is impossible.

Alterations in Respiration

Alterations in tissue respiration can result from dysfunction of any of the three essential processes previously outlined.

Alterations in Ventilation

Ventilation depends on patent airways, the ability to clear airways, chest expansion, and compliant alveoli. Many factors and disease processes can interfere with adequate ventilation, including (1) any limitation in ability to clear airways (ineffective cough, intubation, decreased level of consciousness); (2) any limitation of alveolar expansion (pneumonia, congestive heart failure, fractured ribs, pain, thoracic deformity,

neurologic disease, respiratory depressants, immobility); and (3) factors that interfere with surfactant activity, which is essential for alveolar inflation (narcotics, anesthetics, hypoventilation, high oxygen flow rates). Inadequate ventilation results in abnormal arterial blood gases (low PO_2 and low SaO_2 , and eventually, an increase in PCO_2).

Pathologic processes that cause ineffective exhalation due to loss of elasticity (overcompliance) of small airways and alveoli also result in an increased PCO_2 (respiratory acidosis). Chronic obstructive pulmonary disease is an example.

Alterations in Diffusion

Diffusion is dependent on a partial pressure difference in gases and an adequate amount of permeable alveolar surface area. Any disease that thickens the alveolar membrane (fibrosis, congestive heart failure) reduces alveolar permeability and leads to a reduced PO_2 (hypoxemia). Alveolar surface area can be reduced by lobectomy or pneumonectomy.

Alterations in Perfusion

For cells to receive oxygen and give off their wastes, blood must flow at both the pulmonary and tissue capillary levels. Adequate perfusion depends on a normal blood volume, an adequate amount of hemoglobin capable of combining with oxygen and carbon dioxide, effective cardiac function, and competent vasculature. Any pathology that interferes with blood cell production, maintenance of blood volume, cardiac function, or vascular patency can result in inadequate tissue perfusion. Likewise, any factor that prevents blood from flowing through pulmonary capillaries (pulmonary embolism) disrupts the process of gas exchange for replenishment of oxygen and the elimination of carbon dioxide.

ASSESSMENT OF RESPIRATORY FUNCTION

Arterial blood gases and pulmonary function tests reflect pulmonary capacity. The pH of the blood is affected by pulmonary function. If carbon dioxide is not eliminated by the lungs due to hypoventilation for any reason, the PCO_2 rises. Since CO_2 creates an acid in the bloodstream, its accumulation (respiratory acidosis) causes the blood pH to decrease (acidemia). *Hypoventilation* is the only mechanism for PCO_2 accumulation

and is encountered when factors depress the respiratory center, inhibit breathing, or a client has a disease, such as COPD, that prevents efficient exhalation. The peak flow meter measures maximum expiratory flow rates. These units are used by asthma clients to regularly self-assess. A declining flow rate (by 20%) may indicate a worsening condition. Serial measurements help the physician to adjust the client's medical regimen. *Hyperventilation* (due to anxiety, neurologic dysfunction, or iatrogenic overventilation) causes the PCO_2 to fall below normal (respiratory alkalosis) and the blood pH to rise above normal (alkalemia).

Arterial blood gas (ABG) studies also evaluate diffusion and perfusion as reflected by the PO_2 and SaO_2 . Pulse oximetry is often preferred over ABGs as a cost-effective laboratory test of SaO_2 .

It is essential that ventilation of alveoli is matched with blood flowing through alveolar capillaries. If alveolar ventilation occurs without matched perfusion (e.g., pulmonary embolism), the PO_2 falls, but the PCO_2 remains normal because of the greater solubility of CO_2 ; the PCO_2 may even decrease due to hyperventilation (respiratory alkalosis). Conversely, if the alveoli are perfused but not ventilated (as in atelectasis), the blood is not adequately oxygenated. This condition results in a low PO_2 and a normal PCO_2 , because carbon dioxide is highly diffusible. Continued hypoventilation, however, eventually results in an increased PCO_2 (respiratory acidosis).

Normal pulmonary ventilation and perfusion are reflected by *normal blood gas values*: *Note*: Pulse oximetry (SpO_2) allows noninvasive estimation of SaO_2 .

pH	7.35–7.45
PCO_2	35–45 mmHg
HCO_3	22–26 mEq/L
PO_2	80–100 mmHg (breathing room air)
SaO_2	90%–100%

Pulmonary function (spirometry) tests measure lung volumes and capacity and help differentiate restrictive and obstructive defects of ventilation.

VC (vital capacity)	75%–80% of that predicted by age, sex, and height (decreased in restrictive disease)
FEV (forced expiratory volume)	65%–85% of VC in 1 second and 95% in 3 seconds (decreased in obstructive disease)
FEV ₁ (forced expiratory volume in 1 sec)	Normal = 75% VC (decreased in obstructive disease)
FEV 25–75	Measures expiratory flow capacity of small airways; most sensitive measure of small airway disease

Nursing Interventions

The goal of respiratory nursing interventions is to maintain, restore, or to artificially provide the vital functions of the respiratory system.

Nursing interventions are used routinely to help prevent pulmonary complications for clients with known pulmonary problems, for clients at risk for pulmonary complications (e.g., immobility), or for surgical clients who have undergone general anesthesia and who experience pain.

These interventions include pain management; maintaining adequate hydration (2–3 L of water/day unless contraindicated); turning to help ventilate dependent lung areas; deep breathing to stimulate surfactant and inflate hypoventilated alveoli; coughing to remove retained secretions; airway suctioning to assist ineffective airway clearance; and early ambulation. Protective splinting of operative sites promotes client comfort, adherence, and prevents wound strain.

Continuous positive airway pressure (CPAP)/bilevel positive airway pressure (BiPAP) is the noninvasive application of positive pressure to upper airways to prevent their obstruction by the soft tissues that surround them. This mode improves alveolar ventilation and decreases PCO_2 , respiratory rate, and the work of breathing. Clients with obstructive sleep apnea (OSA), central sleep apnea, or respiratory insufficiency may benefit from this therapy. It can also provide life support for clients who have decided to forego endotracheal intubation.

Similarly, oscillating positive expiratory pressure devices function as a cough support to assist COPD clients to clear their airways.

Techniques such as postural drainage, chest percussion, and vibration (CPT) utilize gravity and mechanical energy to help mobilize secretions. These measures are reserved for the client who produces excessive amounts (>25 mL/day) of thick secretions that are difficult to mobilize.

A variety of devices are used to deliver supplemental oxygen to the hypoxic client (SaO_2 under 90%). These devices differ in the degree that they control the client's inspired air.

The most common clinical manifestations indicative of inadequate ventilation are:

- Tachycardia (heart rate over 100/min)
- Tachypnea (breathing rate over 24/min)
- Anxiety reflected in facial expression
- Restlessness or confusion
- Use of accessory muscles for breathing
- Change in cognition or level of response
- Increased blood pressure

Early recognition of these indicators of possible hypoxemia should prompt further investigation and appropriate intervention

Artificial means to establish and maintain patent airways include oral/pharyngeal and endotracheal devices. Bypassing the body's natural protective airway and communication processes, these devices render the client dependent and at risk for serious respiratory complications. Clients with artificial airways require additional nursing measures to ensure ventilation and to protect the respiratory system. Such skills include suctioning, tracheostomy care, providing a means for communication, and regular oral hygiene.

If air or fluid accumulates in the intrapleural or mediastinal space due to trauma, disease, or surgery, the lung cannot expand. Cardiac tamponade with decreased cardiac output can occur due to decreased venous return secondary to compression of mediastinal structures. Chest tubes are placed to evacuate air and fluid from the pleural or mediastinal space to facilitate lung re-expansion and prevent increased mediastinal pressure. In certain postoperative settings, chest drainage may be reinflated to replace blood lost.

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to use on client care plans when the components are related to respiratory conditions.

NURSING DIAGNOSIS	RELATED FACTORS
Activity Intolerance	Imbalance between oxygen supply and demand
Ineffective Airway Clearance	Fatigue; excessive secretions; pain; immobility; neuromuscular disease; chronic obstructive pulmonary disease
Aspiration, Risk for	Depressed airway protective mechanisms; presence of artificial airway; enteral feeding, neuromuscular disease
Ineffective Breathing Patterns	Immobility; fatigue, pain; neuromuscular impairment; chronic respiratory disease; pharmacologic agents
Impaired Gas Exchange	Ventilation/perfusion imbalance; hypoventilation, chronic obstructive pulmonary disease, airway obstruction, heart failure, pulmonary edema
Disturbed Sleep Pattern	Obstructive airway (sleep apnea)

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infection is hand hygiene. *Remember to wash your hands or use antibacterial gel before and after each client contact.*

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Respiratory Preventive and Maintenance Measures

Nursing Process Data

ASSESSMENT Data Base

- Observe client’s physical ability to perform exercise (e.g., to assume Fowler’s position, energy level, degree of pain experienced, and need for pain medication).
- Observe rhythm, rate, and depth of breathing.
- Auscultate breath sounds.
- Note client’s report of dyspnea or signs of increased work of breathing.
- Note presence of adventitious sounds.
- Note proximity of incision to muscles necessary for breathing and coughing.
- Assess need for supported ventilation/resuscitation.

PLANNING Objectives

- To improve pulmonary ventilation.
- To conserve energy and decrease the work of breathing.
- To loosen secretions and promote clear airways.
- To prevent hypoventilation and hypoxemia.

IMPLEMENTATION Procedures

- Instructing Client to Deep Breathe 1168
- Instructing Client to Cough 1168
- Teaching Diaphragmatic Breathing 1169
- Teaching Use of Incentive Spirometer (IS) 1169
- Teaching Peak Flow Measurement 1170
- Teaching Use of Oscillating Positive Expiratory Pressure (PEP) Cough Support Device 1171
- Providing CPAP/BiPAP 1172
- Providing Bag–Valve–Mask Ventilation 1173

EVALUATION Expected Outcomes

- Breath sounds are normal; adventitious sounds are cleared.
- Vital capacity, pulmonary ventilation, and gas exchange are improved/supported.
- Client reaches predetermined tidal volume level when using incentive spirometer.
- Client’s energy is conserved and work of breathing is eased.
- Secretions are loosened and airways are clear.
- Client monitors peak-flow appropriately.
- Client experiences an improved sleep pattern.

Critical Thinking Application 1174

- Expected Outcomes 1174
- Unexpected Outcomes 1174
- Alternative Actions 1174

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Instructing Client to Deep Breathe

Equipment

Straight chair or hospital bed at 90° elevation

Preparation

1. Perform hand hygiene.
2. Provide privacy.
3. Explain the rationale for the procedure.
4. Help client to sit straight up in bed with knees slightly flexed or on side of bed. ► **Rationale:** This position promotes maximum lung expansion.

Procedure

1. Demonstrate the deep breathing steps, allowing time for client to practice each step.
2. Place your hand or have client place hands palm down around the sides of client's lower ribs. ► **Rationale:** This action supports deep breathing and assists you to evaluate depth of inspiration.
3. Tell client to breathe in slowly through nose until chest expands and abdomen rises visibly.
4. Have client hold a sustained maximal inspiration 3–5 seconds, then exhale slowly through the mouth.
5. Evaluate client's response to determine how often exercise should be performed—diminished breath sounds or presence of crackles indicates need for frequent deep breathing, turning, and early ambulation.

▲ Nurse demonstrates placement of hands on either side of incision for support.

EVIDENCE-BASED PRACTICE

Improving Oxygenation

Studies show that the PO_2 is lower when the client with unilateral lung disease is positioned on the diseased side. Since the dependent lung has greater blood flow, placing the healthy lung down improves oxygenation.

Source: Bridges, E. (2001). Ask the experts. *Critical Care Nurse*, 21(6), 66.

Instructing Client to Cough

Equipment

Straight chair or hospital bed at 90° elevation
Pillows for positioning and incisional support
Tissues for secretions
Protective gear (gloves, gown, goggles, mask)
as indicated

Preparation

1. Premedicate client if indicated for pain relief.
2. Perform hand hygiene.
3. Provide privacy.
4. Explain procedure to client.
5. Don protective gear if indicated.
6. Provide client with tissues.

Procedure

1. Place client in upright position, upper body positioned slightly forward. ► **Rationale:** This position assists client to cough more effectively.
2. Ask client to slowly take two or three deep breaths through the nose and exhale through the mouth.
3. Instruct client to inhale deeply, hold breath for several seconds, lean forward, and cough, using abdominal, thigh, and buttock muscles. ► **Rationale:** This promotes a more effective cough.
4. Instruct client with pulmonary condition to exhale through pursed lips and to “huff” while coughing in mid-exhalation (not at end of deep inspiration).
► **Rationale:** The “huff cough” maintains an open glottis; helps prevent high expiratory pressures that collapse diseased airways, thus facilitating movement of secretions along the tracheobronchial tree; and reduces fatigue.

Clinical Alert

Deep breathing is indicated, but coughing is *contraindicated* for the client post-eye, -ear, -brain, or -neck surgery, or if efforts are nonproductive.

- Support any incision with the palms of your or client's hands, or place a rolled pillow firmly against the incision. ► **Rationale:** This prevents incisional strain and encourages client to cough more effectively.
- Encourage client to deep breathe and cough more frequently if cough is productive. Explain why coughing is beneficial and keep tissues and disposal receptacle handy. ► **Rationale:** Accumulated secretions in airways promote bacterial growth and interfere with ventilation.

▲ Holding pillow against incision when coughing prevents incision strain.

Teaching Diaphragmatic Breathing

Equipment

Hospital bed in flat position

Preparation

- Check physician's orders and client care plan.
- Perform hand hygiene.
- Provide privacy.
- Inform client that the purpose of this exercise is to learn how to breathe by using abdominal muscles.

NOTE: Clients with COPD tend to overwork the upper chest muscles and suck in the abdomen on inspiration, making it difficult for the diaphragm to descend. This exercise improves breathing efficiency.

Procedure

- Place your hands on client's abdomen, below ribs.
- Have client breathe in through the nose and try to push stomach outward against your hands.
- Instruct client to hold breath for 3–5 seconds to keep alveoli open.
- Have client breathe out slowly through the mouth as you apply slight pressure at the base of the ribs.
- Encourage client to practice diaphragmatic breathing frequently, using own hands to feel the abdomen rise.
- Placing progressive increments of weight on the abdomen (recumbent position) strengthens the diaphragm, while practice improves neuromuscular coordination of diaphragmatic breathing.

Teaching Use of Incentive Spirometer (IS)

Equipment

Hospital bed or straight chair

Incentive spirometer with flow rate indicator (save bag for storage of device)

Tissues for secretions

Preparation

- Check physician's orders and client care plan.
- Gather equipment.
- Perform hand hygiene.
- Explain purpose and procedure to client.

- If preoperative measurement was not done, use guide in spirometer package to determine client's volume goal, and set marker at this goal.
- Attach open end of tubing to stem on front of exerciser.
- Auscultate lungs before and after using IS. ► **Rationale:** This evaluates effectiveness of spirometry.

Procedure

- Instruct client to hold exerciser, place mouth tightly around mouthpiece, and breathe in a trial breath through the mouth. ► **Rationale:** Client can see the flow rate indicator on side of unit to visualize appropriate *rate* for inhalation.

▲ Client places mouth tightly around mouthpiece and inhales slowly, while watching yellow flow rate indicator, to promote lung expansion.

2. Explain that a slow deep breath is better than a fast breath.
3. Instruct client to exhale completely, then place mouth tightly around mouthpiece.
4. Instruct client to inhale slowly to raise and maintain yellow flow rate indicator at the “best” flow rate range, and continue inhaling to try to raise piston to prescribed (or preoperative measured) volume level.
5. Instruct client to remove mouthpiece but hold breath at maximum inspiration 3–5 seconds, then exhale through pursed lips. Repeat a few times, then cough.
6. Encourage client to use spirometer hourly, coordinating use with TV program breaks, for instance, as a reminder.
7. Provide positive feedback as client uses IS to regain predetermined inspiratory capacity, using marked goal as an incentive.
8. Replace unit in bag when not in use and keep in accessible place for client.

EVIDENCE-BASED PRACTICE

In patients undergoing coronary artery bypass grafting, there is no evidence of benefit from incentive spirometry compared with preoperative education or standard postsurgical PT for preventing postoperative pulmonary complication, improving pulmonary function and oxygenation, and reducing length of hospital stay. There is evidence that IS may have some drawbacks compared with positive airway pressure techniques.

Source: Freitas, E. R., Soares, B. G., Cardoso, J. R., & Atallah, A. N. (2007). Incentive spirometry for preventing pulmonary complications after coronary artery bypass graft. *Cochrane Database of Systematic Reviews*, (3), CD004466.

Teaching Peak Flow Measurement

Equipment

Peak flow meter with instructions for client

Preparation

1. Check physician’s orders or client care plan.
2. Gather equipment.
3. Perform hand hygiene.
4. Explain purpose of procedure and provide instruction sheet to client.

Procedure

1. Assist client to follow product instructions to assemble meter.
2. Instruct client to attach mouthpiece to peak flow meter, if desired. ► **Rationale:** Most meters can be used with or without mouthpiece.
3. Slide indicator to bottom of meter scale to zero position.
4. Instruct client to inhale as deeply as possible, then place mouth around mouthpiece, forming a tight seal. If possible, client should be standing.

▲ Slide indicator to bottom of meter scale to bring indicator to zero point.

▲ Have client blow out through mouth as hard and fast as possible—indicator moves up scale to record peak expiratory flow (L/min).

5. Have client blow out through mouth as hard and fast as possible. ► **Rationale:** As client forcefully exhales, indicator moves up scale to record client's peak expiratory flow (liters per minute).
6. Repeat peak flow measurement three times and record highest value. ► **Rationale:** Client may keep daily record of peak flow values and report significant changes.
7. Instruct client to clean unit weekly, following manufacturer's instructions.

EVIDENCE-BASED PRACTICE

Peak Flow Monitoring

Color-coded zones indicate forced expiratory volume. The green zone indicates 80–100% of the individual's best, yellow zone indicates 60–80%, red zone is less than 60%. Client should take appropriate actions prescribed by the healthcare provider if peak flow is below the red zone.

National Heart, Lung, and Blood Institute Expert panel report 3: Guidelines for diagnosis and management of asthma (2007). <http://www.nhlbi.nih.gov/guidelines/asthma/asthgdln.pdf>

Teaching Use of Oscillating Positive Expiratory Pressure (PEP) Cough Support Device

Equipment

“Flutter valve system” with adjustment dial, one-way inspiratory valve, and detachable mouthpiece

Preparation

1. Identify client.
2. Explain use and purpose of device. ► **Rationale:** The device functions to maintain positive pressure throughout exhalation to facilitate pulmonary secretion removal—cough support device.
3. Open packet and save for device storage.
4. Secure all device connections.
5. Adjust vibration frequency dial clockwise to low resistance setting when initiating therapy. ► **Rationale:** Higher frequency of vibrating pressure waves and higher resistance of opening changes produce higher resistance to exhalation.
6. Position client sitting with elbows resting on table.

Procedure

1. Instruct client to place mouthpiece in mouth with tight seal during exhalation.

2. Have client take a deep breath in and hold it for 2–3 seconds.
3. Instruct client to exhale through the device, prolonging exhalation actively (not forcefully, but three to four times longer than inhalation) as the device vibrates.
4. If client cannot maintain exhalation for 3–4 seconds, adjust dial clockwise to increase resistance and allow client to exhale at a lower flow rate. ► **Rationale:** Proper resistance range produces inspiratory to expiratory (I:E) ratio of 1:3 or 1:4.
5. Once a proper range is determined, the client may change adjustments for harder or softer exhalation to meet a subjective comfort with the device. ► **Rationale:** Adjustments may be necessary to meet client needs.
6. Clean mouthpiece and return device to storage bag.
7. Encourage client to use the “PEP” device for 10–20 minutes, four times a day.

NOTE: This device directs exhaled air through an opening that alternately closes and opens the path of air flow. This maintains a vibratory positive pressure through exhalation (common lay term is “flutter valve”).

Providing CPAP/BiPAP

Equipment

- Nasal mask, full face mask, or nasal pillows of proper size (S, M, L)
- Indelible marker
- Airflow generator
- Delivery tubing
- If ordered:
 - Oxygen source
 - Oxygen tubing
 - Pulse oximetry

Preparation

1. Check physician's orders or client's care plan.
2. Gather equipment.
3. Perform hand hygiene.

Clinical Alert

Clients with obstructive sleep apnea (OSA) are at risk for cardiovascular complications including hypertension, stroke, arrhythmias, heart failure, and myocardial infarction.

4. Explain purpose of procedure to client and provide written instructions for home use.
5. Have client wash face.

Procedure

1. Connect CPAP/BiPAP device delivery tubing to pressure generator.
2. Plug pressure generator into grounded outlet.
3. Connect oxygen delivery tubing into device tubing adapter port (if ordered).
4. Turn on pressure generator.

▲ Client receiving CPAP via face mask. Machine is capable of CPAP and BiPAP.

5. Establish CPAP/BiPAP parameters:
 - a. RAMP: time frame for pressure achievement, usually 5–15 minutes.
 - b. CPAP or BiPAP setting.
 - c. Respiratory rate if applicable.
 - d. FIO₂ if applicable.
6. Apply device over client's nose or face, avoiding tight fit, and mark straps for future proper fit. ► **Rationale:** Tight fit is uncomfortable for the client and unnecessary for device functioning.
7. Establish continuous pulse oximetry if ordered.
 - a. ABGs may be obtained before and within the first hour of BiPAP initiation.
 - b. Monitor vital signs, pulse oximetry, mental status, and work of breathing every 30 minutes X2, every hour X6, and every 2 hours X8.

Clinical Alert

Respiratory therapy and biomedical engineering departments must check to ensure proper functioning and electrical safety of outside equipment (e.g., CPAP) brought from home to be used in an agency.

- CPAP provides single positive pressure to establish minimal airway value (e.g., 5 mmHg) at end of exhalation.
- BiPAP provides two positive airway pressures, one to assist peak pressure on inhalation (e.g., 10 cm H₂O) and a lower one (e.g., 5 cm H₂O) to establish minimal airway value at end of exhalation.
- BiPAP with Rate Set provides two positive airway pressures and a set respiratory rate to augment breathing for the client with respiratory insufficiency. This capability qualifies this unit as a “noninvasive mechanical ventilator.” The client is spared intubation.
- BiPAP Autotitration Device senses and measures the client's airflow and adjusts its pressure setting automatically to maintain airway patency.

Clinical Alert

Clients using CPAP/BiPAP are constantly at risk for aspiration and subsequent respiratory complications. The candidate must be alert and responsive orally, must demonstrate airway protective measures (cough and swallow), and must not be restrained or sedated. Opioids relax the pharynx and contribute further to airway obstruction.

CPAP/BiPAP should never be used on a sedated client. There is great danger of aspiration should the client vomit.

8. Tell client to detach tubing from face device if getting up during the night.
9. Monitor client periodically.
10. Teach client to clean device according to manufacturer's instructions.

Providing Bag–Valve–Mask Ventilation

Equipment

- Manual resuscitator bag with nonrebreathing valve
- Oxygen source and tubing
- Airway adapter or face mask

Preparation

1. Determine that client's breathing is absent or inadequate.
2. Summon an assistant if client is not intubated.
 - ▶ **Rationale:** If no artificial airway present, two responders are preferred. Assistant holds mask while nurse compresses resuscitator bag.
3. Gather equipment.
4. Place client in supine position.
5. Connect mask or airway adapter to bag.
6. Connect oxygen tubing and oxygen flow meter to bag inlet.

Procedure

1. Turn oxygen flow meter wide open to 15 L/min (“flush”).
2. Stand at client's head and hyperextend client's neck.
3. Place apex of mask over client's nose and place base of mask between client's lower lip and chin. ▶ **Rationale:** This ensures a tight seal.
4. Use dominant hand to compress central portion of resuscitator bag until client's chest rises (1–2 seconds),

then allow exhalation. ▶ **Rationale:** Overinflation may result in gastric distention.

5. Provide ventilations every 5 seconds for an apneic adult, noting that client's chest rises and falls with each compression.
6. Check to see if client breathes spontaneously; if so, give compressions in synchrony to support ventilation.
7. Observe for possible gastric distention. ▶ **Rationale:** Gastric insufflation may result in regurgitation and aspiration.
8. Reposition client's head if gastric distention is present and reduce compression volume, noting that client's chest rises.
9. Notify physician or respiratory care practitioner for further client evaluation.

Clinical Alert

If client's chest does not rise with ventilations, suspect foreign body airway obstruction. See Chapter 31 for Abdominal Thrust maneuver.

▲ The BiPAP Vision noninvasive ventilator support system has most features of any standard mechanical ventilator.

▲ Compress central portion of resuscitator bag until client's chest rises, then allow exhalation.

Bag-Valve-Mask With Rescue Pod

The bag-valve-mask with Rescue Pod (circulatory enhancer) is used only for clients who are *unable to breathe spontaneously* (e.g., during CPR). This device with one-way valve is attached between the resuscitator bag and mask or airway tube. It allows the rescuer to deliver air to the client.

The system accepts attachment of an expiratory filter for epidemiologic considerations and an external PEEP device for maintaining positive expiratory pressure to enhance diffusion (PO_2) during its use. A pressure manometer indicates pressure from resuscitator bag compression. Desired pressure is sufficient to achieve adequate chest wall movement (normally 15–25 cm H_2O). Maintaining minimal necessary ventilation pressure helps prevent barotraumas to lung tissue and/or gastric air insufflation. The Rescue Pod device must be removed *immediately* if the client is able to resume spontaneous breathing.

DOCUMENTATION for Respiratory Preventive and Maintenance Measures

- Pre- and post-intervention breath sounds and adventitious sounds
- Frequency of deep breathing exercises or use of IS
- Whether cough is productive or not
- Amount and character of secretions expectorated
- Changes in vital signs, SpO_2 , or other client responses
- Inspiratory capacity attained with IS
- Circumstances necessitating use of mask and bag resuscitator
- Client outcome after manual breathing
- Peak flow measurement: highest of three therapy sequential measures
- Client teaching and return demonstration

For CPAP/BiPAP

- Type of CPAP/BiPAP device used
- Established parameters
- Respiratory rate if programmed
- FiO_2 if ordered
- SpO_2 findings pre- and post- therapy
- Client's tolerance of therapy

CRITICAL THINKING Application

Expected Outcomes

- Client coughs effectively, supporting incision to prevent strain.
- Client is able to breathe through nose without distress.
- Client demonstrates appropriate use of incentive spirometer.
- Client experiences benefits of CPAP/BiPAP with undisturbed sleep.

Unexpected Outcomes

Client is unwilling to complete exercise because of misunderstanding or fear of pain or wound dehiscence.

Alternative Actions

- Inform client that fresh incision is secure.
- Instruct again on rationale and necessity for procedure.
- Support incision area more fully, using the palms of your hands or a firmly rolled pillow to allay fears of dehiscence.
- Medicate 30–60 minutes before using spirometer and coughing.

Nasal congestion inhibits client's breathing capability.

- Ask client to blow nose before the breathing exercise.
- Check with physician to prescribe medications, such as saline spray to open nasal passages.

Client is unable to master use of incentive spirometer device.

- Instruct client to start slowly and increase volume over several exercise sessions.
- Supervise practice with encouragement.
- Provide positive reinforcement with increments in volume.
- Ensure that client does regular deep breathing if device interferes with client adherence.
- Turn client every 2 hr and encourage ROM and early ambulation to help stimulate deep breathing and secretion mobilization.
- Instruct client to deep breathe effectively without using the spirometer: to inhale slowly and deeply through the nose, hold the breath several seconds, then exhale.

Client doesn't tolerate BiPAP therapy.

- Loosen the appliance since some leakage is acceptable and does not compromise function of the device.
 - Increase RAMP time to improve tolerance/increase comfort.
 - Use nasal spray (saline solution) to reduce nasal congestion.
 - Find a more individually suited device.
 - Reassess true need for BiPAP.
-

Chapter 30

UNIT 2

Chest Physiotherapy (CPT)

Nursing Process Data

ASSESSMENT Data Base

- Note any contraindicating conditions for CPT: acute exacerbation of COPD, pneumonia *without* evidence of significant sputum production, osteoporosis, lung cancer, cerebral edema.
- Determine rate and depth of breathing and heart rate/rhythm.
- Auscultate breath sounds and check for adventitious sounds or excessive sputum production (over 25 mL/day).
- Note time elapsed since eating (perform CPT between meals to prevent regurgitation).
- Observe quality of secretions. Thick, tenacious secretions may require aerosol therapy before treatment.
- Note client's ABGs/SPO₂ and changes on chest x-ray report.

PLANNING Objectives

- To decrease respiratory rate and improve ventilation and gas exchange
- To reduce client's feeling of shortness of breath
- To facilitate clearance of retained secretions
- To assist client to cough more productively and effectively
- To decrease adventitious lung sounds
- To decrease risk of infection due to stasis of secretions

IMPLEMENTATION Procedures

- Preparing Client for CPT1177
- Performing Postural Drainage1177
- Performing Chest Percussion1178
- Performing Chest Vibration1178
- Using an Airway Clearance System (Wrap)1179

EVALUATION Expected Outcomes

- Chest x-ray shows improvement.
- Breath sounds and adventitious sounds improve on auscultation.
- Shortness of breath is reduced.
- Sputum production is over 25 mL/day (to justify continuation of CPT).
- ABGs/SPO₂ values are improved.

Critical Thinking Application	1180
• Expected Outcomes	1180
• Unexpected Outcomes	1180
• Alternative Actions	1180

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Preparing Client for CPT

Equipment

- Hospital bed or other surface to place client in head-down position
- Gown or towel (optional)
- Tissues
- Container for sputum
- Clean gloves
- Stethoscope
- Pulse oximeter (if indicated)
- Mouthwash/oral hygiene product

Procedure

1. Validate physician's order for CPT. ► **Rationale:** These procedures are tiring to clients, time-consuming, and contraindicated in cases of osteoporosis, pulmonary embolism, cardiac conditions, lung cancer, or other conditions not associated with excessive sputum production.
2. Perform hand hygiene.
3. Administer CPT before or at least 2 hr after meals to prevent vomiting.
4. Establish the location of lung segments if the entire lung field is to undergo CPT; the affected segment should be

drained first. ► **Rationale:** Usually, the lower areas are the most affected.

5. Provide privacy.
6. Prepare client by explaining CPT and purpose.
7. Auscultate chest for breath sounds and adventitious sounds before therapy.
8. Obtain pulse oximetry (SPO₂) if indicated before therapy.
9. Place towel over skin when performing CPT (optional).

▲ Lobes of lungs.

Performing Postural Drainage

Equipment

See Preparing Client for CPT.

Preparation

1. See Preparing Client for CPT.
2. Perform hand hygiene.

Procedure

1. Loosen any tight clothing.
2. Lower head of bed slowly so that client's head is positioned at no greater than a 25° downward angle.
 - **Rationale:** Gravity helps mobilize secretions.
3. Place sputum container and tissues in client's reach.
4. Tell client to remain in position for 3–15 minutes.
 - **Rationale:** Percussion and vibration may be added to help mobilize secretions (*skills to follow*).
5. Instruct client to expectorate secretions.
6. Instruct client to turn to other side, then to supine position, then repeat procedure.

NOTE: Clients should deep breathe between position changes.

7. Assist client to slowly return to normal sitting position after coughing in dependent positions.
8. Determine pulse oximetry if ordered.
9. Auscultate chest areas for improved breath sounds.
10. Note character and measure sputum, then discard.
11. Remove gloves and perform hand hygiene.
12. Offer oral hygiene after secretion expectoration.

EVIDENCE-BASED PRACTICE

Bronchial Hygiene Therapy

There is no firm scientific evidence that CPT measures are effective in preventing pulmonary complications. In order to justify continuation of postural drainage, the client must demonstrate one or more of the expected outcomes listed on unit opening page.

Source: Goodfellow, L., & Jones, M. (2002). Bronchial hygiene therapy. *American Journal of Nursing* 102(1), 38.

Performing Chest Percussion

Equipment

See Preparing Client for CPT.

Preparation

1. See Preparing Client for CPT.
2. Perform hand hygiene.

Procedure

1. Cover area to be percussed with gown or cloth towel (optional).
2. Holding arms with elbows slightly flexed, cup your hands with thumbs and fingers closed. Keeping wrists loose and relaxed, rhythmically flex and extend wrists to clap over area to be drained. ► **Rationale:** This motion produces vibrations that loosen secretions for easier removal with coughing or suctioning.
3. Percuss by alternating hands and listen for hollow sound with strikes.
4. Slowly and rhythmically percuss each area for 3–5 minutes.
5. Do not percuss over bony prominences, breasts, or tender areas. ► **Rationale:** Vibrations are not transmitted to the chest wall through bone or breast tissue and percussion in these areas can cause discomfort.
6. Encourage client to “huff” cough after percussion of lung areas.
7. Auscultate all lung areas for changes in breath sounds.
8. Don gloves, note character and measure quantity of sputum, and discard.

9. Remove gloves and perform hand hygiene.
10. Offer oral hygiene.
11. Document procedure and client’s response.

▲ Perform percussion and vibration with each position change.

Clinical Alert

Since chest percussion is taxing and time-consuming for both client and nurse, it is indicated only in clients with serious secretion retention (e.g., client with cystic fibrosis).

Performing Chest Vibration

Equipment

See Preparing Client for CPT.

Preparation

1. See Preparing Client for CPT.
2. Perform hand hygiene.

Procedure

1. Perform vibration after postural drainage and percussion in each position.
2. Cover area to be vibrated with gown or towel (optional).
3. Instruct client to breathe in through nose and exhale slowly through pursed lips.
4. Place your hands flat over area to be vibrated or place one hand on top of the other. Keep your arms and shoulders straight and wrists stiff.
5. Have client inhale deeply.

6. As client exhales through pursed lips, use moderate pressure to vibrate chest by quickly contracting and

▲ Place hands flat over area to be vibrated, keeping wrists stiff.

relaxing your arms and shoulders. ► **Rationale:** This increases the turbulence and velocity of exhaled air and loosens and mobilizes secretions from peripheral airways.

7. Vibrate for three or four exhalations over the area.
8. Encourage clients to “huff” cough before changing positions.
9. Assess vital signs, pulse oximetry, and auscultate breath sounds.
10. Don gloves.
11. Measure and note character of expectorated secretions, then discard.
12. Remove gloves and perform hand hygiene.
13. Provide oral hygiene.
14. Document procedure and client’s response.

Using an Airway Clearance System (Wrap)

Equipment

- See Preparing Client for CPT
- Disposable inflatable chest wrap of appropriate size (small, medium, large, or extra large)
- Air pulse generator with connecting tubes

Preparation

1. Validate physician’s order for high-frequency chest wall oscillation therapy, frequency, and duration of therapy.
2. Perform hand hygiene.
3. Identify client by name and birth date.
4. Provide privacy.
5. Explain function and purpose of vest/wrap.
6. Assess lung sounds before therapy.

Procedure

1. Elevate head of bed or have client sit in chair.
Alternately, place wrap on bed and roll client onto wrap.
2. Apply wrap over single layer of clothing, wrapping deflated vest around client’s chest, just beneath axillae; have client inhale deeply; and secure with Velcro fasteners. ► **Rationale:** Wrap should fit snugly, but not be uncomfortable.

▲ Vest/wrap high-frequency chest wall oscillation therapy increases mobilization and clearance of airway secretions.

3. Adjust generator to a comfortable working height.
4. Lock generator castors. ► **Rationale:** To prevent movement.
5. Slide air hose into connector port on front of generator using a twist and push motion.
6. Slide other end of hose into disposable vest slits.
7. Fasten Velcro loops to secure air hoses in position.
8. Plug the power cord into the power inlet on back of air pulse generator.
9. Plug power cord into grounded outlet.
10. Adjust arrows up or down to set frequency, pressure, and treatment time, confirming that setting on screen matches those prescribed.
11. Press “ON” button to inflate disposable vest.
► **Rationale:** Air pulsation provides vibration to client’s chest. Treatment will last 10 minutes, but then must be restarted if indicated. Usual treatments are 10–20 minutes qid.
12. Press “OFF” button to end treatment before set time and wrap will deflate.
13. “Session complete” message will show on screen when treatment set time is complete and wrap will deflate.
14. Unplug system and remove disposable air hoses and vest from client.
15. Store vest and air hoses in client’s area and return generator to storage for future use.
16. Reassess client’s breath sounds; note character and amount of coughed/suctioned secretions.
17. Assist client to a comfortable position.
18. Perform hand hygiene.

EVIDENCE-BASED PRACTICE

Vest/Wrap Therapy Causes Compromised Monitoring

EKG and hemodynamic monitoring are distorted with artifact during airway clearance with vest/wrap therapy. The respiratory care practitioner should notify the nurse before initiating therapy to determine that it is safe to have monitoring compromised for the time period of therapy.

Adams, M. et al., 2005: Beside monitoring of spinal cord injuries, *AJCC*, Vol. 14, #1

Vest/wrap high-frequency chest wall oscillation therapy increases mobilization of secretions while requiring no caregiver skill and no special positioning, and many clients require no assistance.

Clinical Alert

Strenuous coughing should be avoided with head-down position since it raises intracranial pressure.

DOCUMENTATION for CPT

- Time, specific treatment, and duration of therapy
- Pre- and post-therapy vital signs, breath sounds, and pulse oximetry
- Quantity and character of sputum produced
- Client's physical tolerance of procedures

CRITICAL THINKING Application

Expected Outcomes

- Client tolerates postural drainage.
- CPT facilitates expectoration of secretions.

Unexpected Outcomes

Client experiences dyspnea during postural drainage.

Alternative Actions

- Change client's position so head is no lower than 25° below horizontal.

Client vomits with CPT treatment and coughing.

- Perform treatments between or before meals.

Client tires with manual chest vibration.

- Notify physician to alter therapy with a mechanical device for chest vibration.
- Limit total CPT time.

Slapping sounds produced with percussion.

- Cup hands more and ensure that clapping is with wrist flexion and extension only.

Oxygen Administration

Nursing Process Data

ASSESSMENT Data Base

- Review client's ABG or pulse oximetry values.
- Assess client's vital signs.
- Observe client for signs of increased work of breathing.
- Assess skin under oxygen mask for irritation.
- Assess for signs of carbon dioxide narcosis.

PLANNING Objectives

- To return arterial PO₂ or SPO₂ values to normal or acceptable range
- To correct hypoxic condition
- To assist breathing to return to normal rate and effort
- To increase client's comfort, breathing efficiency, and activity tolerance

IMPLEMENTATION Procedures

- Monitoring Clients Receiving Oxygen 1182
- Using Pulse Oximetry 1182
- Using an Oxygen Cylinder 1183
- Using Nasal Cannula 1184
- Using an Oxygen Face Mask 1185
- Using an Oxygen Hood 1187

EVALUATION Expected Outcomes

- Arterial PO₂ and SPO₂ values return to normal or acceptable range.
- Signs and symptoms of hypoxia are relieved.
- Comfort, breathing efficiency, and activity tolerance increased.
- Complications of oxygen use do not occur.

Critical Thinking Application 1188

- Expected Outcomes 1188
- Unexpected Outcomes 1188
- Alternative Actions 1188

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Monitoring Clients Receiving Oxygen

Equipment

- Oxygen supply source
- Oxygen delivery device

Procedure

1. Check physician's orders for mode of oxygen delivery and prescribed oxygen liter flow.
2. Perform hand hygiene.
3. Employ safety precautions for oxygen administration.
4. Place client in semi- or high-Fowler's position to facilitate lung expansion.
5. Turn and reposition client frequently to promote ventilation.
6. Encourage deep breathing and coughing exercises unless directed otherwise.
7. Ensure adequate fluid intake, especially if secretions are thick.
8. If ordered, humidify oxygen.
9. Assess client's progress by frequently checking vital signs, color, level of consciousness, and presence of hypoxia—the best indicator of oxygen delivery problems.

Clinical Alert

Oxygen is indicated for clients with COPD, but is used conservatively. High levels of oxygen may suppress breathing stimulus, cause hypoventilation and CO₂ retention, and lead to respiratory arrest due to CO₂ narcosis.

▲ Oxygen flow meter indicates liters per minute delivered to administration setup.

10. Assess clients with COPD frequently for signs of carbon dioxide narcosis:
 - a. Bounding peripheral pulses
 - b. High blood pressure
 - c. Altered sensorium
 - d. Increased pulse pressure
 - e. Warm, clammy skin
11. Evaluate SPO₂ 30 minutes after any change in oxygen flow rate.

Using Pulse Oximetry

Equipment

- Oximeter (battery or line power operated)
- Sensor (clip-on or disposable adhesive sensor)

Preparation

1. Evaluate client's health status before using oximetry.
 - ▶ **Rationale:** Inaccurate oximetry readings can be found in clients with:
 - a. Alkalosis, acidosis
 - b. Fever, hypothermia
 - c. Poor peripheral blood flow
 - d. Carbon monoxide poisoning
 - e. Recent dye injection studies
 - f. Shivering or excessive movement
2. Remove dark nail polish or artificial nails, if using finger for sensor placement. ▶ **Rationale:** These substances can distort readings.
3. Obtain appropriate sensor. ▶ **Rationale:** Sensor probes are designated for specific sites (clips for finger or earlobe, wraps for toes or across the nose).

Procedure

1. Identify client and explain purpose and procedure for pulse oximetry.
2. Plug unit into electric outlet.
3. Turn on power.
4. Apply sensor probe to selected site flush with skin and secure. Make sure both sensor probes are aligned directly opposite each other. ▶ **Rationale:** Oximeter sensors contain both red and infrared light-emitting diodes (LEDs) and a photo detector. The photo detector registers light passing through vascular bed, the basis for microprocessor determination of oxygen-saturation.

Clinical Alert

- Avoid placing SPO₂ clip sensor on the thumb or edematous site. Wrap sensors can be used on the thumb or great toe.
- Avoid extremity with an intra-arterial catheter or noninvasive automatic BP cuff.

- Set alarms to predetermined saturation levels or pulse rate.

NOTE: New motion-tolerant pulse oximeters are associated with fewer false alarms.

- Read oxygen saturation level on digital readout monitor.
- Evaluate findings with previous saturation levels and changes in oxygen therapy.
- Rotate site of clip-on probes every 4 hr. Replace disposable probes every 24 hr. ► **Rationale:** Skin irritation can occur with continuous usage.
- Validate that oximeter pulse rate is consistent with manually assessed pulse rate.
- Document findings on appropriate hospital record.

Pulse Oximetry SpO₂

Arterial blood gas (ABG) analysis has been used for decades to determine a client's gas exchange and oxygenation transport ability. Pulse oximetry technology allows for more cost- and time-efficient PRN or continuous monitoring of arterial oxygen saturation (SaO₂). The primary advantages of this method are:

- It is cost-effective.
- It is a noninvasive evaluation tool.
- Minute-to-minute changes in saturation can be assessed and timely intervention made to meet client needs.
- The client's response to treatment can be evaluated immediately and ongoing.

EVIDENCE-BASED PRACTICE

Pulse oximetry measures the arterial saturation of available hemoglobin. The anemic patient may have a normal SpO₂ and not have adequate tissue oxygenation because available hemoglobin is maximally saturated with oxygen.

Source: Bridget, P. (2009). Pulse points. *Nursing* 2009, 39(2), 8.

▲ Sensor probe placed on finger with continuous oximeter unit display of hemoglobin oxygen saturation (SpO₂) and pulse rate. Alarms are set at predetermined limits.

Safety Precautions for Oxygen Administration

- Set up “No Smoking” and “Oxygen in Use” signs at the site of administration and at the door, according to agency policy.
- Provide cotton gown—synthetics and wool may generate sparks of static electricity.
- Remove matches, lighters, and ashtrays from bedside (these items should NOT be present as hospitals are smoke-free facilities).
- Remove any friction-type or battery-operated toys/devices.
- Disconnect ungrounded electric equipment.
- Remove all volatile or flammable materials (alcohol, oils, petroleum products).
- Make sure that all electrical monitoring equipment is *properly* grounded.
- Locate fire extinguishers and unit/area oxygen meter turn-off lever.

Using an Oxygen Cylinder

Equipment

- Steel cylinder portable oxygen tank
- Regulator/flow meter
- Oxygen delivery tubing

Procedure

- Place oxygen cylinder in carrier in secure upright position. ► **Rationale:** If cylinder of compressed air falls accidentally, unit becomes a missile with uncontrollable force and direction.
- Using hexagon key, slowly turn cylinder release valve clockwise (left is loose) to crack tank open for a brief period, then close (right to tighten). ► **Rationale:** This action removes lint from system.
- Check pressure gauge on front of tank to determine amount of oxygen pressure in tank. ► **Rationale:** Full status is 2,200 PSI.
- Attach flow meter regulator unit over neck of cylinder, aligning pins with green “O” ring openings.
- Use turn key to tighten regulator to cylinder neck.

▲ Attach regulator to cylinder neck, attach tubing, open cylinder release valve, and adjust oxygen flow rate (L/min) as prescribed.

6. Connect delivery tubing to “Christmas tree” adapter on regulator unit.
7. Open cylinder release valve using hexagon key on top of cylinder. ► **Rationale:** This allows oxygen flow.
8. Slowly open regulator/flow meter and adjust to prescribed rate of oxygen delivery in liters per minute.

Clinical Alert

Oxygen cylinders are mandated by the Compressed Gas Association to be green or incorporate a green collar at the gauge and flowmeter mechanism. Wall outlets are also green for oxygen, yellow for air, and white for suction.

Signs and Symptoms of Hypoxia ($\text{SaO}_2 < 90\%$ or below desired range for client's situation)

Early Symptoms

- Restlessness
- Headache
- Visual disturbances
- Confusion or change in behavior
- Tachypnea
- Tachycardia
- Hypertension
- Dyspnea
- Anxious face

Advanced Symptoms

- Hypotension
- Bradycardia
- Metabolic acidosis (production of lactic acid)
- Cyanosis

Chronic Hypoxia

- Polycythemia
- Clubbing of fingers and toes
- Peripheral edema
- Right-sided heart failure
- Chronic Po_2 less than 55 mmHg; O_2 saturation less than 87%
- Elevated PCO_2 (respiratory acidosis)

Using Nasal Cannula

Equipment

- Oxygen source
- Oxygen flow meter
- Disposable humidifier if ordered (flow rate over 4 L/min or per agency policy)
- Nasal cannula and tubing

Preparation

1. Check physician's order for oxygen prescription (flow rate).
2. Gather equipment.
3. Insert oxygen flow meter into wall outlet.
4. Connect cannula tubing to flow meter.

5. Place disposable humidifier unit between flow meter and cannula tubing if humidification is ordered.
6. Perform hand hygiene.

Procedure

1. Explain purpose and procedure of oxygen use to client.
2. Place nasal prongs of cannula into client's nares.
3. Fit cannula tubing around client's ears and adjust tubing slide under client's chin.
4. Adjust flow of oxygen. Should be limited to 6 L/min or less, FiO_2 : 24%–44%, flow: 1–6 L. ► **Rationale:** Since atmospheric air mixes with prescribed oxygen

concentration as client inhales, the FiO_2 varies depending on the flow and nature of client's breathing. Deep breathing dilutes rather than enhances the FiO_2 because more room air is inhaled.

NOTE: Oxygen therapy is not corrective for hypoxia caused by anemia, abnormal hemoglobin, or vascular insufficiency.

5. Monitor vital signs and check client's condition regularly.
6. Provide nares care every 4 hr—use ONLY water-soluble products and avoid petroleum products. ► **Rationale:** Petroleum products are combustible, not absorbed by the body, and difficult to clear from the mucosa.
7. Monitor for pressure around ears and pad cannula tubing for comfort if indicated.

Clinical Alert

Humidification of low-flow oxygen through nasal cannulae is not considered essential and is contraindicated because it supports bacterial growth.

▲ Oxygen administration by nasal cannula.

Using an Oxygen Face Mask

Equipment

- Oxygen mask
- Four types of masks:
 - Simple face mask
 - Partial rebreather mask with reservoir bag
 - Nonrebreather mask with reservoir bag
 - Venturi mask used to specifically control oxygen concentration
- Oxygen source
- Oxygen flowmeter
- Disposable humidifier (if indicated)

Preparation

1. Check physician's orders for oxygen.
2. Gather equipment.
3. Perform hand hygiene.

▲ Simple face mask delivers moderately high flow of oxygen.

Procedure

1. Explain procedure and rationale for administration of oxygen to client.
2. Check size of face mask to make sure it fits client.
3. Turn on oxygen flow to liters prescribed. If reservoir bag is attached, partially inflate it with oxygen.
4. Place client in semi- or high-Fowler's position.
5. Fit mask to client's face from nose downward during expiration. If reservoir bag is attached, oxygen flow must be at a level to prevent bag from collapsing.
 - **Rationale:** A tight fit prevents oxygen from escaping around eyes or nose.

▲ Oxygen face tent delivers unpredictable oxygen flow with high humidity.

▲ Left: Partial rebreather mask provides higher FI_{O_2} than a simple mask, but is seldom used. Right: Nonrebreather mask provides highest FI_{O_2} .

▲ Venturi mask with oxygen percent control pieces.

6. Place elastic band around client's head.
7. Stay with client until client feels at ease with mask.
 - ▶ **Rationale:** Clients may be afraid of suffocating.
8. Assess client's condition by checking vital signs and oxygenation status.
9. Change mask and tubing according to agency policy and provide skin care to face.
10. Check equipment frequently. If humidifier is attached, check water level, dispose, and change PRN.

TABLE 30-1 Oxygen Delivery Devices (FI_{O_2} Numbers Are Approximate)

Nasal Cannula

This equipment is easily tolerated by most clients. It is also simpler than a mask. The fraction of inspired oxygen (FI_{O_2}) varies depending on the oxygen liter flow and the rate and depth of client breathing.

FI_{O_2} :	24%–38%	Flow:	1–2 L
FI_{O_2} :	30%–35%	Flow:	3–4 L
FI_{O_2} :	38%–44%	Flow:	5–6 L

Simple Face Mask

This equipment requires fairly high oxygen flow to prevent rebreathing of carbon dioxide. About 75% of the inspired volume is room air drawn in through side holes in the mask. Accurate FI_{O_2} is difficult to estimate.

FI_{O_2}	35%–65%	Flow:	8–12 L
------------	---------	-------	--------

Mask With Reservoir Bag

The reservoir allows higher FI_{O_2} to be delivered. At flows of less than 6 L/min the risk of rebreathing carbon dioxide increases. Two types are available:

Partial rebreather mask: No inspiratory valve so that the beginning portion of exhaled air returns to the bag and mixes with the inspired air. Ports are present so that most expired air escapes. The reservoir bag remains one-third to one-half inflated.

FI_{O_2}	40%–60%	Flow:	6–10 L
------------	---------	-------	--------

Nonrebreather: Valve closes during expiration so that exhaled air does not enter reservoir and is not rebreathed. Valves on mask side ports allow exhalation but close on inspiration to prevent inhalation of room air.

FI_{O_2}	60%–100%	Flow:	6–15 L
------------	----------	-------	--------

Venturi Mask

This system utilizes different-sized adapters to deliver a fixed or predicted FI_{O_2} . The FI_{O_2} is dependent on liter flow and/or entrainment port size. It is used effectively on clients with COPD when accurate FI_{O_2} is necessary. Carbon dioxide buildup is kept at a minimum. Humidifiers usually are not used. FI_{O_2} is dependent on liter flow and/or entrainment port size.

FI_{O_2}	24%–50%
------------	---------

Face Tent

This soft aerosol mask fits loosely around the face and neck. It is an alternative to an aerosol mask for clients who feel claustrophobic, but it is sometimes difficult to keep in place. It is convenient for providing humidification and oxygenation; however, oxygen concentration cannot be controlled.

FI_{O_2} :	28%–100%	Flow:	8–12 L
--------------	----------	-------	--------

TABLE 30-1 Oxygen Delivery Devices (FIO₂ Numbers Are Approximate) (Continued)**Oxygen Hood**

This disposable vinyl box fits over a child's head to provide warm humidified oxygen at a controlled temperature.

FIO ₂ :	28%–40%	Flow:	5–8 L
FIO ₂ :	40%–85%	Flow:	8–12 L

Less than 5 L flow may lead to carbon dioxide narcosis.

Oxygen Tent

This canopy encloses the child and is used to provide oxygen, humidification, and/or a cool environment to control temperature.

FIO ₂ :	Up to 50%	Flow:	10–15 L
--------------------	-----------	-------	---------

Using an Oxygen Hood

Equipment

- Disposable oxygen hood
- Oxygen source
- Oxygen analyzer
- Flexible oxygen tubing

Procedure

1. Check physician orders for oxygen level.
2. Perform hand hygiene.
3. Place hood around child's head and/or upper body and attach tubing to oxygen supply.
4. Close ports and lid, but do not obstruct neck opening.
 - ▶ **Rationale:** Obstructing neck opening can lead to carbon dioxide accumulation.
5. Infants are cared for through portholes or lid.
 - ▶ **Rationale:** This prevents excessive oxygen leakage.
6. Maintain oxygen levels at 40%–50%, and check for moisture that accumulates inside hood.
7. Observe usual oxygen administration precautions.

New Trends Hyperbaric Oxygen Therapy (HBOT)

Intermittent HBOT supports healing and alleviates symptoms in a number of acute and chronic health problems where blood flow and tissue oxygenation are reduced. This modality:

- Increases oxygen concentration in body tissues, even those with inadequate blood flow
- Reduces local tissue edema
- Stimulates growth of new blood vessels
- Causes rebound vasodilation after therapy
- Stimulates the body's immune response, production of antioxidants, and free radical scavengers
- Enhances WBC activity and potentiates effects of antibiotics

HBOT is used intermittently to deliver 100% oxygen at greater than normal atmospheric pressure (1 atmosphere absolute). The client reclines on a cot in a transparent cylinder ("chamber") with room air and breathes 100% O₂ through a hood or mask while pressure in the chamber is increased 1.5 to 2 times atmospheric pressure. Treatments usually last 1 hr, during which the client can watch TV, read, sleep, or converse

▲ Delivery of 100% oxygen at greater than atmospheric pressure is used for a number of acute and chronic health problems where blood flow and tissue oxygenation are reduced. (Courtesy: Sechrist Industries, Inc.)

with others outside of the chamber. At completion of treatment the client is gradually decompressed to normal atmospheric pressure. Studies regarding the usefulness of HBOT are ongoing.

DOCUMENTATION for Oxygen Administration

- Type of equipment used for oxygen administration, liter flow, F_{IO_2}
- Arterial PO_2 and SaO_2 or pulse oximetry results
- Vital signs
- Client's tolerance of device
- Client and family teaching and indication of understanding

Legal Considerations

Gordon v. Presbyterian Hospital: In this case a patient was being received for emergency surgery. Available oxygen tanks were empty in the holding area, so the nurse obtained a tank from one of the surgical suites. The room was dark, color of the tank was not appreciated, and the patient received CO_2 (gray tank) rather than O_2 (green tank). When discovered, a CODE BLUE was called. The patient remained comatose for several weeks before her death.

Manning v. Twin Falls Clinic & Hospital, Inc.: There was substantial evidence in medical malpractice action against a nurse to support award of punitive damages

where the plaintiff's expert witness concluded that the nurse's conduct in disconnecting supplemental oxygen to the client during the client's transfer to another room was extreme deviation from the standard of care. Evidence was also present that the nurse disconnected oxygen despite pleadings from family members present who claimed that the client could not survive without his oxygen and who requested that he be provided with a portable oxygen unit preparatory to the move. From this evidence, the jury could have found that the nurse's conduct was grossly negligent and that she acted with disregard for consequences that were likely to follow.

CRITICAL THINKING Application

Expected Outcomes

- Client breathes without distress.
- Oxygen administration does not have adverse effects.
- Breath sounds are normal in all lung fields.
- Client's respiratory rate remains within normal limits.
- SPO_2 values do not vary significantly.
- SPO_2 false alarms do not occur.
- Client remains comfortable with oxygen therapy delivery.

Unexpected Outcomes

Client reports having difficulty breathing (dyspnea).

Client shows these abnormal signs and symptoms: changes in blood pressure, tachycardia, tachypnea, abnormal color, restlessness, or altered sensorium.

Client develops atelectasis.

Alternative Actions

- Check SPO_2 and compare with previous findings.
- Encourage client to describe what he or she is experiencing.
- Place client in Fowler's position.
- Assist with all ADLs to conserve client's energy.
- Employ measures to alleviate pain or anxiety.
- Check ABGs for drop in blood pH (acidemia) or rise in PCO_2 (respiratory acidosis) and report if found. These conditions can occur if hypoxic drive is blunted by the administration of high oxygen concentration.
 - a. Check oxygen delivery setting.
 - b. Reduce oxygen concentration as ordered.
- Clients who chronically retain carbon dioxide may require controlled oxygen concentration delivery device (e.g., Venturi mask).
- Encourage deep breathing, range of motion, frequent position changes, and early ambulation if possible.
- Use sedatives or other respiratory depressants carefully.
- CPT may be ordered.
- Check breath sounds. (They are usually decreased with this condition and crackles are frequently heard at the end of inspiration in dependent lung areas and may clear after client coughs.)

Client develops tachypnea.

- Report change and check SpO_2 immediately, since inadequate flow rates may be causing the problem.
- Increase flow rate as ordered and monitor.
- Monitor vital signs and correlate with client findings as pulmonary embolus may be the cause.
- Check client's breathing pattern and breath sounds and report significant change.

Oxygen toxicity occurs.

- Toxicity occurs soon after initiation of oxygen use and is directly related to the FiO_2 .
- Monitor closely for nausea, restlessness, pallor, lethargy, weakness, and dyspnea.
- Validate that sensor and oximeter are from the same manufacturer.
- Do not exceed 40% oxygen concentration (FiO_2) unless using continuous monitoring of SpO_2 .

Oxygen saturation (SpO_2) findings are erratic.

- Check that sensor probes are aligned to prevent photodetector picking up light from sources other than sensor.
- Check that appropriate sensor site was selected for specific probes (e.g., finger site for finger sensor).

Pulse oximeter alarm sounds frequently.

- Do not disarm the system.
- Encourage client to immobilize sensor site. Movement scrambles signals from photodetector, interfering with readings.
- Obtain wrap sensor if thumb or toe is used.
- Place sensor on different site.
- Avoid placing sensor on hand of arm used for continuous blood pressure monitoring.

Client experiences discomfort with nasal prongs.

- Obtain smaller-gauge pediatric cannula.
- Obtain mustache pad or foam wrap for easing tube pressure behind ears.

Chapter 30

UNIT 4

Intubated Airways

Nursing Process Data

ASSESSMENT Data Base

- Assess client's level of consciousness.
- Determine whether gag/swallow reflex is present.
- Assess breath sounds in all lung fields, SPO₂, ABGs.
- Observe for shortness of breath, labored breathing, tachypnea, or tachycardia.
- Note presence of adventitious sounds.
- Note character of secretions.

PLANNING Objectives

- Oropharyngeal or nasopharyngeal intubation:
To provide patent airway
- Endotracheal intubation:
To provide patent airway
To provide route for mechanical ventilation
To facilitate removal of airway secretions
To improve gas exchange

IMPLEMENTATION Procedures

- Inserting an Oropharyngeal Airway 1191
- Inserting a Nasopharyngeal Airway (Nasal Trumpet)..... 1191
- Assisting With Endotracheal Intubation..... 1192
- Inflating a Tracheal Tube Cuff..... 1193
- Providing Care for Client With Endotracheal Tube..... 1194
- Extubating an Endotracheal Tube..... 1195

EVALUATION Expected Outcomes

- Patent airway is established.
- Intubation assessment parameters indicate correct placement.
- Accidental extubation does not occur.

- **Critical Thinking Application** 1195
- Expected Outcomes 1195
- Unexpected Outcomes 1196
- Alternative Actions 1196

nursing.pearsonhighered.com

Prepare for success with NCLEX[®]-style practice questions and Skill Checklists

Inserting an Oropharyngeal Airway

Equipment

- Oropharyngeal tube
- Tongue depressor
- Clean gloves
- Suction catheter
- Suction source

Procedure

1. Ensure that client is unresponsive and has NO gag reflex. ► **Rationale:** Conscious client may vomit and aspirate or develop laryngospasm during tube insertion.
2. Select appropriate size airway—length should be from corner of mouth to corner of ear tragus.
3. Perform hand hygiene; don gloves.
4. Gently open client's mouth with crossed finger technique, placing your thumb on client's lower teeth and index finger on the upper teeth and gently pushing them apart. You may need to use modified jaw thrust to insert tube.
5. Perform oral suctioning.
6. Hold tongue down with tongue depressor and advance airway to back of tongue OR advance airway upside down (curved upward) and, as airway passes uvula, rotate the airway 180°.
7. Check that concave curve fits over tongue. It should extend from the lips to the pharynx, displacing the tongue anteriorly. ► **Rationale:** Proper positioning helps prevent injury to lips, teeth, tongue, and posterior pharynx.
8. Tape top and bottom of airway in position. ► **Rationale:** Stabilization of the tube prevents injuries.
9. Position client on side to facilitate drainage.
10. Remove gloves, discard, and perform hand hygiene.
11. Observe position of airway and evaluate quality of client's spontaneous breathing.

▲ Oropharyngeal airway is initially inserted upside down (curved upward), then rotated 180°.

Inserting a Nasopharyngeal Airway (Nasal Trumpet)

Equipment

- Flexible nasopharyngeal airway
- Water-soluble lubricant
- Clean gloves

Procedure

1. Select appropriate size tube (length from tip of nose to earlobe and lumen slightly narrower than client's naris).
2. Perform hand hygiene; don gloves.
3. Lubricate entire length of tube.
4. Explain procedure to client.
5. Insert entire tube gently through naris, following anatomic line of nasal passage. If obstructed, try other naris.
6. Validate position by:
 - a. feeling exhaled air through tube opening

▲ Nasal trumpet protects airway from repeated trauma with upper airway (nasopharyngeal) suctioning.

- b. Inspecting for tube tip behind uvula.
7. Position client on side to facilitate drainage of secretions.
8. Remove gloves, discard, and perform hand hygiene.
9. Continue to monitor position of airway and client's response.
10. Suction upper airway PRN using clean technique.

Assisting With Endotracheal Intubation

Equipment

- “Crash cart” (contains most needed supplies)
- Laryngoscope with several blade sizes
- Styler to guide endotracheal tube (*ONLY for oral intubation*)
- Endotracheal tubes
- Water-soluble lubricant
- McGill forceps
- Suction source
- Oxygen source
- Bag–valve–mask
- Twill, adhesive tape, or Velcro holder
- 10-mL syringe for cuff inflation
- Stethoscope
- CO₂ detector (for airway placement validation)
- Oral airway or bite block
- Clean gloves and personal protective equipment including face shield
- Established pulse oximetry and cardiac monitoring if available
- Wrist restraints (if ordered by physician)
- Prepared sedative as ordered
- Labeled container for client's dentures

NOTE: Noninvasive positive pressure ventilation methods (CPAP, BiPAP) provide an appropriate alternative to intubation for many clients with ventilatory insufficiency.

Clinical Alert

The presence of an endotracheal tube bypasses defenses that normally protect the lower airways (filtration, humidification, and hydration of inspired air and epiglottal closure). In addition, mucociliary transport of secretions and trapped pathogens is impaired. These alterations place intubated clients at risk for aspiration pneumonia.

Preparation

1. Determine that client has *no protective airway reflexes*.
2. Bring crash cart to client's doorway.
3. Check that all necessary equipment is functioning (oxygen/suction source and delivery systems, laryngoscope batteries).
4. Inflate and deflate airway cuff to determine whether it is intact.

5. Perform hand hygiene and don gloves. Don personal protective equipment.
6. Insert styler into tube (only for oral intubation); ensure that stylus does not extend beyond tube tip.
7. Lubricate tube.
8. Administer medication as ordered.
9. Remove client's dentures/bridgework and place in labeled container.
10. Review Procedure for Bag–Valve–Mask Ventilation.

Procedure

1. Don clean gloves and personal protective gear.
2. Place client in flat supine position with pillow under shoulders to hyperextend neck and help open airway. Position so that mouth, pharynx, and trachea are aligned.
 - ▶ **Rationale:** Proper positioning facilitates intubation.
3. Restrain client's wrists only if necessary.
4. Premedicate client as ordered.
5. Preoxygenate client for several minutes, using bag–valve–mask. ▶ **Rationale:** To create an “oxygen reserve.”

Clinical Alert

While cuff pressures are typically maintained at 20–25 mmHg, an individual client's tracheal capillary pressure cannot be determined and excessive cuff pressure is the best predictor of tracheo-laryngeal injury.

Clinical Alert

Even if spontaneously breathing, the client should be preoxygenated with 100% O₂ for endotracheal tube placement. Ventilation must not be interrupted for over 30 seconds.

6. Using thumb and index finger, apply cricoid pressure during tube insertion. ▶ **Rationale:** This facilitates tracheal placement and protects against aspiration of gastric contents.
7. Maintain cricoid pressure while inflating cuff to “minimal leak” inflation by placing stethoscope at client's suprasternal notch and noting a slight hissing sound at peak of inspiration.
8. Attach bag–valve–mask, provide ventilation, and look for chest to rise. ▶ **Rationale:** If chest does not rise, esophageal intubation is likely.
9. Check tube placement using CO₂ detector. ▶ **Rationale:** Presence of CO₂ indicates tracheal intubation.

▲ CASS-ETT® has a lumen that opens above the tube cuff. Lumen (white tip) is connected to continuous suction to remove subglottic secretions that accumulate above the cuff in order to prevent pneumonia due to aspiration of these secretions.

10. Place stethoscope over epigastrium. ► **Rationale:** If gurgling is heard and abdominal distention noted, esophageal placement is likely.
11. Auscultate lung fields for bilateral breath sounds.
 - **Rationale:** This ensures that accidental right main stem intubation has not occurred.

Clinical Alert

Cricoid pressure may be used only if the client:

- Is nonresponsive
- Is not vomiting
- Does not have a cuffed tracheal tube in place

Clinical Alert

CDC guidelines recommend orotracheal over nasotracheal intubation to reduce the incidence of sinus infection.

12. Mark tube at level of client's front teeth and tape securely with twill or adhesive tape or Endotube stabilizer. ►
 - Rationale:** Securement prevents tube displacement.
13. Recheck tube placement with the previous measures (steps 9–11).

▲ Endotube stabilizer distributes equipment weight and pressure evenly on the client's face and facilitates easy periodic relocation of tube from side-to-side to prevent oral tissue trauma.

14. Place bite block or oral airway if ET tube has been positioned orally.
15. Attach O₂ source to ET tube.
16. Discard disposable equipment, remove protective gear and gloves, and perform hand hygiene.
17. Position client in position as ordered.
18. Obtain chest x-ray to confirm tracheal placement of ET tube.
19. Place call bell and writing material within client's reach (as indicated).
20. Reposition right, center, left, then repeat (using velcro or Endotube stabilizer.) ET tube every 4 hours.

Clinical Alert

Low-pressure tracheal tube cuffs provide adequate blood flow to trachea, thus decreasing potential of tracheal tissue necrosis. These cuffs do not need periodic deflation.

Inflating a Tracheal Tube Cuff

Equipment

- 10-mL syringe
- Suction equipment
- Stethoscope
- Clean gloves

NOTE: The tracheostomy tube with foam cuff (Binova) does not require injected air. Air enters the balloon when port is open.

Procedure

1. Don clean gloves.
2. Attach 10-mL syringe to distal end of inflatable cuff port, making sure seal is tight.

▲ Attach 10-mL syringe to inflate tube cuff.

3. Inflate cuff for a minimal leak or minimal occlusive volume detected by auscultating over the suprasternal notch for a hissing sound at peak of inspiration.
 - ▶ **Rationale:** This provides an adequate seal without risking tracheal pressure necrosis.
4. Ask client to speak—if voice is heard, inflation is inadequate for mechanical ventilation.
5. Connect ventilator or T-piece to tracheal tube opening if indicated.
6. Assess breath sounds every 2 hr. ▶ **Rationale:** Presence of bilateral breath sounds indicates proper tube position in trachea.

▲ Inflate endotracheal or tracheostomy tube cuff to minimal occlusive volume.

7. Monitor cuff pressure regularly. ▶ **Rationale:** This may detect inadvertent cuff overinflation and prevent potential necrosis of tracheal tissue. Pressure is usually maintained at 20 to 25 mmHg to prevent tracheal necrosis. However, an individual client's tracheal capillary pressure cannot be determined.

Clinical Alert

Tracheal tube cuff inflation is essential for mechanically ventilated clients. Without cuff inflation, delivered air diverts out through the nose and mouth, and lungs are not ventilated.

Providing Care for Client With Endotracheal Tube

Procedure

1. Monitor breath sounds every 4 hr. Breath sounds should be heard equally throughout lung fields bilaterally.
2. Check marked points on tube at insertion level.
 - ▶ **Rationale:** This determines whether tube has moved.
3. Inspect positioning and stabilization of tube.
 - ▶ **Rationale:** A change of position can obstruct airway or cause erosion and necrosis of tissues.
4. Inspect and clean mouth and nose. Observe for pressure areas or ulceration.
5. Reposition ET tube every 4 hours (right, center, left) noting tube depth each time.
6. Support client's head and tube when turning.
 - ▶ **Rationale:** This prevents tube from becoming dislodged or airway from becoming obstructed.
7. Place call bell within reach and provide alternative means of communication when cuffed tube is in place.
 - ▶ **Rationale:** No air passes over larynx, so client is not able to summon help or communicate.
8. Support client by spending extra time, using touch, and anticipating client's needs.
9. Ensure adequate hydration. ▶ **Rationale:** Artificial airways bypass the humidifying process of normal breathing.
10. Provide suction toothbrushing every 12 hr, oral swabbing every 2 hr, and oropharyngeal subglottal suctioning every 6 hr. ▶ **Rationale:** This reduces oropharyngeal bacteria and helps prevent pulmonary infection.

Clinical Alert

Even with appropriate cuff inflation, intubated clients receiving gastric/enteral tube feedings are at high risk for aspiration.

Extubating an Endotracheal Tube

Equipment

- Suction source
- Oral suction catheter (or Yankauer)
- Sterile suction catheter set
- Clean gloves
- Sterile gloves
- Personal protective equipment
- Oxygen source
- Postextubation oxygen delivery device
- Syringe for cuff deflation

Preparation

1. Assess client's readiness for extubation.
2. Obtain vital signs.
3. Explain procedure to client.
4. Prepare postextubation oxygen administration device.
5. Place client in Fowler's position.

Procedure

1. Perform hand hygiene and don clean gloves and personal protective equipment.
2. Perform oral or nasopharyngeal suctioning.

3. Have client take several slow deep breaths. ► **Rationale:** This hyperoxygenates client in preparation for extubation.
4. *Deflate* tube cuff using syringe.
5. *Untie* the endotracheal tube.
6. Remove gloves, perform hand hygiene, and don sterile gloves.
7. Connect sterile catheter to suction source.
8. Insert sterile suction catheter into airway until resistance is met, then retract slightly.
9. Leave suction catheter in place.
10. Have client take a deep breath. ► **Rationale:** This dilates the vocal cords and makes removal easier and less traumatic.
11. Apply suction while removing catheter and airway at the same time.
12. Immediately apply supplementary oxygen device.
13. Monitor client frequently at first, then regularly.
14. Dispose of equipment, remove gloves, protective gear, and perform hand hygiene.

Clinical Alert

Do not feed client orally immediately after extubation. Seek consult for a feeding trial for clients at risk for aspiration.

DOCUMENTATION for Intubation

- Clinical manifestations indicating need for intubation
- Specific reason for intubation
- Premedication administered
- Size and type of inserted endotracheal, nasopharyngeal, or oropharyngeal tube
- Minimal occlusive pressure for cuff inflation or measured mmHg pressure
- Preoxygenation and postoxygenation when suctioning
- Quantity and character of secretions
- Pre- and post-procedure vital signs
- Client's tolerance of procedure
- Settings of ventilator or other oxygen mode

CRITICAL THINKING Application

Expected Outcomes

- Patent airway is established.
- Intubation assessment parameters indicate correct placement.
- Accidental extubation does not occur.

Unexpected Outcomes

Naso/oropharyngeal airway cannot be placed.

Alternative Actions

- Change size of tube; change naris; do not force insertion.
- Hyperextend client's neck.
- Direct insertion of nasopharyngeal tube more medially.
- Insert oropharyngeal rather than nasopharyngeal airway.
- Use tongue depressor to facilitate insertion of oropharyngeal tube.
- Relubricate airway and attempt to reinsert.
- Call Rapid Response Team if indicated.

Laryngospasm occurs when endotracheal tube is inserted.

- Remove tube and wait a few minutes.
- If severe, administer sedation per physician order.
- Possibly prepare for immediate cricothyroidotomy or tracheotomy.

Tube placement is incorrect: air movement heard over epigastrium; bilateral breath sounds not heard; CO₂ indicator does not register.

- Withdraw tube and assist with reintubation.
- Verify tube placement with x-ray (tube tip should be between larynx and carina).
- Recheck CO₂ indicator for correct placement.
- Recheck for bilateral breath sounds and SpO₂ status.
- Ensure that mark is visible at insertion level for monitoring ETT placement.

Accidental extubation occurs.

- Immediately call a CODE or Rapid Response Team for airway replacement.
- Call for crash cart/emergency supplies.
- Immediately seek assist to provide bag–valve–mask ventilations.
- Assess marker on tube frequently to ensure proper placement.

Suctioning

Nursing Process Data

ASSESSMENT Data Base

- Assess client's need for suctioning.
- Observe vital signs for increases in pulse and respiration.
- Auscultate breath sounds and for presence of adventitious sounds.
- Observe respiratory status for tachypnea, shortness of breath, and restlessness.
- Observe for signs of hypoxia.

PLANNING Objectives

- To provide patent airway
- To remove secretions
- To improve ventilation
- To decrease breathing rate
- To increase tissue oxygenation

IMPLEMENTATION Procedures

- Suctioning With Multi-Use Catheter in Sleeve 1198
- Suctioning With Closed Suction System 1199

EVALUATION Expected Outcomes

- Secretions removed without complication.
- Tube-fed client does not aspirate feeding.

Critical Thinking Application 1201

- Expected Outcomes 1201
- Unexpected Outcomes 1201

Suctioning With Multi-Use Catheter in Sleeve

NOTE: For Suctioning Using Single-Use Catheter for Tracheostomy, see Unit 6.

Equipment

- Portable suction machine or wall suction unit with receptacle and tubing
- Appropriate length suction catheter in protective sleeve packet (with pop-up cup)
- Clean gloves
- Sterile saline/water
- Receptacle for used equipment
- Oxygen source and administration device (e.g., bag–valve device with tube adapter)
- Personal protective equipment—gown, goggles, mask if splash anticipated
- Stethoscope

Preparation

1. Check physician's orders.
2. Gather equipment.
3. Recruit an assistant for manual ventilation, if indicated.
4. Attach resuscitator bag to oxygen tubing, if indicated.
5. Perform hand hygiene.
6. Assess lung sounds and heart rate and rhythm.
7. Open saline flush solution bottle.
8. Set suction control regulator at 100–120 mmHg vacuum.
9. Don protective gown, mask, and goggles. ► **Rationale:** For self-protection if splash anticipated.

Procedure

1. Explain procedure and rationale to client regardless of client's level of consciousness.

▲ Connect resuscitator bag to hyperoxygenate before and after suctioning.

2. Place client in semi-Fowler's or Fowler's position.
3. Turn on suction.
4. Remove cap from saline bottle.
5. Open catheter kit. Pour sterile saline/water flush solution into pop-up cup.
6. Don gloves.
7. Administer 100% oxygen (oxygen flowmeter to maximum "flush") for 1–2 minutes. Use resuscitator bag with tracheal tube adapter to hyperoxygenate client. ► **Rationale:** Suction removes residual lung volume, resulting in hypoxemia and potential cardiac arrest. Hyperoxygenation prevents these complications.
8. Hold catheter in protective covering and attach end to suction tubing.
9. Retract sleeve enough to lubricate sterile catheter tip by dipping it into cup with sterile saline/water.
10. Advance catheter into client's artificial airway approximately 28 cm (11 in.), or 1 cm beyond tip of ET tube or trach tube, while retracting protective sleeve before applying suction. ► **Rationale:** Suctioning during insertion deprives client of oxygen and inhibits catheter advancement. Deep suctioning traumatizes tissue.
11. Apply suction and withdraw catheter using a rotating motion as the catheter is retracted back into protective sleeve.
12. Suction intermittently by placing and releasing thumb over catheter suction port. ► **Rationale:** Intermittent versus continuous application of suction may help to reduce airway injury.
13. Limit suction to no more than 10 seconds. ► **Rationale:** This prevents hypoxemic complications induced by suctioning.
14. Reattach oxygen delivery device to artificial airway and have client take several deep breaths, or hyperoxygenate client's lungs with resuscitator bag for 30 seconds.
15. Flush suction catheter and tubing with sterile saline/water and retract back into protective sleeve.

▲ Hold catheter in protective covering and attach to suction tubing.

16. Catheter remains in sleeve and attached to suction tubing. ► **Rationale:** To allow PRN use. Reuse same catheter (according to agency policy).
17. Replace catheter in sleeve packet at time interval according to agency policy (e.g., 24 hr).

NOTE: A separate catheter must be used for pharyngeal suctioning.

18. Perform hand hygiene.
19. Assess lung sounds and heart rate and rhythm for changes. ► **Rationale:** Suctioning usually causes tachycardia, but hypoxemia and vagal response may cause serious bradycardia/cardiac arrest.

20. Don clean gloves to empty suction receptacle PRN or at end of every shift, noting character of secretions.
21. Ensure call bell is within client's reach.

EVIDENCE-BASED PRACTICE

Instillation of normal saline should not be performed with endotracheal suctioning. No studies have found this practice to be beneficial; it places patients at risk for hospital-acquired pneumonia. Saline does not liquefy or mobilize secretions; it acts as a vehicle to wash bacteria that normally cling to the inner aspects of the artificial airway into the lung. Instillation of saline also adversely affects arterial oxygenation.

Source: Halm, M. A., & Krisko-Hagel, K. (2008). Instilling normal saline with suctioning: beneficial technique or potentially harmful sacred cow? *American Journal of Critical Care, 17*(5), 469–472.

EVIDENCE-BASED PRACTICE

Nasotracheal suctioning is a blind procedure that should not be used except in an emergency/resuscitation situation. It is probable that the catheter does not enter the airway and that nasopharyngeal suctioning is actually performed.

Repeatedly injuring an unprotected airway must be avoided. The presence of an artificial airway reduces the risk of mechanical trauma.

NTS has many contraindications and complications in addition to those for any type of suctioning (hypoxemia, arrhythmia, changes in blood pressure), including sinusitis, laceration of nasal turbinates, perforation of the pharynx, uvular edema, and gagging/vomiting. Passing a catheter through the nose into the lower airway may lead to bacterial (*Methicillin-resistant Staphylococcus aureus*) colonization, resulting in healthcare-associated pneumonia.

Source: (2004). Nasotracheal suctioning: 2004 revision & update. *Respiratory Care, 49*(9), 1080–1082.

Suctioning With Closed Suction System

Equipment

- In-line closed system (ET or tracheostomy connected) suction unit with catheter enclosed by plastic sleeve
- 10 mL of normal saline in unit dose vial
- Suction source
- Connecting tubing

Oxygen source and side-arm connector (e.g., bag–valve device or ventilator)

Clean gloves

NOTE: In-line closed system suctioning allows rapid suctioning for intubated clients and does not interrupt ventilator/client interface.

Procedure

1. Explain procedure and rationale to client regardless of client's level of consciousness.
2. Perform hand hygiene and don gloves.
3. Place client in semi-Fowler's or Fowler's position.
4. Turn on suction source.
5. Connect oxygen source to side arm of tube connector.
6. Hyperoxygenate client with 100% oxygen, using manual bag or mechanical ventilator (100% oxygen source with several manual sighs, if indicated.)
7. Open access valve and advance catheter within plastic sleeve into client's artificial airway using your dominant hand. ► **Rationale:** Sterility is maintained because catheter is enclosed by plastic cover and slides within it.
8. With nondominant hand, activate suction valve. Intermittently apply suction (for no more than 5 to 10 seconds) while rotating and withdrawing catheter *completely* back into plastic sheath. ► **Rationale:** If not totally out of the airway, the catheter impairs client ventilation.

▲ Mechanical ventilator provides 100% oxygen for hyperoxygenation.

9. Repeat steps 4–6 as necessary to clear secretions; allow time between suctioning for hyperoxygenation.
 - ▶ **Rationale:** Repeated suctioning without hyperoxygenation causes complications such as hypoxemia and cardiac dysrhythmias.
10. Attach saline vial to catheter irrigation port; inject saline while applying suction to rinse catheter and tubing, then close irrigation port and suction valve.
 - ▶ **Rationale:** Rinsing prevents catheter occlusion by dried secretions.
11. Remove syringe, release suction, and lock mechanism. ▶ **Rationale:** Locking catheter prevents inadvertent catheter advancement and occlusion of client's airway.
12. Remove gloves and perform hand hygiene.
13. Ensure that call bell is within client's reach.

