Creating a Floor-Ready Nurse

Instructor Resources—Redefined!

INTRODUCING

Classroom Preparation Resources (Learning Object Gallery)

- **New and Unique!**
Correlation to Today's Nursing Standards!
 - Correlation guides link book and supplement content to nursing standards such as the *2010 ANA Scope and Standards of Practice*, *QSEN*, *National Patient Safety Goals*, *AACN Essentials of Baccalaureate Education* and more!
- **New and Unique!**
Pearson Nursing Lecture Series
 - Highly visual, fully narrated and animated, these short lectures focus on topics that are traditionally difficult to teach and difficult for students to grasp
 - All lectures accompanied by case studies and classroom response questions for greater interactivity within even the largest classroom
 - Useful as lecture tools, remediation material, homework assignments and more!
- **Textbook Resources for Educators**
 - Find assets such as **videos, animations, lecture starters, classroom and clinical activities** and more!
 - **Add selected resources** to presentations that can be shown online or exported to PowerPoint™ or HTML pages
 - Organized by topic and **fully searchable** by type and keyword
 - **Upload your own resources** to keep everything in one place
 - **Rate resources** and view other instructor ratings!

- **Pearson Nursing Question Bank**
- Even **more** accessible with both pencil and paper and online delivery options
 - **All NCLEX®-style** questions
 - **Complete rationales** for both correct and incorrect answers mapped to learning outcomes

Book-specific resources also available to instructors including:

- Instructor's Manual and Resource Guide
- Image library

REAL NURSING SIMULATIONS

- 25 simulation scenarios that span the nursing curriculum
- Consistent format includes learning objectives, case flow, set-up instructions, debriefing questions and more!
- Companion online course cartridge with student pre- and post-simulation activities, videos, skill checklists and reflective discussion questions

Brief Contents

Notice: Care has been taken to confirm the accuracy of the information presented in this book. The authors, editors, and the publisher, however, cannot accept any responsibility for errors or omissions or for consequences from application of the information in this book and make no warranty, express or implied, with respect to its contents.

The authors and the publisher have exerted every effort to ensure that drug selections and dosages set forth in this text are in accord with current recommendations and practice at time of publication. However, in view of ongoing research, changes in government regulations, and the constant flow of information relating to drug therapy and drug reactions, the reader is urged to check the package inserts of all drugs for any change in indications of dosage and for added warnings and precautions. This is particularly important when the recommended agent is a new and/or infrequently employed drug.

The authors and publisher disclaim all responsibility for any liability, loss, injury, or damage incurred as a consequence, directly or indirectly, of the use and application of any of the contents of this volume.

Acknowledgments

Stanford University Hospital

El Camino Hospital

St. John Medical Center, Tulsa, OK

The authors express their thanks to the many people who assisted with the editorial and production phases of this edition of *Clinical Nursing Skills*, with special thanks to Kelly Trakalo, Nursing Editor, and the Team at PreMedia Inc. We especially wish to thank our Developmental Editor, Karen Hoxeng, for support, guidance, and editorial advice. We also thank our photographers, Rick Brady and Celina Burkhart, and models Heather Wright, Wendy Ogden, Virginia Williams, Christine Lieso, Jeff Sevey. In addition, we thank Cathy Patton and June Brown and the Nursing Education Department at El Camino for their consulting expertise, time and support.

The authors also express their sincere appreciation to the hospitals and staff who have so generously offered their assistance and support for our extensive photography in the appropriate clinical environment. We especially thank Stanford University Medical Center, Stanford, CA; El Camino Hospital, Mountain View, CA; Regional Medical Center, San Jose, CA; St. John Health System, Tulsa, OK; Sutter Hospital, Santa Cruz, CA; and Salinas Valley Medical Center, Salinas, CA.

Once again, we thank our families and friends for their encouragement and support while we were preparing this new edition.

Thank You

A special thank you to all of the nurse educators and practicing nurses who have spent their time reviewing and contributing to this new edition.

Preface

A highly acclaimed skills book since its first edition in 1982, *Clinical Nursing Skills* applies to all levels of nursing education. It is also used as a procedure manual by many hospitals systems. Current with both the National Council Test Plan for RN and the NCLEX[®], this textbook offers faculty a format for teaching nursing skill content that is both progressive and innovative. Content flows from the most basic to the more complex skills, and teaches the student how to assess the client, formulate nursing diagnoses, perform the procedure according to accepted and safe protocols, evaluate the outcomes and document the pertinent data.

The content continues to be organized around the nursing process and is both theoretical, as an introduction to the skills, and practical. Within each of the 34 chapters, skills are grouped together into units. Nursing process data is then provided for each unit. Unlike other skill textbooks, *Clinical Nursing Skills* conceptualizes the nursing process data for each unit (including Assessment, Planning, Implementation, and Evaluation) so that it does not have to be repeated with every skill. This avoidance of repetition allows us to offer more than 800 complete nursing skills, significantly more than other skills textbooks. Each skill includes a list of equipment necessary to perform the skill, preparation, and step-by-step nursing interventions. Critical steps include relevant rationale for the nursing action.

The clear and concise format of the eighth edition enables the student to easily access key material for immediate reference in the clinical area. Extensive color photographs and drawings within each unit illustrate the concepts presented and enable students to visualize each step that must be performed.

NEW TO THIS EDITION

- **More than 800 new and updated skills** provide the most up-to-date nursing techniques recommended by current standards of practice.
- **New! Chapter on Neurological Management.** As head trauma and neurological conditions require a high level of nursing competence, this chapter provides the skills to achieve this objective.
- **Expanded! Evidence-Based Nursing Practice** boxes that present specific scientific studies that validate the skills protocols. Research studies are included to emphasize new information related to improving client care.

- **Expanded! Legal Alerts**, which assist nurses in recognizing legal pitfalls so that when performing nursing actions they are aware of the actions that constitute legal malpractice.
- **New! New Trends** feature presents new equipment and systems that are being incorporated in 21st century nursing care.
- **Expanded! Critical Thinking Strategies** in the form of case studies have been expanded at the end of each chapter to assist students to apply critical thinking principles to clinical situations. The **Critical Thinking Application section** includes Expected Outcomes, Unexpected Outcomes, and Alternative Actions.

HALLMARK FEATURES

Clinical Nursing Skills' all-inclusive, clear, and concise format teaches the student to:

- Learn each skill from basic to advanced in a contextual framework.
- Understand the theoretical concepts that serve as a foundation for skills.
- Apply this knowledge to a clinical situation with a “client need” focus.
- Use critical thinking to assess and evaluate the outcome of the skill and consider unexpected outcomes.
- Appreciate cultural diversity principles as they apply to client situations.
- Validate clinical skills by applying evidence-based nursing practice data and studies.
- Function in, and adapt to, the professional role by understanding management responsibilities.

Our primary goal in writing *Clinical Nursing Skills* is to produce a relevant, useful, and comprehensive text that is flexible for various education programs and learning needs of students. Further, we hope that faculty will find this textbook a valuable teaching tool and reference for clinical practice.

The Only Skill Resource You'll Need . . .

Complete Coverage of over 800 Skills in an Innovative Format!

19

Nutritional Management and Enteral Intubation

LEARNING OBJECTIVES

1. List the essential nutrients necessary to sustain life.
2. Describe the functions of the gastrointestinal system and accessory organs.
3. Identify the categories important for a total nutritional assessment.
4. Discuss feeding techniques and precautions used for dysphagic clients.
5. Identify clients who are candidates for modified diets.
6. List foods that are restricted or supplemented for clients who are receiving modified diets.
7. Outline steps for inserting a nasogastric tube.
8. Describe ways to determine placement of a nasogastric/intestinal tube.
9. Outline the steps of administering a tube feeding.
10. List possible complications of GI tract decompression.
11. Describe emergency management to decontaminate the GI tract of toxic poisons.
12. Compare and contrast aspects of gastric versus intestinal tube feedings.
13. Discuss problems that may occur with tube.

CHAPTER OUTLINE

Nutritional Management	633	UNIT 19 Nasogastric Tube Therapies	652
Macronutrients	634	UNIT 19 Enteral Feeding	663
Micronutrients	635	Gerontologic Considerations	676
Nutritional Assessment	636	Management Guidelines	677
Assimilation of Nutrients	638	Delegation	677
Gastrointestinal Dysfunctions	639	Communication Network	677
Normal and Therapeutic Nutrition	640	Critical Thinking Strategies	677
UNIT 19 Modified Therapeutic Diets	642	Scenarios	678
UNIT 19 Nutrition Maintenance	648	NCLEX® Review Questions	678

UNIT 19 Modified Therapeutic Diets	642	UNIT 19 Nutrition Maintenance	648
Nursing Process Data	642	Nursing Process Data	648
Procedures	642	Procedures	648
Restricting Dietary Protein	643	Serving a Food Tray	649
Restricting Dietary Fat	643	Assisting the Visually Impaired Client to Eat	649
Restricting Mineral Nutrients (Sodium, Potassium)	643	Assisting the Dysphagic Client to Eat	650
Providing Consistent Carbohydrate Diets	644	UNIT 19 Nasogastric Tube Therapies	652
Providing Nutrient-Enhanced Diets	644	Nursing Process Data	652
Providing Progressive Diets	645	Procedures	652
Providing Altered Food Consistency Diets	646	Inserting a Large-Bore Nasogastric (NG) Tube	653

Each chapter opens with **Learning Objectives** and a **Chapter Outline** for easy reference and review of chapter contents.

Skill procedures within each chapter are grouped together in **Units** and organized around a Nursing Process Framework.

Key **Terminology** is included at the beginning of the chapter for easy review. ▶

TERMINOLOGY

- | | |
|--|---|
| Alimentary of or pertaining to nutrition. | Gavage introduction of nourishment into the GI tract by mechanical means. |
| Anabolism reaction in which small molecules are put together to form larger ones—repairing or building up cells. | Gastrointestinal term that pertains to the stomach and intestines. |
| Anorexia loss of appetite for food. | Hematemesis vomitus containing blood. |
| Aspirate to remove fluids or gases by suction. | Hydrogenation a chemical process by which hydrogens are added to monounsaturated or polyunsaturated fats, making the fats more saturated, termed <i>trans fats</i> . |
| Aspiration accidental inspiration of fluid or a foreign body into the airway. | Hyperalimentation the process of nourishing the body through parenteral means. |
| Calorie the amount of heat necessary to raise the temperature of 1 kilogram of water 1°C. This is the “small” calorie. The dietary, or large, Calorie represents 1,000 of these calories, or 1 kilocalorie. | Hypoglycemia condition characterized by an increase in blood sugar. |
| Carbohydrates a group of chemical substances, including sugars, glycogen, starches, dextrans, and celluloses, that contain only carbon, oxygen, and hydrogen. | Hypertonic solution having a higher osmotic pressure or tonicity than a solution to which it is compared. |
| Cardio prefix pertaining to the heart. | Hypoglycemia condition characterized by a deficiency of sugar or glucose in the blood. |
| Carina point at which the trachea divides into the right and left bronchi. | Ileus obstruction of the intestine caused by paralysis of the intestinal muscles. |
| Cardiovascular term that pertains to the heart and blood vessels as cardiovascular system. | Ingest the process of taking material into the gastrointestinal tract. |

Cultural Awareness

Cultural Accommodations for Special Diets

When a special diet is prescribed, it should be consistent with the client’s cultural preferences and religious practices. For example, Jewish people do not combine certain foods. So, to comply with kosher laws, do not combine meat and dairy products at the same meal.

Food Is One of the Most Interesting Aspects About Any Culture

- American acculturation tends to *replace* traditional habits, tastes, and preferences with a detrimental *switch* to highly processed foods.

- This may account for increased rates of illness and death from heart disease and cancer in some populations.
- While not all cultural food habits are healthy, they are *usually* higher in fiber and vitamins than the typical American diet and should be encouraged.

General Recommendations

- Food preferences should be maintained.
- Focus education on food practices and preparation, possible health hazards, and importance of role modeling for children.

◀ **Expanded! Cultural Awareness** sections remind nurses of issues surrounding diversity and providing culturally responsive client care.

... for Accurate and Safe Skill Performance!

Legal Considerations

Nimodipine capsules were dispensed to clinical area where they were used for patients who could not swallow. In one case, a nurse softened the gelatin capsule in hot water, withdrew the medication into a parenteral syringe, and the dose was inadvertently

administered as IV instead of via a feeding tube. Subsequently, the patient died. A boxed warning has now been added to the nimodipine labeling to caution about this type of administration error.

Source: ISMP Medication Safety Alert, *Nurse Adviser*, April 2010.

◀ **Legal Considerations** boxes highlight legal pitfalls and make nurses aware of legal malpractice.

New! New Trends feature presents new equipment and systems that are being incorporated in 21st century nursing care.

New Trends—Electronic Stethoscope

A new electronic stethoscope is now available. It measures a client's blood pressure via Bluetooth-Enabled Cardioscan and sends the results directly into the client's computer record for immediate evaluation.

Source: Courtesy 3M® Littman®.

NURSING DIAGNOSES

The following nursing diagnoses are appropriate to use on client care plans when the components are related to nutritional problems or nutritional health maintenance.

NURSING DIAGNOSIS	RELATED FACTORS
Aspiration, Risk for	CVA, neuromuscular disease, NG intubation, artificial airway, decreased level of consciousness, oral/cervical surgery
Dentition, Impaired	Poor oral hygiene, oral surgery, injury, ill-fitting dentures
Knowledge, Deficient	Lack of appropriate dietary information, misinterpretation of information, cognitive limitation, inadequate motivation
Noncompliance	Chronic illness, disease-related symptoms, side effects of therapy, financial status, cultural practices
Imbalanced Nutrition: Less than Body Requirements	Impaired swallowing, faulty metabolism, altered level of consciousness, inadequate absorption, eating disorders
Imbalanced Nutrition: More than Body Requirements	Lack of basic nutritional knowledge, excessive intake in relation to metabolic requirements, decreased activity patterns, decreased metabolic needs, eating disorders
Impaired swallowing	Esophageal obstructive disorder, chronic neurologic disorder (multiple sclerosis, ALS, myasthenia gravis), muscle dysfunction (stroke, dementia, Parkinson's disease)

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. Remember to wash your hands or use antibacterial gel before and after each and every client contact.

IDENTIFY CLIENT Before every procedure, check two forms of client identification, not including room number. These actions prevent errors and conform to the Joint Commission standards.

◀ **Nursing Diagnoses** for each chapter give quick and clear guidelines for appropriate use of nursing diagnoses in client care plans.

Nasogastric Tube Therapies

Nursing Process Data

ASSESSMENT Data Base

- Validate order for NG tube type and purpose.
- Assess overall status necessitating NG decompression (gastric surgery, intestinal obstruction).
- Assess status of GI function (presence of nausea, vomiting, abdominal distention, presence/absence of passage of flatus or bowel movement).
- Assess patency of nares.
- Assess risk for aspiration.
- Assess client's I&O balance and relevant lab data (electrolytes, hemoglobin and hematocrit, coagulation studies).
- Assess type of IV fluid replacement therapy client is receiving.

PLANNING Objectives

- To remove fluid and gas from the gastrointestinal tract
- To maintain decompression tube patency
- To perform gastric lavage to remove blood, fluid, or particles, or to prevent digestion and absorption of poison

IMPLEMENTATION Procedures

- Inserting a Large-Bore Nasogastric (NG) tube 653
 - For Testing Blood in Gastric Specimen 655
 - For Decompressing the GI Tract 655
- Flushing/Maintaining Nasogastric (NG) Tube 657
- Performing Gastric Lavage 659
- Administering Poison Control Agents 659
- Removing an NG or Nasointestinal (NI) Tube 660

EVALUATION Expected Outcomes

- NG tube is placed without complication.
- NG tube functions effectively (gastric contents are decompressed).
- Toxic substances are removed by lavage/not absorbed.

Critical Thinking Application

- Expected Outcomes 662
- Unexpected Outcomes 662
- Alternative Actions 662

Pearson Nursing Student Resources

Find additional review materials at nursing.pearsonhighered.com
Prepare for success with NCLEX®-style practice questions and Skill Checklists

◀ Within each chapter, **Units** open with a complete overview of the Nursing Process Data that applies to the Procedures.

New! The **Online Student Resources** for each unit contains competency checklists for each procedure and NCLEX® review questions.
(Visit nursing.pearsonhighered.com)

Nasogastric (NG) Tube

(single-lumen tube)
(men Salem sump n.)

- Water-soluble lubricant
- Tape (2.5 cm or 1 in.) or commercial tube holder
- pH chemstrip or Gastrocult test card and developer
- Towel
- Emesis basin
- Tissues
- Safety pin and rubber band
- Tongue blade
- Glass of water with straw
- 50-mL catheter-tip syringe
- Clean gloves
- Indelible pen or piece of tape for marking tube
- Spindle adapter
- Suction tubing and suction source

Preparation

1. Check physician's order and client care plan for inserting an NG tube.
2. Check client's Ident-A-Band and have client state name and birth date.
3. Discuss procedure with client. ▶ **Rationale:** Demonstration and display of items to be used helps to allay client's fear and to gain cooperation.
4. Provide privacy.
5. Gather equipment.

Procedure

1. Perform hand hygiene. Don clean gloves.
2. Position client at 45° angle or higher with head of bed elevated.
3. Examine nostrils, and select the most patent nostril by having client breathe through each one. ▶ **Rationale:** The nostril with greater airflow should be chosen for insertion.
4. Place a towel over client's chest, an emesis basin and tissues within reach; establish a cueing signal for client to use to stop you momentarily. ▶ **Rationale:** Client may experience discomfort or gag during tube insertion.

Clinical Alert

Nurses never insert or withdraw an NG tube for clients recovering from gastric surgery. The suture line could be interrupted, and hemorrhage could occur. The physician should be notified of dislodgement.
Never insert an NG tube in a client after nasal, craniofacial, or hypophysectomy surgery.

▶ **Step-by-Step Skills.** More than 250 full-color photographs, line drawings, charts, and tables depict step-by-step nursing procedures. Clear, concise skills complete with rationales provide nurses of all levels the ability to visualize, perform, and evaluate skills in any clinical setting.

▶ **Clinical Alerts** throughout the skills call attention to safety issues, essential information, nursing judgment and actions that require critical decision making.

Gastric (Salem) Sump Tube

This gastric tube is a double-lumen radiopaque plastic tube. One lumen is used for decompression. The blue lumen with a blue pigtail provides an air vent to allow atmospheric pressure to enter the stomach to prevent tube adherence to gastric mucosa when the tube is attached to suction. It is NOT used for irrigation, obtaining a specimen, etc. However, if the vent lumen is blocked and requires flushing, after the flush, the pigtail should be cleared with an injection of 20 mL air. The pigtail should be kept above the level of the client's stomach to prevent stomach contents from siphoning into the air vent lumen, making it dysfunctional.

Salem Sump Tube With Gientri Port

This nasogastric system has selector knobs to allow a change in modes for suctioning (decompression), feeding, irrigating, and medication administration all through one closed port. The anti-reflux valve/air vent lumen allows atmospheric air to enter the stomach similar to the way the double lumen tube with blue pigtail functions.

▲ Salem Sump w/Gientri port.

EVIDENCE-BASED PRACTICE

Determining Proper NG Tube Placement

A number of methods have been proposed to determine whether a tube has been inadvertently placed into the pulmonary tree, including air insufflation, observation of respiratory symptoms, pH testing of aspirated fluid, visual inspection of aspirated fluid, detection of carbon dioxide in the tube, and x-ray tube location verification. The best method of confirming the location of a blindly inserted gastrointestinal tube is by chest/abdominal x-ray.

Rauen, C. A., Chulay, M., Bridges, E., Vollman, K. M., & Arbour, R. (2008). Seven evidence-based practice habits: putting some sacred cows out to pasture. *Critical Care Nurse*, 28(2), 98–123.

◀ **Expanded! Evidence-Based Practice** boxes present specific scientific studies that validate skill protocols.

Each unit ends with **Documentation** to remind nurses to document important data regarding the skill, the outcome, and the client response. ▶

DOCUMENTATION for Nasogastric Tube Therapies

- Type of tube inserted
- Technique used to assess NG tube placement
- Character and amount of drainage
- Type of suction and pressure setting used
- Frequency and solution used for flush or irrigation
- Gastrointestinal assessment findings (e.g., passage of flatus, bowel movement)
- Net return for lavaged client (amount of irrigant instilled subtracted from amount of aspirated return).
- Frequent vital signs (if indicated)
- Nasal and oral hygiene measures
- Client's tolerance of decompression
- Results of gastric specimen testing (blood, pH)
- Decontaminating agents instilled

CRITICAL THINKING Application

Expected Outcomes

- NG tube is placed without complication.

Unexpected Outcomes

NG tube is difficult to advance.

Client coughs, is unable to speak and becomes cyanotic during tube insertion.

Salem sump pigtail leaks gastric contents.

Client has ingested a large number of tablets which cannot be removed by lavage.

- NG tube functions effectively (gastric contents are decompressed).
- Toxic substances are removed by lavage/not absorbed.

Alternative Actions

- Select more patent nostril: Have client compress each nostril and breathe in to determine which is more patent.
- Rotate tube or withdraw slightly, then try to advance, but do not force.
- Relubricate tube and try again.
- Curl tube around fist and hold under warm running water to soften for easier insertion.
- Have client hold ice chips in mouth for a few minutes to numb nasal passage and suppress gag reflex.
- Remove tube immediately as these indicate that tube is being advanced into client's airway.
- Flush pigtail with normal saline, then with air to clear.
- Keep blue pigtail at level above client's stomach.
- Maintain antireflux valve plug insertion (blue side into blue pigtail lumen).
- Whole bowel irrigation is more effective for ingestion of enteric coated or sustained-release tablets.
- Repeated dose of activated charcoal may be indicated to speed drug elimination.
- Prepare for possible arrangement for hemodialysis.

◀ **Critical Thinking Applications** review Expected Outcomes, and provide Alternative Actions to take with Unexpected Outcomes.

Comprehensive End-of-Chapter Information Helps Tie Everything Together!

GERONTOLOGIC Considerations

Dietary Needs of the Elderly

Energy (caloric) requirement: 2,000–2,400 kcal/day (may adjust to energy expenditure and physical activity).

Protein: 10% of energy requirement, increases to 20% of energy requirement during periods of stress (surgery, infection, burn).

Fiber: 20–35 g/day of fiber (five servings of fruit per day).

Fluids: 1,500–2,000 mL of water/day or 30 mL/kg body weight.

Vitamins: same as for younger adult except for vitamins D, B₆, and B₁₂. *Significant deficiencies in serum levels of vitamins and minerals are rare in healthy older adults.*

Vitamin D requirement is 10 mg/day for adults 51–70 and 15 mg/day for those over age 70.

Vitamin B₆ intake should be 1.7 mg/day for men and 1.5 mg/day for women over age 51 (25% of elderly are deficient in vitamin B₆).

Vitamin B₁₂ intake should be 2.4 mg for all adults over age 51 (about 15% of elderly are deficient in vitamin B₁₂).

Minerals: increased need—10 mg/day of iron.

The elderly are at high risk for malnutrition due to age-related physiologic changes, healthcare status, and lifestyle factors.

Physiologic Changes Associated with Aging

- Between ages 25 and 70, percentage of body fat doubles and lean body mass decreases by about one third.
- Metabolic rate decreases 20% in men and 13% in elderly

Health Status Factors

- Poor dentition (up to 37% of elderly are edentulous). Loss of dentition is not due to the normal aging process but to improper oral hygiene and/or inadequate nutrition beginning at an earlier age.
- Ill-fitting dentures causing pain limiting variety and quantity of intake.
- Swallowing or self-care deficit disorders (e.g., neuromuscular disorders, Parkinson's, Alzheimer's).
- Psychological changes (depression, cognitive impairment).
- Effect of medications (altered metabolism, anorexia, nausea, diarrhea, cognitive disturbance).
- Inappropriate diet prescription (low-salt, low-cholesterol, or low-calorie diet).
- Medical conditions (e.g., COPD, heart failure, cancer resulting).

Lifestyle Factors

- Alcoholism
 - Inadequate income
 - Decreased physical activity, lack of transport, isolation
 - Cultural values
 - Lack of monitoring/caregiving
- Assessment parameters for nutritional status of the elderly client in addition to the above risk factors include:
- Anthropometric values:
Ideal body weight = men should weigh 106 lb for 5 feet plus 6 lb for each additional inch in height. Women should

◀ **Gerontologic Considerations** help nurses consider special adaptations for care of the older adult.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- Each state identifies the scope of practice for RNs and LVN/LPNs. Several states have identified that the LVN/LPN has a specific role in IV therapy, but the scope of practice is always dictated by each agency (e.g., initiating, regulating, discontinuing IVs). The LPN/LVN educated in IV therapy is the minimum level practitioner to assist in tasks delegated by the RN for the delivery of IV therapy. The RN may be assisted by an LVN/LPN educated in IV therapy, but the RN remains responsible for the care given.
- Policies outlining the responsibility of the IV nurse vary significantly among agencies. A written policy should clearly outline all aspects of this role, and all staff should be familiar with its scope. Policies and procedures should follow national guidelines and standards of practice established by the Centers for Disease Control and Prevention, the American Association of Blood Banks, and the IV Nurses Society. All nurses must be aware of the many physical hazards associated with IV therapy and related OSHA rules to be observed.
- Central line catheter management must be done by an RN.
- The nurse who delivers IV therapy must be qualified by specific knowledge and experience to perform such highly specialized skills. Many agencies utilize a team of specialty educated and experienced certified IV nurses who focus their attention solely on aspects of IV therapy (initiation, drug preparation, fluid/blood/drug administration, regular client assessment and site care, as well as monitoring product integrity). While these nurses are freed from other care responsibilities, the professional nurse must provide for ongoing client care and ensure client safety.
- TPN and lipids may be administered only by an RN according to specific physician orders.