▲ Intubated client with in-line closed suction catheter being advanced.

▲ Apply suction while instilling saline to flush catheter and tubing.

Clinical Alert

Monitor client closely and suction PRN, as coughed secretions may accumulate at the suction catheter/client's airway interface and obstruct airflow to client's lungs.

▲ Note black indicator to ensure that catheter is completely withdrawn.

▲ Lock access valve when suctioning is complete.

DOCUMENTATION for Suctioning

- Frequency of suctioning
- Amount and character of secretions
- Pre- and postsuctioning hyperoxygenation
- Breath sounds, respiratory rate, heart rate and rhythm, and SPO₂
- Client's tolerance of procedure
- Reestablishment of oxygen therapy and L/minute

CRITICAL THINKING Application

Expected Outcomes

- Secretions are removed without complication.
- Tube-fed client does not aspirate feeding.

Unexpected Outcomes

Hypoxemia and tachycardia or bradycardia occur with suctioning.

Excessive secretions necessitate frequent suctioning.

Aspiration is suspected in enterally tube-fed intubated client.

Alternative Actions

- Suction only as needed.
- Preoxygenate before and postoxygenate after suctioning, seeking assistance if necessary.
- Limit suctioning time to no more than 10 seconds.
- Ensure that catheter diameter is no larger than half the inner diameter of the airway it enters.
- Suction more frequently but administer 100% oxygen before and after suctioning.
- Establish in-line catheter in sleeve, check frequently and suction secretions PRN.
- Allow rest period before suctioning again.
- Turn client regularly to mobilize secretions.
- Notify physician for CPT or other therapy.
- Maintain adequate hydration.
- Check suctioned secretions for presence of glucose. (Secretions should not contain blood for accurate determination.)
- Recommend use of continuous aspiration of subglottic secretions ET tube.
- Maintain 30°–45° elevation of HOB at all times if feeding is continuous.
- Monitor gastric residuals regularly.
- Advocate small-bore enteral versus gastric tube feeding.

Chapter 30

UNIT 6

Tracheostomy Care

Nursing Process Data

ASSESSMENT Data Base

- Note presence of dried or moist secretions surrounding cannula or on tracheal dressing.
- Note excessive coughing or expectoration of secretions.
- Assess whether routine tracheal care is adequate for this client.
- Assess respiratory status: breath sounds, respiratory rate, use of accessory muscles for breathing.
- Observe for signs of respiratory distress while tracheal tube is capped: labored breathing, anxious face, flaring of nares, tachypnea, tachycardia.
- Monitor pulse oximetry (SpO₂).
- Auscultate for minimal occlusive cuff inflation pressure.

PLANNING Objectives

- To ensure a patent airway
- To suction secretions more easily
- To improve ventilation
- To prevent infection
- To prevent aspiration while feeding

IMPLEMENTATION Procedures

- Assisting With Tracheostomy 1203
- Suctioning Using Single-Use Catheter for Tracheostomy 1205
- Cleaning the Inner Cannula and Ostomy 1207
- Changing Tracheostomy Tube Ties 1209
- Capping With a Passy–Muir Speaking Valve 1210

EVALUATION Expected Outcomes

- Tracheostomy tube remains stable.
- Tracheostomy tube provides a patent airway.
- Client is able to communicate with speaking valve placement.

Critical Thinking Application 1212

- Expected Outcomes 1212
- Unexpected Outcomes 1212
- Alternative Actions 1212

Prepare for success with NCLEX[®]-style practice questions and Skill Checklists

Assisting With Tracheostomy

Equipment

- Sterile tracheostomy tray
- Antimicrobial solution
- Lidocaine for local anesthesia
- Two sterile tracheal tubes
- Sterile gloves
- Clean gloves
- Personal protective equipment
- Suction equipment
- Oxygen source
- Manual resuscitator bag with adapter
- Mechanical ventilator if indicated
- Sterile normal saline
- Sterile preslit 4 × 4 dressing
- Twill (or commercial holder)
- Prescribed premedication
- Stethoscope
- Soft wrist restraints (if indicated)

Preparation

1. Explain procedure and rationale to client.
2. If not an emergency situation, obtain permission from client or other legally responsible individual before tracheostomy.
3. Perform hand hygiene.
4. Don personal protective equipment.
5. Assemble all necessary equipment.
6. Set up tracheostomy tray where sterile field can be maintained; open tray when physician is ready.

Procedure

1. Explain procedure as it is being done.
2. Medicate or restrain client, if necessary, with soft wrist restraints. ► **Rationale:** Interference during insertion can result in injury to client.

▲ Attach 10-mL syringe to distal end of inflatable cuff.

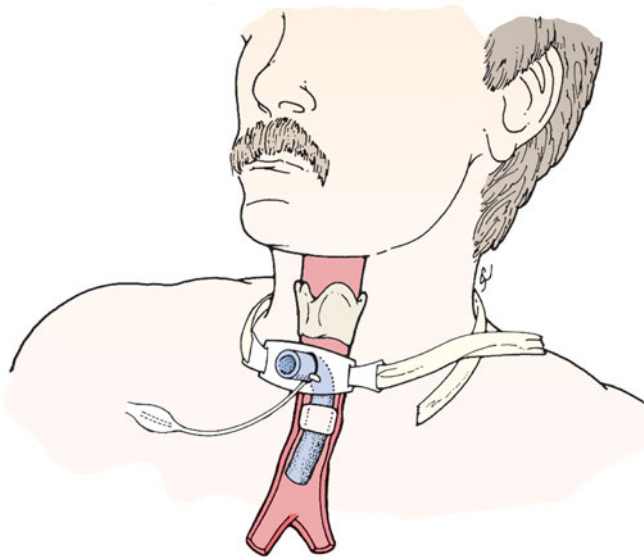

▲ Attach 10-mL syringe to distal end of inflatable cuff. (Tracheostomy tube shown.)

▲ Inflate cuff for minimal leak using minimal occlusive pressure. (Tracheostomy tube shown.)

3. Open sterile gloves for physician. Don clean gloves.
4. Assist physician by pouring antimicrobial solution into sterile containers on tray. To maintain sterile technique, lidocaine is usually held by the nurse while the physician draws it out of vial.
5. Have suction and oxygen administration equipment ready when trach tube is inserted. (Use suction catheter with diameter half the inner diameter of the tracheostomy tube.) ▶ **Rationale:** Introduction of a foreign body increases secretion production. In addition, tube presence hinders effective coughing.
6. Inflate tube cuff. (See *Inflating a Tracheal Tube Cuff* on page 1193.)

▲ Anatomic placement of a tracheostomy tube.

▲ Tracheal flex-tube of various lengths has adjustable neck flange and flexible wire reinforced shaft that can be adjusted to accommodate diverse neck shapes.

7. Hyperoxygenate client, then don sterile gloves and, *using sterile technique*, suction when tube is in place. Hyperoxygenate after suctioning.
8. Attach tracheostomy tube with adapter to mechanical ventilator if indicated.

▲ Bivona Fome-Cuf® tube with obturator. Tube cuff expands passively and is evacuated with special device to collapse the Fome-Cuf®.

▲ Fome-Cuf® is actively deflated with special syringe device.

Preventing Infection

- Maintain sterile technique during suctioning.
- Maintain good hand hygiene.
- Change gloves when providing respiratory care to prevent cross-contamination from another part of the client's body.
- Administer oral care routinely per protocol.
- Avoid instillation of saline into airways.
- Change ventilatory equipment only when visibly soiled or malfunctioning.
- Do not allow condensation in circuit to drain toward client.

Clinical Alert

Suction client's airway PRN. Secretions are usually more copious after the irritation of intubation.

9. Cleanse tracheostomy site with sterile normal saline, secure tube with twill (or commercial holder), and dress site with presplit 4 × 4.
10. Position client for comfort. Semi-Fowler's position makes breathing easier.
11. Tape trach tube obturator to head of bed and place second sterile tracheostomy tube at client's bedside.
 - ▶ **Rationale:** If tube inadvertently decannulates, a replacement will be available.
12. Discard used disposable equipment and remove gloves. Perform hand hygiene.
13. Place *call bell* where client can reach it and provide a means of *communication* (e.g., paper and pencil).
 - ▶ **Rationale:** Tracheostomy tube bypasses the upper airway and prevents ability to vocalize.
14. Perform tracheostomy care every 8 hr and PRN.
15. Provide oral care and oropharyngeal suctioning per protocol and PRN.

Suctioning Using Single-Use Catheter for Tracheostomy

Equipment

- Portable suction machine or wall suction unit with receptacle and tubing
- Oral suction catheter (e.g., Yankauer)
- Suction catheter set with: suction catheter, sterile gloves, container (or pop-open cup) for sterile saline
- Select catheter of appropriate length—6–8 in. (15–20 cm)
- Sterile saline or sterile water (mark time and date bottle is opened and discard in 24 hr)
- Receptacle for used equipment
- Oxygen source and administration device (e.g., bag–valve device with tracheal tube adapter)
- Personal protective equipment—gown, goggles, mask if splash anticipated
- Stethoscope

Preparation

1. Check physician's orders and client care plan.
2. Gather equipment.
3. Recruit an assistant for manual ventilation if indicated.
4. Attach resuscitator bag to oxygen tubing, if indicated.
5. Perform hand hygiene.
6. Assess lung sounds and heart rate and rhythm.
7. Set suction control regulator at 100–120 mmHg vacuum.
8. Don protective gown, mask, and goggles. ▶ **Rationale:** For self-protection if splash anticipated.

NOTE: This skill is more safely performed with an assistant who manages the resuscitator bag for hyperoxygenation while the nurse performs suctioning.

Clinical Alert

Suction catheter diameter should be no larger than one-half the inner diameter of the artificial airway. To determine catheter diameter size, multiply the artificial airway's diameter times 2 (e.g., for 8-mm tube, use a 16-French suction catheter).

Indications for Suctioning

- Ineffective cough
- Client with depressed level of consciousness
- Thick, tenacious mucus
- Impaired pulmonary function

Procedure

1. Explain procedure and rationale to client regardless of client's level of consciousness.
2. Place client in semi-Fowler's or Fowler's position.
3. Turn on suction (100–120 mmHg vacuum).
4. Remove cap from saline bottle.
5. Open catheter kit using wrapper as sterile field.
6. Carefully open container (pop open cup) and fill with sterile saline/water.
7. Administer 100% oxygen (oxygen flowmeter to maximum “flush”) for 1 minute, or have assistant use resuscitator bag with adapter to hyperoxygenate client. ► **Rationale:** Suction removes oxygen, resulting in hypoxemia and potential cardiac arrest. Hyperoxygenation prevents these complications.
8. Don sterile gloves. *Dominant* hand will remain sterile, *nondominant* hand becomes “clean.”
9. Holding catheter connecting end with *dominant* (sterile) hand, attach to suction tubing held with *nondominant* hand (nondominant hand is no longer sterile at this point).

▲ Turn wall suction or other source to 100–120 mmHg vacuum.

Clinical Alert

Hyperoxygenate the client before and after each time the airway is entered for suctioning, and wait 1 minute before suctioning again to prevent severe hypoxemia.

10. Lubricate sterile catheter tip by dipping it into cup with sterile normal saline/water.
11. Using *dominant* (sterile gloved) hand, insert catheter into tracheostomy without applying suction. ► **Rationale:** Suctioning during insertion deprives client of oxygen and inhibits catheter advancement.
12. Advance catheter quickly 1–2 cm beyond end of trach tube until resistance is felt, even if client coughs. ► **Rationale:** Deep suctioning traumatizes tracheal mucosa.
13. Suction intermittently by placing and releasing *nondominant* thumb over catheter suction port while withdrawing catheter using a rotating motion. ► **Rationale:** Intermittent versus continuous application of suction may help to reduce airway injury.
14. Limit suction to no more than 10 seconds. ► **Rationale:** This prevents hypoxemic complications induced by suctioning.
15. Reattach oxygen delivery device and have client take several deep breaths, or hyperoxygenate client's lungs with resuscitator bag.
16. Flush suction catheter and tubing with sterile saline/water.
17. Use same catheter (according to agency policy) and repeat suctioning procedure one time, if necessary. Allow 1 minute between suctioning attempts for hyperoxygenation.
18. After lower airway suctioning, use the same catheter to suction client's oropharyngeal secretions. ► **Rationale:** Lower airway is sterile; upper airway is not.
19. Coil suction catheter around hand and deglove over it to discard.
20. Discard gloves and catheter and remove personal protective equipment.
21. Turn off suction source.
22. Assess lung sounds and heart rate and rhythm for changes. ► **Rationale:** Suctioning usually causes tachycardia, but hypoxemia and vagal response may cause serious bradycardia/cardiac arrest.
23. Perform hand hygiene.
24. Empty suction receptacle PRN or at end of every shift, noting character of secretions.
25. Ensure call bell is within client's reach.

▲ Connect resuscitator bag to hyperoxygenate before and after suctioning.

▲ Hold sterile catheter with dominant (sterile) hand and connect suction tubing to catheter.

▲ Guide catheter into tracheostomy tube using sterile hand.

▲ Rinse catheter and connecting tubing to clear.

▲ Coil catheter around fingers and pull glove over it for disposal.

Cleaning the Inner Cannula and Ostomy

Equipment

NOTE: Most agencies use disposable inner cannulas that eliminate the need for cleaning.

Tracheal cleaning tray (includes two sterile basins, pipe cleaners, 4 × 4 gauze pad)

Sterile gloves

Suction equipment

Complete tracheal tube set for emergency use

Disposable inner cannula of same size

Sterile normal saline

Sterile nonraveling presplit dressings

Clean tracheal ties or commercial tube holder

Preparation

1. Check physician's orders.
2. Assemble equipment.
3. Make sure suction equipment and additional tracheal tubes are available. Suction trach tube before cleaning if indicated.
4. Perform hand hygiene.

Procedure

1. Explain procedure and rationale to client.
2. Open trach tray and put on one sterile glove.
3. With gloved hand, separate basins; with ungloved hand, pour saline into basin.

4. Don second sterile glove. Secure outer cannula neck plate with index finger and thumb. Unlock inner cannula by turning left about 90°.
5. Gently pull the inner cannula slightly upward and out toward you.
6. Soak nondisposable cannula in sterile basin with saline to remove dried secretions.
7. Cleanse the lumen and outer surface of the cannula with pipe cleaners moistened with saline.
 ▶ **Rationale:** To remove dried secretions.
8. Rinse cannula thoroughly with saline.
9. Place clean tube on sterile 4 × 4 gauze pad and dry tube thoroughly.
10. Replace inner cannula carefully, stabilizing outer flange of the cannula, with your other hand.
11. Lock the inner cannula by turning the lock to the right so that it is in an upright position.

▲ Gently pull inner cannula upward and outward to remove.

▲ Disposable inner cannula eliminates need for cannula cleaning.

▲ Clean around tracheostomy site and outer cannula.

▲ Inner cannula is removed for cleaning. Outer cannula is not.

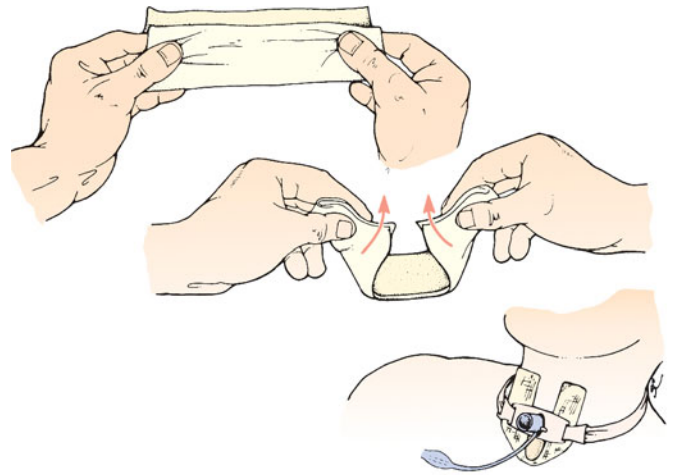

▲ Apply precut nonraveling dressing around tracheostomy.

▲ A precut nonraveling sponge is used for the trach dressing to prevent fibers from entering trach site.

12. Cleanse around tracheostomy site with applicator soaked in normal saline.
13. Cleanse outer cannula with separate applicator.
14. Apply precut, nonraveling trach dressing around insertion site (flaps pointing up), and change tracheal ties if needed. ► **Rationale:** Nonraveling dressing prevents fibers from entering trach tube.
15. Discard soiled dressings, tapes, cleaning equipment, and gloves.
16. Perform hand hygiene.
17. Ensure call bell is within client's reach.

▲ Folded 4 × 4 trach dressing for use if presplit dressing is not available.

Clinical Alert

An obturator is kept at the bedside for emergency use. If the tracheostomy tube is inadvertently dislodged, it can be reinserted immediately using the obturator.

Changing Tracheostomy Tube Ties

Equipment

- Scissors
- Forceps
- Twill tape or commercial tracheostomy tube holder.

Preparation

1. Seek assistance from another person. ► **Rationale:** It is safer to have someone hold the trach tube in place when changing ties.
2. Explain procedure to client.
3. Perform hand hygiene.
4. Gather equipment.
5. Place client in semi- to high-Fowler's position.

Procedure

For Twill Tape Ties

1. Cut trach ties length you desire, if not precut.
2. Fold ends of the trach ties over 1½ in., and cut a slit in the piece starting at the folded edge.
3. If available, have assistant hold the trach tube in place. Cut the old trach ties, remove, and discard. ► **Rationale:**

Clinical Alert

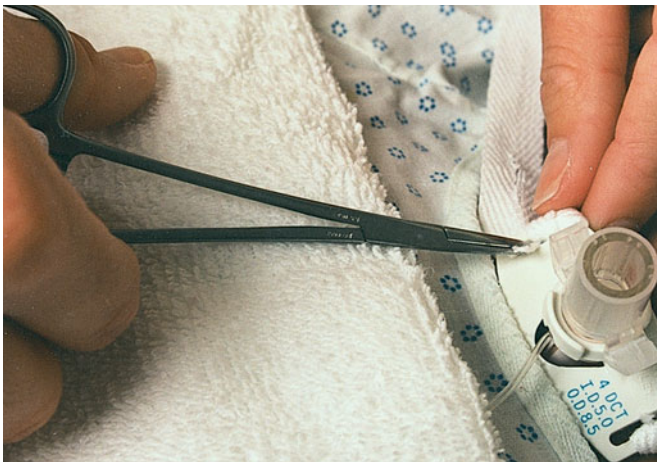

Some agencies recommend that tracheostomy tube and ties not be changed for the first 72 hr because of risk for stoma closure.

Securing tube helps prevent accidental extubation if client coughs.

4. Pass the slit end of the ties through the flange loop of the trach tube about 2–3 in. (you may use Kelly forceps to grab tie). ► **Rationale:** Leave the old trach tie in place if you are changing the ties without assistance. This prevents accidental dislodging of the trach tube.
5. Thread the other end of the tie all the way through the slit. Pull it firmly in place. ► **Rationale:** This action anchors the tie around the flange loop.
6. Repeat steps 4 and 5 on other flange loop.
7. Bring ties around client's neck and tie in a square knot to one side of neck, leaving one finger-breadth slack under tie. ► **Rationale:** Slack prevents pressure on the neck and jugular vein.
8. Cut off soiled trach ties if not already done and discard.
9. Position client for comfort.
10. Perform hand hygiene.

Alternate Method

1. Using a long piece of twill, pull end of tape through flange slit.
2. Double tape around back of neck.
3. Thread one end through other flange slit and tie to other end.
4. Apply new tape before old one is cut off and removed (doesn't require an assistant).

▲ Use forceps to thread tape through tracheostomy neck plate flanges.

▲ Thread other end of tie through slit and pull in place.

▲ Allow one finger-breadth slack under trach ties to prevent pressure on neck and jugular vein. Note: Velcro is frequently used for track ties in place of twill tape.

▲ (a) Use a long piece of twill. Pull end through flange slit and double tape around back of neck. (b) Thread one end through other flange slit and tie to other end of twill in square knot.

Capping With a Passey–Muir Speaking Valve

Equipment

- Passey–Muir speaking valve and storage container
- Fenestrated uncuffed tracheostomy tube (preferred)
- Suction source
- Two suction catheters
- Clean gloves
- 10 mL syringe

NOTE: A fenestrated uncuffed tracheostomy tube has openings that allow the client's exhaled air to flow through the upper airway as well as the tracheostomy opening. When the outer cannula is capped with a one-way valve, exhaled air flows over the vocal cords for speech production.

Preparation

1. Check physician's orders and client care plan.
2. Determine that client has been screened with trial for candidacy by a speech pathologist and respiratory care practitioner.
3. Determine type of tracheostomy tube present.
 - ▶ **Rationale:** A fenestrated uncuffed tube is preferred. The valve is *not* used with endotracheal tube.
4. Review client's vital signs, SpO₂, breath sounds, work of breathing.
5. Perform hand hygiene.
6. Gather equipment.
7. Explain procedure to client.
8. Place client in Fowler's position. ▶ **Rationale:** This assists with lung expansion and helps to maintain a patent airway.
9. Don clean gloves.

Clinical Alert

The speaking valve should be removed during sleep.

▲ Tracheostomy tube is capped with a one-way valve to allow client to speak.

EVIDENCE-BASED PRACTICE

Use of a One-Way Speaking Valve

Subglottal air pressure is lost when a tracheostomy tube is in place. This reduction in air pressure is thought to be the primary mechanism responsible for aspiration in tracheostomized clients. Placement of a one-way speaking valve may restore this air pressure as well as improve laryngeal and pharyngeal sensation, may improve ability to expel material from the laryngeal vestibule either through throat clearing or coughing, and may improve swallow safety.

Source: Suiter, D. M., McCullough, G. H., & Powell, P. W. (2003). Effects of cuff deflation and one-way tracheostomy speaking valve placement on swallow physiology. *Dysphagia*, 18(4), 284–292.

Procedure

1. Using clean technique, suction nasopharynx *if cuffed tube in place*. ► **Rationale:** This removes secretions that have pooled above cuff and prevents their mobilization into lower airways upon cuff deflation.
2. Attach syringe and **DEFLATE TRACHEAL CUFF** if present. ► **Rationale:** If tracheostomy tube is capped and cuff is not deflated, client has no airway.

Passey–Muir Speaking Valve

The Passey–Muir Speaking Valve can be used on or off a ventilator and is safe for infants and adults in acute or home care. The valve expedites mechanical ventilation weaning and reduces decannulation time.

The speaking valve opens only during inspiration and closes automatically before the beginning of the expiratory cycle, restoring exhaled airflow through the oronasopharynx. The valve restores a more normal “closed respiratory system,” resulting in many benefits including hands-free, clear, uninterrupted speech production; improved swallowing; reduced aspiration; and stronger, more effective cough. Additionally, use of the valve restores the sense of smell and taste, thus improving appetite and promoting nutritional intake.

Clinical Alert

If a cuffed tracheostomy tube is capped and cuff is not deflated, client has no airway. Place notice: “*Do not inflate cuff with cap in place*” on pilot balloon, over bed, and on client’s chart. An uncuffed fenestrated tube is preferred when speaking valve is used.

3. Allow the client to adjust to cuff deflation. ► **Rationale:** Initiation of upper airway breathing increases resistance to airflow.
4. Place speaking valve over opening of tracheostomy tube.
5. Place notice: “Do not inflate cuff with speaking valve in place” on pilot balloon, over bed, and on client’s chart.
6. Gently stabilize the tracheostomy tube to remove the valve and place in container.
7. When the valve is removed, reinflate tube cuff (if indicated).
8. Discard gloves and perform hand hygiene.

DOCUMENTATION for Tracheostomy Care

Tracheostomy Procedure

- Name of physician performing procedure
- Size and type of tube inserted
- Respiratory status before and after procedure
- Client’s tolerance of procedure
- Amount and character of secretions
- Any equipment attached to tracheal tube (ventilator or other oxygen delivery device and percent oxygen delivered)
- Provision of means to communicate and summon help.

Tracheostomy Tube Suctioning

- Frequency of client suctioning
- Before and after suctioning hyperoxygenation
- Amount, color, and consistency of secretions
- Client’s tolerance to procedure
- Unanticipated problems and client’s response

Cleaning the Inner Cannula and Ostomy

- Time and date of care
- Ostomy site status
- Cannula cleaning or disposable cannula replacement
- Tracheostomy ties or holder replacement

Capping Tracheostomy Tube

- Type of tracheostomy tube in place
- Type of speaking valve utilized
- Tracheal tube DEFLATION status
- Baseline data before procedure
- Client's tolerance of valve placement

- Respiratory/O₂ status during valve use
- Client's ability to speak and swallow

Tracheal Tube Cuff Inflation

- Cuff inflation auscultated for minimal occlusive pressure.
- Bilateral breath sounds present on auscultation.

CRITICAL THINKING Application**Expected Outcomes**

- Tracheostomy tube remains stable.
- Tracheostomy tube provides a patent airway.

- Client is able to communicate with speaking valve placement.

Unexpected Outcomes

Client experiences tracheostomy tube decannulation.

Alternative Actions

- Call a "CODE" immediately.
- For new stoma:
 - If present, pull tracheal retention sutures apart to lift the trachea and hold the stoma open.
 - Or: Cover stoma and have assistant provide bag-mask ventilations.
 - Or: Obtain new tracheostomy tube, place obturator and insert tube into client's stoma, then remove obturator.

Client experiences distress—tracheostomy tube is obstructed; breath sounds not heard.

- Call Rapid Response Team or "CODE" or immediately.
- Deflate cuff.
- Cut tracheostomy ties.
- Remove tube.
- See above options.

Client experiences distress with speaking valve placement.

- Request repeat assessment by speech pathologist and respiratory care practitioner.
- Monitor client's SPO₂.
- Downsize tracheostomy tube.
- Reduce time of valve use.
- Remove speaking valve if respiratory distress occurs.
- Administer O₂ per nasal cannula if desaturation occurs.
- Obtain Passy-Muir valve with oxygen adapter to administer O₂ if indicated.
- Remind client that use of the speaking valve is a step toward trach tube removal.

Chest Drainage Systems

Nursing Process Data

ASSESSMENT Data Base

- Assess client's respiratory status, vital signs.
- Note placement site of chest tube (intrapleural or mediastinal).
- Assess that all drainage system connections are securely taped.
- Note prescribed amount of negative pressure to be established.
- Check patency of chest drainage system.
- Assess for signs of mediastinal shift.
- Note character and amount of chest drainage.

PLANNING Objectives

- To evacuate air and/or fluid from intrapleural space to promote lung re-expansion
- To reestablish negative intrapleural pressure
- To facilitate drainage of fluid from the mediastinum after cardiac surgery
- To administer autotransfusion after cardiac surgery

IMPLEMENTATION Procedures

- Maintaining a Chest Gravity Drainage/Suction Bottle System1214

Maintaining Chest Gravity Drainage/Suction Bottle System

Equipment

- Three-bottle chest drainage system in holder with manufacturer's instructions for use
- Tape
- Suction source, if indicated (e.g., wall suction or Emerson pump)
- Clean gloves and personal protective equipment

Procedure

For Underwater Seal (One-Bottle System)

1. Don gloves and personal protective equipment.
2. Fill water seal bottle with 300 mL of water to submerge water seal tube.

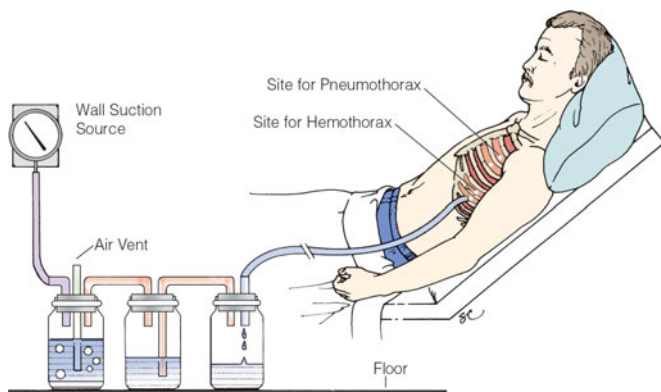

▲ Pneumothorax refers to air in the intrapleural space and hemothorax to blood in the intrapleural space around the lung; both conditions lead to buildup of positive pressure, compression of lung tissue, and possible compression of mediastinal structures with decreased venous return and decreased cardiac output.

3. Attach client's chest tube drainage tubing to water seal tube to prevent atmospheric air from entering client's pleural space.
4. Check that water seal bottle air vent is open to atmosphere. ► **Rationale:** The bottle stopper has two openings, one for inlet from the client, one for outlet to the atmosphere. Air vent allows air from client's intrapleural space to escape and to maintain negative pressure relative to client's intrapleural pressure.
5. Coil drainage tubing from client's chest tube to water seal bottle so that there are no dependent loops. ► **Rationale:** Dependent loops will inhibit air removal.
6. Make sure all tubing and bottle connections are sealed to ensure system is airtight.
7. Ensure patency of system by noting "tidaling" in underwater tube. Fluid should rise on inhalation and descend on exhalation.
8. Note occasional bubbling of air from the water seal tube. ► **Rationale:** This is sign that air is being evacuated from the client's intrapleural space.
9. Check tubing for obstruction. ► **Rationale:** Tidaling ceases when lung has re-expanded or tube system is obstructed.
10. Report event of continuous bubbling in the water seal bottle. ► **Rationale:** This is indicative of an air leak. See steps for locating air leak, page 1216.
11. Assess for return of breath sounds or obtain chest x-ray to determine re-expansion.

Clinical Alert

Chest tubes should not be clamped except briefly while checking for an air leak or for changing a disposable collection system.

▲ Keep collection system at least 12 in. below client's chest. Coil tubing to prevent dependent loops.

For Gravity Drainage (Two-Bottle System)

1. Don gloves and personal protective equipment.
2. Attach client's chest tube drainage tubing to collection bottle. ► **Rationale:** Chest tube drainage is monitored in this bottle.
3. Attach drainage bottle outlet tube to submerged inlet tube of underwater seal bottle.
4. Follow steps 4–10 in previous skill for underwater seal system.

For Suction (Three-Bottle System)

1. Follow steps 1–6 in previous skill for gravity drainage.
2. Submerge suction control tube of third bottle under prescribed amount of water. ► **Rationale:** The third bottle stopper has three openings, one for inlet from the second bottle, one for suction control and air venting, and one for connection to a suction source. Depth of immersion of the suction control tube dictates the amount of suction applied to the three-bottle system (20 cm of water produces –20 cm of water suction).
3. Connect water seal (second) bottle outlet tube to stopper of third bottle.
4. Leave suction control tube open to atmosphere. ► **Rationale:** This provides the outlet for air from client's intrapleural space.
5. Connect suction source tubing to wall suction.
6. Regulate wall suction to a point where water in the second bottle just bubbles. ► **Rationale:** This indicates that desired suction has been reached.
7. Note *occasional* bubbling of air in the water seal bottle. ► **Rationale:** This indicates that air is being evacuated

Using Chest Drainage/Suction Bottle Systems

One-Bottle System

One bottle functions as a drainage collection bottle as well as water seal. Used mainly to reestablish negative intrapleural pressure to reinflate lung from pneumothorax.

Two-Bottle System

Water-seal bottle and drainage collection bottle are separate. System not usually connected to suction source. Used after thoracic or cardiac surgery.

Three-Bottle System

Third bottle is connected to an external suction source. The other two bottles are the same as for two-bottle system. Used after thoracic or cardiac surgery.

Small Mobile Chest Drains Allow Mobility and Early Discharge From the Hospital. Examples Include:

Heimlich one-way valve, which, attached to the client's chest tube, allows *air* to escape, but not enter; the distal end of the valve remains open. It, and the chest tube, should be taped to the client's chest. The Heimlich valve is not used for chest tube drainage.

Pneumostat is a plastic device that has a one-way valve and a gravity drainage collection chamber. The unit can be clipped to the client's clothing.

- from client's intrapleural space. *Continuous* bubbling in water seal bottle should not occur.
8. Note *continuous* bubbling of air through open end of control tube in the suction bottle.
9. Monitor fluid levels in water seal and suction control bottles.
10. Note and mark chest tube drainage on drainage bottle. Notify physician if there is more than 100 mL of drainage per hour. ► **Rationale:** This amount represents excessive bleeding requiring medical management; however, drainage of old blood may increase with position change.
11. Continue to monitor client's SPO₂ and vital signs.

Setting Up and Maintaining a Disposable Water Seal Chest Drainage System

Equipment

Disposable water seal chest drainage system and stand
Suction source
Connecting tubing and adapter

60-mL sterile syringe with catheter tip
Sterile water in pouring bottle
Tape
Gloves
Personal protective equipment

▲ Disposable water-seal chest drainage system principles correspond to the three-bottle drainage system.

NOTE: Placement of chest tubes in the mediastinum for drainage after cardiac surgery is common. Intrapleural pressure is not affected.

Procedure

1. Gather equipment.
2. Perform hand hygiene; don gloves and personal protective equipment.
3. Unwrap water seal chest drainage system.
4. Place unit in stand on floor at bedside or hang from foot of bed frame.

▲ This dry suction system (OASIS) requires that water be added to the water seal, but does not require water in the suction chamber. The suction is wall regulated. These systems are quieter and easier to use.

Check Points for Chest Tube Air Leaks

Check Insertion Site

- Pinch or briefly clamp with padded hemostat tube at chest insertion site. Bubbling stops in the water seal chamber if there is an air leak at insertion site.

Check Tubing

- Pinch rubber connecting tubing. Bubbling stops if there is a leak at chest tube connector site.

Check Water Seal Drainage System

- Pinch rubber connecting tubing. Bubbling continues if there is a leak in water seal connection.

Observe water seal chamber. There should not be excessive continuous bubbling. A small amount of bubbling is seen in the water seal:

- When suction is first initiated.
- As air is displaced by drainage in the collection chambers.
- As client exhales and coughs and air is forced out of intrapleural space.

When lung has re-expanded, the bubbles cease.

▲ Padded hemostat or plastic tube clamp is used for clamping chest tube. Tube clamped only if ordered.

5. Remove plastic connector on short tube attached to water-seal chamber.
6. Remove plunger from 60-mL syringe and attach barrel of syringe to short tube.
7. Pour specified amount of sterile water into barrel of syringe, filling water seal chamber to 2-cm level (according to package directions). ► **Rationale:** This level provides sufficient fluid to create a one-way valve to prevent atmospheric air from entering client's intrapleural space.
8. For gravity drainage: leave suction control source tubing open to air.
9. For suction drainage: remove plastic plug from atmosphere vent to suction control chamber.
10. Attach 60-mL syringe barrel to atmosphere vent and pour sterile water into suction control chamber.
11. Fill suction control chamber to 20-cm level.
► **Rationale:** Fluid level controls amount of negative pressure created throughout system.

NOTE: Some chest drainage systems do not require water in either chamber, or only the suction control chamber. See manufacturer's instruction for waterless system use. Dry suction is quieter and capable of achieving greater degrees of negative pressure (up to -40 cm H₂O). These units may have a "dry suction control" dial usually set at -10 to -20 cm H₂O. Turn on suction source until orange bellows appears in indicator window to establish suction.

Clinical Alert

Subcutaneous emphysema (air in tissue) may be felt around the chest tube insertion site, but should be reported if it extends beyond this.

12. Remove long tube adapter from collection chamber and connect it to client's chest tubing.
 13. Tape connection.
 14. Coil tubing loosely on the bed, but provide a straight line of tubing from bed to collection system.
► **Rationale:** Straight-line tubing prevents pooling of fluid pressure alterations and system obstruction.
 15. Make sure tubing is free and not kinked. Do not use pins or restrain tubing. ► **Rationale:** Pins could puncture tubing, causing an air leak.
 16. Attach short rubber tube on water-seal chamber to wall suction tubing using an adapter.
 17. Turn suction device on slowly until bubbling occurs in suction control chamber.
 18. Monitor water levels daily in both water seal chamber and suction control chamber.
 19. Maintain pressure.
 - a. Keep drainage system at least 12 in. below client's chest level. ► **Rationale:** Raising the unit can cause backflow of drainage into client's intrapleural space.
 - b. Maintain wall suction to create gentle bubbling in suction control chamber.
 - c. Maintain water seal level (2 cm). ► **Rationale:** Water seal prevents room air from entering pleural space.
 - d. Maintain suction control chamber water level at 20 cm or as ordered.
20. Maintain chest tube patency. Only if physician orders, milk chest tubes to maintain drainage and tube patency.
 - a. If ordered, milk tube by alternately folding or squeezing and then releasing drainage tubing.
► **Rationale:** This provides intermittent suction to the chest tube but generates extreme negative pressure in intrapleural space.
 - b. Milk tube away from client toward the drainage receptacle (disposable system or bottles).
 21. Strip chest tubes *only* if physician orders.
 - a. To strip chest tube, pinch tubing close to client's chest with one hand and, using a lubricated thumb and forefinger, compress and slide fingers down tube toward drainage chamber/bottle. (Lubricant material is usually petrolatum or alcohol swab.)
 - b. Release pressure on tube and repeat stripping action until reaching receptacle. Increased negative pressure can occur.
 22. Keep rubber-tipped hemostat at the client's bedside.
► **Rationale:** In emergency, tube can be clamped nearest to chest insertion site.
 23. Keep collection system at least 12 in. below client's chest level. ► **Rationale:** This enables fluid to flow by gravity.
 24. Mark drainage on disposable system collection chamber hourly, or every shift. Drainage should be measured at eye level. Report drainage exceeding 100 mL/hr.
 25. Assess client's status.
 - a. Instruct client to deep breathe and cough at frequent intervals. ► **Rationale:** Frequent deep breathing helps to expand the lungs. Coughing helps evacuate air from intrapleural space.
 - b. Encourage client to change positions frequently. Chest tube drainage does not limit client activity.
 - c. Observe and report any adverse change in SPO₂, vital signs, or client's tolerance.

Clinical Alert

Strip and milk chest tubes *only* with physician's orders. Excessive negative pressure created by stripping and milking increases negative pressure in intrapleural space.

Administering Autotransfusion Using Pleur-evac ATS

Equipment

- Sterile disposable Pleur-evac ATS including blood collection bag
- Replacement bag
- Microaggregate filter
- Clean gloves
- Sterile saline or water in parking bottle

NOTE: A variety of sterile chest drainage systems provide evacuation of air and/or fluid from the chest or mediastinum. Evacuated blood may be simultaneously reinfused or collected and reinfused in postoperative or trauma cases.

Procedure

1. Perform hand hygiene and don gloves.
2. Connect client's pleural or mediastinal chest tube by following steps 1 through 3 printed on Pleur-evac unit.
 - ▶ **Rationale:** Tight connection establishes water-seal drainage system.
3. Check that ALL clamps are open on blood collection bag and drainage tubing and that connections are airtight.
4. Check that blood begins collecting in bag.
5. Mark time and amount of drainage on bag.
6. Close clamp on chest drainage tubing and collection bag and connect new bag to drainage system. Make sure all connections are tight.
7. Depress button on high-negativity relief valve and release it when negativity drops to desired level.
 - ▶ **Rationale:** This reduces excess negativity before removing first collection bag.

▲ Pleur-evac autotransfusion system (ATS) frequently placed in cardiac surgery.

8. Close white clamp on client tubing, then close two white clamps on top of collection bag, and disconnect all connectors on first bag.
9. Remove protective cap from collection tubing on replacement bag. Maintain aseptic technique when changing tubing.
10. Use red connectors to connect unit's collection tubing to client's chest drainage tube.
11. Remove protective cap from replacement bag's suction tube.
12. Use blue connectors to attach replacement bag's suction tube to Pleur-evac unit.
13. Open all clamps, and check that system is airtight.
14. Attach red (female) and blue (male) connector sections on top of autotransfusion bag.
15. Move out and disconnect metal support arms, and disconnect foot hook.
 - ▶ **Rationale:** Releasing these connections allows you to remove bag from drainage unit.
16. Attach replacement bag by using foot hook and support arm.
17. Slide bag off support frame and invert bag with spike port pointing up.
 - ▶ **Rationale:** This position allows blood to be reinfused from original collection bag.
18. Remove protective cap from spike port, and insert a microaggregate filter. Twist filter into position.
 - ▶ **Rationale:** Filter is essential for reinfusion.
19. Prime filter by gently squeezing inverted bag until drip chamber is half full.
20. Close clamp on reinfusion line, and remove residual air from bag.
21. Invert bag on IV pole.
22. Flush IV tubing to remove air, then reinfuse blood by gravity or pump according to hospital policy. Blood should be totally reinfused within 6 hr from *start of collection*.
23. Remove gloves and perform hand hygiene.
24. Assess neurologic signs and pulmonary status every 4 hr.
 - ▶ **Rationale:** Microemboli can occur with autotransfusion.

Clinical Alert

Reinfusion is not indicated unless system is primed with drainage and an additional 50 mL of drainage has been collected for reinfusion.

No more than 6 hr should elapse from time of *beginning* collection to *completion* of reinfusion.

Refer to evacuation/reinfusion system manufacturer's package insert for indications, contraindications, and instructions for use.

Assisting With Removal of Chest Tube

Equipment

- Suture removal set
- Rubber-tipped hemostat
- Disposable underpad
- Sterile 4 × 4 gauze for mediastinal tube
- Or
- Sterile petrolatum gauze dressings for intrapleural tube
- Tape (elasticized foam tape for intrapleural tube)
- Sterile gloves
- Personal protective equipment (face mask/shield)
- Prescribed premedication

Preparation

1. Identify client using two forms of identification and introduce self.
2. Gather equipment and prepare client for procedure, including instruction to take a deep breath and hold it or to hum during tube removal.
3. Premedicate client (as ordered), allowing time for peak effect upon tube removal.

Procedure

1. Perform hand hygiene and don personal protective equipment.
2. Place client in semi-Fowler's position.
3. Don sterile gloves.

Clinical Alert

The chest tube can be removed when drainage is less than 50–100 mL in 24 hr, or, if inserted for blood removal, drainage has become serous or sero serosanguineous and less than 100 mL in the past 8 hr.

4. Assist physician to remove dressing, clip suture securing chest tube, and clamp chest tube.
5. Instruct client to take a deep breath or hum during tube removal.
6. Hold sterile dressing in place while chest tube is being removed.
7. Dispose of chest tube and drainage equipment.
8. Remove personal protective gear, gloves, and discard.
9. Perform hand hygiene.
10. Reevaluate client's status regularly. ► **Rationale:** Client should be assessed for unstable vital signs, diminished or absent breath sounds, or respiratory distress (pneumothorax, mediastinal shift) after removal of chest tube.

▲ Chest tube is clamped in preparation for removal.

▲ Sutures anchoring chest tube are cut.

▲ Dressing is applied immediately upon tube removal.

DOCUMENTATION for Chest Drainage Systems

Chest Drainage System

- Site and size of chest tubes inserted and drainage system established
- Negative pressure established
- Client's tolerance of procedure
- Vital signs
- Breath sounds
- Drainage—amount, color
- Any problem with the system and its management
- Client activity (turning, ambulation)
- Chest-tube milking/stripping if performed

Autotransfusion

- Amount of blood reinfused
- Time collection started to completion of reinfusion
- Signs and symptoms of any complications encountered
- Changes in coagulation times or hemoglobin, hematocrit
- Client's response to treatment

Chest Tube Removal

- Breath sounds
- Premedication administered
- Name of physician removing tube
- Status of insertion site and dressing applied
- Client's tolerance of procedure

CRITICAL THINKING Application

Expected Outcomes

- Chest drainage system is patent.
- Mediastinal shift does not occur.

- Chest tube remains securely placed.

Unexpected Outcomes

Air leak is present.

Alternative Actions

- Check for specific leak area by briefly clamping chest drainage tube between client and bottle closest to client.
 - a. If water-seal bottle continues to bubble, the leak is in the tubing.
 - b. If water-seal bottle stops bubbling, the leak is in the client's chest tube at insertion site.
- Secure all connections with tape.
- Change tubing if necessary (obtain physician's order).
- Apply sterile petrolatum gauze around chest tube insertion site if leak is at that site.

Drainage system is obstructed.

- Assess tubing for kinks or clots.
- Loop tubing on bed to allow straight drainage to collection system.
- Obtain physician's order to milk or strip tubing.
- Note signs of respiratory distress and call Rapid Response Team or "CODE" immediately. Check drainage tube for patency. Prepare to assist with thoracentesis.

Client develops signs of mediastinal shift (trachea deviated to unaffected side, paradoxical pulse develops, jugular veins distend, cardiac output decreases).

- Clamp chest tube near chest insertion site.
 - a. Replace extension tubing leading from chest tube and submerge into open bottle of sterile water to create underwater seal.
 - b. Unclamp chest tube as soon as extension tubing is placed underwater or connected to new system.
- Secure connecting sites with tape to prevent disconnection.
- Assess client for signs of respiratory distress due to pneumothorax and report.

Chest tube becomes disconnected from drainage system.

Chest tube becomes dislodged.

- Notify physician.
- Instruct client with external chest disruption to exhale and apply sterile nonporous 4 × 4 gauze dressing with tape on three sides to allow air to escape on exhalation but inhibit air intake on inspiration.

GERONTOLOGIC Considerations

The Physiologic Age Changes That Occur in the Elderly Affect the Respiratory System.

- The respiratory muscles lose their strength and the rib cage becomes more rigid.
- The alveoli increase in size and decrease in number as well as become less elastic and more dilated.
- Gas exchange is reduced; the PaO₂ decreases 1 mm/year after age 60, so a reading of 77 mmHg is not unusual in an elderly client.
- Skeletal alterations affect posture and may restrict lung expansion.

Pulmonary Disorders Occur More Frequently in the Elderly. COPD is the Fourth Leading Cause of Death.

- Respiratory reserves are reduced with aging; the elderly are at greater risk for respiratory failure.
- Pneumonia may develop primarily or secondary to other conditions. Because it is a major cause of death in the

elderly, pneumonia vaccine, influenza vaccine, and other preventive measures should be employed.

- Asthma may occur as a problem in the elderly who have never had the disease.
- Cancer of the lung is the leading cause of cancer death in the elderly.

It Is Important to Implement Nursing Actions That Support the Respiratory System in the Elderly.

- Deep breathing and exercise help promote ventilation.
- Hydration helps to liquefy secretions and reduce risk for infection.
- Monitor oxygen therapy closely with the elderly—note signs of hypoxia and decreased responsiveness due to possible carbon dioxide narcosis.
- The elderly are at risk for hypoxemia with bedrest (PO₂ may drop to 40 mmHg even with a night's sleep). Position change, range of motion, and early mobilization all stimulate ventilation and must be encouraged in all clients.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- Each state identifies the scope of practice for RNs, LVN/LPNs, and Respiratory Care Practitioners. States may differ in defining responsibilities of respiratory care by these practitioners. Usually, the respiratory care practitioner is licensed to perform invasive procedures such as suctioning, changing tracheostomy inner cannulas, and administering medication by aerosol. The initiation of oxygen administration by various modes and utilization of biophysical parameters (ABGs, etc.) and standard protocols in decision making and management of the mechanically ventilated client are also within the scope of respiratory care practice.
- All professionals collaborate in the care planning and evaluation of client responses to respiratory care interventions. The nurse must be aware of the unique role competencies, responsibilities, and accountabilities of specialty personnel when a variety of care providers are involved.
- The nurse should ensure that regular turning and deep breathing are encouraged by the CNA/UAP to promote ventilation and prevent complications of immobility in bedfast clients.
- The CNA/UAP should be familiar with appropriate client positioning to promote airway patency and reduce risk for aspiration of oral intake.

- Even though hospitals are “smoke free” today, all personnel must take precautions when oxygen is in use: No petrolatum products around nose or mouth; no battery-operated equipment or friction-type toys to be used. The area surrounding the client is oxygen-rich and can support combustion.
- All personnel should be able to locate the main oxygen supply valve to the area for discontinuation of oxygen flow in case of fire.
- The nurse must verify that the CNA/UAP understands the importance of oxygen administration so that it is appropriately maintained. The nurse ensures that the CNA/UAP seeks assistance so portable oxygen can be provided if it is required during client ambulation.
- Unlicensed personnel should be informed that aspiration is an ever-present danger for the client with a tracheostomy tube.
- Clients who require oxygen administration may be unable to perform activities of daily living independently. The CNA/UAP providing basic care should be *instructed to assist* the client with these activities (e.g., set up food tray, provide bed or partial bath).
- All care providers must be familiar with the location of emergency supplies and should be prepared to retrieve equipment and assist with manual respiratory resuscitation if necessary.

Communication Matrix

- The CNA/UAP usually performs routine vital signs assessment and documentation (including respiratory rate).

The nurse should request that respiratory rates less than 12 or greater than 20 be reported immediately, as more specific assessment may be indicated.

- The CNA/UAP should know to *report* any change in the client's breathing status or tolerance of activity. The character and amount of sputum production should also be reported and saved for the nurse's inspection and documentation.
- While the nurse or respiratory care practitioner is responsible for suctioning clients, the CNA/UAP must recognize the client's need for such and *report* it immediately.

- The PO status of intubated clients must be clearly communicated to all personnel. NPO status should be clearly posted at the bedside.
- All care providers must ensure that the intubated client has nonvocal means for summoning help (call bell) and communicating (paper and pencil).
- There should be clear postings at the bedside of the client for swallowing precautions, oxygen precautions, communication through nonvocal means, intubation precautions.

CRITICAL THINKING Strategies

Scenario 1

Mrs. Harvey, age 72, has a history of chronic obstructive pulmonary disease (COPD) with components of emphysema and chronic bronchitis. She has frequent recurrence of respiratory infection requiring hospitalization. With her most recent hospitalization, she has developed pulmonary hypertension and right-sided heart failure with weight gain and systemic edema. After treatment with IV antibiotics, she is ready for discharge, but will be sent home with continuous low-flow (1.5 L) oxygen therapy. Her ABGs at the time of discharge shows elevated PCO_2 (respiratory acidosis), elevated bicarbonate level (metabolic alkalosis), PO_2 of 60 mmHg, and O_2 saturation of 90% on oxygen. Her blood pH is low normal due to the *compensated* respiratory acidosis.

1. What is the rationale for home oxygen therapy for Mrs. Harvey?
2. What are the hazards that accompany home oxygen therapy?
3. What should the client know about home oxygen therapy?
4. What are the expected outcomes of home oxygen therapy (ABGs)?

Scenario 2

Joe Snodgrass has been referred to the sleep laboratory for an overnight polysomnogram (sleep study) due to his complaints of excessive fatigue, daytime sleepiness, awakening with a headache, and his heart racing. In addition, his wife reports that he snores a lot and has breathing pauses when he's sleeping that frighten her.

Outcomes of his study reveal that Mr. Snodgrass has obstructive sleep apnea (OSA). His physician has prescribed nasal continuous positive airway pressure (nCPAP) for night-time use. As his nurse, you are to obtain follow-up assessment data regarding your client's tolerance, adherence, and response to this therapy.

1. What is obstructive sleep apnea?
2. What are the risk factors for developing obstructive sleep apnea?
3. What are potential complications of untreated OSA?
4. How does CPAP benefit the client with OSA?
5. Why do many clients fail to adhere to CPAP therapy?
6. Are there other treatment options available for the client who cannot tolerate CPAP?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. Instructions for use of an incentive spirometer device should include to inhale through the mouthpiece
 1. Quickly to maximum level, then exhale slowly through the nose.
 2. Slowly to maximum level, hold several seconds, then exhale forcefully.
 3. Quickly to maximum level, hold for several seconds, then exhale slowly with mouth open.
 4. Slowly to maximum level, hold for several seconds, then exhale through pursed lips.
2. Chest Physical Therapy (CPT) only benefits
 1. Clients with pneumonia.
 2. Clients with retained secretions.
 3. COPD clients with acute exacerbation.
 4. Mechanically ventilated clients.
3. CPAP/BiPAP mask application should not be used for clients who are
 1. Allergic to latex.
 2. Sedated.
 3. Asleep.
 4. Claustrophobic.

4. The greatest oxygen delivery (FIO_2) is provided by
 1. Nasal cannula.
 2. Face mask.
 3. Venturi mask.
 4. Nonrebreathing mask with reservoir bag.
 5. Hemoglobin saturation measurement by pulse oxymetry (SpO_2) is less reliable in _____.
Select all that apply.
 1. Anemic clients.
 2. Black clients.
 3. Hypovolemic clients.
 4. Hypertensive clients.
 5. Clients post dye injection.
 6. The purpose of tracheal intubation/tracheostomy tube placement is to
 1. Provide mechanical ventilation.
 2. Establish a patent airway.
 3. Prevent aspiration.
 4. Provide oxygenation.
 7. Inflation of an endotracheal or tracheostomy tube cuff
 1. Allows the client to eat.
 2. Prevents aspiration of pharyngeal secretions.
 3. Prevents tube migration.
 4. Allows mechanical ventilation.
 8. The Bivona Fome Cuff differs from other tracheostomy tubes in which of the following ways?
 1. The cuff is inflated with sterile water.
 2. It does not require an obturator for insertion.
 3. Air must be withdrawn to deflate the cuff.
 4. Decannulation cannot occur.
 9. The client with a tracheostomy tube that is capped with a speaking valve must have
 1. Mechanical ventilation.
 2. Tube cuff deflated.
 3. Tube cuff inflated.
 4. A Bivona Fome Cuff tube.
 10. Place the following steps in correct sequence for suctioning a client's airway with a single-use catheter:
_____.
 1. Hyperoxygenate client.
 2. Suction client's oropharynx.
 3. Pour catheter flush solution into container.
 4. Attach catheter to end of suction tubing.
 5. Set suction source to 100 mmHg.
 6. Don sterile gloves.
 7. Apply suction.
 8. Advance catheter into client's airway.
-

Circulatory Maintenance

LEARNING OBJECTIVES

1. Identify four properties of the cardiac muscle and define cardiac output.
2. Define the words *inotropic* and *chronotropic*.
3. Locate the following sites to palpate the pulse: temporal, carotid, brachial, radial, femoral, popliteal, posterior tibial, and dorsalis pedis.
4. Outline the assessment actions for a client who is hemorrhaging.
5. Identify two interventions for treating heart failure.
6. Define the term *ischemia*.
7. List the nine pressure points in the body that can be used to control bleeding if hemorrhage occurs.
8. Identify two potential problems that could occur in clients who are bleeding, and state one suggested intervention for each problem.
9. Describe how to measure for appropriate-size graduated compression stockings.
10. List at least four potential problems for clients requiring CPR and two suggested interventions for each problem.
11. Outline the steps in administering CPR with one rescuer and with two rescuers.
12. Demonstrate performing the Heimlich maneuver.
13. Describe four steps in using the automatic external defibrillator (AED).
14. State two nursing diagnoses relevant to clients with alterations in circulation.
15. Differentiate between a normal and abnormal ECG pattern.
16. Describe lead placement for a 12-lead ECG.
17. Describe the rationale for use of a permanent pacemaker versus a temporary pacemaker.
18. Compare and contrast the various types of pacemakers.
19. Identify three benefits of internal cardiac defibrillator (ICD).
20. Discuss teaching for home care clients with cardiac pacemakers.
21. Determine symptoms requiring physician notification when reviewing the diary of a client using a Holter monitor.

TERMINOLOGY

- Aberrancy** abnormally conducted beat or cardiac rhythm.
- Afterload** resistance or impedance to blood flow during ventricular systole.
- Antiembotic** a preventive measure used to help prevent the formation of an embolism, such as elastic hosiery.
- Atherosclerosis** accumulations of lipid-containing material within inner and middle layers of the arterial wall forming a fixed atheromatous plaque.
- Cardiovascular** pertaining to the heart and blood vessels.
- Chronotropic** factors known to alter the heart rate through external causes (e.g., medication).
- Conductivity** the electrical conducting capability of a substance.
- Congestion** excessive accumulation of blood or fluid within a blood vessel, tissue, or organ.
- Contractility** having the ability to contract or shorten.
- Cyanosis** bluish, purplish, discoloration of the skin resulting from reduced hemoglobin or oxygen in the blood.
- Diastole** relaxation filling phase of the cardiac cycle.
- Dilatation** expansion of an organ or vessel.
- Dorsiflexion** flexion of the foot in an upward direction so as to bend the joint toward the dorsum.
- Dysrhythmia** an abnormality in cardiac rhythm.
- Ecchymosis** escape of blood into the tissues from a ruptured blood vessel causing a discoloration of the skin; color is blue-black, changing to greenish brown or yellow.
- Ectopy** beat originating in the heart other than from the sinoatrial node.
- Edema** an excessive accumulation of fluid within tissue or bodily cavity.
- Embolism** sudden obstruction of a blood vessel by debris (e.g., a blood clot, plaque).
- Endocardial** arising from the endocardium.
- Endocardium** serous lining membrane of the inner surface and cavities of the heart.
- Endotracheal** within the trachea.
- Epistaxis** hemorrhage from the nose.
- Heart failure** a condition whereby the heart is unable to pump sufficient blood at either an adequate rate or volume to meet the metabolic demands of the body.
- Hematemesis** vomiting of blood.
- Hematoma** a swelling or mass of blood, usually clotted, confined to a specific space and caused by a break in a blood vessel.
- Hemodynamic** the study of blood flow within the systemic circulation.
- Hemoptysis** expectoration of blood from the larynx, trachea, bronchi, or lungs.
- Hemorrhage** abnormal internal or external bleeding.
- Homan’s sign** pain in the calf when the foot is dorsiflexed.
- Hydrostatic** is a pressure of liquids in equilibrium and to the pressure exerted by the liquids.

Hypotension a low systolic blood pressure that is insufficient to maintain adequate tissues and/or organ perfusion.

Immobilize to fix a body part to reduce or eliminate motion.

Inotropic influencing the contractibility of muscle tissue.

Ischemia a decrease in circulation to tissue, organ, or limb due to obstruction of the inflow of arterial blood, which is reversible if blood flow is reestablished promptly.

Manubrium the sternum articulating with the clavicle and first pair of costal cartilages.

Pacemaker a device that provides electrical stimulation to the heart muscle.

Perfusion passing of fluid through spaces; the circulation of blood through tissues.

Petechiae small, purplish, hemorrhagic spots on the skin.

Phlebitis inflammation of a vein.

Precordial pertaining to the precordium or occurring in front of the heart.

Preload length or stretch of the cardiac muscle fiber imposed by the volume of blood in the ventricles at the end of diastole.

Purpura hemorrhage into the skin, mucous membranes, internal organs, and other tissues.

Resuscitation act of bringing one back to consciousness.

Sclerosis hardening or induration of an organ or tissue due to excessive growth of fibrous tissue.

Shock term used to designate a clinical syndrome with varying degrees of disturbances of reduced blood flow and oxygen supply to the tissues.

Stasis standing still; stagnation of normal flow of fluids.

Syncope fainting, transient loss of consciousness due to inadequate blood flow to the brain.

Thrombosis formation of a blood clot.

Vertigo sensation of moving or having objects moving around when they are actually still.

THE CIRCULATORY SYSTEM

The heart is a three-layered organ, approximately the size of an adult fist, weighing approximately 250–350 g. The pericardium is a double-walled, strong nondistensible sac that encloses the heart, the aorta, and the other great vessels attached to the heart. The pericardium contains a fibrous and a serous layer, the function of which is to restrict excessive movement of the heart and act as a lubricated container during cardiac contraction. The pericardium protects the heart from positional changes and infection and prevents friction between the heart and other organs. There are two layers of the serous pericardium, the parietal and visceral layers. These two layers are separated by a thin fluid-containing cavity, the pericardial sac, which contains 50 mL of pericardial fluid that lubricates and facilitates the movement of the heart. The fibrous pericardium and parietal layer of the serous pericardium are supplied by the phrenic nerve, whereas the visceral layer of the serous pericardium is innervated by the sympathetic nervous system and the vagus nerve. Both influence reflex changes in the heart rate and blood pressure. The myocardium is the thickest layer of the heart and is composed of cardiac muscle cells. Cardiac muscle

cells are unique and possess four properties: (1) automaticity—ability of some cardiac cells to initiate an impulse spontaneously and repetitively; (2) conductivity—cells can transmit the electrical impulses; (3) contractility—which characterizes all muscle; however, a cardiac contraction is an all-or-nothing response to an impulse as opposed to partial contractions in skeletal muscles; and (4) excitability—the ability to respond to an external stimuli, resulting in a contraction. The endocardium is the innermost lining of the heart and is continuous with the endothelium that lines arteries, veins, and capillaries.

The heart serves as a pump and is made up of four chambers: the right atrium, right ventricle, left atrium, and left ventricle. Unidirectional blood flow is regulated through the heart by four valves: the tricuspid, pulmonary, mitral, and aortic valves. Venous blood enters into the right atrium of the heart from the

▲ Blood flow pattern through the right and left side of the heart.

▲ Blood flow in coronary arteries.

superior and inferior vena cava. Blood flows from the right atrium into the right ventricle via the tricuspid valve, then into the lungs for oxygenation via the pulmonary valve. After gases exchange in the pulmonary system, the blood enters the left atrium, left side of the heart, by way of four pulmonary veins. These are the only veins within the body that carry oxygenated blood. From the left atrium, blood flows into the left ventricle via the mitral valve, then out into the aorta via the aortic valve. Blood flows to all parts of the body through the systemic circulation system. The heart pumps the entire circulating volume each minute (4–7 L of blood).

Arteries carry oxygenated blood from the heart throughout the body from the largest vessel, the aorta, to the smallest, arterioles. Arteries have three layers: endothelium, smooth muscle, and connective tissue. Capillaries join the arterial system to the venous system and are a single cell layer that allows for the exchange of gases, nutrients, and waste material.

Capillaries are also known as capacitance vessels, which serve to regulate blood flow within the venous system by returning it to the right side of the heart.

Cardiac Output

Cardiac output (CO) is the amount of blood flow ejected by the heart within 1 minute and is measured in liters per minute. Heart rate and stroke volume determine cardiac output. Cardiac output (CO) is determined by multiplying the amount of volume ejected from the heart with each contraction, or stroke volume (SV), by the heart rate (HR).

$$\text{CO} = \text{SV} \times \text{HR}$$

(Cardiac Output = Stroke Volume × Heart Rate)

In order to maintain its continuous pumping activity, the heart muscle must receive oxygen and nutrients. Approximately 5% of blood leaving the heart and pumped into the aorta enters the coronary circulation for oxygenation and waste removal from cardiac tissue. The coronary arteries branch from the aorta, extend over the surface of the heart, supply blood to all areas of the heart muscle, and fill during diastole. The major coronary arteries are the right coronary artery and the left coronary artery, which divides into two branches, the anterior descending artery and the circumflex artery.

If the blood flow in the coronary arteries to the heart muscle is severely reduced, ischemia or injury can occur, but it is reversible. If the flow is blocked completely for a prolonged

▲ Intrinsic conduction system of the heart.

period, necrosis will occur; necrosis is irreversible. This is referred to as a myocardial infarction or “heart attack.”

After supplying the heart muscle, 15% of the cardiac output (600–500 mL) travels to the brain, 25% (1000–1750 mL) goes to the kidneys, and another 25% to the other viscera. The extremities and skin normally receive approximately 30% of the cardiac output.

ELECTRICAL CONDUCTION

Cardiac muscle cells have the ability to generate their own rate and rhythm that allows for their spontaneous, repetitive self-stimulation, previously mentioned as automaticity. The rate and rhythm of cardiac contractions are primarily determined by this self-generated impulse. The autonomic nervous system influences the heart rate. Sympathetic stimulation increases heart rate, speeds the conduction through the atrioventricular (AV) node, and increases force of contraction. Parasympathetic stimulation slows the heart rate by decreasing the firing rate of the sinoatrial (SA) node and decreasing the speed of conduction through the AV node.

Normally, the electrical impulse originates within specialized cells within the SA node located on the posterior wall of the right atrium, just right of the opening of the superior vena cava. It functions as the pacemaker for the heart. The SA node initiates approximately 60–100 impulses each minute. The impulse travels to the AV node, located in the right atrial wall near the tricuspid valve. If there is a problem with the impulse being generated in the SA node, the AV node can actually take over as the pacemaker. Over the long term, this may present a problem because the intrinsic rate of the AV node is only 40–60 impulses per minute. The AV node coordinates the incoming electrical impulse from the atria and relays an impulse to the ventricles, via the septum and through the

bundle of His specialized conduction fibers, which divide into the right and left bundle branches. Then, the impulse continues to the Purkinje fibers, where it terminates. Further depolarization of the myocardium takes place by conduction through the muscle fibers themselves. If both the SA and AV node are dysfunctional, or there is blockage in the bundle of His, the Purkinje fibers are capable of maintaining their own intrinsic rate, but the rate is less than 40 beats/min.

Electrocardiogram (ECG)

The electrocardiogram (ECG) is used to detect abnormalities associated with the conduction system of the heart. The waveforms, which indicate the electrical activity of the myocardium, are analyzed using the ECG tracing. (See page 1251 for illustration.)

P wave—represents atrial depolarization, indicating the contraction of both atria. The P wave is usually smooth and upright or “positive.”

PR interval—is measured from the beginning of the P wave (onset of atrial depolarization) to the R wave. It represents the time required for atrial depolarization and for the impulse to travel through the entire conduction system, including the Purkinje fiber network. Normal PR interval is 0.12 to 0.20 seconds.

QRS complex—represents depolarization of the ventricles, which causes the ventricular contraction. It is measured from the beginning of the Q wave (or R) to the end of the S wave. Not all leads have a Q wave. The normal QRS interval duration is 0.06–0.12 seconds and represents the time required for depolarization of both ventricles.

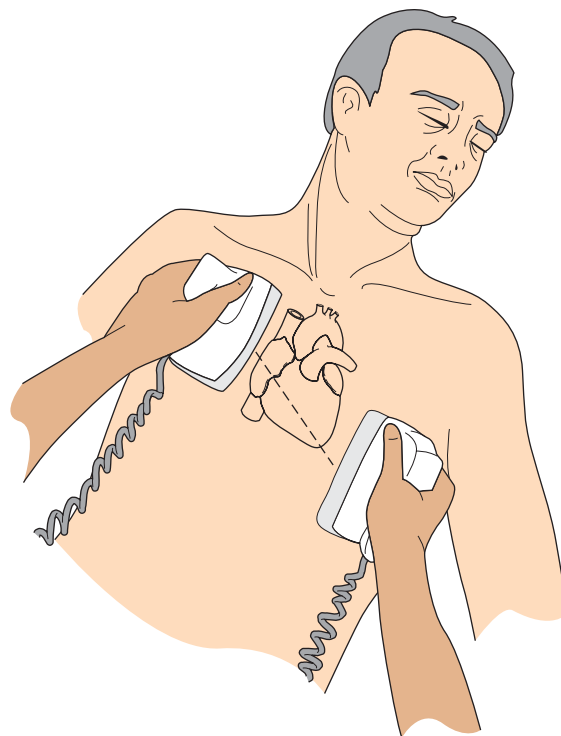

ST segment—represents the period of early ventricular repolarization. The ST segment is normally isoelectric (line is flat). The segment normally is not elevated >1 mm or depressed >0.5 mm from the isoelectric line.

QT interval—represents the total time required for ventricular depolarization and repolarization. It is measured from the beginning of the QRS complex to the end of the T wave and represents ventricular systole (contraction). The normal QT interval is 0.34–0.43 seconds.

T wave—represents ventricular repolarization or the return of the ventricles to a resting state. The wave is normally asymmetrically rounded and upright or “positive.” The end of the T wave marks the end of systole.

Segments and waves are measured for duration (time) and configuration. Abnormalities in duration or configuration may indicate a problem is occurring in that specific area of the heart.

Any disturbance in the rate or rhythm of the heartbeat is termed *dysrhythmia*. Historically, the term *arrhythmia* has been used in the literature. Although the terms are often used interchangeably, *dysrhythmia*, which means a disturbance in cardiac rhythm, is more accurate. *Dysrhythmias* are classified according to their site of origin. The sites include sinus, atrial, junctional, ventricular, and AV nodal tissue. A sinus *dysrhythmia* usually reflects a change in rate or rhythm. An atrial *dysrhythmia* results from a disturbance with the SA node or atria indicated by an abnormality in the P wave configuration.

▲ Defibrillation pads applied to chest wall.

A junctional *dysrhythmia* occurs when there is a problem associated with the AV node as indicated by a change in the PR interval. A ventricular *dysrhythmia* results from a problem with the ventricle and is indicated by an abnormality in the configuration of the QRS complex. Although many *dysrhythmias* have no clinical manifestations, many others have serious consequences. A ventricular *dysrhythmia* is the most life-threatening because it compromises cardiac output.

Cardiac Monitoring

The choice of monitoring is dependent on the client's clinical condition and determined by the *arrhythmias* most likely to occur and the potential severity of the *arrhythmia*. Any lead that displays a clear P wave and QRS complex can identify premature atrial complexes, abnormal sinus rhythms, and most heart blocks. Most leads recognize atrial fibrillation by the irregular R-R intervals and chaotic atrial activity. When the QRS complex becomes wide, as it does when the client is in bundle branch block or has ventricular rhythms, the lead that best differentiates these findings is selected. The V1 and V6 leads (equivalent to MCL1 and MCL6) are the best leads to differentiate the wide QRS rhythms. Multiple lead monitoring is best for observing and detecting these *arrhythmias*. The newer bedside monitors allow monitoring of two leads simultaneously, but only allow monitoring of one precordial (V) lead at a time. Most bedside monitoring is now done using the five-lead system. The three-lead system is still used in the emergency rooms and when monitoring clients during procedures.

ST-segment monitoring is now being used in clients with a potential for ischemia (clients admitted with chest pain or unstable angina or clients having a surgical procedure who have a history of cardiac disease). This monitoring identifies any reocclusion to the affected heart vessels. If the 12-lead

ECG is not available, the American Association of Critical-Care Nurses recommends leads III and V3 for monitoring clients with acute coronary syndrome.

If the client has had a previous episode of ischemia, an ischemic fingerprint can be obtained. It is the unique pattern of ST-segment changes noted during a period of ischemia. This pattern is observed during an episode of chest pain or if the client undergoes balloon inflation during angioplasty. If the fingerprint is unknown, the best leads to use are III and V3 for the monitoring.

Refer to Chapter 33: *Advanced Nursing Skills for life-threatening dysrhythmias.*

Pacemakers

Pacemakers are electronic devices that stimulate the heart with electrical impulses to produce a heartbeat or to override an abnormally fast rhythm. Most commonly, a pacemaker is used for a slow heart rate (bradycardia) or when the conduction system within the heart is diseased and unable to maintain effective cardiac output due to conduction disturbances such as heart block. The use of a temporary or permanent pacemaker may be necessary to provide an electrical impulse to pace the heart when the inherent electrical system fails.

Temporary pacemaker A temporary pacemaker is inserted invasively to stimulate cardiac contraction until the underlying pathology is treated or a permanent pacemaker can be placed. Clients with temporary pacemakers require hospitalization with continuous monitoring. The pulse generator of the temporary pacemaker is located outside the body, and the leads are positioned to provide low-voltage electrical stimuli to the myocardium. The leads are positioned in one of several ways:

- The pacemaker wires are threaded percutaneously through the subclavian, external jugular, or femoral vein or through a cutdown in the brachial vein. The lead is advanced through the vena cava, to the right atrium, or advanced through the tricuspid valve and positioned in the right ventricle on the endocardial surface. The lead is then attached to the external pulse generator.
- During cardiac surgery, the pacing leads are attached to the outer surface of the heart (epicardially). This type has wires (electrodes) located in the lower chest and can be attached to an external pulse generator if pacing the heart postoperatively is necessary.

In emergency situations, such as in cases of symptomatic bradycardia, these external pacing pads are applied to the chest wall (transcutaneously), according to the manufacturer guidelines. The machine delivers approximately 25 joules of electricity through the pads to the heart, via the chest wall. These pacing pads resemble defibrillator pads.

Permanent pacemaker The decision to place a permanent pacemaker and the type of pacemaker selected depends on multiple factors, including:

- The exact nature and underlying cause of the conduction disturbance

- Whether the condition is temporary or permanent
- The presence or absence of symptoms and the impact on activities of daily living
- The potential risk for life-threatening dysrhythmias

Permanent pacemakers are intended for long-term use. The pulse generator is implanted into the subcutaneous tissue of the upper chest. The pacemaker leads are typically inserted into a major vein in the neck or shoulder (transvenously) and advanced into the right side of the heart until they are secured within the intended region(s) of the myocardium. The other ends of the leads are attached to the implanted pulse generator.

The pacemaker continuously monitors the heart's electrical activity and the type of pacemaker selected is designed to meet different needs. The three basic types of permanent pacemakers include:

- **Demand Pacemaker**—monitors the heart's natural rate and discharges an electrical impulse only when the rate falls below a programmed minimum rate.
- **Fixed-rate Pacemaker**—discharges a steady electrical impulse at a programmed rate, regardless of the underlying heart rate.
- **Rate-responsive Pacemaker**—increases or decreases the discharge electrical impulse rate (pacing rate) to meet the body's demands. The pacemaker monitors various physical changes in the body and alters the rate of discharge according to changes in the client's activity and rest.

Pacemakers can send electrical impulses to one or more chambers of the heart. These signals stimulate the heart to contract in a regular rhythm.

Types of Pacemakers

Types of pacemakers include atrial, ventricular, or dual-chamber pacemakers.

Single-chamber In a single-chamber pacemaker, one lead is located in either the right atrium or right ventricle. Atrial pacemakers are indicated when the SA node is diseased or damaged but the remaining conduction system through the heart is normal. A pacemaker spike precedes the P wave because the pacing electrode is placed within the atria. Ventricular pacemakers are indicated when conduction abnormalities occur above the ventricles. The pacing lead is located in the ventricle and when discharged results in a pacemaker spike before the QRS complex, producing a wide QRS complex because of the abnormal conduction pathway.

Dual-chamber In a dual-chamber pacemaker, two leads, one in the right atrium and one in the right ventricle, can monitor and initiate impulses to one or both chambers. The dual-chambered pacemaker can produce an atrial contraction followed closely by a ventricular contraction, thereby mimicking the normal cardiac cycle while preserving atrial contraction and thus ventricular filling.

Triple-chamber or biventricular pacing With this type of pacemaker, one lead in the right atrium, one in the right

▲ Permanent pacemaker: single chamber.

▲ Permanent pacemaker: double chamber.

ventricle, and one in the coronary sinus stimulate the lateral wall of the left ventricle. These pacemakers are inserted in clients who have a weakened myocardium (heart muscle) or a severely depressed myocardial function, causing problems with shortness of breath and inability to tolerate physical activity. With left ventricle enlargement, the wave of depolarization and repolarization is prolonged. Placing a third lead in the coronary sinus facilitates a coordinated wave of depolarization and repolarization simultaneously within the myocardium, allowing for the heart to contract in a more unified manner, thus improving the cardiac output.

ALTERATIONS IN CIRCULATION

The closed circulatory system is made up of the heart, arteries, veins, and capillaries. Alteration in the structure or function of any part of the system will result in impaired circulation. There are many ways to categorize circulatory disorders. For the purposes of this chapter, alterations in circulation will include hemorrhage, shock, pump failure, ischemia, thrombosis, and embolism.

Hemorrhage

Hemorrhage may occur when trauma or disease disrupts the closed circulatory system. Normally, when a blood vessel ruptures or is severed, compensatory mechanisms protect the body from significant blood loss. The wall of the injured vessel contracts immediately. A platelet plug forms at the site, blood clots, and new connective tissue penetrates the clot for permanent closure of the injured site.

For the client with hemorrhage, the nurse assesses the nature of the bleeding as external, internal, or both. An assessment is made to determine the body's response and establish baseline data, including vital signs and urinary output (see Table 31-1, Assessment Guide for Hemorrhaging). A priority of care is to monitor the client frequently and regularly and minimize the client's stress, thus decreasing the sympathetic

response. Sympathetic nervous system stimulation will increase heart rate (chronotropic effect) and force of contraction (inotropic effect), thereby increasing bleeding.

Interventions for clients who are hemorrhaging include restricting activity, elevating involved body areas above the heart if possible, applying direct pressure, and replacing lost fluid volume. A tourniquet is generally not used unless there has been a traumatic amputation, because a tourniquet crushes the underlying tissues and results in ischemia to the affected limb. But, if used, it is placed proximal to the site of the traumatic limb amputation.

Shock

Hemorrhage is the most common cause of hypovolemic shock, a potentially life-threatening condition, which is the most common cause of preventable post-injury deaths. Hypovolemic (hemorrhagic) shock means there is insufficient intravascular volume (insufficient venous return) to maintain adequate tissue perfusion. Rapid assessment of the client's hemodynamic status is mandatory. Level of consciousness (LOC), skin color, pulse, and urinary output are four elements that can be determined rapidly during clinical observation. LOC is impaired when blood flow to the brain is reduced because of lack of circulating blood volume. The earliest signs include anxiety, agitation, and dizziness coupled with orthostatic hypotension. Skin color is important to immediately assess because clients with pink skin are rarely critical, whereas clients with ashen gray facial color and/or a white exsanguinate extremity are ominous hypovolemic signs of shock. Pulse is determined by accessing central pulse, either the carotid or femoral artery, and assessing the quality, rate, and rhythm. If the client's pulse is slow, regular, and full, these are indications that the client is normovolemic, whereas if the pulse is rapid (tachycardic) and thready, then the client is hypovolemic, although other factors may also contribute to this sign. If the pulse is rapid and irregular, then cardiac dysfunction is occurring. This sign is a

signal for rapid assessment, immediate resuscitation measures, and rapid replacement of volume. Urinary output is a good indicator for kidney perfusion. If blood flow is normal to the kidneys, then hourly urine output is maintained greater than 30 mL/hr. However, if blood flow to the kidneys is compromised, the first indication is decreased urinary output less than 30 mL/hr.

Children, because of their remarkable physiologic reserve, display very minimal early signs of hypovolemic shock even after severe volume depletion. However, when symptoms are manifested in a child, these symptoms are precipitous and may be catastrophic.

Hemorrhagic shock occurs on a continuum. In the initial phases, there are subtle changes in the hemodynamic status of the client. However, as blood loss continues and the intravascular blood volume continues to decrease, organ involvement worsens because of lack of perfusion. For example, in the kidneys, the client initially becomes oliguric, but as the blood flow continues to be reduced to the kidneys, the client becomes anuric. The pulse gradually increases, whereas the blood pressure continues to drop precipitously. Eventually, if rapid interventions are not implemented immediately to stop this downward spiral of events, then death will be the eventual outcome.

TABLE 31-1 Assessment Guide for Hemorrhaging

1. Observable bleeding from skin, mucous membranes. Check under the person's clothing, dressing, casts.
2. Observable bleeding into the skin, mucous membranes. Check for petechiae, ecchymosis, hematomas, purpura.
3. Observable bleeding from body orifice. Check for epistaxis, hematemesis, hemoptysis.
4. Observable bleeding from tubes. Check drainage tubes, endotracheal tubes, suction drainage, urinary catheters.
5. Generalized signs and symptoms of bleeding.
 - a. Thirst.
 - b. Narrow pulse pressure.
 - c. Positional vital sign changes.
 - d. Low blood pressure (systolic below 90 mm-Hg and diastolic below 50 mm-Hg).
 - e. Tachycardia.
 - f. Weak pulses or absence of pulses.
 - g. Clammy skin and central cyanosis.
 - h. Deep, rapid respirations (above 24/min).
 - i. Low body temperature (one or more degrees below 98.6°F, or 37°C, oral temperature).
 - j. Reduced urine output (less than 30 mL/hr).
 - k. Behavioral changes.
 - l. Syncope and visual disturbance.
 - m. Loss of consciousness.

Interventions for Hypovolemic Shock

- Maintain airway.
- Place client in supine position.
- Administer supplemental oxygen.
- Keep client warm.
- Immediately establish two large-bore intravenous catheters—the loss of significant blood volume requires rapid infusion of at least 2–3 L of warmed intravenous solution.
- Fluid and blood replacement: isotonic crystalloids, such as Ringer's solution, are preferred over 0.9% normal saline to replace extracellular volume. Colloid solutions, such as blood transfusions or serum albumin, may also be given to expand intravascular space. Packed RBCs are used for acute blood loss.
- Drug administration: only occurs after adequate fluid replacement. Vasopressor agents, such as vasopressin, norepinephrine, or dopamine, may be given, if volume replacement is unsuccessful.

Heart Failure

Heart failure results from any condition that reduces the ability of the heart to effectively pump blood. When this occurs, the cardiac output is decreased, which impedes adequate blood flow to all tissues. Causes of heart failure are numerous, with coronary artery disease being the most common cause. Other causes of heart failure include valvular heart disease, myocardial infarctions, myocardial infections, and/or toxin.

Heart failure may involve either right, left ventricle, or both ventricles. Although most heart failure begins on the left side, as the disease process progresses, the right ventricle may become involved; this is known as *bi-ventricular failure*.

Do Not Use Trendelenburg Position

Placing shock clients in Trendelenburg position or a modified Trendelenburg position (client lying flat with the lower extremities raised) has not been proven to significantly raise the systolic pressure in prehospital hypotensive clients. Of the 30 articles written on Trendelenburg positioning, only 9 articles were peer reviewed. Trendelenburg or modified Trendelenburg did increase the risk of aspiration, and in cardiogenic shock clients, pulmonary edema worsened.

Additionally, although CVP and PAP pressures increase with Trendelenburg position, intrathoracic blood volume and cardiac function do not increase.

Source: Wesley, K. (2009). The myth of Trendelenburg position. *JEMS: A Journal of Emergency Medical Services*, April 5, 2009.

Source: Reuter, D. A., Felbinger, T. W., Schmidt, C., Moerstedt, K., Kilger, E., Lamm, P., & Goetz, A. E. (2003). Trendelenburg positioning after cardiac surgery: Effects on intrathoracic blood volume index and cardiac performance. *European Journal of Anaesthesiology*, 20(1), 17–20.

Cardinal manifestations of heart failure are dyspnea and fatigue, with limited activity tolerance. When the heart is unable to adequately pump, the blood begins to back up. In left-sided failure, the left ventricle is unable to pump effectively, which leads to the buildup of fluid in pulmonary capillaries, termed *pulmonary edema*. Pulmonary edema is the most common result of left ventricle pump failure and is a life-threatening condition. As fluids accumulate in alveoli of the lungs, gas exchange is impaired. Clinical manifestations of left-sided failure include dyspnea; moist, hacking cough; bibasilar crackles; distended neck veins; and orthopnea. Increased pulmonary vascular pressure may cause right-sided heart failure with resultant reduction of circulation into the pulmonary artery, causing a backup of fluid in the systemic venous circulation. Clinical manifestations of right-sided heart failure include weight gain, peripheral edema, oliguria, hepatomegaly, ascites, and fatigue.

The goal of treatment for heart failure is to reduce workload on the heart, increase efficiency of contractions, and reduce fluid retention. Both physiological and pharmacological interventions are necessary to meet this goal. Bedrest during the most critical time may be ordered to reduce the workload on the heart. Oxygen therapy is essential to maximize the oxygen available to the tissues, as well as both reduced sodium intake and restricted fluid intake to decrease fluid volume and edema. Pharmacological interventions include:

- Diuretics—furosemide, spironolactone
- Nitrates—nitroglycerine because of vasodilating properties
- Antihypertensive agents
- Angiotensin-converting enzyme (ACE) inhibitors
- Antidysrhythmics, if needed
- Inotropic medications—digitalis
- Beta-blockers
- Potassium chloride (KCl)—client cannot be on potassium-sparing diuretics, such as spironolactone

Ischemia

Tissue ischemia results when blood flow is reduced to a critical level. Hypotension can cause relative ischemia because blood flow is insufficient to meet the metabolic demands. Absolute ischemia is usually due to a sudden, complete occlusion of a blood vessel, resulting in tissue necrosis. Leaving a tourniquet on an extremity for more than 15 minutes may cause tissue necrosis. Other causes of ischemia due to decreased blood flow include Raynaud's disease, Buerger's disease, thromboembolism, mechanical obstruction, arteriosclerosis, and atherosclerosis.

Deep Vein Thrombosis (DVT)

Venous thromboembolism is a frequent cause of preventable illness and death in hospitalized clients. The incidence of DVT in clients without DVT prophylaxis is unacceptably high in both surgical and medical hospitalized clients. As a result, this is considered a high client safety indicator by The Joint Commission, the Agency for Healthcare Research and Quality (AHRQ), and the Center for Medicare and Medicaid Services because of the underutilization of simple, cost-effective prophylactic measures.

Most hospitalized clients, whether medical or surgical, have multiple risk factors for developing deep vein thrombosis. Risk

factors include thrombophilia; hypercoagulability states regarding clotting factors; cancer; obesity; pregnancy; smoking; surgery; trauma; head injury; medications (birth control pills, hormone replacement therapy, tamoxifen); surgical conditions involving the hip, pelvis, or knee; prolonged sitting for more than 6 hr in aircraft; or when on bedrest.

The exact incidence of deep vein thrombosis is unknown because most studies are limited by the inaccuracy of clinical diagnosis. The known data probably underestimate the true incidence of DVT and suggest that about 80 cases per 100,000 population occur annually. Approximately 1 person in 20 will develop a DVT during their lifetime. Approximately 600,000 hospitalizations per year in the United States occur from DVTs. The incidence of hospitalized clients experiencing DVTs varies from 20%–70%.

The classic symptoms of a DVT, if present, include swelling, pain, warmth, and redness in the involved extremity. Some may experience a dull ache or tightness in the calf upon walking, and may show slight edema, a palpable cord, venous collateral distention, low-grade fever, cyanosis, and a positive Homan's sign. Homan's sign, which was previously a mainstay for the diagnosis of DVT, is no longer considered accurate. It is present in less than one-third of clients with confirmed DVTs and is found in more than half of clients without DVTs.

Hypercoagulable state, thrombophilia, venous stasis, and vascular (endothelial) injury are factors that may lead to platelet aggregation, fibrin, WBC and RBC deposition, and eventual formation of a free-floating clot. In 80% of cases clots begin in deep veins of the calf. Within 7 to 10 days, the clot adheres to the vein wall, phlebitis develops, the clot is invaded by fibroblasts, scar is formed, and blood flow is restored, but the vein valves are usually permanently damaged. The clot propagates proximally; pieces can break off and embolize to the heart and obstruct the pulmonary circulation, with resultant right heart failure, atelectasis, hypoxemia, decreased cardiac output, or cardiac arrest.

DVT prophylaxis is indicated for all moderate- to high-risk medical and surgical clients. Low-molecular-weight heparin and unfractionated heparin decrease incidence of asymptomatic or symptomatic DVT and pulmonary emboli by 50%–65%.

Compression stockings, also known as TED hose, reduce venous stasis and reduce the incidence of postoperative venous thrombosis in low-risk surgical patients and moderate-risk neurosurgical clients. Mechanical devices (sequential compression devices [SCDs]) prevent venous thrombosis by improving blood flow through the deep leg veins, which prevents venous

DVT Statistics for Hospitalized Clients

50–70% of clients hospitalized with venous thromboembolism occur on the medical services. In hospitalized, high-risk clients not receiving prophylaxis, DVT was diagnosed by means of a venography in 10.5 to 14.9% of patients. Additionally, in high-risk surgical clients, without DVT prophylaxis, 20% of patients undergoing hip or knee arthroplasty or hip surgery developed proximal DVT. Proximal DVT, meaning proximal in a limb, is the most life threatening as this frequently leads to pulmonary embolism.

stasis. Additionally, SCDs reduce plasminogen activator inhibitor, which increases fibrinolytic activity, although the exact mechanism is not known. SCDs are effective in reducing the incidence of DVT in moderate-risk surgical clients, including neurosurgical and coronary artery bypass clients. They are not as effective in calf vein thrombosis in orthopedic surgical clients. SCDs are beneficial when used in conjunction with anticoagulant therapy. Other interventions to prevent development of DVT in bedrest clients include:

- Assessment of risk factors
- Early ambulation
- Adequate hydration
- Foot and leg exercises while in bed
- Minimal interruptions during application
- Accurate assessment, measurement, and application of devices

NOTE: These measures help venous flow, but do not decrease the incidence of pulmonary embolism.

The goal of treatment for *existing* thrombophlebitis is to prevent clot propagation, pulmonary emboli, and thrombus recurrence. Care interventions include early ambulation, avoidance of rubbing or massaging the affected extremity, and adequate hydration. Pharmacological (systemic) intervention includes anticoagulation with heparin drip to a goal of 1.5 to 2 times normal PTT, or use of low-molecular-weight heparin to stop propagation of the clot. This is followed by oral warfarin therapy for 3 or 6 months or longer, with a therapeutic international normalized ratio goal of 2.0 to 3.0.

ALTERED CIRCULATION

Assessment

Alterations in circulation are indicated by a variety of signs and symptoms. If bleeding exists, external and/or internal sites must be identified. Attention is given to disease conditions of major organs or coagulation and the family history. Although a variety of sophisticated devices are available to monitor the client's circulatory status, direct observation is also reliable. Baseline data are obtained for vital signs and arterial blood pressure. Note the color, temperature, and condition of the skin. Abnormalities of superficial veins often indicate obstruction or pooling. Additional assessment data include:

- Vein distention
- Edema (fluid retention)
- Petechiae (platelet abnormalities)
- Homan's sign (calf tenderness with dorsiflexion); positive in less than 50% of cases; therefore, not frequently used

Information obtained from the client's medical history, medications, and lifestyle influences selection of nursing interventions. Trauma victims require especially close inspection since more overt signs and symptoms may not appear until days later. Table 31-1 illustrates an assessment of a hemorrhaging client.

Emergency Life Support Measures

The 2010 American Heart Association Guidelines for Cardiopulmonary Resuscitation (CPR) and emergency cardiovascular care (ECC) are recommendations designed to improve

survival from sudden cardiac arrest and acute life-threatening cardiopulmonary incidents. According to the AHA, *basic life support* includes recognition of signs of sudden cardiac arrest (SCA), myocardial infarction (heart attack), cerebral vascular accident (stroke), and foreign-body airway obstruction (FBAO); cardiopulmonary resuscitation (CPR); and defibrillation with an automated external defibrillator (AED).

The 2010 Guidelines focus on giving chest compression first to keep the blood and the oxygen in the blood flowing to the heart and brain. Chest compressions act like an artificial heart by pumping blood to the heart and brain.

There is a significant amount of oxygen in the bloodstream capable of sustaining brain tissue for several minutes even without breathing. Many who believe doing only chest compressions is sufficient for adequate blood flow feel that interrupting compressions with rescue breathing doesn't allow oxygen to reach vital organs.

Studies published in the American Journal of Medicine and The Lancet have shown that there is a better outcome of victims who had only chest compressions. Not all cardiac arrests are from heart disease. Victims of drowning, drug overdose, or respiratory problems that lead to cardiac arrest will need rescue breathing.

To provide the victim with the best chance of survival these actions must occur within the first moments of a cardiac arrest.

- a. Activate the EMS System (Emergency Medical Services) by calling 911.
- b. Begin chest compressions at 100 compressions/minute with a depth of at least 2 inches in the adult client.
- c. Send for and initiate the Automated External Defibrillator.

The new CPR Guidelines are termed CAB: compression, airway, breathing. This replaces the ABCs of CPR.

Use of airway devices by trained medical personnel will deliver air to the lungs rather than the stomach, greatly reducing complications such as aspiration and pneumonia. Mouth-to-mouth resuscitation is not done with the new guidelines if the rescuer is not trained in CPR, or they do not want to do it.

After 30 compressions, the trained CPR individual will open the victim's airway using the head-tilt, chin lift method. After pinching the nose and making a seal over the victim's mouth give the victim a breath big enough to make the chest rise. It is recommended that the rescuer use a CRP mask when performing rescue breathing.

Infants and children may still require mouth-to-mouth resuscitation by a trained CPR individual as breathing issues are more common in this age group. Lay personnel are now trained to do compression only CPR.

The American Heart Association guidelines place priority on caring for victims of stroke as well as those with an acute myocardial infarction (MI). Early fibrinolytic treatment for the MI client is necessary; also, clients with a stroke require treatment within 3 hr of onset of symptoms for a quality outcome. EMS personnel are trained to provide stroke screening tools and then rapidly transport stroke clients to the nearest hospital where fibrinolytic therapy can be administered within 1 hr of arrival at the facility.

The *Automated External Defibrillator* (AED) is a battery-operated computerized defibrillator that analyzes the heart rhythm, recognizes a shockable rhythm, and advises the operator when

TABLE 31-2 Summary of Basic Life Support ABCD Maneuvers for Infants, Children, and Adults (Newborn Information Not Included)

Maneuver	Adult 8 Years and older	Child 1 Year to 8 Years	Infant Under 1 Year of Age
Compression landmarks	Lower half of sternum (center between the nipples to prevent compression over the xiphoid)		Just below nipple line (lower half of sternum)
Compression method Push hard and fast Allow complete recoil	Heel of one hand, other hand on top	Heel of one hand or as for adults	2 or 3 fingers (2 rescuers): 2 thumb-encircling hands
Compression depth	2 in.	2 in.	1.5 in.
Compression rate	Approximately 100/min		
Compression-ventilation ratio	30:2	30:2	
Airway	Head tilt–chin lift (suspected trauma, use jaw thrust)		
BREATHING Initial	2 breaths at 1 second/ breath, after 30 compressions Use CPR mask	2 effective breaths at 1 second/breath, after 30 compressions	
HCP: Rescue breathing without chest compressions	10 to 12 breaths/min (approximate)	12 to 20 breaths/min (approximate)	
HCP: Rescue breaths and CPR with advanced airway	30 compressions, 2 breaths	1 breath every 3–5 seconds	
Foreign-body airway obstruction	Abdominal thrusts		5 Back blows 5 chest thrusts
Defibrillation AED	Use adult pads Witnessed: Use AED, shock as indicated Unwitnessed: AED after 5 cycles of CPR	Use AED after 5 cycles of CPR (out of hospital) Use child pads for child 1 to 8 years if available HCP: For sudden collapse (out of hospital) or in-hospital arrest use AED as soon as available.	No recommendation for infants

Note: Maneuvers used by only healthcare providers are indicated by “HCP.”

Source: Field, J. M., Hazinski, M. F., & Gilmore, D. (2006). *Handbook of Emergency Cardiovascular Care for Healthcare Providers*, Guidelines CPR/ECC, p. 1. Dallas, TX: American Heart Association.

Note: The American Heart Association (2010) announces new CPR sequence in 2010 AHA Guidelines for CPR and Emergency Cardiovascular Care: No more A-B-Cs, now C-A-B.

the victim should be shocked. Outside the hospital facility, AEDs should be accessible in areas where there is a high probability of cardiac arrest situations and when EMS is 5 minutes or more away from the location. Laypersons, properly trained, can recognize signs of cardiac arrest and apply and operate the AED.

Early Defibrillation Programs in Hospitals

The American Heart Association standard-of-care recommendation is that the collapse-to-shock interval be less than 3 minutes in all areas of the hospital and ambulatory care facilities. Even though emergency (crash) carts with defibrillators are available in hospitals, Automated External Defibrillators (AEDs) should be available on the nursing units if the cart is more than 3 minutes away. It is estimated that time from collapse to first defibrillation in hospitals can be 5 to 10 minutes.

The major benefit for AED usage throughout noncritical care units within the hospital is that other healthcare providers and noncritical care nurses can easily provide defibrillation within the AHA standard of 3 minutes. Every minute is crucial if the person is in ventricular fibrillation, the most common cause of sudden death in adults. Survival decreases 7%–10% for each minute that defibrillation is not completed.

Planning and Intervention

Once an initial assessment of a client for alterations in circulation has been made, the nurse develops a plan of care and prioritizes interventions. Interventions for circulatory problems usually fall into three broad categories: inputs, outputs, and pressure supports. Inputs include arterial lines, venous lines, fluids, drug regimens, transfusions, and blood component therapies. Outputs include suctioning with specialized equipment such as

Hemovac and chest tubes and procedures such as thoracentesis. Pressure supports include dressings, direct compression, tourniquets, and cardiopulmonary resuscitation. An evaluation of the planned actions, based on the client's response, should be continuous and modified as the client's condition dictates.

In coping with alterations in circulation, care should be directed toward promoting, maintaining, or regaining the best possible cardiopulmonary function. The design for nursing action is to assess the situation and client for stressors. The client should be interviewed if possible, observed, and examined to identify actual and/or potential circulatory problems. The client's responses are appropriate, deficient, or excessive, and interventions should be planned accordingly. The nurse attempts to reduce client stress, supports adaptive behaviors, replaces deficiencies, modifies or removes excessive responses, and prevents injury and complications. The nurse should always assist in the evaluation of planned actions, report client responses, and assist in modifying the interventions as indicated.

Adaptations to Home Care

Circulatory skills performed in the home setting are similar to those in the hospital. Vital signs are taken using the same equipment and procedures. CPR and Heimlich maneuver are performed exactly the same way. Care of the pacemaker client, however, is somewhat different.

Clients with permanent pacemakers are expected to monitor pacemaker function on a daily basis. While in the hospital, the client is taught how to monitor pulse, vital signs, symptoms of pacemaker failure, and indications of infection at the pacemaker insertion site. When the client returns home, the home health nurse needs to reinforce the teaching that was initiated in the hospital.

The client should be taught to monitor the pulse daily on awakening to identify altered pacemaker function. This may indicate a need for a battery change earlier than scheduled. Normally, lithium batteries last 6 years or more, whereas mercury-zinc batteries last 5 years. Nuclear-powered pacemakers (plutonium-238) can last 20 years or more. Some batteries can be recharged externally.

The generator is usually placed in the abdominal subcutaneous tissue or under the clavicle on the left side where the

outline of the generator can be easily observed. The client must be taught to assess the site during the postoperative period for erythema, edema, and warmth, which may indicate the presence of infection.

A periodic telephone pacemaker check may be used for clients living in rural settings or in areas where a cardiologist is not easily available with the longer lasting batteries. The client usually does not need to check the pacemaker unless there are indications that alterations in the pulse or other symptoms are occurring. Heart sounds can be transmitted via telephone signals and recorded on an ECG strip. The technician at the clinic compares a baseline ECG strip that is on file with that of the newly recorded ECG. If there are any alterations from normal, the client is asked to call his or her physician, and the technician also notifies the physician. This procedure identifies early pacemaker dysfunction and aids in preventing complications. New pacemakers usually do not need to be checked except with routine physician visits.

For client safety, it is imperative to stress the importance of having someone present while checking for pacemaker malfunction when a magnet is used. The telephone number of the pacemaker clinic should be kept readily accessible in case of an emergency situation, particularly when testing the magnet.

New “wireless pacemakers” are available. It has a small radio transmitter inside the pacemaker that talks to a base station attached to a phone. The physician can more easily and quickly evaluate the pacemaker function in his office. Most clients do not use this system; they are checked during a routine physician's office visit.

A Holter monitor, also called an ambulatory electrocardiology (ECG) monitor, is a small battery-operated device that the client wears. The monitor shows the heart's electrical activity while the client performs usual activities. The monitor will show how fast a heart beats, and if it beats in a regular pattern. If the client has a heart problem, the signals in the heart may not function properly, resulting in vertigo, chest pain, or death. As with the pacemaker, the Holter monitor is now being replaced by Event Monitoring and Signal-Averaged ECG monitoring. These monitors can measure the heart function periodically and do not necessarily measure only for 24–36 hr.

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to use on a client care plan when the components are related to circulation.

NURSING DIAGNOSIS	RELATED FACTORS
Decreased Cardiac Output	Cardiac disease states, altered electrical conduction, altered contractility, altered preload and afterload drug side effects, hypovolemia
Deficient Fluid Volume	Blood loss from hemorrhage, dehydration
Ineffective Peripheral Tissue Perfusion	Altered blood supply, arterial or venous, hypovolemia, shock
Impaired Gas Exchange	Ventilation–perfusion imbalance, abnormal blood gases, tachycardia
Excess Fluid Volume	Compromised regulatory mechanism, heart failure
Deficient Knowledge	Understanding pacemaker function, corrective lifestyle habits for heart failure

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. Remember to perform hand hygiene or use antibacterial gel before and after each and every client contact.

IDENTIFY CLIENT Before every procedure, check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Chapter 31

UNIT 1

Control of Bleeding

Nursing Process Data

ASSESSMENT Data Base

- Observe the amount of bleeding.
- Check for the source of bleeding.
- Observe the extent of the wound.
- Identify familial history of bleeding disorders.
- Assess baseline vital signs and blood pressure readings.
- Observe color, temperature, and condition of the skin.
- Current medications taken by client.

PLANNING Objectives

- To detect source of bleeding
- To stop or control bleeding or hemorrhage before large blood loss occurs
- To provide pressure as an assist (adjunct) to stop bleeding
- To minimize capillary seepage, hematoma, and serum accumulation

IMPLEMENTATION Procedures

- Using Digital Pressure1237
- Using Pressure Dressing1237

EVALUATION Expected Outcomes

- Early detection of bleeding occurs and loss of blood is minimized.
- Pressure dressing is applied and bleeding is controlled.
- Peripheral circulation is preserved.
- Vital signs are within normal limits.

Critical Thinking Application1238

- Expected Outcomes1238
- Unexpected Outcomes1238
- Alternative Actions1238

 and Skill Checklists

Using Digital Pressure

Equipment

- Towels or gauze dressing if available
- Gloves

Procedure

1. Perform hand hygiene and don gloves (sterile preferred).
2. Identify the closest artery proximal to the bleeding site.
 - ▶ **Rationale:** The rapid loss of more than 40% of the total blood volume will lead to death if rapid aggressive intervention is not implemented.
3. Apply direct pressure to artery using your gloved finger.
4. If towels or 4 × 4 gauze pads are available, apply direct pressure to site if wound does not contain glass particles.
 - ▶ **Rationale:** If pressure is placed on wound when glass is present, additional tissue damage can occur.
5. Raise the affected limb above the level of the heart about 30°.
 - ▶ **Rationale:** This decreases arterial blood flow to area and promotes venous return.
6. Maintain direct pressure on site for 5 minutes.
 - ▶ **Rationale:** This action promotes clot formation.
7. When bleeding has subsided, proceed to gently clean and dress the wound.
8. To control nose bleeds (epistaxis), place client in sitting position, with head tilted forward. Pinch nose for 5 minutes. Apply ice pack to back of neck.
 - ▶ **Rationale:** This assists in vasoconstriction.
9. Remove gloves when bleeding subsides.
10. Perform hand hygiene immediately.
 - ▶ **Rationale:** To protect yourself from possible contamination should any leakage have occurred through the gloves.

▲ Pulse sites that may be used to control bleeding.

Clinical Alert

Determine whether individual is receiving medications or herbal therapies which affect blood coagulation (e.g., Coumadin). If so, increase time of applying pressure.

Using Pressure Dressing

Equipment

- 4 × 4 gauze pad
- Sterile dressings—number and size depend on wound
- Sterile gloves
- Cleansing solution
- Tape

Preparation

1. Check physician's orders.
2. Assemble necessary supplies according to extent of wound.
3. If time permits, explain procedure to client and provide light and privacy.

4. Perform hand hygiene thoroughly if time permits.
5. Set up sterile field and prepare cleansing solution if time permits.

Procedure

1. Put on sterile gloves.
2. Cleanse wound and apply dressing. Use several layers of 4 × 4 gauze pads.
3. Place tape tightly over entire dressing to provide an occlusive dressing. Do not completely circle an extremity or the body.
 - ▶ **Rationale:** Encircling an extremity with a bandage acts like a tourniquet and may prevent blood flow.

4. Check for pulses distal to pressure site. ▶ **Rationale:** To ensure that collateral blood flow is maintained.
5. Place all soiled materials in biohazard bag. ▶ **Rationale:** To prevent cross-contamination and ensure proper disposal.
6. Remove gloves and perform hand hygiene.
7. Monitor vital signs and observe for signs of shock.

8. Continue to monitor extremity distal to pressure dressing. ▶ **Rationale:** Ensures adequate circulation.
9. Position client for comfort.
10. Elevate extremity ▶ **Rationale:** To minimize bleeding.
11. Monitor frequently for signs of bleeding and hematoma.

NOTE: Hematomas feel spongy even under bandages.

DOCUMENTATION for Control of Bleeding

- Size (in centimeters), location based on anatomical landmark, condition of wound
- Color, odor, amount of drainage
- Type and number of dressings used
- Approximate amount of blood loss
- Condition of dressing when removed (e.g., saturated with drainage)

CRITICAL THINKING Application

Expected Outcomes

- Early detection of bleeding occurs and loss of blood is minimized.
- Pressure dressing is applied and bleeding is controlled.

- Peripheral circulation is preserved.
- Vital signs are within normal limits.

Unexpected Outcomes

Even with direct pressure and application of pressure dressing, bleeding continues.

Alternative Actions

- Reinforce pressure dressing.
- Maintain IV infusion.
- Notify physician and be prepared to send client to surgery for wound closure.
- Monitor closely for signs of shock (LOC, vital signs, oliguria or anuria, tachycardia, narrow pulse pressure, hypotension).
- Apply pressure directly or proximal to wound.
- Place tourniquets proximal to site of hemorrhage to control bleeding if all other actions are unsuccessful, notify physician immediately, and prepare for surgery.

Wound edges do not approximate.

- Notify physician.
- Be prepared to assist with wound closure or to send client to surgery.

Glass particles are evident in wound.

- Irrigate wound profusely with sterile saline solution as ordered.
- If large amount of glass or if glass is difficult to extract, notify physician, and be prepared to send client to surgery for wound cleansing and debridement.
- Do not apply direct pressure or pressure dressing to wound containing glass.

Circulatory Maintenance

Nursing Process Data

ASSESSMENT Data Base

- Evaluate client’s overall physical status, particularly client’s risk for venous thrombus formation.
- Assess baseline vital signs before procedures are initiated.
- Determine whether client is at risk for pooling of blood in extremities or decreased venous return. Clients who require use of graduated stockings or sequential compression devices are postoperative clients, those who are immobile, and those with a history of venous insufficiency.
- Assess peripheral pulses, observing skin color and temperature, and fluid accumulation or edema.
- Compare findings with contralateral extremity.

PLANNING Objectives

- To prevent venous stasis
- To prevent thrombus formation and subsequent emboli
- To use compression stockings or sequential compression devices to prevent venous stasis

IMPLEMENTATION Procedures

- Applying Graduated Compression Stockings (Elastic Hosiery)1240
- Applying Pneumatic Compression Devices1241
- Applying Sequential Devices (SCDs)1242

EVALUATION Expected Outcomes

- Compression stockings remain wrinkle-free and pressure is evenly distributed.
- Peripheral pulses are present during use of sequential stockings and elastic hosiery.
- Compression devices function properly.
- Client’s skin remains intact while using compression stockings.

Critical Thinking Application1244

- Expected Outcomes1244
- Unexpected Outcomes1244
- Alternative Actions1244

 and Skill Checklists

Applying Graduated Compression Stockings (Elastic Hosiery)

Equipment

- Tape measure
- Specific type of hosiery (e.g., below-the-knee or above-the-knee)

Preparation

1. Check physician's orders for type and specifications.
2. Gather supplies, identify client, and explain procedure.
3. Perform hand hygiene, and provide for client's privacy and comfort.
4. Apply drape as top linens are removed. Bathe and ensure legs are dry before applying stockings.
5. Assess lower extremities for edema, dry skin, and palpable pulses.
6. Position client in dorsal recumbent position, and elevate bed to working height.
7. Measure client for hosiery size (Table 31-3). Length is determined by measuring distance from gluteal fold to bottom of the heel.
 - a. For thigh-high stockings, measure midcalf and midhigh circumference to determine size.
 - b. For below-the-knee stockings, measure from the Achilles tendon to the popliteal fold, and measure the midcalf circumference.
8. Compare your measurements with manufacturer's chart to obtain correct hose size.

Procedure

1. Invert foot of stocking back to heel area.
2. Holding both sides of hose at inverted foot area, pull hose over toes and ease gently toward top of foot.
3. Gather top of hose down to heel area, and with curving motion, cover heel. Pull hose up leg, positioning support section on inner thigh.
4. Reposition client, lower bed, and perform hand hygiene.
5. Observe that stockings are wrinkle-free and correctly placed on extremity. ► **Rationale:** Stockings tend to roll down and create a tourniquet effect that inhibits venous return.

▲ Gather elastic hose and pull over toes and then to top of foot.

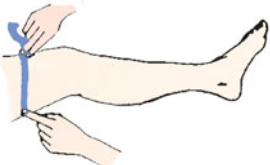

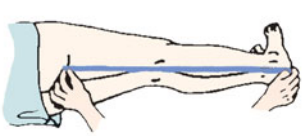

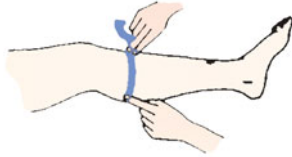

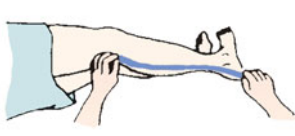

6. Check client in 30 minutes for adequate circulation, assessing for warmth, color of feet, blanching of nail beds, and edema above level of stockings.
7. Remove hose two to three times daily for 30 minutes. Assess skin integrity and peripheral circulation and perform neurovascular checks (CMS).
8. Wash hose in mild detergent and warm water daily and hang to dry.

NOTE: A second pair of hose should be available to use when hose are drying.

Effectiveness of Graduated Compression Stockings

Compression stockings, whether alone or in combination with anticoagulation, are beneficial for the reduction of post-thrombotic syndrome (PTS), a sequelae of events that occur after a DVT. The research supporting the use of compression stockings in the prevention of DVT in moderate- to high-risk clients is variable and inconclusive. The data do not support the use of compression stockings for DVT reduction, only for reduction of PTS. In low- or moderate-risk clients, compressive stockings may be of benefit. Stockings reduce stasis and PTS. They are inexpensive and have minimal side effects if applied properly.

TABLE 31-3 Measuring for Graduated Compression Stockings (Elastic Hosiery)

Thigh-High Measuring		Knee-High Measuring	
Circumference	Length	Circumference	Length
Measure mid-thigh circumference	Measure leg from bottom of heel to fold of buttocks	Measure calf at largest circumference	Measure leg from Achilles tendon to popliteal fold
			

▲ Ensure hose fits properly without wrinkles over toe or heel.

▲ Position support section on inner thigh.

EVIDENCE-BASED PRACTICE

Compression Stockings—Safe Practice Issues

This study explored the use of graduated compression stockings and found that poorly fitting hose can be a direct cause of DVT and of pressure ulcers on heels and the top of foot due to tourniquet effect. Thigh-length hose are more difficult to apply and more apt to wrinkle and are less comfortable. Clients often complain of stockings being painful, hot, and itchy. It is important that nurses measure the client's legs for correct fit, assess extremities regularly, and encourage compliance through client education.

Source: Hayes, J., Lehman, C., & Castoguy, P. (2002). Graduated compression stockings: Updating practice, improving compliance. *MEDSURG Nursing*, 11(4), 163.

In a randomized controlled clinical study, 180 clients, after their first episode of asymptomatic proximal DVT, received conventional therapy and were randomly assigned to wear or not to wear knee-high compressive stockings for 2 years after the initial DVT event. The results revealed that PTS was reduced by 50% when below-the-knee compressive stockings were worn as compared with the control group.

Source: Prandoni, P., Lensing, A. W., Prins, M. H., Frulla, M., Marchiori, A., Bernardi, E.,... & Girolami, A. (2004). Below the knee elastic compression stockings to prevent post-thrombotic syndrome: A randomized, control trial. *Annals of Internal Medicine*, 141(4), 249–256.

Applying Pneumatic Compression Devices

Equipment

- Disposable leg sleeve(s): knee length or thigh length
- Tubing assembly
- Compression controller (motor)
- Measuring tape

Preparation

1. Review physician's orders for type of disposable leg sleeve needed.
2. Identify client and explain that this device decreases the risk of developing deep-vein thrombosis (DVT) for clients after surgery or those on long-term bedrest.
 - ▶ **Rationale:** This device counteracts blood stasis by increasing peak blood flow velocity. It helps to carry pooled blood from vein.

3. Assess client for potential problems and contraindications for use of these devices. ▶ **Rationale:** Clients with ischemic conditions, massive edema of the leg, dermatitis, gangrene, on long-term bedrest, or with preexisting DVT within last 6 months are not candidates for these devices.
4. Complete a neurovascular assessment. Include an evaluation of skin color, temperature, sensation,

Clinical Alert

Postoperative deep vein thrombosis of the lower extremity is often asymptomatic, and in many clients a fatal pulmonary embolism is the first clinical sign of postoperative venous thromboembolism.

Source: Agnelli, G. (2004). Prevention of venous thromboembolism in surgical patients. *Circulation*, 110(24 Suppl 1), IV4–IV12.

Clinical Alert

In hospitalized high-risk clients not receiving prophylaxis, DVT was diagnosed by means of venography in 10.5% to 14.9% of clients. Additionally, in high-risk surgical clients without DVT prophylaxis, 20% undergoing hip or knee arthroplasty or hip surgery developed proximal DVT. If DVT occurs at the proximal end of a limb, it is more life-threatening, as this frequently leads to pulmonary embolism.

Source: Francis, C. W. (2007). Prophylaxis for thromboembolism in hospitalized medical patients. *New England Journal of Medicine*, 356(14):1438–1444.

capillary refill, and presence and quality of pedal pulses. Document findings. ► **Rationale:** This assessment provides baseline data for evaluating neurovascular changes while devices are used.

5. Assemble equipment. Read manufacturer's directions for connecting and operating compression controller.
6. Read directions for setting sleeve pressure (between 35 and 45 mmHg). Maximum pressure should not exceed client's diastolic pressure.
7. Locate and identify the indicator lights on the controller for the ankle, calf, and thigh pressure.
 - **Rationale:** Light is on when the pressure is applied to the three leg sleeves.

Procedure

1. Remove sleeve from plastic bag.
2. Unfold sleeve and follow directions to fit sleeve to client's leg. Leg is placed on white side (lining) of sleeve. Markings on the lining indicate the ankle and popliteal area.
3. Place client's leg on sleeve. Position back of knee over popliteal opening.
4. Starting at the side, wrap sleeve securely around client's leg.

5. Attach Velcro straps securely.
6. Check the fit by placing two fingers between client's leg and sleeve to determine whether sleeve fits properly. Readjust Velcro as needed. ► **Rationale:** To ensure sleeve does not constrict circulation.
7. Attach tubing and connect to plugs on leg sleeve by pushing ends firmly together.
8. Connect tubing assembly plug to controller at the tubing assembly connector site.
9. Ensure tubing is free of kinks or twists. ► **Rationale:** Kinks and twists can restrict airflow through system.
10. Plug controller power cable into grounded electric outlet and attach unit to bed frame.
11. Turn controller power switch to ON. Monitor that alarms are audible.
12. Check that pressure indicator lights are functioning properly.
13. Monitor that compression cycles are correct.
14. Monitor neurovascular checks every 2–4 hr. Turn machine off immediately if the client complains of numbness or other signs of DVT.
15. Monitor client's tolerance of device.
16. Turn off machine at prescribed time intervals to assess skin and to provide skin care.
17. To remove sleeve, turn power switch OFF, and disconnect tubing assembly from sleeve at connection site. Unwrap sleeve from leg.

Clinical Alert

Follow hospital policy for amount of time alternating pneumatic compression devices are removed during the day. The effectiveness of the mechanical device is dependent on appropriate fitting and being consistently applied, with minimal interruptions, in order to prevent clot formation.

Applying Sequential Compression Devices (SCDs)**Equipment**

Disposable leg wraps (knee- or thigh-length) or foot wraps
Tubing set
Pump controller

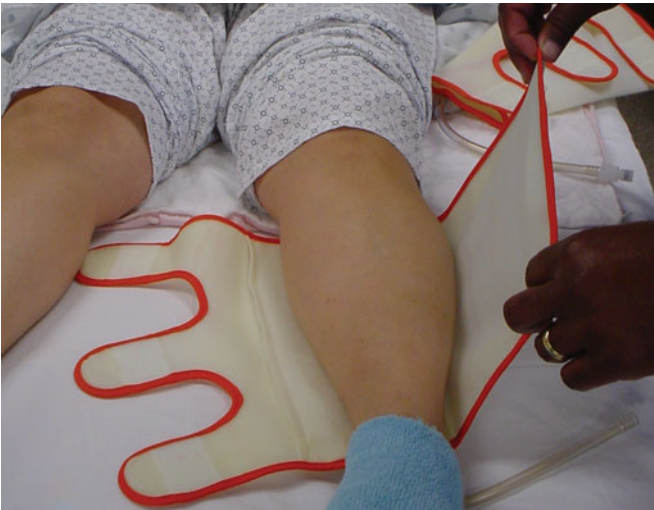

Preparation

1. Review physician's order for type/length of SCD.
2. Determine that device is not contraindicated for client (see box on page 1244).
3. Review product information for application and use.

4. Gather equipment.
5. Perform hand hygiene.

Procedure

1. Introduce yourself and identify client.
2. Provide privacy.
3. Perform neurovascular assessment noting circulation, motion, and sensation in lower extremities.
 - **Rationale:** To provide a baseline of ongoing assessment of neurovascular status after devices are in place.

▲ Place inflatable bladder directly behind client's calf.

▲ Slip two fingers under wrap to ensure that it is not too tight.

▲ Attach tubing from wrap to tubing connected to pump.

4. Explain the purpose of the sequential compression device:
 - a. They are used to reduce risk of developing deep vein thrombosis by improving blood flow through the leg veins.
 - b. The wraps must be used continuously (unless ambulating) in order to be effective.
5. Plug the pump into the electrical wall outlet but leave unit turned *off*.
6. Remove wraps from plastic bag (leg wraps and foot wraps can be used on either leg).
7. Connect tubing set to the pump, making certain a connecting click is heard.
8. Unfold wrap and place the inflatable bladder directly behind client's calf.
9. Wrap the device around client's leg and secure the fastener tabs. Repeat process on other leg.
10. For foot (venous plexus) wraps (see photo of foot pump):
 - a. Place foot in center of wrap with back of wrap in line with client's heel.
 - b. Bring large wrap over top of foot, holding it in place.
 - c. Bring the two narrower wraps over foot and secure.
 - d. Bring the heel strap around back of heel and fix in place to secure wrap.
11. Check that wrap is not too tight by slipping two fingers underneath. ► **Rationale:** To validate that wraps do not constrict circulation distally.
12. Attach the wraps to the tubing set, making certain a connecting click is heard.
13. Adjust pump pressure regulator to product-recommended pressure (130 mmHg pressure, with 3 seconds inflation phase and 30 seconds cycle time), or as physician has ordered. ► **Rationale:** Intermittent compression and relaxation reduces venous stasis and thus improves the body's natural fibrinolytic activity.
14. Ensure that tubing is free of kinks. ► **Rationale:** Kinks can restrict airflow through the system.
15. Turn the pump on, noting that green light illuminates.
16. Place client in position of comfort; place call bell in reach.
17. Inform client to notify nurse if tingling, numbness, or discomfort develops. ► **Rationale:** Wraps should be removed should any of these occur.
18. Perform hand hygiene.
19. Regularly remove wraps for skin inspection and neurovascular assessment.

Compression Pattern

Each sleeve in the sequential devices is inflated in sequence. The inflation begins at the ankle and progresses to the knee or mid-thigh. Pressures range from a maximum pressure in the ankle of 45–50 mmHg, 35 mmHg at the calf, and 30 mmHg at the thigh. Compression duration is 11 seconds, with a 60-second relaxation time between compressions.

For intermittent devices, sleeve inflates, then deflates, alternating from one leg to the other.

Clinical Alert**Contraindications to Use of Sequential Compression Devices**

- Known or suspected acute DVT, phlebitis, severe atherosclerosis, or ischemic peripheral vascular disease.
- DVT within last 6 months.
- Pulmonary embolism.
- Any condition where an increase in venous return to the heart might be detrimental.
- Local conditions such as dermatitis, gangrene, recent skin graft, infected leg wound, or ulcer.

EVIDENCE-BASED PRACTICE**Recommend Bedrest for DVT?**

Recent prospective studies show that routine bedrest should not be recommended as part of standard care for clients with DVT. While elevation and rest of a swollen extremity provide some symptomatic relief, bedrest has been shown to increase the risk of clot propagation and does not decrease the rate of pulmonary embolism. Early ambulation may provide more rapid relief of pain and swelling.

Source: McRae, S., & Ginsberg, J. (2004). Initial treatment of venous thromboembolism. *Circulation*, 110(9 Suppl), 1–3.

Foot Pumps

Foot pumps gently squeeze the sole of the foot to mimic circulatory effects of walking. The plexus of veins in the foot act as a powerful venous pump in the weight-bearing phase of ambulation. The foot pump is designed to mimic natural effects of walking on blood circulation in feet and legs. These pumps increase circulation and decrease edema and pain to the lower extremities in clients who are not ambulatory.

Example shown is the Kendall Sequential Compression Device (SCD) Foot Pump.

**DOCUMENTATION for Circulatory Maintenance****Elastic Hosiery**

- Size and type of elastic hose applied
- Condition of skin
- Presence of pulses
- Capillary refill time
- Edema formation below or above hose
- Time and length of time hose removed

Compression Devices

- Neurovascular assessment baseline data
- Neurovascular assessment after application
- Condition of skin
- Presence of SCDs
- Type of sleeve used; thigh high, knee high

CRITICAL THINKING Application**Expected Outcomes**

- Compression stockings remain wrinkle-free, and pressure is evenly distributed.
- Peripheral pulses are present during use of sequential stockings and elastic hosiery.

- Compression devices function properly.
- Client's skin remains intact while using compression stockings.

Unexpected Outcomes

For Graduated Compression Stockings

Graduated compression stockings are not available.

Alternative Actions

- If ordered, use elastic (Ace) bandages. Anchor bandages on top of the foot and proceed up the leg. Bandage should overlap one-third of bandage width; for a 4-in. width each turn overlaps by 1.5 in. Ensure pressure is evenly distributed throughout bandage application.

	<ul style="list-style-type: none"> • Assess that elastic bandages are tight enough for support but do not obstruct arterial flow. Assess neurovascular status 20 minutes after bandages applied and every 2–4 hr thereafter. • While making each turn, place a finger between the bandage and skin with rotation to prevent bandage from becoming too tight.
<p>Graduated compression stockings are loose and don't provide support</p>	<ul style="list-style-type: none"> • Remeasure legs and compare with chart to determine correct size. • Hosiery may be old with no elasticity and should be discarded; ensure line drying rather than with electric dryer.
<p>Graduated compression stockings do not provide support.</p>	<ul style="list-style-type: none"> • Need to order different knit design and elastomeric yarn denier that will increase pressure. Pressure ranges from less than 15 mmHg to 30–40 mmHg at the ankle. Check physician's order for appropriate order.
<p><i>For Compression Devices</i> Client complains of numbness or tingling in leg.</p>	<ul style="list-style-type: none"> • Remove devices immediately. • Suggest use of foot pulse device as alternate. • Complete neurovascular assessment. • Notify physician of assessment findings.
<p>Buildup of excess sleeve pressure (above 80 mmHg).</p>	<ul style="list-style-type: none"> • Check tubing for kinks or twists. • Turn power switch to OFF position and then ON to restart system.

Chapter 31

UNIT 3

Electrocardiogram (ECG)

Nursing Process Data

ASSESSMENT Data Base

- Determine whether there is preexisting cardiac disease or chest pain.
- Assess client's level of understanding and cooperation with procedure.
- Determine client's fear or anxiety regarding diagnosis, procedure, or outcome.
- Identify pharmacologic agents currently prescribed.
- Determine other factors that may precipitate conditions, such as fever, anxiety, alcohol, tobacco, or caffeine ingestion.
- Determine subjective complaints of diaphoresis, palpitations, dizziness, or fainting.
- Identify electrolyte abnormalities affecting the electrocardiogram, particularly potassium and calcium deficiencies or excesses.

PLANNING Objectives

- To obtain 12-lead ECG
- To continuously monitor a client on telemetry
- To identify ECG changes
- To determine cardiac dysrhythmias
- To identify and treat potentially dangerous rhythms accordingly

IMPLEMENTATION Procedures

- Monitoring Clients on Telemetry1247
- Interpreting an ECG Strip1251
- Recording a 12-Lead ECG1255
- ST-Segment Monitoring1256

EVALUATION Expected Outcomes

- ECG leads applied appropriately and without difficulty.
- Abnormal ECG findings interpreted accurately.
- Heart rate calculated correctly.
- Monitor wave forms are distinct and readable.

Critical Thinking Application1257

- Expected Outcomes1257
- Unexpected Outcomes1258
- Alternative Actions1258

Monitoring Clients on Telemetry

Equipment

- Telemetry transmitter box with 9-volt battery
- Electrode pouch or gown with transmitter pocket
- 5-lead electrode cable and wires
- Electrodes
- Skin prep pad or alcohol swab

Preparation

1. Review the client's cardiac assessment. ► **Rationale:** The choice of monitoring lead is based on the client's assessment and potential arrhythmias that could occur.

- **Abnormal sinus rhythms**, premature atrial complexes, and most heart blocks can be recognized in any lead that displays a clear P wave and QRS complexes.
- **Atrial fibrillation** can be recognized in most leads by the irregular R-R intervals and chaotic atrial activity.
- **Bundle branch block** and ventricular rhythms are depicted by a widened QRS complex. Leads V_1 and V_6 (or MCL_1 and MCL_6) are the best leads for differentiating a widened QRS rhythm. These leads aid in differentiating ventricular tachycardia from supraventricular tachycardia with aberrant conduction. It is best to monitor the client with multiple leads or a 12-lead ECG.
 - i. The V_1 and V_6 leads are obtained by using the 5-lead bedside monitoring cable and limb electrodes. Arm electrodes are placed on the shoulders as close as possible to where the arms join the torso. Leg electrodes are placed at the level of the lowest ribs on the thorax or on the hips.
 - ii. To monitor lead V_1 , place the chest electrode in the 4th intercostal space (ICS) at the right sternal border and select "V" on the bedside monitor.
 - iii. To monitor lead V_6 , place the chest electrode in the 5th ICS at the left midaxillary line and select "V" on the bedside monitor.
- A second method used to diagnose the widened QRS complex is to use the V_1 and the bipolar lead MCL_6 together by placing the electrodes accordingly:
 - i. Arm electrodes placed on shoulders.
 - ii. Right leg electrode placed on right thorax or right hip.
 - iii. Left leg electrode placed in the V_6 position (5th ICS, left midaxillary line).
 - iv. With the electrodes in place, select "V" on the first channel of the monitor to display " v_1 " and select lead III on the second channel to display MCL_6 .

▲ Transmitter box, cable, and lead wires for telemetry.

▲ Insert electrode cable into transmitter box.

2. Gather equipment and perform hand hygiene.
3. Place a fresh 9-volt battery in the telemetry transmitter box, if needed.
4. Attach lead wire securely into color-coded transmitter box, ensuring colors match.
5. Explain procedure to client. Radio waves transmit the heart's electrical activity to a central monitoring station. This system allows the client to move around while his/her heart is constantly being monitored. Explain that the telemetry range is limited; therefore, client cannot wander out of the range, which is usually the nursing unit. If client goes off the unit, nurse must be notified.
6. Instruct the client to notify the nurse if the electrode falls off.

Electrode Placement**White** to right shoulder**Black** to left shoulder**Red** to left midclavicular upper abdominal area (lead II positive electrode)**Brown** to fourth intercostal space, right sternal border (MCL₁ or precordial lead V₁), or left sternal border, or alternatively at left 5th intercostal space, anterior axillary line (V₅ position)**Green** to right abdomen or other convenient area (ground electrode)**NOTE:** Limb leads and any one chest lead can be monitored using these electrode positions.**Procedure**

1. Check the expiration date on the electrode packet.
▶ **Rationale:** To ensure electrode gel is moist.
2. Select electrode sites according to leads to be used for monitoring. Ensure they are not over bony prominence, muscular area, joints, breasts, or skin creases. ▶ **Rationale:** Placing electrodes on these areas can lead to artifact on the monitor screen. See diagrams for lead placements.

NOTE: If client is overly obese, electrodes may have to be placed on the bones, since a large amount of adipose tissue results in poor image on the oscilloscope.

3. Assess skin site before placing electrode. Wipe skin areas using alcohol swab. Allow site to dry thoroughly

▲ Color-coded lead wires and placement of electrodes for ECG monitoring.

before affixing electrode. ▶ **Rationale:** This removes oily substances and dead skin for better adherence of electrodes. Rub skin until slightly red. If client's chest is hairy, then clip hair. ▶ **Rationale:** This enables electrode to adhere well to skin and minimizes artifact.

4. Attach lead wires to chest electrodes.
5. Apply electrodes to client's chest: peel off paper backing on electrode disc. Check that sponge pad in center of

TABLE 31-4 Telemetry Electrode Placement

• **Lead I:** Records activity between a negative electrode (below right clavicle) and a positive electrode (below left clavicle). This lead looks at the heart's left lateral wall. Atrial arrhythmic activity is poorly identified.

• **Lead II:** * Records activity between a negative electrode (below right clavicle) and a positive electrode (midclavicular line on left flank). This lead looks at left inferior wall. It is used to diagnose supraventricular rhythms which arise from the atrial and junctional nodes. It best detects atrial activity.

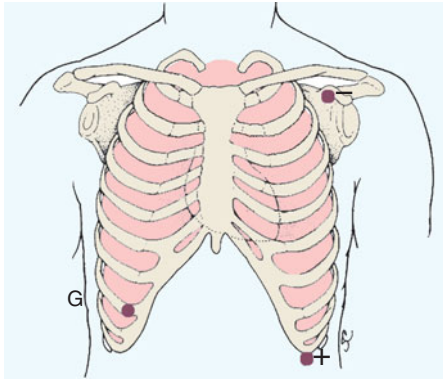

TABLE 31-4 Telemetry Electrode Placement (Continued)

- **Lead III:** Records activity between a negative electrode (below left clavicle) and a positive electrode (lowest rib, left midclavicular line). It looks at left inferior wall.

- **Lead MCL₆:** Records activity between a negative electrode (below left clavicle) and a positive electrode (fifth intercostal space, left midaxillary line). It monitors ventricular conduction changes much like MCL₁. Not as frequently used.

- **Lead MCL₁:** * Records activity between a negative electrode (below left clavicle) and a positive electrode (fourth intercostal space, right of sternum). It is used to differentiate between ectopy versus abnormally conducted beats such as supraventricular tachycardia with aberrancy versus ventricular tachycardia.

*Most popular leads for telemetry.

Note: Check frequency and flush solutions according to agency protocols.

- electrode is moist with conductive jelly. Place electrode on skin with adhesive side down. Press edges down to secure.
- Attach wire into transmitter box, matching the color codes of the cable wires to the telemetry box.
 - ▶ **Rationale:** Mismatch of the colors will cause the client's rhythm pattern to appear inverted.
- Have base station run an ECG strip to check clarity of transmission.
- Set HIGH and LOW alarm limits on the monitor. Turn alarm buttons to ON per agency/unit protocol (e.g., 50 low, 100 high).
- Assess skin surrounding electrode for signs of irritation regularly.
- Check lead placement at least once a shift unless notified by client or monitoring station that electrodes are not functioning properly.
- Change electrodes at least every 3 days or if ECG strip indicates poor conduction of wave form.

Two New Systems for Monitoring 12-Lead ECGs Using Smaller Cable Systems

EASI™ (Philips Medical Systems)

The electrode configuration is very similar to the standard five-lead system with four limb electrodes, but with two precordial electrodes located at lead V1 and lead V5. This system simulates a 12-lead ECG reading.

Electrode Placement:

- Brown (Br) electrode (labeled E on the electrode) is located along sternum between white and red electrodes, horizontal with the 5th ICS.
- Red (R) electrode (labeled A on the electrode) is located opposite white electrode, at left mid-axillary line, 5th ICS
- Black (B) electrode (labeled S on the electrode) is located along upper sternum below sternal angle.

▲ EASI™ Lead System.

▲ Five-lead wire ECG system using lead V5.

- White (W) electrode (labeled I on the electrode) is located at right mid-axillary line, 5th ICS.
- Green (G) or ground electrode can be positioned in convenient site on torso.

▲ Five-lead wire ECG system using lead V1.

Interpolated 12-Lead System Using a Six-Cable System (General Electric Medical Systems)

The electrode system uses six-wire ECG system to produce 12-lead ECG reading.

Electrode placement:

- Electrode placement is similar to standard five-lead wire ECG.
- Four limb electrodes.
- Two precordial electrodes located at lead V1 and lead V5.

▲ Interpolated 12-lead system using 6-cable system.

Interpreting an ECG Strip

Equipment

- Calipers (optional)
- ECG rhythm strip

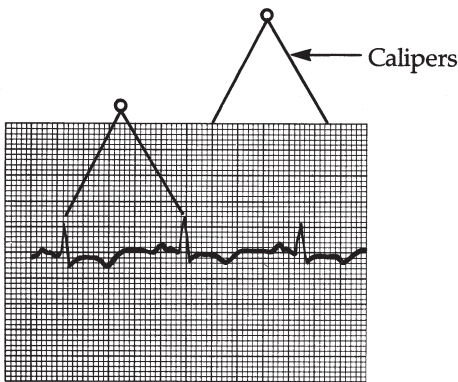

Procedure

1. Assess ECG grid.
 - a. Each small square represents 0.04 seconds (horizontal measurement).
 - b. Each large block (five small squares) represents 0.20 seconds.
 - c. 15 large blocks represent 3 seconds.
2. Determine heart rate by calculating ventricular rate; normal is 60–100 per minute.
 - a. Count the number of R waves in a 6-second period (30 large blocks) and multiply this by 10 to obtain the heart rate.
 - b. For true accuracy, count client's apical heart rate for 1 full minute.
3. Determine the regularity of ventricular rhythm (R waves should be equally spaced).
4. Determine the P wave rate (atrial depolarizations).
 - a. There should be one P wave in front of each QRS complex.
 - b. Note if there are more P waves or fewer P waves than QRS complexes.

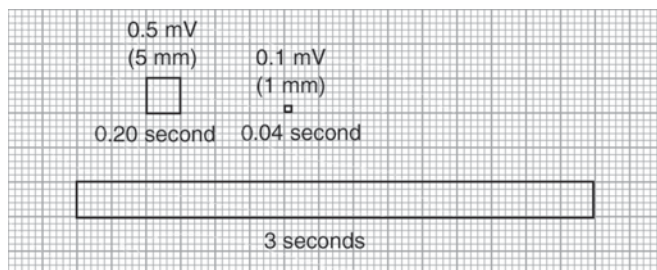

5. Determine the regularity of the P waves; are they all equally spaced?
6. Measure the PR interval (beginning of the P wave to the beginning of the QRS complex); represents conduction time through the electrical tissue to the ventricles (from the SA node, through the AV Node, bundle of His, bundle branches, and Purkinje fibers); normal is 0.12 to 0.20 seconds. Normally shortens as the heart rate increases.

▲ It is important to determine configuration and location of wave pattern to interpret an ECG accurately.

▲ Use calipers to measure heart rate.

▲ ECG grid.

▲ ECG pattern and lead placement are depicted on oscilloscope.

7. Measure the QRS duration from beginning of the Q wave, if present, to end of the S wave (normal is less than 0.12 seconds).
8. Interpret the client's cardiac rhythm and place ECG rhythm sample strip in client's chart, according to hospital policy.

TABLE 31-5 Normal Sinus Rhythm

Regular configuration, uniform P wave precedes each QRS
 Atrial rate 60–100
 PR interval 0.12–0.2 seconds
 QRS width < 0.12 seconds
 Ventricular rate 60–100

TABLE 31-6 Selected Cardiac Rhythms and Dysrhythmias

Sinus Tachycardia

Sinus Bradycardia

Regular rhythm >100/min
 P waves—normal
 Atrial rate—>100/min
 PR interval—0.12–2.0 seconds
 QRS complex width—0.06–0.08 seconds usually normal

Regular rhythm <60/min
 P waves—normal
 Atrial rate—<60/minute
 PR interval—0.20 seconds
 QRS complex width—0.08 seconds usually normal

Note: A moderately faster heart rate can be a physiological normal variant. Note: A slow heart rate can be physiologically normal for some clients.

Etiology

Underlying causes such as anxiety, fever, shock, drugs, exercise, electrolyte disturbances

Etiology

Drugs, hypoxia, altered metabolic states (hypothyroidism), cardiac diseases, athletes

Initial Treatment

Immediately initiate cardioversion if unstable
 Treatment dependent on elimination of cause
 Decreasing anxiety
 Pain relief
 Antipyretics
 O₂
 Medications (sedatives, tranquilizers, anti-anxiety, etc.)
 Calcium channel blockers and beta-blockers

Initial Treatment

Maintain patent airway; assist breathing as needed
 Oxygen
 IV
 Atropine 0.5–1 mg bolus IV while awaiting pacemaker
 May repeat to a total dose of 3 mg
 Then, epinephrine (2–10 mg/min) or dopamine (2–10 mg/kg/min) infusion while awaiting pacer
 Transcutaneous pacing

Multifocal Premature Ventricular Contraction (PVCs)

Ventricular Tachycardia

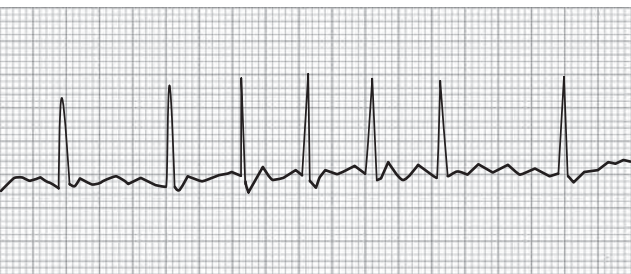

TABLE 31-6 Selected Cardiac Rhythms and Dysrhythmias (Continued)

Multifocal Premature Ventricular Contraction (PVCs) (Continued)	Ventricular Tachycardia (Continued)
<p>Irregular rhythm P waves—none with premature beat, impulse originates in ventricle Atrial rate—undetermined PR interval—none with premature beat QRS width—greater than 0.12 seconds for premature beat Ventricular rate—varies</p> <p><i>Note: Each PVC has different configuration as foci are from different areas of heart.</i></p> <p>PVCs may be the result of an imbalance between oxygen demand versus supply, thereby making the myocardium irritable.</p>	<p>Regular rhythm Atrial rate—cannot differentiate PR interval—none QRS width—greater than 0.12 seconds Ventricular rate—130–250</p> <p><i>Note: Ventricular tachycardia is a result of myocardial irritability and is life-threatening.</i></p>
<p>Etiology</p> <ul style="list-style-type: none"> • Heart disease, MI • Hypoxia • Acidosis • Electrolyte imbalances • Myocardial ischemia • Drug toxicity (especially digitalis) <p>Initial Treatment</p> <ul style="list-style-type: none"> • Oxygen • Potassium or magnesium if electrolytes dictate • Lidocaine bolus—1–1.5 mg/kg; may repeat doses of 0.5–0.75 mg/kg every 5–10 minutes up to 3 mg/kg • Refractory to lidocaine: amiodarone or procainamide • Continuous IV drip may be started • Correct underlying cause 	<p>Etiology</p> <ul style="list-style-type: none"> • Acute MI • Coronary artery disease, cardiomyopathy • Electrolyte imbalance • Drug intoxication (digitalis) <p>Initial Treatment</p> <ul style="list-style-type: none"> • Lidocaine 1.5 mg/kg bolus; may repeat in 3–5 minutes to maximum dose of 3 mg/kg • Amiodarone 300 mg IV/IO can be followed by 150 mg IV/IO • Cardioversion if cardiac output is compromised • Pulseless ventricular tachycardia—follow treatment for ventricular fibrillation (epinephrine)
Atrial Fibrillation	Atrial Flutter
	
<p>Irregularly irregular rhythm Disorganized atrial activity—greater than 350 BPM P waves—none identifiable</p> <p>PR interval—not measured QRS—variable QRS complex: irregular</p> <p>Etiology</p> <ul style="list-style-type: none"> • Heart failure • Rheumatoid heart disease • Coronary heart disease • Hypertension • Hyperthyroidism 	<p>Regular or irregular rhythm (depending on block) Atrial rate greater than 250 beats/min P wave usually sawtooth pattern; PR interval cannot calculate PR interval—regular Ventricular rate can be irregular QRS complex—0.6 to 0.10 seconds</p> <p>Etiology</p> <ul style="list-style-type: none"> • Sympathetic nervous system stimulation (i.e., anxiety), caffeine, and alcohol intake • Thyrotoxins • Coronary heart disease; MI; pulmonary embolism
<p>Initial Treatment</p> <ul style="list-style-type: none"> • Cardioversion 	<p>Initial Treatment</p> <ul style="list-style-type: none"> • Cardioversion—if symptomatic

Continued

TABLE 31-6 Selected Cardiac Rhythms and Dysrhythmias (Continued)**Atrial Fibrillation (Continued)****Diltiazem**

Beta-blocker: Carvedilol or Toprol XI

Digoxin

Quinidine

Procainamide

Amiodarone or Dronedarone

Ibutilide

Anticoagulant to reduce risk of clot formation and stroke, if atrial fibrillation duration new in onset but older than > 48 hr

Atrial Flutter (Continued)**Diltiazem**

Calcium channel blocker (Cardizem) or beta-blocking agents to slow ventricular response

Followed by ibutilide, quinidine, procainamide

Ventricular Fibrillation

Irregular, totally chaotic rhythm

Atrial rate—cannot differentiate

PR interval—none

QRS width—fibrillating waves only

Ventricular rate—cannot differentiate

*Note: Ineffective quivering of ventricles with no audible heartbeat, pulse, or respirations.***Etiology**

- Myocardial ischemia, Acute MI
- Coronary artery disease
- Cardiomyopathy
- Acid-base imbalance
- Severe hypothermia
- Electrolyte imbalance

Initial Treatment

- Immediately defibrillate, shock
- CPR—100 chest compressions/minutes—no cycles
- Ventricular fibrillation continues—give a vasopressor (epinephrine 1 mg IV push), repeat 3–5 minutes
- Defibrillate again and continue CPR
- Second-line drugs may be used, such as amiodarone (300 mg IV), lidocaine

Third-Degree Heart Block

Regular atrial and ventricular rhythm

Atrial rate—greater than ventricular rate

PR interval—varies

QRS width—less than 0.12 seconds if pacemaker cell in junction; greater than 0.12 seconds if cell in ventricle

Ventricular rate—40–60 beats/min if pacemaker from bundle of His; < 40 if from Purkinje fibers in ventricle.

*Note: Electrical impulse originates in SA node but is blocked in either the AV node, the bundle of His, or Purkinje fibers. There is no correlation between the atrial rate and the ventricular rate.***Etiology**

- Digitalis toxicity
- Myocardial infarction: inferior or anterior wall
- Organic heart disease

Initial Treatment

- Atropine bolus
- Transcutaneous pacing
- Dopamine or epinephrine
- Prepare for pacemaker insertion

Clinical Alert

Always assess client to determine whether the abnormal rhythm is potentially life-threatening and emergency measures should be taken. Signs of hemodynamic instability include:

- Ongoing chest pain
- Shortness of breath
- Change in mental status
- Systolic blood pressure (SBP) <90 mmHg
- Heart rate <150 per minute.

Recording a 12-Lead ECG

Equipment

- Electrodes
- Skin prep pad or alcohol swab
- ECG machine
- Cable

Preparation

1. Review physician's order for ECG and perform hand hygiene.
 2. Identify client using two forms of ID and explain procedure. Reassure client that machine will not cause discomfort or electrocution.
 3. Assess chest for placement of electrodes.
 4. Determine whether skin site care is necessary. If so, cleanse areas with skin prep pad, alcohol swab, or clip hair if needed. Allow area to dry thoroughly before placing electrodes. ► **Rationale:** This will ensure a more secure fit for the electrodes and provide a better ECG tracing.
 5. Attach wires to electrodes before pressing onto client's chest. ► **Rationale:** This prevents pressure being applied to chest area. This is particularly necessary after open heart surgery or chest trauma.
 6. Check the color coding on the manufacturer's directions before placing electrodes to ensure they are correct.
3. Place the four limb leads, one on each limb, according to the color coding. Three standard leads will be recorded on the 12-lead ECG.
 - a. **Lead I:** Right arm wrist (negative electrode) white; and left arm (positive electrode) black. Records activity between the two arms.
 - b. **Lead II:** Right arm (negative electrode) and left leg ankle (positive electrode) red. Records activity between arm and leg.
 - c. **Lead III:** Left arm (negative electrode) black and left leg (positive electrode) green. Records activity between arm and leg.
 4. Three augmented limb lead tracings are obtained on the ECG as follows.
 - a. **aVR:** Records activity between the center of the heart and right arm.
 - b. **aVL:** Records activity between the center of the heart and left arm.
 - c. **aVF:** Records activity between the center of the heart and the left leg or foot.
 5. Place the chest leads as follows. (See photo below.)
 - a. **V₁:** Fourth intercostal space, right sternal border. Records activity between the center of the heart and the fourth intercostal space; P wave is shown best here.
 - i. Palpate the jugular notch above sternum (feels like a depression).

Procedure

1. When placing electrodes, ensure lead wires are all going in the same direction.
2. Place electrodes on fleshy areas, avoiding bone and muscle. ► **Rationale:** To ensure good electrical conduction and clear ECG tracings.

▲ Electrode placement for chest leads V₁–V₆.

▲ Portable ECG machine for taking 12-lead ECG tracing.

▲ Normal 12-lead ECG.

- ii. Move finger down and palpate the manubrium of sternum (feels solid).
- iii. Continue to move finger down to the angle of Louis, which is at the top of the sternal body.

- iv. Move finger to the right of the angle of Louis to the second right rib.
- v. Below the rib is the second intercostal space.
- vi. Move fingers down, palpating the next two ribs. Below the fourth rib and to the right of the sternal body is the fourth intercostal space. Place electrode in this area.
- b. **V₂**: Fourth intercostal space, left sternal border.
- c. **V₃**: Midway between **V₂** and **V₄**, between 4th and 5th ICS.
- d. **V₄**: Fifth intercostal space, left midclavicular line.
- e. **V₅**: Fifth intercostal space, anterior axillary line.
- f. **V₆**: Fifth intercostal space, left midaxillary line.
6. Begin taking the ECG according to manufacturer's directions on machine.
7. Place tracing copy on client's chart.
8. Remove electrodes; perform hand hygiene.

ST-Segment Monitoring

Equipment

- 12-Lead ECG machine
- Electrodes
- Cable
- Skin Prep

Procedure

1. Check physician's orders for type of ST-segment monitoring. If the 12-lead ECG is not available, then the lead selected is based on the coronary artery involved in the acute infarction or interventional procedure being performed. ► **Rationale:** The best ST-segment monitoring is using the 12 lead as it provides a global view of the heart.
2. Use the most appropriate leads based on client's needs and risk for ischemia and/or dysrhythmia if 12-lead monitoring is not available.
 - a. Acute coronary syndromes (ACS) with a known "ST fingerprint," obtained during ST-Segment Elevation, myocardial infarction (STEMI), or percutaneous coronary intervention (PCI), use the lead(s) that best display the client's "ST fingerprint" when monitoring.
 - i. If the "ST fingerprint" is not known in ACS, use leads III and **V₃**.
 - ii. If the client's diagnosis is not confirmed as ACS, but it is being ruled out, use leads III and **V₅**.
 - iii. In noncardiac clients undergoing surgical procedures or admitted to the ICU, lead **V₅** is the best lead to identify demand-related ischemia, which appears to be more common in these clients.
 - b. Use the lead selection for ST-segment monitoring if specific coronary artery injury is known.

▲ ST-segment and J point ECG waveform.

- i. Circumflex (lateral wall injury): use lead I, aVL, **V₅**, or **V₆**. **V₅** is preferred for noncardiac clients undergoing surgery.
- ii. Right coronary (inferior wall): lead III is preferred, then a **V_F** or II.
- iii. Left anterior descending (anterior wall): lead **V₂** or **V₃** preferred, then **V₄**. **V₁** and **V₂** are associated with the septal wall. **V₃** is preferred for clients with ACS who do not have an ST fingerprint.
3. Introduce yourself and identify client using two forms of identification.
4. Explain the monitoring procedure to the client.
5. Perform hand hygiene.

ST-Segment Monitoring

This monitoring is used to detect myocardial ischemia, electrode imbalance, and coronary artery reocclusion in clients who have received thrombolytic therapy or interventional cardiology procedures such as atherectomy, stents, or rotablation. It is also used to detect silent ischemia and in evaluating chest pain in clients presenting with atypical pain and nondiagnostic ECGs.

6. Connect cable to ECG machine and turn on the machine.
7. Clean skin before applying electrodes to skin. Cleanse skin with alcohol and clip hair where electrodes are placed, if needed. ► **Rationale:** To rid skin of oil and hair to provide a secure adherence of the electrodes to the skin.
8. Attach lead wires in chest electrodes.
9. Place electrodes in appropriate area of the chest with the adhesive side down. Ensure the electrodes are placed on the site for leads being used in ST-segment monitoring. ► **Rationale:** Appropriate placement is

imperative as just a 1 cm change in the placement of the lead can interfere with the waveform patterns. This is particularly a problem when the precordial leads are not properly positioned.

10. Press edges of electrode pad down on skin. ► **Rationale:** To secure the electrode to the skin to provide a good ECG waveform.
11. Attach wire into transmitter box.
12. Check the clarity of the waveform transmission.

Clinical Alert

Ischemia can be easily detected by observing the T wave. If it is inverted and/or the ST segment is depressed, it indicates ischemia has occurred. The ST segment depression is often seen in combination with a sharp angle at the junction of the ST segment and the T wave.

Evaluate ST segment with the client in the supine position, set the ST alarm parameter 1–2 mm above and below the client's baseline ST segment, and measure ST segment changes 60 ms beyond the J point of the ECG complex. ST depression or elevation of 1–2 mm that lasts for at least 1 minute can be clinically significant, and further assessment is necessary.

DOCUMENTATION for ECG Monitoring

- 12-lead ECG taken
- Telemetry initiated
 - ST-segment monitoring initiated and monitoring leads used
 - Findings based on the interpretation of the ECG strip
- Nursing interventions carried out, based on the ECG findings
- Rhythm strips entered into client's record at least once each shift
- Telemetry strip documentation:
 - Lead monitored
- Interpretation of ECG strip to include:
 - Rate
 - Rhythm
 - PR interval
 - QRS complex
 - Q-T interval
- Document a telemetry strip for:
 - Any change in client condition
 - Client symptoms during procedures as appropriate
 - Administration of medications as appropriate (i.e., lidocaine)
- Health teaching completed
- Physician notification of abnormal findings

CRITICAL THINKING Application

Expected Outcomes

- ECG leads applied appropriately and without difficulty.
- Abnormal ECG findings interpreted accurately.
- Heart rate calculated correctly.
- Monitor wave forms are distinct and readable.

Unexpected Outcomes*For ECG Interpretation*

ECG is not clearly displayed on monitor.

Electrodes do not adhere to skin and interference appears on oscilloscope.

Alarms ring without change in pattern.

ECG pattern is abnormal.

Electrical interference appears on monitor.

Electrodes cause skin irritation.

Chaotic rhythm appears on monitor.

High or low alarms on monitor continue to sound.

Electrodes conduct poorly on diaphoretic client.

Asystole displays on monitor.

For Telemetry

ECG only provides partial information on heart activity.

Alternative Actions

- Ensure that electrodes are applied in correct position and are securely attached.
- Observe for electrical interference resulting in a 60-cycle interference on oscilloscope.
- Observe for excessive client activity resulting in artifact display on oscilloscope.

- Change placement of electrodes to another area. Clip hair if needed for improved skin contact.
- Recleanse skin thoroughly using skin prep or alcohol and allow to dry.

- Check HIGH and LOW parameters. They may need to be changed.
- Check GAIN. It may be too low to sense pattern.

- If client is asymptomatic, recheck lead placement and ensure cables are attached properly.
- Check if pattern is a life-threatening arrhythmia (for ventricular tachycardia, call rapid response team; for ventricular fibrillation, call code).
- Increasing PVCs—notify Rapid Response Team.
- Notify physician immediately.

- Check all other electric equipment in the immediate environment.
- Check for proper grounding of monitor.
- Change electrodes and cable; poor conduction may cause 60-cycle interference.
- Check that monitor is calibrated.

- Remove electrodes, cleanse site, and reapply electrodes on new site.

- Assess client's vital signs and level of consciousness.
- Check electrode contact on skin, and ensure that wires are in contact with cable.

- Check for loose electrodes or try a different lead.
- Observe activity level of client.
- Check that alarm parameters on monitor are not set too close to client's pulse.
- Check client's position.
- Reposition electrodes, avoiding large muscle masses or bone.

- Clean skin sites as usual; apply benzoin to the skin and let dry and apply electrodes.
- Clean skin sites as usual; apply spray deodorant to the skin, allow skin to dry, and apply electrodes.

- Check client's LOC and electrodes, wires, and cable connection.
- If the client has an arterial line, check for an arterial waveform in the absence of an ECG waveform.

- Obtain 12-lead ECG. It portrays activity in all areas of heart except posterior aspect—monitor different lead (i.e., MCL).

Client experiences life-threatening arrhythmia.

- Begin treatment for arrhythmia. Notify Rapid Response Team. Obtain 12-lead ECG when client is stable.

Telemetry signal not picked up at base station.

- Check that client hasn't wandered to an area where transmission is not available.
- Check that transmitter battery is functioning.
- Check that transmitter is ON.
- Change wires.
- Usual cause is a dry electrode. Replace electrodes.

For 12-Lead ECG

Interference apparent on ECG tracing.

- Ensure that lead wires are hanging in same direction on corresponding extremities.
 - Assess chest to determine whether chest dressing is interfering with ECG electrode placement or signal.
 - Breast tissue may be interfering with ECG signal. Reapply electrodes under the breast as close to the heart as possible.
 - Instruct client to remain still.
-

Chapter 31

UNIT 4

Emergency Life Support Measures

Nursing Process Data

ASSESSMENT Data Base

- Assess client for signs of cardiac or respiratory arrest (responsiveness, breathing, circulation, etc.).
- Know emergency number to summon help and identify location of AED.
- Identify location of emergency cart.
- Identify procedure for activation of Rapid Response Team.

PLANNING Objectives

- To provide adequate oxygenation of lungs through mechanical support
- To support ventilation and circulation
- To reestablish a patent airway for client with foreign body airway obstruction

IMPLEMENTATION Procedures

- Administering Basic Life Support to an Adult or Child1261
 - For Unresponsiveness1261
 - For Airway1261
 - For Rescue Breathing1262
- Administering Basic Life Support to an Infant (Under 12 Months)1263
- Placing Victim in Recovery Position1264
- Providing Bag–Valve–Mask (BVM) Ventilation1264
- Using an Automated External Defibrillator (AED)1265
- Administering the Abdominal Thrust (Heimlich) Maneuver to an Adult or Child1267
- Administering the Abdominal Thrust (Heimlich) for Unresponsive Client1267
- Calling for Rapid Response Support1268

EVALUATION Expected Outcomes

- Basic life-support measures established within 3 minutes after arrest.
- Emergency measures performed according to established protocol.
- Client is stabilized/resuscitated with basic life support measures.
- No permanent neurologic damage is sustained.
- Obstructed airway is reestablished.

- Critical Thinking Application**1270
- Expected Outcomes1270
 - Unexpected Outcomes1270
 - Alternative Actions1270

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Administering Basic Life Support to an Adult/Child

Equipment

- Cardiac board
- AED
- CPR mask or Ambu bag

Procedure

For Unresponsiveness

1. Quickly approach client.
2. Check responsiveness. Tap shoulders. Shout, “Are you OK?” ► **Rationale:** To determine responsiveness of client.

Clinical Alert

Institute CPR within 3 minutes. Cardiopulmonary resuscitation is usually not effective in preventing brain damage unless initiated within 4 minutes of an arrest.

3. Call out or phone for help. Get AED (should be stored by telephone).
4. Move victim to flat, firm surface and position yourself next to victim, left side near head of victim. ► **Rationale:** Left side is preferred when using AED. A firm surface enhances effective compression between chest wall and sternum.
5. Place heel of hand in middle of chest. Place other hand on top of first with fingers interlaced.
6. Start chest compressions at 100/min with a depth of 2 in. for adults.

For Airway

1. The old guidelines were A, B, C: airway, breathing, and compressions. The new guidelines (2010) are C, A, B: compressions, airway, and breathing.
2. Press backward on forehead, if no suspected head or neck injury. ► **Rationale:** This causes head to tilt back and open airway.
3. Lift chin by placing two fingers under chin. Lift chin up and forward until teeth are nearly closed.
4. Pinch nose and make a seal over victim’s mouth, either with your mouth or, preferably, a CPR mask or Ambu bag.

▲ Check for response: tap victim, speak loudly and clearly.

▲ Call for help and retrieve AED before starting CPR.

▲ Pull CPR release to place bed in flat position for CPR.

5. Perform 30 compressions; open airway if trained in CPR. Otherwise, continue chest compressions.
6. Apply AED immediately if witnessed collapse, or attach after 1 minute of CPR if collapse was not observed.

Clinical Alert the New CPR (2010)

1. Check for response: “Are you all right?” Tap shoulder. If person does not respond, roll client on back.
2. Start chest compression: “Push hard, push fast” at a rate of 100/minute, allowing chest to recoil compress chest at least 2 inches in adults and children (new CPR guidelines as of Oct. 2010).
3. Activate the EMS system and send someone for the AED, or call 911.
4. If you have been trained in CPR, open the airway and check for adequate breathing: head tilt–chin lift.
5. Give rescue breath: 2 rescue breaths, each 1 second with enough volume to produce visible chest rise.
6. Continue compressions and breaths—30 compressions, two breathless until help arrives.

For Rescue Breathing

1. Evaluate respiratory function:
 - a. Check for rise and fall of chest. ► **Rationale:** If chest movement occurs but you cannot feel or hear air, then airway is obstructed.
 - b. Repeat rescue breath.
2. Reposition head and try again if chest does not rise. Give 2 more breaths.

1 Begin compressions at 100 per minute, unless other instructions are provided.

2 Open airway by tilting client's head back and lifting chin after 30 compressions.

3 Reposition head and try ventilation again, if chest does not rise.

3. Repeat 30 compressions and 2 breaths for 5 cycles.
4. Stop compressions after 2 minutes and check for breathing. If not breathing, continue compressions and breathing until help arrives or AED is activated.

NOTE: It is recommended that a barrier device be used when performing rescue breathing.

4 Ventilate with two rescue breaths using bag–valve–mask or CPR mask.

EVIDENCE-BASED PRACTICE

Chest Compressions for CPR

An observational study concluded that chest compressions are the most important aspect of CPR. The chest is able to fully recoil during each compression, thereby lowering intrathoracic pressures, which promotes improved cardiac preload and improved filling of the coronary arteries. Interruptions in chest compressions, even if brief, produce a dramatic decline in coronary perfusion pressures and worsens outcomes. For a single rescuer, it is believed that continuous cardiac compression will improve outcomes. Chest compressions first has now been approved by the AHA and released October, 2010.

Source: SOS-KANTO Study Group. (2007). Cardiopulmonary resuscitation by bystanders with chest compression only (SOS-KANTO): An observational study. *The Lancet*, 369(9565), 920–926.

Clinical Alert

There have been no documented cases of transmission of HIV, hepatitis, or tuberculosis during mouth-to-mouth or mouth-to-mask ventilation.

Source: American Heart Association.

Clinical Alert

If victim has been nonresponsive for more than 4 minutes, provide five cycles of CPR before applying AED.

CPR Guidelines—2010

The most significant new recommendations (changes) in the guidelines are as follows:

- Compressions, Airway, Breathing (CAB) rather than previous guidelines Airway, Breathing, Compressions (ABC).
- Chest Compressions first: “push hard and push fast, allow full chest recoil after each compression,” about 100 compressions/minute for all victims. Minimize interruptions in chest compressions. Mouth to mouth breathing is only done if client’s condition warrants, and a CPR mask is used, unless an Ambu bag is available (AHA, 2008).
- Universal Compression-to-Ventilation Ratio: 30:2 for all victims (except newborns)
- Rescue Breathing: Each breath (2) should last for 1 second and should result in a visible rise of the chest. 12–20 breaths/minute or 1 breath every 3–5 seconds.
- Defibrillation: In witnessed arrests, use AED. Single shock followed by immediate CPR. In unwitnessed arrest, first five cycles CPR then use AED.
- Rhythm check: After about five cycles or approximately 2 minutes.
- AEDs: Use in children beginning at age 1 through adult only.

The AHA guidelines emphasize the need to use bag–mask ventilations or other airway devices such as the Combitube if the BLS rescuer is trained in the use of these devices.

Barrier Devices

Face Shield: Clear plastic or silicon sheet placed over victim’s face to prevent direct contact with victim during rescue breathing. Face shields are small, flexible, and portable.

Face Mask: Hard plastic device that fits over mouth and nose. They cost more than face shields and are bulkier, preventing people from carrying them on their person.

New Trends

CPR in a Box

The American Heart Association has designed a \$30 instructional kit that teaches CPR in 20 minutes. The purpose of the kit is to raise cardiac survival rates by having community teachers share the CPR information. In one situation an instructor, in 2 hours, trained 96 school students and they went home and trained their families. The kit includes a mini-inflatable manikin, booklet, and DVD. The principles include starting cardiac compressions immediately. Kits can be ordered at 877-242-4277 or www.cpranytime.org.