- The CNA/UAP providing personal hygiene must understand that the IV system is a closed one and must be able to give care without disrupting the system. The components of the CVAD system must never be disconnected. Doing so places the client at risk for infection and air embolism. The CNA/UAP should receive training in changing the client's gown without disrupting the CVAD system.
- For the client with a CVAD allowed to shower, the RN should disconnect infusion lines, place a dry sterile gauze (4 × 4) over the dressed site and exposed tubing(s), then cover all with a large transparent dressing for waterproofing. Post-shower removal of the covering and inspection of the dressing should also be performed by the RN.

Communication Matrix

While the professional monitors the IV infusion site regularly, the CNA/UAP provides vital data to the professional nurse by immediately reporting:

- Observations of redness or swelling around the CVAD insertion site (signs of possible infiltration, hematoma, sepsis).
- Presence of crepitus (bubble-wrap feeling) on the client's chest (sign of possible subcutaneous emphysema that can lead to respiratory distress).
- Observations of respiratory distress in any client with recent (24 hr) placement of a central line (symptoms of possible pneumothorax).
- Any client complaint of arm, shoulder, or neck pain (symptom of possible thrombosis or infiltration).
- Temperature elevation (fever—sign of possible catheter-related infection if otherwise unexplainable).
- Infusion device alarms to prompt the professional to further assess the client.
- Presence of blood backup in the catheter.
- A loose or soiled/wet dressing.

◀ **Management Guidelines** include a **Delegation** section which teaches nurses to delegate tasks within safe, legal, and appropriate parameters. A **Communication Matrix** section helps nurses learn to prioritize and communicate relevant client information to members of the healthcare team.

CRITICAL THINKING Strategies

Scenario 1

Mr. John Baker is a 68-year-old retired pharmacist who has just returned from surgery after placement of a tunneled CVAD with a Groshong valve. He will be started on a long-term intermittent chemotherapy regimen for acute lymphocytic leukemia. His wife is a retired RN who worked in the operating room for many years.

1. Identify at least three advantages for inserting the tunneled catheter for his treatment.
2. His wife is very concerned about the initial care of the catheter. What explanation will you give her?
3. After the explanation regarding the care of the catheter, Mrs. Baker asks you how they can prevent an infection of the catheter.
4. The client needs to be instructed on how to flush the catheter. What are the most important directions you should provide to him?

5. Mrs. Baker asks you to describe what symptoms require reporting to the physician. What is your best response to this question?

Scenario 2

Seth Eley, age 24, has been admitted to your unit with the diagnosis of inflammatory bowel disease (Crohn's disease) with exacerbation of fever, severe diarrhea, right lower quadrant pain, weight loss, and anemia. Short-term total parenteral nutrition and bowel rest are planned. A triple-lumen central venous catheter has been placed for these purposes.

1. Based on these data, what generalizations can you make about the purpose of hyperalimentation for this client?
2. Why is central venous access necessary?
3. Develop several scenarios about the most common complications of central catheter placement.
4. How does TPN affect fluid and electrolyte balance?

◀ **Critical Thinking Strategies** provide case scenarios that help nurses develop clinical reasoning skills.

NCLEX® Review Questions. ▶ NCLEX®-style questions have been included at the end of each chapter and reflect the Practice Analysis of newly Licensed Registered Nurses upon which the NCLEX® is based. Answers with complete rationales are in the Answers Appendix.

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. Trans fats are polyunsaturates and monounsaturates that:
 1. Have been hydrogenated.
 2. Are unsaturated.
 3. Primarily come from vegetables, nuts, and seeds.
 4. Come from animal sources.
2. Which of the following clients would mostly likely be placed on a potassium restricted diet?
 1. Heart failure client
 2. Renal failure client
 3. COPD client
 4. Burn client
3. Which of the following are helpful for the dysphagic client?

Select all that apply.

 1. Swallowing liquid foods.
 2. Eating food accompanied by liquids.
 3. Swallowing thickened liquids.
 4. Eating food without accompanying liquid.
 5. Using a straw for liquids.
 6. Being fed with a syringe.
4. The purpose of the Salem NG decompression tube's blue lumen is to:
 1. Prevent esophageal reflux of gastric contents.
 2. Allow siphoning of gastric contents if they stagnate.
 3. Provide a port for continuous feeding.
 4. Prevent tube adherence to the gastric mucosa.
5. Which of the following is the least reliable indicator of the return of bowel function?
 1. Appetite
 2. Bowel sounds
 3. Presence of flatus
 4. Bowel movement
6. The best way to determine NG tube placement with continuous feeding is to:
 1. Auscultate for injected air sound over the epigastrium.
 2. Aspirate secretions and check for an acid pH.
 3. Note the character of aspirated secretions.
 4. Use capnography to detect presence of carbon dioxide.
7. An intermittent NG tube feeding should be withheld if the residual volume is:
 1. 50 mL.
 2. 100 mL.
 3. 150 mL.
 4. >200 mL.
8. The best way to prevent clogging of a small bore feeding tube is to:
 1. Flush frequently with cola.
 2. Flush frequently with cranberry juice.
 3. Flush frequently with warm water.
 4. Replace the tube weekly.
9. The most effective way to promote small bore feeding tube advancement into the small intestine is to:
 1. Place the client right side-lying.
 2. Place the client left side-lying.
 3. Administer prokinetic medication before tube insertion.
 4. Reinsert guidewire to advance the tube.
10. The most appropriate method for extended nutritional support is:
 1. Nasogastric tube feeding.
 2. Nasointestinal tube feeding.
 3. Gastrostomy tube feeding.
 4. Parenteral nutrition.

Reconstituting <i>Vaccinia</i> Vaccine for Smallpox	479
Administering Reconstituted Smallpox Vaccine	480
Understanding Post-Vaccination Reactions	482
Instructing Client in Post-Vaccination Evaluation	482
Identifying Indications for <i>Vaccinia</i> Immune Globulin (VIG) Administration	483
Collecting and Transporting Specimens	484
Identifying Chemical Agent Exposure	484
Triage for Chemical Agent Exposure	485
Managing Care After Chemical Agent Exposure	486
Identifying Acute Radiation Syndrome	486
Dealing With a Nuclear Disaster	487

UNIT 3 Personal Protective Equipment and Decontamination 489

Nursing Process Data	489
Procedures	489
Implementing Hospital Infection Control Protocol	490
Decontaminating via Triage	492
Choosing Protective Equipment for Biological Exposure	493
Choosing Protective Equipment for Chemical Exposure	494
Choosing Protective Equipment for Radiological Attack	495
Decontaminating Victims After a Biological Terrorist Event	496
Decontaminating Victims After a Chemical Terrorist Event	496
Decontaminating Victims After Radiation Exposure	497
Controlling Radiation Contamination	498

UNIT 4 Triage, Treatment, and a Communication Matrix 500

Nursing Process Data	500
Procedures	500
Establishing Triage Treatment Areas	501
Establishing Public Health Parameters	501
Developing a Communication Network	501
Establishing Viable Communication	502
Carrying Out Steps of Triage	503
Treating Life-Threatening Conditions	503
Assessing Victims Post-Triage	504
Caring for Those Who Died	505
Caring for Clients With Psychological Reactions	505
Identifying Post-Traumatic Stress Disorder (PTSD)	506
Gerontologic Considerations	507
Management Guidelines	507

Delegation 507

Communication Matrix 508

CHAPTER 16

Pain Management 510

LEARNING OBJECTIVES 510

CHAPTER OUTLINE 510

TERMINOLOGY 511

THEORETICAL CONCEPTS

COPING WITH PAIN 512

NONINVASIVE PAIN RELIEF 516

TECHNIQUES FOR PAIN CONTROL 517

UNIT 1 Pain Assessment 520

Nursing Process Data 520

Procedures 520

Assessing Pain 521

Assessing Pain in a Cognitively Impaired or Nonverbal Client 522

Assessing Pain in Young Children 522

UNIT 2 Nonpharmacological Pain Relief 523

Nursing Process Data 523

Procedures 523

Alleviating Pain Through Touch (Massage) 524

Using Relaxation Techniques 524

UNIT 3 Pharmacological Pain Management 527

Nursing Process Data 527

Procedures 527

Administering Pain Medications 528

Improving Client Satisfaction With Pain Control 528

Administering Epidural Narcotic Analgesia 530

Managing Pain With Patient-Controlled Analgesia (PCA) 533

Qualifying the Client for PCA 533

Preparing for PCA IV Administration 534

Administering IV PCA to a Client 534

Loading PCA–Alaris Model 534

Priming PCA 535

Changing Syringe on PCA 535

Changing Program/Mode 536

Checking PCA at Shift Evaluation 536

Giving Bolus Dose 538

Stopping Bolus, Loading, or PCA Dose 538

Ongoing Assessment of the PCA Client 539

Teaching PCA to a Client 539

Gerontologic Considerations 542

Management Guidelines 543

Delegation 543

Communication Matrix 543

Critical Thinking Strategies 543

Scenarios 543

Medication Administration 569

LEARNING OBJECTIVES 569

CHAPTER OUTLINE 569

TERMINOLOGY 570

Theoretical Concepts

PHARMACOLOGIC AGENTS 571

BIOLOGIC EFFECTS OF DRUGS 571

ADMINISTERING MEDICATIONS SAFELY 572

UNIT 1 Medication Preparation 574

Nursing Process Data 574

Procedures 574

Preparing for Medication Administration 575

Converting Dosage Systems 576

- Calculating Dosages 577
- Using the Narcotic Control System 577
- Using an Automated Dispensing System 578
- Administering Medication Protocol 580
- UNIT 2 Oral Medications 584**
- Nursing Process Data 584**
- Procedures 584**
- Preparing Oral Medications 585
- Administering Oral Medications to Adults 587
- Administering Medications per Enteral (NG/NI) Feeding Tube 587
- UNIT 3 Topical Medication Administration 590**
- Nursing Process Data 590**
- Procedures 590**
- Applying Topical Medications 591
- Applying Creams to Lesions 591
- Applying Transdermal Medications 592
- Instilling Ophthalmic Drops 593
- Administering Ophthalmic Ointment 594
- Irrigating the Eye 594
- Administering Otic Medications 595
- Irrigating the Ear Canal 596
- UNIT 4 Mucous Membrane Medication Administration 598**
- Nursing Process Data 598**
- Procedures 598**
- Administering Sublingual Medications 599
- Instilling Nose Drops 599
- Administering Metered-Dose Inhaled (MDI) Medications 600
- Using MDI With Spacer 601
- Administering Dry Powder Inhaled (DPI) Medication 602
- Administering Medication by Nonpressurized (Nebulized) Aerosol (NPA) 603
- Administering Rectal Suppositories 604
- Administering Vaginal Suppositories 604
- UNIT 5 Parenteral Medication Administration 607**
- Nursing Process Data 607**
- Procedures 607**
- Preparing Injections 608
- Administering Intradermal Injections 612
- Administering Subcutaneous Injections 613
- Preparing Insulin Injections 614
- Using an Insulin Pen 617
- Administering Subcutaneous Anticoagulants (Heparin, LMWH, Arixtra) 619
- Administering Intramuscular (IM) Injections 621
- Using Z-Track Method 623
- Gerontologic Considerations 625**
- Management Guidelines 626**
- Delegation 626
- Communication Matrix 626
- Drug Supplement 626**
- Calculations of Solutions 626
- Preparing Solutions 626
- Abbreviations and Symbols 627
- Conversion Tables 628
- Critical Thinking Strategies 628**
- Scenario 1 628
- Scenario 2 629
- Scenario 3 629

- CHAPTER 19**
- Nutritional Management and Enteral Intubation 631**
- LEARNING OBJECTIVES 631**
- CHAPTER OUTLINE 631**
- TERMINOLOGY 632**
- Theoretical Concepts**
- NUTRITIONAL MANAGEMENT 633**
- MACRONUTRIENTS 634**
- MICRONUTRIENTS 635**
- NUTRITIONAL ASSESSMENT 636**
- ASSIMILATION OF NUTRIENTS 638**
- GASTROINTESTINAL DYSFUNCTIONS 639**
- NORMAL AND THERAPEUTIC NUTRITION 640**
- UNIT 1 Modified Therapeutic Diets 642**
- Nursing Process Data 642**
- Procedures 642**
- Restricting Dietary Protein 643
- Restricting Dietary Fat 643
- Restricting Mineral Nutrients (Sodium, Potassium) 643
- Providing Consistent Carbohydrate Diets 644
- Providing Nutrient-Enhanced Diets 644
- Providing Progressive Diets 645
- Providing Altered Food Consistency Diets 646
- UNIT 2 Nutrition Maintenance 648**
- Nursing Process Data 648**
- Procedures 648**
- Serving a Food Tray 649
- Assisting the Visually Impaired Client to Eat 649
- Assisting the Dysphagic Client to Eat 650
- UNIT 3 Nasogastric Tube Therapies 652**
- Nursing Process Data 652**
- Procedures 652**
- Inserting a Large-Bore Nasogastric (NG) Tube 653
- Flushing/Maintaining a Nasogastric (NG) Tube 657
- Performing Gastric Lavage 659
- Administering Poison Control Agents 659
- Removing an NG or Nasointestinal (NI) Tube 660