Administering Basic Life Support to an Infant (under 12 months)

NOTE: Basic Life Support guidelines for Healthcare Providers defines “infant victims” as less than 12 months old, whereas “pediatric victims” are defined as victims from about 1 year of age to the onset of adolescence or puberty, as defined by the presence of secondary sex characteristics.

Procedure

1. Try to wake the infant by gently tapping infant. Small infants respond to rubbing and tapping the soles of their feet.
2. If infant does not wake up have someone call 911. If no one is available, call 911 and then begin CPR.
3. Begin chest compressions, place two fingers on the breastbone directly between the baby’s nipples. Push straight down an 1 ½ inches and 13 depth of baby’s chest.
4. Allow chest to rise back to usual position. Complete 30 compressions, about 2 compressions per second.
5. Trained CPR rescuers begin rescue breathing. If not trained, continue compressions until help arrives.
6. Cover the baby’s entire mouth and nose with your mouth and gently blow until you see the chest rise. Let the air escape and the chest go back to normal. Give a second breath
7. If chest does not rise and fall, adjust the baby’s head and try again. If chest still does not rise and fall, continue with 30 chest compressions and try rescue breathing again.
8. Continue to give 2 minutes of CPR, if no help has arrived, call 911 again.
9. Continue CPR until help arrives.

For Foreign Body

1. If foreign body or aspiration is suspected:
 - a. *Infant:* clear airway by administering back and chest thrusts.
 - b. *Conscious Infant*
 - (1) Position infant over your forearm, head lower than trunk. Support the head by holding it firmly while resting your arm on your thigh.

Clinical Alert

AEDs are not used in infants; only in clients older than 1 year.

Use adult pads if child is 8 years or older—child pads are preferred if available for 1 to 8 years.

- (2) With free hand, deliver five sharp blows to infant's back, over spine and between shoulder blades. If object is not expelled, then:
 - (3) Turn infant as a unit to supine position, maintaining head support. Deliver five chest thrusts by placing two fingers over sternum and providing thrusts.
- c. *Unconscious Infant*
- (1) Attempt to ventilate. If unable, reposition head and try again. Lift chin. ► **Rationale:** Trachea can collapse if neck is hyperextended.
 - (2) Form tight seal by encircling mouth of child and mouth and nose of infant. ► **Rationale:** Maintain tight seal.
 - (3) If unable to ventilate, then commence CPR.
2. Administer two breaths.
 - a. Give breaths slowly—1 second/breath.
 - b. Fill cheeks with air and use short puffing breaths for infants. Do not use full breaths for children or infants. ► **Rationale:** Small breaths prevent overinflation of the lungs and abdominal distention.
 3. Between breaths, release seal for exhalation, and turn your head to side.
 4. Administer one breath every 3 to 5 seconds.
 5. Continue ventilations until infant is intubated or Ambu bag is available.

Placing Victim in Recovery Position

Procedure

1. Assess for potential head or neck trauma; if you suspect injury, do not tilt or turn client's head. If no trauma and client has a pulse and is breathing adequately, place in recovery position.
2. Straighten victim's legs.
3. Place victim's arm nearest to you at right angles to his/her body with elbow bent and palm upward.
4. Place other arm across chest and place hand near his/her cheek.
5. Grasp victim's far-side thigh above knee; pull thigh up toward his/her body.
6. Roll victim toward you onto his/her side.
7. Ensure upper leg (including knee and hip) is bent at right angles over the lower leg.
8. Tilt head back to maintain open airway, place hand under cheek to maintain head tilt, if necessary. (This is hand that was placed near cheek.)
9. Monitor victim closely until transported to facility.

▲ Place on side to assume recovery position.

Providing Bag–Valve–Mask (BVM) Ventilation

Equipment

- Manual resuscitator bag with non-rebreathing valve, clear face mask, and reservoir bag
- Oxygen source and tubing
- Airway adapter

Preparation

1. Determine that client's breathing is absent or inadequate.
2. Summon an assistant if client is not intubated.
 - **Rationale:** If no artificial airway present, two responders are essential. Assistant holds mask while nurse compresses resuscitator bag.
3. Gather equipment.
4. Place client in supine position.

▲ Compress central portion of resuscitation bag.

5. Connect mask, airway adapter to bag, attach reservoir bag if not attached.
6. Connect oxygen tubing and oxygen flowmeter to bag inlet.

Procedure

1. Turn oxygen flowmeter wide open to 15 L/minute (“flush”) and ensure reservoir bag is filled with oxygen.
 - ▶ **Rationale:** reservoir bag delivers 90%–100% concentration of oxygen at 15 L/min.
2. Standing at client’s head, hyperextend client’s neck, if no suspected trauma.
3. Clear airway of any secretions or vomitus, then place apex of mask over client’s nose and place base of mask between client’s lower lip and chin.

Clinical Alert

Cricoid pressure may be used only if the client:

- Is nonresponsive—deeply unconscious (no cough or gag reflex)
- Is not vomiting
- Does not have a cuffed tracheal tube

- ▶ **Rationale:** Reduces incidence of aspiration, improves oxygenation, and provides for tight seal.
4. Using dominant hand, compress central portion of resuscitator bag just until client’s chest rises, then allow exhalation. ▶ **Rationale:** Overinflation may result in gastric distention.
 5. Provide ventilations every 5–6 seconds for an apneic adult, noting that client’s chest rises and falls with each compression.
 6. If client breathes spontaneously, give compressions in synchrony to support ventilation.
 7. Observe for possible gastric distention. ▶ **Rationale:** Gastric insufflation may result in regurgitation and aspiration.
 8. If gastric distention is suspected in the unresponsive client, have assistant apply pressure to the cricoid cartilage in the trachea. ▶ **Rationale:** Protect airway from aspiration of client’s gastric secretions. Anticipate insertion of Naso/oro gastric tube to remove gastric secretions.
 9. Notify physician or respiratory care practitioner for further client evaluation.

NOTE: Refer to respiratory chapter for similar skill.

Using an Automated External Defibrillator (AED)

Equipment

AED unit

Procedure

1. Place AED near head on left side of victim.
 - ▶ **Rationale:** This placement facilitates easy use of machine by rescuer.
2. Open AED. This automatically turns on power in some devices.
3. Press power button on, if not automatically part of opening AED. Sound alerts, lights, and voice prompts will tell you that power is on and will direct you in use of the AED.
4. Remove victim’s clothing on torso.
5. Ensure chest is dry. ▶ **Rationale:** To ensure electrode pads will stick to chest.
6. Open package of adhesive electrode pads. Most defibrillation electrode pads are preconnected to cables. If pads are dry, then discard and obtain new adhesive electrode pads. ▶ **Rationale:** Dry pads will prevent accurate rhythm analysis and conduction.
7. Peel off protective plastic backing from pads to expose adhesive surface.
8. Place two adhesive electrode pads directly on chest skin following pictures on pads.
 - a. First pad goes on upper right side of victim’s chest, with top edge touching bottom of clavicle.
 - b. Second pad (marked with a ♥) goes to outside of left nipple, with top margin of pad at anterior axillary line, or may be placed posteriorly between the two scapulas.
 - c. Do not place pads directly over nitroglycerin patches.
 - d. Do not place pads within 1 in. of implanted devices such as pacemakers or ICD. If ICD is in process of delivering a shock and the rescuer is in contact with the client, he/she will feel the shock. Wait for 30–60 seconds for device to complete the shock cycle. ▶ **Rationale:** ICD are designed to shock the client’s lethal rhythm back into their normal rhythm. If effective, then AED shock may not be required.
9. Stop CPR if CPR is being performed. Instruct everyone to not touch the victim, in order for AED to analyze rhythm. You may need to push ANALYZE button to start the analysis. Some machines begin analyzing rhythm as soon as pads are applied.

10. If analysis indicates and commands a shock, push SHOCK on AED. (It may automatically charge when the rhythm indicates the need to shock. A voice message will inform everyone to “stay clear.”)

NOTE: A voice prompt will inform you if electrode pads are not securely attached to chest.

▲ After connecting defibrillator pad to AED unit, remove backing and apply pads to victim's chest.

▲ Apply pads to chest, one below right clavicle, one below and lateral to heart.

▲ If AED indicates need for shock, push SHOCK on AED.

11. Give one shock, then immediately begin CPR for five cycles or 2 minutes. Press ANALYZE button on AED. Repeat this procedure.
12. If victim is not in need of shock, rescuer immediately checks for pulse and begins CPR, beginning with chest compressions (30:2 ventilations).
13. When shockable rhythm is not present, AED will signal “no shock indicated” or “no shock advised.”
14. Check for presence of pulse—if none found, resume CPR.
15. Leave AED electrodes attached to victim's chest and leave AED in ON position.
16. Follow protocol for rescue breathing or CPR as victim's condition warrants.

Clinical Alert

AEDs should be used as soon as possible in the hospital setting. However, if 4 or 5 minutes have passed, the rescuer should provide five cycles of CPR (about 2 minutes) before attempting defibrillation in an unwitnessed collapse. The ventricular fibrillation waveform deteriorates rapidly within a few minutes of cardiac arrest as the heart consumes all available oxygen. Providing CPR initially will make the shock more likely to eliminate the ventricular fibrillation, and the heart more likely to function after defibrillation.

Source: American Heart Association. (2005–2006, Winter). Healthcare provider basic and advanced life support. *Currents in Emergency Cardiovascular Care*, 16(4), 16.

Pediatric adhesive electrode pads are available for children. The AED machine automatically converts the pediatric defibrillation threshold. Currently, there are no recommendations to use AED in infants.

Source: Aehlert, B. (2007). *ACLS Study Guide* (3rd ed.). Toronto, Canada: Elsevier.

Clinical Alert

The AutoPulse, an automated, noninvasive cardiac support pump, delivers chest compressions using a “hands-free” approach to restore blood flow faster and at a higher rate than manual resuscitation after a cardiac arrest.

The number of shocks an AED delivers and the energy level for each shock are preset by the manufacturer. Follow the AED voice and visual prompts. The shock sequence is usually completed three times if the client remains in fibrillation.

Administering the Abdominal Thrust (Heimlich) Maneuver to Adult or Child

Procedure

1. Be familiar with choking signs:
 - a. Ask client if he or she can speak.
 - b. Ask client to hold hand on neck if choking.
 - ▶ **Rationale:** This is the universal sign for choking.
2. If unable to talk or coughing becomes ineffective, begin abdominal thrusts.
3. Stand behind client. Place your arms around the client's waist.
4. Position hands halfway between xiphoid process and umbilicus. (Identify area by placing thumb near xiphoid and index finger on umbilicus.)

NOTE: For pregnant or obese client, chest thrusts rather than abdominal thrusts are used.

5. Make a fist with one hand and press thumb side of fist into victim's abdomen above umbilicus. Place other hand over the fist.
6. Press your fist into client's abdomen.
7. Using a rotating motion of the hands, forcefully thrust your hands in an upward direction to assist in expelling

the foreign body. (Client will probably fall over your arms.)

8. Repeat measures until foreign body is expelled or the client becomes unconscious.

Clinical Alert

Foreign bodies may partially block airway but still allow good air movement. When victim remains conscious and can forcefully cough and speak—do nothing!

Airway Obstruction Signs

- Poor air exchange
- Weak, ineffective cough
- Inability to speak
- High-pitched noise with inhalation
- Cyanosis

▲ Determine whether client is choking.

▲ Position hands to perform Heimlich.

▲ Make fist and place other hand on top.

Administering the Abdominal Thrust (Heimlich) for Unresponsive Client

Procedure

For Unresponsive Adult

1. Immediately activate EMS system.
2. Open mouth and use finger sweep to remove visible foreign object.
3. Begin cardiac compressions at 100/minute until foreign object is ejected. ▶ **Rationale:** Chest compressions have been shown to increase intrathoracic pressure higher than abdominal thrusts. Attempt 2 rescue breaths. Check if chest rises.
4. Look in mouth for foreign body each time the airway is opened for rescue breath.

5. Use finger sweep only to remove a visible foreign body.

6. Continue compressions and rescue breaths.

For Unresponsive Child

1. Begin cardiac compressions at 60/minute, continuing for five cycles (2 minutes) before summoning EMS (unless another rescuer is available to do so immediately).
2. Activate EMS after five cycles, then return to child to continue CPR until EMS arrives.

▲ Open mouth and use finger sweep only to remove visible foreign object.

▲ If client is unresponsive, begin CPR.

▲ Place on side to assume recovery position.

Calling for Rapid Response Support

Preparation

1. Be familiar with facility's pre-arrest response team policy ("Condition C," Rapid Response Team, "Light Code").
 ▶ **Rationale:** This team is summoned to assist in preventing avoidable deaths. The facility's team may consist of a bedside nurse, ICU nurses, respiratory therapists, physician, physician assistant, and pharmacists have been added to many teams.
2. Identify location of emergency equipment and medications.

Procedure

1. Identify clients at risk for pre-arrest at the beginning of each shift.
2. Monitor client frequently and closely for signs of a potentially serious complication. ▶ **Rationale:** Most in-hospital arrests are preceded by a change in the client's physiological/mental responses.
3. Establish a flow sheet for more intensive monitoring of client's vital signs, neurological assessment, urinary output, etc., as indicated.
4. Anticipate need for emergency equipment (e.g., bag–valve–mask, oxygen) and crash cart and place close at hand in case crisis occurs.
5. Check that identified client has established venous access. ▶ **Rationale:** IV access is necessary for infusion of fluids and administration of emergency medications.
6. Recognize deteriorating trends or patterns of signs and symptoms that require resources to stabilize the client (physician and other specialized personnel on Rapid Response Team).
7. Request a more experienced colleague to assist in validation of concerns, if indicated. ▶ **Rationale:** Novice nurses may be uncertain of findings and inexperienced in recognizing a "pattern" of change in clients.
8. Act upon findings and intuition by calling RRT for early intervention to stabilize the client if indicated.

Pre-Arrest Indicators

According to Ehlenbach et al. (2009), survival to discharge rates for in-hospital cardiopulmonary resuscitation averages 18.3%. Nurses must anticipate and recognize pre-arrest indicators of a serious complication and intervene before an arrest occurs. Criteria for calling the Rapid Response Team (RRT) are as follows:

Any acute change in:

- Heart rate 130 beats/min
- Systolic blood pressure, 90 mmHg
- Respiratory rate, 28
- Oxygenation saturation <90% despite O₂ supplementation
- LOC
- Urinary output <50 mL in 4 hours

Source: Ehlenbach, W. J., Barnato, A. E., Curtis, J. R., Kreuter, W., Koepsell, T. D., Deyo, R. A., Stapleton, R. D. (2009). Epidemiologic study of in-hospital cardiopulmonary resuscitation in the elderly. *New England Journal of Medicine*, 361(1), 22–31. Institute for Healthcare Improvement. Establish a rapid response team. Retrieved July 15, 2009, from <http://ihi.org/IHI/Topics/CriticalCare/IntensiveCare/Changes/EstablishaRapidResponseTeam.htm>

EVIDENCE-BASED PRACTICE

Benefits of Using Rapid Response Team

Statistics show the benefits of using a Rapid Response Team to intervene before a code is called or serious medical problems occur:

1. 4-month period in Australia: Cardiac arrest deaths dropped from 37 to 16, ICU days after cardiac arrest dropped from 163 to 33, and inpatient deaths dropped from 302 to 222.
2. Memphis, TN: A 28% drop in codes since implementing Rapid Response Team.

Source: Healthcare Management Council. (2006, May). http://wiki.hmcentral.com/index.php/Rapid_Response_Teams.

9. Obtain AED if client is nonresponsive.
10. Call for emergency equipment and assistance of two professional nurses, provide privacy, and remain with the client.
11. Set up O₂ and suction if not already at bedside.
12. Position client on back board.
13. *If CPR is not indicated:*
 - a. Continue to assess client.
 - b. Response team brings emergency supplies, establishes cardiac monitoring/AED, obtains IV access if not present.
 - c. Check client's blood glucose.
14. *If CPR is indicated:*
 - a. Begin CPR.
 - b. Use bag–valve–mask for ventilation, establish cardiac monitoring/AED. Obtain IV access if not present.
 - c. Another professional colleague retrieves supplies, supports family, accesses client's chart, and shares information with response team when they arrive.

15. Rapid Response Team takes action: orders blood tests, x-ray, medications, transfers client to intensive care setting or calls a code if indicated.

NOTE: In some hospitals, a modified RRT program is implemented, called a RAT (Rapid Assessment Team). This modified approach is directed by RNs functioning under protocols for patient management. If the team leader believes the client's condition is deteriorating, then a code is called.

Recognizing Client Changes that may Trigger Calling an RRT

- Complaints of chest pain unrelieved by nitroglycerine
- Subjective feeling that client is in danger—wary/anxious
- Sudden loss of movement or weakness in face, legs, arm
- Change in color of central or peripheral skin

Rapid Response Team Functions

Role of Rapid Response Team members:

- Airway management—MD/CRND
 - Ventilates client
 - Intubates if needed
- Airway assistant—RN/RT
 - Assists with ventilation
 - Manages oxygen and suction
- Bedside assessment—ICU RN/bedside RN
 - Assesses IV site and access
 - Administers medications
 - Applies defibrillator pads
- Crash Cart manager—ICU RN
 - Prepares medications
 - Records Code events
- Treatment leader—MD
 - Directs medical treatment
 - Determines client triage decisions
- Circulation manager—RN/MD/RT
 - Checks pulse
 - Performs chest compressions
- Procedure clinician—MD/NP/PA
 - Performs medical procedures, i.e., chest tube
 - IV central line insertion
- Data manager—RN
 - Records interventions
 - Reviews test results

Source: Scholle, C., & Mininni, N. (2006). How a Rapid Response Team saves lives. *Nursing* 2006, 36(1), 36–40.

Calling a Code

NOTE: See Procedure in Chapter 33: Advanced Skills, p. 1342.

Maintaining the Emergency “Crash” Cart

NOTE: See Procedure in Chapter 33: Advanced Skills, p. 1342.

Performing Defibrillation

NOTE: See Procedure in Chapter 33: Advanced Skills, p. 1342.

DOCUMENTATION for Emergency Life Support

- Time victim found in pre-arrest or unresponsive state
- Description of victim when found
- Time emergency measures were initiated
- Nature/description of emergency life support measures provided (CPR, use of AED, Heimlich, RRT actions, medications administered, including name, dosage, route)
- Names and titles of rescue participants (e.g., RRT)
- Duration of emergency measures provided
- Outcome of pre-arrest interventions or resuscitation efforts (client outcome)
- Recorded data from AED, monitors used, and place strips on chart per hospital policy.

CRITICAL THINKING Application

Expected Outcomes

- Basic life-support measures established within 3 minutes after arrest.
- Emergency measures performed according to established protocol.
- Client is stabilized/resuscitated with basic life support measures.
- No permanent neurologic damage is sustained.

- Obstructed airway is reestablished.
- Unresponsive client is rescued by timely intervention (calling EMS, retrieving the AED, and initiating CPR).
- Choking victim expels foreign body in response to Heimlich maneuver.
- Client has a positive outcome after emergency life support.

Unexpected Outcomes

Choking client is found on floor, Heimlich maneuver cannot be performed in usual manner.

Client is revived but maintained on life support system.

Attempts at ventilation for rescue breathing are ineffective, chest does not rise, no air is felt.

Rescuer cannot continue efforts at what appears to be unsuccessful CPR.

AED fails to analyze rhythm after 15 seconds.

Pulse does not return after AED shock.

There is no response to your EMS call for help (e.g., 911).

Chest does not rise with delivered breaths.

AED prompt says “no shock indicated.”

Alternative Actions

• Initiate CPR (100 chest compressions/min), perform procedure for administering the Heimlich maneuver for unconscious client.

• Assist in transferring client to ICU. Provide support for family and explain where ICU is and visitation policy.

• Reposition head.
• Perform CPR, look in mouth each time rescuer opens airway. Remove object if seen.

• Stop CPR if exhaustion or endangerment to rescuer.

• Resume CPR at 100 chest compressions/minute and attempt to analyze rhythm after five cycles or about 2 minutes.

• Resume CPR at 100 chest compressions/minute for five cycles or 2 minutes, reanalyze rhythm, check for pulse, and deliver shock if ventricular fibrillation continues.

• Suspect that your location is not programmed into EMS system. Try local area dial for highway patrol (e.g., *55).
• Be familiar with your local emergency response system’s summoning directives.

• Reposition head to establish airway and try again.

• Immediately resume CPR, starting at 100 chest compressions/minute; if CPR trained can start with ventilations, continue for five cycles (2 minutes) before reanalyzing heart rhythm per AED.

Choking client becomes unresponsive after several attempts at Heimlich maneuver.	<ul style="list-style-type: none">• Suspect client has nonshockable rhythm such as pulseless electrical activity; hypovolemia is most common cause.• Rule out possible causes: hypovolemia, hypoxia, hypothermia, hypoglycemia.
Client is obese or pregnant, making abdominal thrust impossible or inappropriate to perform.	<ul style="list-style-type: none">• Initiate CPR (30 compressions to 2 ventilations).• Look in victim's mouth each time airway is opened, but do not perform blind finger sweep to check for object.• Attempt to remove foreign body, only if seen.• Perform chest thrusts rather than abdominal thrusts.
Client develops complications (signs of stroke, heart attack, hypotension, altered mental status, dyspnea, tachycardia).	<ul style="list-style-type: none">• Monitor client intensely, using flow chart to trend changes in status (tachypnea, decreased urinary output).• Note client's condition and document findings.• Determine and locate equipment or anticipate procedures client might require if deterioration continues.• Initiate RRT for decision making and early intervention before crisis occurs.• Be cognizant of client's advance directives regarding resuscitation measures.

Chapter 31

UNIT 5

Pacemaker Management

Nursing Process Data

ASSESSMENT Data Base

- Assess preexisting cardiovascular status.
- Assess cardiac monitor rhythm and rate.
- Assess heart sounds.
- Observe client's general appearance for pallor, dyspnea, or edema.
- Assess for hemodynamic abnormalities related to low cardiac output, including dizziness, weakness, altered level of consciousness, low blood pressure, and decreased urinary output.
- Ensure intravenous access for administration of fluids and medications.
- Identify client's or family's knowledge of procedure.

PLANNING Objectives

- To provide temporary cardiac electrical stimulation for conditions resulting in alterations of heart rate
- To prevent bradycardia
- To overdrive fast heart rates
- To improve cardiac output

IMPLEMENTATION Procedures

- Monitoring Temporary Cardiac Pacing (Transcutaneous, Transvenous, Epicardial)1273
 - For Transcutaneous Pacing (TCP)1273
 - For Epicardial Pacing1273
 - For Transvenous or Epicardial Pacing1274
- Assisting With Pacemaker Insertion.....1274
- Maintaining Temporary Pacemaker Function1276
- Providing Permanent Pacemaker Client Teaching1277

EVALUATION Expected Outcomes

- Client's cardiac rate is maintained through use of a pacemaker.
- Client is prepared psychologically and physically for insertion of the pacemaker.
- Pacemaker is inserted without complications.
- Heart rate and cardiac output improve.

- Critical Thinking Application** 1277
- Expected Outcomes.....1277
 - Unexpected Outcomes.....1278
 - Alternative Actions1278

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Monitoring Temporary Cardiac Pacing (Transcutaneous, Transvenous, Epicardial)

Equipment

- Cardiac monitor
- Transcutaneous: pacing generator, pacing electrodes
- Appropriate temporary pulse generator (select for single- or dual-chamber pacing)
- 9-volt battery for pulse generator (single- or dual-chamber)
- Bridging cable for epicardial wires
- Clean gloves
- Established continuous cardiac monitoring—see Telemetry Monitoring skill

Preparation

1. Validate that informed consent has been obtained for temporary pacing.
2. Identify client by checking two forms of client ID.
3. Explain rationale for temporary pacing and necessary restrictions/precautions, and provide reassurance of close continuous monitoring.
4. Perform a baseline assessment: vital signs, urinary output, LOC, heart rate, rhythm, and skin color. If life-threatening dysrhythmia is assessed, prepare for pacemaker insertion. ► **Rationale:** Transcutaneous pacemakers are used for symptomatic bradycardia unresponsive to atropine or high-degree atrioventricular block causing hemodynamic compromise. If transcutaneous pacing is ineffective, then prepare for transvenous pacemaker insertion.
5. Assess IV site for patency; if no IV, establish line. ► **Rationale:** IV access is needed for drug administration.
6. Document client's cardiac rhythm according to hospital policy.
7. Perform hand hygiene.
5. Turn switch selector to "Monitor On." ECG waveform will appear.
6. Set alarm, press "Alarm On." Ensure alarm parameters are set 20 beats higher and lower than client's desired rate.
7. Record waveform by pressing "Start/Stop" button.
8. Apply pacing pads as marked, first removing posterior pad covering, then placing posterior (back) pad left of spine between the scapulas. Place anterior "front" pad to left side of lower sternum.
9. Press firmly on and around pacing electrodes. ► **Rationale:** This ensures good skin contact.
10. Attach pacing cable to pace connector on defibrillator/monitor.
11. Select "Pacer" button and green light will appear.
12. Set pacing rate to 60–80 beats/min.
13. Assess cardiac rhythm on oscilloscope and observe the QRS for sensing marker.
14. Set milliamperes (mA) threshold initially at 0. ► **Rationale:** This prevents pacemaker discharge while setting adjustment.
15. Activate pacing by depressing "Start/Stop" button.
16. Increase mA slowly, increasing it until capture appears.
17. Assess pulse and blood pressure ► **Rationale:** These parameters assess for perfusion.
18. Record ECG strip and document pacing parameters.
19. Continually assess client's need for sedation. ► **Rationale:** Pacing causes discomfort.

Procedure

For Transcutaneous Pacing (TCP)

1. Sedate client. ► **Rationale:** TCP causes discomfort.
2. Clip hair, if necessary. Do not shave under electrode placement. Do not use alcohol or tincture of benzoin because they can cause burns to occur. ► **Rationale:** Improve conduction between electrode and skin. Shaving may cause nicks in skin, which may increase discomfort with pacing.
3. Ensure client is on cardiac monitoring with either lead I, II, or III. Lead II is customary as it assesses atrial activity.
4. Connect ECG cable to input connection on pacing generator.

Clinical Alert

Transcutaneous pacing is not beneficial in asystole or pulseless electrical activity (PEA). If transcutaneous pacing fails to capture and/or increase the pulse, then transvenous pacing is required. If defibrillation is required because of ventricular defibrillation, immediately select "charge" button, as pacing will cease and defibrillation will occur.

For Epicardial Pacing

1. Don clean gloves. ► **Rationale:** Gloves are worn to prevent microshock to client.
2. Locate epicardial pacing wires on client's chest wall.
3. Securely connect pacing wires to external generator. ► **Rationale:** This promotes pacemaker impulse reception from and transmission to the myocardium.
4. Connect cable to pulse generator (positive to positive, negative to negative). ► **Rationale:** Pacing stimulus goes from pulse generator to the negative terminal and back to pulse generator by the positive terminal.
5. Remove protective cover to dial settings.

Clinical Alert

Transvenous single-chamber (ventricular) pacing is most commonly used as an emergency measure to support ventricular contraction and cardiac output. Epicardial pacing occurs when pacing electrodes are inserted into the epicardium of the right ventricle during cardiac surgery. If the physician wants to initiate atrioventricular sequential pacing, then the surgeon places an additional electrode in the right atrium. The pacing wires are then pierced through the chest wall and may be attached to the external pulse generator, which is placed on standby mode should pacing become necessary. If no pacing is indicated at this time, insert the pacing wires in either a sterile rubber glove or finger cot. Place sterile gauze and occlusive dressing over pacing wires and insertion site to prevent microshock and/or infection. Epicardial pacing electrodes provide either single-chamber atrial pacing, single-chamber ventricular pacing, or dual-chamber pacing, known as A-V sequential pacing, which is used to simulate normal pump function (atrial followed by ventricular stimulation/contraction).

6. Select pacing mode (e.g., atrial, ventricular, AV synchronous, or demand).

For Transvenous or Epicardial Pacing

1. Set dial at prescribed pacing rate (atrial and/or ventricular).
2. Set energy *output* (milliamperes or mA) on pulse generator to prescribed level (set for both atrial and ventricular pacing). ▶ **Rationale:** Energy output setting

ensures that pacemaker stimulates the client's myocardium.

3. Return plastic cover to protect generator dial settings and hang generator from pole at client's bedside.
4. Monitor pacemaker function for *sensing* (light indicates client's QRS complexes), *capture* (pacemaker spike is followed by QRS complex), and pacemaker *rate*.
5. Monitor client's heart rhythm, vital signs, and other responses to pacing, including femoral pulsation palpable with captured beats. ▶ **Rationale:** These demonstrate effectiveness of pacemaker support.
6. Remove gloves and perform hand hygiene.
7. Evaluate electrode insertion/exit sites and dress according to agency protocol.

▲ Type of external pacemaker.

Assisting With Pacemaker Insertion**Equipment**

Emergency cart with defibrillator
 External pacemaker pulse generator
 Pacing catheter electrodes
 ECG monitor
 Client cable
 Rubber glove
 Sterile antiseptic solution
 Sterile gloves, gown, and mask
 Sterile towels
 Lidocaine, 1%–2%
 Alcohol wipes
 Syringe
 Needles
 Suture with attached needle
 Sterile 4 × 4 gauze pads
 Tape

Cutdown tray

Gloves

Preparation

1. Complete hand hygiene.
2. Provide sedation as necessary. Diazepam (Valium) or Versed is frequently used. Conscious sedation may be used.
3. Connect client to a continuous ECG monitor.
4. Place the client in a supine position with head flat or slightly lower than body.
5. If either the subclavian or external jugular vein is to be used, place a towel roll under the client's shoulders to provide better exposure of the insertion site.

Procedure

1. Assist physician as needed.
 - a. Physician dons mask, sterile gown, and gloves.

- b. Insertion site is cleansed with sterile antiseptic solution.
 - c. Drape area with sterile towels.
 - d. Break single-dose vial of lidocaine and hold at angle for physician withdrawal.
 - e. Physician withdraws lidocaine, using filtered needle, then changes to 25-gauge needle and injects skin.
 - f. Insertion is accomplished (transvenous method via cutdown or percutaneously). Catheter electrode wires are positioned, and skin sutures are applied.
2. Continuously monitor the ECG and client status during the insertion.
 3. Don gloves to prevent microshock to client.
 4. Connect the pacing electrode to the appropriate outlet terminal (unipolar to negative and bipolar to both the positive and negative terminals).
 5. Turn on power switch on external pacemaker.
 6. Set rate according to physician's orders.
 7. Set milliamperes (mA) by determining threshold. To do this, observe the ECG while slowly increasing the number of milliamperes from its lowest setting to a point where each QRS complex is captured and preceded with a pacing spike.
 8. Multiply the threshold level according to hospital policy (usually two to four times) to adjust the milliampere setting.
 9. Set sensitivity mode according to physician's order (usually 1.5 mV).
 10. Secure all connections. Put plastic cover back over pacemaker controls if required.

11. Place external pacemaker and exposed wires in a rubber glove to ensure insulation against electric shock to client.
12. Apply sterile dressings to insertion site, and tape securely.
13. Obtain chest x-ray after insertion to validate lead placement if pacemaker not inserted using fluoroscopy.
14. Obtain 12-lead ECG.

Safety Alert: Electrical

- Use only grounded equipment; use common ground.
- Remove and tag any defective equipment.
- Maintain environmental humidity at 50%–60%.
- Do not roll equipment over electrical cords.
- Avoid placing wet articles on electrical equipment.
- Insulate exposed pacing electrodes at all times.
- Wear rubber gloves when handling pacing electrodes or terminals.
- Do not touch any electric equipment while handling wire or terminals.
- Discharge static electricity by touching faucets or other metal that communicates with ground.

Safety Alert

When temporary transvenous pacemakers are used, the balloon air port is *not* to be used for IV access.

Revised NASPE/BPEG Generic Code for Antibradycardia Pacing*

I Chamber(s) Paced	II Chamber(s) Sensed	III Response to Sensing	IV Rate Modulation	V Multisite Pacing
0 = None	O = None	O = None	O = None	O = None
A = Atrium	A = Atrium	T = Triggered	R = Rate modulation	A = Atrium
V = Ventricle	V = Ventricle	I = Inhibited		V = Ventricle
D = Dual (A+V)	D = Dual (A+V)	D = Dual (T+I)		D = Dual (A+V)
S = Single (A or V) [†]	S = Single (A or V) [†]			

NASPE policy statement: The NASPE/BPEG defibrillator code. *Pacing and Clinical Electrophysiology*, 16, 1776–1780. Hayes, D. L. (2009). Modes of cardiac pacing: Nomenclature and selection. Retrieved July 19, 2009 from <http://www.uptodate.com/online/content/topic.do?topicKey=carrhythm/26065&view=print.htm>
 From Bernstein, A. D., Daubert, J. C., Fletcher, R. D., Hayes, D. L., Lüderitz, B., Reynolds, D. W.,... Sutton R. (2002). The revised NASPE/BPEG generic code for antibradycardia. Adaptive-rate, and multisite pacing. *Pacing and Clinical Electrophysiology*, 25(2), 260–264.

Maintaining Temporary Pacemaker Function

Equipment

- Battery
- Oscilloscope

Procedure

1. Observe for failure to sense.
 - a. Observe the oscilloscope for presence of pacemaker artifact (spikes): artifact before QRS complex in ventricular paced or preceding the P waves and QRS waves in AV sequential pacing.
 - b. Check connections for secure, tight fit.
 - c. Observe that pace–sense needle deflects to right, indicating pacing is occurring.
 - d. Check sensitivity dial to determine whether sensitivity threshold is set correctly.
2. Observe for failure to pace.
 - a. Check that external generator is ON.
 - b. Check battery to ensure it is functioning.
 - c. Check lead connector sites.
 - d. Check pace–sense indicator. (Absence of or slight deflection of the pace–sense indicator reveals battery failure.)
3. Observe for failure to capture.
 - a. Observe for pacing artifact not followed by QRS complex. ► **Rationale:** This indicates a failure of the stimulus to trigger a ventricular response.
 - b. Check the setting of the mA, or output dial, to determine whether setting should be increased.
 - **Rationale:** The myocardial threshold may be altered as a result of disease or drugs.
 - c. Check all connector sites for secure, tight fit.
4. Observe that sutures are intact.
5. Assess insertion site for bleeding, hematoma formation, or infection.
6. Obtain chest x-ray post insertion.
7. Monitor client's response to therapy.
 - a. Assess urine output. ► **Rationale:** Decreased urine output indicates poor cardiac output.

▲ Temporary pacemakers have two parts, the pulse generator and the electrode. The pulse generator is external to the body. (A) Epicardial ventricular pacemaker. (B) Transvenous ventricular pacemaker.

Pacemaker Spike

▲ ECG tracing showing pacemaker spike triggering ventricular depolarization (QRS).

▲ ECG showing examples of pacemaker spikes.

▲ Equipment for external monitoring including belts, gel, and transducers.

- b. Observe for dyspnea, crackles, heart rate, decreased blood pressure.
- c. Monitor temperature.
- d. Observe client for signs of anxiety. Complete pacemaker teaching as necessary.

Clinical Alert

Observe for pacemaker failure:

- Decreased urine output
- ECG pattern change
- Decreased blood pressure
- Bradycardia
- Shortness of breath

8. Obtain and analyze a strip for functioning of pacemaker.
9. Observe for battery failure.
10. Observe for electrical interference and development of microshocks.
 - a. Ground all electrical equipment in close proximity to client.
 - b. Cover exposed wires with nonconductive material.
 - c. Wear gloves when handling generator/lead wires.
11. Complete pacemaker teaching as necessary.

Providing Permanent Pacemaker Client Teaching

Equipment

- Audiovisual aids
- Written material

Procedure

1. Ascertain what client already knows and understands.
2. Determine client's ability and level of interest in learning about pacemaker.
3. Recognize client's fears, and provide opportunity to talk about them.
4. Review facts: heart anatomy and physiology and pacemaker information. Use illustrations and audiovisual aids.
5. Clarify misconceptions and allay fears.
6. Provide rationale for any mobility restrictions.
7. Answer questions and provide additional opportunities to discuss procedure.
8. Check pacemaker function regularly per instructions. With new pacemakers, physicians check them on routine visits.
9. Instruct client in clinical manifestations related to pacemaker failure and when to contact physician or pacemaker clinic.

Pacemaker Clinics

Some clients use telephone transmission of the generator's pulse rate to determine status of pacemaker function. Special equipment is used to transmit information concerning function of the pacemaker over the telephone to a receiving system in a pacemaker clinic. The equipment converts information to electronic signals that are permanently recorded on ECG strip. Physicians monitor client's records and can intervene quickly when abnormalities appear on ECG strip. This type of clinic is very common in outlying areas where clients are unable to go to a clinic easily.

10. Provide client with pacemaker information ID card (provided by manufacturer) and instruct to carry in wallet.
11. Suggest a Medical Alert band be worn at all times.

NOTE: Inform client of electromagnetic interference restrictions:

- a. No MRI; do not place cell phone or cardiovert over generator.
- b. Avoid airport hand wand, high-voltage areas, and diathermy.
- c. If dizziness experienced, move away from area.

DOCUMENTATION for Pacemaker Management

- Date and time of temporary pacing
- Pacemaker settings (rate, outputs, sensitivity, AV interval)
- Client's response to treatment
- Vital signs, heart rhythm
- Rhythm strips of pacing obtained during insertion

CRITICAL THINKING Application

Expected Outcomes

- Client's cardiac rate is maintained through use of a pacemaker.
- Client is prepared psychologically and physically for insertion of the pacemaker.
- Pacemaker is inserted without complications.
- Heart rate and cardiac output improve.

Unexpected Outcomes

Temporary pacing is ineffective.

Alternative Actions

- Check for battery depletion and change if necessary (9-V batteries).
- Record rhythm strip and correlate to client's signs and symptoms.
- Monitor vital signs, mental status.
- Check sensitivity setting. (If too high, P or T wave may be sensed; if too low, fixed-rate pacing occurs.)
- Check mA setting (may be too high).
- Check pace indicator for movement.
- Check rate setting.
- Check all connections.
- Check catheter insertion site for swelling, hematoma.

Client does not understand function of pacemaker.

- If client is frightened, reassure him or her that a pacemaker is not dangerous.
- If client does not understand pacemaker or procedure, use illustrated learning aids.
- Allow time for questions and further explanations.
- Orient your teaching to the client's intellectual and interest level.

Electromagnetic interference occurs.

- Check all electric equipment for proper grounding. Use common ground.
- Remove unnecessary electric equipment from vicinity of client.
- Insulate generator terminals and exposed electrodes in a rubber glove.

Inflammation occurs at insertion site.

- Provide daily site care using strict aseptic technique.
- Keep dressings dry at all times.
- Monitor vital signs.
- Instruct client to limit extremity movement.

Diaphragmatic pacing occurs.

- Observe for hiccoughs or muscle twitching.
- Change client's position.
- Decrease the amperage (mA).
- Notify physician that endocardial perforation may have occurred.

Failure to capture is suspected.

- Check client's heart rate. If heart rate less than the rate set on generator, and if pace indicator shows firing, suspect failure to capture.
- Check all connections.
- Anticipate that pacer wires are dislodged.
- Check battery.
- Change position of extremity.
- Turn client on left side; catheter may float back to epicardial wall.
- Increase amperage (mA) after checking threshold.
- Obtain chest x-ray and 12-lead ECG.
- Anticipate change of batteries, electrode terminals, or generator.

Battery depletion occurs.

- Have atropine and isoproterenol available.
- Anticipate possible CPR.
- Turn on power switch, and observe pace indicator. If there is little or no movement, replace battery immediately.
- Record clock hours of battery usage. (Record should be taped to back of generator.)
- Determine rate fluctuations.
- Label each pacemaker with the date battery is inserted.
- Store extra batteries in refrigerator and put new battery in pacemaker before use.
- Disconnect catheter from pacemaker before replacing battery. Contact with battery terminal may be dangerous to the client.

Adaptations for Home Care

Nursing Process Data

ASSESSMENT Data Base

- Assess client's ability to monitor pulse accurately.
- Identify client's and/or family's knowledge of pacemaker function and safety measures.
- Assess pacemaker site for signs and symptoms of infection.
- Assess for signs and symptoms related to pacemaker dysfunction, including dizziness, weakness, altered level of consciousness, irregular pulse, low blood pressure, decreased urine output, and fatigue.
- Assess client's ability and knowledge related to contacting the pacemaker clinic.

PLANNING Objectives

- To provide client teaching related to monitoring pulse and use of magnet
- To evaluate client's knowledge base about pacemaker clinic
- To increase client's knowledge base about pacemaker function

IMPLEMENTATION Procedures

- Monitoring Pacemaker at Home 1280
- Checking With Pacemaker Clinic via Telephone. . . . 1280
- Instructing in Use of Holter Monitor 1281
- Teaching Care of Implantable Cardioverter–Defibrillator 1282

EVALUATION Expected Outcomes

- Client is able to accurately monitor pulse.
- Client's cardiac rate and rhythm are maintained through use of a pacemaker.
- Battery failure is identified early and major complications prevented.
- Client is knowledgeable about pacemaker function.
- Client is able to contact pacemaker clinic easily and comply with directions for pacemaker check.

- **Critical Thinking Application** 1283
- Expected Outcomes.....1283
- Unexpected Outcomes.....1283
- Alternative Actions.....1283

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Monitoring Pacemaker at Home

Equipment

Clock or watch with second hand
Daily record
Pacemaker magnet

Procedure

- Instruct client in care immediately after pacemaker insertion.
 - Keep site clean and dry for at least 2–4 days.
 - Demonstrate daily dressing change using sterile gauze and paper tape.
 - Do not use any ointments on incision site unless physician has instructed to do so.
 - Assess site daily for signs of erythema, edema, or drainage. Call physician if any of these symptoms occur.
 - Leave Steri-strips in place until they fall off.
 - Take a bath, but keep dressing dry. Place “baggie” over dressing.
 - Limit activity for 1 week. **► Rationale:** To avoid damaging the pacemaker.
 - Do not lift arm above shoulder level on side of pacemaker for 1–2 weeks.
 - Do not hit or rub insertion site or manipulate pacemaker under skin.
 - Avoid lifting (objects weighing more than 5 lb), running, or contact sports for at least 2 weeks.
- Establish a daily routine check. **► Rationale:** Battery failure can be identified in early stages by routine monitoring of pulse.

Clinical Alert

Instruct client to notify physician if incision site becomes painful or looks infected, or if he or she has a fever of 100.4°F or higher.

Clinical Alert

Pacemaker check with magnet should be done only if someone else is present, never if client is alone, because of possible magnet-induced ventricular arrhythmias. Newer temporary pacemakers are continuously monitored in the pacemaker clinic. They do not connect to a telephone for monitoring in physician’s office.

- Sit on side of bed.
 - Check pulse for 1 full minute before arising.
 - Record on daily record.
- Contact physician if any of these symptoms occur:
 - Sudden slowing or increasing in pulse rate.
 - Irregular pulse.
 - Pain or erythema over incision site.
 - Check with pacemaker magnet if ordered by physician.
 - Sit on side of bed.
 - Place magnet over pacemaker generator.
 - Take pulse for 1 full minute.
 - Record.
 - Teach safety factors to client and family.
 - Wear Medic-Alert identification band and carry pacemaker identification card at all times. **► Rationale:** This alerts healthcare providers to the fact that pacemaker is in place and identifies manufacturer’s name.
 - Avoid sources of electromagnetic interference (i.e., large engines, strong magnets, airport screening devices, alarm systems, radio transmitting towers, ham radios, and MRI diagnostic testing). **► Rationale:** These devices emit intense magnetic fields that cause temporary pacemaker dysfunction.
 - Avoid leaning over open hood of running automobile because its electrical field can interfere with pacemaker.
 - Use microwave ovens in good working order.
 - Use cellular phones on a different side from pacemaker or place in a shirt pocket.
 - If dizziness occurs, check pulse. Pulse should return to normal within 5 minutes; otherwise, seek medical attention.

Wireless Pacemaker

This is a pacemaker with a built-in small radio transmitter. It communicates to a base station attached to a phone line and is similar to a cordless phone. With this device physicians can monitor the client at home through the Internet.

Source: Dr. Wes (2009). Wireless home monitoring of pacemakers is here. Retrieved from <http://www.medpagetoday.com/Blogs/15548>

Checking With Pacemaker Clinic via Telephone

Equipment

Electrodes (e.g., finger, wrist, underarm)
Telephone
Transtelephonic transmitter
Magnet

NOTE: This is not used as often with newer devices now available.

Procedure

- Arrange schedule of calls with nurse at pacemaker clinic.
- Follow directions of monitoring service.
- Place electrodes on the skin.
- Turn on ECG transmitter.

5. Transmitter connects pulse and pacemaker data into a signal. This transmits a single-lead ECG pattern to a monitor in the clinic.
6. Instruct client to contact physician if:
 - a. Pulse is five beats or more per minute less than before magnet use.

- b. ECG pattern is altered from baseline ECG on file in clinic.

NOTE: Many clinics require that you have a touch-tone phone to use services.

Instructing in Use of Holter Monitor

Equipment

- Adhesive electrodes and lead wires
- Magnetic recorder with cassette tape
- Shoulder strap or belt clip
- Paper and pencil or diary

Procedure

1. Explain that heart rate and rhythm are monitored during entire time monitor is in place. The Holter monitor is used to obtain a continuous graphic tracing of a client's pulse while ADLs are performed.
2. Explain that Holter monitor will be in place 24–48 hr; depending on symptoms, it may be in place up to seven days.
3. Place electrodes at both negative and positive poles, as directed by laboratory staff. There are either five or seven leads.
4. Assist client in strapping monitor in place. Monitor is placed in a pouch and worn on belt device or over the shoulder.
5. Connect electrodes to recorder.
6. Instruct client to record any unusual pain, abnormal signs, symptoms, activity, or stressful situations, stating the exact time. ► **Rationale:** Unusual pain, signs, symptoms, and activity are evaluated with findings from ECG tape to assist in diagnosing cardiac problems.
7. Write down the time medications are taken, when driving to work, taking a nap, or change in activity level.
8. Explain that while wearing a Holter monitor the following directions must be followed:
 - a. Sleep on back, not abdomen.

- b. Take sponge bath only, avoid shower. ► **Rationale:** If pads become wet they will fall off and heart monitoring will not occur.
 - c. Call for instructions if an electrode falls off.
 - d. Maintain normal activity level.
 - e. Instruct client to stay away from magnets, metal detectors, high-voltage areas, and electric blankets.
9. Explain to client that he or she can call the laboratory or clinic any time during the period the Holter monitor is in place if they have questions. Call if monitor lead falls off or quits working, skin erythema occurs, or client exhibits symptoms mentioned above. Provide client with phone number of appropriate facility.
 10. Instruct client to take recorder, strap, and paper documentation to laboratory as directed.

NOTE: Diary should include:

- a. Exact time unusual symptoms, such as pounding in chest, irregular heartbeats (fluttering in chest), shortness of breath, or trouble breathing, vertigo, or fainting occurs.
- b. Time medications taken.
- c. Driving to run errands or to work.
- d. Stressful events or activities.
- e. Exact time monitor was activated.

Clinical Alert

Two new cardiac monitors are currently in use, the Marquette and the King of Hearts recorder. These are smaller monitors, lighter in weight, and have only two leads, which provide fewer restrictions for clients.

Newer Monitoring Devices

Event Monitoring: monitors infrequent symptoms by instructing client to push a button on the device. The device records and stores electrical activity for 2 minutes of pre-activity and 2 minutes of post-event ECG tracings. The small card style unit is worn around the client's neck on a lanyard. These devices are used for weeks to months. The information is transmitted to the physician.

Signal-Averaged ECG: a painless test used to assess the client's risk of developing fatal heart arrhythmias. Test is similar to ECG, but uses sophisticated technology to test for arrhythmias.

Teaching Care of Implantable Cardioverter–Defibrillator

Procedure

1. Instruct client in the following:
 - a. Call physician immediately if three shocks in a row are felt, dyspnea develops, or feet or ankle edema occurs.
 - b. Take a bath whenever, but don't take a shower until incision is dry and completely healed.
 - c. Do not change any medications for treating the arrhythmia unless specifically instructed by the physician.
 - d. Take all medications prescribed by the physician. Carry information about medications at all times, including name and dose.
 - e. Refrain from wearing tight clothing over defibrillator or lead wires if ICD is in abdomen. (Most ICDs are now implanted in the chest, so clothing restriction is not as much of an issue.) Women can wear bras.
 - f. Do not participate in contact sports or activities that could damage the defibrillator.
 - g. Drink caffeinated beverages in moderation.
 - ▶ **Rationale:** Caffeine increases heart rate and could disturb heart rhythm.
 - h. Carry medical alert band and ICD number at all times. Know settings on ICD (cutoff points in heart rate that triggers pacing and defibrillation).
2. Explain the symptoms associated with infection and instruct client to phone physician if they occur.
 - a. Erythema, edema, or tenderness surrounding incision
 - b. Fluid accumulation around surgical site
 - c. Fever of 100°F or higher
3. Instruct client to not lift anything over 5 lb the first month after surgery. Do not excessively push, pull, or twist during this time.
4. Instruct client to not exercise arms or overuse them for at least 3 months after surgery.
5. Instruct client not to resume the following activities until approved by physician:
 - a. Returning to work.
 - b. Doing household chores.
 - c. Traveling.
 - d. Resuming sexual activity.
 - e. Walking, swimming, sports.
 - f. Using large electrical appliances or electrical motors in the workplace until they have been tested to determine whether there is any effect on defibrillator.
6. Remind client that he or she should not undergo an MRI test.
 - ▶ **Rationale:** The equipment has a strong magnetic field and is unsafe for the defibrillator.
7. Remind client that wand metal detectors can affect the ICD, and walking through security checkpoint will set off alarms; therefore, they need to be searched by hand and allowed to enter the search area without going through scanner.
8. Explain that the following devices will not interfere with the defibrillator:
 - a. Electric razor.
 - b. Small kitchen appliances, including microwave ovens and small power tools.
 - c. Analog cellular phones are OK but digital phones may be sensed as abnormal and affect ICD.

Clinical Alert

For an interaction between a small electromagnetic device and the defibrillator to occur, they must be within 10 cm of each other. The greater the output power of the device, the greater the possibility of an interaction with the defibrillator.

AED at Home

- FDA-approved AED (automatic external defibrillator) for home use.
- Used for adults and children 8 years and older and weighing at least 55 lb.
- Used for person believed to be in sudden cardiac arrest, does not respond when tapped, is not breathing normally, and absence of circulation.
- When activated, machine guides user through procedure.
- Defibrillator analyzes heart rate when pads attached. Low-energy biphasic therapy initiated if needed.
- Specific directions provided for CPR and calling 911.
- AED performs daily self-tests to ensure it works properly.

DOCUMENTATION for Home Care

- Complete appropriate health assessment forms, care plans, teaching forms
 - Include outcomes from printouts from Holter monitor, pacemaker, or defibrillator—include number of times and type of incidents
 - Symptoms that elicited graph tracings or transmission to physician's office
 - Areas of erythema surrounding implanted defibrillator or pacemaker
 - Document report sent to physician via phone or other means of communication
 - Use of AED; necessity for use and client outcome
-

CRITICAL THINKING Application

Expected Outcomes

- Physician's office will keep apprised of client's condition through use of monitoring systems.
- Client is knowledgeable with use of Holter monitor and method of transmitting information to physician's office using cardiac devices.

Unexpected Outcomes

Pacemaker malfunction with magnet.

Alternative Actions

- Check pacemaker function.
 - Contact physician.
 - Check that client is not near older microwaves, large magnets, or uses excessive minutes on the cell phone.
 - Instruct client to use cell phone on opposite side of body from pacemaker.
 - Clean and dry area for new pad application.
 - Instruct client to not get pads wet.
 - Ensure client documents in diary that pads were changed.
-

Holter monitor pads come off.

GERONTOLOGIC Considerations

Stressful Physical and Emotional Conditions May Have an Especially Adverse Effect on the Elderly Client.

- The heart may be unable to respond to these changes with an adequate increase in rate, which could precipitate heart failure.
- Changes in the heart lead to decreased myocardial contractility, increased left ventricular ejection time, and delayed conduction, which plays a role in this phenomenon.

Cardiac Output Is Decreased as a Result of Tachycardia or Atrial Fibrillation, Which Is Evidenced on the ECG.

- Tachycardia causes a shortened ventricular filling time.
- Atrial fibrillation causes the loss of the atrial kick (blood volume delivered to the ventricle as a result of a coordinated atrial contraction).

ECG May be Abnormal Due to a Chronic Disease Such as Heart Failure.

- Assess client for behavioral changes, changes in level of consciousness, palpitations, dyspnea, fatigue, and falls. These are indicators of a dysrhythmic heart.
- Dysrhythmias, such as PVCs and premature atrial contractions (PACs), may be very common and not cause for alarm unless they change in number or configuration.
- Pacemaker spikes are evident on ECGs for clients with pacemakers.

Geriatric Changes in Cardio Vascular System

- Exercise—↓ cardiac response.
- Cardiac valves—thicker and stiffer.
- Sino-atrial node—↓ of pacemaker cells;
- Sympathetic nervous system:
 - ↓ response to physical stress
 - ↓ response to emotional stress
 - Less sensitive to β -adrenergic agonist drugs
- Arterial blood vessels—thicker, ↓ elasticity = ↑ BP.
- Hypertension should NOT be considered a normal consequence of aging.

Client Requiring CPR Has Dentures in Place.

- Keep dentures in place to provide for good seal around mouth.
- Bag-value breathing is more effective when tight seal around mouth is maintained.

Peripheral Vascular Assessment Is Essential When an Elderly Client Is Using Elastic Hosiery or Sequential Stockings.

- Elderly clients may very well have altered peripheral circulation before this treatment is started.
- Stockings that are too tight can interfere with the already compromised vascular blood flow, leading to ulceration of the lower extremity.
- Check color, warmth, capillary refill, and presence of pedal pulses every 4 hr when client is using these devices.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- All healthcare workers are trained in basic cardiac life support or CPR and Heimlich maneuver; therefore, anyone can initiate CPR or perform the Heimlich maneuver.
- CPR training renewal is provided frequently in the healthcare facility to ensure all employees stay current in the skill.
- RN staff assigned to the critical care units, emergency department, and operating room must also be certified in advanced cardiac life support (ACLS). These staff members can be delegated as members of the Code Team in the facility. The operating room staff does not respond to codes outside the operating room.

- RN staff may be assigned to a rapid response team for the hospital.
- It is not the usual protocol that LVN/LPNs are assigned to the critical care unit. If they do have responsibility for client care in these settings, additional education regarding ECG monitoring must be provided.
- All healthcare workers assigned to the team can measure and apply elastic hosiery.
- Ancillary staff members may have additional training in monitoring ECGs (monitoring technicians) and in taking a 12-lead ECG (ECG technician). These individuals can be delegated to perform these tasks.

Communication Matrix

- If the RN is not directly involved in monitoring the ECG, it is imperative that the technician have specific parameters for reporting the findings. These parameters must be defined during the staff report at the beginning of each shift.

- For clients on telemetry, it is critical that the staff nurse assigned to care for the client on the nursing unit be apprised of any unusual ECG findings. The telemetry nurse must place an ECG tracing on the client's chart according to hospital policy.
- During a code, the nurse caring for the client should be relieved from performing CPR duties to answer questions, obtain information, and assist others in the code team to perform the necessary skills to promote a positive outcome of the event.
- During shift report, ensure that the on-coming shift is apprised of any client who is at risk for developing cardiac complications or is considered a potential "code."
- Orders for a code or no-code status should be addressed so that all staff are aware of the client's status. The code cart should be placed near the client's room if the code is imminent.
- Call the rapid response team if client is decompensating.
- Copy of advance directives should be placed in client chart.

CRITICAL THINKING Strategies

Scenario 1

You work day shift in the transitional care unit (TCU) and have been assigned two clients who require total care. Each client is on a cardiac monitor.

Client 1: A 65-year-old male in heart failure, responding well to drug therapy of Lasix and digoxin. His lungs are clear, and he has lost 5 lb since yesterday.

Client 2: A 70-year-old female with a myocardial infarction 2 days ago. She is considered unstable and is receiving close monitoring.

1. What is your first nursing action of the morning?
2. What alterations will you expect in the assessment of Client 2? Provide rationale for your answer.
3. Which client will you attend to first? Provide rationale.
4. Complete the interpretation of the ECG for Client 1.
5. Determine the following:
 - a. Heart rate
 - b. Regularity of rhythm
 - c. PR interval
 - d. QRS duration
6. Identify the rhythm based on the information in question 5.
7. Is this a life-threatening arrhythmia?
8. What is your priority intervention?
9. Identify the rhythm strip for Client 2.
10. What are implications for the condition of this client?
11. Identify why this client may have this type of ECG reading.
12. Identify the most effective drug treatment for this arrhythmia and provide the pharmacologic action to support your answer.
13. Identify the possible side effects of the drug and the clinical manifestations you will be monitoring in your assessment.
14. As you are preparing to provide hygienic care to Client 2, you look at the monitor and see the following ECG findings.
 - a. What rhythm is depicted on the above strip?
 - b. Describe what is happening to the client in this rhythm.
 - c. What priority intervention should be done?
 - d. What is the second intervention if the priority intervention is not effective?

Scenario 2

During nursing report the nurse indicates she is very concerned about a client who has been unstable all night. You decide to check that client first on your rounds.

1. What is the initial client assessment you will make when you enter the room?
2. Is this a client who might be a candidate for the Rapid Response Team? Provide rationale for your answer.
3. Describe the function of the RRT.
4. What role does the RN taking care of the client assume on the RRT?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. The client you are caring for is placed on telemetry. As you assess the ECG findings, you remember the QRS complex represents
 1. Atrial depolarization.
 2. The time it takes for atrial depolarization.
 3. Depolarization of the ventricles.
 4. The time required for ventricular depolarization and repolarization.
2. An atrial dysrhythmia results from a disturbance
 1. With an SA node.
 2. In the AV node.
 3. In the Purkinje fibers.
 4. In the bundle of His.

3. A demand pacemaker is used for which one of the following cardiac needs? It
 1. Alters the rate of discharge according to changes in activity and rest.
 2. Discharges a steady electrical impulse at a certain rate regardless of the underlying heart rate.
 3. Discharges an electrical impulse only when the heart rate falls below a programmable heart rate.
 4. Discharges an electrical impulse only when a ventricular dysrhythmia occurs.
 4. The morning report indicated the client you are assigned to care for is at risk for hemorrhage. When assessing the client, which one of the following symptoms would *not* lead you to suspect a hemorrhage is occurring?
 1. Urine output of 30–40 mL/hour for the last 4 hr.
 2. Diastolic pressure of 90 mmHg the last 2 hr.
 3. Respirations of 18–20 and shallow.
 4. Clammy skin and central cyanosis.
 5. As you go by a client's room, the son comes running out and says, "My dad isn't breathing!" You go quickly to the bedside and determine he needs CPR. You initiate it by first
 1. Compressing the chest five times and then completing two deep breaths.
 2. Administering 30 chest compressions and two breaths.
 3. Defibrillating the client with the AED.
 4. Check for breathing by opening mouth and listening for breaths.
 6. The preoperative client has an order for thigh-high graduated compression stockings before surgery. Your first action is to measure the client for the correct hosiery size. You will measure by
 1. First checking the circumference of the largest area of the calf.
 2. Measuring from the Achilles tendon to the popliteal fold.
 3. Measuring from the gluteal fold to bottom of the heel.
 4. Checking the distance between one handbreadth above the knee to the ankle.
 7. The contraindications to use of sequential compression devices include which of the following conditions?

Select all that apply.

 1. Heart failure.
 2. Dermatitis, gangrene.
 3. Conditions that increase venous return to the heart.
 4. Pulmonary embolism.
 8. While making a home visit, you find a client who seems to be choking on food. Your initial response in this emergency is to
 1. Perform an abdominal thrust.
 2. Begin CPR at the rate of 30 compressions and two breaths.
 3. Ask the client if he can speak.
 4. Strike the client on the back.
 9. Which statement is incorrect?
 1. Rescue breathing is more effective when a tight seal around the mouth is maintained.
 2. Children have the same physiological reserve as adults, thus require infrequent assessment.
 3. Transcutaneous external pacemakers are used to treat symptomatic bradycardia.
 4. Pulmonary veins carry oxygenated blood.
 10. A Rapid Response Team is called when
 1. A client is in imminent need of CPR.
 2. An avoidable death can be prevented.
 3. The use of AED is required during the CODE.
 4. The client needs to be transferred to the ICU.
-

Neurologic Management

LEARNING OBJECTIVES

1. Review the structure and function of the cerebrum, cerebellum, and brainstem.
2. Describe the unique metabolic demands of the central nervous system.
3. Outline the role of structures that protect the brain.
4. Discuss the brain's ability to autoregulate cerebral blood flow.
5. Identify the three components that dictate intracranial pressure.
6. Calculate cerebral perfusion pressure (CPP) based on available data: mean arterial pressure (MAP) and intracranial pressure (ICP).
7. Discuss physiologic compensatory mechanisms that occur with an increased intracranial pressure.
8. Describe the process of assessing the neurologic client experiencing increasing intracranial pressure.
9. Discuss limitations and alternatives to the use of the Glasgow Coma Scale in comatose clients.
10. Identify various assessment tools used to evaluate pain and sedation level in the nonverbal client.
11. State criteria used to determine brain death.
12. Explain the rationale for monitoring intracranial pressure (ICP).
13. Identify components of a normal intracranial pressure (ICP) wave-form.
14. List physical and environmental/contextual factors that increase intracranial pressure.
15. Explain rationale for therapies used to treat intracranial hypertension.
16. Outline nursing responsibilities in the care of a client with an ICP monitoring system and/or ventriculostomy for cerebrospinal fluid drainage.

TERMINOLOGY

Anisocoria pupils of unequal size.

Autoregulation ability of the brain to maintain, *within limits*, a constant blood flow despite significant changes in systemic blood pressure.

Brain Death medical–clinical diagnosis based on cessation of all brain function (unresponsiveness, absence of brainstem reflexes, apnea) when the cause is known and irreversible.

Cerebral Perfusion Pressure a calculated value derived from intracranial pressure (ICP) and mean arterial pressure (MAP) ($\text{MAP} - \text{ICP} = \text{CPP}$); an indirect method of evaluating adequacy of cerebral blood flow; normal CPP ranges from 60–160 mmHg.

Cognition skill for thinking and remembering, including paying attention, being aware of surroundings, reasoning, judgment, and problem solving.

Coma clinical state of altered consciousness in which a client is nonresponsive to environmental stimuli (cannot be aroused) due to diffuse bilateral cerebral hemispheric dysfunction, involvement of the brainstem, or both; coma level based on motor response to noxious stimulus.

Concussion complex pathophysiological process affecting the brain, induced by traumatic biomechanical forces (e.g., blow to the head or elsewhere with impulsive force transmitted to the head); may or may not result in loss of consciousness. Cumulative (repeated) events affect white matter (axons).

Consciousness a state of wakefulness (arousal) and general awareness (cognition) of self and environment, including orientation to time, place, and person. (Terminology used to describe various levels of consciousness include full consciousness, confusion, lethargy, obtundation, stupor, and coma.)

Confusion disoriented in time, place, or person; short attention span; inability to think with normal speed and clarity; impaired judgment and decision making; difficulty following commands; may have hallucinations, be agitated, restless, irritable, increasingly confused at night.

Contralateral on the opposite side.

Contusion neurologic dysfunction caused by acceleration/deceleration injury (e.g., blow to the head)

often associated with coup (injury at site of impact) and contrecoup (injury at side opposite the impact) due to movement of the brain within the skull.

Craniectomy removal of a bone flap to allow decompression (expansion of edematous brain tissue) and reduce intracranial pressure.

Cushing's Triad systolic hypertension, widening pulse pressure, and bradycardia indicative of medullary ischemia.

Decerebration abnormal posturing associated with midbrain (upper brainstem) dysfunction.

Decortication abnormal posturing associated with a direct lesion of the thalamus or mass that compresses the thalamus (above the brainstem).

Diplopia seeing two separate images of the same object in visual space due to images falling on each retina at different points rather than on the same points.

Disorientation beginning loss of consciousness; impaired awareness of time, then place and memory, then recognition of self.

FOUR-Score Coma Scale “Full Outline of Un-Responsiveness” grading system (0 to 4) used to assess eye response, motor response, brainstem reflexes, and respiration.

Glasgow Coma Scale assessment tool designed to standardize observations of a patient's level of consciousness (comatose states).

Hydrocephalus progressive dilation of the ventricles due to overproduction of CSF or abnormalities of CSF circulation or reabsorption.

Intracranial Pressure (ICP) the sum of pressures exerted by intracranial contents (cerebrospinal fluid, blood, and brain tissue); normal range is 5–15 mmHg.

Ipsilateral on the same side.

Lethargy limited spontaneous movement or speech but easily aroused by speech or tactile stimulation; sluggish thought, but oriented to time, place, and person.

Level of Consciousness a continuum of responsiveness ranging from arousal/wakefulness, orientation, comprehension, and expression to nonresponsiveness to bodily or environmental stimuli.

Locked-In Syndrome state of normal level of consciousness but complete body paralysis except for vertical eye movements and ability to blink on command (paralysis below CN III).

MAP (Mean Arterial Pressure) average cardiac cycle arterial pressure:

$$\text{MAP} = \frac{(\text{SBP}) + (\text{DBP} \times 2)}{3}$$

Medial Longitudinal Fasciculus (MLF) pathway that interconnects the vestibular nuclei (CN VIII) with motor nuclei that innervate the extraocular eye muscles (CN III, IV, VI).

Microsensor fiberoptic “transducer tipped” intraventricular or intraparenchymal bolt catheter used to monitor intracranial pressure.

Neuromuscular Blockade chemical paralysis used as restraint to control increased blood pressure and ICP due to restlessness, agitation, posturing, ventilator dyssynchrony.

Nystagmus involuntary drift of the eye with rapid correction in the opposite direction; the direction of fast correction describes the nystagmus.

Obtundation state of reduced awakesness/alertness and limited response to the environment; rousable but falls asleep unless stimulated orally or by touch; responds minimally to questions.

Reticular Activating System center located in the brainstem that interacts with the cerebral hemispheres to maintain normal consciousness.

Rostrocaudal descending the long axis of the body (top downward).

Secondary Injury cascade of events including brain tissue ischemia and cerebral edema that occurs, causing damage to surrounding tissue after primary traumatic brain injury.

Stupor having minimal spontaneous movement; unresponsive except to vigorous repeated stimuli; may have unintelligible sounds or eye opening; responds appropriately to painful stimulus; may withdraw from or grab at the stimulus.

Tragus cartilaginous projection in front of the external auditory canal.

Vegetative State state in which client with bilateral hemispheric disease (metabolic encephalopathy), initially comatose, may show improvement so that the client is awake, but unaware.

Ventriculostomy a hollow ventricular catheter placed through a burr hole in the skull and advanced into the lateral ventricle of the nondominant hemisphere; used to monitor ICP, provide therapeutic CSF drainage to relieve pressure, and allow specimen sampling.

INTRODUCTION

This chapter presents a nursing process approach to care, focusing on techniques of assessing the neurologic client with altered levels of consciousness and the management of intracranial hypertension. (See chapter 11 for basic information and neurologic assessment.)

THE CONSCIOUS STATE

The nervous system includes two interdependent subsystems: the central nervous system (CNS) composed of the brain and spinal cord and the peripheral nervous system (PNS) composed of nerve fibers (cranial, spinal, and autonomic) that relay information between the CNS and other parts of the body. This complex system involves automatic feedback mechanisms that allow us to respond to stimuli from the internal and external environments through cognitive, behavioral, autonomic, and motor responses in a way that enables us to maintain a steady state, or *homeostasis*.

The brain is composed of left and right cerebral hemispheres (each divided into four functional lobes), the cerebellar lobes, and brainstem (midbrain, pons, and medulla). The conscious state includes both *wakefulness* and *awareness* of one’s self and the environment (*orientation* to time, place, and person) and depends on an intact interaction between the reticular activating system (RAS) located in the brainstem and thalamus, which controls wakefulness, and the higher cerebral cortical centers, which are responsible for orientation. Altered levels of consciousness (coma) can occur with intracranial (structural) or extracranial (metabolic) disorders. The vast majority (85%) of coma cases are due to

metabolic disorders, such as hypoxia, respiratory failure, hypo/hyperglycemia, uremia, or drug overdose, which cause diffuse dysfunction of both cerebral hemispheres and/or involvement of the ascending RAS. Intracranial disorders such as infection (meningitis, encephalitis) or concussion (brain trauma) can also cause coma with diffuse dysfunction.

In contrast to diffuse dysfunction, unilateral cerebral hemispheric lesions such as infarction (“brain attack”), hematoma, hemorrhage, or tumor cause *focal* neurologic signs of dysfunction related to the particular area or functional lobe involved. Focal lesions expand and, along with edema formation, increase intracranial pressure, may decrease cerebral blood flow, displace contralateral structures, and exert rostrocaudal (downward) compression on the brainstem (RAS) such that deteriorating levels of consciousness follow.

Normal function of the cerebral lobes, diencephalon (located above the brainstem), cerebellum, and brainstem and findings associated with dysfunction of these areas are reviewed in Table 32-1.

▲ Lobes of the brain.

TABLE 32-1 Functions of the Cerebral Cortex, Cerebellum, and Brainstem

Structure	Function	Dysfunctional Behaviors
Frontal Lobe Cortex	Memory, judgment, problem solving, concentration, personality, mood Initiation of motor activity and voluntary movement Expressive (motor) speech (left hemisphere)	Difficulty with attention and problem solving; inflexible thinking; personality change; behavioral changes (emotional, social, sexual) Left CVA results in contralateral hemiparesis or hemiplegia and hemisensory loss in the same distribution; expressive aphasia; contralateral homonymous hemianopsia; limited right conjugate gaze; shortened attention span; hesitancy Right CVA results in contralateral hemiparesis or hemiplegia and hemisensory loss in the same distribution; contralateral homonymous hemianopia; left visual and sensory neglect; poor left conjugate gaze; impulsive behavior; unaware of deficits.
Temporal Lobe Cortex	Memory, hearing, understanding (receptive) language Emotional affect	Short-term memory loss; may verbalize, but is unable to understand what is said by others; aggressive behavior; difficulty identifying objects; difficulty recognizing faces; disturbed selective attention; change in sexuality Auditory, visual, and sensory hallucinations
Parietal Lobe Cortex	Sense of touch, pain, position, pressure, vibration Recognition of object size, shape, texture. Spatial perceptual orientation Awareness of one's body parts Visual perception Receptive speech (written, oral) function	Difficulty naming objects; problems of reading and writing; right/left confusion; math difficulties Inability to focus visual attention; problems with eye-hand coordination; lack of awareness/inattention to body parts Receptive language dysfunction; expressive "word salad"
Occipital Lobe Cortex	Interpretation of visual stimuli (impulses from cranial nerve [CN] II)	Visual field defects; difficulty identifying colors; hallucinations/visual distortions; word blindness; difficulty reading and writing
Diencephalon: Thalamus	Relay center for all sensory and motor pathways All sensory pathways (except olfactory, CN I) going to the brain are processed here before being sent to the cerebral cortex Awareness of pain, temperature, and light touch; reticular activating system focuses attention, stimulates cortex and ANS	Impaired consciousness Sensory and motor dysfunction Decorticate (abnormal flexor) posturing associated with a direct lesion or compression from hemispheres
Diencephalon: Hypothalamus	Stimulates the autonomic nervous system: regulates temperature, water balance, thirst, appetite, visceral and somatic activities Controls pituitary hormone release Coordinates body behavioral responses to emotion Sleep-wakefulness cycle, circadian rhythm	Impaired consciousness Alterations of body temperature Diabetes insipidus (polyuria) Syndrome of inappropriate antidiuretic hormone (water retention with hyponatremia) Cheyne-Stokes respiration (rhythmic rise and fall in rate and depth of breathing with long periods of apnea)

TABLE 32-1 Functions of the Cerebral Cortex, Cerebellum, and Brainstem (Continued)

Structure	Function	Dysfunctional Behaviors
Cerebellum	Maintains posture, balance Coordination of voluntary muscle activity and muscle tone Controls fine movement/skilled motor activity	Problems with fine movement/coordination; inability to make rapid movements Lack of coordination Inability to grasp objects; tremors/dizziness; slurred speech; inability to walk
Brainstem: Midbrain	Contains nuclei for CN III and IV Center for auditory and visual reflexes Lies directly beneath the diencephalon (thalamus and hypothalamus) Contains aqueduct of Sylvius Pathway between cerebral hemispheres and lower brain	Ipsilateral pupil dilation with head injury/uncal herniation Both eyes deviate medially or laterally Neurogenic hyperventilation (sustained deep breathing with no apneic periods) Decerebrate (abnormal extensor) posturing
Brainstem: Pons	Contains nuclei for CN V through VIII Medial longitudinal fasciculus tract connects CN III, IV, and VI with vestibular portion of acoustic nerve (CN VIII), allowing coordinated eye movement in response to noise, motion, position, and arousal Relays information to and from the brain Contains fourth ventricle Contains vital centers for breathing (length of inspiration/expiration, rate)	Alterations of extraocular movements <i>See Oculocephalic and Oculovestibular Testing</i> Apneustic breathing (has prolonged inspiratory or expiratory pauses)
Brainstem: Medulla	Contains nuclei for CN IX through XII Controls vital functions: swallowing, vomiting, hiccoughing, coughing, heart rate, arterial constriction, respiratory rhythm Motor tracts cross to opposite side, descend the spinal cord for contralateral voluntary movement	Cluster breathing (irregular gasping respirations with long periods of apnea) Ataxic respiration (irregular deep and shallow breathing with periods of apnea) “Cushing’s Triad”: bradycardia, systolic hypertension, widened pulse pressure Arrhythmias, atrioventricular block

STRUCTURES AND FUNCTIONS THAT PROTECT THE BRAIN

Skull, Meninges, and Spinal Fluid

The brain is protected by an unyielding skull, the meninges that cover the brain (dura, arachnoid, and pia mater), and cerebrospinal fluid (CSF), which circulates within the subarachnoid space to provide protective shock absorption. The ventricles produce 120 mL of CSF each day, while an equal amount is reabsorbed through arachnoid projections (villi) and returned to the venous circulation such that CSF pressure remains constant. If the villi become obstructed, the ventricles may dilate, causing a “normal pressure hydrocephalus” with a classic triad of gait instability, urinary incontinence, and altered mental status. This problem, occurring mostly in older clients, can be relieved by placement of a VP shunt that diverts CSF from the ventricles to the peritoneal cavity.

The dura mater lies close to the skull and creates a vertical fold (falx) that separates the right and left frontal lobes and a horizontal fold (tentorium) that separates the occipital and cerebellar lobes. With increasing intracranial pressure, brain tissue may herniate around these dural folds.

Fractures of the temporal and parietal bones may be associated with epidural (between the skull and dura) meningeal artery bleed that spreads freely and causes a rapid change in level of consciousness. An epidural hematoma is a surgical emergency. In contrast, a subdural bleed is venous in nature, slower, and may be associated with delayed signs of altered consciousness. This type of injury is more commonly seen in elderly clients with head injury associated with a fall that may or may not have been documented or remembered.

Fractures of the basal skull bones may be missed because they are not visible on skull or sinus x-rays but are often associated with tearing of the dura, causing CSF leakage from the ear (otorrhea) or nose (rhinorrhea) or altered CN VII function. These findings may be delayed, but should be reported immediately as they increase risk for infection. Leakage is usually self-limiting, but if it persists for 4–5 days, lumbar CSF drainage may be necessary to allow the dural tear to heal.

Autoregulation

The brain requires a continuous supply of oxygen and glucose to maintain its energy requirements. While it makes up only 2% of body weight, it receives 15% of the cardiac output and

uses 20% of blood oxygen. Despite fluctuations in blood pressure, the brain is able to regulate its own blood flow by arteriolar dilation when blood pressure falls or constriction when blood pressure rises. This protective function requires a mean arterial pressure (MAP) of 50–150 mmHg and is disrupted with any increase in intracranial pressure or decrease in cerebral perfusion pressure. Then, if blood pressure rises, cerebral blood volume increases, causing an increased intracranial pressure. While hypertension must be controlled, a MAP sufficient to provide adequate cerebral perfusion must be maintained if intracranial hypertension exists. Target cerebral perfusion pressure (CPP) is 70–80 mmHg and is calculated by subtracting the intracranial pressure (ICP) from the MAP ($\text{MAP} - \text{ICP} = \text{CPP}$).

INTRACRANIAL HYPERTENSION

Intracranial pressure, normally 3–15 mmHg, is dictated by three components: 80% brain tissue, 10% cerebral blood volume (with 80% being venous blood), and 10% CSF. Volumes of these constituents are kept relatively constant, but pathologic conditions can cause an increase of one of these components that must be compensated for by a decrease in one or both of the other components in order to maintain a normal ICP (Monro-Kellie hypothesis).

An increase in brain tissue occurs with edema that accompanies any type of injury (trauma, CVA) or a mass such as a tumor. An increase in cerebral blood flow occurs with an intracranial bleed or subarachnoid hemorrhage, or even cerebral vasodilation due to hypoxemia, hypocarbia, or certain medications. An increase in CSF occurs with blockage of its outflow paths or obstructed reabsorption by subarachnoid villi.

The brain has limited ability to control increased ICP by: (1) shunting CSF from the intracranial to the lumbar space, where CSF reabsorption is increased; (2) by compression of the cerebral venous system to reduce cerebral blood volume; and (3) by displacement of brain tissue, but this is adaptive only with a slowly expanding mass or hematoma condition. When these compensatory mechanisms are exhausted, ICP rises exponentially, cerebral perfusion is impaired, and brain tissue displaces or herniates through available openings. (See page 1305, herniation progression.)

When ICP increases to a level that compresses arterial flow ($\text{ICP} = \text{MAP}$), the Cushing reflex (bradycardia, increased SBP with widened pulse pressure, erratic breathing pattern) is activated to protect the brain from inadequate blood flow. Unfortunately, these changes in vital signs are late indicators of rostrocaudal deterioration.

Intracranial pressure monitoring systems may be used to measure the mean pressure exerted in the skull and alert the nurse to increases in ICP before external signs such as altered level of consciousness or pupillary changes occur. Monitoring also guides early intervention before damage occurs, assists the nurse in determining effects that care measures have on the client's ICP responses, and serves as a basis for ongoing evaluation of goal achievement and maintenance of desired outcomes: e.g., target $\text{ICP} \leq 20$ mmHg and $\text{CPP} \geq 70$ –80 mmHg.

A number of medical and nursing measures help to control ICP by selectively manipulating the three components that dictate intracranial pressure. Brain volume can be reduced by decreasing cerebral edema with osmotic diuretics (mannitol) and hypertonic saline, which also improve cerebral blood flow by decreasing blood viscosity and reducing serum hematocrit. During the acute phase, cerebral metabolic needs, refractory elevations of ICP, and effects of secondary brain injury can be modulated by induced hypothermia. CSF volume is reduced by continuous or intermittent external drainage of cerebrospinal fluid (ventriculostomy). Cerebral blood volume can be reduced with hyperventilation (PCO_2 25–30 mmHg), which can cause vasoconstriction with global or localized cerebral ischemia but may be used briefly as a bridge to more appropriate therapy. Blood volume can also be reduced by supporting jugular venous return with neutral head alignment, 30° bed elevation, and by preventing surges in central venous pressure associated with maneuvers that increase intra-abdominal and intrathoracic pressure. Cautious use of analgesics and sedatives is an integral component of managing ICP as these modalities blunt the ANS response to noxious stimuli, decrease O_2 consumption, and enhance psychological well-being. These agents have adverse side effects that may increase ICP and necessitate continuous assessment of the client's response to their use and impact on ventilation and oxygenation.

NURSING CARE OF THE NEUROLOGIC CLIENT

The Glasgow Coma Scale (GCS; see Glasgow Coma Scale, Chapter 11) has been used for several decades to evaluate level of consciousness (LOC) by requiring the client to hear the examiner and respond with (1) eye opening, (2) oral, and (3) motor responses. If the client is unresponsive to these, abnormal posturing response (decortication, decerebration) to shaking or noxious stimuli is assessed. Clients with a score of 8 or less are considered to be comatose and are typically intubated to protect the airway and facilitate mechanical ventilation if required. A “T” is added to their GCS score to indicate this functional limitation. Using this scale, a client with spinal cord injury who is paralyzed may receive a coma score of 8, be intubated, but not be comatose. It follows that the GCS cannot be used to assess neurologic signs in clients who are unable to respond orally (e.g., clients who are intubated, sedated, aphasic, have impaired hearing or altered level of consciousness).

The Full Outline of Un-Responsiveness (“FOUR score”) coma scale is an alternative tool for assessing the comatose client, especially one with an acute metabolic or other non-structural brain injury/disorder because it detects early changes in consciousness such as inability to follow the examiner's commands, altered brainstem reflexes, and Cheyne-Stokes breathing. It is also used to differentiate vegetative from minimally conscious states, locked-in syndrome, uncal herniation, and brain death.

Pain, general discomfort, fatigue, anxiety, restlessness, and agitation increase cerebral metabolism, heart rate, blood pressure, and intracranial pressure, but the neurologic client's inability to communicate confines the nurse to observing the behavioral and physiologic indicators of distress without the ability to identify or validate a potential cause. Since nonverbal responses have many possible stimuli that require different treatment, they may be misinterpreted and inadequately managed. For instance, failure to recognize that pain often leads to agitation may lead to excessive administration of sedatives, leaving pain untreated. It is essential to use reliable assessment tools to differentiate among distressful stimuli so that appropriate therapies can be provided. The Critical Care Pain Observation Tool and a number of sedation/agitation assessment scales have been determined to be valid and reliable to use with neurologic clients who are unable to communicate verbally.

Caring for neurologic clients challenges the nurse's insight and ability to appreciate the client's unique experience, to assess patiently, to identify distressful stimuli, and to respond empathically with informed actions. Comprehensive care also includes ongoing support of all body systems and prevention of a wide range of complications that can occur. Emotional support is provided by communicating with the client, whether or not he or she is responsive. This has been shown to help relieve anxiety and fear and serves as a means of preventing acute surges in ICP. Concerned others are also supported by answering questions and explaining how technical aspects of care contribute to the client's progress as they inform and help direct decision making. Once the client is stable, family members can be encouraged to participate in simple comforting care measures and engage in providing gentle sensory stimuli, which may enhance arousal and awareness as the client regains the conscious state.

CULTURAL AWARENESS

African Americans

May be wary of discussions of advanced directives and organ donation, especially if the client is seriously ill.

May view client's condition as God's punishment for improper behavior or as the work of the devil or that a spell has been cast. May have a fatalistic attitude about illness.

View organ donation as desecration of the body and consent may hasten one's death.

Generally do not consider organ transplantation except for immediate family members.

Believe life support should not be withdrawn, considering it a gift of God.

American Indians

Open expression is usually reserved for close of kin and friends.

May be wary of signing consents (based on historical abuse of signed documents).

Organ donation is usually not practiced.

If family members are unavailable to sign consent, procedures should be minimally invasive.

If cutting hair is necessary, ask client or family whom they prefer to do this.

May be reluctant to give up body parts. Ask client or family how hair should be disposed of; some tribes require hair to be stored by the family or to be disposed of ceremoniously.

A designated person may need to wash and style hair of seriously ill clients.

A child or family friend may be family spokesperson. Ask who should receive information.

Family should be informed if death is imminent so that arrangements can be made and loved ones can gather.

With death family may request that the body be cleansed by a special person before it is moved.

Mexican Americans

Many have special amulets (crucifix, religious medal) that should be kept near the client. Such items or special clothing should be handled carefully and given to a family member for safe-keeping if indicated.

May use a variety of home/folk remedies (teas, etc.) for symptom management.

Prefers words rather than numbers to describe intensity of symptoms.

Family unit may make decisions regarding treatment. Ask client how decisions are made.

Limited visiting policy may be viewed as attempt to hide something from the family.

May fear that speaking about death will hasten or cause it.

May be wary of nurse practitioners, thinking care is substandard, but many experience midwives as the only healthcare providers available.

May request priest or hospital chaplain to administer sacrament of the sick and may be indicated after death, before the body is removed.

Family members may be emotionally distraught and need extra time to remain with the deceased. Feelings about death and its sequel are greatly influenced by religious beliefs.

May believe the body must be buried intact and have a negative attitude about organ donation.

NURSING DIAGNOSES

The following nursing diagnoses are appropriate to use on client care plans when the components are related to clients who require focused neurologic assessment and management of increased intracranial pressure.

NURSING DIAGNOSIS	RELATED FACTORS
Aspiration, Risk for	Altered level of consciousness Airway intubation
Imbalanced Body Temperature, Risk for	Traumatic brain (hypothalamic) injury
Acute Confusion	Brain injury
Decreased Intracranial Adaptive Capacity	Increased intracranial contents (blood, tissue, spinal fluid)
Imbalanced Fluid Volume, Risk for	Traumatic brain (hypothalamic) injury
Impaired Verbal Communication	Altered level of consciousness, neuromuscular blockade, airway intubation
Ineffective Thermoregulation	Brain injury
Impaired Bed Mobility	Neuromuscular blockade; invasive monitoring
Ineffective Cerebral Tissue Perfusion, Risk for	Increased intracranial pressure
Infection, Risk for	Invasive monitoring catheters; pathologic (rhinorrhea, otorrhea) and therapeutic cerebral spinal fluid drainage
Impaired Skin Integrity, Risk for	Sedation, neuromuscular blockade (paralysis) Restricted positioning due to monitoring devices

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. Remember to wash your hands or use antibacterial gel before and after each and every client contact.

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Assessment of the Neurologic Client

Nursing Process Data

ASSESSMENT Data Base

- Determine a neurologic client’s level of consciousness
- Determine deviations and implications for care for the client with altered brainstem reflexes
- Identify signs of basilar skull fracture
- Recognize changes in vital signs that occur with altered level of consciousness
- Utilize the FOUR-Score Coma Scale for nonverbal clients
- List criteria used to determine brain death in adults

PLANNING Objectives

- To determine a neurologic client’s level of consciousness
- To assess brainstem reflexes in the neurologic client
- To employ protective measures for the client with altered brainstem reflexes
- To recognize signs of basilar skull fracture and implications for care
- To identify changes in brainstem reflexes and vital signs associated with herniation syndromes
- To compare features of the Glasgow Coma Scale with those of the FOUR-Score coma scale
- To assist the physician with determination of brain death
- To support a family/caregiver of a deceased organ donor

IMPLEMENTATION Procedures

- Assessing Levels of Consciousness (Descending Categories)1296
- Assessing Cranial Nerves (Brainstem Reflexes)1296
- Assessing the Oculocephalic (Doll’s eye) Reflex1298
- Assessing the Oculovestibular Reflex: “Cold Calorics Test”1298
- Assessing for Signs of Basilar Skull Fracture1299
- Assessing Vital Signs1299
- Assessing Coma in the Neurologic Client (FOUR-Score Coma Scale)1301
- Determining Brain Death—Assessing for Apnea (CO₂ Challenge)1301
- Supporting the Family or Caregiver1302

EVALUATION Expected Outcomes

- Appropriate tools are used to evaluate a neurologic client’s level of consciousness.
- Ongoing assessment of brainstem reflexes and vital signs are used to identify increasing intracranial pressure in the neurologic client.
- Signs of possible basilar skull fracture are identified.
- Established criteria are used to determine brain death.
- Supportive communication is provided for family or caregiver of a deceased organ donor.

- Critical Thinking Application** 1303
- Expected Outcomes 1303
 - Unexpected Outcomes 1303
 - Alternative Actions 1303

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Assessing Levels of Consciousness (Descending Categories)

NOTE: There is no internationally accepted taxonomy of definition of LOC, no precise terminology, and no agreement on behaviors of various stages.

Procedure

1. Describe client behaviors assessed rather than using labels such as the following. ► **Rationale:** Behaviors are

more helpful and allow others to easily note changes in client functioning.

2. Record client's response (e.g., responds appropriately to oral questioning).
3. See Table 32-2 below.

TABLE 32-2 Assessing Levels of Consciousness

Category	Findings and Implications for Care
Conscious	Responds immediately to minimal external stimuli. Is alert, fully awake and oriented to time, place, purpose, and person. Understands spoken and written word and expresses ideas orally or in writing. Alterations in LOC reflect cerebral and metabolic disorders very quickly.
Confused	Disoriented to time, and place, but usually oriented to person. Has short attention span, impaired memory. Has difficulty following instruction; may have hallucinations, be agitated, restless, irritable, and more confused at night. <i>Frequent observation/supervision is indicated.</i>
Lethargic	Drowsy, sluggish in speech and mental and motor responses. Requires increased stimulus to awaken. Oriented to time, place, and person. <i>Frequent observation/supervision is indicated.</i>
Obtunded	Drowsy, arouses to stimulus but with minimal response. Responds appropriately to painful stimulus. <i>Needs complete care.</i>
Stuporous	Arouses only by vigorous and continuous stimulus. Has little spontaneous movement. May appropriately localize or withdraw from stimulus. May open eyes, make incomprehensible sounds. <i>Needs complete care.</i>
Comatose	Cannot be aroused. Has no voluntary response to stimuli, including pain. Coma level is based on motor response to painful stimulus. May or may not have protective brainstem reflexes (e.g., gag). <i>Needs total dependent care, with airway a priority.</i>

Assessing Cranial Nerves (Brainstem Reflexes)

NOTE: In most clients with increasing intracranial pressure, level of consciousness deteriorates before changes in cranial nerve reflexes, motor response, and vital signs occur. See Chapter 11, Physical Assessment, for basic assessment.

Procedure

1. Record the stimulus applied and the client's response (e.g., responds appropriately to oral questioning).
2. See Table 32-3 below.

Clinical Alert

Change in pupil size, shape, or reactivity should be reported immediately. This may be an early sign of transtentorial herniation requiring immediate intervention.

- Flexor (decorticate) posturing indicates loss of all function *above* the brainstem.
- Extensor (decerebrate) posturing indicates brainstem dysfunction.
- Loss of cough, gag, or corneal (blink) reflex indicates loss of brainstem integrity.

TABLE 32-3 Assessing Cranial Nerves (Brainstem Reflexes)

Cranial Nerve	Significance of Alteration
CN II (sensory) and CN III (motor) Pupil size, shape, and reactivity	Normal pupils are round, usually 3–5 mm diameter, equal in size, and react (constrict) consensually (both pupils respond) and briskly to light. <i>Alternately, have client look at an object 4 in. from the eyes and then at something on the wall behind the observer. The pupils should constrict (accommodate) when focusing on the near object.</i> Anisocoria (unequal pupil size) may be found in up to 20% of healthy clients. Smaller than average pupils may occur with metabolic coma. Pinpoint pupils may indicate pontine ischemia or opiate overdose. Oval pupils are early indication of CN III compression or increased ICP (18–35 mmHg), but pupils may be round in presence of increased ICP. Ipsilateral pupil dilation with head injury indicates uncal herniation with compression of CN III. <i>Bilateral</i> dilated (small ring of iris) and fixed pupils indicate extremely increased ICP causing pontine compression with complete CN III palsy. Absence of pupillary light reflex is consistent with comatose state. Hypothermia, barbiturate coma, and opiate overdose may mimic comatose states with unreactive pupils.
CN III, IV, and VI (all motor) Assess extraocular movements in the conscious client	<i>Note: See below for assessment of the conscious client (six fields of gaze).</i> Inability to move the eye inward or downward may be seen with head trauma (midbrain compression of CN IV). Inability to move the eye outward (pontine compression of CN VI) may be due to intracranial hypertension. The client has diplopia (double vision) when turning the right eye, if affected, to the right and same for the left turning leftward. Consciousness with complete body paralysis except for vertical eye movements occurs with a lesion in the ventral pons as seen in locked-in syndrome.
CN III, IV, and VI (all motor) Oculocephalic (Doll's eyes) reflex in unconscious client	"Doll's eye reflex" is used to test extraocular movements—integrity of the pontine-midbrain level (CN III, IV, and VI) in the <i>unconscious</i> client. Damage to the reticular activating system may damage these nerves, which pass through the midbrain to innervate extraocular movements. Reflex may be absent in severe metabolic encephalopathy. <i>See skill that follows.</i>
CN V (sensory) and VII (motor) Corneal blink reflex	Reflex is frequently absent in the comatose client. Periorbital swelling may prevent eyelid closure. Loss of ability to blink indicates need for corneal protection (instillation of eye lubricant) to prevent corneal drying and scarring. Polyethylene film may be taped over the eyes, extending beyond the eyebrows.
CN VIII (sensory) and III, IV, VI (all motor) Oculovestibular (Cold caloric) reflex in unconscious client (<i>test performed by physician</i>)	Used for final assessment of brainstem function in the unconscious client and can be used when cervical spine precautions must be maintained. Test may elicit abnormal posturing in comatose client. Reflex may be temporarily absent in client with metabolic encephalopathy. <i>See skill that follows.</i>
CN IX (sensory) and X (motor) Cough and gag reflex	Normally this medullary reflex protects the airway; its absence places the client at high risk for aspiration. Loss of this reflex is a poor prognostic sign.

The Six Cardinal Directions of Gaze

This test assesses CNs III, IV, and VI which innervate the six extraocular muscles that move the eyes as a pair in the same direction. These eye movements interact with the internuclear pathway of the medial longitudinal fasciculus (MLF) and cerebral cortex, to coordinate focus in a given direction.

Test the six extraocular muscles (conjugate eye) movement in the conscious client:

Procedure

1. Ask the client to follow your finger through an "H" sequence: client looks rightward, leftward, left

upward, left downward, then right upward and right downward.

2. Assess that both eyes move simultaneously, symmetrically, in the same direction, and in alignment.
3. Dysconjugate movement (one eye deviating from mid position at rest), *diplopia* (double vision), impaired movement (gaze paresis or paralysis) or

nystagmus (eye drift with rapid correction in the opposite direction) indicates cranial nerve injury.

Coordinated eye and *head movement* incorporates complex reflexes of the eyes plus *vestibular systems* (CN VIII) and the *cerebral cortex*. The **oculocephalic** reflex (doll's eyes response) and the **oculovestibular** reflex (caloric stimulation) are used to assess brainstem reflexes in the unconscious client.

Assessing the Oculocephalic (Doll's eyes) Reflex

Preparation

1. The purpose of this test is to assess extraocular movements in the unconscious client by determining presence and extent of structural damage.
 - a. Cranial nerves III, IV, and VI pass through the midbrain to innervate the extraocular muscles.
 - b. The medial longitudinal fasciculus (MLF) also passes through the midbrain and coordinates eye movements with head and body position changes.
 - c. *If the eyes are able to cross the midline, the medial longitudinal fasciculus and midbrain through which it passes are considered to be intact.*
2. Determine that neck injury has been ruled out before this test is performed.

Procedure

1. Hold client's eyes open.
2. Briskly turn client's head to one side, then briskly turn head to the other side, noting client's eye movement.
 - ▶ **Rationale:** The intact brainstem will attempt to keep the eyes looking forward even as the head is rotated laterally.
3. Assess for an intact oculocephalic reflex, when the eyes briefly remain in the direction opposite that of the head turn (positive doll's eye reflex).
4. Assess if eyes remain midline and move with the head, or if the eyes rove or move in opposite direction; this

abnormal oculocephalic reflex indicates a lesion at the pontine-midbrain level of the brainstem.

5. *For an alternative method:* Flex the neck and note that the eyes look upward, then extend the neck and note that the eyes look downward, indicating a normal or positive "doll's eye" reflex.

▲ Oculocephalic reflex: eyes briefly remain in the direction opposite that of the head turn (positive doll's eye reflex).

Assessing the Oculovestibular Reflex: "Cold Caloric Test"

NOTE: This test is performed by a physician. This noxious stimulation may elicit abnormal posturing in the comatose client.

Equipment

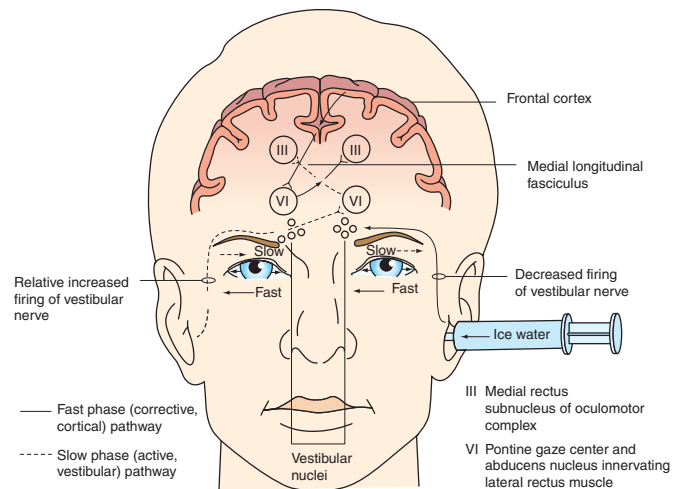

- Otoscope
- Catheter tip syringe
- 50 mL ice water

Preparation

1. Purpose of test is to assess brainstem integrity in the unconscious client.
2. Inspect to validate that client's tympanic membrane is intact.
3. Raise client's head to a 30° angle.

Procedure

1. Physician injects 20–50 mL of ice water into the external auditory canal. ► **Rationale:** This cools the mastoid bone and disturbs the endolymph flow in the inner ear. A signal passes from the medulla to the midbrain, triggering compensatory eye movements.
2. Check both eyes that tonically move toward the side of the cold water infusion, then rapidly correct back toward midline with bursts of nystagmus, indicating an intact brainstem; cortical function is overriding the tonic deviation of the eyes caused by the cold stimulation.
 - a. Ipsilateral absence of eye movements despite eye deviation on the side with the intact MLF indicates unilateral dysfunction.
 - b. No eye movement indicates little or no brainstem function.
3. Physician test may repeat in the other ear to test integrity of the *contralateral* side of the brainstem.

▲ Oculovestibular reflex: both eyes tonically move toward the side of cold water infusion, then rapidly back toward midline, with bursts of nystagmus (cold caloric test).

Assessing Signs of Basilar Skull Fracture

NOTE: Fractures of basal skull bones usually are not visible on skull or sinus x-rays but are often associated with tearing of the dura. A possible basilar skull fracture is suspected if the client develops leakage of CSF from the nose (rhinorrhea) or ears (otorrhea) or altered facial nerve (CN VII) function. These findings should be reported immediately as they are associated with increased risk for infection.

Procedure

1. Assess for *rhinorrhea* (leakage of blood or CSF from client's nose): Look for yellow CSF ring around bloody drainage on drip pad ("Halo sign"). ► **Rationale:** Drainage may indicate a basilar skull fracture with dural tear and risk for infection (meningitis). Drainage should not be obstructed but allowed to drip freely from the nose onto a sterile "mustache" dressing. Nasal suctioning and nose blowing must be avoided.
2. Assess auditory canal for *otorrhea* (leakage of blood or CSF from the client's ear). Look for yellow CSF ring around bloody drainage on drip pad ("Halo sign"). ► **Rationale:** Drainage may indicate a basilar skull fracture with dural tear, ruptured tympanic membrane, and risk for infection (meningitis). Drainage should not be obstructed.

3. Place client on side of drainage and allow fluid to drain freely from the ear onto a sterile towel (drip pad).
4. Assess for *Battle's sign*. Look for ecchymosis or bruising behind the ear. ► **Rationale:** May indicate a basilar skull fracture and associated with CN VII defect. Finding may be delayed and should be reported.
5. Assess for *raccoon eyes*. Look for ecchymosis or bruising around the eyes, which may be accompanied with *rhinorrhea*. ► **Rationale:** May indicate a basilar skull fracture. Finding may be delayed and should be reported.

Clinical Alert

Otorrhea and rhinorrhea are suggestive of CSF leakage, but drainage is often combined with blood, so glucose determination is unreliable to detect presence of CSF. Laboratory analysis of chloride content of drainage is more reliable because CSF chloride concentration is greater than that of serum.

If basilar skull fracture is suspected, do not insert a nasogastric tube. Orogastric placement is indicated and should be performed before orotracheal intubation in order to prevent aspiration.

Assessing Vital Signs

NOTE: Changes in vital signs are late indicators of decompensation.

Procedure

1. Measure temperature. ► **Rationale:** Hyperthermia or hypothermia may indicate hypothalamic injury, infection, or noninfectious fever.

2. Assess heart rate/rhythm. ► **Rationale:** Various arrhythmias occur with abrupt changes in ICP. Bradycardia develops in high spinal cord injury and with medullary ischemia.
3. Assess respiratory rate, and pattern.

NOTE: See Chapter 10, Vital Signs, for patterns.

► **Rationale:** Respiratory changes occur early, even before alterations of LOC.

For example:

- Cheyne Stokes respiration (an exaggerated pattern of normal breathing) is associated with structural disorders above the midbrain, may be present in metabolic encephalopathy, and may be observed in healthy individuals during sleep or those with heart failure.
- Hyperventilation may indicate acidemia (low blood pH) or may occur early with pontine pathology.
- Erratic breathing patterns, which may include periods of apnea, develop with midbrain and pontine (upper brainstem) injury.

NOTE: It is best to describe the breathing pattern as it is seen rather than to use names of breathing patterns. Description of the pattern clarifies the assessment finding and helps others to recognize changes.

Clinical Alert

Cushing's triad (bradycardia, systolic hypertension, and widening pulse pressure) may indicate intracranial hypertension or herniation syndrome. The presence of any component calls for further assessment and intervention.

4. Measure blood pressure. ► **Rationale:** Hypotension (SBP ≤ 90 mmHg) directly relates to cerebral ischemia and secondary brain injury.

Systolic hypertension and widening pulse pressure are responses to maintain cerebral blood flow in the presence of pressure on the brainstem (medullary ischemia).

NOTE: Loss of autoregulation occurs with any type of brain injury. If blood pressure increases, cerebral blood flow, blood volume, and ICP also increase. Systemic hypertension must be controlled, but the MAP must be maintained to support adequate cerebral blood flow (CPP near 80 mmHg) when ICP is increased.

EVIDENCE-BASED PRACTICE

Febrile patients with no evidence of infection are considered to have noninfectious fever.

Documented infections tend to be more common among febrile patients with traumatic brain injury, while noninfectious fever is more frequent among patients with subarachnoid hemorrhage associated with vasospasm.

Source: Rabinstein, A. A., & Sandhu, K. (2007). Non-infectious fever in the neurological intensive care unit: Incidence, causes and predictors. *Journal of Neurology, Neurosurgery, and Psychiatry*, 78(11), 1278–1280.

Assessing Coma in the Neurologic Client Using the Full Outline of Un-Responsiveness (FOUR) Score Coma Scale

This tool scores four components of impaired consciousness: eye response, motor response, brainstem reflexes, and respiration. It differs from the Glasgow coma scale by not requiring a verbal response. It is useful for assessing agitated and confused clients without impaired consciousness and those who are alert but unable to respond verbally, including clients who are intubated, stuporous, or comatose. It is also useful for sedated clients (since sedation affects eye opening and motor response, but not brainstem reflexes and respiration) and for clients developing early changes in consciousness who are unable to follow commands, to track examiner's finger movements, and have Cheyne-Stokes respirations.

▲ FOUR (Full Outline of Un-Responsiveness) score coma scale is used to assess coma in the neurologic client. Courtesy of and by permission of Mayo Foundation for Medical Education and Research. All rights reserved.

Assessing Coma in the Neurologic Client (FOUR-Score Coma Scale)

Procedure

1. Determine score for each of the four components: 0 is worst response and 4 is best response. Scores are not totaled.
 - a. **Assess eye response:** E4 = eyelids open or opened, tracking, or blinking to command; E3 = eyelids open but not tracking; E2 = eyelids closed but open to loud voice; E1 = eyelids closed but open to pain; E0 = eyelids remain closed with pain.
 - b. **Assess motor response:** M4 = thumbs-up, fist, or peace sign; M3 = localizing to pain; M2 = flexion response to pain; M1 = extension response to pain; M0 = no response to pain or generalized myoclonus status.
 - c. **Assess brainstem reflexes:** B4 = pupil and corneal reflexes present; B3 = one pupil wide and fixed; B2 = pupil or corneal reflexes absent; B1 = pupil and corneal reflexes absent; B0 = absent pupil, corneal, and cough reflex.
 - d. **Assess respiratory pattern:** R4 = not intubated, regular breathing pattern; R3 = not intubated, Cheyne-Stokes breathing pattern; R2 = not intubated, irregular breathing; R1 = breathes above ventilator rate; R0 = breathes at ventilator rate or apnea.

Determining Brain Death

The diagnosis of brain death is a medical–clinical diagnosis based on “irreversible cessation of all functions of the entire brain, including the brainstem: coma (unresponsiveness) with a known cause, absence of brainstem reflexes, and apnea.”

- Recovery of neurologic function has not been reported after the clinical diagnosis of brain death has been established using these criteria.
- Minimally acceptable observation period has not been determined.
- Non–brainmediated spontaneous movements (e.g., spinal and deep tendon reflexes) can falsely suggest retained brain function.
- Ventilator triggering may falsely suggest patient-initiated breathing.

Source: Wijdicks, E. F., Varelas, P. N., Gronseth, G. S., Greer, D. M., & American Academy of Neurology. (2010). Evidence-based guideline update: Determining brain death in adults: Report of the Quality Standards Subcommittee of the American Academy of Neurology. *Neurology*, 74(23), 1911–1918.

Determining Brain Death—Assessing for Apnea (CO₂ Challenge)

NOTE: Institutional protocol may vary slightly.

Preparation

1. Determine that client lacks all evidence of responsiveness. ► **Rationale:** This confirms coma.
2. Determine that cause of coma has been established and is irreversible.
3. Before diagnosis of brain death is attempted, clinical conditions such as acid–base or electrolyte or endocrine disturbance, hypothermia, presence of CNS depressant drugs or alcohol, and recent administration of neuromuscular blockade should be normalized, if possible, since these conditions can confound making diagnosis of brain death.
4. Adjust therapies so that client is normotensive (SBP \geq 100 mmHg), normothermic, euvolemic, eucapnic (PCO₂ 35–45 mmHg), without history of COPD or severe obesity and has normal PO₂. ► **Rationale:** The objective of the test is to determine apnea.
5. Determine that client has absence of brainstem reflexes:
 - a. Pupil, oculocephalic, oculovestibular, and corneal reflexes
 - b. Pharyngeal (gag) and tracheal (cough) reflexes.
 - c. Facial muscle movement to noxious stimulus.

- d. Absence of motor response to noxious stimuli in all four limbs.

Procedure

1. Preoxygenate client with 100% oxygen for 10 minutes. ► **Rationale:** To achieve a PO₂ \geq 200 mmHg.
2. Reduce ventilation rate to 10 breaths per minute. ► **Rationale:** To achieve eucapnia.
3. Reduce ventilator PEEP mode to 5 cm H₂O. (See Chapter 33, Advanced Nursing Skills.)
4. Obtain baseline ABGs if SPO₂ is 95%.
5. Disconnect client from ventilator. ► **Rationale:** This is the only way to determine apnea.
6. Immediately change to T-Tube with 100% FiO₂ or place small catheter through endotracheal tube to level of carina and deliver 100% O₂ at 6 L/min. ► **Rationale:** To maintain oxygenation.
7. Physician continuously observes for respiratory effort (chest, abdominal excursion) for 8–10 minutes. ► **Rationale:** If client shows any effort to breathe, respiratory support is reestablished according to agency protocol or consistent with measures predecided by client’s family and agency’s client advocate.

8. Abort test if SBP decreases to <90 mmHg or if SpO_2 is $<85\%$ for >30 seconds and retry procedure with T-piece, CPAP 10 cm H_2O , and 100% O_2 at 12 L/min.
 - ▶ **Rationale:** Deterioration of vitals signs and oxygenation should not precede proof of apnea.
9. Repeat ABGs after 8 minutes if no respiratory drive is observed.
10. If no respiratory drive is observed and PCO_2 is 60 mmHg or 20 mmHg over baseline, apnea test result is positive. ▶ **Rationale:** These findings support a clinical diagnosis of brain death.
11. Brain death reexamination is not required, but may need to be repeated depending on etiology of coma. Recommended minimal time intervals between first and second clinical examinations:
 - a. 6 hr after trauma or hemorrhage.
 - b. 24 hr after an anoxic injury.
 - c. Time interval may decrease to 12 hr if ancillary test is utilized.
- d. If there is obvious evidence of bilateral brain injury, potentially only one exam is needed to declare brain death.
12. An ancillary test may be performed to confirm brain death. ▶ **Rationale:** These may be indicated if uncertainty exists or apnea test cannot be fully performed, but these tests cannot replace a neurologic examination.
 - a. Cerebral angiography: positive if there is no intracerebral filling at carotid bifurcation or circle of Willis.
 - b. Electroencephalography (EEG): positive if there is no electrical activity throughout 30 minutes of recording.
 - c. Transcranial doppler ultrasonography.
 - d. Cerebral radionuclide perfusion scan: positive if there is no isotope uptake in brain tissue.
 - e. CT angiogram.
 - f. MRI/MRA.

Supporting the Family or Caregiver

Procedure

1. Respectfully reinforce that brain death is determined according to established and specific medical–legal criteria. ▶ **Rationale:** Some believe that brain death is recoverable or comparable to a coma.
 2. Discontinue all medical interventions after brain death is declared. ▶ **Rationale:** This is ethically and legally justified.
 3. Refer to the remains as a “body” rather than a “patient.”
 4. Avoid the words “patient,” “care,” and “treatment” while talking to family members. ▶ **Rationale:** It should not be implied that treatment or care is being provided or continued after a person has died.
 5. Discontinue conversation with the “body.” ▶ **Rationale:** Directing thoughts away from the body and toward family needs helps the family understand and accept the reality of death.
 6. Encourage the family to talk, touch, and hold if they choose; allow private time.
 7. Contact grief counselor or clergy as indicated.
 8. Clarify concerns about the deceased donor receiving artificial support:
 - a. Use the term “artificial support” in place of “life support.”
 - b. Clarify that the only justification for continuing artificial support is to maintain organs for transplant.
 - c. Reinforce that even though artificial support continues, the equipment is not supporting life, but maintaining body organs.
 - d. Reinforce that the time of death is when the client was declared dead, not when donated organs are removed.
- NOTE:** As many as 60% of deaths from stroke, heart disease, and traumatic brain injury may involve some kind of treatment withdrawal, making it one of the most common pathways to death in the United States.

DOCUMENTATION for Assessment of the Neurologic Client

- Level of consciousness:
 - Description of stimulus applied and client’s response
 - Physician notification of significant changes
 - Care measures provided if indicated
- Brainstem reflexes:
 - Physician notification of significant changes
 - Protective care measures provided if indicated
- Signs of basilar skull fracture:
 - Presence of otorrhea, rhinorrhea, Battle’s sign, or raccoon eyes
 - Altered function of CN VII
 - Physician notification
 - Protective care measures implemented

- Vital signs:
Frequency according to agency protocol
Physician notification of significant changes
- FOUR-Score Coma Scale:
Record score for each individual component:
eye response, motor response, brainstem reflexes,
and respiration.
Scores are not totaled.
- Brain death determination: Physician completes an extensive checklist for determination of brain death, including:
Prerequisites for brain death determination testing
Neurologic examination
Apnea testing
Ancillary testing
Time of brain death (time PCO₂ reached target value or time ancillary test is officially interpreted)

Legal Alert

- Brain death is a medical diagnosis made by a physician. State laws and hospital policy may vary on criteria for this diagnosis.
- According to the Uniform Anatomical Gift Act (revised in 2006 in many states), a donor's declared intent to be an organ donor (documented on driver's license) is sufficient evidence of consent for organs removal. Consent of spouse or family, regardless of their objections, is not necessary. This act also requires that hospital personnel ask patients on admission if they would consider being organ donors. If a person dies and didn't declare to be a donor, hospital or medical personnel must ask the person's relatives or surrogates whether they would be interested in donating the person's organs.
- The act allows medical personnel to remove organs without receiving explicit consent from a potential donor or donor's relative as long as medical personnel have made a reasonable effort to discover any objection by the donor or donor's family.

CRITICAL THINKING Application

Expected Outcomes

- Appropriate tools are used to evaluate a neurologic client's level of consciousness.
- Ongoing assessment of a client's brainstem reflexes and vital signs are used to determine compensated versus decompensating neurologic status.
- Signs of possible basilar skull fracture are identified.
- Established criteria are used to determine brain death.
- Supportive communication is provided for family or caregiver of a deceased organ donor.

Unexpected Outcomes

Neurologic client's comatose state cannot be determined using Glasgow Coma Scale due to inability to respond verbally.

Client shows signs of decreasing level of consciousness.

Head injury client with NG tube is having watery drainage from the nose.

Family of brain-dead organ donor has difficulty understanding why cardiac monitoring and mechanical ventilation are continued.

Alternative Actions

- Recognize that a nonverbal client cannot respond to parameters assessed using the Glasgow Coma Scale.
- Utilize the FOUR-Score Coma Scale to assess separate components of eye response, motor response, brainstem reflexes, and respiration for the nonverbal client.
- Reassess to validate findings.
- Notify physician of findings immediately.
- Report finding of rhinorrhea as it may indicate spinal fluid leakage and unrecognized basilar skull fracture.
- Change to orogastric tube placement to allow fluid drainage and prevent infection.
- Request drainage fluid analysis for chloride level to determine presence of CSF.
- Allow fluid to drain freely onto a drip "mustache" dressing.
- Reinforce that the deceased client has been declared to be brain dead but donated organs are being maintained by supportive measures until time of removal.

Chapter 32

UNIT 2

Intracranial Pressure Monitoring and Management

Nursing Process Data

ASSESSMENT Data Base

- Identify signs and symptoms of increasing intracranial pressure.
- Relate signs of intracranial hypertension to rostrocaudal changes in levels of consciousness.
- Identify factors that increase/prevent/manage intracranial hypertension.
- Recognize a normal intracranial pressure waveform.
- Assess indicators of pain in the nonverbal client.
- Utilize a variety of scales to assess a client's level of sedation.
- Monitor functioning and client response to ventricular CSF drainage.

PLANNING Objectives

- To identify early signs of increasing intracranial pressure in the neurologic client
- To differentiate a normal ICP waveform from one indicating decreased cranial compliance
- To provide care that prevents/manages increased ICP.
- To respond to indicators of pain in the nonverbal client
- To provide adequate but minimal depth of sedation in the client with intracranial hypertension

IMPLEMENTATION Procedures

- Recognizing Signs and Symptoms of Increasing Intracranial Pressure 1305
- Assisting Surgeon to Insert ICP Microsensor (Fiberoptic Transducer-Tipped Catheter) 1306
- Monitoring Client Response to Sedation 1309
- Assisting Surgeon to Insert a Ventriculostomy Catheter 1310

EVALUATION Expected Outcomes

- Signs and symptoms of increasing intracranial pressure are recognized.
- Factors that increase intracranial hypertension are identified.
- Client responds favorably to measures provided to prevent/manage intracranial hypertension.
- Microsensor displays client's intracranial pressure waveform.
- Client responses to pain management and sedation are evaluated.
- Ventriculostomy drains CSF appropriately to manage client's ICP.

Critical Thinking Application 1312

- Expected Outcomes 1312
- Unexpected Outcomes 1312
- Alternative Actions 1312

Recognizing Signs and Symptoms of Increasing Intracranial Pressure

NOTE: Some of these changes are subtle and may be confused with contextual factors (e.g., interpreting that client is drowsy from fatigue rather than an increasing intracranial pressure).

Procedure

1. Assess change in level of consciousness (LOC).
 - ▶ **Rationale:** Change in LOC is the most sensitive indicator of increasing ICP. Change may be sudden, dramatic, or very subtle.
2. Assess for headache. ▶ **Rationale:** Headache can be due to pressure on surrounding tissues, including the cerebral arteries, veins, and cranial nerves. Headache due to increased ICP worsens with activities that increase intrathoracic/intracranial pressure: coughing, straining, bearing down, etc.
3. Assess for vomiting. ▶ **Rationale:** Vomiting that is due to increased ICP typically occurs *without nausea*, is unexpected, is projectile, and is due to direct pressure on vagal motor centers located in the fourth ventricle in the medulla.
4. Assess for change in visual responses. ▶ **Rationale:** Altered responses of cranial nerves (II, III, IV, and VI) that are under pressure from brain swelling cause loss of visual acuity or eye movement. Altered pupillary (CN III) response, ipsilateral (same side) pupil dilation due to head injury, early sign of uncal herniation on side of injury, and altered level of consciousness may accompany or soon follow.
5. Assess for decrease in motor function. ▶ **Rationale:** Contralateral (opposite side) hemiparesis (weakness) and hemiplegia (paralysis) due to pressure increases in right and left hemispheres.
6. Assess for abnormal posturing that occurs due to noxious stimuli or spontaneously. ▶ **Rationale:** Decorticate (abnormal flexion) response indicates lesion above the brainstem (see Chapter 11, Physical Assessment, for description). Decerebrate (abnormal extension) response indicates brainstem lesion.

▲ Central herniation differs: deterioration of LOC precedes contralateral hemiparesis.

7. Assess for change in vital signs. ▶ **Rationale:** Change in vital signs can be due to increased pressure on thalamus, hypothalamus, pons, and medulla. Changes in respiratory pattern occur early. Cushing's triad: Increasing systolic blood pressure, widened pulse pressure, and slow heart rate, indicating medullary ischemia are late signs of decompensation.

Clinical Alert

It is always best to rule on the side of caution and notify the attending physician of changes so that appropriate care decisions can be made.

Factors That Affect Intracranial Pressure

Factors That Increase ICP (Goal is < 20 mmHg)

Clustered nursing care activities

Hypotension SBP ≤ 90 to 120 mmHg

(goal is 140–160 mmHg)

CPP < 60 mmHg

(goal is > 60–70 mmHg)

Hypoxemia

(goal is SpO₂ > 90 mmHg)

Increased/decreased PCO₂

(goal is 35 mmHg)

Acidemia (low arterial blood pH)

MAP < 85 mmHg (goal is to support

CPP > 60–70 mmHg)

Ventilator dyssynchrony

Measures to Prevent/Manage Increased ICP

Note client's ICP response to various activities and space activities/procedures to allow ICP to return to baseline.

Administer IV fluids, pressor agents (norepinephrine), osmotic diuretic, hypertonic saline, CFS drainage if ICP is > 20 mmHg
Surgical decompressive craniectomy for ICP persistently > 35 mmHg.

Promote oxygenation: Monitor and maintain SpO₂ > 90% with supplemental oxygen; determine whether desaturation occurs with a particular client position; maintain patent airway; suction PRN using prophylactic lidocaine and pre- and post-hyperoxygenation. Monitor breath sounds for atelectasis/infiltration. Provide chest percussion therapy; obtain chest x-ray; consult respiratory care practitioner regarding client/ventilator harmony.

Noxious stimuli, emotional upset

REM sleep

Factors that increase intrathoracic pressure and impede venous return from the brain: isometric muscle movement, Valsalva's maneuver coughing, vomiting, straining, neck or hip flexion, abnormal posturing, suctioning

Fever

Manage pain: assess for signs of pain in nonverbal client; provide analgesia; provide sedation at lowest doses with daily interruption.

Control environment: maintain calm, quiet room; minimize stimulation; limit visitation; avoid prolonged hand-holding; no television

Maintain positioning: head in neutral alignment without flexion or rotation. HOB elevation $\geq 30^\circ$ if hemodynamically stable and CPP maintained; avoid hip flexion.

Administer antiemetics, antipyretics; initiate early enteral nutrition.

Promote elimination: administer stool softeners; initiate a bowel program.

Provide prophylactic induced hypothermia for 48+ hr for traumatic brain injury; cooling blanket for increased temperature (avoid shivering).

Clinical Alert

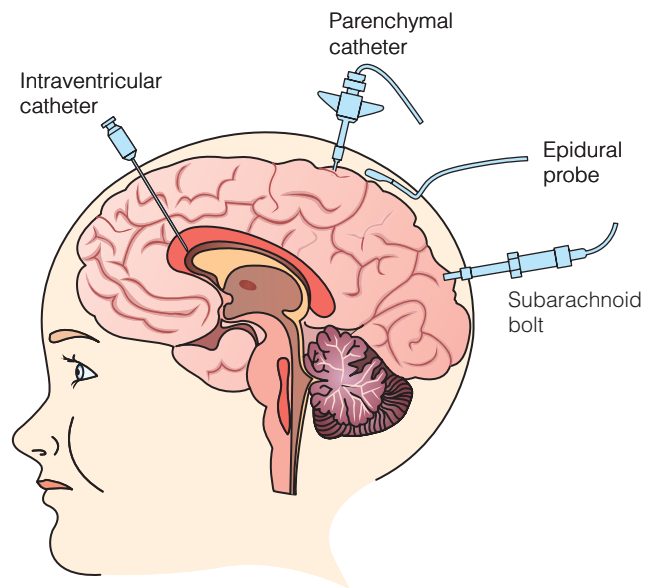

Hyperventilation ($\text{PaCO}_2 < 25 \text{ mmHg}$) was utilized in the past to manage increased ICP. A lowered PaCO_2 constricts cerebral arteries, and by the rules of the Monro-Kelly Doctrine, the ICP is lowered. This is used only briefly as a bridge to move appropriate therapy because constricting the cerebral arteries leads to ischemia, further damage, and edema.

NOTE: Sensitivity to and ongoing communication with the neurologic client and family are important aspects of care. Help the family understand that a healing brain needs little stimulation (avoid constant hand-holding and stimuli such as television, limit visitation, etc.). Family members may experience an extreme feeling of powerlessness; the client's injury may result in disabilities that have far-reaching implications on family dynamics.

EVIDENCE-BASED PRACTICE

The high-tech world of the ICU has historically introduced technology before its effects on outcome could be studied. Intracranial pressure (ICP) monitoring has not been proven to clearly improve outcomes in all patient populations in which it is utilized. Further testing of ICP versus CPP as treatment goals is another area for future research.

▲ Sites for ICP monitoring.

Assisting Surgeon to Insert ICP Microsensor (Fiberoptic Transducer-Tipped Catheter)

Equipment

PPE: Sterile surgical gown, mask with face shield or eye protection, cap
Sterile gloves for surgeon and nurse
Sterile tray

Prepared medication for sedation, if ordered
Hair clippers
Cranial access kit with hand drill
1% or 2% lidocaine without epinephrine
3-mL syringe with 18-gauge needle for withdrawal

25-gauge needle for topical anesthetic injection
 Chlorhexidine-based antimicrobial scrub/wipes
 Scalpel with #11 blade
 Sterile drape/towels
 Clean gloves
 Microsensor (fiberoptic transducer-tipped bolt catheter)
 External ICP microsensor monitor and monitoring cable to connect microprocessor to primary bedside monitor system
 Needle drivers
 2.0 silk suture
 Sterile 2 × 2 gauze
 Sterile clear occlusive dressing
 Permanent marker

Preparation

1. Validate that client's informed consent has been obtained.
2. Perform hand hygiene.
3. Check client's identification band and have client state name and birth date, if possible.
4. Explain rationale for procedure to client.
5. Validate that client has an established peripheral IV site. ► **Rationale:** For administration of emergency fluids or medication if needed.
6. Validate that client has established arterial blood pressure monitoring. ► **Rationale:** To determine the MAP, which is used along with the ICP to calculate cerebral perfusion pressure (CPP).
7. Prepare and assemble external monitoring system following manufacturer's instructions.
8. Raise the bed height to comfortable working position.
9. Don clean gloves.
10. Clip and save client's hair and scrub selected site with antimicrobial solution. **Rationale:** Client's hair should not be discarded, but should be returned to client or family.
11. Administer additional medication for sedation if ordered.

Procedure

1. Open sterile gloves and gown for surgeon.
2. Open sterile drape for surgeon.
3. Place cranial access kit, microsensor, and suturing materials on sterile tray within surgeon's reach.
4. Assist the surgeon to numb client's scalp.
5. Maintain cervical alignment while surgeon dissects the skin, drills the skull, and places microsensor.
 - a. Before the microsensor is placed in the parenchyma, it must be zeroed. This can only be done once before the microsensor is placed and secured. ► **Rationale:** After insertion, there is no need for zero-referencing while the catheter is in use.
 - b. Surgeon submerges the end of the sensor in an aqueous solution that is inside the sterile field.
 - c. Zero the sensor by surgeon's request. The microsensor will give a reference number.

▲ ICP microsensor (fiberoptic catheter) senses changes in ICP. This system may be used to measure intraventricular, parenchymal, subdural, or epidural pressure.

- d. Document reference number on the transducer using a permanent marker. ► **Rationale:** Used as reference if cables are disconnected for transport.
6. Don sterile gloves to assist surgeon as necessary.
 7. After insertion, surgeon sutures microsensor in place. (Microsensor can be inserted into the lateral ventricle, subarachnoid space, subdural space, brain parenchyma, or under a bone flap.)
 8. Site is covered with clear occlusive dressing (2 × 2 gauze optional).
 9. Hand external monitor cable to surgeon.
 10. Connect the external monitor to a central monitoring system to verify that a waveform is present.
 11. Record ICP and calculated CPP ($\text{MAP} - \text{ICP} = \text{CPP}$).
 12. Discard disposable equipment.
 13. Dispose of gloves and perform hand hygiene.

Clinical Alert

Increased intracranial pressure can decrease blood flow to the brain. Pressures within various locations in the cranium vary. The closer the ventricular catheter to the pathology, the higher the ICP and more accurate and reliable the reading.

▲ Monitor displays digital readouts and pressure waveforms of the ECG, arterial BP, SPO₂ and calculated CPP ($\text{MAP} - \text{ICP} = \text{CPP}$).

Intracranial pressure waveforms reflect transmission of arterial and venous pressure through cerebrospinal fluid and brain tissue. A normal ICP waveform has three pressure peaks:

P1 reflects myocardial systole (arterial blood flow)

▲ Intracranial pressure waveforms.

P2 reflects myocardial diastole (drop in systolic blood flow) and coincides with the arterial dirotic notch.

P3 follows the dirotic notch (closure of the aortic valve) and correlates with venous pressure.

▲ Increased P2 wave.

NOTE: P2 elevation greater than P1 ($P2:P1 > 0.8$) demonstrates an increase in intracranial pressure and loss of intracerebral compliance, especially when ICP is > 10 mmHg. Frequent neurologic assessments are indicated. Changes in client status should be reported to the physician immediately.

EVIDENCE-BASED PRACTICE

This study (sample of 28 patients undergoing ICP monitoring) demonstrated that mechanical chest percussion used to treat and prevent pneumonia does not increase intracranial pressure and can be performed safely on neurologically injured patients at risk for intracranial hypertension.

Olson, D. M., Thoyre, S.M., Bennett, S. N., Stoner, J. B., & Graffagnino, C. (2009). Effect of mechanical chest percussion on intracranial pressure: A pilot study. *American Journal of Critical Care, 18*(4), 330–335.

Monitoring Client Response to Pain

Medscape		www.medscape.com	
Indicator	Description	Score	
Facial expression	No muscular tension observed	Relaxed neutral	0
	Presence of frowning, brow lowering orbit tightening, and elevator contraction	Tense	1
	All of the above facial movements plus eyelid tightly closed	Grimacing	2
Body movements	Does not move at all (does not necessarily mean absence of pain)	Absence of movements	0
	Slow, cautious movements, touching or rubbing the pain site, seeking attention through movements	Protection	1
	Pulling tube, attempting to sit up, moving limbs thrashing, not following commands, striking at staff, trying to climb out of bed	Restlessness	2

Medscape		www.medscape.com	
Indicator	Description	Score	
Muscle tension	No resistance to passive movements	Relaxed	0
Evaluation by passive flexion and extension of upper extremities	Resistance to passive movements	Tense, rigid	1
	Strong resistance to passive movements, inability to complete them	Very tense or rigid	2
Compliance with ventilator (intubated patients)	Alarms not activated, easy ventilation	Tolerating ventilator or movement	0
	Alarms stop spontaneously	Coughing but tolerating	1
OR	Asynchrony: blocking ventilation, alarms frequently activated	Fighting ventilator	2
Vocalization (extubated patients)	Taking in normal tone or no sound	Taking in normal tone or no sound	0
	Sighing, moaning	Sighing, moaning	1
	Crying out, sobbing	Crying out, sobbing	2
Total range			0–8

NOTE: *The Critical Care Pain Observation Tool* has demonstrated acceptable validity and reliability for use with both verbal and nonverbal clients.

Source: American Association of Critical-Care Nurses. (2008). *American Journal of Critical Care*.

Monitoring Client Response to Sedation

Equipment

Sedation scales

Procedure

1. Consider nonpharmacologic interventions: (gentle touch, reassuring voice; frequent repositioning; use of distraction, music therapy, environmental control; use of complementary therapies such as massage) before sedation is initiated. ► **Rationale:** This may reduce or eliminate the need for sedation and muscle relaxation.
2. Select sedation scale to use for ongoing assessment and documentation of client response to pharmacologic intervention. ► **Rationale:** The selected scale should be used consistently and routinely by all caregivers.
 - a. *Ramsay Sedation Scale* (goal 2–3) assesses rousability and is useful whenever sedative drugs or narcotics are administered, but cannot be used for the client receiving neuromuscular blocking drugs.
 - b. *Riker Sedation-Agitation Scale* (goal 3–4) differs from the Ramsay Sedation Scale by defining degrees of agitation.
 - c. *Richmond Agitation Sedation Scale* (goal –2 to –3) distinguishes between responses to verbal and physical stimuli. This 10-level scale has confirmed validity and reliability for use in sedated and nonsedated clients.
 - d. *AACN Sedation Assessment Scale* is most comprehensive, evaluating five domains: consciousness, agitation, anxiety, sleep, and client-ventilator synchrony.
3. The Institute for Healthcare Improvement recommends “the use of dosing protocols and automatic dose reductions for benzodiazepines and other sedatives and hypnotics in target (e.g., ICU) populations.” Daily sedation interruption is conducted to allow assessment of neurologic status.

Clinical Alert

Most neurologic clients have normal lungs, but may require mechanical ventilation due to lack of airway protection (swallow, cough) secondary to neuronal injury, the secondary effects of increased ICP due to the primary injury/pathology, neurogenic pulmonary edema, a concomitant pulmonary process, or management with sedative medication. ICP and CPP can be adversely affected by positive pressure ventilation and must be monitored closely. Extubation should not be delayed solely on the basis of depressed neurologic function.

EVIDENCE-BASED PRACTICE

Intermittent lightening of sedation and daily interruption of sedation (withholding all sedative and analgesic medications until patients are awake) limits excessive sedation, reduces duration of mechanical ventilation and length of ICU stay, reduces the number of neurodiagnostic tests, and reduces frequency of complications associated with critical illness. This practice has benefits, but is underutilized due to a number of barriers that prevent its incorporation into clinical practice.

Dotson, B. (2010). Daily interruption of sedation in patients treated with mechanical ventilation. *American Journal of Health-System Pharmacy*. 67 (12). 102–1006.

Assisting Surgeon to Insert a Ventriculostomy Catheter

NOTE: ICP-lowering therapy is initiated with pressures above 20 mmHg.

Equipment

- PPE: Sterile surgical gown, mask with face shield or eye protection, cap
- Sterile gloves for surgeon and nurse
- Clean gloves
- Sterile tray
- Hair clippers
- Cranial access kit with hand drill
- 2% lidocaine with epinephrine (local anesthetic)
- 3-mL syringe with 18-gauge needle for withdrawal
- 25-gauge needle for topical anesthetic injection
- Sedative to be administered if indicated
- Chlorhexidine-based antimicrobial scrub/wipes
- Sterile drape or towels
- Twist drill and bits
- Scalpel with #11 blade
- Needle drivers
- 2.0 silk suture
- Intraventricular catheter
- Sterile 2 × 2 gauze (optional)
- Sterile clear occlusive dressing
- 20-mL syringe filled with preservative-free sterile saline for flushing system
- IV pole
- CFS drainage system (collection tubing, chamber, and bag)
- Transducer (see Chapter 33, Advanced Nursing Skills)

Preparation

1. Validate that client's informed consent has been obtained.
2. Perform hand hygiene.
3. Check client's identification band and have client state name and birth date, if possible.
4. Explain rationale for procedure to client.
5. Validate that client has an established peripheral IV site. **► Rationale:** For administration of emergency fluids or medication if needed.

6. Prepare and assemble monitoring system (transducer and stopcocks) following manufacturer's instructions.
7. Level and zero monitoring system with air-fluid interface of zeroing stopcock level with client's foramen of Monro (level of client's tragus) or higher as determined by surgeon. **► Rationale:** For accuracy, the same point should be used consistently for all ICP readings.

NOTE: The transducer must be relevelled with any change in client's head position if continuous drainage is performed.

8. Remove tubing attached to an IV bag that establishes a pressurized flush system and discard.
9. Replace flush system with a 20-mL syringe filled with preservative-free sterile saline. **► Rationale:** Preservatives added to medication vials are neurotoxic.
10. Flush all lumens and transducer with flush solution and leave syringe attached.
11. Raise bed to a comfortable working position.
12. Don clean gloves
13. Clip and save client's hair. **► Rationale:** Client's hair should be returned to client or family.
14. Scrub selected site with antimicrobial solution.
15. If applicable, administer additional medications for sedation.

Procedure

1. Open sterile gloves and gown for surgeon.
2. Open sterile drape for surgeon.
3. Place cranial access kit, ventriculostomy, and suturing materials on sterile tray within surgeon's reach.
4. Don sterile gloves to assist surgeon as necessary.
5. Assist surgeon to numb client's scalp.
6. Maintain cervical alignment while surgeon dissects the skin, drills the skull, and places ventriculostomy drain.
7. Surgeon caps the drain once it is in place.
8. Surgeon sutures drain in place and applies clear occlusive dressing (2 × 2 gauze optional).
9. Hand surgeon the primed line to the drainage system to attach it to the client.
10. Position drain as directed by the surgeon.

Ventriculostomy Drainage System

This external drainage system is used to intermittently or continuously drain CSF from the ventricles of the brain or the lumbar subarachnoid space to a drainage bag. System components facilitate CSF drainage, CSF sampling, and ICP monitoring.

Components of the system include:

- Closed sterile fluid path.
- Height-adjustable, calibrated burette with stopcock which provides view of flow and clarity of the CSF, and allows reading volume of CSF before fluid enters the drainage bag.
- Drainage bag with needleless sampling site.
- Fluid-filled ICP monitoring transducer can be attached to the *red* capped port of the patient stopcock at the zero reference position to show drainage pressure.

▲ Ventriculostomy catheter: nurse with drainage system.

Lumbar Subarachnoid CSF Drainage

Based on the same principles and setup as ventriculostomy drainage, lumbar puncture placement (L4–L5) of a catheter into the subarachnoid space may be performed to lower CSF pressure to allow a dural tear to heal (e.g., basilar fracture with otorrhea that persists 4–5 days).

1. The catheter is connected to a closed system to allow intermittent or continuous CSF drainage to divert CSF away from the site of the leak, lower CSF pressure, and allow the site to heal.
2. The zero reference point is the insertion site with the bed flat and client supine.
3. Drainage bag height is manipulated to drain the prescribed volume each hour (e.g., 10–20 mL/hr) based on CSF production of 20–30 mL/hr.
4. If the drainage bag is lowered, more CSF is drained.
5. The drain must be clamped if the client sits up.

11. Calculate and record ICP/ CPP readings hourly.
 - **Rationale:** To determine adequate cerebral blood flow.
12. Return drain to open position for continuous drainage of excess CSF or open closed system intermittently to drain CSF when ICP exceeds set limits. ► **Rationale:** Reducing CSF volume improves cerebral perfusion.
13. Discard disposable equipment.
14. Dispose of gloves and perform hand hygiene.

NOTE: If leakage persists for 4–5 days, lumbar CSF drainage may be necessary to allow resolution of dural tear. (See Lumbar Subarachnoid CSF Drainage.)

Clinical Alert

Never flush a ventriculostomy or lumbar drain toward the client. This would increase risk for infection. Additionally, instilling medications (including saline) is not within the scope of nursing practice.

EVIDENCE-BASED PRACTICE

Parenteral Nutrition in the Critically Ill Client

Bedrest and neuromuscular blockade during mechanical ventilation result in skeletal muscle wasting and inhibit protein anabolic processes. Drugs such as corticosteroids increase skeletal muscle breakdown, vasopressors decrease splanchnic blood flow, and diuretics increase excretion of electrolytes, minerals, and water-soluble vitamins. Multiple stressors increase energy expenditure and need for protein and micronutrients. Early initiation of appropriate nutrition is important for brain repair; malnutrition can contribute to cerebral edema. Most critically ill clients who require specialized nutrition (85%–90%) can be fed enterally via gastric/intestinal tube. If enteral nutrition is contraindicated (10%–15%), complete parenteral nutrition may be provided to support vital cellular and organ function, immunity, tissue repair, protein synthesis, and capacity of skeletal, cardiac, and respiratory muscles.

Source: Ziegler, T. (2009). Parenteral nutrition in the critically ill patient. *New England Journal of Medicine*, 361, 11.

Ventilator-Associated Pneumonia

Mechanically ventilated neurologic clients are especially susceptible to ventilator-associated pneumonia (VAP) due to decreased level of consciousness, an unprotected airway, and inability to swallow properly. Monitoring devices, ventriculostomy, disease processes, and inability to temporarily stop sedation for clients with increased ICP preclude some VAP prevention strategies.

Source: Fields, L. B. (2008). Oral care intervention to reduce incidence of ventilator-associated pneumonia in the neurologic intensive care unit. *Journal of Neuroscience Nursing*, 40(5), 291–298.

Oral Care for Ventilator Clients

Oral health deteriorates significantly during intubation and improves to near baseline levels 48 hr after extubation. Intubation is associated with an increase in oral gram-negative bacteria and yeast and risk of ventilator-associated pneumonia. This study demonstrated that providing oral care does not seem to affect intracranial pressure adversely.

Prendergast, V., Hallberg, I., Jahnke, H., Kleiman, C., & Hagell, P. (2009). Oral health, ventilator-associated pneumonia, and intracranial pressure in intubated patients in a neuroscience intensive care unit. *American Journal of Critical Care*, 18(4), 368–376.

DOCUMENTATION for Intracranial Pressure Monitoring and Management

- Surgeon placing the microsensor or CSF drain (ventriculostomy)
- Location of microsensor or CSF drain placement
- Medications administered
- Client's tolerance of procedure
- Appearance of insertion site
- Dressing applied
- Client position during obtained measurements
- Obtained measurements: ICP and calculated CPP
- Amount and color of CSF drainage from ventriculostomy
- Appearance of the site, dressing, and length of monitoring/drainage catheter insertion site
- Interventions used to manipulate ICP/ CPP if indicated

CRITICAL THINKING Application

Expected Outcomes

- Signs and symptoms of increased intracranial pressure are recognized.
- Factors that increase intracranial hypertension are identified.
- Measures to prevent/manage intracranial hypertension are initiated.
- Microsensor displays intracranial pressure waveform.
- Client responses to pain management and sedation are evaluated.
- Ventriculostomy drains appropriately to manage client's ICP.

Unexpected Outcomes

Client is very agitated with frequent nonpurposeful movements, despite increased frequency of sedative administration.

Alternative Actions

- Try to find a cause for the client's change in behavior.
- Attempt an analgesic trial to determine whether the client's pain is managed. This trial may be therapeutic as well as diagnostic.

Microsensor fails to display a waveform.

- Verify that cable to the monitor and monitor cable are functioning appropriately and all connections are secure.
- Reassess length of microsensor exiting insertion site. If microsensor has migrated from the parenchyma, it will no longer give an appropriate waveform.

Ventriculostomy drain shows a waveform but does not drain.

- Client may not have excess CSF that needs to be drained. Lower drain below the tragus until two to three drops of CSF are drained to ensure patency still remains. If patent, return drain to the ordered position. If no drops of CSF are released, notify the physician.
- Do not strip tubing even if clots are visible. Stripping causes increased negative pressure and microbleeds and tears can occur.

The ventriculostomy drain fails to display a waveform.

- The drain might be clotted; lower drain as directed above to verify patency.
- Verify all clamps and stopcocks are positioned in an open to the monitor position.
- Verify that the cable to the monitor and monitor cable are functioning appropriately and all connections are secure.
- Reassess length of drain exiting the insertion site. If the drain has become dislodged from the ventricle, it will no longer give an appropriate waveform. In this instance, it is rare that there will still be drainage of excess CSF.

Ventriculostomy drain insertion site dressing is damp.

- Inspect system for leaks.
- Suspect CSF leak (test for glucose in fluid or chloride concentration if draining includes blood).
- Apply new sterile occlusive dressing over insertion site.
- Notify physician.

Ventriculostomy drainage bag has sudden increase in CSF.

- Immediately check for inadvertent placement of bag below prescribed level; rapid drainage can cause ventricular collapse and intracerebral hemorrhage.
- Immediately reposition drainage bag to appropriate level.
- Discuss benefits of intermittent rather than continuous drainage.

GERONTOLOGIC Considerations

Neurologic Disorders Are the Most Common Cause of Disability in Older Adults.

- While age-related changes do not follow a predictable course, normal neurologic system changes due to aging include:
 - Decreased brain size but no decline of intelligence with age
 - Alterations of thermoregulation (reduced heat production, increased heat loss)
 - Slower fine-motor movement
 - Diminished deep tendon and gag reflexes and vibratory sense
 - Reduced ability to respond to multiple stimuli
 - Slowed righting reflexes
 - Smaller pupil size
 - Reduced stage 3 and 4 sleep
 - Modest reduction in ability to learn new things

- The brain atrophies with age, leading to an increase in space between the skull and the brain and an increase in size of ventricles. This increased space can result in greater risk for cerebral contusions and cerebral vessel damage with acceleration/deceleration injuries. Damage can also be compounded if the patient is taking an anti-coagulant.
- Older clients are less likely to experience common symptoms of increased intracranial pressure (e.g., headache) and more likely to demonstrate mental status changes.
- Pathology of any organ system can precipitate neurologic dysfunction in an older client.
- As many as 60% of older hospitalized clients may experience delirium.
- Lethargy and confusion may be indications of infection among the elderly.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

All personnel in the critical care setting must know how to quickly summon assistance and locate and use emergency/resuscitation equipment.

In advanced care settings, the RN simultaneously assesses, analyzes, makes decisions, intervenes, and evaluates clients on

a continual basis. Complexities of care and unpredictability of outcomes necessitate *intense* ongoing client monitoring and evaluation and personal continuing education. Detection and interpretation of subtle areas of change in the client's status require the knowledge and skill of the professional nurse.

- Collaboration with the physician and respiratory care practitioner helps to support client's weaning from mechanical ventilation.
- The nurse should not assume care for any client who requires care beyond the caregiver's expertise.
- Many agencies provide emergency care protocols or standing orders of action responses to specified changes in client status. The professional nurse must be familiar with conditions for which the nurse is delegated medical care decisions guided by such protocols.
 - It is the responsibility of nursing faculty to ensure that students participating in client care (in any setting) are prepared to do so. Likewise, it is the duty of the student to refuse to perform a function he or she is not qualified or competent to perform.
 - The UAP providing personal care for the neurologic client must space activities and maintain a controlled environment to prevent overstimulation and fatigue.
 - The UAP must understand that continuous HOB elevation with the neck in neutral position is to be maintained for the neurologic client with external ventricular drainage, while the client with a lumbar drain remains supine with the bed flat.
 - The UAP must know to leave an arterial catheter site uncovered for easy observation.
- The UAP must not move tubing drainage receptacles (e.g., ventriculostomy drip chamber).

- The UAP must understand that IVs, drainage systems, and ventilator circuits and systems are closed and must be able to give care without disrupting system integrity or disconnecting components for the convenience of care (e.g., as in changing the client's gown or position).
- The UAP has a limited role in the care of clients who require invasive monitoring. The UAP can offer valued assistance in moving/positioning clients and providing personal hygiene and comfort measures under the direction of the professional nurse.
- The UAP assists the client, preserving an interface between technology and reality, by providing a human dimension of tactile presence while providing basic physical care for clients requiring sophisticated technological monitoring. This link assists all caregivers in their attempts to minimize client's feelings of alienation.

Communication Matrix

Although certain tasks may be delegated, the UAP also can provide vital data to the professional nurse by immediately *reporting*:

- Disconnected systems, loose electrodes, tubing leaks, wet/soiled dressings
- Subjective or objective change in the client's status (e.g., pain, restlessness, respiratory distress, acute change in cognition)
- Equipment alarms (e.g., ventilator alarms)
- Near-empty infusion bags
- Near-full collection devices

CRITICAL THINKING Strategies

Scenario 1

A 27-year-old male has been admitted to the neuro trauma ICU after surgical evacuation of a right parietal epidural hematoma that occurred secondary to a linear skull fracture sustained in a motorcycle accident.

1. Where does an epidural bleed occur and what is the typical source of bleeding?
2. How does an epidural hematoma differ from a subdural hematoma?
3. What behaviors/deficits might occur with injury to the right parietal lobe?
4. What signs would indicate uncal herniation due to increasing intracranial pressure?
5. List five nursing interventions that can help prevent increased intracranial pressure.

Scenario 2

A young man has been admitted to the trauma unit after evaluation in the ED and repair of a scalp laceration sustained

when he was struck in the back of the head with a baseball. No cervical spine injury, internal injury, or skull fracture was identified. He had no motor or sensory deficits. Ongoing observation and neurologic assessments were indicated since the client had experienced a brief loss of consciousness and continued to have vertigo, irritability, and nausea. His Glasgow Coma Score was 13.

At 0400 the nurse awakened him for vital signs and neuro assessment and noticed a bloody stain circled by yellow discoloration on his pillowcase. It had apparently come from his ear. Drainage from the ear (otorrhea) typically results from head injury involving basal skull fracture.

1. Why was the diagnosis of basilar skull fracture missed on initial evaluation in the ED?
2. How can it be determined that the drainage includes CSF?
3. What is the major potential complication of CSF leakage?
4. How should the client be positioned?

5. How should the drainage be managed?
6. What is the typical medical management if CSF leakage persists?
7. Compare the principles of lumbar drainage and external ventricular drainage.
8. Contrast the care of a client with a lumbar drain versus one with a ventriculostomy.

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. A client with a blood pressure of 130/80 and an intracranial pressure of 12mm Hg would have a cerebral perfusion pressure of
 1. 65.
 2. 80.
 3. 85.
 4. 97.
2. The nurse caring for a neurologic client obtains an ICP reading of 12mmHg. The nurse understands this reading reflects
 1. A severe decrease in cerebral perfusion pressure.
 2. A marked decrease in the CSF production.
 3. Normal balance of brain, blood, and CSF.
 4. A malfunction of autoregulation.
3. A client has been admitted to the hospital with a suspected brain tumor. The family report him being hateful, having outbursts of cursing, and right sided hemiparesis. These behaviors indicate that the tumor is affecting the
 1. Frontal lobe.
 2. Parietal lobe.
 3. Occipital lobe.
 4. Temporal lobe.
4. Metabolic causes of coma can be differentiated from structural causes. Metabolic causes are characterized by having
 1. Rostrocaudal deterioration.
 2. Asymmetric motor deficits.
 3. Motor deficits preceding coma.
 4. Preserved pupil reflexes.
5. Factors that lead to cerebral vasodilation and increased intracranial pressure include
 1. Hypocapnea (low PCO₂).
 2. Alkalemia (low blood pH).
 3. Hypoxemia (low blood O₂).
 4. Hypothermia.
6. Pressure on the midbrain would be expected to be accompanied by
 1. Loss of gag reflex.
 2. Loss of pupil response.
 3. Widening pulse pressure.
 4. Loss of blink reflex.
7. The most sensitive indicator of increasing intracranial pressure is
 1. Altered level of consciousness.
 2. Change in respiratory pattern.
 3. Lack of pupil response to light stimulus.
 4. Increase in blood pressure with slowed heart rate.
8. A ventriculostomy is the most reliable system used to monitor intracranial pressure. This method includes:
 1. A subarachnoid bolt or screw.
 2. An intraventricular catheter with external drainage system and transducer.
 3. An intraparenchymal fiberoptic transducer-tipped catheter.
 4. A subdural or epidural catheter.
9. ICP monitoring provides guidance in managing ICP elevations and hemodynamic status. Normal intracranial pulse waveforms are characterized by:
 1. P-2 waveform greater than P-1 and P-3.
 2. All waveforms of equal elevation.
 3. P-3 waveform greater than P-1 and P-2.
 4. P-1 waveform greater than P-2 and P-3.
10. Which of the following ancillary tests are used to confirm brain death?
 1. Spinal fluid analysis and cold calorics test.
 2. EEG and Cerebral angiography.
 3. MRI and brainstem reflexes.
 4. Deep tendon reflexes and blood pressure.

Advanced Nursing Skills

LEARNING OBJECTIVES

1. List hemodynamic information obtained by means of a pulmonary artery (balloon-tipped flow-directed) catheter.
2. Discuss the purpose and method for leveling and zeroing the monitor.
3. Differentiate waveforms for pulmonary artery and pulmonary capillary wedge pressures.
4. State three ways to troubleshoot pulmonary artery catheter problems.
5. Describe the rationale for arterial blood pressure monitoring.
6. Outline the steps in performing the Modified Allen's test.
7. Identify a normal arterial blood pressure waveform.
8. Explain the procedure for obtaining a blood sample from an arterial line.
9. Outline safety precautions for the client with an arterial line.
10. Explain how the intraaortic balloon pump assists cardiac function.
11. Describe nursing responsibilities in anticipating and responding to cardiac emergencies.
12. Ensure client and staff safety during electrical counter-shock procedures.
13. Differentiate various ventilator support "modes."
14. Discuss nursing care needs of the mechanically ventilated client.
15. Describe the process of weaning a client from mechanical ventilation to independent breathing.

TERMINOLOGY

Adjunctive accessory to or assisting with.

Afterload resistance against which the heart must pump to eject blood during systole. Pulmonary vascular resistance (PVR) presents afterload to the right heart; systemic vascular resistance (SVR) presents afterload to the left heart.

Barotrauma alveolar injury and air leak due to positive pressure mechanical ventilation.

Blood conservatory process blood sampling process that requires no blood wasting.

Bolus rapid administration of a volume of fluid or a drug intravenously.

Calibrate to check or adjust a transducer to a standard measurement.

Cannulation insertion of a tube into a blood vessel for purposes of invasive pressure monitoring. The cannula is attached to a transducer which in turn converts the pressure to a monitored waveform display.

Cardiac index (CI) the cardiac output in relation to a client's body surface area.

Cardiac output (CO) amount of blood ejected by the heart per minute. Determined by multiplying heart rate by stroke volume ($HR \times SV = CO$).

Central venous pressure (CVP) reflects filling pressure of the right heart. Measures central preload.

Diastole period when ventricles are relaxed; a period of ventricular filling and coronary artery perfusion.

Dicrotic notch component of the arterial waveform that represents closure of aortic valve at the end of ventricular contraction (systole).

Diffusion movement of a gas from an area of high pressure to an area of lower pressure.

Distal area farthest away from point of reference (fingers are most distal part of upper extremity; cannulated catheter tip is most distal).

Dysrhythmia abnormality of heart rate or rhythm.

ECC emergency cardiovascular care.

Electrical potential charges on cell membrane are separated into negative and positive charged particles.

Electrocardiogram (ECG) graphic representation of the variations in electrical potential caused by depolarization of the heart muscles.

Electrode an adhesive patch applied to the skin to transmit cardiac electrical activity to a machine for display.

Hemodynamic movement of blood.

Hypercarbia increased PCO_2 on ABGs.

Invasive involves puncturing or incising the skin for insertion of a tube or instrument into the body.

Left ventricular end-diastolic pressure (LVEDP) pressure of blood in the left ventricle at the end of diastole; a measure of left ventricular preload.

Lumen the inside, channel, or opening of a blood vessel or tube.

Mean arterial (blood) pressure (MAP) average pressure within the cardiovascular system throughout one cardiac cycle. Determined by adding systolic pressure to two times the diastolic pressure and dividing the sum by three.

Mixed venous oxygen saturation (SvO₂) hemoglobin saturation of RBCs measured in the pulmonary artery.

Modified Allen's test manual test to determine patency of the ulnar or radial artery. Digital pressure is applied directly over the radial and ulnar arteries. When pressure on one vessel is released, blood flow to palm and fingers indicates obstruction is not present in that vessel.

Oscilloscope instrument that displays a visual representation of electrical activity on a monitor screen.

Perfusion blood flow to tissues.

Phlebostatic axis the crossing of two reference lines to determine the point at which the zero mark on manometer is level with this axis.

Preload a measure of venous return; end diastolic filling pressure (stretch) in the ventricles.

Proximal refers to an area closest to the point of reference; humerus of upper extremity is more *proximal* to the body than the fingers.

Pulmonary artery pressure (PAP) waveform representing systolic and diastolic pressures in the pulmonary artery, usually displayed by hemodynamic monitoring. Pulmonary artery diastolic pressure is often used as equivalent to pulmonary artery wedge pressure.

Pulmonary artery wedge pressure (PAWP) also referred to as pulmonary artery occlusive pressure, or PAOP, an indirect indicator of left ventricular pressure—normal PAWP is 8 to 13 mmHg. Elevations are seen in left ventricular failure.

Refractory period period during which cardiac cells are not responsive to electrical stimulation (QRS and ST segment of the ECG is the absolute refractory period for the ventricles).

Repolarization period during which ionic changes restore the heart cells to resting potential.

Surfactant a phospholipid synthesized by the lungs; acts to lower alveolar tension and increase lung compliance.

Thermodilution method of calculating cardiac output by injection of solution into the proximal lumen of a pulmonary artery catheter and determining the solution's temperature change at the thermistor (distal) lumen of the catheter.

Transducer device that converts one form of energy into another (e.g., biophysical event is converted into electrical waveform, which is displayed on the oscilloscope).

Vasculature vascular system of the body.

Vasodilator causes dilation of the blood vessels. A venodilator reduces preload; an arterial vasodilator reduces afterload.

Vasopressor an agent used to increase blood pressure by constricting blood vessels.

Vasospasm intermittent constriction of a vessel due to spasm.

Ventricular systole contraction phase of the cardiac cycle during which the ventricles eject blood into receiving arteries.

Voltage electromagnetic force measured in volts.

Volutrauma iatrogenic alveolar injury due to large tidal volumes delivered by mechanical ventilation.

Waveform pictorial representation of a pressure or electrical activity of the heart, depicted on an oscilloscope.

Weaning gradual withdrawal of mechanical ventilation and the reestablishment of spontaneous breathing.

ADVANCED SKILLS IN NURSING PRACTICE

This chapter presents a nursing process framework for nursing actions used in the maintenance of homeostasis during life-threatening conditions. Provision of competent care during critical periods requires a knowledge of physiologic monitoring techniques, skill in the analysis of data, diagnostic reasoning, and decision-making. Working with monitors and providing client care at the same time can be a challenging experience for the nurse.

Monitoring techniques are useful adjunctive tools that provide the practitioner with critical information for management of select clients in intensive care settings. Interpretation and integration of this information assists in the assessment of major body systems and recognition of altered hemodynamic states (e.g., fluid deficit or fluid overload). Continuous surveillance of cardiovascular pressure readings and other dynamic measures serves as a guide for identifying appropriate nursing diagnoses, developing a plan of care, and evaluating the client's response to therapy.

In the clinical setting, nurses are constantly faced with new equipment, new techniques, and better and more sophisticated evaluative methods. To keep pace in the area of technologic advancement can be a monumental task, one that challenges the nurse's energy, patience, and abilities. The nurse's role in assessment, planning, intervention, and evaluation is based in part on the nurse's familiarity with monitoring data.

Hemodynamic monitoring has evolved over the years from continuous ECG monitoring, to measuring CVP (right heart pressure), to direct determination of cardiac output, and indirect measurements of left heart filling pressures. Hemodynamic monitoring techniques require that equipment be properly positioned and function correctly and that the monitor waveforms be representative of the client's physiologic variables and be interpreted correctly.

A multi-lumen, balloon-tipped, flow-directed catheter (e.g., Swan-Ganz VIP) is used to measure intracardiac pressures. Individual lumens reflect measures of right atrial pressure (RAP or CVP), pulmonary artery pressure (PAP), and, when advanced briefly to an occlusive position, pulmonary artery

wedge pressure (PAWP or PAOP). Cardiac output (CO), systemic and pulmonary vascular resistance (SVR, PVR), and mixed venous oxygen saturation (SvO₂) are other valuable measures obtained with this catheter. It is simultaneously used for the infusion of fluids and medications. Placement of the catheter is verified by chest x-ray.

Waveforms (pressure signals) are transmitted from the catheter to a transducer by means of fluid-filled tubing. The signal is then amplified and displayed on an oscilloscope both as a visual (analog) waveform and a digital display. The client's physiologic pressure signals provide continuous data to help

▲ Sophisticated technology facilitates the intensive care of clients.

specialized nurses make critical assessments necessary for safe and effective care decisions, such as the titration of drugs and IV fluids.

Similarly, a catheter can be placed in a peripheral artery and direct blood pressure can be monitored continuously using these same principles. Therapeutically, arterial blood pressure signals can be used to trigger timing of counterpulsation circulatory assistance (intraaortic balloon pump) in clients with compromised cardiac output, while the client's pulmonary artery catheter hemodynamic information is used to evaluate the effectiveness of intraaortic balloon pump (IABP) therapy. This is an example of the complementary power of technology and its value as an integrated aspect of care for clients receiving intensive care.

Ability to integrate all available data is essential to providing excellent nursing care. While advanced technology provides essential measures that augment more overt client data, it is important that this technology not become more important than the client. The first goal is to care for the client, not

to tend the equipment. One way to achieve a balance of mastery over complex skills and the attainment of high-quality client care is to become familiar with technical equipment so that it no longer causes anxiety and uncertainty. Once this level of confidence is realized, the focus is on the client, rather than the monitoring equipment.

CULTURAL AWARENESS

Some cultures view critical illness as a curse, an imbalance of heat and cold, or disharmony with the universe rather than pathology or injury to an organ system. Western medicine's healthcare system utilizes much technology and sophisticated equipment. This approach may clash with another culture's beliefs in folk medicine, rituals, and religious healing.

Individuals of the same culture will vary in response to critical illness; therefore, the nurse must explore the meaning of the experience with each individual client in order to provide sensitive care.

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to include in a client care plan when the components are related to advanced nursing skills.

NURSING DIAGNOSIS	RELATED FACTORS
Aspiration, Risk for	Presence of tracheostomy or endotracheal tube Incompetent lower esophageal sphincter Gastrointestinal tube Tube feedings Increased gastric residual
Ineffective Breathing Pattern	Decreased minute volume Decreased vital capacity Bradypnea (respiratory rate <11) Tachypnea (respiratory rate >24)
Decreased Cardiac Output	Altered heart rate or rhythm Altered preload (increased or decreased intracardiac pressures) Altered afterload (increased or decreased systemic or pulmonary vascular resistance) Altered contractility (low stroke volume cardiac output/cardiac index)
Impaired Verbal Communication	Physical barrier (tracheostomy, intubation) Medications Lack of information
Impaired Gas Exchange	Alveolar-capillary membrane changes (barotrauma, volutrauma) Ventilation-perfusion mismatch
Infection, Risk for	Inadequate primary defenses (broken skin, decreased ciliary action, altered pH secretions, altered peristalsis) Invasive procedures Pharmaceutical agents Trauma
Imbalanced Nutrition: Less Than Body Requirements	Inability to ingest food (e.g., presence of endotracheal tube, NPO status) Difficulty chewing or swallowing Hypermetabolic state
Powerlessness	Healthcare environment Illness-related regimen Chronic or terminal illness Impaired ability to communicate

Impaired Spontaneous Ventilation	Metabolic factors Respiratory muscle fatigue
Ineffective Tissue Perfusion	Hypovolemia Shock (hypovolemic, cardiogenic, distributive) Decreased cardiac output Peripheral vascular disease
Dysfunctional Ventilatory Weaning Response	Inadequate nutrition Sleep pattern disturbance Ventilatory muscle atrophy/neuromuscular decline Inadequate pain management Oversedation without periodic interruption Anxiety or fear Inadequate preparation for weaning process Powerlessness

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. *Remember to wash your hands or use antibacterial gel before and after each and every client contact.*

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Pulmonary Artery Pressure (Hemodynamic) Monitoring

Nursing Process Data

ASSESSMENT Data Base

- Determine purpose of hemodynamic monitoring and significance of data obtained.
- Evaluate client's understanding of the procedure.
- Assess for preexisting cardiovascular disease.
- Obtain baseline pulmonary, cardiovascular, hemodynamic, peripheral vascular, neurologic findings.
- Assess insertion site for inflammation or infection.
- Assess patency of all lines.
- Determine pressure on saline flush bag.
- Level and zero the monitoring system.
- Monitor PA systolic, PA diastolic, PA mean, PAWP.
- Note any laboratory data abnormalities.
- Assess cardiac output using thermodilution technique.

PLANNING Objectives

- To maintain a patent pulmonary artery monitoring system
- To administer intravenous solutions and determine response to fluid therapy
- To obtain specific hemodynamic measurements for decision making
- To measure cardiac output

IMPLEMENTATION Procedures

- Leveling and Zeroing the Monitor System1323
- Assisting Physician With Catheter Insertion1324
- Obtaining Pressure Readings1326
- Measuring Cardiac Output1327

EVALUATION Expected Outcomes

- Pulmonary artery catheter remains patent.
- Pulmonary artery, systolic, diastolic, and pulmonary artery wedge pressure measurements are measured accurately.
- Cardiac output measurements are obtained.