UNIT 4 Enteral Feeding 663**Nursing Process Data** 663**Procedures** 663

Administering an Intermittent Feeding via Large-Bore Nasogastric Tube 664

Dressing the Gastrostomy Tube Site 669

Inserting a Small-Bore Feeding Tube 669

Providing Continuous Feeding via Small-Bore Nasointestinal/Jejunostomy Tube 671

Gerontologic Considerations 676**Management Guidelines** 677

Delegation 677

Collecting Midstream Urine 685

Collecting 24-Hour Urine Specimen 686

Collecting a Specimen From an Infant 686

Teaching Clients to Test for Urine Ketone Bodies 687

UNIT 2 Stool Specimens 689**Nursing Process Data** 689**Procedures** 689

Collecting Adult Stool Specimen 690

Collecting Stool for Ova and Parasites 690

Collecting Infant Stool Specimen 691

Testing for Occult Blood 691

Collecting Stool for Bacterial Culture 692

Teaching Parents to Test for Pinworms 692

UNIT 3 Blood Specimens 694**Nursing Process Data** 694**Procedures** 694

Withdrawing Venous Blood (Phlebotomy) 695

Using Vacutainer System 696

Understanding Blood Chemistry Tests 698

Withdrawing Arterial Blood 698

Understanding Arterial Blood Gases (ABGs) 699

Collecting a Blood Specimen for Culture 700

Calibrating a Blood Glucose Meter (One Touch Ultra) 700

Obtaining Blood Specimen for Glucose Testing (Capillary Puncture) 701

Monitoring Glucose: Sure Step Flexx 702

UNIT 4 Sputum Collection 705**Nursing Process Data** 705**Procedures** 705

Obtaining Sputum Specimen 706

Using Suction Trap 707

Collecting Specimen by Transtracheal Aspiration 707

UNIT 5 Swab Specimens 709**Nursing Process Data** 709**Procedures** 709

Obtaining a Throat Specimen 710

Obtaining a Gum Swab for HIV Antibodies 710

Obtaining Wound Specimen for Aerobic Culture 711

Obtaining Wound Specimen for Anaerobic Culture 712

Collecting an Ear Specimen 713

Gerontologic Considerations 714**Management Guidelines** 714

Preparing for X-Ray Studies 723

UNIT 2 Nuclear Scanning 732**Nursing Process Data** 732**Procedures** 732

Preparing for Nuclear Scans 733

Teaching for Nuclear Scans 736

UNIT 3 Barium Studies 737**Nursing Process Data** 737**Procedures** 737

Preparing for Barium Studies 738

UNIT 4 Endoscopic Studies 740**Nursing Process Data** 740**Procedures** 740

Preparing for Endoscopic Studies 741

UNIT 5 Fluid Analysis and Microscopic Studies 746**Nursing Process Data** 746**Procedures** 746

Assisting With Lumbar Puncture 747

Assisting With Liver Biopsy 748

Assisting With Thoracentesis 749

Assisting With Paracentesis 750

Assisting With Bone Marrow Aspiration 751

Assisting With Vaginal Examination and Papanicolaou (Pap) Smear 751

Assisting With Amniocentesis 752

Gerontologic Considerations 753**Management Guidelines** 754*Delegation* 754*Communication Matrix* 754**Critical Thinking Strategies** 754*Scenarios* 754**NCLEX® Review Questions** 755**CHAPTER 22****Urinary Elimination** 756**LEARNING OBJECTIVES** 756**CHAPTER OUTLINE** 756**TERMINOLOGY** 757**Theoretical Concepts****URINARY SYSTEM** 758**ALTERATIONS IN URINARY ELIMINATION** 759

Nursing Interventions 760

Adaptations for Home Care 761

UNIT 1 Intake and Output 763**Nursing Process Data** 763**Procedures** 763

Measuring Intake and Output 764

UNIT 2 External Urine Collection System 767**Nursing Process Data** 767**Procedures** 767

Applying a Condom Catheter for Urine Collection 768

Attaching Urine Collection Condom Catheter to Leg Bag 768

UNIT 3 Catheterization 771**Nursing Process Data** 771**Procedures** 771

Using a Bladder Scanner 772

Draping a Female Client 772

Inserting a Straight Catheter (Female) 773

Inserting a Straight Catheter (Male) 775

Inserting a Retention Catheter (Female) 777

Inserting a Retention Catheter (Male) 781

Providing Catheter Care 783

Removing a Retention Catheter 784

UNIT 4 Bladder Irrigation 787**Nursing Process Data** 787**Procedures** 787

Irrigating by Opening a Closed System 788

Irrigating a Closed System 789

Maintaining Continuous Bladder Irrigation 790

UNIT 5 Suprapubic Catheter Care 792**Nursing Process Data** 792**Procedures** 792

Providing Suprapubic Catheter Care 793

UNIT 6 Specimens From Closed Systems 795**Nursing Process Data** 795**Procedures** 795

Collecting Specimen From a Closed System 796

UNIT 7 Urinary Diversion 798**Nursing Process Data** 798**Procedures** 798

Applying a Urinary Diversion Pouch 799

Obtaining Urine Specimen From an Ileal Conduit 801

Catheterizing Continent Urinary Reservoir 802

UNIT 8 Hemodialysis (Renal Replacement Therapy) 804**Nursing Process Data** 804**Procedures** 804

Providing Hemodialysis 805

Providing Ongoing Care of Hemodialysis Client 807

Terminating Hemodialysis 807

Maintaining Central Venous Dual-Lumen Catheter (DLC) 808

UNIT 9 Adaptations to Home Care 811**Nursing Process Data** 811**Procedures** 811

Using Clean Technique for Intermittent

Self-Catheterization 812

Providing Suprapubic Catheter Care 812

Administering Continuous Ambulatory

Peritoneal Dialysis (CAPD) 813

Changing Dressing for CAPD Client 815

Gerontologic Considerations 816**Management Guidelines** 816*Delegation* 816*Communication Matrix* 816**Critical Thinking Strategies** 817*Scenarios* 817**NCLEX® Review Questions** 817**CHAPTER 23****Bowel Elimination** 819**LEARNING OBJECTIVES** 819

Providing Assistive Digital Evacuation 828

Providing Digital Stimulation 829

Developing a Regular Bowel Routine 829

Administering a Suppository 831

Inserting a Rectal Tube 832

Instructing Client in Colostomy Irrigation 832

Instructing Home Care Client in Colostomy Irrigation 833

Implementing the Zassi Bowel Management System 833

UNIT 2 Enema Administration 838**Nursing Process Data** 838**Procedures** 838

Administering a Large-Volume Enema 839

Administering an Enema to a Child 841

Administering a Small-Volume Enema 842

Administering a Retention Enema 843

Administering a Return Flow Enema 843

UNIT 3 Fecal Ostomy Pouch Application 846**Nursing Process Data** 846**Procedures** 846

Applying a Fecal Ostomy Pouch 847

Gerontologic Considerations 853**Management Guidelines** 853*Delegation* 853*Communication Matrix* 853**Critical Thinking Strategies** 854*Scenarios* 854**NCLEX® Review Questions** 854**CHAPTER 24****Heat and Cold Therapies** 856**LEARNING OBJECTIVES** 856**CHAPTER OUTLINE** 856**TERMINOLOGY** 857**Theoretical Concepts**

Temperature Regulation 857

Conditions Affecting Temperature Regulation 858

The Inflammatory Response 859

Local Heat Therapies (Thermotherapy) 859

Local Cold Therapies (Cryotherapy) 860

Temperature Management Therapies 861

UNIT 1 Local Heat Therapies (Thermotherapy) 863**Nursing Process Data** 863**Procedures** 863

Applying a Commercial Heat Pack 864

Applying an Aquathermic Pad 864

Applying a Hot Moist Pack 865

Assisting With a Sitz Bath 866

UNIT 2 Local Cold Therapies (Cryotherapy) 868**Nursing Process Data** 868**Procedures** 868

Applying an Ice Pack/Commercial Cold Pack 869

Applying a Disposable Instant (Chemical) Cold Pack 870

Applying a Circulating Cold Therapy Pad 871

UNIT 3 Temperature Management Therapies 873**Nursing Process Data** 873**Procedures** 873

Using a Neonatal Incubator/Infant Radiant Warmer 874

Using a Warm Air Blanket 875

Providing Tepid Sponging 875

Using a Cooling Blanket 876

Using a Hypothermia Garment (Body Wraps) 879

Gerontologic Considerations 882**Management Guidelines** 882*Delegation* 882*Communication Matrix* 882**Critical Thinking Strategies** 882*Scenarios* 882**NCLEX® Review Questions** 883**CHAPTER 25****Wound Care and Dressings** 884**LEARNING OBJECTIVES** 884**CHAPTER OUTLINE** 884**TERMINOLOGY** 885**Theoretical Concepts****WOUND HEALING** 886**WOUND CLASSIFICATION** 887**TYPES OF WOUND HEALING** 887**MAJOR FACTORS AFFECTING WOUND HEALING** 887**GOALS OF WOUND CARE** 888**WOUND INFECTIONS** 888**ADJUNCTIVE WOUND CARE THERAPY** 890**HOME CARE** 891**UNIT 1 Measures to Prevent Infection** 892**Nursing Process Data** 892**Procedures** 892

Completing Surgical Hand Antisepsis 893

Donning Sterile Gloves 894
 Pouring From a Sterile Container 895
 Preparing a Sterile Field 896
 Preparing a Sterile Field Using Prepackaged Supplies 897
 Preparing for Dressing Change With Individual Supplies 897

UNIT 2 Dressing Change 899

Nursing Process Data 899

Procedures 899

Changing a Dry Sterile Dressing 900
 Removing Sutures 901
 Removing Staples 902

UNIT 3 Wound Care 904

Nursing Process Data 904

Procedures 904

Determining Surgical Site Infections (SSIs) 905
 Assessing a Wound 905
 Changing a Wound Dressing 908
 Packing a Wound 910
 Assessing a Venous Ulcer 910
 Changing Dressing—Venous Ulcer 911
 Assessing Ankle–Brachial Index (ABI) 915
 Caring for a Wound With a Drain 915
 Applying an Abdominal Binder 917
 Maintaining Wound Drainage System 918
 Irrigating Wounds 919
 Teaching Wound Care for Clients 920

UNIT 4 Promoting a Moist Environment 923

Nursing Process Data 923

Procedures 923

Applying Wet-to-Moist Dressings 924
 Using Hydrocolloid Dressings 926
 Using a Hydrocolloid Wafer 927
 Using a Foam Dressing 928
 Applying a Transparent Film 929

UNIT 5 Pressure Ulcers 932

Nursing Process Data 932

Procedures 932

Preventing Pressure Ulcers 935
 Providing Care for Clients With Pressure Ulcers 935

UNIT 6 Adjunctive Wound Care Therapy 940

Nursing Process Data 940

Procedures 940

Using Electrical Stimulation 941
 Using Noncontact Normothermic Wound Therapy 942
 Using Negative Pressure Wound Therapy 945
 Using Hyperbaric Oxygenation for Diabetic Ulcers 947

Gerontologic Considerations 949

Management Guidelines 950

Delegation 950

Communication Matrix 950

Theoretical Concepts

THE SURGICAL EXPERIENCE 954

PERIOPERATIVE CARE 954

UNIT 1 Stress in Preoperative Clients 960

Nursing Process Data 960

Procedures 960

Preventing Anxiety and Stress 961
 Reducing Anxiety and Stress 961
 Assisting the Client Who Uses Denial 962

UNIT 2 Preoperative Teaching 964

Nursing Process Data 964

Procedures 964

Providing Surgical Information 965
 Providing Client Teaching 966
 Providing Family Teaching 967
 Teaching for Laser Therapy 967
 Teaching for Lithotripsy 968
 Teaching for Laparoscopy 969
 Instructing in Deep Breathing Exercises 971
 Instructing in Coughing Exercises 972
 Providing Instruction to Turn in Bed 972
 Instructing in Leg Exercises 972

UNIT 3 Preoperative Care 975

Nursing Process Data 975

Procedures 975

Obtaining Baseline Data 976
 Preparing the Surgical Site 976
 Preparing the Client for Surgery 978
 Administering Preoperative Medications 980

UNIT 4 Moderate (Conscious) Sedation 983

Nursing Process Data 983

Procedures 983

Preparing Client for Moderate (Conscious) Sedation 984
 Monitoring Client During Procedure 985
 Caring for Client After Moderate (Conscious) Sedation 986

UNIT 5 Postanesthesia Care Unit (PACU) and Discharge 988

Nursing Process Data 988

Procedures 988

Providing Postanesthesia Care	989
Discharging Client From Postanesthesia Unit to Nursing Unit	990
Discharging Client From Phase II Unit to Home	991
UNIT 6 Postoperative Care	993
Nursing Process Data	993
Procedures	993
Providing Postoperative Care	994
Administering Postoperative Medications	995

Professional Nursing

LEARNING OBJECTIVES

1. Discuss what is meant by the concept “professional role of the nurse.”
2. Discuss the ANA Code of Ethics.
3. Define the purpose of “A Code of Academic and Clinical Conduct.”
4. Define professional nursing.
5. Define the term *accountable*.
6. List three ways you can assist the client to assume and adapt to the client role.
7. Identify the guidelines that will assist the nurse to convey nursing competence to the clients.
8. Describe the purpose of the Nurse Practice Act.
9. Discuss major sections of the Nurse Practice Act.
10. Define the term *nurse licensure*.
11. State four functions of the Board of Registered Nursing.
12. Discuss four grounds for licensure revocation for professional misconduct.
13. Explain the legal issues of drug administration.
14. Describe what is meant by “clients’ rights.”
15. Explain what is meant by “Advance Directives.”
16. List four actions or guidelines that you need to complete to prepare for daily client care.
17. Describe the steps of planning for client care.

PROFESSIONAL ROLE

As you enter the profession of nursing, you will experience some of the most frustrating and some of the most rewarding situations of your life. To decrease the frustrations and increase the positive experiences, this chapter introduces you to the role of the nurse. Emphasis is placed on those procedures that will assist you to become a functioning member of the health team, even with limited experience.

The information in this chapter will help you through the first few critical days of your clinical experience. In addition, legal aspects of the nursing profession are discussed to help you become aware of the far-reaching consequences of nursing actions. Clients’ rights and the Nurse Practice Act (also called the Nursing Practice Act in some states) are also presented for your information.

Nurses must function within the Nurses’ Code of Ethics. The Code of Ethics is a set of formal guidelines for governing professional action. It assists the nurse in problem solving where judgment is required. More emphasis is now being placed on the professional organizations to uphold the Code of Ethics and to admonish those nurses who violate the code. The Code of Ethics was revised in June 2001 by the American Nurses Association (ANA). The Code should be reviewed as you progress in the program. The National Student Nurses Association, Inc., also developed a Code of Academic and Clinical Conduct in April 2001. The Code provides guidance for nursing students in the personal development of an ethical foundation as both a nurse and human being.

American Nurses Association: Code of Ethics for Nurses

1. The nurse in all professional relationships practices with compassion and respect for the inherent dignity, work, and uniqueness of every individual, unrestricted by considerations of social or economic status, personal attributes, or the nature of health problems.
2. The nurse's primary commitment is to the patient, whether an individual, family, group or community.
3. The nurse promotes, advocates for, and strives to protect the health, safety, and rights of the patient.
4. The nurse is responsible and accountable for individual nursing practice and determines the appropriate delegations of tasks consistent with the nurse's obligation to provide optimum patient care.
5. The nurse owes the same duties to self as to others, including the responsibility to preserve integrity and safety, to maintain competence, and to continue personal and professional growth.
6. The nurse participates in establishing, maintaining, and improving healthcare environments and conditions of employment conducive to the provision of quality health care and consistent with the values of the profession through individual and collective action.
7. The nurse participates in the advancement of the profession through contributions to practice, education, administration, and knowledge development.
8. The nurse collaborates with other health professionals and the public in promoting community, national, and international efforts to meet health needs.
9. The profession of nursing, as represented by associations and their members, is responsible for articulating nursing values, for maintaining the integrity of the profession and its practice, and for shaping social policy.

Source: Fowler, M. (Ed.) (2008). *American Nurses Association, Guide to the Code of Ethics for Nurses: Interpretation and Application*. Silver Spring, MD: American Nurses Association.

Definition of Professional Nursing

The American Nurses Association in 2003 defined professional nursing as the protection, promotion, and optimization of health and abilities, prevention of illness and injury, alleviation of suffering through the diagnosis and treatment of human responses, and advocacy in the care of individuals, families, communities, and populations.

ANA's Nursing's Social Policy Statement, second edition in 2003, identifies six essential features of professional nursing. These features include:

- Provision of a caring relationship that facilitates health and healing.
- Attention to the range of human experiences and responses to health and illness within the physical and social environments.

- Integration of objective data with knowledge gained from an appreciation of the patient's or group's subjective experience.
- Application of scientific knowledge to the processes of diagnosis and treatment through the use of judgment and critical thinking.
- Advancement of professional nursing knowledge through scholarly inquiry.
- Influence on social and public policy to promote social justice.

American Nursing Association. (2010). *Scope and Standards of Practice* (2nd ed.). Silver Spring, MD.

Assuming the Nursing Role

Your actions, both verbal and nonverbal, influence the client's feelings and ideas regarding your level of competence, the role of nursing in administering care, and the client's overall adaptation to healthcare facilities. Assuming a professional role means that you behave as a professional person. Following the guidelines below will assist you to convey nursing competence, not only to clients, but also to your peers and other nursing staff.

- Always dress neatly in appropriate, clean attire, and follow the dress code of your school or facility.
- Cover visible tattoos and body piercing with clothing or band-aid/dressing according to nursing program policies and procedures.
- Keep hair off collar and fingernails cut short. Wear clear nail polish, not colored polish. Synthetic nails are not allowed as they harbor bacteria and fungus.
- Speak in correct English without slang or inappropriate language, using medical terminology appropriate to the situation.
- Relate to the clients as worthwhile individuals who deserve respect and consideration. Call the client by his or her surname, and use the appropriate honorific (Mr., Ms., Miss, Mrs.). Do not use nicknames (such as "grannie" or "sweetie") or first names.
- Do not "talk down" to or patronize the client. Remember that the client knows more about his or her own body, symptoms, feelings, and responses than anyone else. Listen and pay attention to what the client says about himself or herself or the underlying feelings that are not expressed.
- Remain in a professional role at all times. Do not socialize with the clients. Clients should view you as a knowledgeable professional who brings healing, caring, and teaching roles to the relationship.
- Use yourself as a therapeutic tool to convey caring and healing. Use body language to reinforce honest and direct verbalization, not to contradict it.
- Be accountable and answerable for your behavior and nursing actions and the nursing care you are expected to provide. If you do not understand what is expected, seek assistance from a staff member or your instructor. Your responsibility is to remain reliable, honest, and trustworthy in administering nursing care.
- Maintain client confidentiality. Do not talk about clients in public areas. Follow HIPAA standards (see "HIPAA" section later in this chapter).

A Code of Academic and Clinical Conduct

As students are involved in the clinical and academic environments, we believe that ethical principles are a necessary guide to professional development. Therefore, within these environments, we:

1. Advocate for the rights of all clients.
2. Maintain client confidentiality.
3. Take appropriate action to ensure the safety of clients, self, and others.
4. Provide care for the client in a timely, compassionate, and professional manner.
5. Communicate client care in a truthful, timely, and accurate manner.
6. Actively promote the highest level of moral and ethical principles and accept responsibility for our actions.
7. Promote excellence in nursing by encouraging life-long learning and professional development.
8. Treat others with respect and promote an environment that respects human rights, values, and choice of cultural and spiritual beliefs.
9. Collaborate in every reasonable manner with the academic faculty and clinical staff to ensure the highest quality of client care.
10. Use every opportunity to improve faculty and clinical staff understanding of the learning needs of nursing students.
11. Encourage faculty, clinical staff, and peers to mentor nursing students.
12. Refrain from performing any technique or procedure for which the student has not been adequately trained.
13. Refrain from any deliberate action or omission of care in the academic or clinical setting that creates unnecessary risk of injury to the client, self, or others.
14. Assist the staff nurse or preceptor in ensuring that there is full disclosure and that proper authorizations are obtained from clients regarding any form of treatment or research.
15. Abstain from the use of alcoholic beverages or any substances that impair judgment in the academic and clinical setting.
16. Strive to achieve and maintain an optimal level of personal health.
17. Support access to treatment and rehabilitation for students who are experiencing impairments related to substance abuse and mental or physical health issues.
18. Uphold school policies and regulations related to academic and clinical performance, reserving the right to challenge and critique rules and regulations as per school grievance policy.

Source: National Student Nurses' Association, Inc. April 6, 2001.

The Client Role

Assisting the client to adapt to hospitalization and ensuring that the client is as comfortable as possible will assist him or her to be less anxious and more open to receiving treatment during hospitalization. The nurse can assist in adaptation by understanding that all clients have individual needs, concerns, and perceptions that require discussion and planning as they take on the role of client in the healthcare setting. You must accept the client's perceptions of his or her new surroundings. If possible, try to accommodate client's wishes, assess previous concepts of illness and hospitalization, and discuss previous experiences. Be aware that anxiety is a natural reaction to an unfamiliar setting, to new procedures, and to new people. If, for example, a client is extremely fatigued or overwhelmed by traveling to the hospital and the admission procedure, you can help him or her adapt to the surroundings, regain a sense of control and identity, and accept the changed circumstances.

Another way to assist the client to retain his or her identity and uniqueness is to communicate with the client as an individual. Ask questions and observe verbal responses as well as nonverbal cues. Provide ways to care for a client's personal possessions, clothing, and physical comfort so that the client adapts more easily to the change in environment and feels more secure and in control.

Be aware that the medical condition is only one part of the client's life and that the changes that have led up to admission

affect other areas of his or her well-being. Clients may have concerns about new routines, financial matters, their families, or their future. By responding to clients' total needs at the time of admission, you can help them establish a positive attitude toward their total care.

▲ Relate to clients as worthwhile individuals who deserve respect and consideration.

Acknowledge and accept any statements or behavior the client uses to adapt to his or her new surroundings. Even though various cultures and groups differ in their response to illness and some responses may differ from your personal beliefs, acknowledge the client's individuality. These specific groups often utilize their own identified and respected traditional healthcare providers. Concepts of illness, wellness, and health are part of the client's total belief system and must be recognized by the nurse as part of what makes the client an individual. Support the client's beliefs and behavior as long as they do not increase the risk of injury or illness. Be sensitive to any past healthcare experiences that may influence the client's feelings at the time of admission. A prior experience in the hospital may determine how a client responds to the current environment and how he or she accepts treatment. If they are present and the client is negative or fearful, allow time for the client to discuss these feelings. Try to answer questions they may have about this hospitalization in light of earlier admissions.

STANDARDS AND STATUTES

Legal issues and regulations play a dominant role in nursing practice today. The law provides a framework for establishing nursing actions in the care of clients. Laws determine and set boundaries and maintain a standard of nursing practice.

The Nurse Practice Act defines professional nursing practice and recommends those actions that the nurse can practice independently and those actions that require a physician's order before completion. Individual states allow other healthcare providers who have prescriptive rights—such as nurse practitioners, physician assistants, dentists, and so on—to write orders.

Each state has the authority to regulate and administrate healthcare professionals. Although the provisions of Nurse Practice Acts are quite similar from state to state, it is imperative that the nurse know the licensing requirements and the grounds for license revocation defined by the state in which he or she works.

Legal and ethical standards for nurses are complicated by a myriad of federal and state statutes and the continually changing interpretation of them by the courts of law. Nurses are faced today with the threat of legal action based on negligence, malpractice, invasion of privacy, and other grounds. This chapter covers the basic legal issues and topics, from clients' rights and nurses' liability in the administration of drugs to grounds for proceedings to address professional misconduct.

The Nurse Practice Act

The Nurse Practice Act is a series of statutes enacted by a state to regulate the practice of nursing in that state. Subjects covered by Nurse Practice Acts include definition of the scope of practice, education, licensure, and grounds for disciplinary actions. Nurse Practice Acts are quite similar throughout the United States, but the professional nurse is held legally responsible for the specific requirements for licensure and regulations of practice as defined by the state in which she or he works.

The responsibilities of the professional nurse involve a level of performance for a defined range of healthcare services. These services include assessment, planning, implementation,

and evaluation of nursing action, as well as teaching and related services, such as counseling. Skills and functions that professional nurses perform in daily practice include:

- Providing direct and indirect client care services.
- Performing and delivering basic healthcare services.
- Implementing testing and prevention procedures.
- Observing signs and symptoms of illness.
- Administering treatments per physician's order.
- Monitoring treatment reactions and responses.
- Administering medications per physician's order.
- Monitoring medication responses and any side effects.
- Observing general physical and mental conditions of individual clients.
- Providing client and family teaching.
- Acting as a client advocate when needed.
- Documenting nursing care.
- Supervising allied nursing personnel.
- Coordinating members of the healthcare team.