Critical Thinking Application1328

- Expected Outcomes1328
- Unexpected Outcomes1329
- Alternative Actions1329

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Tissue oxygen consumption depends on cardiac pump performance, adequate blood volume, arterial oxygen content, and vascular distribution (perfusion). Hypovolemia, heart failure, or other conditions (e.g., sepsis) alter intracardiac pressures, tissue perfusion, and tissue oxygen consumption. Since direct measurement of left heart chamber pressures is not possible in the clinical setting, an indication of these measures is obtained by *indirect* means via the right side of the heart.

A balloon-tipped, flow-directed catheter is inserted into a central vein percutaneously or through a cut-down and advanced *transvenously* to the right atrium. Partial inflation of the balloon at the tip of the catheter allows the catheter to float through the tricuspid valve, the right ventricle, and the pulmonary valve into the pulmonary artery. Here the balloon is *deflated* and pulmonary artery pressure is monitored, permitting continuous *indirect* measurement of left ventricular function for monitoring and assisting care of hemodynamically unstable clients. Abnormal pressures can indicate changes in a client's fluid balance, heart pumping action, or vascular tone.

The pulmonary artery catheter typically has four or five lumens. Two lumens are used for pressure measurements. The proximal lumen is used to measure central venous pressure (right atrial pressure), assist in measuring cardiac output, and to inject selected solutions. The distal lumen is used to measure pulmonary artery pressure (PAP) and pulmonary artery wedge pressure (PAWP/PAOP). The third lumen is used for balloon inflation. The fourth lumen is attached to a thermistor tip that assists in the measurement of cardiac output and blood (core) temperature.

At the end of diastole (ventricular filling), the mitral valve is open, and the left ventricle, left atrium, and pulmonary vasculature momentarily act as a single chamber in which the pressure is equal throughout. Since the normal pressures of these chambers and vessels are known, pressure changes in the pulmonary artery can be used to reflect changes in left ventricular end-diastolic pressure (LVEDP). Reduced cardiac function is manifested primarily by two hemodynamic abnormalities: decreased cardiac output (or cardiac index) and increased LVEDP. The pulmonary artery catheter indirectly measures the LVEDP by directly measuring pulmonary artery and pulmonary artery wedge pressures.

If pulmonary artery wedge pressure measurement is required, the balloon is *briefly* inflated and the catheter is

carried by blood flow through the pulmonary circulation until it “wedges.” During this brief occlusion (wedge) time, pressure reflected back on the tip of the catheter allows indirect measurement of LVEDP. The balloon is then deflated passively and floats back to the pulmonary artery.

To calculate cardiac output, a bolus of cold or room temperature fluid is injected into the right atrial lumen. The fluid's temperature change is then detected in the pulmonary artery by the catheter-tip thermistor. The temperature change over time is computed and represents the cardiac output. Finally, mixed venous blood oxygen saturation monitoring using a fiber optic pulmonary artery catheter provides information about the balance between tissue oxygen delivery and tissue oxygen consumption (SvO_2), which is particularly valuable for monitoring clients with sepsis.

Data derived from physiologic monitoring have diagnostic and therapeutic value in the care of select critically ill (hemodynamically unstable) clients.

TABLE 33-1 Normal Pressures

Right atrial (RAP): 2–8 mmHg

Right ventricle (RV): $\frac{25}{5}$ mmHg

Pulmonary artery pressure (PAP): $\frac{25}{5}$ mmHg

PA mean (\bar{P}_A): <15 mmHg

PAWP/PAOP: 10

Left atrial (LA): 5–10 mmHg

Left ventricle (LV): $\frac{130}{5-10}$ mmHg

Aorta: $\frac{130}{80}$

Mean arterial pressure (MAP):

$77-90$ (Diastolic $\times 2$) + (Systolic $\times 1$) $\div 3$

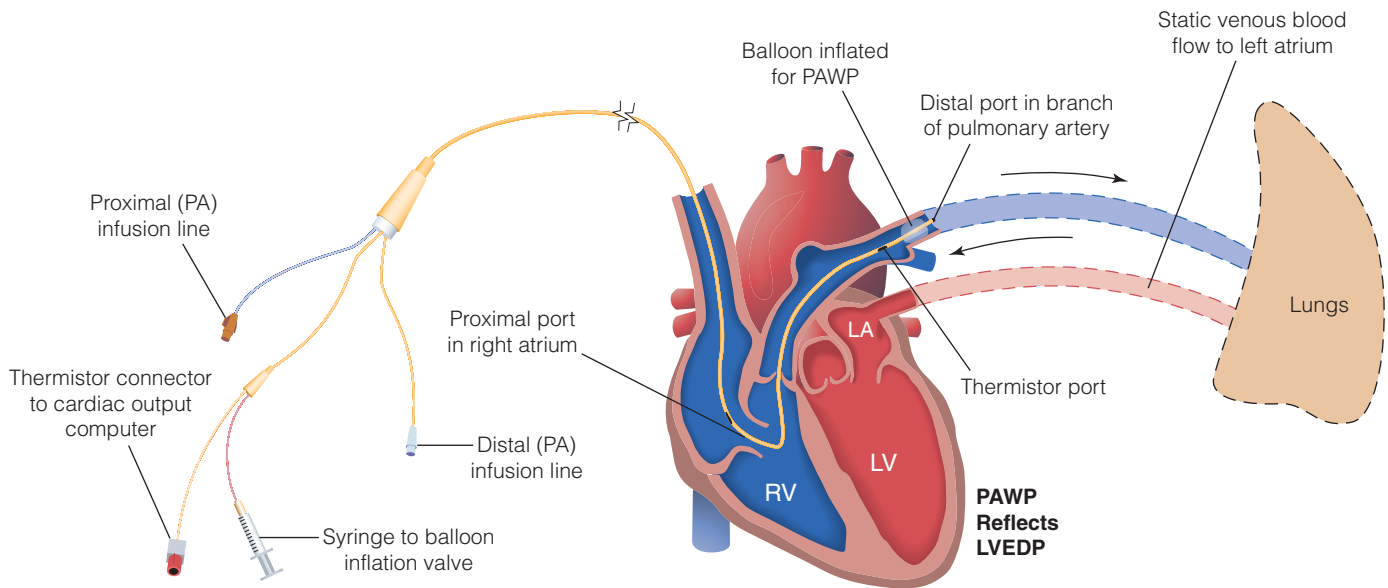

or $\frac{(SBP) + 2(DBP)}{3}$

▲ Balloon-tipped, flow-directed catheter with balloon inflated briefly for pulmonary artery wedge (occlusion) pressure determination.

▲ Balloon-tipped catheter has multiple lumens (internal tubes) with openings used to measure intracardiac pressures and other dynamic measures.

▲ Pulmonary artery catheter provides intracardiac pressure measurements—used to derive multiple cardiac function indices.

Leveling and Zeroing the Monitor System

Procedure

1. Perform hand hygiene.
2. Reassure client and explain what you are doing.
3. Calibrate system.
 - a. Using carpenter’s level, adjust height of transducer to level of client’s atrium or phlebostatic axis.
 - ▶ **Rationale:** Transducer must remain level with client’s right atrium for accurate monitoring. Higher transducer position yields low readings and vice versa.
 - b. To zero monitor, remove port cap (maintain sterility), open stopcock above transducer to air, closing it to the client and the flush system. ▶ **Rationale:** This action opens transducer to atmospheric pressure.
 - c. Push the “zero” monitor button, and check if monitor reading is zero. ▶ **Rationale:** When reading is zero, transducer is balanced to atmospheric pressure (actually 760 mmHg).
4. Check that oscilloscope shows a flat wave at zero line.
 - ▶ **Rationale:** This ensures accurate reading as it changes from zero point.
5. Recap port and close stopcock to reestablish flush system.

▲ Adjust height of transducer to level of client’s phlebostatic axis.

Clinical Alert

Level the air/fluid interface stopcock (on top of the transducer) to client’s phlebostatic axis (intersection of lines at mid anterior–posterior chest and fourth ICS) every 8 hr and any time the bed or client’s position is changed.

EVIDENCE-BASED PRACTICE

Determining the Phlebostatic Axis

Since all clients’ chests are not equal, the midaxillary line is not an accurate external reference point for the phlebostatic axis. Reference the intersection of two lines on the right side of the chest: one drawn vertically at the fourth intercostal space and one drawn horizontally at the midpoint between the anterior and posterior chest.

Source: McGhee, B., & Bridges, E. (2002). Monitoring arterial blood pressure: What you may not know. *Critical Care Nurse*, 22(2), 60–79.

Assisting Physician With Catheter Insertion

Equipment

- Sterile gloves
- Percutaneous introducer kit
- IV pole
- Premix flush solution (usually 500 mL of normal saline with 1,000 units of heparin 2 units/mL)
- IV tubing
- Pressure transducer system with pressure bag, tubing, flush device, and transducer
- Pressure monitor
- Clean gloves
- Sterile towels
- Antiseptic solution (2% chlorhexidine)
- Sterile 4 × 4 sponges
- Stethoscope
- Lidocaine 1%–2%
- 3-mL syringe with 18- and 25-gauge needle for topical anesthetic
- Antimicrobial wipes
- Occlusive dressing or tape
- Suture with attached needle
- Sterile needle holder or clamp
- Cutdown tray, sterile gown, mask, and cap
- Emergency cart
- Sterile syringes filled with 5 mL or 10 mL of normal saline (cardiac output)

Preparation

1. Validate that client's informed consent has been obtained.
2. Identify client's room and client's Ident-A-Band and have client state name and birth date.
3. Explain rationale for procedure to client.
4. Validate that client has an established peripheral IV site. ► **Rationale:** For administration of emergency fluids or medication if needed.
5. Perform hand hygiene.
6. Connect IV tubing to flush fluid bag.
7. Place prepared flush solution bag in pressure bag and inflate to 300 mmHg pressure. ► **Rationale:** This maintains a rate of flow through the flush device (3 mL/hr).
8. Prepare and assemble pressurized monitoring system (transducer, system flush device, and stopcocks) following

manufacturer's instructions. Attach stopcocks to proximal and distal ports. Flush all lumens with flush solution.

9. Attach distal port stopcock to connecting tubing and heparinized flush solution, then attach to pressure monitoring unit, making sure all connections are tight.
10. Place client in Trendelenburg's position and turn client's head to opposite side. ► **Rationale:** This position distends central veins and prevents air embolism during the procedure.
11. Level and zero system according to manufacturer's instructions. The stopcock on top of the transducer must be at the level of client's atrium or phlebostatic axis (fourth intercostal space at the midchest line).
12. Scrub selected site with antiseptic solution.
13. Open sterile gloves for physician.
14. Open drape for physician.
15. Cleanse lidocaine vial with antimicrobial wipe.
16. Continuously monitor client's ECG throughout insertion of catheter. ► **Rationale:** Rhythm changes may occur.

Procedure

1. Don sterile gloves to assist physician as necessary.
 - a. Physician dons sterile mask, cap, gown, and gloves. Catheter is tested for leaks by inflating balloon with 0.5–1.5 mL (amount determined by catheter size) of air while balloon is submerged in sterile basin filled with sterile irrigating solution.
 - b. Physician aspirates lidocaine with 18-gauge needle, changes to 25-gauge needle, and injects lidocaine under skin.
 - c. Physician performs cutdown or percutaneous insertion. Subclavian vein usually used; however, the jugular or a peripheral vein may be selected.
 - d. Physician aspirates and flushes sheath with sterile normal saline before inserting catheter. ► **Rationale:** This clears air and prevents air embolism. The use of D₅W rather than normal saline reduces risk of microshock to the client.
 - e. While client performs Valsalva's maneuver or hums, catheter is attached to fluid-filled transducer system. ► **Rationale:** This prevents inhalation and possible air embolism. Continuous pressure monitoring is observed during advancement of catheter.
 - f. Catheter is advanced with a balloon partially inflated until correct right atrial waveform appears on monitor (strip A).
 - g. Physician inflates balloon (1–1.5 mL air) to assist in catheter's flow through tricuspid valve into right ventricle.
2. Observe for higher and more pronounced pressure waveform, indicating catheter's presence in right ventricle (strip B).

Clinical Alert

By zeroing to atmospheric pressure, the system negates the effect of atmospheric pressure on the pressure being measured.

▲ Waveforms depicted on monitor correspond with right heart chambers and pulmonary artery pressures.

- Record right ventricular pressure (systolic and diastolic reading) and observe for dysrhythmias: premature ventricular contractions (PVCs) or ventricular tachycardia.
- Observe monitor for *higher* diastolic pressure and appearance of dicrotic notch on pulmonary arterial waveform (strip C). ► **Rationale:** Right ventricular systolic and pulmonary artery systolic pressures are similar, but pulmonary artery *diastolic* measure “steps up.”
- Remove syringe to allow balloon to deflate passively. (A special syringe is used that prevents overinflation of the balloon.)

- Record pulmonary artery systolic (PAS), diastolic (PAD), and mean pressures.

NOTE: Measure all pulmonary artery pressures at end of expiration.

- Inflate balloon fully (1.5 mL maximum) or until a change is seen in waveform (pulmonary artery to artery wedge pressure) (strip D). ► **Rationale:** Inflated balloon assists passage of catheter into distal pulmonary artery.
- Record PAWP (pulmonary artery wedge pressure).
- Deflate balloon by releasing pressure on syringe plunger or remove syringe to allow passive deflation. ► **Rationale:** Active aspiration of air from balloon with a syringe plunger can cause balloon damage.
- Determine balloon deflation by observing return of pulmonary artery waveform. ► **Rationale:** This ensures balloon deflation. Continued occlusion of vessel can cause pulmonary infarction.
- Repeat steps and measurements to verify function.
- Leave balloon lumen port open at all times except during advancement for wedge pressure (PAWP) measurement.
- Clear catheter using fast flush device.
- Apply occlusive dressing to site after physician secures catheter with sutures.
- Reposition client for comfort.
- Auscultate chest for presence of breath sounds.
- Validate catheter placement by chest x-ray. ► **Rationale:** Pneumothorax can occur with jugular or subclavian vein cannulation.
- Dispose of equipment, remove gloves, and perform hand hygiene.

EVIDENCE-BASED PRACTICE

Confirming Digital Measurements

This study showed lack of agreement between digital and graphic measurements of CVP and PAD, which ranged from as small as 1 mmHg to as great as 40 mmHg, especially in patients with respiratory rate >20. Digital measurements should be confirmed by waveform analysis of a graphic measurement before assuming that the value is accurate.

Source: Ahrens, T., & Schallom, L. (2001). Comparison of pulmonary artery and central venous pressure waveform measurements via digital and graphic measurement methods. *Heart & Lung, 30*(1), 26–38.

Clinical Alert

For PAWP (pulmonary artery wedge pressure), inflate balloon *briefly* (8 to 15 seconds), just until PAP changes to PAWP waveform, then allow balloon to deflate by releasing pressure on syringe plunger or removing syringe.

Obtaining Pressure Readings

Preparation

1. Level transducer, and zero (calibrate) monitor at the beginning of every shift. ▶ **Rationale:** This ensures accurate and consistent readings.
2. Check catheter, tubing, and connection points to ensure patency and security.
3. Mark client's midchest level at fourth ICS for consistent readings.
4. Place client flat supine or up to 20° elevation.

NOTE: Consistent position is preferred for all readings.

5. Perform hand hygiene.

Clinical Alert

Do not use the PA catheter for infusion of blood or other viscous fluids as they may occlude the catheter or alter pressure measurements.

Procedure

1. Check that air reference port (stopcock) of pressure transducer is at level of client's atrium (phlebostatic axis). ▶ **Rationale:** This ensures accurate pressure reading. Level must be adjusted if client's position is changed.
2. Expose distal port to the transducer. ▶ **Rationale:** All pulmonary artery pressure readings are taken from distal lumen of catheter, and right atrial pressures are taken from RA or proximal lumen.
3. Open balloon inflation port-locking device.

Clinical Alert

Pulmonary artery diastolic pressure is an acceptable equivalent of PAWP (if correlation determined) and eliminates need for occlusion (wedge) readings.

4. Attach syringe filled with proper amount of air and align stopcock to open position.
5. Slowly inject 0.8 or 1.5 mL of air into balloon. Inflate sufficient volume only to support float and change in waveform.

EVIDENCE-BASED PRACTICE

Measuring Hemodynamic Pressures

Analog data (printed strip) rather than digital data or "stop-cursor" freezing the monitor screen remains the recommended method for measuring hemodynamic pressures. Mean pressures are determined by bisecting the waveform (areas above and below bisecting line are equal).

Source: Bridges, E. (2000). Monitoring pulmonary artery pressures: Just the facts. *Critical Care Nurse*, 20(6), 59–75.

▲ Monitor display of ECG, pressure waveforms, and digital readouts for continuous client assessment.

6. Observe waveform change from pulmonary artery to pulmonary artery wedge pressure on the monitor.
7. Balloon should be inflated only long enough to observe PAWP waveform (8–15 seconds).
 - ▶ **Rationale:** Longer inflation can cause overwedging (falsely high pressure readings) and damage to pulmonary tissue.
8. Allow balloon to deflate passively. ▶ **Rationale:** Aspirating air with syringe may damage balloon.

Clinical Alert

Suspect balloon rupture if no resistance is encountered on inflation, syringe plunger fails to retract spontaneously, or if blood returns from balloon lumen. Mark stopcock: "DO NOT INFLATE."

9. Ensure readings are always taken at end of expiration whether or not client is on ventilator (document if client is on ventilator). ▶ **Rationale:** Slightly higher readings are obtained if client is on a ventilator.
10. Use analog strip chart recording to obtain the most valid pressure measurements.
11. Maintain empty syringe on balloon port.
12. Flush line with fast flush device system.
13. Record readings; verify and report unusual findings to physician if they persist.

Mixed Central Venous Oxygen Saturation (SvO₂) Monitoring

The SvO₂ reflects a dynamic relationship between tissue oxygen delivery and tissue oxygen consumption, providing an indication of overall oxygen balance. This value has diagnostic, prognostic, and therapeutic value in the care of critically ill clients, particularly those with acute MI, heart failure, and cardiogenic, hypovolemic, or septic shock.

A fiberoptic pulmonary artery catheter analyzes light absorption reflecting RBC hemoglobin saturation (similar to a pulse oximeter). An oximeter computer with microprocessor converts this information into an electrical display (graphic trend, numeric display, or both) for continuous monitoring. Since analysis occurs in the pulmonary artery, the value reflects a measurement of overall venous oxygen saturation, reflecting oxygen consumption at the tissue level. Whereas arterial oxygen content (SaO₂) is 100%, a

normal SvO₂ value is 70%–80%. Clinically significant changes in SvO₂ (±5%–10%) can be an early indicator of physiologic instability.

Low SvO₂ may be due to inadequate oxygen delivery caused by decreased cardiac output (increased heart rate or decreased stroke volume), reduced hemoglobin, low oxygen saturation, or excess tissue extraction of oxygen (e.g., due to pain or nursing procedures). Management will focus on optimizing preload, afterload, cardiac contractility, oxygen delivery, and increasing blood hemoglobin with transfusion. Adaptations in nursing care can reduce the client's oxygen requirement and utilization.

High SvO₂ occurs with low tissue extraction of oxygen, as seen in patients who are sedated, or may indicate hyperdynamic blood flow or tissue inability to utilize oxygen delivered, as occurs in sepsis.

Clinical Alert

Changes in intracardiac pressures and volumes may be altered by changes in myocardial compliance. Any pressure should be interpreted in relation to the client's clinical assessment.

14. Place client in comfortable position.
15. Change dressings per agency policy, and observe for complications at site of catheter insertion.

Measuring Cardiac Output

Equipment

Established pressure monitoring system
 Closed system cardiac output set (COSET)
Includes: 500-mL bag of NS (injectate), tubing with 3-way stopcock, syringe
 Cardiac output cable

Preparation

1. Check physician's orders.
2. Identify client's room, check Ident-A-Band, and ask client to state name and birth date.
3. Perform hand hygiene.
4. Spike injectate solution bag with tubing/stopcock.
5. Unclamp injectate tubing, prime tubing and stopcock, and then reclamp tubing.
6. Connect primed system to client's PA catheter proximal port.
7. Stop any medication being infused through proximal port. ► **Rationale:** To prevent medication bolus during cardiac output measurement.
8. Note pulmonary artery waveform on monitor.
 ► **Rationale:** To verify catheter position.

9. Connect computer cable to thermistor port of pulmonary artery catheter (according to manufacturer's instructions). ► **Rationale:** Change in injectate temperature from proximal injectate port to thermistor port at distal lumen is computer calculated and displayed as the cardiac output in L/min.
10. Obtain client's height and weight measures.

Procedure

1. Place client in position used with previous hemodynamic readings; client should be supine, but may be elevated up to 20°. ► **Rationale:** Consistency of position decreases measurement variability.
2. Slowly flush proximal injectate lumen if any medications were being infused. ► **Rationale:** To prevent bolus medication delivery during cardiac output measurement.

Clinical Alert

Vasoactive medications should not be infused through the proximal port; the Swan Ganz VIP catheter provides a separate proximal port for infusion.

3. Select *cardiac output* on bedside monitor menu.
4. Check and set computation constant to reflect size of catheter, volume (5 or 10 mL) of injectate, cold versus room temperature injectate, and injectate volume (see PA catheter manufacturer's instructions). ▶ **Rationale:** These are factored into computer-derived hemodynamic measures. A 5-mL bolus may be indicated for a fluid-restricted client.
5. Unclamp injectate solution tubing.
6. Attach syringe to stopcock and open stopcock to withdraw 10 mL of injectate into syringe.
7. Ensure that client is quiet. ▶ **Rationale:** Movement may cause inaccurate readings.
8. Open stopcock to client and inject rapidly (2–4 seconds). ▶ **Rationale:** Slower injectate results in inaccurate readings.
9. Note and record monitor display of client's cardiac output measure.
10. Repeat procedure two more times for cold injectate; repeat four more times for room temperature injectate, waiting 1–2 minutes between injections.
11. Obtain curves and discard abnormal curves or those with wandering baselines.
12. Record the average of remaining cardiac output measures.
13. Clamp injectate tubing.
14. Open stopcock to continue previous infusion to client.
15. Preserve closed cardiac output system by leaving tubing, stopcock, and syringe connections intact. ▶ **Rationale:** This eliminates need to open system each time measurements are made.
16. Determine derived values using client's cardiac output measure: stroke volume, systemic vascular resistance, pulmonary vascular resistance, cardiac index (client's height and weight factored into the cardiac output).

The value of routine use of the pulmonary artery catheter for broad groups of clients has not been substantiated. Lack of benefit may be due to ineffective or improper changes in management based on PAC data rather than to lack of potential benefit of the PAC data.

DOCUMENTATION for Pulmonary Artery Pressure Monitoring

- Physician who placed catheter
- Size of pulmonary artery catheter inserted
- Vessel placement and technique used to insert catheter (cutdown or percutaneous)
- Site care and dressing applied
- Client position during measurements
- Pressure readings obtained (specify digital or analog measures)
- Strip recordings attached
- Client's response to procedure
- Cardiac output results
- Problems arising and interventions performed

Legal Alert

A nurse caring for a client after gastric bypass surgery suspected that the client was experiencing cardiac tamponade due to displacement of the pulmonary artery catheter. In spite of the nurse's requests, the nurse manager refused to examine the client, stating that the client was agitated, restless. As the client deteriorated, the nurse attempted to contact the physician, but this was "cut off" by the manager. The client was eventually

taken to emergency surgery but suffered severe brain damage and died a week later. The jury found that, with prompt reporting and medical attention, the client's condition could have been easily treated with pericardiocentesis. The jury decided against the hospital and awarded \$7.3 million for the negligence of its nursing staff.

Source: Wilkinson, A. (1998). Nursing malpractice. *Nursing* 98, 28(6), 34.

CRITICAL THINKING Application

Expected Outcomes

- Pulmonary artery catheter remains patent.
- Pulmonary artery systolic, diastolic, and pulmonary artery wedge pressure are measured accurately.
- Cardiac output measurements are obtained.

Unexpected Outcomes

Pulmonary artery catheter is not patent.

Alternative Actions

- Check that tubing is not kinked.
- Ensure continuous heparinized flush or normal saline infusion. (Check hospital policy.) Check stopcock connections. (Do not use dextrose solution.)
- Attempt to aspirate clotted blood through line by pulling back on plunger of a small syringe placed at proximal port. Remove clot, then flush line.
- Notify physician if unable to clear line.
- Fast flush system and flick tubing to eliminate tiny bubbles.

Pressure waveforms are significantly abnormal.

- Check that tubing is not kinked.
- Check stopcock level.
- Correlate with client for possible change in clinical condition.
- Tighten all connections.
- Look for air in any system port.
- Eliminate added stopcocks and tubing extensions.
- Ask client to cough or change position to help free catheter.
- If condition persists, notify physician to reposition line, and assess client.

Analog waveform is inconsistent with digital display.

- Validate leveling at client's phlebostatic axis.
- Validate zeroing of system to atmospheric pressure ("0" baseline).
- Record analog strips and median measured values on chart—do not rely on digital measures.

No pressure tracing.

- Determine that power is ON.
- Check for loose connections.
- Check for clotted blood in line (damping is an early sign). Try to aspirate; never flush.
- Check stopcocks to make sure they are turned appropriately.

No pulmonary wedge pressure tracing.

- Check and deflate balloon.
- Suspect that catheter is not adequately advanced. Chest x-ray may be ordered to check placement of pulmonary artery catheter.
- Reposition client.
- Suspect possible balloon rupture if no resistance is felt on inflation.

Cardiac output measurements vary significantly.

- Determine whether measurements have been performed with consistent client positioning (supine or elevation degree).
- Compare measurements when client is in supine and elevated position as client's hemodynamic status may account for positional differences.
- Establish and document consistency in client positioning for cardiac output measurements.

Chapter 33

UNIT 2

Arterial Blood Pressure Monitoring

Nursing Process Data

ASSESSMENT Data Base

- Determine need for direct arterial blood pressure monitoring.
- Assess collateral perfusion of the hand using the Modified Allen's Test.
- Measure arterial (direct) systolic and diastolic blood pressure readings.
- Observe the mean arterial pressure on the monitor and validate using analog strip measurement.
- Observe for trends in arterial pressure readings.
- Validate 300 mmHG pressure on infusion system.
- Assess catheter insertion site for signs of infection or bleeding.
- Assess circulation, temperature, motion, and sensation of extremity distal to catheter insertion site.
- Monitor systemic response to circulatory assistance (IABP)

PLANNING Objectives

- To maintain a patent arterial catheter
- To directly measure systolic, diastolic, and mean arterial blood pressures
- To provide essential information regarding fluid volume, cardiac function, and perfusion to vital organs
- To provide immediate access for arterial blood gas samples
- To provide circulatory assistance (IABP) for selected clients

IMPLEMENTATION Procedures

- Performing the Modified Allen's Test1332
- Assisting With Arterial Line Insertion1332
- Monitoring Arterial Blood Pressure1333
- Monitoring Intraaortic Balloon Pump Circulatory Assistance1334
 - For Monitoring Balloon Pump Function1334
 - For Monitoring Client Response1334
- Withdrawing Arterial Blood Samples1335
 - For Blood Conservatory Process1336
- Removing Arterial Catheter1336

EVALUATION Expected Outcomes

- Blood supply to hand is adequate before and after arterial catheter placement.
- Arterial cannulation is accomplished without complication.
- Arterial blood pressure monitoring system functions reliably and accurately.
- Intraaortic balloon pump circulatory assist improves cardiac output: afterload and preload are reduced.
- Arterial blood samples are obtained.

- Critical Thinking Application** 1337
- Expected Outcomes 1337
 - Unexpected Outcomes 1338
 - Alternative Actions 1338

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Direct blood pressure monitoring allows continuous measurement of the client's systolic, diastolic, and mean arterial pressures (MAP) to facilitate evaluation of perfusion to vital organs. A short single-lumen catheter is placed in the client's radial artery (brachial artery may be used), then attached to a pressure transducer and high-pressure infusion system and a display monitor. Direct pressure readings are typically 10–20 mmHg higher than simultaneously measured indirect (cuff) readings.

To maintain patency of the intraarterial catheter, a continuous flush of 1–3 mL/hr of heparinized normal saline solution is administered under 300 mmHg pressure.

NOTE: The use of dextrose supports bacterial growth. Heparinized solution may be contraindicated for clients at risk for heparin-induced thrombocytopenia.

Invasive monitoring is appropriate for surgical clients, clients on mechanical ventilators, or those requiring vasodilator or vasopressor drugs or frequent arterial blood gas studies.

Continuous arterial waveforms are observed on the oscilloscope, and numerical pressures are displayed. Blood pressure

▲ Arterial pressure waveform. The dicrotic notch indicates aortic valve closure (and end of systole).

Hemodynamic Monitoring System Components

- Invasive **catheter** with high-pressure tubing connected to transducer
- **Flush/infusion system** with pressure bag at 300 mmHg maintains patency of system
- **Transducer**—converts physiologic wave to electrical energy
- **Monitor**—converts electrical energy, displays pressure waveform and digital reading in mmHg

Intraaortic Balloon Pump (IABP) Circulatory Assist Device

An example of integrative technology is the intraaortic balloon pump (IABP) which incorporates both hemodynamic and arterial blood pressure monitoring information. The IABP provides indirect short-term circulatory assistance for clients with compromised cardiac function due to myocardial infarction with complications, temporary left ventricular failure, cardiac injury, septic shock, or those awaiting cardiac transplantation. The goals are to decrease heart work, reduce afterload, improve cardiac output, enhance coronary and peripheral perfusion, and ultimately reduce preload.

The balloon catheter is inserted percutaneously into the descending aorta via the femoral artery and advanced proximally so that the balloon is positioned just below the left subclavian artery, yet above the renal artery.

The vacuum pump cyclically drives helium to inflate and deflate the balloon. Performing on the principle of counter-pulsation, the catheter balloon inflates at the onset of diastole enhancing perfusion and oxygen delivery to tissues antegrade and to the coronary arteries retrograde. The balloon deflates just before systole, creating a relatively negative suction effect, thereby reducing afterload and supporting ventricular ejection and antegrade blood flow.

Direct blood pressure waveform correlation to the cardiac cycle is represented by the symbols shown in the figure.

- *a* represents a sharp upstroke, correlating with ventricular systole and the QRS complex of the electrocardiogram.
- *b* represents peak systole; its numerical value is the systolic pressure recorded.
- *c* represents the notch on the downstroke of the waveform. This notch is called the *dicrotic notch* and represents closure of the aortic valve.
- *d* represents diastole and is represented by a continuous decline in pressure. The numerical value at the lowest point is the diastolic pressure.

deviations can immediately be detected and appropriate therapy instituted without delay. The arterial line also provides easy access to blood sampling for ABGs and other lab values. Arterial blood gas values assist in determining respiratory and metabolic acid–base status (Tables 33-2 and 33-3) as well as lung capacity to provide oxygen. The measurements serve as a guide for implementing and evaluating treatment.

Performing the Modified Allen Test

Procedure

1. Perform the Modified Allen Test to determine distal peripheral perfusion. ► **Rationale:** This procedure assesses blood supply to client's hand to determine that radial and ulnar artery are functioning before an arterial line is inserted.
2. Compress both arteries at client's wrist for about 1 minute.
3. Instruct client to clench and unclench fist several times. ► **Rationale:** This causes blanching in the hand and palm.
4. With client's hand in open, relaxed position, release pressure on ulnar artery.
5. Observe how quickly (≤ 7 seconds) the palm color flushes. ► **Rationale:** If color returns quickly, good collateral blood supply to the hand exists. If normal color does not return, there is insufficient collateral circulation to the hand should radial artery occlusion occur.
6. Repeat procedure with release of the radial artery.
7. Report to physician if collateral blood flow is insufficient. ► **Rationale:** A Doppler flow study may be used to help determine collateral blood flow.

Assisting With Arterial Line Insertion

Equipment

- 20-gauge Teflon catheter with introducer and flexible guidewire
- 500 mL of normal saline for flush
- Heparin 1,000 units/mL
- One-mL unit dose syringe
- Pressure bag for flush infusion
- IV tubing
- Short wide-bore, high-pressure tubing
- Three-way stopcocks with nonvented caps
- Established pressure monitor system
- Clean gloves, sterile gloves
- Personal protective equipment (PPE)
- Sterile towels and drape
- Skin prep solution (2% chlorhexidine)
- Sterile 4 × 4 gauze sponges
- Lidocaine 1% (without epinephrine)
- 3-mL syringe with 18- and 25-gauge needles for *topical* anesthetic
- Alcohol wipes
- 000 silk suture (if used)
- Sterile transparent dressing
- Atropine for reversal of bradycardia

Preparation

1. Validate that informed consent has been obtained.
2. Determine whether client has received anticoagulant therapy. ► **Rationale:** Coagulation studies may be indicated.
3. Identify client, check Ident-A-Band, and ask client to state name and birth date.
4. Explain rationale for procedure.
5. Gather equipment.
6. Perform hand hygiene.

7. Add heparin to normal saline solution and label bag with additive and date (commonly 2 units of heparin/mL fluid). Follow hospital protocols.
8. Connect IV tubing to solution bag.
9. Remove *all air* from flush solution bag.
10. Insert flush infusion bag into pressure bag and hang bag on IV pole.

Clinical Alert

Arterial catheter alarms should always be enabled to detect disconnection, alterations in blood pressure, or pulseless electrical activity.

11. Prepare and assemble pressurized monitoring system (transducer, continuous flush device, and stopcocks) following manufacturer's instructions.
12. Level stopcock above transducer to client's phlebostatic axis (see previous skill).
13. Inflate pressure bag to 300 mmHg using hand pump on bag.

Procedure

1. Don gloves and PPE and prepare to assist the physician as needed.
 - a. Skin is prepped briskly with 2% chlorhexidine for 3 seconds.
 - b. Lidocaine vial is cleansed with alcohol wipe.
 - c. Physician dons sterile gloves.
 - d. Sterile drape is placed over arterial insertion site.
 - e. Physician aspirates lidocaine with 18-gauge needle, changes needle, and injects client's skin with 25-gauge needle. ► **Rationale:** For local anesthesia.
 - f. Percutaneous insertion is made at arterial insertion site, and arterial catheter is inserted.
 - g. Physician advances catheter in artery.

- h. Arterial catheter is sutured in place with 000 silk suture secured with transparent dressing.
2. Observe for pulsating bright-red blood spurting retrograde into catheter. ► **Rationale:** This evidence ensures arterial catheter position.
3. Attach catheter to primed pressure-monitoring system tubing—make certain all connections are secure.
4. Press fast flush valve to clear system.
5. Observe oscilloscope for arterial waveform.
6. Apply sterile transparent dressing (with date and initials) to site after catheter is sutured into place.
7. Remove gloves and perform hand hygiene.
8. Set monitor alarms for both HIGH and LOW parameters.

Monitoring Arterial Blood Pressure

Equipment

Disposable pressure transducer, dome, and amplifier
 Flush valve with flush system
 Display monitor (oscilloscope)
 Sterile stopcock cap
 Sterile transparent dressing
 Gloves
 Carpenter's level
 Marker

Procedure

1. Leveling and zeroing (calibrating) the system.
 - a. Calibrate system at beginning of each shift.
 - **Rationale:** Monitor readings are altered by changes in atmospheric pressure.
 - b. Position client with HOB flat or up to 45° elevation.
 - c. Using carpenter's level, align stopcock above transducer level with client's left atrium (phlebostatic axis) and mark client's chest for future readings. ► **Rationale:** Readings will be inaccurately high or low if stopcock above transducer is not level with client's phlebostatic axis.
 - d. To zero ("calibrate") the system, turn stopcock near transducer off to client. Remove cap from stopcock, opening it to air.
 - e. Depress "zero" button on monitor, release button, and note monitor reading is zero. ► **Rationale:** Zero reading indicates monitor is calibrated to atmospheric pressure.
 - f. Replace cap or place new sterile cap on stopcock.
 - g. Turn stopcock so transducer is open to client.
2. Observe waveform at eye level for the sharp systolic upstroke, peak, dicrotic notch, and end diastole.
3. Fast flush the continuous flush system and quickly release. A sharp upstroke followed by a horizontal line, then a brisk downstroke descending below, then returning to baseline indicates that the system requires no adjustment.
4. Ensure pressure bag is maintained at 300 mmHg.
5. Leave cannulated extremity uncovered for easy observation. Assess site for signs of infection every shift.

▲ (A) Arterial line—normal waveform. (B) Arterial line—flattened waveform. Flattened arterial waveform indicates damping. Damping results from obstruction in arterial line or imbalance of transducer.

▲ Arterial line allows direct measurement of blood pressure—monitor displays digital and wave form.

6. Assess circulation, motion, and sensation of extremity distal to cannulation site every 2 hr initially, then every 8 hr.
7. Immobilize extremity if necessary.

EVIDENCE-BASED PRACTICE

Monitoring Arterial Blood Pressure

The use of an indirect brachial blood pressure measurement to determine whether an arterial pressure monitoring system is accurate is not evidence-based. It is more important to determine that technical aspects of the method are optimized and the blood pressure is adequate. In addition to obtaining an absolute measure, monitoring for trends or changes in blood pressure over time is equally important for guiding clinical decisions.

Source: Rauen, C. A., Chulay, M., Bridges, E., Vollman, K. M., & Arbour, R. (2008). Seven evidence-based practice habits: Putting some sacred cows out to pasture. *Critical Care Nurse*, 28(2), 98–123.

▲ Fast flush the continuous flush system and quickly release. A sharp upstroke, followed by a horizontal line, then a brisk downstroke descending below and then returning to baseline indicates the system requires no adjustment (square wave test).

8. Change flush solution and tubing every 96 hr (according to agency policy).
9. Change dressing weekly or if it becomes loose or soiled.
 - ▶ **Rationale:** Loose or soiled dressings increase risk of infection at site.

▲ Radial artery catheter provides continuous blood pressure monitoring and easy access for blood sampling.

TABLE 33-2 Causes of Acid–Base Imbalance

Acidemia	Alkalemia
Hypovolemia	
Hypoventilation	Hyperventilation
COPD	Hypokalemia
Cardiac arrest	Pulmonary embolus
Diabetic ketoacidosis	Diuretics/steroids
Severe diarrhea	Prolonged vomiting
Renal failure	NG suction

- a. Put on gloves.
- b. Remove dressing and discard in biohazard container.
- c. Apply transparent dressing, date, and initials.
10. Remove gloves and PPE and perform hand hygiene.
11. Monitor site to ensure hemostasis occurs.
12. Monitor extremity distally for adequacy of perfusion.

Monitoring Intraaortic Balloon Pump Circulatory Assistance

Procedure

For Monitoring Balloon Pump Function

1. Validate that balloon catheter tip is at second to third ICS per daily chest x-ray.
2. Assess that balloon is precisely synchronized with the client's EKG cardiac cycle or arterial wave form:
 - a. Inflation starts at the dicrotic notch of the arterial wave form (closure of the aortic valve).
 - b. Deflation occurs before the QRS complex (systole).
3. Maintain frequency of assist at 1:1 or other ratio as ordered.
4. Assess IABP device timing and document by recording strip of arterial pressure in 1:2 assist. ▶ **Rationale:** Cardiac output may decrease if timing is not precise.

For Monitoring Client Response

1. Check balloon insertion site hourly for bleeding/hematoma and signs of infection.
2. Assess circulation hourly: color, temperature, capillary refill; bilateral radial and pedal pulses. ▶ **Rationale:** To validate balloon position does not occlude major run-off from aorta.
3. Monitor urine output hourly; report drop in UO or <30 mL/hr × 2 hr. ▶ **Rationale:** To validate adequate renal perfusion.
4. Assess neurologic status every shift. ▶ **Rationale:** To assess effect on cerebral perfusion.
5. Note CO, CI and record every 2 hr. ▶ **Rationale:** To determine improved cardiac function.

▲ Assess IABP device timing by recording strip of arterial pressure in 1:2 assist. Timing must be precise.

6. Monitor bowel sounds and assess abdomen for pain.
 - ▶ **Rationale:** Abnormal findings may indicate inappropriate balloon placement and should be reported.
7. Report client experience of chest discomfort or any pain, numbness, or tingling in arms or legs.
8. Report decrease in platelet count per daily CBC.
 - ▶ **Rationale:** Catheter function damages platelets.
9. Monitor coagulation profile results. ▶ **Rationale:** Neither clot formation nor bleeding should occur.

Withdrawing Arterial Blood Samples

Equipment

- One 6-mL sterile syringe
- ABG kit with one 3-mL syringe with dry lithium heparin; air filter device
- Or: Vacutainer with Luer-Lok adapter cannula; blood specimen tubes
- Gloves
- Face shield
- Container with ice (paper cup, emesis basin)
- Two specimen labels
- Bubble packaging
- Biohazard specimen bag
- Gauze sponges/pads

Preparation

1. Identify client, check Ident-A-Band, and ask client to state name and birth date.
2. Gather equipment and explain procedure to client.
3. Attach label to specimen syringe with client's name, hospital number, room number, time, and date. Also add client's current temperature and FIO_2 .
4. For blood gas (ABG) specimen, maintain client's current oxygen delivery setting for 20 minutes before obtaining specimen.

EVIDENCE-BASED PRACTICE

Mean Arterial Blood Pressure

In general, the MAP (mean arterial pressure) provides a more accurate interpretation of a patient's hemodynamic status. It provides the best estimate of central aortic pressure and is less sensitive to over- and under-damping distortions.

Source: McGhee, B., & Bridges, E. (2002). Monitoring arterial blood pressure: What you may not know. *Critical Care Nurse*, 22(2), 60–79.

Clinical Alert

“In-line” blood sampling systems eliminate the need for discarding blood, thus reducing blood loss and associated risks.

5. Fill paper cup or emesis basin with ice.
6. Perform hand hygiene and don gloves.

Procedure

1. Momentarily disengage arterial alarms.
2. Turn stopcock off to client.
3. Remove protective cap from open blood sampling port on three-way stopcock closest to arterial line insertion site.
4. Attach syringe or Vacutainer with Luer-Lok adapter cannula to open port of three-way stopcock.
5. Turn stopcock off to flush solution.

▲ Engage syringe or Vacutainer to sample port to obtain arterial blood.

6. Attach syringe or blood specimen tube into Vacutainer to establish blood draw.
7. Discard obtained sample. ► **Rationale:** This discard ensures a specimen that is free of heparin or flush solution.

NOTE: For an ABG blood sample, discard volume should be twice the dead space volume of the catheter and tubing up to the sampling site. For coagulation studies, discard volume should be six times the dead space volume.

8. Engage ABG specimen tube into Vacutainer.
9. Obtain arterial blood gas specimen.
10. Turn stopcock off to open port. ► **Rationale:** This reestablishes flow between flush solution and client.
11. Remove Vacutainers for Blood Conservatory Process.

For Blood Conservatory Process

- a. Don clean gloves.
 - b. Aspirate blood into reservoir tubing.
 - c. Close stopcock to reservoir tubing.
 - d. Access sampling port (closest to client) using blunt cannula with tube holder (Vacutainer).
 - e. Engage blood collection tubes into tube holder and allow to fill. ► **Rationale:** Obtaining specimens using a blood conservatory system helps to prevent nosocomial anemia.
 - f. When sampling is complete, remove blunt cannula and tube holder.
 - g. Open stopcock to reservoir tubing and return contents to client.
12. Place arterial blood gas specimen tubes in container filled with ice.
 13. Fast flush remaining blood onto gauze pad.
 14. Reattach protective cap on open port.
 15. Validate good arterial waveform on monitor.
 16. Reactivate monitor alarms.
 17. Wrap syringe/specimen in bubble packaging and place in biohazard bag with ice.
 18. Remove gloves and perform hand hygiene.
 19. Send specimens to laboratory immediately and notify lab that tubes are being sent.

TABLE 33-3 Arterial Blood Gas Values in Acid–Base Imbalances

Normal ABG Values		
pH	7.35–7.45	
PCO ₂	35–45 mmHg	
HCO ₃ ⁻	22–26 mEq	
Respiratory Acidosis		Compensation
pH: decreased	<7.35	7.35
PCO ₂ : increased	>45 mmHg	
HCO ₃ ⁻ : normal	24	>26 mEq
Respiratory Alkalosis		Compensation
pH: increased	>7.45	7.45
PCO ₂ : decreased	<35 mmHg	
HCO ₃ ⁻ : normal	24	<22 mEq
Metabolic Acidosis		Compensation
pH: decreased	<7.35	7.35
HCO ₃ ⁻ : decreased	<22 mEq	
PCO ₂ : normal	40	<35 mmHg
Metabolic Alkalosis		Compensation
pH: increased	>7.45	7.45
HCO ₃ ⁻ : increased	>26 mEq	
PCO ₂ : normal	40	>45 mmHg

▲ When sampling is complete, open stopcock to reservoir tubing and return contents of blood conservatory system to client.

Removing Arterial Catheter

Equipment

- Gloves
- Personal protective equipment
- Two 4 × 4 gauze pads
- Suture removal set
- Tape

Preparation

1. Check physician's orders.
2. Check client's coagulation lab results (values).
3. Gather equipment.
4. Perform hand hygiene.

5. Identify client; check Ident-A-Band, have client state name and birth date, and explain procedure to client.
6. Disarm monitor alarms.

Procedure

1. Don gloves and PPE.
2. Remove dressing, and discard in appropriate container.
3. Clip retaining sutures if present.
4. Apply finger pressure approximately 2 cm *above* skin puncture site. ► **Rationale:** The artery puncture site is proximal to the skin puncture site.

Clinical Alert

Apply pressure to puncture site for at least 10 minutes if client is on anticoagulation or antithrombotic therapy.

5. Place folded 4 × 4 gauze pad over cannula site with nondominant hand, and apply gentle pressure.
6. Pull arterial cannula straight out of artery with quick, even pressure.
7. Apply firm pressure over and just above cannula site for at least 5–10 minutes. ► **Rationale:** This action achieves hemostasis and prevents formation of a hematoma.
8. Place folded 4 × 4 gauze pad over puncture site, and tape tightly. ► **Rationale:** This provides additional pressure to site to prevent bleeding.
9. Discard supplies, remove gloves, PPE, and perform hand hygiene.
10. Check cannulation site frequently. ► **Rationale:** To observe for bleeding or thrombosis.
11. Check distal extremity for temperature, circulation, motion, and sensation intermittently for several hours, then routinely after catheter removal. ► **Rationale:** Delayed complications (thrombosis) may occur.

DOCUMENTATION for Arterial Blood Pressure Monitoring

- Size of arterial catheter inserted
- Name of physician inserting catheter
- Pressure readings (systolic, diastolic, and MAP)
- Direct and indirect pressure measurements
- Distal neurovascular status of cannulated extremity (temperature, color, motion, sensation)
- Position of client during readings
- Unexpected outcomes and appropriate interventions
- Client response and tolerance of procedure
- Appearance of catheter insertion site
- Monitor strip recordings

Arterial Blood Sampling

- Time specimen obtained
- Client's temperature and FIO₂ at the time blood was drawn

Arterial Site Dressing Change

- Condition of insertion site
- Type of dressing applied

IABP Circulatory Assist

- IABP assist timing ratio (e.g., 1:1)
- Femoral artery insertion site status every hour
- Peripheral circulation status every hour (pulses, color, temperature, capillary refill)
- Urine output every hour
- Abdominal and neurologic assessment every 8 hr
- Hemodynamic parameters every 2 hr (CO, CI, SVR)
- Client reports of chest or abdominal discomfort, any pain, numbness in extremities, including problem-solving interventions

Removing Arterial Catheter

- Time of removal
- Manual pressure and dressing applied
- Condition of insertion site
- Presence and quality of distal pulses
- Motion and sensation of involved extremity

CRITICAL THINKING Application

Expected Outcomes

- Blood supply to hand is adequate before and after arterial catheter placement.
- Arterial cannulation is accomplished without complication.
- Arterial blood pressure monitoring system functions reliably and accurately.
- Intraaortic balloon pump circulatory assist improves cardiac output: Afterload and preload are reduced.
- Arterial blood samples are obtained.

Unexpected Outcomes

Absence of collateral circulation noted when performing the Modified Allen Test (negative Modified Allen Test).

Cannulated extremity develops diminished distal perfusion.

Hypotension and bradycardia occur during arterial puncture or catheter removal.

Hematoma or bleeding occurs at arterial insertion site.

Signs of infection or inflammation appear at insertion site.

Arterial waveform loses definition and digital pressures drop.

Direct blood pressure readings vary significantly.

Arterial blood sample is unobtainable.

Alternative Actions

- Assess contralateral extremity.
 - Avoid radial artery.
 - Notify physician. (An alternate artery may be selected—femoral.)
-
- Check periphery for changes in color, temperature, motion, and sensation resulting from possible thrombus occlusion or circulatory “steal.”
 - Notify physician immediately.
 - Prepare for catheter removal.
-
- Reverse response with atropine administration.
-
- Apply direct pressure over artery while you check for leaks in the system.
 - Check all stopcocks: check if catheter is inserted in artery as it should be.
 - Keep cannulated extremity exposed for observation.
 - Remove catheter if oozing continues.
-
- Use sterile transparent dressings exclusively.
 - Always use aseptic technique with dressing changes; change dressing weekly.
 - Cap open port on stopcock to maintain asepsis.
 - Do not apply ointment to insertion site.
 - Change tubing, flush solution and transducer every 96 hr or with catheter change using sterile technique.
 - Flush open port after obtaining blood specimens.
 - Prepare for catheter removal if infection suspected.
-
- Reverse response with atropine administration.
 - Use low compliance (rigid) short (<3–4 ft) monitor tubing.
 - Check for thrombus formation by aspirating blood through stopcock and then flushing system.
 - Be sure to fast-flush arterial line thoroughly after arterial blood samples are obtained or system is zeroed.
 - Make sure all stopcocks are closed to air.
 - Maintain 300-mmHg pressure in pressure bag.
 - Ensure secure fit of all stopcocks and connections. Avoid adding stopcocks and line extensions.
 - Change position of extremity in which catheter is placed.
-
- Flick tubing system to remove tiny air bubbles escaping the flush solution.
 - Recheck transducer and client position to ensure accurate data.
 - Recalibrate transducer.
 - Flush system after sampling and zeroing.
 - Keep flush bag adequately filled and cleared of air.
 - Maintain bag external pressure at 300 mmHg.
 - Check that connections are tightly secured.
-
- Suspect arterial spasm; allow spasm of artery to stop, then attempt to aspirate blood with gentle pressure using a 6-mL syringe rather than Vacutainer.
 - Reposition client’s arm, making sure there is no pressure at catheter insertion site.
 - Check that catheter is in artery (note waveform on oscilloscope), flush catheter, then attempt to obtain sample.

Intra-aortic balloon ruptures.

- Turn console off and notify physician. Balloon must be removed within 30 minutes.
-

Console fails.

- If problem not resolved in 30 minutes, use syringe filled with 40 mL of room air to manually inflate and deflate balloon to move balloon folds in order to prevent clot formation.
-

Client has decreased urinary output or develops signs of radial artery occlusion.

- Suspect balloon migration.
 - Maintain HOB elevation at less than 45° to prevent kinking and migration of catheter.
 - Immobilize cannulated extremity to prevent catheter migration.
-

Chapter 33

UNIT 3

Cardiac Emergencies

Nursing Process Data

ASSESSMENT Data Base

- Assess client's responsiveness, breathing, and circulation.
- Identify lethal heart rhythms on the ECG recording.
- Assess availability of emergency support response and emergency supplies.
- Identify appropriate drugs needed for an emergency situation.

PLANNING Objectives

- To be prepared to respond to the needs of unstable clients
- To locate necessary supplies and appropriate medications used in emergency situations
- To provide emergency defibrillation to convert lethal arrhythmias (dysrhythmias) to normal sinus rhythm
- To assist with cardioversion to convert rapid supraventricular rhythms or unstable ventricular tachycardia to normal sinus rhythm

IMPLEMENTATION Procedures

- Maintaining the Emergency Cart1341
- Checking Contents of the Emergency Cart1342
- Calling a Code1342
- Performing Defibrillation1342
- Administering Advanced Cardiac Life-Support Medications1345
- Assisting With Synchronized Cardioversion1347

EVALUATION Expected Outcomes

- Supplies and medications are readily available in an emergency situation.
- Client's heart rhythm is restored to normal after defibrillation or synchronized cardioversion.

Critical Thinking Application..... 1349

- Expected Outcomes 1349
- Unexpected Outcomes 1349
- Alternative Actions 1349

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Early recognition is essential for prompt and effective treatment of cardiac emergencies. Interventions for treating emergencies such as hemodynamic instability and flash pulmonary edema include measures to decrease heart work, correct lethal dysrhythmias, and remove excess body fluid.

If left untreated, symptomatic bradycardias and supraventricular or ventricular tachyarrhythmias can cause reduced cardiac output and inadequate tissue perfusion. Life-threatening tachyarrhythmias are terminated by delivering an externally applied electrical countershock to the heart. This countershock depolarizes the myocardium, interrupts the dysrhythmia, and allows the normal pacemaker (sinoatrial node) of the heart to resume control of the heart rhythm. Two types of electrical countershock applications are used: cardioversion and defibrillation.

Defibrillation is an emergency procedure in which fairly large amounts of electric current are delivered without concern for synchronization with ventricular depolarization (QRS wave)

on the ECG. Defibrillation is used to terminate ventricular fibrillation or *pulseless* ventricular tachycardia.

Cardioversion is a procedure used to convert supraventricular tachyarrhythmias and ventricular tachycardia in unstable clients. The electrical countershock is synchronized with ventricular depolarization (QRS wave on ECG) to avoid discharge during the T wave (vulnerable period). This procedure may be elective (planned) or emergent.

The “crash cart” contains essential life support medications and supplies used in emergency situations in the hospital setting. Familiarity with its location and contents, including typical emergency drugs, will assist hospital staff to provide quick, competent care to clients during cardiac emergencies. The crash cart should be kept fully stocked and located in an area that is accessible and obvious to all. Nurses must have a working knowledge of the contents of each drawer of the cart to quickly find necessary supplies.

Maintaining the Emergency Cart

Equipment

- Emergency cart with locking drawers
- Emergency cart checklist
- Airway equipment
- Oxygen equipment
- Suction equipment
- Monitor leads and electrodes
- Defibrillator
- Oscilloscope
- IV equipment
- Emergency drugs

▲ Fully equipped emergency cart is placed in a readily accessible area, visible to staff. Defibrillation and respiratory supplies are kept on the top of the cart.

Procedure

1. Identify supplies and medications commonly used in emergency situations.
2. Gather equipment.
3. Maintain supplies in drawers according to priority use in the most commonly occurring emergency situations. Leave defibrillator plugged into electrical outlet at all times or check batteries every shift.
4. Lock drawers when cart is not in use. ► **Rationale:** This prevents personnel from using supplies for situations other than emergencies and not replacing it.
5. Place emergency cart checklist on outside of cart in visible area. ► **Rationale:** Cart contents are checked on a daily basis (and every 8–12 hr in critical care units) to ensure medications are not outdated, equipment is in working condition, and cart is locked.
6. Place cart in designated, easily accessible, and visible area of the nursing unit. ► **Rationale:** Provides for less confusion if the cart is needed.
7. Familiarize all personnel with location and contents of cart, function of equipment, and emergency procedures.
8. Practice retrieving and setting up equipment through mock situations. ► **Rationale:** This ensures that all personnel are able to use cart during an emergency situation.
9. Check cart daily and document; restock immediately after use. ► **Rationale:** If cart is not restocked, delays can occur during an emergency situation, jeopardizing client care.

Checking Contents of the Emergency Cart

Equipment

NOTE: Emergency cart contents vary among agencies.

Top of Cart

Defibrillator/monitor and related supplies
Respiratory supplies
Gloves, face shield

Front of Cart

Cardiac arrest board

First Drawer

Emergency medications

Second Drawer

IV access supplies

IV solutions and tubing

Syringes, special needles

Third Drawer

NG tubes

Blood pressure cuff, stethoscope

Flashlight

Suction catheter kit and supplies

Central line catheter and supplies

Side of Cart

Emergency cart checklist

Cardiac resuscitation recording sheet and clipboard

Suction unit

Calling a Code

NOTE: See procedure in Chapter 27, Circulatory Maintenance, for CPR/AED skill.

For any client who becomes unresponsive, is not breathing, and has no pulse, call a “code” and get the AED.

Clinical Alert

Summon the Rapid Response Team if noting certain “triggers”: tachypnea, hypotension, signs of shock, active bleeding, chest pain, and altered level of consciousness.

NOTE: Tachypnea and hypotension frequently precede cardiac arrest.

Clinical Alert

Clinically “dead” clients may be able to hear and remember events occurring throughout resuscitation procedures.

Clinical Alert

Sudden cardiac death is the most common cause of death, outnumbering the total number of deaths from AIDS, lung cancer, breast cancer, and stroke each year.

Clinical Alert

The Joint Commission requires hospitals to track and evaluate resuscitation attempts in order to improve process and client outcomes. Development of rapid response teams and in-hospital use of AEDs as well as changes in CPR/ECC guidelines are recommendations based on this tracking data.

EVIDENCE-BASED PRACTICE

This 20-month study (including more than 24,000 patients hospitalized before and 25,000 patients hospitalized after initiation of a Rapid Response Team) showed that the RRT failed to achieve its goal of reducing hospital-wide code rates or mortality outside the ICU and raises questions about whether hospitals should devote resources to Rapid Response Teams.

Source: Chan, P. S., Khalid, A., Longmore, L. S., Berg, R. A., Kosiborod, M., & Spertus, J. A. (2008). Hospital-wide code rates and mortality before and after implementation of a rapid response team. *The Journal of the American Medical Association*, 300(21), 2506–2513.

Performing Defibrillation*

Equipment

Defibrillator with ECG recorder
Defibrillator pads or conduction gel for paddles (do not use ultrasound gel)
(or)
“Hands-free” defibrillation electrodes (refer to package for product-specific instructions)
Emergency cart with:

Airway

Cardiac board

Resuscitator bag

Preparation

1. Validate that client is unresponsive.
 - a. Not breathing, or not breathing normally (e.g., only gasping), and
 - b. No pulse is palpable within 10 seconds (no longer).

*Skill only performed by ACLS-trained staff.

2. Call a code and get the AED and crash cart.
3. Place back board under client, deflate air-filled mattress if present, avoiding delay to initiating CPR with chest compressions within 10 seconds.
4. Immediately perform CPR (chest compressions) providing 30 compressions in 18 seconds with a depth of at least 2 inches until AED or cart and response team arrive.

Procedure

1. Plug defibrillator into electric outlet.
2. Turn defibrillator power ON and allow to warm up.
3. Attach monitor/defibrillator.
4. Dry client's chest if necessary (do not use alcohol).
 - ▶ **Rationale:** To prevent skin burns.

Clinical Alert

Early defibrillation (within 3 minutes) is the key to successful resuscitation.

5. Place conducting pads on client's chest, pressing firmly for adhesion, or spread thin coat of defibrillation electrode gel evenly over surface of paddles. One pad is placed below right clavicle near sternum and second pad is placed to left of cardiac apex (below and to the left of left nipple or at the fifth to sixth intercostal space at midaxillary line). Do not place over broken skin.
 - ▶ **Rationale:** Conductive medium decreases skin resistance and reduces degree of burns.

Clinical Alert

Before beginning defibrillation or cardioversion procedure, remove any transdermal medication patch on chest. Avoid placing paddles over electrodes/leads; avoid pacemaker or ICD generator by at least 8 cm.

▲ Gel pads are placed below right clavicle and left of cardiac apex.

6. Alternatively, apply “hands-free” defibrillation pads.
7. Insert electrodes connector into cable. Push firmly for proper connection.
8. Turn on ECG recorder.
9. Validate that client has shockable rhythm (pulseless VT or VF is present).
10. If **nonshockable** rhythm is present (PEA, asystole), continue CPR for five cycles and administer fluids/medications before attempting defibrillation.
11. Be certain defibrillator is NOT in synchronized mode.
 - ▶ **Rationale:** The machine will not respond to ventricular fibrillation if set to synchronized mode.
12. Set standard monophasic defibrillator to charge at 360 watt seconds; set biphasic device at 200 watt seconds.

Clinical Alert

During defibrillation attempts, ensure the room ventilation is adequate. An oxygen enriched atmosphere (e.g., high-flow oxygen directed across the chest) may support fire caused by spark.

13. Command all persons to move away from bed area and any equipment connected to client.
14. Stand away from bed area yourself.
15. Apply paddles with firm pressure (25 lb). ▶ **Rationale:** Firm pressure decreases transthoracic resistance; this is not necessary with hands-free pads.
16. Depress discharge buttons on paddles simultaneously to ensure appropriate discharge or push “shock” button on defibrillator for hands-free pads—delivering ONE shock.
17. Immediately resume chest compressions. Do not delay for rhythm reanalysis or pulse check.
18. Immediately resume CPR for five cycles.

NOTE: After advanced airway placed, breaths (8–10 per minute) are given along with *uninterrupted* chest compressions (100/min).

Clinical Alert

Gel pads may need to be replaced after three shock deliveries because of drying out.

19. Analyze ECG. If sinus rhythm is established, check for pulse, vital signs, LOC.

Defibrillation

Defibrillation is used for these lethal arrhythmias: pulseless ventricular tachycardia, ventricular fibrillation.

Synchronized Cardioversion

Synchronized cardioversion is used to convert supraventricular tachyarrhythmias and ventricular tachycardia (with pulses) if the client shows serious signs of hemodynamic instability (e.g., ventricular rate \geq 150, SBP $<$ 90 mmHg).

DEFIBRILLATION ARRHYTHMIA

▲ Pulseless ventricular tachycardia.

▲ Ventricular fibrillation.

20. Recharge defibrillator for second attempt at 360 watt seconds (monophasic) or 200 watt seconds (biphasic) if shockable rhythm continues.
21. Deliver ONE shock, then resume CPR immediately for five cycles.

Clinical Alert

Monophasic versus Biphasic Defibrillators

Traditional monophasic defibrillators use a single pulse of energy that travels from one electrode to the other in one direction. Biphasic defibrillators send the current from one electrode to the other, then back to the first electrode with equal success of defibrillation at lower levels of energy (120 joules for the first shock, 200 joules being the maximum). Biphasic defibrillators also adapt to the transthoracic impedance of the particular client and adjust the appropriate current accordingly (e.g., AEDs).

Advantages of the biphasic model include lower risk of skin burns, less myocardial injury, and more rapid return of heart function and MAP. Models are also smaller, weigh less, are easier to maintain, and can be used as well for synchronized cardioversion at 30 joules.

Source: Tuite, P., & George, E. (2005). Biphasic defibrillation: Know your equipment. *Nursing* 2005, 35(3), 32ccl.

▲ CODEMASTER.

CARDIOVERSION ARRHYTHMIAS

▲ Atrial fibrillation with rapid ventricular response.

▲ Supraventricular tachycardia.

▲ Ventricular tachycardia with pulses.

▲ Apply paddles with firm pressure over conducting pads.

▲ Hands-free pads provide defibrillation and protect provider.

22. Give epinephrine 1 mg IV/IO during CPR; repeat every 3–5 minutes or give Vasopressin 40 units IV/IO in place of first or second dose of epinephrine.
23. Repeat steps 19, 20, and 21.
24. May administer amiodarone (300 mg IV/IO) once, or lidocaine (1–1.5 mg/kg) once, then 0.5–0.75 mg/kg IV/IO, maximum three doses, or magnesium (1–2 g IV/IO) for polymorphic VT (torsade de pointes).
25. Repeat steps 19–22.
26. For asystole or pulseless electrical activity (PEA), continue CPR for five cycles, administer vasopressors

EVIDENCE-BASED PRACTICE

Family Support During CPR

Family members should be offered the opportunity to be present during resuscitation efforts. Ideally a staff member should be assigned to support the family and answer questions.

Source: American Heart Association Guidelines CPR/ECC 2005: *Handbook of Emergency Cardiovascular Care*.

Clinical Alert

The most common cause of PEA (pulseless electrical activity) is hypovolemia. Other contributing factors include: hypoxia, hydrogen ion imbalance (acidemia), hypo or hyperkalemia, hypoglycemia, hypothermia, toxins, tamponade (cardiac), tension pneumothorax, thrombosis (MI, PE), and trauma.

- (see step 22). Consider treatable factors and correct (see Clinical Alert p 86).
27. Check the ECG for *shockable* rhythm, and repeat process starting with step 11 if present.
 28. Continue CPR throughout entire resuscitation process.
 29. Clean reusable equipment, discard used supplies, perform hand hygiene.

Three Phases of Cardiac Arrest

Electrical phase lasts about 5 minutes; early defibrillation is the priority intervention.

Hemodynamic phase lasts from 4 to 10 minutes; use of uninterrupted chest compressions is the priority intervention to maintain coronary perfusion (since the left heart is empty and the client is essentially in pulseless electrical activity [PEA]); use of AED can be harmful.

Metabolic phase uninterrupted chest compressions are vital to maintain coronary perfusion; medications and hypothermia may be used.

Source: Futterman, L., & Lemberg, L. (2005). Cardiopulmonary resuscitation review: Critical role of chest compressions. *American Journal of Critical Care*, 14(1), 81.

Administering Advanced Cardiac Life-Support Medications

Equipment

Client's medical record (note client's weight for drug dosage determination)

Emergency "crash" cart with medications (may be supplied in ampules, multiple dose vials, or "unit-of-use" containers [cartridge/needle units or cartridge/syringe units])

Preparation

1. Familiarize self with most commonly used medications, their action, usual dose, route and rate of administration, and side effects.

EVIDENCE-BASED PRACTICE

Induced hypothermia (32 to 34°C for 12 to 24 hours) might benefit comatose adult patients with ROSC after out of hospital arrest from a nonshockable rhythm, or cardiac arrest in hospital.

Source: 2010 AHA Guidelines for CPR and ECC. *Circulation* 2010; 122: S640-S656. part 8, p 15.

EVIDENCE-BASED PRACTICE

Vasopressors (epinephrine or vasopressin) may improve return of spontaneous circulation (ROSC), but there is insufficient evidence to suggest they improve survival to discharge.

Source: 2010 American Heart Association Guidelines for Cardiopulmonary Resuscitation and Emergency Cardiovascular Care Science. *Circulation* 2010, 122: S640–S656.

2. Review skill for Administration of Intravenous Medications (Chapter 28).
3. Client should be intubated and airway placement confirmed (see Respiratory Care, Chapter 26).
4. Establish IV access if not already present (intraosseous [IO] or bone access may be necessary in emergency situations).
5. Continue client cardiac monitoring.

Procedure

1. Prepare cartridge/syringe unit by removing caps from cartridge vial and injector.

▲ Remove caps from cartridge and injector.

2. Insert vial into injector, rotating clockwise until medication enters injector needle.
3. Remove protected needle or male Luer-Lok cover and gently press vial to initiate medication flow.
4. Swab IV port with antimicrobial swab and insert system for medication injection.
5. Administer emergency medications as ordered.

▲ Insert cartridge/vial into injector and rotate clockwise until medication enters needle.

▲ Protected needle or Luer-Lok system may be used for drug administration per IV tubing port.

TABLE 33-4 Advanced Cardiac Life Support Medications May Be Given IV or IO

Medication ^a	Dose	Indication
Vasopressin	40 U IV/IO one time only in place of 1st or 2nd dose of epinephrine	For VF/pulseless VT, asystole, pulseless electrical activity
Epinephrine	1 mg IV/IO/ET; repeat every 3–5 minutes during resuscitation	Same as above, symptomatic bradycardia not responsive to atropine
Amiodarone	300 mg IV/IO, then 150 mg, only once (dilute in 20–30 mL D ₅ W)	Recurrent VF/VT
Lidocaine	1–1.5 mg/kg IV/IO, then 0.5–0.75mg/kg IV in 5–10 min	ET dose is 2–4/mg/kg/F for V7 pulseless VT, stable VT
Procainamide	20 mg/min to 17 mg/kg max	Stable VT, PSVT
Magnesium sulfate	1–2 g diluted in 10 mL D ₅ W over 5–20 minutes IV/IO	Suspected hypomagnesemia or torsade de pointes (polymorphic VT)
Atropine	0.5 mg IV/IO or ET*; repeat every 3–5 min up to 3 mg	Symptomatic bradycardia
Adenosine	6 mg <i>rapid</i> push, then in 1 to 2 minutes give 12 mg; may repeat 12 mg after 1 to 2 minutes	Terminate narrow complex AV nodal reentrant supraventricular tachycardia AVNRT in stable client
Atenolol	5 mg slow IV (over 5 minutes); may repeat after 10 minutes	Control ventricular rate in supraventricular tachyarrhythmias (atrial fibrillation, atrial flutter, PSVT)
Diltiazem	15–20 mg (0.25 mg/kg) IV over 2 minutes; after 15 minutes may give 20–25 mg over 2 minutes	Same as above

1. Follow each drug administered IV with 20-mL normal saline bolus flush, then elevate the extremity 10–20 seconds.
2. CPR and shocks are continued when drugs are administered.

Assisting With Synchronized Cardioversion

Equipment

- Defibrillator monitor with ECG recorder set to SYNCHRONIZATION mode
- Paddles—anteroposterior or anterolateral or hands-free pads
- Conductive gel or conductive pads
- Emergency cart with medications and supplies

- Review precardioversion laboratory values (electrolytes, digoxin level, ABGs). **Rationale:** Electrolyte imbalance, particularly hypokalemia, or digitalis toxicity may increase risk of dysrhythmias after cardioversion.
- Check that client has been receiving anticoagulation therapy (Coumadin) for chronic atrial fibrillation.
- Withhold food, medications, and fluids for 6–12 hr before elective cardioversion.
- Obtain baseline 12-lead ECG, and label it “precardioversion.”

Preparation for Elective Cardioversion

- Review cardioversion orders and make sure consent form is signed. Check that equipment is functioning properly.

Synchronized Cardioversion

Synchronized cardioversion is used for elective conversion of hemodynamically stable atrial fibrillation or atrial flutter.

It is also used as emergency management for hemodynamically unstable tachyarrhythmias (narrow and wide QRS complex tachycardias with pulses).

Rhythms which may require emergency synchronized cardioversion are:

- Atrial fibrillation with rapid ventricular response
- Atrial flutter 2:1
- Paroxysmal supraventricular tachycardia with signs of instability (HR > 150, SBP ≤ 90 mmHg)
- Ventricular tachycardia with pulses

6. Obtain baseline vital signs and ECG rhythms.
7. Assess peripheral pulses and neurologic status.
8. Notify anesthesiologist and physician of readiness.
9. Place emergency cart in room.
10. Perform hand hygiene.

Procedure

1. Validate client's identity: Check Ident-A-Band and have client state name and birth date.
2. Remove any jewelry. ► **Rationale:** metal conducts electricity, burns could occur.
3. Remove transdermal medication patches.
4. Establish IV line, and administer fluids at "keep open" rate.
5. Administer oxygen if ordered.
6. Plug in defibrillator and turn power switch ON.
7. Turn **synchronizer** switch ON. ► **Rationale:** Shock delivery synchronized with QRS of ECG reduces possibility of inducing ventricular arrhythmias by the electrical shock being delivered on the T wave.
8. Test synchronization by pushing manual synchronization button.
9. Disconnect all electric equipment from client except ECG monitor and cardioverter.
10. Administer sedative as ordered by physician (anesthetist/anesthesiologist may do this).
11. Charge defibrillator to level specified by physician. Note that designated charge is reached.
12. Place client in supine position.
13. Make sure client's chest is dry.
14. Apply conductive gel to surface of paddles, or use "hands-free" defibrillator pads and place on client's chest.
 - a. Antero-lateral handheld paddles are placed as in defibrillation, one below the right clavicle and the other placed to the left of the cardiac apex (below and to the left of the nipple or at the 5th or 6th intercostal space at the midaxillary line).
 - b. Apex-posterior self-adhesive defibrillation pads are placed over the left precordium and posteriorly below the right or left scapula.

TABLE 33-5 Stepwise Energy Levels for Cardioversion

Cardioversion	Energy Level (J)*
Paroxysmal supraventricular tachycardia	50–100–200–300, then 360/J.
Atrial flutter	50–100–200–300 then 360/J.
Atrial fibrillation	200–300, then 360/J.
Unstable ventricular tachycardia (VT with pulses)	100 to 200 to 300 to 360/J.

*1 joule = 1 watt second

15. Observe ECG rhythm on monitor and start recording continuous printout using lead II to display a large R wave.
16. Discontinue oxygen. ► **Rationale:** To prevent combustion.
17. Ensure that synchronization indicator is superimposed on R wave of ECG.
18. Give command to "stand clear," and stand clear yourself.
19. The physician depresses discharge buttons on paddles and keeps them depressed until cardioversion countershock is delivered. The shock may not occur instantly, since machine waits until the next R wave in the ECG to discharge.
20. Observe postcardioversion rhythm.
21. Provide postcardioversion care.
 - a. Support airway and ventilation, and oxygenate as needed.
 - b. Obtain 12-lead ECG, and label it "postcardioversion."
 - c. Monitor heart rhythm continuously.
 - d. Evaluate vital signs, ECG, level of consciousness, peripheral pulses, and neurologic status, until stable, then routinely. ► **Rationale:** Thromboemboli to the brain, lungs, or systemic circulation may occur after cardioversion for atrial fibrillation; Coumadin therapy is continued indefinitely postcardioversion.
 - e. Keep client under observation for 12 to 24 hr. ► **Rationale:** Transient hypotension and minor dysrhythmias may occur.
22. Clean reusable equipment and discard used supplies.
23. Perform hand hygiene.

Clinical Alert

If repeat cardioversion is necessary, reset defibrillator to *synchronize* mode. Most defibrillators default back to unsynchronized mode (immediate shock).

Elective cardioversion is usually not done in an acute care setting because of staff time constraints. Client is sent to cardiovascular lab where personnel use "moderate sedation" for the procedure.

DOCUMENTATION for Cardiac Emergencies

Defibrillation

- Time of event and call for code
- Time chest compressions were started
- Client assessment before and after defibrillation
- Pre- and post-defibrillation ECG rhythm printout
- Number of defibrillation attempts and watt seconds (Joules) used
- Other resuscitative measures
- Time resuscitation discontinued
- Outcome of resuscitation
- Medications administered
- Record of responses and interventions (time and personnel) on Code Record
- Family support provided

Cardioversion

- Elective cardioversion client preparation completed
- Precardioversion rhythm and vital signs
- Name of anesthetist/anesthesiologist and physician performing elective cardioversion
- Number of cardioversion attempts
- Watt seconds for each attempt
- Postcardioversion rhythm with each attempt
- Postcardioversion problems, if any
- Medications administered
- Postcardioversion monitoring

Legal Alert

In *Odem v. State ex rel Dept of Health and Hospitals* (1999), evidence supported holding nurses negligent for improperly inactivating the client's cardiac and apnea monitors. Doctors issued orders to leave monitor alarms on at all times; no nurse heard a monitor alarm, and

post-death investigation indicated that the monitor alarm was not engaged. The electronic engineer from the monitor's manufacturer testified that the monitor was functional when he tested it after the incident. Had the monitor alarm sounded, the client might have lived.

CRITICAL THINKING Application

Expected Outcomes

Supplies and medications are readily available in an emergency situation.

Client's heart rhythm is restored to normal after defibrillation or synchronized cardioversion.

Unexpected Outcomes

For Emergency Cart

Equipment cannot be located promptly on cart.

Alternative Actions

- After resuscitation, suggest more logical placement of item (e.g., alphabetize or place with similar equipment).
- After resuscitation, practice mock codes to retrieve items and become more familiar with cart.

Equipment malfunctions.

- Replace malfunctioning equipment immediately.
- Obtain cart from the nearest unit.

For Defibrillation

Electric arc crosses client's chest upon shock discharge.

- Avoid excessive gel on paddles.
- Wipe off any conductive gel or perspiration between the paddle sites, and defibrillate again.
- Remove transdermal medication patches.

After defibrillation, rhythm changes to asystole or rhythm shows on monitor, but carotid pulse is absent (pulseless electrical activity).

- Call a code and start CPR.
- Administer IV fluids and oxygen.
- Assess for treatable contributing factors.
- Administer emergency medications as ordered.

For Cardioversion

Precardioversion laboratory findings reveal electrolyte imbalance, drug toxicity, or abnormal ABGs.

- Notify physician of findings.
- Reassure client that there is not a life-threatening problem. Procedure may be delayed or postponed.

Monitor shows asystole.

- Assess client for breathing and pulse.
- View a different ECG lead; increase amplitude of lead.
- Immediately institute CPR if indicated.
- Assist physician in advanced cardiac life-support measures.

Ventricular fibrillation develops after cardioversion.

- Call a code and proceed with defibrillation CPR process.

Mechanical Ventilation

Nursing Process Data

ASSESSMENT Data Base

- Assess client for presence of risk factors for acute respiratory distress syndrome: sepsis, massive trauma, massive fat embolism, aspiration pneumonia, and other disorders characterized by abnormal ventilation and interstitial pulmonary edema.
- Auscultate heart and lung sounds for baseline data.
- Assess vital signs and measure arterial blood gases and hemodynamic pressures if Swan–Ganz catheter is in place.
- Identify whether need for mechanical ventilation is present. Criteria for non-COPD clients:
 - Vital capacity is less than 15 mL/kg of body weight.
 - Negative inspiratory pressure is less than -25 cm H_2O .
 - PCO_2 is below 30 mmHg or above 50 mmHg.
 - Alveolar–arterial oxygen difference ($A-a \Delta PO_2$) is greater than 350 mmHg on 100% oxygen.
 - Pulmonary shunt is greater than 30%.
 - Dead space-tidal volume (V_D-V_T) ratio is greater than 60%.
 - PO_2 is less than 60 mmHg on an FIO_2 of 1.0 (100%).
- Observe for trend of respiratory values (trend is more important than isolated measurements).
- Assess client for indications for PEEP:
 - Inability to maintain arterial PO_2 of at least 70 mmHg on 50% oxygen during continuous mechanical ventilation.
 - Failure of other methods to reduce pulmonary shunt (e.g., treatment of cardiac failure or pneumonia).
 - Normovolemia (normal blood volume).
- Check physician's orders for ventilator mode and other specified settings.
- Assess client's readiness for ventilator weaning.
- Assess client's response to ventilator weaning.

PLANNING Objectives

- To provide or augment pulmonary function
- To promote gas exchange and maintain acid/base balance
- To prevent ventilator-associated pneumonia
- To wean the client from mechanical support to independent breathing as safely and quickly as possible

IMPLEMENTATION Procedures

- Alterations of Ventilation and Gas Exchange 1352
- Caring for the Mechanically Ventilated Client 1352
- Weaning the Mechanically Ventilated Client 1355

EVALUATION Expected Outcomes

- Mechanical ventilation maintains client's respiratory function.
- ABGs remain within an acceptable range during mechanical ventilation.
- Client does not develop ventilator associated pneumonia (VAP).
- Weaning to independent breathing is accomplished safely and as quickly as possible.

Critical Thinking Application 1357

- Expected Outcomes 1357
- Unexpected Outcomes 1357
- Alternative Actions 1357

Alterations of Ventilation and Gas Exchange

Adequate gas exchange in the lungs depends on the effective ventilation of air matched with the perfusion of blood to ventilated alveoli. The thickness and permeability of the alveolar membrane, the amount of surface area available for diffusion, and the pressure gradients are also factors that affect gas exchange. The pressure gradient is the difference between the partial pressures of PO_2 and PCO_2 in the alveolar air and the pulmonary capillary blood. The pressure gradients drive the inward diffusion of oxygen from alveolar air to the blood and the outward diffusion of carbon dioxide from the blood to the alveolar air for exhalation. These pressures are obtained by arterial blood gas testing.

Ventilation replenishes the supply of oxygen in the alveoli and removes the carbon dioxide released by the capillaries. If ventilation and perfusion are not matched, blood oxygenation is reduced, resulting in a right (heart) to left (heart) “shunt.” Right to left shunting is characterized by a low PO_2 (hypoxemia).

Ventilation–perfusion mismatch problems are usually the result of chronic conditions such as chronic obstructive pulmonary disease (COPD). They may also occur acutely due to perfusion failure (e.g., pulmonary embolism), ventilatory failure (e.g., drug overdose, pulmonary disease, sepsis), or pulmonary edema affecting diffusion.

Mechanical ventilation provides support for the work of breathing and ensures alveolar ventilation. This intervention, however, may require intubation of the client, interferes with normal airway defenses, and increases the risk of pulmonary injury and health-care associated infection. It is desirable to decrease the level of controlled ventilatory support as soon as possible to assist the client to extubation and the return to independent breathing. Newer techniques of ventilation allow weaning by titrating from high support to minimal support modes to facilitate the transition.

Clients (especially those with underlying disease) who require mechanical ventilation for even a day may develop “ventilator dependence.” All efforts focus on identifying and addressing the physiologic and psychological factors that delay successful weaning. This complex process requires the collaborative efforts of a skilled multidisciplinary team including physician, nurse, respiratory care practitioner, dietitian, and speech pathologist. Final clinical outcomes range from successful weaning to incomplete weaning (client remains on ventilatory support at home or in a subacute setting) or terminal weaning at the client’s or family’s request. Terminal weaning may be facilitated with a continuous infusion of morphine or a sedative to ease the client’s death.

Caring for the Mechanically Ventilated Client

Equipment

- Specific ventilator ordered (i.e., Puritan-Bennett 840, Servo 900C, Servo 300/300A, Siemens I, Dräger Evita)
- Handheld resuscitator bag connected to oxygen flowmeter
- Airway connector
- Sterile suction supplies
- Ventilator flow sheet
- Means for client communication

Preparation

1. Double-check the ventilator settings against those ordered by the physician.
2. Plug the machine in and turn it ON.
3. Familiarize yourself with location of alarm systems on the ventilator and turn on all alarm systems.
4. Validate that tube cuff inflation is appropriate with minimal occlusive volume or minimal leak (squeak heard at end inspiration) while auscultating over suprasternal notch.
5. Connect the ventilator tubing to client’s endotracheal tube or tracheostomy tube.

▲ Siemens 300I computerized mechanical ventilator.

EVIDENCE-BASED PRACTICE

Kinetic Rotation for Ventilatory Clients

This study examined the effect of kinetic systematic mechanical rotation of clients with 40° turns for 18 hr per day on pulmonary function and prevention of ventilator-associated pneumonia. Of the 255 client enrollees (137 in the control group who were manually turned side to supine to side every 2 hr and 118 in the kinetic therapy group), 21% of the kinetic therapy group could not tolerate bed rotation.

The study outcome supported benefits of kinetic therapy on pulmonary function and reduction of VAP, but no shorter duration of mechanical ventilation or hospitalization or improvement in survival.

The authors recommend kinetic therapy be used judiciously in clients who can tolerate it, especially neurologically depressed or sedated clients.

Source: Ahrens, T., Kollef, M., Stewart, J., & Shannon, W. (2004). Effect of kinetic therapy on pulmonary complications. *American Journal of Critical Care*, 13(5), 376–383.

Clinical Alert

Many client/ventilator systems include heat moisture filters that replace the need for external humidification of inspired gases. The use of these filters is only safe if pressure monitors are set properly so the machine can warn of impending heat moisture exchange filter occlusion.

EVIDENCE-BASED PRACTICE

Enteral Nutrition for Critically Ill Clients

While enteral nutrition is usually preferred over parenteral nutrition in critically ill clients, this study found that repeated interruptions of enteral tube feedings based on GI intolerance and elective withholding of feedings for procedures results in significant underfeeding in 68% of these mechanically ventilated clients. Thirty-eight percent of clients received less than half of their calculated daily energy requirements, 30% received adequate nutritional intake, and 1.7% were overfed due to additional kilocalories received from concomitant administration of propofol.

Source: O'Leary-Kelley, C. (2005). Nutritional adequacy in patients receiving mechanical ventilation who are fed enterally. *American Journal of Critical Care*, 14(3), 222.

Initial Ventilator Settings

- Tidal volume of 8–12 mL/kg (based on ideal body weight)

Note: Reduced volume (6 mL/kg) is indicated for clients with reduced lung compliance (e.g., ARDS) to prevent volutrauma.

- Respiratory rate of 10–15 per minute
- Inspiratory–expiratory (I:E) ratio 1:2. (I:E ratio should be less than 1:1 to prevent air trapping in the lungs.)
- Pressure limit 20% above peak airway pressures delivered.
- FiO_2 of 40%–100%.

Airway Pressure Modes

IPPB—Intermittent positive pressure breathing—inspiration by positive airway pressure; expiration is passive.

CVM/ACV—Invasive or noninvasive continuous mandatory ventilation—total support ventilation with set ventilation rate (e.g., 12) and set tidal volume (e.g., 750 mL). Client-initiated breaths receive set volume and if client does not initiate breath, set rate and volume are guaranteed (sometimes referred to as ACV, assist control ventilation).

SIMV—Synchronous intermittent mandatory ventilation—spontaneous ventilation intermittently augmented by positive pressure ventilation.

PEEP—Positive end-expiratory pressure—an expiratory airway pressure modality in which the airway pressure is maintained above atmospheric at the end of expiration. Some machines may have capability to vary the PEEP level according to a preset pattern. Stimulates surfactant production, increases FRC (functional residual capacity).

CPAP—Invasive or noninvasive continuous positive airway pressure—spontaneous ventilation with maintenance of airway pressures above atmospheric throughout the respiratory cycle.

BIPAP—Spontaneous breathing with maintenance of a bi-positive airway pressure: one set for positive inspiratory pressure and a lesser one set for positive expiratory pressure.

APRV (airway pressure release ventilation)—The ventilator maintains an inspiratory pressure throughout the inspiration time. A short pressure release at the end of the respiratory cycle allows airway pressure to return to zero for a short time.

PSV—Pressure support ventilation—in addition to other ventilator settings, 6–10 cm H₂O pressure support is provided to compensate for the added resistance imposed by artificial airways, making breathing easier; it also supports a larger tidal volume with less work of breathing. This is used as a major mode with pressure support level set to achieve optimal minute ventilation.

PCV (pressure control ventilation)—The ventilator minimizes the pressure used to deliver an acceptable tidal volume. Some machines measure the compliance of the client/ventilator interface and calculate the ideal acceptable minimum tidal volume using the least pressure necessary. The pressure control level is adjusted to some maximum number, then the machine electronically selects the appropriate tidal volume based on PCV value set and previously calculated compliance. This is also used as a major mode.

Procedure

1. Monitor client's heart rate and blood pressure until stable.
2. Obtain arterial blood gases 15 minutes after ventilation is established.

3. Monitor ventilator settings and delivered values: tidal volume, inspiratory pressure, peak pressure, rate, FIO₂, inspiratory–expiratory (I:E) ratio, ventilatory modes. Modern ventilators monitor these parameters continuously.
4. Ensure adequate heat and humidification of inspired gases.
5. Check humidifier fluid level every 8 hr and refill as necessary, if applicable.
6. Record intake, output, and daily weights.
7. Suspend ventilator tubing from an IV hook or support it on a pillow. ► **Rationale:** This reduces traction on the endotracheal or tracheostomy tube.
8. Change ventilator tubing if necessary, minimizing frequency of circuit opening. ► **Rationale:** Epidemiologic studies indicate that maintenance of a closed ventilatory/client interface is desirable.
9. Check vital signs every hour and auscultate lungs. ► **Rationale:** Positive pressure ventilation may decrease venous return and cardiac output.

NOTE: Continuous pulse oximetry facilitates constant assessment of clients receiving ventilatory assistance.

▲ Double-check all ventilator settings with physician's orders.

10. Observe and listen for possible cuff leaks around tracheostomy or endotracheal tubes.
11. If necessary, discard accumulated water in the ventilator tubing via inline closed circuit drain. ► **Rationale:** Opening circuit exposes client to environmental pathogens. Frequency of circuit opening should be minimized.
12. Provide client with call bell and method of communication, such as a “magic slate.”
13. If ordered, test the gastric fluid pH, and administer medication (H₂ antagonists) as ordered. ► **Rationale:** Upper GI bleed is frequently associated with mechanical ventilation, so gastric pH should be maintained above 5.

Clinical Alert

In clients with reduced lung compliance (e.g., ARDS), tidal volume may be reduced to 6 mL/kg to prevent volutrauma. This will result in hypercarbia (increased PCO₂) and reduced blood pH (7.2 lowest acceptable). Sedation and paralytic agents may be necessary to control ventilation in these clients.

14. Test the nasogastric fluid and stool for occult blood if ordered.
15. Assess lung compliance frequently. ► **Rationale:** Lung compliance falls before changes are evident in blood gas analysis or clinical manifestations. Compliance is determined by

$$\frac{V_t}{PIP - PEEP}$$

where V_t = tidal volume; PIP = peak inspiratory pressure; and PEEP = positive end-expiratory pressure.

16. Implement methods for stress reduction, such as careful explanation of procedures, pain management, administration of sedatives, or neuromuscular blocking agents, as indicated.

Clinical Alert

Paralytic agents have no effect on wakefulness or sensory perception, including perception of pain. With complete paralysis, pain might be manifested as increased heart rate, increased blood pressure, or sweating. Never assume that a client receiving a paralytic agent is asleep. Continually inform client about care, offer reassurance, and provide pain relief while the paralyzing effect of the drug persists.

Clinical Alert

The use of sedatives in mechanically ventilated clients prolongs its duration as well as length of hospitalization and ICU stay.

Clinical Alert

Some “smart care” machines allow CPAP and PS plus an individualized weaning process based on preset client parameters, including disease process. The machine gradually decreases the degree of support as long as the client remains in a breathing comfort zone. The machine then displays a message indicating it is appropriate to extubate the client.

Cultural Awareness

Touch button voice systems are available that allow ventilated English or non-English-speaking clients to tap a touch screen that delivers preprogrammed audible words, phrases, or symbols to hold two-way communication with staff.

17. Check that ventilator alarm parameters are set.
18. Maintain appropriate “sigh” delivery. ► **Rationale:** This extra volume breath assists in preventing atelectasis and stimulates surfactant production.

NOTE: Some newer ventilators do not have “sighs”—they periodically deliver a low-level “PEEP” period to achieve the same result.

19. Monitor client frequently to detect changes in status.

EVIDENCE-BASED NURSING PRACTICE

Delirium in Mechanically Ventilated Patients

This study validated sensitivity, specificity, and interrater reliability of an instrument (CAM-ICU) for detection of delirium in mechanically ventilated patients. Delirium occurred in 83.3% of mechanically ventilated patients, 40% of whom were in a neutral level of sedation (neither agitated nor overly sedated), while they were in the ICU.

Source: Ely, E. W., Inouye, S. K., Bernard, G. R., Gordon, S., Francis, J., May, L., ... Dittus, R. (2001, December). Delirium in mechanically ventilated patients. *Journal of the American Medical Association*, 286(21), 2703–2709.

Oral/Dental Care Strategies to Reduce Risk of VAP

Assess client’s teeth, lips, tongue, and check oral mucosa for ulcerations; look for signs of gingival disease daily (red, spongy smooth, and shiny gingiva may be diseased).

To remove dental plaque, use a soft bristle toothbrush with antibacterial toothpaste to brush all surfaces of the teeth, gums and tongue twice daily. Rinse with alcohol-free mouth rinse.

Note: Sponge toothettes do not remove plaque, a mass that grows by layering of bacteria on the surface of teeth and surrounding soft tissues and increases over time in the ICU setting. There is a link between increases in dental plaque and the development of VAP.

Use an oral swab with 1.5% hydrogen peroxide to cleanse the oral cavity and surrounding tissues and gums every 4 hr.

Provide suctioning of subglottic secretions continuously, or intermittently every 2 hr.

Apply moisturizer to oral mucosa and lips every 2–4 hr.

Source: Garcia, R., Jendresky, L., Colbert, L., Bailey, A., Zaman, M., & Majumder, M. (2009). Reducing ventilator-associated pneumonia through advanced oral-dental care: A 48-month study. *American Journal of Critical Care*, 18(6), 523–532.

Weaning the Mechanically Ventilated Client

Equipment

- Oxygen source
- T-piece adaptor or tracheostomy mask if ordered
- Suctioning equipment
- Arterial blood gas-sampling supplies
- Continuous pulse oximetry unit
- Stethoscope

Preparation

1. Validate order for weaning trial and assess client’s readiness.
 - Spontaneous tidal volume ≥ 7 mL/kg/ideal body weight (IBW)
 - Respiratory rate between 12 and 20 breaths/min
 - Minute ventilation (respiratory rate \times TV) ≥ 10 L/min

Vital signs stable (SBP ≥ 90) normal heart rate and rhythm

Vital capacity ≥ 10 mL/kg IBW

Negative inspiratory force is -20 cm H₂O or higher

ABGs: pH 7.35–7.5, PO₂ ≥ 60 mmHg on FIO₂ $\leq 40\%$ or SpO₂ 90%

Able to protect airway and responsive on minimal sedation

2. Note client’s work of breathing and use of accessory muscles.
3. Note current ECG pattern for baseline.
4. Explain weaning process to client. Reassure client that transition will be based on client’s responses.
 - **Rationale:** When client is included in weaning process and rationale for change, anxiety is lessened.

Reducing Risk of Ventilator Associated Pneumonia (VAP)

NOTE: Half of critically ill clients require mechanical ventilation. VAP occurs in 25% of clients who receive mechanical ventilation and is the leading cause of death from health-care associated infections.

Perform orotracheal rather than nasotracheal intubation.

Use dual lumen ET tubes (with dorsal lumen above the cuff) to allow continuous or intermittent suctioning of subglottic secretions. This decreases VAP by as much as 20%–40%.

(See Respiratory Care, chapter 26, CASSETT tube.)

Ensure secretions are cleared from above the tube cuff before deflating the cuff.

Use only sterile fluid to flush the reusable suction catheter of secretions.

Prevent gastric reflux and oropharyngeal secretions aspiration by keeping the head of bed elevated 30–45 degrees.

Routinely verify placement of feeding tubes.

Change ventilator circuit only when visibly soiled or malfunctioning.

Drain tubing condensation away from the client.

Prevent or modulate oropharyngeal colonization with implementation of a comprehensive oral/dental hygiene program (see Box: Oral/Dental Care Strategies).

Don gloves upon entering the client's room.

Perform hand hygiene before and after putting on gloves, before and after contact with mucous membranes, respiratory secretions, or before and after contact with any respiratory device.

Use personal protective equipment as indicated.

Optimize sedation, interrupt it daily, and promote early mobilization (e.g., sitting on side of bed).

Source: Adapted from CDC Guidelines for preventing health-care associated pneumonia, 2004.

Source: Grap, M. (2009). Not-so-trivial pursuit: Mechanical ventilation risk reduction. *American Journal of Critical Care*, 18(4), 299–309.

5. Suction client. Hyperoxygenate client's lungs with 100% oxygen before and after suctioning.
6. Maintain endotracheal or tracheostomy cuff at minimal occlusive pressure (minimal leak) while mechanically ventilated.

7. Establish continuous oximetry. ► **Rationale:** Client's oxygen status should be continually assessed.

Procedure

1. Elevate head of the bed to facilitate client's diaphragmatic excursion.
2. If physician orders endotracheal tube cuff deflated during weaning, suction secretions that have accumulated above the cuff as follows:
 - a. Provide positive pressure to end of tube with a handheld-resuscitation bag and 100% oxygen.
 - b. Place tip of suction catheter in the posterior pharynx.
 - c. Deflate cuff and apply suction to catheter.
 - **Rationale:** Positive pressure blows the secretions into the pharynx, where they can be suctioned out.

NOTE: Steps a–c are not necessary if a CASSETT is in place.

- d. Hyperoxygenate lungs with 100% oxygen for three to five breaths.
3. If ordered, connect T-piece to wide-bore oxygen tubing leading to the gas source.
4. Set oxygen concentration as ordered by physician, usually 10% *higher* than the ventilator FIO₂ the client has been receiving.
5. If appropriate remove ventilator tubing from airway and connect T-piece to client's airway.
6. Cover end of ventilator tubing with sterile gauze.
7. Observe for vital sign changes, apprehension, diaphoresis, and dysrhythmias. ► **Rationale:** A mild increase in blood pressure, pulse, and respiratory rate is normal. Mild-to-moderate anxiety is also normal.

Clinical Alert

Clustering nighttime care activities to allow clients undisturbed sleep periods may facilitate the weaning process.

8. Measure arterial blood gases 1 hr after initiating weaning if client tolerates.
9. Proceed with weaning procedure as ordered.
 - **Rationale:** Gradual weaning may be necessary.
10. If client tolerates no ventilator support (other than PSV), extubate client. (See Chapter 26.)
11. After weaning, continue to monitor vital signs, vital capacity, SpO₂, inspiratory pressure, blood gases, and subjective response.

DOCUMENTATION for Mechanical Ventilation

- Type of ventilator or other device used
- Ventilator or device settings; modes used in weaning process
- Time initiated
- Any problems and actions taken
- Suctioning (i.e., frequency, amount, and character of secretions)
- Indication that client is making spontaneous breathing efforts or is not triggering the machine
- Endotracheal tube location and minimal leak established
- Arterial blood gas and other lab values
- Vital signs and hemodynamic values
- Findings on pulmonary and cardiac assessment

- Ventilator modes utilized in weaning transition process
- Dental/oral care (type, frequency)
- HOB degree elevation
- Medications administered

CRITICAL THINKING Application

Expected Outcomes

- Mechanical ventilation maintains client's respiratory function.
- ABGs remain within an acceptable range during mechanical ventilation.

Unexpected Outcomes

Client develops signs of decreased pulmonary compliance (e.g., ARDS).

Client needs to be transported for diagnostic testing.

High pressure alarm is activated.

Low pressure alarm is activated.

Arterial blood gases (ABGs) are not maintained within normal range.

Po₂ is not maintained at 80–100 mmHg.

Cardiac output decreases significantly.

- Client does not develop ventilator-associated pneumonia.
- Weaning to independent breathing is accomplished safely and as quickly as possible.

Alternative Actions

- Check for signs of fluid in lungs (x-ray, increase in PAWP, crackles on auscultation, hypoxemia).
- Decrease the tidal volume being delivered.
- Suction client to maintain a patent airway.
- Increase the level of PEEP to prevent alveolar closure.
- Consider prone positioning.
- Start oxygen flow through handheld ventilating device.
- Attach expiratory resistance, for example PEEP.
- Disconnect ventilator tubing from airway at end of inspiration.
- Attach handheld ventilator to airway during expiration.
- Watch chest, and provide breaths with client's inspirations or at rate of 10–12/min.
- Turn and deep breathe or sigh client several times an hour to reopen atelectatic alveoli.
- Check for obstructions in tubing and take corrective measures.
- Suction client for possible mucous obstruction of airway.
- Check for disconnected tubing or loose connections, and tighten them if present.
- Check client for artificial airway displacement and provide emergency measures if indicated.
- Deflate and reinflate the airway cuff to minimal occlusive pressure to adjust a possible cuff leak.
- If unable to identify and relieve cause immediately, disconnect ventilator tubing, hand ventilate client, and summon help.
- Notify physician of grossly abnormal ABGs, and obtain order for alteration in ventilator settings (i.e., increased percentage of oxygen, decreased tidal volume, addition of "dead space").
- Maintain mechanical ventilation. Do not attempt to wean or extubate client.
- Suction client as needed to maintain airway patency.
- Continue delivery of PEEP as ordered. If not effective, notify MD.
- Do not attempt to wean client off PEEP until desired parameters are obtained.
- Anticipate that client may have difficulty adjusting to increased intrathoracic pressure during weaning process.
- Decrease PEEP and notify physician for weaning adjustment.

Weaning attempt is unsuccessful.

- Continue use of ventilator.
- Cluster nighttime care activities to allow uninterrupted sleep.
- If client is extubated, consider noninvasive ventilation (CPAP).
- Recruit skilled multidisciplinary team to identify and address physiologic and psychological factors that interfere with weaning success.

Decreased level of consciousness, dyspnea, severe anxiety, or fatigue occurs during weaning process.

- Note client's SpO₂ (anxiety may be due to hypoxemia).
- Place client on supportive ventilation.
- Provide thorough explanation, and increase reassurance.
- Evaluate present use of sedatives or narcotic agents administered.

Client develops unstable vital signs.

- Place client back on more supportive ventilator mode.
- Monitor vital signs more frequently, and obtain blood gases to determine oxygen concentration.
- Increase FIO₂.

Client develops ventilator-associated pneumonia.

- Use a continuous aspiration subglottic secretion ET tube.
- Use closed in-line system for suctioning.
- Maintain HOB elevation 30–45° to prevent gastric reflux aspiration.
- Discontinue mechanical ventilation as soon as possible.
- Change the ventilator circuit only if soiled or malfunctioning.
- Perform hand hygiene before and after contact with mucous membranes, secretions, contaminated objects.
- Drain circuitry condensate away from the client.
- Implement meticulous oral and oropharyngeal hygiene strategies.

GERONTOLOGIC Considerations

Elderly Clients in the Critical Care Unit Require More Intensive Observation and Consideration

- Aging is normally accompanied by a silent physiologic decline and diminished reserve in all body systems. These changes are not pathologic, but do make the elderly less adaptable to stress and illness. The elderly have a greater prevalence of chronic conditions that make them vulnerable to acute exacerbations. Over half of critical care

clients are over age 65. Hospitalization is almost twice as long as that for clients under age 65 and survival is 81% compared with 98% in younger clients. However, quality of life after discharge from a critical care unit is not age-related.

- Refer to previous chapters for organ-system changes and other functional alterations as well as socioeconomic and lifestyle changes that affect care of the elderly client.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- All personnel in the critical care setting must know how to quickly summon assistance and locate and use emergency/resuscitation equipment.
- In advanced care settings, the RN simultaneously assesses, analyzes, makes decisions, intervenes, and evaluates clients on a continual basis. Complexities of

care and unpredictability of outcomes necessitate *intense* ongoing client monitoring and evaluation and personal continuing education. Detection and interpretation of subtle areas of change in the client's status require the knowledge and skill of the professional nurse.

- The RN collaborates with the physician and respiratory care practitioner for ventilator settings.
- It is the responsibility of nursing faculty to ensure that students participating in client care (in any setting) are prepared to do so. Likewise, it is the duty of the student to refuse to perform a function he or she is not qualified or competent to perform.

- The nurse should not assume care for any client who requires care beyond the caregiver's expertise.
- Many agencies provide emergency care protocols or standing orders of action responses to specified changes in client status. The professional nurse must be familiar with conditions for which the nurse is delegated medical care decisions guided by such protocols.
- The CNA/UAP must know to leave arterial catheter site uncovered for easy observation.
- The CNA/UAP must not move tubing drainage receptacles (e.g., Pleur-evac) without supervision.
- The CNA/UAP must understand that IVs, drainage systems, and ventilator circuits and systems are closed and must be able to give care without disrupting system integrity or disconnecting components for the convenience of care (e.g., as in changing the client's gown or position).
- The UAP has a limited role in the care of clients who require invasive monitoring. They can offer valued assistance in moving/positioning clients and providing personal hygiene and comfort measures under the direction of the professional nurse.
- The UAP assists the client, preserving an interface between technology and reality, by providing a human dimension of tactile presence while providing basic physical care for clients requiring sophisticated technological monitoring. UAP links to the client assist all caregivers in their attempts to minimize client's feelings of alienation.

Communication Matrix

Although certain tasks may be delegated, the CNA/UAP also can provide vital data to the professional nurse by immediately *reporting*:

- Disconnected systems, loose electrodes, tubing leaks, wet/soiled dressings.
- Subjective or objective change in the client's status (e.g., pain, respiratory distress, acute change in cognition).
- Equipment alarms (e.g., ventilator alarms).
- Near-empty infusion bags.
- Near-full collection devices.
- Collaboration with an interdisciplinary team helps to support client's weaning from mechanical ventilation.

CRITICAL THINKING Strategies

Scenario 1

Mr. Jones has a history of COPD and heart failure and has been admitted to your unit with a diagnosis of acute respiratory failure. He has the following arterial blood gas values: pH 7.2, Pco₂ 66 mmHg, HCO₃ 25 mEq, and Po₂ 49 mmHg. He is intubated and receiving mechanical ventilation to support his breathing and improve gas exchange and is being sedated with Versed.

On the third day of hospitalization, he is being weaned from mechanical ventilation, but attempts are unsuccessful due to difficulty breathing and development of pulmonary edema.

1. How does mechanical ventilation differ from the normal physiologic process of breathing?
2. How will resultant changes in intrathoracic pressure affect venous return and cardiac work?
3. What measures should be employed to help achieve successful weaning and extubation in this client?

Scenario 2

Mr. Hooper has been admitted to the coronary care unit with the diagnosis of anterior septal myocardial infarction

with lateral ischemia and potential for infarct extension. He is being monitored by a balloon-tipped, flow-directed catheter for hemodynamic response to therapy. Myocardial infarction (tissue necrosis) results from an imbalance between heart work (demand for oxygen) and coronary supply of oxygen.

Mr. Hooper's hemodynamic measures include: cardiac index 1.8 (low), blood pressure 94/74, mean arterial pressure (MAP) 80 (normal), stroke volume 21 mL (low), pulmonary artery wedge pressure (PAWP) 24 (elevated), heart rate 110, systemic vascular resistance increased.

1. Explain the relationship between "heart work" and need for oxygen.
2. Discuss the parameters that can be monitored with the balloon-tipped catheter.
3. Identify two drugs that could be used to decrease "heart work" and nursing measures that would enhance their effectiveness.

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. In the multilumen balloon-tipped flow-directed catheter, the distal lumen is used to
 1. Measure cardiac output.
 2. Measure pulmonary artery pressure.
 3. Inject solutions.
 4. Measure central venous pressure.
2. The client's phlebostatic axis is used for the transducer level in order to obtain accurate monitoring. The phlebostatic axis is determined by joining lines at the _____.

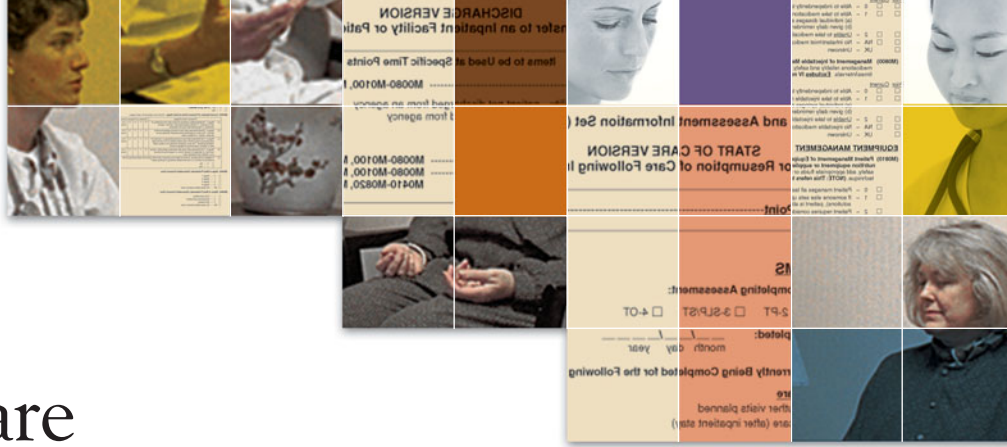

Select all that apply.

1. Midaxilla horizontally.
 2. Fourth intercostal space horizontally.
 3. Mid-anterior/posterior chest horizontally.
 4. Manubrium horizontally.
 5. Anterior axillary fold vertically.
 6. Mid-anterior/posterior chest vertically.
 7. Fourth intercostal space vertically.
3. Which of the following statements is true regarding arterial blood pressure monitoring?
 1. Measures are less accurate, but continuous, therefore more convenient.
 2. It allows intermittent sampling of venous blood.
 3. It may interfere with distal perfusion of the extremity.
 4. It can be used for calculating the heart rate.
 4. Rationale for use of the blood conservatory system for arterial blood sampling is that it
 1. Eliminates the need for blood wasting.
 2. Eliminates the need to open the tubing system.
 3. Eliminates the need to disengage alarms.
 4. Is less time-consuming than standard sampling.
 5. After successful cardioversion for atrial fibrillation, the client must continue
 1. Antiarrhythmic therapy.
 2. Anticoagulant therapy.

3. Pacemaker interrogation (monitoring).
 4. Monthly cardioversion.
6. Lethal cardiac rhythms requiring defibrillation include _____.

Select all that apply.

1. Pulseless ventricular tachycardia.
 2. Unstable ventricular tachycardia.
 3. Ventricular fibrillation.
 4. Atrial fibrillation with ventricular response (rate >150).
 5. Asystole.
 6. Pulseless electrical activity.
7. The most common cause of pulseless electrical activity is
 1. Peripheral vascular disease.
 2. Hyperkalemia.
 3. Hypovolemia.
 4. Heart failure.
 8. Which of the following is the most supportive of all the airway pressure modes used in mechanical ventilation?
 1. PEEP (positive end expiratory pressure).
 2. SIMV (synchronous intermittent mandatory ventilation).
 3. PS (pressure support).
 4. CMV (continuous mandatory ventilation).
 9. Of the following statements, the best rationale for the use of paralytic agents in the mechanically ventilated client is that they
 1. Allow the client to sleep.
 2. Eliminate the need for restraints.
 3. Allow ventilator-patient synchrony.
 4. Reduce pain perception.
 10. The biggest cause of ventilator associated pneumonia is
 1. Aspiration of subglottic secretions.
 2. Accumulation of condensation in the tubing circuit.
 3. Saline injection into the airway before suctioning.
 4. Immobilization and inability to turn the client.

End-of-Life Care

LEARNING OBJECTIVES

1. Discuss the stages of the grief process.
2. State the main characteristics observed in a person experiencing grief.
3. Identify the factors that influence the outcome of the grieving process.
4. Explain three assessment parameters for observing psychological and somatic symptoms that accompany the grief process.
5. Describe the stages of dying outlined by Elisabeth Kübler-Ross.
6. Discuss at least two nursing interventions for each stage of grief.
7. Explain what is meant by providing emotional care for the dying client.
8. Discuss at least four nursing interventions that assist the client during the end-of-life process.
9. Describe the three-step Analgesic Ladder for Pain Control for the Dying Client.
10. Describe the steps in providing post-mortem care.

TERMINOLOGY

Adjuvant analgesic drugs enhance the analgesic efficacy of opioids; treat recurrent symptoms that exacerbate pain and provide independent analgesic effects.

Agitation excessive restlessness; increased mental and physical activity.

Anger a feeling of extreme displeasure, hostility, indignation, or exasperation toward someone or something.

Anorexia loss of appetite occurring from a variety of possible reasons.

Anxiety a troubled or apprehensive feeling; experiencing a sense of dread or fear.

Cope to contend with, strive, or handle.

Corneal reflex closure of eyelids resulting from direct corneal irritation or touch.

Counseling giving assistance to or guidance.

Crisis a crucial point or situation in the course of life; turning point.

Denial refusal to grant the truth of a statement or allegation.

Depression being dispirited, saddened; low in mood.

Empathy objective awareness of an insight into the feelings, emotions, and behavior of another person.

Esteem regard, respect.

Fear feeling of fright or dread related to a specific source (e.g., fear of pain or dying).

Grief intense mental anguish, deep remorse, sorrow.

Homeostasis an internal state of equilibrium or balance.

Hospice a multidisciplinary approach that focuses on client care during the last phase of life.

Idealization to regard as ideal; to make or regard someone or something as perfect.

Insomnia inability to sleep; difficulty with sleeping.

Loss the state of being deprived of or being without something that one has had, for example, the loss of a spouse or friend.

Opioids drugs such as morphine, methadone, and Numorphan, used to treat severe pain.

Pain an unpleasant sensory and emotional experience arising from actual or potential tissue damage or described in terms of such damage; whatever the experiencing person says it is, existing whenever he or she says it does.

Palliative Care client and family-centered care that optimizes quality of life by anticipating, preventing, and treating suffering throughout the continuum of illness, involving physical, intellectual, emotional, social, and spiritual needs and facilitating patient autonomy, access to information, and choice.

Psychosomatic pertaining to phenomena that are both physiologic and psychologic in origin.

Quality of Life (QOL) in the context of advanced, progressive, incurable illness, the subjective experience of an individual living with the interpersonal psychologic and existential or spiritual challenges that accompany the process of physical and functional decline and the knowledge of impending demise. A person's QOL can range from suffering associated with physical distress and/or a sense of impending disintegration to the completion of developmental work and the mastery of developmental landmarks.

Resolution the state of having made a firm determination; a course decided on.

Restitution a return to a former status.

Somatic referring to the body.

Stress a physically or emotionally disruptive or disquieting influence.

Suffering to feel pain or distress; includes fear of or actual physical distress, fear of dying, changing self-perceptions, relationship concerns, the need to find meaning in any given life experience, and past experiences of witnessing another person's distress.

Therapeutic having medicinal or healing properties.

Withdrawal to pull back or away.

LOSS AND GRIEVING

Loss is part of the experience of dying, both for the individual as well as for family members and significant others. Within the dying experience, several losses can occur including loss of health, possible loss of body parts through surgery or an accident, loss of cognitive functioning. The individual may be unable to participate in religious activities or rituals that give meaning to life and contribute to the individual's spiritual well-being. The ability to work and provide financially for self and others may lead to impoverishment and financial difficulties. In addition, the person may experience a loss of control in decision-making.

Grief is an emotion experienced in relation to loss; it can also be viewed as a behavioral response to death and dying. Human beings experience loss as the emotion of grief and must

withdraw from the painful stimulus to recuperate. Emotions allow us to experience our environment—they are the means of cognition. When we are grieving, we experience the emotion of grief; this experience is accompanied by a definite syndrome with somatic and psychologic symptoms.

Stages of Grief

George Engle, in a classic article in the *American Journal of Nursing*, 1964, describes progression of the grief process in stages. These stages may occur in order, or an individual may skip a stage, become locked in a particular stage, or even return to an earlier stage already worked through.

The first stage is *shock and disbelief*, denial and numbness. The first response on learning of a death is shock and a refusal to accept or comprehend the fact. This reaction is followed by

a stunned, numb feeling and does not allow the person to acknowledge the reality of death. This initial phase is characterized by attempts to protect oneself against severe stress/distress by blocking recognition of the death.

Developing awareness is the second stage. Within minutes or hours the individual becomes acutely and increasingly aware of the anguish of loss. Anger may be present during this time and may be directed toward persons or circumstances held to be responsible for the death. Behavior that frequently accompanies this stage is crying and a regression to a more helpless and childlike state. The crying and regression appear to acknowledge the loss, indicating that conscious awareness is now present.

The third stage is *restitution*, in which the various rituals of the culture, such as the funeral, attire, wake, particular folkways, and mores, help to initiate the recovery process. These rituals serve the function of emphasizing the reality of death, and the very act of experiencing them assists the mourner to face the loss.

As the reality of death becomes accepted, the *resolution* of the loss begins. This stage involves a number of steps. First, the mourner attempts to deal with the painful void created by the loss of a loved one. At this time the thoughts of the mourner are occupied almost exclusively with the deceased. Then the mourner becomes more aware of his or her own body and bodily sensations. Finally, the mourner begins to talk about the dead person, recalling the dead person's attributes and personality and reminiscing about the memories they shared. Resolving the loss is a long and painful phase that continues until the mourner remembers the positive aspects of the dead person.

The next stage that is frequently experienced is that of *idealization*. All hostile and negative feelings toward the deceased are repressed. As the process proceeds, two important changes are taking place: The recurring thoughts about the dead person bring a distinct image of the loss to mind and these memories serve to bring out the more positive aspects of the lost relationship. At the same time the grieving individual begins to assume certain admired qualities of the dead person through the mechanisms of identification or incorporation. The mourner may begin to dress, speak, or develop mannerisms or beliefs similar to the person who was lost. Often, many months are required for this process to be experienced, and as it dissipates, the mourner's preoccupation with the dead person

lessens. It may be at this point that the person begins to reinvest intimate feelings toward other relationships.

The mourning process usually takes a year or more. The clearest evidence of healing is the ability to remember the deceased comfortably and realistically, with both the pleasures and disappointments of the relationship. At this stage the obsession with the loss is ended and the person accepts the responsibility of living his or her own life.

Each individual who experiences loss moves through at least some of these stages as he or she attempts to cope with loss. The stages of grief are the means human beings have of moving through the loss to resolution.

Elisabeth Kübler-Ross first introduced the five stages of dying in her 1969 book, *On Death and Dying*. It described in five discrete stages a process by which people deal with grief and loss, especially when diagnosed with a terminal illness or catastrophic event. Kübler-Ross originally applied these stages to people suffering from terminal illness and later to other forms of emotional trauma or significant life events, such as the death of a loved one, divorce, injury, infertility, or change in financial status. The stages do not necessarily come in the same order, nor are all steps experienced by all individuals. Often, people will experience several stages, going between two or more stages, returning to one or more several times before working through the stages.

The first stage, as Kübler-Ross views this process, is that of denial. The denial may be partial or complete and may occur not only during the first stages of illness or confrontation, but also later on from time to time. This initial denial is usually a temporary defense and is used as a buffer until such time as the person is able to collect himself or herself, mobilize defenses, and face the inevitability of loss or death.

The second stage is often anger. The person feels anger and questions why this is happening to them. This emotion may be directed toward persons in the environment or even projected into the environment at random. Kübler-Ross discusses this reaction and the difficulty in handling it for those close to the person by explaining that we should put ourselves in the client's position and consider how we might feel intense anger at having our life interrupted abruptly, or at experiencing this loss.

The third stage is *bargaining*. The person attempts to strike a bargain for more time to live or more time to be without pain in return for doing something for God. Often during this stage the person turns or returns to religion.

Depression is the fourth stage. Usually, when people have completed the stages of denial, anger, and bargaining, they move into depression. Kübler-Ross writes about two kinds of depression. One is preparatory depression: this is a tool for dealing with the impending loss. The second type is reactive depression. In this form of depression, the person is reacting against the impending loss of life and grieves for himself or herself.

The final stage of grieving is that of *acceptance*. This occurs when the person has worked through the previous stages and accepts his or her own inevitable death or loss. With full acceptance of impending death comes the preparation for it; however, even with acceptance, hope is still present and needs to be supported realistically.

Stages of Grief

- Shock and disbelief
- Developing awareness
- Restitution
- Resolution
- Idealization
- Denial
- Anger
- Bargaining
- Depression
- Acceptance

According to George Engle

According to Elisabeth Kübler-Ross

Many factors influence how individuals, at the end of life, accept death. Personal values and beliefs about life; views of personal successes, both financial and emotional; the way they look physically during the dying process; their family and friends and their families' attitudes and reactions; their past experiences in coping with difficult or traumatic situations; and, finally, the healthcare staff who are caring for them during this process—all affect an individual's attitude toward dying.

HOSPICE AND PALLIATIVE CARE

The philosophy of hospice and palliative care is based on the belief that every person has the right to die pain-free and with dignity, and that the families will receive the necessary support to ensure this happens. The word *hospice* comes from the Latin word *hospitium*, which was originally used to describe a place of shelter for weary and sick travelers. The modern hospice movements began in the 1960s by Dr. Cicely Saunders, a British physician. The first hospice in the United States was established in New Haven, Connecticut, in 1974. The National Hospice & Palliative Care Organization (NHPCO) was founded in 1978 as the National Hospice Organization and added palliative care in February 2000. Today there are more than 4,700 hospice programs with nearly 1.4 million Medicare-enrolled people cared for in 2007 alone. Eighty percent of hospice care is provided in the client's or family member's home and in nursing homes.

Hospice focuses on caring, not curing. Hospice is not a place, but a concept of care. Hospice care addresses the needs and opportunities during the last phase of life utilizing a multidisciplinary approach that focuses on the individual's physical symptoms and the emotional and spiritual concerns of the client and his or her family. Hospice care involves a multidisciplinary team collaboration among nurses, doctors, social workers, pastoral care, family, and others. The team works together to develop a plan of care and to provide services that will enhance the quality of life and provide support for the individual and family during the terminal phases of the illness and the bereavement period.

Hospice supports the philosophy that death is an integral part of the life cycle and that intensive palliative care focuses on pain relief, comfort, and enhanced quality of life as

Patient-Centered Focus of Hospice Care

"As sickness progresses toward death, measures to minimize suffering should be intensified. Dying patients require palliative care of an intensity that rivals even that of curative efforts even though aggressive curative techniques are no longer indicated. Professionals and families are still called upon to use intensive measures, take extreme responsibility, and provide extraordinary sensitivity and heroic compassion."

Hospice and Palliative Care Information

The National Hospice and Palliative Care Organization

1731 King St.
Suite 100
Alexandria, VA 22314
(703) 837-5000
www.nhpco.org

Nonprofit membership organization representing hospice and palliative care programs and professionals in the United States.

Hospice Foundation of America

1710 Rhode Island Ave. NW
Suite 400
Washington, D.C. 20036
www.hospicefoundation.org

Provides programs for healthcare professionals and the public who cope either personally or professionally with terminal illness, death, and the process of grief.

Hospice Net

401 Bowling Ave.
Suite 51
Nashville, TN 37305-5124
www.hospicenet.org

Provides information and support to patients and families facing life-threatening illness.

National Palliative Care Research Center

Brookdale Department of Geriatrics & Adult Development
Box 1070 Mount Sinai School of Medicine
1 Gustave L. Levy Place
New York, NY 10029
www.npcrc.org
(212) 241-7447

NPCRC is a national initiative committed to stimulating, developing, and funding palliative care research directed at improving care for patients with serious illness and their families.

Children's Hospice International

1101 King St.
Suite 360
Alexandria, VA 22314
(800)-2-4-CHILD
www.chionline.org

Nonprofit organization to provide a network of support and care for children with life-threatening conditions and their families.

appropriate goals for those at the end of life. Hospice care clients include those with AIDS and amyotrophic lateral sclerosis (ALS) or children with cardiac anomalies or other congenital conditions who have a life expectancy of 6 months. Hospice can offer any treatment necessary to

relieve suffering and allow a client to die peacefully and comfortably. Hospice neither speeds up nor slows down the dying process. Hospice believes that death is an integral part of the life cycle and that intensive palliative care focuses on pain relief, comfort, and enhanced quality of life as appropriate goals for those at the end of life.

Palliative care is central to the comprehensive treatment of serious or life-threatening illnesses. Palliative care differs from hospice care in that it is appropriate at any point on the illness continuum. The client may receive palliative care at the same time they receive treatments that are meant to improve their health. It does not depend on whether the condition can be cured or not. The purpose of palliative care is to provide relief from distressing symptoms such as pain, shortness of breath, fatigue, constipation, loss of appetite, nausea, and many others. The expected outcome of palliative care is the prevention of suffering and improved quality of life.

Clients in hospice always receive palliative care, but hospice focuses on the final months of life. To qualify for hospice programs, clients must no longer be receiving treatments to cure their illness. Most hospice care is provided in the home; however, there are hospice units in hospitals and clinic sites. The care does not vary from site to site.

CORE PRINCIPLES FOR END-OF-LIFE CARE

The Joint Commission and a significant number of specialty medical societies have endorsed, modified, or adopted a consistent set of Core Principles for End-of-Life Care. The overall philosophy was accepted by most societies, but each one amended or expanded certain issues that directly affect their practice.

The Core Principles for End-of-Life-Care, clinical policies and professional practice guidelines for end-of-life care, should:

1. Respect the dignity of both patient and caregivers.
2. Be sensitive to and respectful of the patient's and family's wishes.
3. Use the most appropriate measures that are consistent with patient choices.
4. Encompass alleviation of pain and other physical symptoms.
5. Assess and manage psychological, social, and spiritual/religious problems.
6. Offer continuity; the patient should be cared for, if so desired, by his/her primary care and specialist providers.
7. Provide access to any therapy that may realistically be expected to improve the patient's quality of life, including alternative or nontraditional treatments.
8. Provide access to palliative care and hospice care.
9. Respect the right to refuse treatment.
10. Respect the physician's professional responsibility to discontinue some treatments when appropriate, with consideration for both patient and family preferences.

11. Promote clinical and evidence-based research on providing care at the end of life.

Source: Principles for Care of Patients at the End of Life: An Emerging Consensus among the Specialties of Medicine, Castle and Foley, December 1999. Milbank Memorial Fund.

SYMPTOM MANAGEMENT

Management of debilitating symptoms has improved in recent years as a result of clinical research and new pharmacologic and behavioral therapies. Individuals who are dying experience a wide variety of symptoms, including pain, nausea, fatigue, constipation, or diarrhea. Pain and pain control has been identified as the primary concern of clients as they approach the end of life. Inadequate assessment of pain and poor pain control continue to be issues, even though much research on these topics has been done.

Assessment of pain in the dying client relies on the evaluation of level of consciousness and awareness, breathing pattern, and hemodynamics. A method to determine the amount of pain a client has is electroencephalographic signals that assess level of consciousness. This procedure has been used as an adjunctive monitor even though it is not considered an end-of-life technique. Invasive technology and monitoring are usually discontinued during this stage.

Through routine assessments, planning of care, and administering the appropriate pharmacologic interventions, the nurse plays a critical role in the management of symptoms for clients receiving hospice and palliative care.

The World Health Organization (WHO) developed a three-step "ladder" that outlines principles of analgesic selection and titration as well as adjuvant drugs that support the effect of the analgesics or counteract adverse side effects. Each step in the ladder defines the type of pain and analgesic most effective for that level of pain. (See Chapter 16, Pain Management.)

In some clients, the pain becomes so severe that even aggressive titration of standard drugs is not sufficient to control the pain. In these cases, sedation should be considered. Sedation for end-of-life clients is considered a comfort measure when there is intractable pain and other symptoms indicate death is near. When sedation is used in this manner, the client usually loses consciousness. Family members, as well as the client, must be informed of this change in client status before sedation is started.

CULTURAL AWARENESS

Cross-Cultural Issues at the End of Life

Kagawa-Singer and Blackhall, in the article "Negotiating Cross-Cultural Issues at the End of Life," state that culture is an important part of how everyone understands their world and how this impacts their decisions, especially on healthcare issues. This includes healthcare professionals as well. Culture influences the way people make meaning out of illness and dying; therefore, it also influences how they utilize the medical community at the end of life. Each individual has a perspective that is also

influenced by factors such as personal psychology, gender, and life experiences. There is a wide variation of beliefs and behaviors within any ethnic population. This leads us to realize that each client needs to be treated individually. Healthcare professionals must not influence clients with their own beliefs or cultures. Failure to take the client's cultural background seriously means we fail to understand the values held by the client.

Lack of cultural sensitivity and skills can lead to inappropriate clinical outcomes and poor interaction with clients and families at a very crucial point in their end-of-life process. Addressing and respecting cultural differences will increase trust, leading to a more satisfactory end-of-life process for both the client and the family.

Source: Kagawa-Singer, M., & Blackhall, L. J. (2001, December 19). Negotiating cross-cultural issues at the end of life. *Journal of the American Medical Association*, 286(23), 2993–3001.

Cultural Diversity at the End of Life

The 2000 census revealed that whites make up about 65% of the U.S. population; 13% are black; 13% are Hispanic; 4.5% are Asian-Pacific Islander; and 1.5% are American-Indian/Alaskan native. The remaining 2.5% list themselves as bi-ethnic. With the makeup of the United States changing, healthcare workers must become more aware of how cultural factors influence clients' reactions to serious illness and how they make decisions and cope with end-of-life issues. There are three basic dimensions in end-of-life treatment that vary culturally: communication of "bad news"; locus of decision making; and attitudes toward advance directives and end-of-life care. Many ethnic healthcare workers conceal adverse diagnoses from clients, believing that it is disrespectful, impolite, or even harmful to the client. Decisions on end-of-life care are most often made by the family or the family in consultation with the physician, not the client. Advance Directives are usually not completed by specific ethnic minority clients because they have a distrust of the U.S. healthcare system.

Source: Searight, H. R., & Gafford, J. (2005, February 1). Cultural diversity at the end of life: Issues and guidelines for family physicians. *American Family Physician*, 71(3), 515–522.

Death Rituals Vary From One Culture to Another

Death rituals occur in every culture and are practiced in a variety of ways. These rituals may be culturally related or part of a religious practice. A person affiliated with a particular

cultural group may or may not practice rituals from that culture. In providing care to any individual who is dying it is essential to learn what is important and meaningful to that person and family as well as how this need can be met. A few general examples related to culture are presented for clarification.

Arab-Americans, many of whom are Muslims, do not openly anticipate death or grieve for a dying person. Most of the Arab-American clients prefer to die in the hospital. There are special rituals after the death, such as washing the body and all orifices. The designated head of the family determines how family members will be notified of the death. Organ donation is usually not allowed out of respect for burying the body whole. They will probably not choose a DNR order; in fact, the family may lose trust in the healthcare system if this option is offered them.

Black Americans vary with respect to dying at home or in the hospital. Many families care for the clients at home until death is imminent, then bring them to the hospital. Some believe it is bad luck to die at home. There are no rituals associated with care of the body. Cremation is usually not done. Organ donation is usually not done except in cases of immediate family need.

Chinese-Americans may be fatalistic when faced with a terminal illness and death. They usually do not talk about it. Chinese believe that dying at home brings bad luck, but others believe the spirit will get lost if death occurs in the hospital. Each client and family should be supported in their belief. Organ donation and autopsy are generally not accepted, as they believe the body should be kept intact.

Native Americans embrace the present. Some tribes avoid contact with the dying, while others will want to be present 24 hours a day. Eating, playing games, and making jokes in the hospital are seen as appropriate for some tribes. Many of the tribes will bring healers to attend to the spiritual health of the dying client. Some family members will wrap the body for burial and not allow a mortuary to prepare the body, while others may avoid all contact with the body. Organ donation is generally not accepted.

Within the Mexican-American (Hispanic) culture, death is considered a family affair. Family members feel obligated to visit frequently. In the traditional Mexican family, a family member must always be with the dying client. The family members will gather in the home or hospital; therefore, it is necessary to find a place for them to congregate.

NURSING DIAGNOSES

The following nursing diagnoses are appropriate to include in a client care plan when a client is in the process of grieving or dying.

NURSING DIAGNOSIS	RELATED FACTORS
Death Anxiety	Worry about death's impact on significant others, feeling powerless over issues related to dying, anticipating pain related to death
Compromised Family Coping	Little support by family, alteration in family role
Verbal Communication, Impaired	Family has unresolved questions
Disabled Family Coping	Surgery, diagnostic tests, treatments, perceived threat to value system, lack of experience in making critical decisions
Fear	Unknown experience related to death; unfamiliarity with environment
Grieving	Loss of significant other, chronic illness, threat of death, perceived loss of biologic integrity
Ineffective Health Maintenance	Lack of motivation, lack of education, religious and cultural beliefs, cognitive impairment
Chronic Pain	Tissue, organ, or skeletal muscle damage as a result of cancer, severe pain at end of life
Spiritual Distress, Risk for	Hospital barriers to practicing spiritual rituals, loss of body part or function, terminal illness, debilitating disease, death or illness of significant other, challenge to belief or value systems

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. *Remember to wash your hands or use antibacterial gel before and after each and every client contact.*

IDENTIFY CLIENT Before every procedure, check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Chapter 34

UNIT 1

The Grief Process

Nursing Process Data

ASSESSMENT Data Base

- Observe for presence of psychologic symptoms:
 - Weeping
 - Guilt
 - Anger and irritability toward others and the deceased
 - Depression
 - Inability to initiate meaningful activity
- Observe for somatic symptoms:
 - Physical exhaustion
 - Insomnia
 - Restlessness and agitation
 - Digestive disturbance
 - Anorexia or overeating
- Determine client's complaints:
 - Sense of unreality
 - Sense of detachment
 - Lack of strength
- Identify stage of grief client is experiencing:
 - Denial
 - Anger
 - Bargaining
 - Depression
 - Acceptance
 - Outcome of grieving process—positive or negative
- Observe for morbid reaction to grief:
 - Delay of reaction
 - Distorted reaction—acquisition of symptoms of the deceased (e.g., psychosomatic illness or disease)
 - Atypical grief syndrome manifested by distorted pictures of grief

PLANNING Objectives

- To assist the client who is experiencing the grief process
- To intervene therapeutically and provide support
- To allow the client to express feelings of loss openly
- To understand and tolerate client's behavior that is related to loss
- To assist the client to move successfully through stages of the grief process

IMPLEMENTATION Procedures

- Identifying Grief1369
- Assisting With Grief1369

EVALUATION Expected Outcomes

- Client is able to progress through stages of grief with support of family and nursing staff.
- Client is accepting of loss and eventual outcome of grief process.
- Cultural sensitivity is maintained throughout grief process.

Critical Thinking Application 1370

- Expected Outcomes 1370
- Unexpected Outcomes 1370
- Alternative Actions 1370

and Skill Checklists

Identifying Grief

Procedure

1. Understand the importance of the deceased person as a source of support.
2. Observe the degree of dependency of the relationship between deceased and others. ► **Rationale:** The more dependent, the more difficult is the task of resolution.
3. Identify the degree of ambivalence felt toward the deceased. ► **Rationale:** When there are persistent hostile feelings, guilt may interfere with the work of mourning.
4. Identify the support system and other relationships the grieving individual has to depend on. ► **Rationale:** A client with few other meaningful relationships has a more difficult time and is less willing to give up the attachment to the deceased.
5. Identify client's cultural influence on grieving process.
6. Identify the number and nature of previous grief experiences. ► **Rationale:** Losses tend to be cumulative in their effects, and unsuccessfully resolved previous losses only aggravate the current loss.
7. Determine the degree of preparation for the loss. ► **Rationale:** In terminal illness, grief work may have begun long before the actual death of the person.
8. Determine the capacity to cope with loss. The more inner resources the client has available, the better his or her coping ability. ► **Rationale:** The physical and psychologic health of the mourner at the time of the loss determines capacity.

Assisting With Grief

Procedure

1. Become familiar with the grief process, stages of grief, and natural responses to grief.
2. Denial stage.
 - a. Allow client denial of grief to give him or her time to move through shock and to mobilize defenses.
 - b. Encourage client to talk when he or she is ready to do so.
 - c. Understand that shock and disbelief may be first response, and anticipate that behavior may be inappropriate or disturbed.
 - d. Accept client's inability to face reality, and allow mood swings and expressions of happier times (which may seem inappropriate at this time).
3. Anger stage.
 - a. Allow "acting-out" of feelings and verbalization of anger.
 - b. Anticipate expression of anger toward others, loved ones, and the environment.
 - c. Understand that unreasonable, insatiable demands are an expression of this stage of grief, and attempt to meet the demands. Anticipate client's needs before demanded.
 - d. Encourage client to take as much control as possible over care and environment, allowing the client to make as many decisions as possible. Avoid criticism and negative feedback at this time.
 - e. Avoid false reassurance and false cheerfulness, which lead to distrust. Also, avoid diversion by introducing cheerful activities or stories. These actions lead client to believe you do not care about his or her feelings.
 - f. Explain and clarify all procedures and treatments to decrease misinterpretation and expansion of fears.
4. Bargaining stage.
 - a. Allow client to move through bargaining stage; listen to verbal expressions without judgment or pointing out reality.
 - b. Encourage client to talk about bargaining with God. This may assist client to cope with guilt and not lose faith.
 - c. Assist with contacting spiritual counselor or hospital chaplain.
5. Depression stage.
 - a. Encourage verbalizations about loss, its meaning in client's life, and feelings about the loss.
 - b. Support client's self-esteem and understand that it is affected by awareness of the loss.
 - c. Encourage and reassure as appropriate; do not give false reassurance at this stage but assist client to be realistic.
 - d. Be aware of your own feelings of sadness and loss so that they do not interfere with therapy.
 - e. Remain with client and share on a nonverbal level.
 - f. Verbalize feelings to client when they are appropriate; do not deny yourself of sadness or empathy (crying) when appropriate.
 - g. Limit association with cheerful, insincere staff, friends, or family.
6. Acceptance stage.
 - a. Allow client to express whatever feelings are present, knowing that he or she has moved through the above stages and may now be feeling totally empty of emotion.
 - b. Spend quiet time with client, interacting on a nonverbal, nondemanding level.
 - c. Encourage client to make preparations for impending death by supporting requests to finish tasks,

discussing options for plans to complete areas in his/her life.

- d. Encourage client to say the things he or she wants to say to those close to him or her.
- e. Honor client's requests to be alone and do not overload client with external information. Client may need a lot of quiet contemplation to prepare for death.

7. Show respect for cultural, religious, and social customs throughout stages of mourning and incorporate client's cultural, religious, and social customs when providing care during the grief process.
8. Offer support and reassurance to family.

DOCUMENTATION for the Grief Process

- Characteristics of the stage of grief client is experiencing and client's ability to cope
- Behavioral manifestations of grief
- Support systems available to client
- Measures nurse has taken to assist client to cope with grief
- Client's response to psychosocial interventions

CRITICAL THINKING Application

Expected Outcomes

- Client is able to progress through stages of grief with support of family and nursing staff.
- Client is accepting of loss and eventual outcome of grief process.

- Cultural sensitivity is maintained throughout grief process.
- Client is able to identify support system.

Unexpected Outcomes

Client experiences a morbid reaction to grief.

Alternative Actions

- Recognize distorted symptoms and be accepting but firm with client.
- Request further assistance from the staff.

Family cannot support grief of client or handle their own grief.

- Know the general response to death by recognizing the stages of the grief process.
- Understand that the behavior of the mourner may be unstable and disturbed.
- Request assistance from nursing staff or appropriate community agencies to cope with the family.

The Dying Client

Nursing Process Data

ASSESSMENT Data Base

- Assess current stage of dying.
- Observe the physical symptoms:
 - Evidence of circulatory collapse
 - Variations in blood pressure and pulse
 - Disequilibrium of body mechanisms
 - Deterioration of physical and mental capabilities
 - Absence of corneal reflex
- Observe the client's ability to fulfill basic needs without complete assistance.
- Assess the nature and degree of pain the client is experiencing.
- Observe for impending crisis or emergency situation.
- Observe for psychosocial condition:
 - Need to establish a relationship for support
 - Availability of support systems
 - Grief pattern and stage of grief the client is experiencing
 - Need to express feelings and verbalize fears and concerns
 - Determine client's awareness of terminal nature of disease
- Determine anxiety level, which may be expressed in physical or emotional behavior.
 - Sleep disturbance
 - Palpitations
 - Digestive complaints
 - Anger or hostility
 - Withdrawal
- Determine depression level that client may be experiencing:
 - High fatigue level or lethargy
 - Poor appetite, nausea, or vomiting
 - Inability to concentrate
 - Perception of unfinished business to be completed
 - Expressions of sadness, hopelessness, or uselessness
 - Assess family members' needs during the loss

PLANNING Objectives

- To assist client near the end of life to maintain comfort, if possible
- To assist the dying client to cope with end-of-life experiences

- To handle own feelings of loss and sadness that arise when caring for a client at the end of life
- To provide support for the client and the client's family during the end-of-life process
- To complete the actions necessary to care for the client who has died

IMPLEMENTATION Procedures

- Supporting the Client Near the End of Life 1372
 - *For Care of Client* 1372
 - *For Interaction with Client and Family Members* 1372
 - *For Management of the Environment* 1373
- Providing Pain Management at the End of Life 1374
- Symptom Management at the End of Life 1375
- Supporting the Family or Caregiver 1375

EVALUATION Expected Outcomes

- Client is able to progress through stages of grief with support of family and nursing staff.
- Client is accepting of loss and eventual outcome of grief process.
- Client is as pain-free as possible.
- Client's cultural beliefs are considered throughout the dying process.
- Client found internal sources to support acceptance of death.
- Family members are supported throughout the dying process.

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Supporting the Client Near the End of Life

Preparation

1. Determine whether client has a Do Not Resuscitate (DNR) signed form in chart or as part of informed consent.
2. Ensure client has current Advance Directive on file in both the healthcare facility and physician's office.
 - ▶ **Rationale:** Even though the Patient Self-Determination Act of 1991 requires healthcare facilities to inform clients of their right to accept or refuse health care and complete an Advance Directive, this is not always done.

NOTE: Asian-Americans, Hispanic Americans, and African Americans are less inclined to write Advance Directives, whereas 40% of whites have them. See Advance Directives, Chapter 1.

3. If client is unable to sign form, ensure that legally recognized surrogate healthcare decision maker has signed the request. ▶ **Rationale:** Without signed DNR orders, staff must perform CPR and begin all lifesaving measures.
4. Determine whether hospice care is appropriate for client.
5. Review agency policies and procedures related to organ procurement. Be prepared to notify the appropriate individual or organization of status of client as death is near. ▶ **Rationale:** Procurement team can be ready to harvest organs and tissues upon client's death.

Procedure

For Care of Client

1. Introduce yourself to client and family members.
2. Determine whether client has specific needs for comfort. ▶ **Rationale:** Comfort is the primary goal of

- therapy for dying clients. Provide daily grooming, skin and mouth care, and exercise as client can tolerate.
3. Encourage client to maintain independence by providing remote controls for TV, radio, lights, and fans. Keep ice and water at the bedside within easy reach by client.
 4. Provide touch like Reiki or other therapeutic touch techniques if culturally appropriate, especially over the area of pain. ▶ **Rationale:** This is soothing and relaxing for client.
 5. Incorporate the use of relaxation techniques in your daily nursing care of the client.
 6. Serve only small portions of food that client requests.
 - ▶ **Rationale:** Serving large portions only overwhelms client and he or she will not want to attempt to eat. Encourage clients to take in as much fluid as they are able.
 7. Keep lemon drops or mint fresheners at bedside and within easy reach for client. ▶ **Rationale:** Breath fresheners make the client feel better especially if they are not eating.

For Interaction With Client and Family Members

1. Determine if and how family members may assist client during this stage and assist family members to provide care as requested. Discuss hospice care with client and family, if appropriate.
2. Provide opportunities for client and family to engage in cultural or religious practices.
3. Visiting hours for family or significant others should be unlimited. Assess if client needs rest by observing for signs of anxiety, restlessness, and voice trembling. When this occurs, ask the visitors to please leave.

TABLE 34-1 Changes During the Dying Process

Change	Signs and Symptoms
Weakness and fatigue	Inability to move self in bed, unable to perform personal hygiene
Skin breakdown	Erythema surrounding bony prominences, wounds
Decreasing appetite	Poor intake, weight loss, loss of muscle and fat, anorexia
Cardiac and renal dysfunction	Oliguria leading to anuria, tachycardia and peripheral cooling, cyanosis, in extremities, hypertension leading to hypotension.
Alterations in level of consciousness	Increasing drowsiness leading to unresponsiveness to verbal or tactile stimuli
Delirium	Agitation, moaning, groaning, nonpurposeful movements of limbs
Respiratory dysfunction	Change in respiratory rate, decreasing tidal volume with increased PCO ₂ level, abnormal breathing patterns from apnea, Cheyne-Stokes, agonal breaths.
Inability to swallow	Coughing, choking, gurgling, loss of gag reflex, dysphagia
Loss of sphincter control	Incontinence of urine or bowel
Pain	Facial grimacing, moaning, agitation, tension in forehead and between eyebrows.
Inability to close eyes	Eyelids remain open with only whites of eyes showing.

CARDIOPULMONARY RESUSCITATION

"FULL SUPPORT"

"LIMITED SUPPORT"

All indicated medical care is provided except that in the event of a cardiac or pulmonary arrest, limitations of therapeutic interventions are indicated:

- Medications.....
 - Routine..... yes no
 - Vasopressors..... yes no
 - Antiarrhythmics..... yes no
 - ACLS drugs..... yes no
- Airway Management.....
 - Intubation..... yes no
 - Extubation if patient on ventilator..... yes no
 - Reintubate after patient is weaned off ventilator or self extubation..... yes no
- Chest Compressions..... yes no
- Defibrillation..... yes no
- Other..... yes no

"COMFORT SUPPORT" *

- New therapeutic measures contraindicated. Possible reasons may include one or more of the following:
 - Irreversible terminal disease/coma; death is imminent.
 - Brain death (defined by statute).
 - Competent patient or incompetent patient with family or surrogate decision-maker expresses desire that no CPR procedures be instituted.
 - Proposed treatment is disproportionate in terms of benefits to be gained versus burdens caused.
 - Congenital anomalies incompatible with life.
 - Care which is necessary to alleviate pain and suffering shall be provided.

***NOTE:** PHYSICIAN MUST ENTER INTO THE PROGRESS NOTES FOR "LIMITED SUPPORT" AND "COMFORT SUPPORT" ORDERS:

- Diagnosis / prognosis / code status.
- Mandatory neurological consultation for diagnosis of brain death.
- Patient / family / surrogate decision-maker involvement in the decision.
- Clear documentation of patient or family or surrogate decision-maker approval or support of decision to withhold future CPR procedures.

REASSESSMENT OF CPR STATUS WILL BE DONE WHEN A PATIENT'S CONDITION OR WISHES CHANGE AND/OR A REQUEST IS MADE TO RESCIND THE ORDERS.

PHYSICIAN'S SIGNATURE: _____ DATE: _____ TIME: _____

NOTED BY: _____ DATE: _____ TIME: _____

▲ CPR form.

- Assist with open communication with clients, family, and health care providers, regarding any cultural, spiritual, or religious issues they wish to discuss relative to end of life. ► **Rationale:** Understanding the client's religious or spiritual concerns will help support client and family during these times.
- Encourage family members to communicate with clients even if unresponsive. ► **Rationale:** Clients reportedly do hear what it said even though unresponsive.

For Management of the Environment

- Move client's bed near window so he or she can see outside vegetation, flowers, sky, etc.
- Reduce extraneous noise. Client's room may need to be moved to accomplish this. Do not place bed near nurses' station. ► **Rationale:** Even a client who is not responding can still hear voices and noises.
- Display cards, photos, "art work" from children, favorite objects that have special meaning for client in an area where client can see them.
- Provide room lighting that is muted and soft, not overhead lighting.

REQUEST TO FOREGO RESUSCITATIVE MEASURES (Request Made by Patient)

I, _____ (name of patient) hereby request to forego resuscitative measures. My physician, _____, has explained to me the nature of resuscitative measures, their risks and benefits, the risks and benefits of refusing such resuscitative measures, and the alternatives to such resuscitative measures. I have had all of my questions answered by my physician.

After carefully considering all of the information my physician discussed with me, I request to forego resuscitative measures.

Signature: _____

Date: _____ Time: _____ A.M. / P.M.

Witness: _____

REQUEST TO FOREGO RESUSCITATIVE MEASURES (Request Made by Legally Recognized Surrogate Decision-maker)

NOTE: If the patient is determined by his or her physician to be incompetent (that is, unable to understand or appreciate the nature and consequences of the medical decision at issue), a legally recognized surrogate health care decision-maker may sign a request to forego resuscitative measures on behalf of the patient.

I, _____ (name of legally recognized surrogate health care decision-maker) hereby request to forego resuscitative measures on behalf of _____ (name of patient). The patient's physician, _____, has explained to me the nature of resuscitative measures, their risks and benefits, the risks and benefits of refusing such resuscitative measures, and the alternatives to such resuscitative measures. I have had all of my questions answered by the physician.

After carefully considering all of the information the physician discussed with me, I request to forego resuscitative measures on behalf of the patient named above.

Signature: _____

Relationship to Patient: _____

Date: _____ Time: _____ A.M. / P.M.

Witness: _____

PATIENT I.D. #	
NAME	
SEX	AGE
BIRTH DATE	SS#
	MED REC. #
	FIN. CLASS

▲ DNR form.

- Eliminate odors: perfume, cigarette smoke.
 - Open windows when possible.
 - Turn on fans.
 - Use air fresheners.
 - Use aromatherapy (oils or lotion) for massage. Provide massage with aromatherapy products if client agrees. ► **Rationale:** Massage reduces stress, decreases pain and discomfort, and stimulates blood circulation.
- Provide soft music according to client's preference for music.
- Use visualization and guided imagery through audiotapes if client desires.

The goal of care for the dying client changes from curative to palliative care. Helping the client achieve a measure of comfort and knowing that family members and significant others are being supported during this process is a comfort for the client.

Providing Pain Management at the End of Life*

Procedure

1. Assess client for factors that influence management of pain.
 - a. Complete detailed history of the client's condition.
 - b. Determine effects of pain relief measures and medications client is currently taking.
 - c. Have client explain characteristics of pain and have him or her use pain scale to determine severity of pain.
 - d. Ask client if there are any cultural issues related to pain that should be known by healthcare providers.
 - e. Assess client's psychosocial needs.
2. Complete physical assessment of client.
3. Assess client for nonverbal clues indicating pain: restlessness, grimacing, moaning, irritability, furrowed brow, or crying, particularly if the client is sedated.
4. Assess client for physiologic signs of pain: elevated blood pressure and pulse.
5. After determining appropriate drug, dose, and route, administer drug and observe for effects of medication on pain relief and for potential side effects.

Clinical Alert

Most medications for pain are administered via oral or parenteral routes. The use of continuous subcutaneous opioid infusions in clients with chronic cancer pain is becoming more popular. High-concentration opioid medications are used with this method because the amount of drug administered must be limited to prevent tissue trauma.

Medications for persistent cancer-related pain are administered around the clock for best efficacy, not on a PRN basis. Additional PRN medications may be administered as needed.

Seventy percent to 90% of clients with advanced cancer experience pain, especially those in long-term care facilities. When properly medicated, more than 95% of the clients gain relief from the pain.

The client's verbal account of his or her pain is accepted for pain measurement. Therefore, it is important to explain the use of the pain scale so the client accurately describes his or her pain because drug therapy is based on the measurement.

WHO Three-Step Analgesic Ladder for Pain Control

Step 1: Nonopioid with or without adjuvant drugs. Acetaminophen, aspirin, or another NSAID for mild to moderate pain.

Adjuvant drugs to enhance analgesic efficacy, treat concurrent symptoms that exacerbate pain, and provide independent analgesic activity for specific types of pain that may be used in this step as well as in the other steps.

Step 2: Opioid for mild-to-moderate pain and nonopioid drugs; may or may not use adjuvant drugs. Add codeine or hydrocodone to the NSAID (do not substitute drugs).

Drugs are administered in fixed-dose combinations with acetaminophen or aspirin. This provides additive analgesia.

Dose-related toxicity might occur with the use of acetaminophen or NSAID.

This may limit the drug combination's efficacy.

Step 3: Opioid for moderate-to-severe pain with or without nonopioid or adjuvant drugs.

This step is used when higher doses of opioids are necessary.

Separate dosage forms of the opioid and nonopioid analgesic are used to avoid exceeding the maximum recommended doses of acetaminophen or NSAID.

Refer to Chapter 16, Pain Management, for additional information on managing pain.

▲ WHO three-step analgesic ladder.

NOTE: The World Health Organization states that when pain is persistent or moderate to severe at the outset, it should be treated by increasing the opioid dosage or using a higher potency. Morphine, hydromorphone, methadone, fentanyl, or levorphanol can replace the codeine or hydrocodone when severe pain exists.

6. Assess client frequently for effects of pain management.
7. Maintain around-the-clock sustained-release medications for continuous pain.
8. Treat breakthrough pain with immediate-release medications.
9. Discuss a combination of medications and alternative therapies such as massage for the management of pain.

Symptom Management at the End of Life

Procedure

1. Minimize the client's discomfort as much as possible.
 - a. Provide warmth.
 - b. Provide assistance in moving and position client frequently.
 - c. Provide assistance in bathing and personal hygiene.
 - d. Administer the appropriate medications before pain becomes severe.
2. Recognize the symptoms of urgency or emergency conditions and seek immediate assistance.
3. Notify the charge nurse or team leader if there is an impending crisis and perform emergency actions until help arrives.
4. Encourage dying clients to do as much as they can for themselves so that they do not just give up—a state that only reinforces low self-esteem.
5. Provide emotional nursing care for the client.
 - a. Form a relationship with the dying client. Be willing to be involved, to care, and to be committed to caring for a dying client.
 - b. Allocate time to spend with the client so that not only physical care is administered.
 - c. Recognize the grief pattern and support the client as he or she moves through it.
 - d. Recognize that your physical presence is comforting by staying physically close to the client if he or she is frightened. Use touch if appropriate and nonverbal communication.
 - e. Respect the client's need for privacy, and withdraw if the client has a need to be alone or to disengage from personal relationships.
 - f. Be tuned in to client's cues that he or she wants to talk and express feelings, cry, or even intellectually discuss the dying process.
 - g. Accept the client at the level on which he or she is functioning without making judgments.
6. Be aware of your own personal orientation toward the dying process.
 - a. Explore your own feelings about death and dying with the understanding that until you have faced the subject of death, you will be inadequate to support the client or the family as they experience the dying process.
 - b. Share your feelings about dying with the staff and others; actively work through them so that negativity does not get transferred to the client.

Supporting the Family or Caregiver

Procedure

1. Introduce yourself to the family or caregiver and explain your role in caring for the client.
2. Support the family of the dying client.
 - a. Understand that the family may be going through anticipatory grief before the actual event of dying.
 - b. Understand that different family members react differently to the impending death and support the different reactions.
 - c. Be aware that demonstrating your concern and caring assists the family to cope with the grief process.
3. Provide honest answers to questions.
4. Reinforce client's wishes for end-of-life care related to DNR orders, living wills, and advance directive.
5. Explain each procedure/intervention you are providing for client.
6. Ask family members or caregiver how they want to participate in client care.
7. Encourage family or caregiver to take time alone to regroup.
8. Provide or obtain psychosocial support and bereavement counseling for family. ► **Rationale:** Family members may exhaust much of their energy, develop sleep deprivation, and exhibit signs of depression, anxiety, and even chronic health problems during this stressful time.
9. Encourage family members to build a support group of friends or other family members. ► **Rationale:** No one should be alone during this time.
10. Remind family or caregiver to eat properly and maintain an exercise schedule.
11. Refer family members to support groups as needed.
12. Refer family members to social services for help with issues such as insurance, living wills, funeral arrangement, and other financial constraints.
13. Prepare family for client's death.

EVIDENCE-BASED PRACTICE**Critical Care Family Needs Inventory**

A meta-analysis of several studies using the Critical Care Family Needs Inventory led to a summary of the 10 most important needs of families of critically ill dying clients:

1. To be with the person.
2. To be helpful to the dying person.
3. To be informed of the dying person's changing condition.
4. To understand what is being done to the client and why.
5. To be assured of the client's comfort.
6. To be comforted.
7. To ventilate emotions.
8. To be assured that their decisions were right.

9. To find meaning in the dying of their loved one.
10. To be fed, hydrated, and rested.

Aspects of major recommendations based on the review include preparation of the client, family, and clinical team; ensuring the comfort of the client; withdrawal of life-sustaining treatments; terminal extubation versus terminal wean; special issues in communicating with families near the time of death; and special ethical issues.

Source: Truog, R. D., Cist, A. F., Brackett, S. E., Burns, J. P., Curley, M. A., Danis, M., ... Hurford, W. D. (2001). Recommendations for end-of-life care in the intensive care unit: The Ethics Committee of the Society of Critical Care Medicine. *Critical Care Medical*, 29(12), 2332–2348.

**DOCUMENTATION for the Dying Client**

- Client's physical symptoms
- Characteristics of the stage of dying and acceptance by client
- Support systems available to client
- Nursing care measures that make the client comfortable
- Family acceptance and interaction with client
- Comfort or limited support measure provided
- DNR orders in place
- Rituals that are being carried out during care

CRITICAL THINKING Application**Expected Outcomes**

- Client is able to progress through stages of grief with support of family and nursing staff.
- Client is accepting of loss and eventual outcome of grief process.
- Client is as pain-free as possible.

- Client's cultural beliefs are considered throughout the dying process.
- Client found internal sources to support acceptance of death.
- Family members are supported throughout the dying process.

Unexpected Outcomes

Nurse is unable to care for the dying client due to her or his own emotional reaction.

Alternative Actions

- Request that other staff members take over, as the objective is to be able to give good nursing care.
- Request assistance from skilled professional so you can work through your own feelings about death in order to be able to cope with the next death experience.

Client loses confidence in the healthcare team.

- Attempt to ascertain exactly what occurred to cause client to lose confidence in the team.
- Report to charge nurse so that staff caring for client may be changed. Be sure to choose experienced personnel who are equipped to cope with a dying client.

Client lingers on and does not fulfill expectation that death would occur in the near future.

- Report status to staff so arrangements may be made for respite-supportive care for family who is having a difficult time coping.
- Discuss hospice care with the client's family.

Pain cannot be controlled adequately with ordered medication.

- Report to physician so alternative pain relief methods may be used.
- Ensure that WHO three-step analysis ladder protocols are being followed.
- Ensure that around-the-clock medication administration is occurring.
- Assist the client to cope by spending additional time and meeting physical needs.

Postmortem Care

Nursing Process Data

ASSESSMENT Data Base

- Verify that appropriate documentation is completed by the physician or other healthcare provider as required by state regulations.
- Identify cultural and/or family needs and desires.
- Identify client by name and client's belongings for labeling.
- Determine organ and tissue donation status.

PLANNING Objectives

- To prepare body for removal from clinical unit
- To acknowledge cultural and/or family rituals applicable to body preparation
- To protect the condition of the body for the purpose of respect for the deceased and his or her family during final viewing
- To document facts and time relating to death
- To identify and label client and client's belongings

IMPLEMENTATION Procedures

- Providing Postmortem Care 1378
- Preparing for Organ and Tissue Procurement 1379

EVALUATION Expected Outcomes

- Postmortem care is completed, maintaining client's dignity.
- Client's family members are supported by staff during grief process.
- Appropriate procedures are carried out for organ and tissue procurement

Critical Thinking Application 1380

- Expected Outcomes 1380
- Unexpected Outcomes 1380
- Alternative Actions 1380

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Providing Postmortem Care

Equipment

- Bathing supplies
- Shroud or morgue bag
- Identification tags
- Protective pads, if necessary
- Rolls of gauze and abdominal pads, if necessary
- Paper bags or plastic bags for personal belongings
- Gurney or specialized morgue cart
- Clean gloves

Procedure

1. If previously determined or requested by client or family, notify appropriate clergy or support person.
2. Determine that client's death has been pronounced per agency policy and determine whether there is going to be an autopsy or a coroner involved.
3. If there are other clients or visitors in the room, carefully explain the situation and ask them to temporarily leave the room if possible. Provide privacy.
4. Collect necessary equipment. Incorporate family requests or cultural preferences when possible.
5. Follow hospital procedure regarding notification of various departments and personnel.
 - a. Determine whether client has signed a donor card and/or has made a decision to donate any organs.
 - b. Follow client's advance directive on file at the hospital for donor instructions.
 - c. Notify appropriate hospital personnel or local procurement organization (OPO) for assistance with organ donation.
 - d. Follow specific procedures for organ transplant according to hospital policy.
6. Maintain proper alignment of the body. Raise the head of the bed 30°. Maintain head elevation throughout care and to morgue. ► **Rationale:** To prevent pooling of fluids in the head or face.
7. Don gloves.
8. Close the eyes. If necessary, use paper tape or gauze pads. You may do this after the family has visited the deceased.
9. Replace dentures and close mouth. ► **Rationale:** It is easier to insert dentures before rigor mortis begins, and this maintains the client's natural appearance.
10. Remove any external objects causing pressure or injury to the skin (e.g., oxygen mask).
11. Remove IV lines, catheters, or tubes per agency policy, unless an autopsy is to be done.

NOTE: Removing catheters and IV lines causes fluid to leak into tissues, resulting in edema and discoloration. Hospital policy may, therefore, direct that all IV lines be converted to hep locks or intermittent infusion devices to prevent fluid leaks. Follow hospital policy.

12. Cleanse the body as needed. A partial bath may be required to remove secretions, wound drainage, or stains.
13. Place protective incontinent pad under buttocks and between legs in diaper fashion.
14. If family is to visit the deceased, provide clean linen and gown for client.
15. Remove equipment used for cleansing the client.
16. Allow the family private time to view the body. Allow as much time as they desire.

Signed by the donor and the following two witnesses in the presence of each other:

Signature of Donor Date of Birth of Donor

Date Signed City & State

Witness Witness

This is a legal document under the Uniform Anatomical Gift Act or similar laws.

For further information consult your physician or

K National Kidney Foundation
116 East 27th Street, New York, N.Y. 10016

▲ To ensure that organs are donated appropriately, instruct client to fill out and keep donor card available at all times.

17. After family and clergy have visited, label the body, attaching ID tags to the big toe, wrist, and morgue bag or as determined by agency policy.
18. Place arms and hands loosely at side or on abdomen.
 - **Rationale:** This prevents discoloration of hands.
19. Place the body in the shroud or in morgue bag.
20. Label all personal belongings and place them in a bag.
21. Remove gloves and perform hand hygiene.
22. Close doors to client's room and clear hallways in preparation to transfer the body to the morgue.
23. Transfer the body to the morgue on a gurney or a special morgue cart. Keep client's head elevated.
24. Place client's personal belongings in the appropriate place determined by hospital policy.
25. Support family members as needed. Provide for emotional and physical comfort.

NOTE: Rigor mortis begins about 4 hr after death and reaches its peak about 10 hr later. It passes from the body after 36 hr. It is best to wait until the body passes through this process before embalming. Therefore, it is not a problem to wait for relatives to view the body within a specified time frame.

Clinical Alert

Inform the funeral home if the client has tuberculosis or any other infectious disease so appropriate care can be taken to prevent contamination of the environment.