Nurse Licensure

The authorization to practice nursing is defined legally as the right to practice nursing by an individual who holds an active license issued by the state in which she or he intends to work. The licensing process is administered by the Board of Registered Nursing, frequently called the BRN (or BON). This board may also grant endorsement or reciprocity to an applicant who holds a current license in another state. The applicant for RN licensure must have attended an accredited school of nursing, be a qualified nursing professional or paraprofessional, or have met specific prerequisites if licensed in a foreign country. Paraprofessionals can sit for the NCLEX if they meet all of the requirement (one example is a medic, in some states).

Board of Registered Nursing Functions

- Establishes and oversees educational standards
- Establishes professional standards
- Determines the candidates' qualifications and checks the candidates paperwork/applications
- Registers and renews nurses' licenses
- Conducts investigations into violations of the statutes and regulations
- Issues citations
- Holds disciplinary hearings for possible suspension or revocation of the license
- Imposes penalties following disciplinary hearings
- Establishes and oversees diversion programs in some states

Standards of Clinical Nursing Practice

The American Nurses Association first published these standards in 1973. The standards were revised in 1991 and updated in 2010. The standards apply to all registered nurses working in

Standards of Clinical Nursing Practice

Standards of Care

- Assessment
- Diagnosis
- Outcome Identification
- Planning
- Implementation
- Coordination of Care
- Health Teaching and Health Promotion
- Consultation
- Prescriptive Authority and Treatments
- Evaluation

Standards of Professional Performance

- Quality of Practice
- Education
- Professional Practice Evaluation
- Collegiality
- Collaboration
- Ethics
- Research
- Resource Utilization

clinical practice regardless of clinical specialty, practice setting, or educational preparation. These standards have shaped nursing practice and have helped both nurses and others understand what nursing is and does.

The standards describe a competent level of professional nursing care and professional performance common to all nurses engaged in clinical practice. This includes descriptions of the responsibility and accountability of the professional.

The standards of practice consist of two segments: Standards of Care, which describe the six standards of Clinical Nursing Practice using the nursing process; and the eight Standards of Professional Performance. These eight standards describe a competent level of behavior in the professional role.

Nurses in specialty nursing practice, such as critical care nursing or neonatal nursing, practice under standards that further define the responsibilities in these settings. The nursing specialties and appropriate groups, with the American Nurses Association, determine these standards.

Nurses practicing at an advanced level are accountable for meeting and maintaining the basic standards of clinical nursing practice in addition to the Scope and Standards of Advanced Practice Registered Nursing.

Standards of Care (Example)

Standard II. Diagnosis

The nurse analyzes the assessment data in determining diagnoses.

Measurement Criteria

1. Diagnoses are derived from the assessment data.
2. Diagnoses are validated with the patient, family, and other healthcare providers, when possible and appropriate.
3. Diagnoses are documented in a manner that facilitates the determination of expected outcomes and plan of care.

American Nurses Association Standards of Professional Performance

- I. **Quality of Practice:** The nurse systematically enhances the quality and effectiveness of nursing practice.
- II. **Education:** The nurse attains knowledge and competency that reflects current nursing practice.
- III. **Professional Practice Evaluation:** The nurse evaluates one's own nursing practice in relation to professional practice standards and guidelines, relevant statutes, rules, and regulations.
- IV. **Collegiality:** The nurse interacts with, and contributes to, the professional development of peers and colleagues.
- V. **Collaboration:** The nurse collaborates with the patient, family, and others in the conduct of nursing practice.
- VI. **Ethics:** The nurse integrates ethical provisions in all areas of practice.
- VII. **Research:** The nurse integrates research findings into practice.
- VIII. **Resource Utilization:** The nurse considers factors related to safety, effectiveness, cost, and impact on practice in planning and delivery of nursing services.

Source: American Nurses Association. (2010). *Nursing Scope and Standards of Practice*. Washington, DC.

Liability and Legal Issues

Each state defines and regulates the grounds for professional misconduct. Even though many states have similar standards, the practicing nurse must know how his or her state defines professional misconduct. The penalties for professional misconduct include probation, censure and reprimand, suspension of license, or revocation of license. The state's Board of Registered Nursing (BRN/BON) has the authority to impose any of these penalties for professional misconduct. Any one of the following actions would be considered professional misconduct:

- Obtaining an RN license through misrepresentation or fraudulent methods.
- Giving false information on application for license.
- Practicing in an incompetent or gross negligent manner.
- Practicing when ability to practice is severely impaired.
- Being habitually under the influence of drugs and/or alcohol.
- Furnishing controlled substances to himself or herself or to another person.
- Impersonating another certified or licensed practitioner or allowing another person to use his or her license for the purpose of nursing.
- Being convicted of or committing an act constituting a crime under federal or state law.
- Refusing to provide healthcare services on the grounds of race, color, creed, national origin, religion, or beliefs different from your own.

- Permitting or aiding an unlicensed person to perform activities requiring a license.
- Practicing nursing while license is suspended.
- Practicing medicine without a license.
- Procuring, aiding, or offering to assist at a criminal abortion.
- Holding oneself out to the public as a “nurse practitioner” without being certified by the BRN/BON as a nurse practitioner.

Drugs and the Nurse

In their daily work, most nurses handle a wide variety of drugs. Failure to give the correct medication or improper handling of drugs may result in serious problems for the nurse due to strict federal and state statutes relating to drugs. The Comprehensive Drug Abuse Prevention Act of 1970 provides the fundamental federal regulations for compounding, selling, and dispensing narcotics, stimulants, depressants, and other controlled items. Each state has a similar set of regulations for the same purpose.

Noncompliance with federal or state drug regulations can result in liability. Violation of the state drug regulations or licensing laws are grounds for the Board of Registered Nursing to initiate disciplinary action.

Negligence/Malpractice

The doctrine of negligence rests on the duty of every person to exercise due care in his or her conduct toward others from which injury may result. Negligence includes doing something

that the reasonable and prudent person would not do. Anyone, including nonmedical persons, can be liable for negligence. Professionals (nurses) are held to a higher standard of care than nonprofessionals. The doctrine of negligence consists of the following elements: a duty owed to the client, a breach of that duty, damages to the client, and a causal relationship between the damages and the breach of duty. To find liability, it is necessary to identify a breach of duty to act with care, or a failure to act as a reasonable and prudent person (or nurse) would act under similar circumstances.

The standards referenced above form the basis for negligence or malpractice. Malpractice addresses a professional standard of care as well as the professional status of the caregiver. To be liable for malpractice, the person committing the civil wrong must be a professional. Courts define malpractice as any professional misconduct, unreasonable lack of skill, or fidelity in professional or judiciary duties that results in unnecessary suffering, injury, or death to the person.

Gross negligence is the intentional failure to perform a duty in reckless disregard of the consequences affecting the client. It is viewed as a gross lack of care to such a level as to be considered willful and wanton. Gross negligence can be due to improper use of restraints, client falls, or medication errors that lead to a client injury.

Criminal negligence also consists of a duty on the part of the nurse and an act that is the proximate cause of the injury or death of a client. This type of negligence is usually defined by statute and as such is punishable as a crime. The punishable act represents a flagrant and reckless disregard to the safety of others and/or a willful disregard to the injury liable to follow so as to convert the act into a crime when it results in personal injury or death. One is not “negligent” unless he or she fails to exercise the degree of reasonable care that would be exercised by a person of ordinary prudence under all the existing circumstances in view of probable danger of injury. The death or serious injury of a client after a medication or IV error can result in criminal negligence.

Malpractice is any professional misconduct that is an unreasonable lack of skill or fidelity in professional duties. In a more specific sense it means bad, wrong, or injurious treatment of a client resulting in injury, unnecessary suffering, or death to a client, proceeding from ignorance; carelessness; lack of professional skill; disregard of established rules, protocols, principles, or procedures; neglect; or a malicious or criminal intent.

Civil Law	Criminal Law
Contract	Assault
Unintentional tort	Battery
Intentional tort	Murder
Negligence	Manslaughter

The Joint Commission states “Malpractice is a cause of action for which damages are allowed.”

Source: The Joint Commission’s Sentinel Event Glossary of Terms, n.d. http://www.jointcommission.org/SentinelEvents/se_glossary.htm

It is the nurse’s legal duty to provide competent, reasonable care to clients. To ensure that this occurs, the nurse must know the standards of care, develop consistent patterns of practice that meet the standards, and reflect his or her action in accurate

Guidelines for Drug Administration

- Nurses must not administer a specific drug unless allowed to do so by the particular state’s Nurse Practice Act.
- Nurses must not administer any drug without a specific physician order.
- Nurses are to take every safety precaution in whatever they are doing.
- Nurses are to be certain that employer’s policy allows them to administer a specific drug.
- Nurses must not administer a controlled substance if the physician’s order is outdated.
- A drug may not lawfully be administered unless all the above items are in effect.
- Nurses are not permitted to fill prescriptions and in most states cannot write prescriptions, except in the case of nurse practitioners in some states.
- General rules for drug dispensing:
 - Check two forms of client identification before administering medications.
 - Never leave prepared medicines unattended.
 - Always report errors immediately.
 - Send labeled bottles or packages that are unintelligible back to the pharmacist for relabeling.
 - Store internal and external medicines separately if possible.

and complete documentation. Legal action against nurses has been increasing over the last decade. Nursing actions that constitute a breach of a standard of care that can lead to injury of a client include such actions as not inserting a Foley catheter correctly, not taking appropriate steps to decrease a client's temperature, not reporting unusual or worsening condition of the client to his or her physician, and not preventing falls. All of these situations can lead to malpractice suits.

Most lawsuits against nurses are for alleged violations of tort law. A tort is defined as an action or omission that harms someone. Malpractice refers to a tort committed by a professional acting in his/her professional capacity.

Legal doctrine holds that an employer may also be liable for negligent acts of employees in the course and scope of employment. Physicians, hospitals, clinics, and other employers may be held liable for negligent acts of their employees. This doctrine does not support acts of gross negligence or acts that are outside the scope of employment.

HIPAA

The Health Insurance Portability and Accountability Act (HIPAA), enacted into law in 1996 and phased in gradually, requires the Secretary of Health and Human Services (HHS) to devise standards to improve Medicare and Medicaid programs and the efficiency and effectiveness of the healthcare system. It ensures continuing healthcare insurance if the client has had existing group insurance and the client either changes or loses his/her job, proposes standards for electronic transactions and security signatures, and ensures privacy of individual health information.

The privacy rule component went into effect on April 14, 2003. The Privacy Rule applies to health plans, to healthcare clearinghouses, and to any healthcare provider who transmits health insurance information in electronic form. This is based on adopted HIPAA standards. A major purpose of the Privacy Rule is to define and limit the circumstances in which an individual's protected health information may be used or disclosed by the entities listed above. Information is disclosed only if allowed by the Privacy Rule.

Under this act, the client can request copies of his/her medical record and request that corrections be made if he or she identifies errors. The act specifies that personal healthcare information may not be used for any purpose not related to health care. The act also provides for client information to be given only to the client, or his/her representative, unless directed to do otherwise.

Compliance with HIPAA regulations is mandatory. Non-compliance can lead to civil penalties up to \$25,000 per calendar year for multiple violations of a single standard. There are also penalties from \$50,000 to \$250,000 and/or imprisonment up to 10 years for other violations of the act.

Medicare Prescription Act

The **Medicare Prescription Drug Improvement and Modernization Act of 2003** was signed into law on December 8, 2003, although it was not enacted until 2005. This law brings affordable health care and prescription drug coverage

to all Medicare recipients, seniors, and individuals with disabilities; expanded health plan options; improved healthcare access to rural Americans; and preventative care services such as mammograms. This is the first innovative change to the Medicare program since its inception in 1965. There are still proposed changes regarding the legislative healthcare tax credits and expansion of tax-free medical savings accounts.

CLIENTS' RIGHTS AND RESPONSIBILITIES

State and federal regulations governing healthcare facilities mandate that certain rights be afforded clients receiving health care. Hospitals and healthcare facilities must have established policies that discuss client rights and how staff are to adhere to them. The American Hospital Association (AHA) distributes "The Patient Care Partnership" brochure to all clients. This brochure describes what to expect during the hospital stay, the client's rights and privacy, and a short definition of a living will and advance directives. The AHA directs clients to the individual healthcare facility for further information.

Because clients' rights may conflict with nursing functions, you should be familiar with the key elements of these rights. It is important to remember that within a healthcare system, all clients retain their basic constitutional rights, such as freedom of expression, due process of law, freedom from cruel and inhumane punishment, equal protection, and so forth. Clients also have the right to know the identity of all healthcare providers and others involved in their care, which includes student nurses. All healthcare workers must wear a name badge indicating their title (e.g., Jane Doe, Student Nurse). The name of the nursing program is also included on the name badge. Most badges include a photo ID in addition to the name.

Under the Patient's Bill of Rights, hospitals must provide a foundation for understanding and respecting the rights and responsibilities of clients, their families, physicians, and other caregivers. The hospital must ensure and respect the role of clients in decision making about treatment choices and other aspects of their care. There must be a sensitivity to cultural, racial, linguistic, religious, age, and gender differences. In addition, the needs of persons with disabilities must be considered when providing healthcare services. Each hospital is encouraged to tailor its bill of rights to its particular community and client population. Individualization to the community ensures that the families and their specific rights are considered when the bill of rights is written.

Clients have a responsibility for their role in utilizing healthcare facilities. Their responsibilities include providing the physician with a complete history, relevant clinical manifestations, current medications, and herbal remedies. The client is responsible for asking questions and informing the physician of changes in clinical manifestations or general medical situations. Clients also need to respect the hospital personnel and treat hospital property and equipment with respect.

Consent to Receive Health Services

There are two major forms of consent signed by clients in a healthcare facility. The first consent is completed at the time of admission; the client signs the form in the admissions office or in the emergency department, wherever the admission is initiated. This agreement usually indicates that the client has agreed to such things as medical treatment, x-ray examinations, blood transfusions, and injections. The second type of consent is for invasive testing procedures, such as a liver biopsy, surgery, special studies involving contrast media, or other treatments in which there are risks associated with the procedure.

Consent is the client's approval to have his or her body touched by specific individuals, such as doctors, nurses, and laboratory technicians. Informed consent refers to the process of informing the client before granting a consent regarding treatment, such as tests and surgery, and must be understood by the client in terms of the intended outcome and the potential harmful results. The client may rescind a prior consent verbally or in writing.

The authority to sign a consent must be given by a mentally competent adult. Court-authorized persons may give consent for mentally incompetent adults. In emergency situations, if the client is in immediate danger of serious harm or death, action may be taken to preserve life without the client's consent.

The practitioner who will perform the procedure is legally responsible for obtaining the client's informed consent. The nurse's liability in terms of consent is to ensure that the client is fully informed before being asked to sign a consent form. The physician, nurse, or other health personnel must inform the client of any potentially harmful effects of the treatment. If this is not done, it may result in the nurse being held personally liable. The nurse must respect the right of a mentally competent adult client to refuse health care; however, a life-threatening situation may alter the client's right to refuse treatment.

In life-threatening emergencies, informed consent may not be required, because the law assumes a client will want treatment to save his or her life. The practitioner therefore

The Client's Bill of Rights

1. The client has the right to considerate and respectful care.
2. The client has the right to and is encouraged to obtain from physicians and other direct caregivers relevant, current, and understandable information concerning diagnosis, treatment, and prognosis. In emergencies, the client is entitled to the opportunity to discuss and request information related to specific procedures and/or treatments, the risk involved, and the financial implications of the treatment choices, etc. Clients also have the right to know the identity of healthcare professionals caring for them, including students, residents, or other trainees. The client has the right to know the immediate and long-term financial implications of treatment choices insofar as they are known.
3. The client has the right to make decisions about the plan of care prior to and during the course of treatment and to refuse a recommended treatment or plan of care to the extent permitted by law and hospital policy and be informed of medical consequences of this action.
4. The client has the right to have an advance directive and have the hospital honor the intent of the directive to the extent permitted by law and hospital policy. The institution must advise clients of their rights under state law and hospital policy to make informed medical choices. Hospitals must identify if a client has an advance directive and place it in the client records.
5. The client has the right to every consideration of privacy including examination, treatment, consultation, and case discussion.
6. The client has the right to expect all communications and records pertaining to his/her care be treated as confidential by the hospital, except in cases of suspected abuse and public health hazards when reporting is permitted or required by law.
7. The client has the right to review the records pertaining to his/her medical care and have the information explained or interpreted as necessary, except when restricted by law.
8. The client has the right to expect that, within its capacity and policies, a hospital will make reasonable response to the request of a client for appropriate and medically indicated care and services. Clients have the right to request a transfer to another facility. After the facility accepts the client, complete information must be provided.
9. The client has the right to ask and be informed of the existence of business relationships among the hospital, educational institutions, other healthcare providers, or payers that may influence the client's treatment and care.
10. The client has the right to consent to or decline to participate in proposed research studies or human experimentation affecting care and treatment or requiring direct client involvement and to have those studies fully explained prior to consent.
11. The client has the right to expect reasonable continuity of care when appropriate and to be informed by physician and other caregivers of available and realistic client care options when hospital care is no longer appropriate.
12. The client has the right to be informed of hospital policies and practices that relate to client care, treatment, and responsibilities, including grievances and conflicts. Clients have the right to be informed of available resources for resolving disputes, grievances, and conflicts.

intervenes appropriately to save the client's life regardless of whether informed consent was obtained.

Confidentiality

As stated earlier, clients are protected by law (invasion of privacy) against unauthorized release of personal clinical data, such as symptoms, diagnoses, and treatments. Nurses, as well as other healthcare personnel, may be held personally liable for invasion of privacy, should litigation arise from the unauthorized release of client data. Advances in technology, including computerized medical databases, the Internet, and telehealth, pose potential (unintentional) breaches of confidentiality and privacy. Changes in technology have changed not only the delivery of health care, but also the system used to record and retrieve health information.

The computer, fax machine, and phone calls between facilities and agencies leave the client at risk for information dissemination to unintended sources. Information is readily available to anyone walking by a fax machine or a computer. Confidential information, however, may be released with the client's consent. Information release is mandatory when ordered by a court or when state statutes require reporting child abuse, communicable diseases, or other incidents. Nurses have a legal and ethical responsibility to become familiar with their employer's policies and procedures regarding protection of clients' information.

Medical records are the key written account of such client information as signs and symptoms, diagnosis, treatment, and responses to treatment. Not only do these records document care given to clients, but they also provide effective means of communication among healthcare personnel. These records contain important data for insurance and other expense claims and are used in court in the event of litigation.

Healthcare professionals are becoming more aware of the implications of clients' rights as society in general becomes more aware of every human being's basic rights. Although there are still gaps in the legal process, many states are beginning to grapple with the status of laws applicable to clients who are hospitalized. It is essential that nurses be aware of the particular state's laws and statutes affecting clients and themselves. Nurses as well as physicians are accountable for their actions, and the threat of civil and criminal prosecution is becoming more prevalent. The American Nurses Association has developed a position statement supporting the principles of client privacy and confidentiality as a commitment to client advocacy. This statement is part of the Code of Ethics for Nurses (Privacy and Confidentiality Interpretive Statements 3.1 and 3.2).

Patient Self-Determination Act

Patient Self-Determination Act of 1991 (PSDA) is a federal law that applies to all healthcare institutions receiving Medicaid funds. It imposes on the state and providers of health care, such as hospitals, nursing homes, hospices, home health agencies, and prepaid health care organizations, certain requirements concerning advance directives and an individual's rights under state law to make decisions concerning medical care; this includes the right to accept or refuse medical or

Classifications of Law Related to Nursing

Classification	Example
Constitutional	Clients' rights to equal treatment
Administrative	Licensure and the state BRN
Labor relations	Union negotiations
Contract	Relationship with employer
Criminal	Handling of narcotics
Tort	
Medical malpractice	Reasonable and prudent client care
Product liability	Warranty on medical equipment

surgical care. This act informs clients about existing rights, but does not create new rights or change existing state law. The act did serve as an incentive for many states to pass durable power of attorney for healthcare statutes. It does not require clients to execute advance directives, but it does require that they be apprised and educated about advance directives. It also requires that assistance be offered in the execution of the advance directives if the client elects to do so. The PSDA defines an *advance directive* as a written instruction, such as a living will or durable power of attorney, for health care. A competent adult can communicate preferences about future medical treatment through the advance directive. Clients must be provided written documentation regarding their rights to formulate advance directives. Clients must be made aware of their rights to make decisions about these issues on admission to all healthcare facilities and health maintenance organizations (HMOs); however, they are not required to sign an advance directive if they do not choose to do so. Client education regarding advance directives should be accomplished outside the acute care setting. The directives allow clients to control their own healthcare decisions, even if they become incapacitated in the future.

Advance Medical Directives

Advance medical directives are of two types: treatment directives, such as living wills, and appointment directives, such as durable power of attorney for health care. An advance medical directive is a document that allows clients to make legal decisions about how they wish to receive future medical treatment. It is written and signed before any such care becomes necessary. The document becomes effective only when the client becomes incapacitated. The directives may be in the form of a living will or durable power of attorney. Within this document, the client may indicate the person or persons he or she wishes to make medical decisions in situations in which the client is unable to do so. An advance directive does not need to be written, reviewed, or signed by an attorney. It must, however, be signed and witnessed by two individuals, and the witnesses should not be hospital employees, relatives, or heirs to the estate. Copies of the document should be kept on file in the physician's office and the hospital. Advance directives vary among states, and therefore the nurse must be knowledgeable about the use and type of directives in the state in which he or she practices.

Advance Directives

An advance directive allows the client to participate in the following decisions:

- Choosing healthcare providers such as physicians and nurses.
- Deciding who may have access to medical records.
- Choosing the type of medical treatments the client desires.
- Consenting to or refusing certain types of medical treatments.
- Choosing the agent who will make decisions about the client's health care when the client is unable to do so.

Living Will A living will is a type of advance directive that indicates the client's wishes regarding prolonging life using life support measures, refusing or stopping medical interventions, or making decisions about his or her medical care when the client is diagnosed as having a terminal or permanent unconscious condition. It does not apply to any other healthcare decisions. Living wills are executed while the client is competent and able to make sound decisions. As conditions change, a living will needs to be evaluated for relevance. (States differ in their acceptance of living wills as legal documents.)

Durable Power of Attorney for Health Care This legal document must be prepared and signed while the client is competent. The document gives power to make healthcare decisions to a designated individual (agent) in the event the client is unable to make competent decisions for himself or herself. The designated person is obligated to follow the directives outlined in the document. The document gives the client's agent specific healthcare decisions or the authority to make any and all healthcare decisions the client would make if able. Decisions regarding withdrawing or using life support, organ donation, or consent to treatment or procedures are included in the directive. As long as the client is competent, the agent does not have the authority to make treatment decisions.

The major difference between living wills and the durable power of attorney is that the durable power of attorney is more flexible. A living will is used only if the client's condition is terminal or they are in a permanently unconscious state. A living will only allows the client to direct that life-sustaining treatments be withheld or withdrawn. The durable power of attorney is not limited to terminal or permanent unconscious conditions. It also addresses all types of healthcare decisions, including life-sustaining treatments.

Clients should be encouraged to carry a card in their wallet indicating that they have a living will and/or durable power of attorney on file. The name of their agent should be listed.

Do Not Resuscitate

Health care facilities must provide written information to clients concerning their right to make decisions regarding their care.

A "Do Not Resuscitate" (DNR; sometimes called "Do Not Attempt to Resuscitate" [DNAR]) order is another type of

advance directive. A DNR is a request to not have cardiopulmonary resuscitation (CPR) if the client ceases to breathe or is unable to sustain a heartbeat. An advance directive form can be signed at any time before or during hospitalization. When signed, the physician places a DNR notation in the client's medical chart. (See Chapter 34.) In some facilities these orders are reviewed every 48 to 72 hours.

If a terminally ill client without a DNR order tells you orally that he/she does not want to be resuscitated in a crisis, document this information and state the client's level of orientation. Notify the physician and administration, legal services, or social services of the client's wishes.

CLINICAL PRACTICE

Legal Issues

As a student nurse, you need to maintain a high standard of practice and protect yourself against legal problems. Most legal actions against nurses result from a claim that the nurse breached a standard of care that results in injury to the client. In order to prevent legal problems, the nurse must always follow the five steps of the nursing process; administer medications following the seven rights of medication administration; continually assess the client, clearly communicate changes in the client's condition to the appropriate individual, and then document findings on proper forms or computer screens (the medical record is a legal document); follow hospital policies and procedures; and understand and use equipment safely and appropriately. Constantly refer to these guidelines to protect the client from harm and to protect yourself from potential lawsuits.

Before your first clinical experience, you should review the most essential components of client care to enable you to practice safe and efficient nursing care. Laws in each state vary in relationship to how the law applies to your practice and the medical record; therefore, check that you are familiar with your individual state laws.

Guidelines for clinical practice, the parts of a client chart or computer printout, communication techniques, principles of medical asepsis, a basic nursing assessment, and protocols for nursing care procedures are presented to give you confidence and background information in providing nursing care.

Guidelines for Safe Clinical Practice

Before attempting to provide client care, you need to familiarize yourself with all aspects of the care the client requires. The following guidelines will assist you in this preparation. Usually, the preparation is completed the night before you go to the clinical setting. If this is not possible, you need to identify those aspects of preparation that will render you a safe practitioner.