Preparing for Organ and Tissue Procurement

Procedure

1. Determine whether organs or tissues are to be "harvested" in a dying client. Check for driver's license information on transplant donor and/or check for Advance Directives or Living Will.
2. Determine appropriate procedure for securing organs and tissues. Check hospital policy and procedure.
 - a. Determine time frame for collecting organs and tissues.
 - **Rationale:** Organs, bones, eyes, skin, and tissues have different time frames for removal in order to preserve them appropriately. If time frame has elapsed, the organs or tissues cannot be used for transplant.
 - b. If death is imminent, contact the local organ-procurement organization (OPO) according to hospital policy. Members of the organization or the coordinator will be present during the organ procurement procedures.
 - c. If client is not identified as an organ donor, notify physician to determine whether client is a candidate for donation. Contact OPO to alert them about a possibility of organ donation.
 - d. After evaluating client's condition, physician should contact family members to determine if they would like to donate organs or tissues. Some organs many not be appropriate for donation, but many times eyes, skin, and tissues are appropriate.
 - e. Client is kept hemodynamically stable while decisions about transplantation are made by family members.
 - f. When the client has been declared brain dead, the local OPO coordinator, who is a nurse or physician's assistant, will assume responsibility for the donor's management. This does include directing clinical nursing care.

DOCUMENTATION for Postmortem Care

- The exact time the physician or healthcare professional was informed and death was pronounced
- When family members or significant others were notified
- Time organ procurement team informed, if appropriate
- Consent forms signed
- Condition of the body and postmortem care delivered
- Time the body was sent to the morgue
- Mortuary contacted, if appropriate
- Disposition of client's belongings
- Disposition of organs and tissues

CRITICAL THINKING Application

Expected Outcomes

- Postmortem care is completed, maintaining client's dignity.
- Client's relatives are supported by staff during grief process.

Unexpected Outcomes

Client is not identified properly when sent to the morgue.

Donated organs are needed.

- Appropriate procedures are carried out for organ donations.
- Appropriate disposition of patient belongings.

Alternative Actions

- Check Ident-A-Band and shroud label before releasing client to mortician. Request another nurse to check labels.
- Provide support to family and give an opportunity for questions.
- Obtain signatures for consent form. (Kidneys should be removed within 1 hr after death. Eyes should be removed within 6–24 hr after death.)
- Examine reverse side of driver's license, or remind the charge nurse to call mortician if burial plans have been made previously, to check on permission for organ donation through a living will.

GERONTOLOGIC Considerations

Three Out of Four Elderly People Die of Heart Disease, Cancer, or Stroke

- Heart disease is leading cause of death, although it has declined since 1968.
- Death rates from cancer have decreased, but lung cancer has increased in women.
- Death statistics for people in the 65–74 age group: heart disease accounted for 38%; cancer, 30% of deaths.
- Two-thirds of hospice clients are over 65 years of age.

Death in the Life Cycle

- In American culture, the obsession with youth often results in denial of death as a natural phase of the life cycle, and death is not considered a positive process.
- Elderly may see death as an end to suffering and loneliness.
- Death is usually not feared if the person has lived a long and fulfilled life, having completed all developmental tasks.
- Spiritual beliefs or philosophy of life are important.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- Assisting the client to deal with grief may be delegated to another healthcare professional who is trained and experienced in working with grief, such as a social worker or hospice nurse. Assigning staff to work with a dying client will involve similar parameters, with the additional criteria that the nurse has worked through his or her own feelings about dying and can deal directly with the subject of death. If a client wishes to discuss dying or fears related to dying, the nurse must be able to listen and appropriately interact with the client. The nurse assigned to care for the dying client should be aware of the importance of the family in terms of support and communication.
- The nurse is responsible for reviewing the Advance Directives in the client's chart for organ donation or the

living will to determine the appropriate members of the team to care for the client.

- Postmortem care may be provided by the staff. However, if there are organs to be donated, the professional nurse is responsible for carrying out the hospital policies and/or orders necessary to preserve the organs for organ transplant.

Communication Matrix

- Because nonprofessional staff are often assigned to care for the basic needs of a dying client, the RN/LVN/LPN must set up a channel of communication (both written and verbal) so the nurse is constantly aware of the status of the client and the family is informed of the client's status. The professional nurse should also provide the family with opportunities to discuss the condition of the client and plans for the future care of the client (including organ donation and hospice care). It would be inappropriate for nonprofessional staff to be assigned these activities.

CRITICAL THINKING Strategies

Scenario 1

You are assigned to care for Mrs. Garcia, an 85-year-old Hispanic client who speaks limited English. Her caregiver at home has been her daughter, who speaks somewhat more English than her mother. A son and grandson visit her often and both of them speak fluent English. Mrs. Garcia has been brought to the hospital in end-stage renal failure. Her BUN and creatinine are both very high. Her blood pressure is 210/110, pulse 110, and respirations 30 and labored. Her skin has a jaundiced appearance and she has many ecchymotic areas throughout her body. She states she “doesn’t want to live like this.” She is debating asking to be taken off dialysis, but that decision has not yet been made.

1. Considering her condition, what priority interventions should you consider? What is the rationale for your answer?
2. Considering her limited English skills, how will you carry out your priority interventions?
3. Her daughter asks you how long she will live without dialysis. What is your best response? Provide rationale for your response.
4. In the evening after the son has been to visit his mother in the hospital, the family discussed her wishes. It was decided that they would stop dialysis. What steps will you take to provide end-of-life care to Mrs. Garcia?
5. Identify at least four interventions you will use to assist the family in coping with the impending death of their mother and grandmother.
6. During the last day, Mrs. Garcia is complaining about mild to moderate pain. What interventions will you use to make her comfortable?

Scenario 2

You are working with a terminally ill client who is in severe pain. The client’s family is considering moving the client to a hospice center.

1. What are some of the advantages for the client if this move is accomplished?
2. What are some of the barriers to hospice care that you would anticipate when discussing this decision with the family?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. Place the stages of grief, according to Elizabeth Kübler-Ross, in the order in which they progress.
 1. Anger.
 2. Depression.
 3. Acceptance.
 4. Denial.
 5. Bargaining.
2. The response in Engle’s third stage of grief, restitution, is described as
 1. A time when all feelings of hostility and negative feelings toward the deceased are repressed.
 2. The beginning of the recovery process, with the onset of cultural and religious rituals that assist the mourner to face the loss.
 3. The stage in which there is a refusal to accept or comprehend the death.
 4. The mourner’s attempt to deal with the painful void created by the loss of a loved one.
3. The Clinical Policies and Performance Practice Guidelines for end-of-life care include

Select all that apply.

 1. Discontinuing alternative and nontraditional care to allow the client to rest.
 2. Allowing the client to refuse treatments.
 3. Managing spiritual/religious problems.
 4. Encouraging family members to minimize time at the bedside to prevent client and family fatigue.
4. Hospice care is recommended for which of the following clients? Those who
 1. Live alone and require rehabilitation services.
 2. Have a life expectancy of less than 6 months.
 3. Are elderly and have a short life expectancy.
 4. Require comfort care but not treatments.
5. Family members need instructions in what behaviors and/or responses they can expect by the client when he/she is in the anger stage of the grief process. The most appropriate response is
 1. “Inappropriate or disturbed behavior occurs during the stage of denial, so this would not be observed during the anger stage.”
 2. “You should not expect acting out of feelings and verbalization of anger at this stage.”
 3. “Clients usually yell out at God and blame him for their problems.”
 4. “During this time it is helpful if you make as many decisions as possible for the client.”
6. Nursing interventions carried out when the client is near death include
 1. Placing the client in a room near the nurses’ station.

2. Displaying a favorite object or children's photos within easy sight.
 3. Pulling the curtains around the client so he/she does not need to look at the activity outside the door.
 4. Ensuring that room is well-lit to provide continuous assessment of the client's condition.
7. Which cultural group is most likely to have completed advance directives?
1. Caucasians.
 2. Asian-Americans.
 3. African Americans.
 4. Hispanic Americans.
8. Using the WHO Three-Step Analgesic Ladder for pain control, which description best illustrates Step 2 of the ladder?
1. Opioid drugs such as codeine are added to NSAIDs to treat mild-to-moderate pain.
 2. Nonopioid drugs, such as aspirin, are used for pain without adjuvant drugs.
 3. Opioid drugs such as morphine sulfate are used for moderate pain without adjuvant drugs.
 4. Nonopioid drugs and methadone are used for pain control only in stage II.
9. As the client is dying, the nurse needs to provide emotional nursing care for the client. This includes: **Select all that apply.**
1. Demonstrating caring and a willingness to be involved in his/her care.
 2. Utilizing nonverbal communications and touch, if appropriate, based on cultural and religious beliefs.
 3. Coordinating nursing care so it can be completed in a block of time to allow adequate time for communication.
 4. Recognizing that your physical presence is comforting, even if you do not talk with the client.
10. There are three basic dimensions in end-of-life treatment that vary among different cultures. Which one of the four distracters is not included in these basic dimensions?
1. Communication between client and physician regarding treatment.
 2. Locus of decision making.
 3. Attitudes toward advance directives.
 4. Communication of "bad news."
-

NCLEX-RN[®] Answers with Rationale

CHAPTER 1—PROFESSIONAL NURSING

- (2) Even though nurses do care for clients in all types of settings and they do perform ADLs and prepare the clients for home care, these statements do not define nursing (1) and (4). Not all client care is ordered by the physician; nurses have many independent actions (3).
- (1) In both clinical and academic environments, ethical principles are a necessary guide to professional development. This is the rationale for adhering to the code. Answers (2) and (3) are included, but not the most important. Administering medications is not included in the code (4).
- (4) Maintaining the dress code is usually part of the student nurse's responsibility for clinical practice (1). There is no relationship between what staff RNs wear and students' dress code. A professional relationship must be maintained during client care (2). It is unprofessional to call a client by his/her first name (3).
- (3 4 5 6) RN responsibilities cannot be delegated to the LVN/LPN regardless of length of experience (1). (2) CNAs cannot be assigned to a newly admitted client. They cannot complete a health history.
- (3) Nurses in all clinical settings function under the standards, including Advanced Practice Nurses. Each specialty group of nurses develops their specific standards, according to the same protocols.
- (1 2 5) Imprisonment or compensation to cover costs to a facility is not usually associated with professional misconduct cases.
- (3) Examples of malpractice are (1) and (2). (4) is not connected with a legal issue. If the nurse refuses a client assignment after the shift starts, it is considered abandonment of the client and can result in terminating the nurse's employment.
- (1) The first step in providing client care is gathering the appropriate equipment. (4) is an incorrect statement. The client must be identified using two forms of identifiers, such as ID band, asking for date of birth, or asking the client to state his/her name. (2) and (3) are not appropriate actions to determine priority nursing care for a client. It is based on the assessment and by discussing the client's needs.
- (3) An assessment is carried out as one of the priority interventions at the beginning of the shift. This provides the data that is used to prioritize client care throughout the shift (1)(4). A focused assessment includes a basic assessment of all systems, but more in-depth assessment of the system most affected by the diagnosis (2).
- (4) Soiled linen is never placed on the linen cart. It will contaminate the entire linen cart (1). Alcohol will not decontaminate equipment. Equipment needs to be sterilized in central supply (2). Sharing client equipment is never an accepted practice. Cross contamination between clients can occur (3).

CHAPTER 2—NURSING PROCESS AND CRITICAL THINKING

- (4 5 2 3 1) When planning care, the steps in the nursing process are completed in this order.
- (1) and (2) Nursing care is provided to clients based on their individual care needs. Critical thinking is implemented after collecting data and then determining the needs of the client by priority. In addition to the identified attributes, critical thinkers are realistic, good team players, empathetic, and open-minded. Care is not delivered in the same way for all clients.
- (3) If you missed the question, it is suggested that you review nursing diagnosis statements. (4) is a medical diagnosis and (1) and (2) are written incorrectly.
- (1 4 6) These choices represent nursing diagnoses, whereas the other diagnoses are medical. Nursing diagnoses can be treated by a nurse. Medical diagnoses are treated by a physician, or the nurse can collaborate on the treatment. Medical diagnoses require a physician's order before the nurse can provide specific care to the client.
- (1) Nurses should make clinical decisions using the best available research and other evidence that is consistent with policies, procedures, and clinical guidelines. (2) Best practices usually are indicative of the most often used methods of providing client care. They are not necessarily based on research findings. (3) and (4) do not describe, nor are they involved in, Evidence Based Nursing. New techniques may come from EBN but would be an off-shoot of the research, rather than the goal.
- (2) After a complete assessment of the client, a data base of information is then utilized to develop a nursing diagnosis, short- and long-term goals, and appropriate interventions. (1), (3), and (4) actions will take place after the assessment is completed.
- (3) Compliance to client care goals is effectively carried out when the client, family, and other individuals who will be participating in the care take an active role. (4) Teaching plans are best developed using the same group of individuals. (2) The care plan is developed as soon as possible after admission; follow hospital policy and procedure on time frame for completion.
- (3) The nurse would collect additional data if needed, then make the intervention. Gathering data and prioritizing clients' needs (1) are part of the assessment phase of the nursing process. (2) is an action associated with nursing diagnosis phase, and (4) is the last step of the nursing process.
- (4) The major advantage of using the NIC system is that it can be electronically sent to data bases. With the implementation of the electronic health record, standardized nursing languages such as NANDA can be used to provide a broad base of nursing knowledge at the point of care. (3) NIC information can also be used as a paper-based document.
- (3) LVN/LPNs can assist the RN in revising client care plans. These health care workers (1) and (2) cannot complete the tasks identified in the question. UAPs cannot develop a care plan, and CNAs are not allowed to complete tasks prior to discharge, unless it is in their scope of providing hygienic care, moving and positioning, etc. (4) Only RNs can develop the plan of care at admission.

CHAPTER 3—MANAGING CLIENT CARE: DOCUMENTATION AND DELEGATION

- (1 2 4 5 6) The only function that is not a purpose of charting is (3), to remind the nurse of the care and treatments given to the client.
- (2) Nurses tend to rely on data in the computer and do not question it when it may be wrong (perhaps because of wrong input of the data), so this is a major disadvantage. All other answers are positive.
- (3) The correct method is to draw a single line through the entry and write "mistaken entry" above it and initial. It should remain visible.
- (3) Because there may be future legal implications, it is necessary to be very specific and record all of the details, not just those considered major (1) or general (4) details.
- (2) A major advantage is that this form is standardized (not individualized) and multidisciplinary. It is a tool developed to encompass all health team members, so it does not allow for complex clients to receive individual goals.
- (2) The important principle here is to recognize that this is a cultural issue and that the Islamic religion requires ritual bathing after prayers

every day. Telling him to wait or that you are too busy is not acknowledging his cultural/spiritual needs.

7. (1) When making an assignment, the leader should attempt to keep the same nurse with the same client. This allows for better continuity of care. The other choices would help provide continuity of care and stability.
8. (3) Proper delegation requires that the nurse delegating tasks must make sure the person is trained to perform the task, oversees the activity, and evaluates the results. Close supervision will discourage employees and isn't necessary unless a particular problem exists (1). Delegating a task allows the employee to utilize his/her own knowledge (2).
9. (1) By witnessing the signing of a surgical consent form, the nurse is merely attesting that the client has signed the form. Answer (2) describes informed consent. Witnessing the form doesn't mean the nurse believes the client is competent (3). The nurse is not in the position to determine likelihood of success of a procedure (4).
10. (3) Some tasks may not ever be delegated, and each state sets its own requirements; for example, total assessment and evaluation may not be delegated. All other statements are correct.

CHAPTER 4—COMMUNICATION AND NURSE-CLIENT RELATIONSHIP

1. (4) Aphasia leads to feelings of frustration and discouragement. Clients require frequent praise for their efforts and encouragement to continue to try to communicate. Aphasic clients can best provide information by responding to yes or no questions.
2. (3) Termination is an ongoing process, so encouraging the client to follow through with what was learned is a good response. The nurse would *not* encourage the client to stop by, because the relationship was terminated. The last response is *not* encouraging and nontherapeutic.
3. (4) A professional relationship must remain on the professional level even though the nurse sets goals with the client, sets limits, and sets boundaries. Hospital policies are not relevant. The nurse will not necessarily maintain a distance, because a degree of emotional involvement is positive. Client needs are important but are not the focus of the relationship.
4. (3) This is a reflective response, and it opens up communication and allows the client to express whatever concerns or feelings he has without confining the discussion to dying. The other two responses cut the client off and are nontherapeutic.
5. (3) This open-ended question allows the client to further comment and expand on the subject. Answers (1) and (2) are closed ended and can be answered by a yes or no. Also, the last response is more focused, so an open-ended question is best.
6. (2) This response keeps lines of communication open so that the nurse can hear his fears and clarify any medical lack of knowledge. As he verbalizes, he can begin to more realistically cope with his condition. The remaining responses all close off communication and are nontherapeutic.
7. (4) The first intervention is to calmly set limits on the verbally abusive behavior to defuse the situation. Summoning help or sending the client away may escalate the situation. Restraints would only be a last resort.
8. (1 2 3 6 7) The age of the client and whether or not he believes in God are not components of a cultural assessment.
9. (1) The most effective mode of communication if the client is hearing impaired is to use a writing pad and gestures. Speaking, even slowly or loudly, will probably be frustrating and difficult for the client. Nonverbal communication is not as effective as writing.
10. (4) The priority is client safety, so whenever caring for a depressed client who is potentially suicidal, the intervention is to assess frequently and place the client on suicide precautions. Encouraging the client to talk about his feelings will only deepen the depression. Activity is always useful because mobilizing the client is a goal, but it is not the priority here.

CHAPTER 5—ADMISSION, TRANSFER, AND DISCHARGE

1. (3) Only the client has the right to make decisions about resuscitation efforts. This is in compliance with the Client Self-Determination Act.
2. (2) Admitting personnel inquire about Advance Directives so that documents can be added to the client's record, updated, or executed on admission.

3. (1) The individual receives an ID bracelet during the admission process, at which time he/she becomes a client.
4. (2 4) These correlate with the client's medical record. Birth date is not an identifier, and room number may change during hospitalization.
5. (2) A strange environment causes anxiety. Familiarity with the room and equipment promotes independence and control.
6. (1 4) This information is useful and predictable. The client would not use the emergency call system, physician visits are unpredictable, and HIPAA protects against revealing client identity.
7. (1) Smoking is the most preventable cause of morbidity. Hospitalization offers an opportunity to identify clients at risk for smoking-related diseases and to offer smoking cessation counseling.
8. (3) These are the two factors used for calculating BMI.
9. (1) Mistakes in client identification are a major cause of client injury due to errors in administration of medications or procedures to the wrong client, as well as the omission of care intended for another client.
10. (2) The nurse should advocate by determining why the client wishes to leave AMA, since the client's concerns may be alleviated once identified (e.g., further explanation, social service consult, individualized accommodations).

CHAPTER 6—CLIENT EDUCATION AND DISCHARGE PLANNING

1. (4) Nurses are the principal providers of care; therefore, they usually take the leadership role in directing the educational plan. One of the other health team members may play a major role in the teaching; however, the nurse usually directs and guides the process. (1) Physicians usually do not play a major role in education while the client is hospitalized. (3) Discharge planners are pivotal in determining placement of clients on discharge and in obtaining equipment for the home.
2. (2) Clients with multisystem issues usually require education regarding diagnosis, multiple treatments, and medications. (1) Living alone does not necessarily place a client at high risk for discharge. If the client is young, self-sufficient, and has a good support system, the client is not at high risk. Answers (3) and (4), in and of themselves do not place clients in a high-risk category.
3. (4) The first three distractors are essential to determine an appropriate educational plan. (1) The educational level determines the level and scope of information that can be presented. (2) Family members should be included in the educational plan. (3) Ethnic and cultural issues need to be taken into account, especially when discussing items such as dietary alterations. The actual employment or occupation in most cases is not necessary in developing the teaching plan.
4. (2) The amount of time the family spends at the client's bedside may be dependent on their work schedule, family responsibilities at home, etc. Once the teaching needs are determined, then it is important to evaluate their active participation.
5. (4) Knowing the lifestyle and usual daily activity can assist with determining the impact of changes on this activity and the emphasis on the teaching plan. (1) This procedure is not considered a major surgical intervention. Most of the listed procedures are done on an outpatient basis; therefore, the home environment would not be evaluated. There is no need for specialized equipment. (2) All clients having outpatient or short-stay surgery must have someone take them home because of the anesthesia. It isn't important to determine who will be staying at home with the client or when they return to work. The physician will give the client directions on the return-to-work date.
6. (4) The initial teaching plan will support the client in respect to the diagnosis, treatment, medications, and expected outcomes. Teaching is a major part of this initial plan. Of course, determining the support system at home will become more essential as the teaching continues and discharge planning is discussed. (1), (2), and (3) are essential components for the teaching plan and will be integrated within the plan.
7. (1 2 3) Summarizing the teaching content or clarifying misinformation does not evaluate the effectiveness of the teaching strategies. It does provide information on retention of information, which can play a role in how effective the strategies have been. However, you do want to

evaluate the type of strategy utilized in teaching. Basically, what they are doing in (4) and (5) is reiterating information. You cannot evaluate whether they are able to utilize the information that was covered in the teaching.

8. (1) The client will become more agitated with you if you attempt to continue with the teaching. The other responses are all appropriate for this situation. It is best to come back at a different time (3). At that time you may be able to determine why the client is agitated and hostile. (4) Frequently, another nurse is able to establish rapport with a client, and it would be best to ask that nurse for assistance with the client.
9. (1 2 3) This data is important information for other health care workers to have in order to develop an appropriate plan of care for the client. Nursing interventions and I&O records are not necessary unless there is a specific issue with them. For example, if the client's urine output has been low and he/she isn't taking in fluids, that should be included in the discharge summary.
10. (3) Older clients frequently have hearing deficits and extraneous noise impairs their hearing. This can lead to perceiving incorrect information and directions. (2) Older clients remember about 5% of what they read. (1) They remember 50–70% of what they hear and verbalize. (4) Usually, older clients do not learn best in groups, because it can be noisy and disruptive.

CHAPTER 7—SAFE CLIENT ENVIRONMENT AND RESTRAINTS

1. (1) Characteristics influencing adaptation to the environment are provided in (2), (3) and (4). They must be assessed to determine the client's needs and abilities to safely adjust to their immediate surroundings.
2. (4) A large percentage of errors occur as a result of either no communication or incomplete communication regarding client care. (2) and (3) can also lead to sentinel events, but not to the extent of a failure in communication.
3. (2) The order can be renewed every 4 hours for a total of 24 hours. Children between 9 and 17 must have orders renewed every 2 hours, and every 1 hour for children under 9 years.
4. (3) The slip knot allows for a quick release in case of a client requiring release from the restraint. (4) The least restrictive method to prevent the client from falling would be the use of sitters.
5. (1) Keeping the contaminated equipment in the room prevents contamination to other clients. Clients with implants do not usually receive bed baths (2). This protects health care workers from unnecessary exposure to radiation. Client care is provided by standing away from the radiation area, but the time for client care is still limited to 15 minutes/shift by one health care worker (3) and (4).
6. (4) Staying with the client is critical to prevent a complication related to the seizure activity. (1) The client is turned to the side to protect the airway from tongue occlusion. (2) Once a seizure has begun, tongue blades are not inserted in the mouth. (3) Clients are not restrained to prevent injury during the seizure activity.
7. (3) The priority is to remove the clients, if at all possible. The usual priority for fire safety can be remembered by using the mnemonic RACE. R is remove client, A is activate the fire alarm, C is confine the fire, and E is extinguish the fire if possible.
8. (1) Promoting ADLs and exercise will increase the clients' strength and mobility. They should be encouraged to get out of bed. (2), (3), and (4) are all safety precautions that should be practiced for elderly clients to prevent injury.
9. (1) Wedge-roll cushions, use of low-level beds, placing a mat on the floor by the bed can all be used to prevent injury if a client falls. (3) Environmental alterations do not include using a geri-chair; (2) placing a client near the nurses' desk does not prevent the client from falling. (4) Side rails are considered restraints, although if the client is alert and asks that they be raised to assist the client in moving, they can be left in the "up" position.
10. (2 3 4) The vest is placed on the client with the zipper to the back. (3) After vest tails are crossed in back of the chair, the tails are wrapped around the immovable kickspur. The tails are then tied to the kickspur using a half-bow knot.

CHAPTER 8—BATHING, BED MAKING, AND MAINTAINING SKIN INTEGRITY

1. (2) Tucking the sheet under the bed at the top of the bed and going down to the foot of the bed, would take two staff to change the bed. (1). (3) Changing only the drawsheet is not considered a complete linen change. (4) Linen changes are not made just when the bed is soiled.
2. (5 2 3 1 4) A bed bath is completed using the noted sequence. The nurse completes the bath using a head-to-toe approach, working from the front side to the client's back.
3. (3) Because the skin of the elderly client is very thin and fragile, it is imperative that it be kept moist. (2) and (4) are not correct. The bath can be a tub bath or bed bath in addition to a shower. Minimal amounts of mild soap can be used for bathing. (1) Fragrant soaps are not recommended as they can cause drying of the skin.
4. (3) This is considered a medication and therefore requires a physician's order. (1), (2) giving a bath in tepid water does not require an order, nor does using a hydraulic bathtub chair. (4) This type of bath is not ordered by the physician. It is the nurse's discretion based on the client's ability to assist with the bath or to ambulate to the tub or shower.
5. (4) The client can assist with washing his/her hands and face if the exertion is not too much. (1), (2) and (3) would not be appropriate for the client who is short of breath. It would take too much energy to perform any of these tasks.
6. (1 2) These activities are considered part of morning care. (3) and (4) are considered part of providing evening care. These activities are also completed when the bath is provided.
7. (3) Maintaining the pH of the skin prevents drying of the skin. (1) The cost is less using regular linen in most facilities, but convenience is taken into account when facilities do use disposable systems. (2) A wash cloth is also warmed, therefore this is not an advantage of the system. It is not easier or quicker to use.
8. (3) Cleansing the eyes first prevents water and particles from entering the lacrimal duct. (1) The head and scalp are washed last, after taking the infant out of the bath tub. (4) would be completed after the infant's ears and neck are washed.
9. (2) Picking up the skin is a good indicator of hydration of the client. If the skin stays tented, the client is dehydrated. (1) Checking the temperature of the skin is accomplished by placing the back of your fingers or hand on the client's skin. (3) Checking for edema is completed by firmly pressing the finger against the client's skin for several seconds and observing the indentation depth of the skin. (4) Checking the color of the skin of the hands might be done to check for peripheral circulation, not hydration.
10. (2) Using an adherent dressing will assist the wound to heal. (1) The skin is irrigated with normal saline solution, if needed. (3) A dry dressing will adhere to the tear and can cause the tear to open up when the dressing is removed. (4) It is not necessary to immobilize the arm.

CHAPTER 9—PERSONAL HYGIENE

1. (1) Turning the head to the side allows fluids to drain out, facilitates suctioning, and prevents aspiration. (2) is important also, but it is not the major safety action. (3) Padded tongue blades or a bite lock can be used to separate upper and lower sets of teeth to promote cleaning of inner teeth surface. Gloves are used to prevent spread of infection (4); although important, number 1 is the major safety action.
2. (4) Combing starts at the end of the hair shaft and works toward the scalp. (1) It is used to provide routine hair care. (2) Oil is used for coarse or curly hair that has dry or flaky areas on the scalp. (3) Hair picks are used for hair care when the client has coarse or curly hair.
3. (2) Nits within 6 mm of the scalp are usually viable, white in color, and indicate an active infestation. (1) Lice are light to dark brown in color, crawl, and feed on blood 3–4 times/day. (3) Lice eggs hatch in 7–10 days, not 17 days. (4) Lice have six clawed legs and crawl, but do not jump. A fine toothed comb is necessary to extract the nits from the hair.
4. (3) Nits within 6 mm of the scalp are usually viable and indicate an active infestation. (1) and (2) are incorrect. (4) Nits are not easily seen on the hair shaft.

5. (4) Clothing can be washed in hot water when nits or lice are found (1). Rid Home Lice Control Spray is used on furniture and mattresses, or any item that cannot be laundered. Family members are treated once lice or nits are found (2). They are usually not treated prophylactically. Launder bedding when nits or lice are found (3).
6. (2) Most institutions do not allow nurses to cut the nails of clients with peripheral vascular disease or diabetes (3). Skin lesions can occur with cutting nails and this can lead to infection and poor healing. Physicians, or in some instances nurses, should notify the podiatrist to see the client (4). Documentation is important, but the nurse needs to complete the assessment (1).
7. (3) This position prevents the client's knees from buckling. (1) can cause back injury to the nurse if the client loses balance and begins to fall, thus pulling on the nurse. (2) and (4) can lead to the nurse's injury, as it places pressure on back muscles.
8. (3) For uncircumcised clients, the foreskin is retracted to expose the glans penis for cleaning (1). Washing begins at the tip of the penis and proceeds to the base (2). The scrotum is washed after the penis, using a clean washcloth (4).
9. (4) Only rinsing or saline solution can be used to cleanse contact lenses (2). Daily wear lenses cannot be worn overnight (2).
10. (1 2 3) All of these responses are important when teaching care of hearing aids. Batteries should be replaced when necessary.

CHAPTER 10—VITAL SIGNS

1. (2) Loss of peripheral pulses may indicate circulatory collapse, so a further assessment should be made. When peripheral pulses cannot be palpated, a Doppler is used. Thus, the nurse should use a Doppler ultrasound to find the pulse, then report to the physician.
2. (1) A pulse deficit (when apical is greater than radial rate) occurs when rhythm is irregular and atrial dysrhythmia or premature ventricular beats occur. If a significant pulse deficit is found, assess for other abnormal signs.
3. (2) The first intervention is to expand the assessment of vital signs so that you have more data to make a nursing diagnosis. At that point you may request orders for a cooling blanket because it is more efficient than a cool bath. After you report to the physician, there may be an order for a blood culture.
4. (2) If an unexpected low blood pressure is recorded, the nurse needs to first examine her technique. If the cuff is too wide, the blood pressure will be low. The client's arm should be supported horizontally at heart level.
5. (1) The first intervention is to use different equipment because it may be faulty. Then, if it is functioning, validate with another nurse. Finally, check his circulatory status and other vital signs, and notify the physician.
6. (1 3 4 5) These are the breathing patterns considered to be abnormal. Answer (2), respiratory rate 12–20, is normal for an adult.
7. (1) A rise in the pulse rate is one of the earliest signs of shock. A blood pressure of 110/70 and a respiratory rate of 24 are normal and do not reflect shock (2), (3). The temperature of 101 degrees F is not associated directly with a sign of shock, but may indicate other problems (4).
8. (1) Consistency of approach is the best, as changing position of the arm that is used may result in a different reading. The best graph is obtained by using the same approach over time.
9. (2) Pressure close to the tympanic membrane seals the ear canal and allows for an accurate reading. Answer (3) is not wrong, but it is not as complete an answer. Answers (1) and (4) are incorrect.
10. (3) Because vital signs can be assigned to any health care worker as long as their competency has been assessed, it is more man-power effective to have the nursing assistants start the shift assessment with reporting vital signs, then have the day's work assigned based on the clients' conditions. The RN and LVN would then begin caring for the most critically ill clients.

CHAPTER 11—PHYSICAL ASSESSMENT

1. (4) The basic principle to remember when auscultating lungs is to do a comparison between left and right lungs beginning at the top and alternating side-to-side.
2. (3) Rebound tenderness is a symptom of peritoneal irritation such as seen with appendicitis. Hold fingers at 90° angle, push fingers deeply in region away from reported tenderness, then rapidly remove fingers. Rebound of structures indented by this maneuver causes a sharp pain on the side of the inflammation. Painful areas should be examined last (1). The client should breathe normally (2). Client should have knees bent to help relax the stomach muscles (4).
3. (1) Macules are flat, circumscribed, and show a change in color like first-degree burns, petechiae, and purpura. Wheals are elevated, irregular shaped, and solid (2). Vesicles are elevated and fluid-filled (3). Papules are elevated, firm, and circumscribed such as a wart or mole.
4. (3) +2 is a normal response for deep tendon reflexes. +1 is a diminished, low normal response (1). 0 is no response (2) and +4 is brisk and hyperactive (4).
5. (3) IX, glossopharyngeal, is the cranial nerve assessed when testing for the gag reflex. XI, accessory, is the motor nerve that causes contractions of sternocleidomastoid and trapezius muscles (1). VII is the facial, sensory, and motor nerve (2). XII, hypoglossal, is the motor nerve that controls muscles that move the tongue (4).
6. (4) The S₁ heart sound can best be heard at the apex of the heart, over the mitral and tricuspid areas. The pulmonic valve is at the left second intercostal space and the aortic valve is at the right second intercostal space (1). The diaphragm is used to listen to high-pitched sounds like S₁ (2). S₁ is not loudest in the aortic area (3).
7. (4) Flexing the neck slightly reduces muscle tension and enhances palpation. Raising the chin tenses the neck muscles, making it more difficult to palpate nodes (1). Lying in a supine position makes it difficult to assess because access is limited (2). Swallowing water is used to assess the thyroid gland and movement of the cartilages (3).
8. (2) Examining the adjacent area is the next intervention because pulse locations can differ with clients. The follow-up intervention would be to use a Doppler ultrasound stethoscope to locate the pulse (3). Finally, if no pulse is found, you would notify the physician (1).
9. The normal range of specific gravity is 1.003–1.030. Abnormal specific gravity could indicate dehydration or renal failure.
10. (3) You are assessing the client's fund of information, so asking who is the president will reveal deteriorated or impaired cognitive processes. Asking about feelings will not reveal this information (1). With dementia, the client may remember what he did years ago, but cannot remember yesterday (2). Answer (4) is a higher level question that the client may not be able to answer, but it is not as revealing as answer (3).

CHAPTER 12—BODY MECHANICS AND POSITIONING

1. (4) The newest method of preventing caregiver injuries is concentrating on handling equipment and devices. (1), (2), and (3) are older common approaches for moving and turning clients that are no longer accepted practice.
2. (1) 51 pounds is the standard for lifting clients, and this should be done under controlled and limited circumstances. (4) indicates the average weight of clients in the hospital. (2) and (3) are not correct responses.
3. (3 4) Appropriate body mechanics used when moving clients are included in correct answers. (1) is incorrect as the feet are placed flat on the floor to form a strong base of support, with one foot ahead of the other. (2) The abdomen is held firm but the buttocks is tucked in so the spine is in alignment.
4. (1) The most comfortable height for working is between the waist and lower level of the hip joint.
5. (3) It is imperative that you report any injury to your immediate supervisor so he/she can investigate the situation and provide appropriate support for you. (1) You will need to complete an unusual occurrence form; however, this is done after notifying the immediate supervisor. (4) As with any injury, the nurse is usually taken off any client care assignment and sent to the ER for an evaluation.

6. (4) In low-Fowler's position, the client is placed in a 15 degree position. (1) is high-Fowler's position. (2) is Fowler's position, and (3) is semi-Fowler's position.
7. (3) The friction-reducing sheet not only assists in turning the client but prevents skin tears. (1) A second nurse is frequently used to assist in turning, but it is not the best method to be used. (2) The lift team is used only when other methods of turning are not safe or the client is too difficult to move. (4) The client is not asked to move up in bed before the turn. This can be accomplished during the lateral turn.
8. (4) The client turns onto his/her back directly onto the transfer board. (1) The board is placed on the opposite side of the bed before turning the client. (2) The client is placed on his/her back, not in a side-lying position. (3) The client does not roll over the edge of the board to the gurney maintaining a side-lying position. The client remains on his/her back when using the transfer board.
9. (3) Clients with some arm strength and weight-bearing ability can pull themselves up by holding onto the bars. (1) is used for clients who are unable to bear any weight. (2) is used for clients who can bear weight at least on one leg. Client places foot on footrest while a sling is placed under the arms and around the back. (4) assists clients from bed to gurney.
10. (1 2 3 4) All responses are correct.

CHAPTER 13—EXERCISE AND AMBULATION

1. (4) Flexion is a movement that decreases the angle between two bones (1). (2) means turning outward. (3) Adduction is a movement of a bone toward the midline of the body.
2. (1 2 4) A client on strict bedrest with passive range-of-motion exercises ordered will not be completing the exercises independently.
3. (3) Raising the head of the bed slowly several times will stimulate baroreceptors and thus prevent orthostatic hypotension. (1) Client doesn't necessarily need to use a walker. (2) Vital signs are taken, but usually after the client sits up and before standing. (4) Additional assistance may be necessary to help, but this is not directly related to preventing orthostatic hypotension.
4. (3) The weaker side of the body is moved first by supporting body weight using the handles and then advancing the weaker leg. In (1), the client does push off the bed, but is instructed to grasp the hand grips of the walker before doing so.
5. (4) Cane is placed on the unaffected side of the body (1). This promotes stability. (2) Cane is placed about 12 inches in front of the foot and slightly to the outside for greater stability. (3) Cane is moved first and then the affected leg.
6. (4) When going upstairs, the cane and unaffected leg are placed on the step first (1). (2) The affected leg is moved to the step after the cane and unaffected leg. (3) Cane and affected leg are moved to the step after the unaffected leg is placed on the step.
7. (2) Client wears shoes that will be used for walking when measuring for crutches to ensure proper height of the crutches. If height is incorrect, the axilla could rest on the bar of the crutches, causing skin breakdown or nerve involvement. (1) Crutches are measured with client shoes on in bed. (3) Axilla should not rest on crutch arms. This can lead to nerve injury and skin breakdown of the axilla. (4) Client is measured while in bed, at a point 6–8 inches lateral from the heel.
8. (3) Three-point gait is a more rigid version of the four-point gait; therefore, the client can move and bear weight on each leg (1). (2) Client can bear little or no weight on one leg or when the client only has one leg. (4) Usually used when client's lower extremities are paralyzed.
9. (2) Instructions for clients going upstairs with crutches include: First place the uninjured leg and crutches on the same level. Then place crutches on first step. Next move unaffected leg to step where crutches are placed.
10. (3 4) Applies to a client who suffers axillary nerve pressure resulting in numbness and tingling of the fingers (1). (2) Proficiency is not what is needed to prevent slipping; it is having the tips of the crutches covered with rubber to prevent slipping on floors.

CHAPTER 14—INFECTION CONTROL

1. (4) Goggles should be worn when there is a risk of contact with body fluids through spattering or splashing. The remaining three interventions would not present this risk.
2. (2) Standard precaution guidelines dictate that spills be cleaned immediately with 1:10 bleach or according to hospital policy. All of the other answers are incorrect because they do not meet EPA specifications.
3. (2) Isolation protects the immunocompromised child from the environment. The other conditions do not necessarily require isolation.
4. (4) Hand hygiene before giving care and after all diaper changes is an important measure in controlling and preventing the spread of infection. Using sterile technique or antibiotics are incorrect answers, and ill people should not be allowed near infants in the hospital.
5. (2) Placing a container in the home provides the safest means of disposing of contaminated needles. This container needs to be discarded and treated as biohazardous waste when it becomes full or is no longer needed. The needles should not be recapped, disposed of in the trash, or broken.
6. (4) An antiseptic solution is an effective cleansing agent for blood or body fluid contamination. This should be readily available to everyone who is at risk for exposure. Recapping the needle will risk repeated injury and exposure and should never be done (1). Breaking the needle will risk repeated injury and exposure (2). The client will not require gamma globulin, because the needle was contaminated after the injection (3).
7. (2) Standard precautions employ using gloves when touching body fluids containing blood. Gloves are not necessary in this instance. The nurse should continue teaching the nursing assistant by explaining the principles of infection control related to AIDS.
8. (2) There are three primary routes of transmission—contact, droplet, and airborne HAI (nosocomial) infections such as VRE and MRSA are usually caused by poor handwashing or hand hygiene technique by health care workers who move from client to client.
9. (4 3 2 1) The surface below the waist level is considered contaminated; therefore, you would untie the strings before removing gloves, which is the next step. The third step is to take off your mask; then you would perform hand hygiene.
10. (3) Take only needed supplies from bag and place on clean surface.

CHAPTER 15—DISASTER PREPAREDNESS—BIOTERRORISM

1. (2) Research has shown that the triangle of safe space is beside a car or large piece of furniture. If it collapses, you will not be under it, but it will still provide you with some protection.
2. (2) The correct answer is an event of great magnitude that overwhelms current resources. The other answers are all characteristics.
3. (4) Biological agents (bacteria, viruses, or toxins) are the most difficult to identify because they have an insidious onset and symptoms may take days to develop. A nuclear attack and sarin gas would be more readily discovered, and smallpox, after an incubation period, would be easily identified by the skin eruptions.
4. (3) A person can absorb anything under 0.75 Gy and not experience radiation poisoning. If a victim absorbs between 0.75 and 8 Gy, he or she may develop acute radiation syndrome (ARS). A person who absorbs over 8 Gy will probably die.
5. (1 2 4 5) These are all agents that fall into the category of bacteria, viruses, or toxins that can cause a disease which develops into a mass casualty incident. Radiation poisoning is caused by a nuclear weapon. Sarin gas is a chemical weapon.
6. (1) The 5-level system of triage decreases ambiguity of the middle level of emergency care where the majority of casualties fall; thus, it is much more effective in handling large numbers of victims. The other answers are inaccurate.
7. (2 1 4 3) When setting up a decontamination site, first be sure it is upwind from the contamination. The next step is to find a downhill slope so that runoff can be captured. Finally, find a source of water before

supplying personnel with protection equipment and beginning to decontaminate victims.

8. (4) There are some complications such as eczema vaccinatum that can be helped by VIG. Pregnant women should not be vaccinated. Answers 1 and 2 are complications of smallpox, not helped by VIG.
9. (2) Cyanide is a chemical agent, as is chlorine (a pulmonary agent), mustard and nerve agents (sarin, VX). The other agents are biological.
10. (3) A trace of blood indicates that the needle strokes were vigorous enough to transmit the vaccine into the client. The other answers are incorrect.

CHAPTER 16—PAIN MANAGEMENT

1. (3) The endorphin theory is the most accepted because it explains how the brain produces natural opiates which fit into special cells called receptors. Specificity theory suggests that sensory stimuli send pain impulses to the brain, but this theory only deals with the physiologic, not the psychologic, basis for pain. The pattern theory includes factors not explained by the specificity theory, but is not complete. The gate control theory states that there is transmission of neurologic impulses and gate mechanisms along the nervous system that control the transmission of pain. If the gate is open, pain is experienced. None of these theories, however, adequately explains pain.
2. (1 2 3 5) These are the four main factors to measure pain. Pain pathway cannot be measured, and the amount of medication needed is an indication, but not a specific measure, of the degree of pain.
3. (2) The rationale for including pain as a vital sign is that it will be assessed and documented at the same time vital signs are taken. This is important, for if the level of pain is neglected, the client's condition/safety is in jeopardy. (1) and (3) may be correct but do not adequately explain the rationale. (4) is incorrect.
4. (1) Most of the nonpharmacological methods are totally noninvasive, and thus are safer and have fewer complications than pharmacological methods. The other statements are incorrect.
5. (4) The priority safety issue is to be sure that the epidural catheter is not mistaken for an IV line. A sign must be posted over the client's bed and the catheter must be labeled clearly as an epidural catheter. All of the other issues are a concern, but they would not result in fatality.
6. (2) In order to use this method of pain control, the client must be mentally alert and able to follow the procedure instructions, because the client is in control of the narcotic administration. (1) and (3) will be part of the total assessment criteria, but not the priority assessment. (4) is incorrect because this method is commonly used for chronic pain.
7. (3) The correct intervention is to determine that the client is sedated and, because the goal of PCA is to control pain without sedation, notify the physician for new dose parameters. The other answers are incorrect.
8. (1 2 4 5) All of these answers are common dangers and should be avoided. Poor pain relief results are not a common occurrence because drugs and dosage parameters are designed for individual client pain control with the client administering the narcotic.
9. (4) Administration of an epidural must only be done by an RN and may not be delegated to a nonprofessional staff member. In many hospitals, the RN must have special certification because of the safety issues involved with this procedure.
10. (3) The preventive approach to pain control includes administration of the medication before or soon after pain begins. Smaller, more frequent doses of medication will control pain better than larger doses taken less often.

CHAPTER 17—ALTERNATIVE THERAPIES AND STRESS MANAGEMENT

1. (1 2 3 4 5) All of the above are signals of stress. Fatigue and eating disorders fall into physiologic signals; anxiety and anger are psychologic signals, and restlessness is a behavioral indicator.
2. (4) The most complete definition is to consider all aspects of a person relating as an open system. (1) and (2) are accurate, but not complete. (3) is inaccurate.

3. (1) Herbal medicines are one of the most frequently used alternative treatment modes. They are much more frequently used in other parts of the world than in the United States. The other alternative practices are used, but not as frequently as herbs.
4. (1 2 3 5 6) The only adaptation factor that does not influence how the individual adapts to stress is religion. The other factors all influence these patterns.
5. (2) This is a positive suggestion for coping with stress. All of the remaining answers are exactly the opposite of a therapeutic suggestion.
6. (1) More and more research is showing that diet/nutrition is a major contributor to health and the prevention of disease. Although nutrition may influence how long we live, there is no research proving this (2). (3) and (4) may also be true, but again there is no research proving it.
7. (3) This is the most open-ended response and does not place the nurse in legal jeopardy. (1) and (2) close off communication. (4) may result in legal problems, as it may be viewed as practicing medicine.
8. (3) Stress can be controlled and coped with by a variety of methods, including physical activity and relaxation methods such as deep breathing and meditation, not just one, changing thought patterns. All of the other answers are correct and fit Selye's definition of stress.
9. (4) Although there are many signals of stress, including physical, psychologic, and behavioral, often they are difficult to identify in the client because many of them are subtle (for example, lack of interest in life, lack of concentration, irregular heartbeats). All of the other statements about stress are correct.
10. (2) Sitting quietly, clearing the mind, and deep breathing or meditation are the best methods for destressing. The other methods listed may work for certain individuals, but they have not proven to be as effective.

CHAPTER 18—MEDICATION ADMINISTRATION

1. (3) Surveys have found that administering the wrong dose is the most common cause of injury. Route is seldom erroneous, the medication usually validated, and the client identified correctly.
2. (2) The physician would be the authority to clarify rationale for the particular medication's use based on the individual client's need/condition.
3. (4) Systolic pressures less than 90 mm Hg may be associated with decreased cardiac output or orthostatic hypotension.
4. (3 4) Alterations for oral medication administration that are acceptable include mixing liquid from capsules with food and administering sublingual tablets to a client who is NPO.
5. (1) Rapid absorption of drops such as beta blocking agents used for glaucoma can cause serious bradycardia. Pressing the inner canthus helps prevent this adverse effect.
6. (1) For adults, upward and backward pull straightens the ear canal.
7. (2 4) The anterior superior spine of iliac crest and greater trochanter are identified by using the nurse's right hand for client's left hip, or left hand for client's right hip. The acromion process is a landmark for deltoid injection and the posterior superior spine of iliac crest is used for dorsogluteal injection. The gluteal fold is not a bony landmark and is not used to identify any injection site. The upper outer quadrant of the buttocks relates to soft tissue rather than bony landmarks, is highly variable among clients, and is totally unreliable for predicting location of underlying nerves and blood vessels.
8. (3) It is not uncommon for active ingredients to be depleted while propellant remains in the canister.
9. (2 1 4 3) The cloudy insulin should never contact the clear insulin, as it would cause the clear insulin remaining in the vial to lose its intended short action.
10. (4) Pump, tubing, or needle malfunction results in failure to deliver insulin and causes risk of diabetic ketoacidosis due to elevated blood sugar.

CHAPTER 19—NUTRITIONAL MANAGEMENT AND ENTERAL INTUBATION

1. (1) Transfats are polyunsaturated and monounsaturated fats that have an additional hydrogen molecule added to make the fat more saturated.

2. (2) The kidneys are the major organs for potassium excretion, so potassium intake is restricted in clients with renal failure. The other clients listed would all require an increased ingestion of potassium-rich foods or a KCl supplement because their health conditions are associated with potassium loss.
3. (3 4) Swallowing liquids, ingesting liquids and food together, or use of a straw or syringe all increase the dysphagic client's risk of aspiration.
4. (4) The blue "pigtail" allows atmospheric pressure to enter the stomach to counteract the negative pressure suction at the NG tube tip. It thus prevents the decompression tube from adhering to the gastric mucosa, which would interfere with gastric content suctioning.
5. (2) Postoperative intestinal motility is regained first by the small intestine. Bowel sounds may be present, but gastric and large bowel motility may be absent. Presence of appetite, no abdominal distention, having flatus, and bowel movement are reliable indicators of the return of bowel function.
6. (3) Since the pH of aspirate is altered because of formula presence, the best way to verify placement is to note the character of the formula aspirated; it should be curdled or bile tinged.
7. (4) Tube feeding may be continued cautiously with close client monitoring if the residual volume is ≥ 200 mL. Further client assessment is indicated if the residual volume is ≤ 200 mL. The stomach may hold from 10 to 200 mL of gastric fluid normally.
8. (3) The tube should be flushed with warm water every 4–6 hours and before and following medication administration using a gentle push/pull technique. The tube should not require replacement for 4 weeks. Acidic juices or cola curdle feeding formula will increase the incidence of clogging.
9. (3) Positioning has no beneficial effect on feeding tube advancement. The guide wire should never be replaced once removed. Administration of a prokinetic agent *before* tube insertion is the most effective intervention to promote tube advancement.
10. (3) Feeding through a surgically created tube enterostomy reduces risk of aspiration, eliminates nasal irritation, is low profile, and facilitates independent feeding.

CHAPTER 20—SPECIMEN COLLECTION

1. (1) The critical factor is to rinse the mouth before obtaining the sample. The best sputum sample is obtained before eating or drinking (2). Several deep breaths may trigger the cough reflex and raise sputum from the lungs (3). An expectorant could contaminate the sample. Chest physiotherapy is most helpful in mobilizing secretions prior to collection (4).
2. (3) Standard precautions dictate that you should wear gloves during collection of a blood specimen. IV fluid may alter the specimen (1). The skin should be cleansed with an antimicrobial wipe followed by povidone-iodine swab or use hospital policy (2). Contamination of the sample may occur if the needle is used (4).
3. (4) Ova or cysts may not be revealed in the presence of heavy metals. Barium, oil, or laxatives containing heavy metals should not be given for 7 days prior to the stool examination. The time of day to collect specimen does not matter (1). Clean catch is used to collect urine samples (2). Sample should be examined within 30 minutes and kept at body temperature to find organisms in their active state (3).
4. (3) Guaiac is used to test for occult blood in the stool that could be a sign of upper GI bleeding or cancer. A stool culture is used to detect bacteria (1). This test does not test for fat in the stool (2). A paddle test is used to determine presence of pinworms (4).
5. (3) Check with the laboratory because, based on the amount lost, time of loss, and the test to be performed, the collection may be able to be completed as scheduled. You would not stop or extend the collection. Reinforcing to the client to save urine would be done if the test is to be repeated (4).
6. (2) Urine is normally clear, not cloudy—this could be indicative of an infection. Light yellow is the normal color (1). You require at least 30 mL for an adequate sample (3). Urine is normally odorless (4).
7. (4) Cleanse the site with an antimicrobial wipe and allow to dry is the correct technique, because bacteria on the skin surface are reduced if the

skin is allowed to dry. The tourniquet should be 1–2 inches above the client's elbow (1). The client should relax the fist and the tourniquet should be released before the needle is removed (2). Bending the elbow could cause a hematoma, so this is incorrect (3).

8. (4) Allen's test should precede arterial puncture to determine the adequacy of collateral perfusion. Hyperextension of the wrist will stabilize the radial artery (1). Drawing back on a syringe can cause air bubbles to fill the syringe, and inaccurate ABG results will occur (2). Pressure should be maintained for 5 to 10 minutes to prevent bleeding.
9. (3) Adding blood to the strip can cause an erroneous reading. If the meter does not show enough blood, remove the strip and begin again. This is correct—the lancet should be on the lateral side of the finger because it is less painful and prevents bruising (1). Soap and water is best for repeated sticks—alcohol can toughen the skin (2). Stroking gently increases blood flow—squeezing or applying pressure can interfere with blood flow (4).
10. (1) True because recent antibiotic or antifungal therapy may lead to false negative results. Large wounds should have separate cultures taken from different areas with a new swab (2). Specimens should be sealed in a biohazard bag (3). Specimens should not be refrigerated—they should be transported to the laboratory within 30 minutes (4).

CHAPTER 21—DIAGNOSTIC PROCEDURES

1. (2) Nursing actions listed in (1), (3), and (4) are important nursing interventions, but they do not necessarily have to be completed by the nursing staff assisting the physician with interventional radiology.
2. (1) Answer (2) is related to ultrasound procedures. (3) refers to endoscopic procedures, and (4) represents the results from an MRI.
3. (3) Each x-ray has specific restrictions to food or fluids. The other interventions would be completed during preparation for x-ray studies.
4. (2 3 4) All are appropriate instructions to provide for a client having an IVP performed. (1) is incorrect. Fluids are withheld up to 12 hours. No fluids are to be taken the morning of the study.
5. (3) It is important to have a baseline value to determine potential bleeding tendencies and kidney function.
6. (1) Barium falsely increases density of the lumbar spine, therefore an inaccurate reading will be given. The client may feel embarrassed to ask a question because he did have the test before. (3) The client is not placed in a scanning machine for the test; therefore, being claustrophobic is not relevant. (4) There are no complications from the test; therefore the client will not need assistance in getting home.
7. (2) There is no need to fast or be NPO for the mammogram (1). (3) Jewelry needs to be removed from around the neck only. (4) Only the upper clothing, including the bra, needs to be removed.
8. (1) It is imperative to stop the bleeding with a pressure dressing. Then (3) elevate the extremity. (2) It is not a priority to call the lab at this time. Monitoring peripheral pulses is included in postprocedure care.
9. (2) PET scans are very useful to study seizure activity and determine spread of cancer cells because metabolic changes occur before structural changes. 60% of invasive tests or surgeries can be eliminated using the PET scan. Radioactive chemicals are administered to clients (1). PET scans can take up to 75 minutes (3). Foods and fluids are restricted for 4–6 hours (4).
10. (4) Most clients require only a local anesthetic for the procedure (1). (2) The procedure takes less than 2 hours to complete. (3) Only small incisions, large enough to accommodate the scope, are made around the knee.

CHAPTER 22—URINARY ELIMINATION

1. (1) Urine production is directly related to the amount of blood pumped by the heart (cardiac output). A decreased cardiac output decreases renal perfusion and urine production and causes fluid retention and weight gain.
2. (2 4) Pregnancy and the presence of a catheter deflect ultrasound signals, thus interfering with urine volume determination by scanner.

3. (4) The male urethra is long. As the catheter is inserted, some nurses can feel a change as it passes through the prostatic urethra and enters the bladder.
4. (2) The female urethra is quite short. This renders females more susceptible to urinary tract infection.
5. (3) Bladder spasm and UTI may cause leakage around the retention catheter. Use of a larger catheter only increases bladder spasms and discomfort.
6. (1 3 5) Physicians may need to be reminded that the client has a retention catheter and long-term use is associated with increased risk for UTI. Stagnant urine in dependent draining tubing loops promotes bacterial growth and UTI, as does to/fro movement of a catheter that is not properly secured.
7. (1) Continuous bladder irrigation dilutes postoperative bleed and thus prevents clots from forming, as they could occlude the catheter drainage system.
8. (1) Protective barriers contain alcohol, may interfere with pouch sealing, and must be removed with a solvent that increases risk of skin irritation.
9. (2) The term end stage renal disease (ESRD) only indicates that the client is receiving renal replacement therapy (dialysis or transplant).
10. (1) Continuous vascular access is critical for the hemodialysis client. Clotting is the biggest cause of access failure. Stasis of blood flow due to vascular occlusion or constriction in any manner must be avoided.

CHAPTER 23—BOWEL ELIMINATION

1. (1 2 4) The MRI is usually not ordered to rule out issues with fecal incontinence (3).
2. (2) If you were present when the physician discussed the procedure with the client, you can reiterate the information (1). Giving this answer can upset the client as they think something is wrong, (3) and (4) are incorrect information.
3. (1) There is greater fluid loss with an ileostomy as a result of a more liquid stool. The fluid is not reabsorbed into the body as the ileum is resected. Clients with an ileostomy will also need to wear an appliance (2). Many clients with a colostomy do not need an appliance. (3) An ileostomy is usually performed as a result of Crohn's disease or ulcerative colitis, and the ileostomy for these conditions is not reversed. (4) There are fluid and food restrictions.
4. (3) Vagal stimulation as a result of fecal removal can lead to decreased pulse rate resulting from decreasing conductivity at the sino atrial node. (1), (2), and (4) are not completed before the removal occurs. Laxatives can be ordered after the removal to prevent another impaction. Fluids are infused into the lower colon prior to removal. An enema usually precedes the fecal removal, but it is not done just prior to the removal.
5. (4) is correct. Placing the pointed end of the suppository 3–4 inches beyond the internal sphincter will prevent expulsion of the suppository. The client is placed in a Sims position and the suppository is inserted beyond the internal sphincter (1). The client is not asked to bear down when inserting the suppository. (2) The pointed end of the suppository is generously lubricated and then the pointed side is inserted first for ease in passage through the external and internal sphincters. (3) If the suppository is inserted into fecal material, it will not dissolve.
6. (1 2 3) All are contraindications for the use of the BMS system. (4) A history of severe diarrhea is the condition for which the system is utilized.
7. (2 3 1 4) The correct sequence for inserting a BMS system.
8. (2) The client is placed on the left side in a Sims position (1). (3) The height is 18 inches above the rectal area. (4) Solution is instilled slowly to prevent cramps.
9. (2) is correct. The skin and stoma are cleansed with water. Oily substances and soap can prevent good adhesion of the pouch to the skin. The other three distractors are correct steps in applying a fecal ostomy pouch.
10. (3) is correct. Only an RN or an LVN/LPN can administer an enema with medications. Nursing assistants cannot perform a fecal impaction removal (1). The client can have cardiac complications that need to be assessed by an RN or LVN/LPN. (2) Many health care facilities allow UAPs to perform enema administration. (4) An LVN/LPN cannot develop a teaching plan, but he/she can implement a plan.

CHAPTER 24—HEAT AND COLD THERAPIES

1. (1) Internal stimuli (pyrogens, cytokines) cause the hypothalamus to alter the body temperature set point; therefore, a *regulated* rise in temperature occurs.
2. (3) Fever is caused by pyrogens.
3. (3) Shivering muscle activity increases heat production, thereby counteracting the goal of treatment to reduce body temperature.
4. (3) This water temperature is regulated as a safety measure.
5. (1) The surgical client would lose body heat to the environment by radiation because the surgical suite environment is cooler.
6. (1) Sugar-free and caffeine-free beverages are most appropriate for rehydration due to heat-induced dehydration.
7. (2 4 6 7) Flushing, anesthesia, burning, and numbness are expected effects of cryotherapy applications. Therapy should be discontinued on numbness. Pallor and blister formation are adverse effects.
8. (1) The sitz bath causes pelvic vasodilation with diversion of blood flow that could potentially result in orthostatic hypotension on standing.
9. (4) Nerves are sensitive to cold application and are most superficial around joints.
10. (1) Tissue metabolic demand increases as it is heated. If circulation is compromised, the tissue's need for oxygen will exceed what the circulation can provide.

CHAPTER 25—WOUND CARE AND DRESSINGS

1. (3) During the regeneration phase of wound healing, there is rapid growth of epithelial cells to produce a protective covering for a wound. The third phase, maturation (1), is the period when wound contraction takes place. The first phase, inflammatory (2), occurs immediately after an injury. Wound remodeling (4) is another term for maturation.
2. (4) Wounds heal by being left open, such as an infected wound or one that has dehisced. (1) refers to secondary intention. (2) is primary healing. (3) refers to a primary incision.
3. (2) 30–35 Cal/kg/day is required for adequate wound healing.
4. (1) This method is used to decontaminate hands using an alcohol rub. (2) The rub is completed until the alcohol dries, usually 15–25 seconds. (3) Longer times for hand scrubs are associated with the first OR scrub of the day. (4) Alcohol rubs do not require drying hands with a towel.
5. (3) The last flap of the wrapper is placed directly in front of the table nearest the nurse to prevent crossing over the sterile field. The first flap of the wrapper is placed away from the sterile field.
6. (2) Clean gloves are used (1). It is not necessary to use sterile gloves. (3) Curved tip of scissors are used and the cut is next to the knot. (4) Sutures are removed starting at the top or bottom of the incision.
7. (1 2 3) An advantage for the use of hydrogel dressings is (4).
8. (3) is correct. Wounds are not cleansed with hydrogen peroxide (1). (2) and (4) are not correct methods for obtaining a wound culture.
9. (2) After fluffing dressings, a moist dressing is placed over the wound.
10. (1 2 3) These three conditions must be present, as well as sufficient circulation to assist in healing.

CHAPTER 26—PERIOPERATIVE NURSING

1. (3) A moderate sedation would not be provided in the preoperative stage. This drug is usually administered during the intraoperative stage. The other three distractors are all activities that will be performed during the preoperative stage.
2. (4) The physician and the entire operative team identify the correct side and site. The anesthesiologist inserts the IV if it is not already in place (2). The scrub nurse assists the physician throughout the surgical procedure (3).

3. (1) Nurses, both scrub and circulating, monitor sponge and instrument counts before, during and after the procedure. The entire OR staff participate in checking the side and site of the procedure, not just the nurses (2). (3) and (4) are not common malpractice actions taken against nurses.
4. (1 2 3 4) All distractors are correct. All of these interventions can and should be used to reduce anxiety in a preoperative client.
5. (1) Sharp pain under the scapula post-operatively is indicative of carbon dioxide irritation of the phrenic nerve in the diaphragm, causing the referred pain. Very infrequently is a client with a laparoscopy hospitalized to monitor pain, unless there is some extenuating circumstance (2). (3) Usually a stronger acting pain medication is administered for pain following any surgical procedure. (4) Most clients do not return to work the next day; the recovery time for anesthesia is longer than 24 hours.
6. (4) Check for allergies to latex, food, and medications. All latex articles must be removed from the OR, and this client should be scheduled as the first OR case for the day. (2) and (3): The surgical consent form must be signed before the preoperative medication is given. The medication is usually given at least 45 minutes before the OR transporter arrives to take the client to the OR.
7. (3 4) The surgical site is marked by the person performing the procedure (1). All members of the surgical team verify the site (2).
8. (3) A score of ≤ 9 or ± 1 point of the pre-procedural score on the Aldrete Scale must be obtained before the discharge is completed. (1) and (2) are scales used for sedation assessment parameters during the use of moderate sedation. (4) is used for assessing clients who have head injuries or who are not alert.
9. (4) The initial assessment/intervention is to assess for patent airway. If the client is experiencing difficulty breathing, color is pale, skin is cool, oxygen must be administered and the head of the bed slightly elevated. The other interventions should immediately follow this initial assessment and intervention.
10. (2) is correct. Pulmonary complications are usually evident 24–36 hours after surgery. Signs and symptoms of an ileus occur between 24–36 hours postoperatively. Urinary tract infections occur from the third to the fifth post-operative day. Wound infections can occur from 24 hours to 5 days post operatively.

CHAPTER 27—ORTHOPEDIC INTERVENTIONS

1. (1) Positioning the hand higher than the elbow prevents dependent edema in the hand.
2. (4) Natural evaporation allows the cast to dry from inside out. External heat application may cause the cast to dry on the outside but not the inside, causing the cast to weaken.
3. (1 2 6) The selected items are features of synthetic casts. Additionally, they are lighter in weight, but provide less stability and can cause skin burns when drying is activated.
4. (2 4 6) These are early indicators of ischemia. Elevating the extremity worsens ischemia and pain. Pain is out of proportion to the injury and unrelieved by pain medication.
5. (3) Peroneal nerve motor function provides dorsiflexion of the foot. Peroneal nerve injury can result in permanent foot drop.
6. (2) Adduction or leg crossing may cause implant dislocation.
7. (1) Adaptive aids help prevent extremes of flexion that could result in implant dislocation.
8. (5) Studies show that all of the above are increased with CPM.
9. (4) Phantom pain is thought to be a central nervous system response to stored pain sensations from the previously intact limb.
10. (3) Clients have the tendency to abduct and flex the stump postoperatively. Adduction and hip extension exercises help prevent flexion contracture of the stump and help prepare the stump for walking with a prosthesis.

CHAPTER 28—INTRAVENOUS THERAPY

1. (1) Ringer's lactate solution does not require an in-line filter. The other three distractors require the filters in order to filter out microorganisms

and guard against inadvertent infusions of particulate matter, and endotoxins.

2. (4) Using the distal end of the vein reserves the more proximal areas for future IV sites. Superficial veins are palpated and used for peripheral IVs (1). The antecubital vein is not a primary site for IV placement (2). It is used as a last resort. The catheter can become kinked when placed in this area. (3) IV fluid flow will be affected if the IV is inserted in a site below the same vein that is infiltrated or where phlebitis is present.
3. (1 2) A warm cloth is applied to produce vasodilation that assists with insertion of the IV catheter or needle (3). The arm is placed in a dependent position to prevent venous dilation (4).
4. (4) Chlorhexidine swabs are recommended by the Intravenous Nurses Society to prepare the IV insertion site. The other three products have been used in the past; however, evidence-based nursing practice has identified they are not as effective as chlorhexidine.
5. (4) Primary and secondary tubing is changed every 72 hours (1). Primary intermittent tubing is changed every 24 hours (2). TPN and lipids are changed every 24 hours (3).
6. (2) The bevel of the needle is in the up position in order to check the integrity of the end of the catheter (1). (3) The needle is inserted along the side of the needle or about 1/2 inch distal to selected puncture site. (4) After hearing the “pop” sound, check for backflow of blood in the plastic hub.
7. (2) The answer is 15 mL. To review regulating flow rate and determine the IV drops/min. See p. 1090.
8. (3) The pump needs to be reprogrammed with the scanning device. The medication, client's ID, and nurse's ID badge are all rechecked. The pump cannot just be restarted when a “hard” alarm sounds, as this indicates that an error in the drug, dose, or equipment has occurred.
9. (4) Hypotonic solutions are (1) and (2). They hydrate cells and are used to correct dehydration. Hypertonic solutions such as dextrose 10% can be used as a nutrient source (3).
10. (3) One fourth of the medication is injected over a 20-second time period; therefore it takes a minimum of 80 seconds to administer the drug (1). Always check the package insert for the time frame. (2) Flushing of the IV tubing is done when an incompatible drug is being administered. (4) Check the drug compatibility chart to determine the appropriate IV solution that is acceptable for infusing the drug.

CHAPTER 29—CENTRAL VASCULAR ACCESS

1. (1) PICC lines and subcutaneous ports and central catheters are termed central vascular access devices. They can be left in place for longer periods of time and with fewer complications.
2. (1 4) Both are correct statements related to preventing catheter-related bloodstream infections. (2) is incorrect. (3) is incorrect, 2% chlorhexidine with 70% alcohol solution is used as the antibacterial scrub.
3. (1) is the time used when the swab contains chlorhexidine and alcohol. (3) is the time necessary for drying povidone-iodine, and chlorhexidine alone. (4) is the time a 70% isopropyl alcohol solution is used.
4. (3) This is the change time for IVs for infusing parenteral nutrition and for primary and secondary IV tubing changes. The time for changing tubing when lipids are infusing is (1).
5. (4) A plugged filter is the most common problem that occurs when the solution is not infusing at the prescribed rate. If the hyperalimentation flow rate is not infusing at the prescribed time, you do not “catch up” by increasing the flow rate (1). This can lead to hyperglycemia as a result of increasing the amount of glucose from the IV solution. (2) Before notifying the physician, a complete assessment of the situation must occur in order to make an informed decision. (3) It is rare that the dressing is too tight to cause an occlusion of the IV flow.
6. (1 3 2 4) These are the steps in obtaining a central venous pressure reading. Refer to the skill if you missed this question (p. 1144).
7. (3) The port is inserted for long-term care, usually for clients receiving chemotherapy intermittently. The port is irrigated monthly and after each use. Normal saline is used in flushing and followed by heparin infusion.

8. (2) After stopping the IV infusion, the next step is swabbing the hub and cap with an antimicrobial swab. Then the cap is removed (3) and the syringe is flushed with normal saline (4).
9. (3) The port is swabbed with chlorhexidine. After anchoring the port site, the Huber needle is inserted at a 90-degree angle. Check for blood return, and if it is present, the drug can be infused, followed by first infusing normal saline followed by a heparin solution.
10. (4) This creates a positive pressure within the central venous access device, preventing blood from being drawn back into the catheter when the syringe is removed.

CHAPTER 30—RESPIRATORY CARE

1. (4) Slow inhalation maximizes volume; holding allows alveoli to open; and exhalation through pursed lips prevents early airway closure.
2. (2) Only those with serious retention of secretions have been found to benefit from CPT.
3. (2) The sedated client may not be able to remove the mask in the event of nausea and vomiting; there is dangerous risk of aspiration of emesis.
4. (4) The nonbreathing mask with reservoir bag provides the greatest FiO_2 because the client inhales enriched air from the mask as well as the bag and does not rebreathe exhaled air.
5. (1 3 5) Pulse oximetry measures are not reliable in anemic clients because the decreased number of RBCs may be fully oxygenated; hypovolemic clients may be vasoconstricted; and circulating contrast can also confuse readings.
6. (2) Intubation provides a patent airway whether or not mechanical ventilation is necessary. It does not prevent aspiration and is not essential for providing oxygenation unless mechanical ventilation is used.
7. (4) A tube cuff does not prevent aspiration of secretions or food, but its inflation is necessary for ventilated air to enter the lower airways and lungs.
8. (3) This tracheostomy tube inflates passively (automatically) but must be deflated actively using a special syringe with stopcock to extract air from the cuff.
9. (2) If the tube cuff remains inflated and the tube is capped with a speaking valve, the client is unable to inhale air because both the artificial airway and the trachea are occluded.
10. (5 3 1 6 4 8 7 2) This sequence reflects necessary preparation before sterile steps are taken. Hyperoxygenation is performed before sterile equipment is handled; the catheter is advanced before suction is applied. Finally, the oropharynx is suctioned using the same catheter.

CHAPTER 31—CIRCULATORY MAINTENANCE

1. (3) The QRS complex represents the depolarization of the ventricles. Atrial depolarization is represented by the P wave. The PR interval represents the conduction time in the atria. The T wave represents ventricular repolarization.
2. (1) The SA node sends an abnormal rate of impulse generation. A normal cardiac impulse begins in the sinoatrial node. It is transmitted over myocardium; Bachman's bundle, and internodal pathways to the AV node. If there is a disturbance in this transmission, it results in an atrial dysrhythmia.
3. (3) Demand pacemakers are the most frequently used pacemakers. The electrode is triggered to stimulate the heart only when the heart's intrinsic or natural atrial or ventricular pacemaker stimulation fails.
4. (1) The urine output of 30–40 mL/hour is a normal value. When hemorrhaging occurs, the urine output will decrease because of decreased cardiac output as a result of the hemorrhage. The other distractors would be observed when hemorrhage occurs.
5. (1) After moving the client to a flat, firm surface, the next step is to begin compressions at 100/minute. The AED is used only if the client does not have a pulse.
6. (3) The appropriate thigh-hi measurement is from the bottom of the heel to the fold of the buttocks. The circumference is measured at the mid-thigh area, not the largest area of the calf (1).

7. (2 4) The use of compression devices would be contraindicated in diabetic neuropathy ulcers and arterial ischemia ulcers as well as dermatitis, gangrene, and preexisting pulmonary embolism.
8. (3) If the client can speak, you continue to allow them to cough as they should be able to expel the foreign body. The abdominal thrust is completed if the client cannot talk or coughing becomes ineffective (1).
9. (2) Frequency of the contractions are every 40–90 seconds. The contractions are mild in intensity and last 30–50 seconds. (4) is indicative of variable decelerations, (1) is indicative of early decelerations.
10. (2) The Rapid Response Team is utilized when a client is in danger and an avoidable death can be prevented by appropriate interventions. The client may be transferred to the ICU, but this is not the primary purpose of the team (4). CPR is performed by the team, but again, this is not the purpose of the team, as the nursing staff can initiate CPR as well (1).

CHAPTER 32—NEUROLOGICAL MANAGEMENT

1. (C) To determine the cerebral perfusion pressure, the ICP is subtracted from the MAP. The MAP is calculated by adding the SBP plus 2 times the DBP, divided by 3 ($130 + 160 = 290$, divided by 3 = 97). The ICP is 12, so 97 minus 12 = 85. This is an adequate cerebral perfusion pressure.
2. (3) An intracranial pressure of 12 is normal. Therefore, there is no increase in any one of the three intracranial components, or normal pressure has been activated by manipulation of one of the components to compensate for an increase in one of the other components.
3. (1) Frontal lobe dysfunction affects contralateral voluntary motion, and causes changes in personality and behavior.
4. (4) Signs of metabolic coma are usually diffuse, rather than unilateral, with coma preceding motor deficits and without orderly rostrocaudal deterioration, as seen with structural causes. Pupil reflexes are preserved bilaterally, while structural causes of coma are usually associated with a unilateral nonreactive pupil.
5. (3) Of the listed options, only hypoxemia (low blood O_2) causes cerebral vessels to dilate and increase intracranial pressure, making ventilation a priority. Hypocapnea (hyperventilation) constricts cerebral vessels, and may be used briefly to reduce intracranial pressure. Acidemia (rather than alkalemia) causes cerebral vessels to constrict. Hypothermia does not affect cerebral vessels, but is used therapeutically to reduce cerebral metabolic demand.
6. (2) Pupil response (constriction to light) is controlled by CN III (oculomotor nerve) whose nuclei are attached to the midbrain. The nerve's location at the top of the brainstem is the first to be compressed, as intracranial pressure increases, resulting in sluggish or absent pupil response to light.
7. (1) While changes in respiratory pattern accompany neurologic deterioration, they are not specific to neurologic dysfunction. For instance, Cheyne-Stokes respirations occur in clients with heart failure and other systemic disorders. As ICP increases, neurologic deterioration progresses rostrocaudally, the diencephalon (above the brainstem) is compressed, causing impaired consciousness. This occurs before changes due to compression on the midbrain (pupil response) or alterations of blood pressure and heart rate occur. Additionally, changes in vital signs accompany many pathologic conditions.
8. (2) The ventriculostomy is the most cost-effective, accurate and reliable method of monitoring ICP. It is the only method that includes an external drainage system and transducer calibrated or zeroed against a known pressure to ensure consistent and accurate pressure measurements. The indwelling ventricular catheter allows CSF drainage to decrease ICP, is used for medication instillation, and provides access to CSF for laboratory testing.
9. (4) The P-1 waveform reflects systolic BP pulsations transmitted through the choroid plexus and is normally the highest of the 3 waveform components, while the P-3 is the lowest. The P-2 waveform reflects relative brain volume, and is often elevated in response to compromised intracranial compliance.
10. (2) The electroencephalogram is the most commonly used confirmatory test, assessing only cerebral, not brain stem function. The client must have at least 30 minutes without brainstem electrical activity. With brain death, there is absence of intracerebral blood flow from the carotid arteries and circle of Willis.

CHAPTER 33—ADVANCED NURSING SKILLS

1. (2) The distal lumen (placed in the pulmonary artery) measures pulmonary artery systolic and diastolic pressures and, when “wedged,” indirectly measures the left ventricular end diastolic pressure.
2. (6 7) Because not all chests are equal, this is the most accurate way to determine the level of the right atrium in the supine position.
3. (3) Cannulation of the radial artery can result in inadequate blood flow distally. The Allen test is used to assess adequacy of distal perfusion through the ulnar artery before radial artery cannulation.
4. (1) Obtaining arterial blood samples using the conservatory system eliminates the need to waste blood that contains the continuous flush solution, therefore helping to prevent nosocomial anemia.
5. (2) Because atrial fibrillation is frequently recurrent (chronic), the client continues anticoagulation therapy (Coumadin) to prevent cardioembolic stroke.
6. (1 3) These lethal rhythms require immediate defibrillation to convert to sinus rhythm. The others require cardioversion or administration of fluids/medications.
7. (3) A functioning electrical system and a responsive pump in the presence of hypovolemia will produce an ECG without peripheral perfusion (pulseless electrical activity).
8. (4) This mode provides total support. It is used for the client who cannot initiate or who for a clinical situation should not initiate breathing.
9. (3) Asynchrony leads to wasted energy; this is especially important in infants.
10. (1) Accumulation of oropharyngeal secretions above the tube cuff is associated with aspiration of secretions that leads to ventilator-associated pneumonia.

CHAPTER 34—END-OF-LIFE CARE

1. (4 1 5 2 3) This is the sequencing for the stages of dying. Refer to the “Stages of Grief” in the chapter if you did not get this answer correct.
2. (2) The third stage of grief is the beginning of the onset of cultural and religious rituals that assist the mourner to face the loss. The stage of idealization is (1). (3) is the first stage of shock and disbelief. (4) is the stage of resolution.
3. (3) We continue to provide alternative and nontraditional care to improve the client’s quality of life (1). (4) Nurses should be sensitive to the need of family members and should encourage visitation as they desire.
4. (2) Clients requiring rehabilitative services are placed in a rehabilitation unit/facility or long-term care facility (1). (3) Unless the client is terminally ill, he/she would be cared for in a long-term care facility or at home. (4) Treatments can be provided with hospice care.
5. (3) Acting out and verbalizing anger is expected to occur during the anger stage of the process (2). (4) The client should be encouraged to take as much control as possible over his/her care and environment during this phase.
6. (2) This provides a connection with family members or memories of happy times. Clients should be placed in a calm environment, not near the busy nursing station and all the noises (1). (3) It is best to allow clients to look out windows and see activity around them, unless the client requests that curtains be drawn. (4) Lighting in the room should be muted and soft without overhead lighting being turned on.
7. (1) About 40% of Caucasians are more likely to have written advance directives. Other cultures have a distrust of the United States health care system and will not write advance directives.
8. (1) The drugs in (2) are used in Step 1 for pain control that is used for mild to moderate pain. (3) Step 3 utilizes opioid drugs at higher doses for moderate to severe pain. (4) Methadone is used in step 3 for moderate to severe pain.
9. (1 2 4) Nurses need to allot adequate time not only for physical care but time for just talking to the client (3).
10. (1) Some cultures keep adverse diagnoses regarding end-of-life care from the client. Family members discuss the treatment plan with physicians, without input from the client.

Removing Sutures 901
Removing the PICC 1156
Restricting Dietary Carbohydrates 643
Restricting Dietary Fat 643
Restricting Dietary Protein 643
Restricting Mineral Nutrients (Sodium, Potassium) 643
Selecting the Educational Setting 124
Serving a Food Tray 649
Setting Up and Maintaining a Disposable Water Seal
Chest Drainage System 1215

Shampooing Hair 215
Shaving a Client 220
Shrinking/Molding the Stump 1040
Sterilizing Non-disposable Medication
Equipment 1376
Stopping Bolus, Loading, or PCA Dose 538
Suctioning Using Multi-Use Catheter in
Sleeve 976
Suctioning Using Single-Use Catheter for
Tracheostomy 1205
Suctioning with Closed Suction System 1199
Support Surfaces and Specialty Beds 200
Supporting the Client Near the End of
Life 1372
Supporting the Family or Caregiver 1302
Taking an Apical Pulse 261
Taking an Apical-Radial Pulse 263
Teaching Active Range of Motion 382
Teaching Body Relaxation 565
Teaching Care of Implantable
Cardioverter-Defibrillator 1282
Teaching Clients Earthquake Safety 470
Teaching Clients to Communicate with Their
Physicians 72
Teaching Clients to Test for Urine Ketone
Bodies 687
Teaching Controlled Breathing 565
Teaching Coping Strategies 563
Teaching Crutch Walking: Four-Point
Gait 393
Teaching Crutch Walking: Three-Point
Gait 393
Teaching Crutch Walking: Two-Point
Gait 394
Teaching Diaphragmatic Breathing 1169
Teaching for Arthroscopy 970
Teaching for Laparoscopy 969
Teaching for Laser Therapy 967
Teaching for Lithotripsy 968
Teaching for Nuclear Scans 736
Teaching Moving In and Out of Chair with
Crutches 396
Teaching Muscle-Strengthening Exercises 392
Teaching Parents to Test for Pinworms 692
Teaching PCA to a Client 539
Teaching Peak Flow Measurement 1170
Teaching Preventive Measures in the Home Setting 448
Teaching Safer Practices to IV Drug Users 449
Teaching Safety Measures for Oxygen Use 1391
Teaching Swing-To Gait and Swing-Through Gait 394
Teaching Upstairs and Downstairs Ambulation with
Crutches 395
Teaching Use of Incentive Spirometer (IS) 1169
Teaching Use of Oscillating Positive Expiratory
Pressure (PEP) Cough Support Device 1171
Terminating a Nurse-Client Relationship 78
Terminating Hemodialysis 807
Testing for Occult Blood 691
Transferring a Client 93
Transferring Client from Bed to Gurney 357
Transferring Client to Tub or Shower 1371
Transporting Isolation Client Outside the
Room 441
Treating Life-Threatening Conditions 503
Triaging for Chemical Agent Exposure 485
Turning from Supine to Prone 1043
Turning to a Prone Position 352
Turning to Lateral Position 352