- Obtain the clinical assignment in sufficient time to be able to prepare for safe practice.
- Read the client's chart or computer data and obtain information necessary to assist you in client care. This usually encompasses the following items: history and physical,

physician's progress notes, graphic sheet, medication record, laboratory findings, nurses' notes or flow sheets or both, admissions database, client care plan, Kardex card or computer plan of care, and physician's orders. Each of these documents is illustrated later in this chapter.

- Review all procedures that you will provide for the client. Use your skills and fundamentals books for your review.
- Research the medical diagnosis so that you are more aware of signs and symptoms the client may exhibit. Identify alterations from normal such as altered laboratory values, vital signs, and so forth.
- Research nursing diagnoses identified on the chart or potential diagnoses you identify from review of the chart. Your client care will focus on the nursing diagnoses and interventions associated with collaborative care.
- Research all medications you will administer to the client. Many instructors require that medication cards or documents be completed on all medications before administration.
- Plan your day's schedule by developing a time management plan to help keep you organized and to enable you to complete client care in a timely manner.
- Practice charting the procedures you will be administering so that you can identify appropriate vocabulary and include necessary information. Pertinent charting information is included with each procedure described in this text.
- Complete a clinical prep sheet as required by the instructor. The sheet usually has a section for all pertinent data.

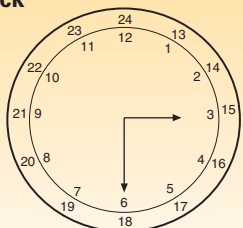

Military Time The use of "military time" is becoming more common in healthcare facilities today. One advantage of using this time frame is that the confusion of whether something is ordered or documented in the AM or PM is avoided. Military time describes time as a 24-hour clock rather than the standard 12-hour clock like your watch. Midnight is identified as 2400, 1:00 AM is 0100, 3:00 PM is 1500, and so on. Review both the 24-hour clock and the chart below to acquaint yourself with this method of keeping time.

Use of PDAs in Clinical Setting

A PDA is a personal digital assistant or handheld computer. Students are becoming more adept in the use of these aids, especially as they have pocket drug guides, diagnostic test guides, and clinical calculators contained within the PDA.

12-hour clock	24-hour clock
12 midnight	2400
1:30 AM	0130
1:59 AM	0159
12 noon	1200
2:18 PM	1418
7:30 PM	1930
9:00 PM	2100

24-HOUR CLOCK

3:30 PM standard time
or 1530 military time.

HIPAA requires that you recognize and protect oral, written, and electronic information that could reveal a client's identity and health-related information. This information is referred to as the PHI (protected health information).

HIPAA has developed guidelines for using a PDA safely. HIPAA recommends that the client's name or any identifying data not be input into the PDA. Personal demographics or client identifiers such as history and physical findings, lab data, physical data, and phone numbers must be input using passwords only. If identifying data must be input into the PDA, the nurse needs to utilize the "Security" feature, which requires a password to enter the system. Most nursing students will not use this type of data entry. It is more usual for a home health nurse to need the personal identifiers.

Providing Client Care

You have prepared for clinical practice before coming to the nursing unit. Information regarding client needs and care is provided through shift report and an individualized, in-depth client report by the team leader or preceptor. Each hospital has a method for presenting the report. Some facilities tape a report from the off-going shift that is listened to by the on-coming staff. Other nursing units give a verbal report in which they review the information obtained by the previous shift. Facilities where primary nursing is practiced have a one-to-one report between the on-coming nurse and the off-going nurse for a specific group of clients. At this time a worksheet is completed that lists times for treatments and medications. Following the report, the team leader or your preceptor nurse goes over all aspects of the care you will deliver for the client. This is the time to ask any questions you may have regarding policy or procedure for the nursing unit or the client.

The following outline of client care will assist you in planning your nursing care for the day. Before you begin client care, you need to review the client's profile or computer plan of care and check that all medications are available in the computer on wheels (COW), Pyxis, or medication care.

1. Perform hand hygiene.
2. Gather equipment, such as a stethoscope, sphygmomanometer, thermometer, and linen.
3. Check two forms of client identification (other than room number). Introduce yourself to the client and explain the nursing care you will be giving.
4. Check if the client has any preference for the order in which the care is to be given when possible.
5. Complete a nursing assessment. You may use the basic nursing assessment outlined in this chapter as a guide if your instructor does not have one she or he prefers you to use.
6. Document your findings as you are completing the physical assessment, and enter it in the nurses' notes section of the chart or on the flow sheet or in the computerized documentation system.
7. Take vital signs if it is the policy of the unit. In some facilities, nursing assistants take vital signs, while nursing staff receives report.

8. If using a PDA to enter client data, follow HIPAA guidelines specific to such devices.
9. Don gloves (if appropriate) and complete all nursing interventions, and document the findings immediately after completion.
10. Administer all medications, including checking two identifiers, according to policies and procedures in the healthcare facility. If gloves were used, remove and wash hands.
11. Document medication administration in the appropriate place, and observe for signs of side effects or unusual findings.
12. During your nursing care, practice good communication techniques.
13. Complete all charting.
14. Terminate the relationship with the client.
15. Report off to the appropriate person.
16. Perform hand hygiene after providing nursing care and before leaving the nursing unit.

Client's Forms

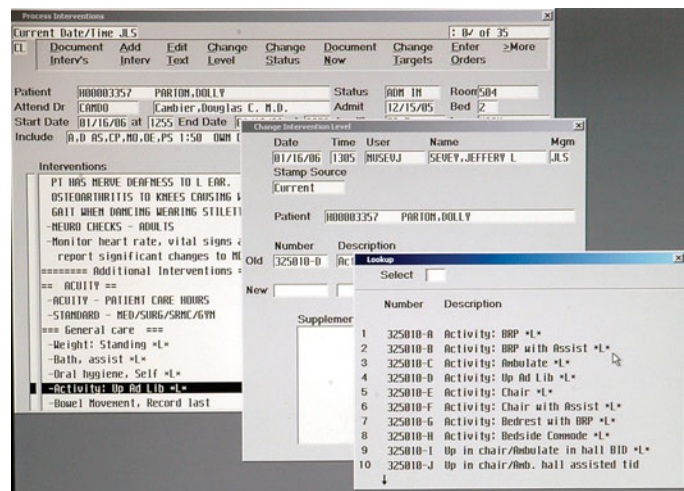

Become familiar with each form or computer screen, its placement in the chart or computer, and the information that it contains. Brief examples of some computer screens are included in this chapter, and examples of these forms are included in Chapter 3.

Kardex/Client Profile The Kardex card or Client Profile represents the “hub” for all client activities. Physician’s orders are transcribed on the card. Laboratory tests, medications, and activity levels are just a few items documented in designated areas of the Kardex or profile.

The computerized plan of care is replacing the Kardex card in many facilities today. The same information is contained in the electronic version, but in many cases, the information is more up to date.

Care Plan Client care plans vary among healthcare facilities. The older individualized handwritten care plan is being replaced by preprinted standardized care plans, computerized care plans, or critical pathways. Regardless of the type of care plan used, the purpose does not change. Care plans are written guidelines for client care that all healthcare workers use to deliver individualized care. Most care plans today are termed *Multidisciplinary Care Plans* because all health team providers document treatments and observations on one form. Pertinent data regarding client care needs can be communicated to all providers using the multidisciplinary care plan. Client teaching is frequently detailed on the same form.

Critical or Clinical Pathway You may see either of these terms used to describe an approach to deliver collaborative, outcome-driven health care to clients. These

▲ Computer-generated client profile.

documents are another approach to providing individualized care to clients. Interventions and outcomes are progressively outlined within the pathway as illustrated.

Client's Chart

Client information is contained on several forms or computer screens, depending on documentation systems used in the healthcare facility. These forms or computer screens are important to your preparation and administration of nursing care. Be sure to familiarize yourself with the specific forms or screens in the healthcare facility where you have your clinical experience. The following forms are intended to be just examples. Refer to Chapter 3 for complete description of forms or screens.

Nurses' Notes *Nurses' notes* are documents that contain clinical observations and nursing interventions. Many facilities have limited the narrative charting format and increased the use of flow sheets and checklists, termed *Patient Care Records* or *Multidisciplinary Team Records*. This type of charting decreases the time it takes nurses to document and promotes comprehensive documentation. Each hospital has developed its own documentation system; therefore, it is important to

COMMUNITY HOSPITAL		CLIENT CARE PLAN Individualized				Client Information

▲ Clinical pathway.

become familiar with the system before beginning to document. Many facilities have gone to computerized charting systems that facilitate a more thorough mechanism for data input. In-service education programs on use of the computer for charting and data retrieval need to be completed before clinical experience is begun to ensure that you can obtain all the necessary information to provide safe care for the client.

Medication Records Medication records are usually similar to those illustrated. All medications should be documented on a medication record. Some facilities chart routine medications on one medication sheet, and PRN and one-time only medications are charted on another sheet. Check the institution's policy for each record's use. Electronic health records also have medication screens.

Graphic Records Vital signs are recorded on the graphic sheet; see also Chapter 3, including blood pressure, pulse, respirations, temperature, and pain level. Most facilities have included the pain scale on the graphic record as it is referred to as the fifth vital sign. Weight is also included on this form. Intake

and output results may be recorded on this record or on a separate form, depending on the facility.

Physician's Orders Physician's orders may be written on forms with carbon copies attached, preprinted, or computerized, depending on the facility. If the orders are carbon copied, copies can be sent to the pharmacy and to the lab, with the original retained in the client's chart. Computerized orders can be easily utilized by all hospital departments.

Physician's Progress Notes Physician's progress notes contain daily observations and thoughts regarding treatments, signs, and symptoms experienced by the client, operative risks explained to the client, and the client's responses to therapy.

History and Physical The physician's report of his/her assessment is written on a special form. Most hospitals type the history and physical from notes dictated by the physician. When this occurs, it may be several days before this information is available.

Laboratory Forms Laboratory results are sent back to the unit on the original laboratory order form. The information from each form may be transcribed to a laboratory data flow sheet. This sheet provides a valuable overview of all laboratory results. Computerized reports of laboratory findings may be used in some facilities.

Basic Nursing Assessment

Each nurse develops her or his own routine for completing a basic nursing assessment.

There is no right or wrong way, although it should be consistent and complete. The following outline for basic assessment is a simple approach to the assessment and one you may wish to adopt until you have established a good system for yourself.

The basic assessment is completed at the beginning of each shift (usually a complete assessment is done once per day and focus assessments at the beginning and end of the other shifts). You should focus on the specific physiologic system that correlates with the client's diagnosis. For a more in-depth discussion of each system in the assessment, see Chapter 11, Physical Assessment.

The following outline will assist you in completing a basic physical assessment.

1. Vital signs:
 - a. Temperature (method dictated by condition)
 - b. Radial or apical pulse (depending on condition)
 - c. Respirations: rate, depth, and rhythm
 - d. Blood pressure: Korotkoff's sounds
 - e. Pain: location and intensity of pain; use pain scale to determine pain level.
2. Response to medications if given.

3. Emotional responses: client behavior, reactions, and demeanor; general mood (crying, depression)
4. Skin, hair, and nails: Skin: presence or absence of abrasions, contusions, tears, erythema, pressure ulcers, incision line, color, turgor, temperature, edema. Inspect hair

5. Musculoskeletal: activity level, general mobility, gait, range of motion
6. Neurologic: pupils (size, response, equality); hand grips; strength and sensation of all extremities; ability to follow commands; level of consciousness
7. Respiratory: breath sounds; sputum color and consistency; cough (productive or nonproductive)
8. Cardiovascular: heart sounds; presence of pulses; edema; observe presence of hair on extremities (lack of indicates poor circulation)
9. Gastrointestinal: bowel pattern and sounds; presence of nausea or vomiting; abdominal distention; consumption of diet
10. Genitourinary: voiding; color, odor, and consistency of urine; dysuria; vaginal drainage or discomfort; penile discharge

If any unusual findings are assessed, complete a more in-depth assessment of the particular system affected. Throughout the day, continue to assess changes in the client's condition by paying particular attention to the alterations from normal that you identified in the initial assessment. At the end of the shift, make a notation of any changes in the client's condition.

MEDICAL ASEPSIS PRINCIPLES

Microorganisms are found everywhere in nature. Pathogenic microorganisms, or pathogens, cause disease; nonpathogenic microorganisms, or nonpathogens, do not cause disease. Some microorganisms are nonpathogens in their normal body environment. An example of this is *Escherichia coli*, which is normally present in the intestinal tract and does not cause a problem until it inhabits another environment such as the urinary tract.

The spread of microorganisms is prevented by the use of two forms of asepsis: medical asepsis and surgical asepsis. Medical asepsis occurs when there is an absence of pathogens. Surgical asepsis occurs when there is an absence of all organisms. Medical asepsis is often referred to as “clean technique,” whereas surgical asepsis is termed “sterile technique.” A discussion of surgical asepsis can be found later in this book. This chapter discusses medical asepsis as it affects nursing care.

Principles of medical asepsis are used in all aspects of client care. In fact, the use of medical asepsis begins before you report to the nursing unit. To ensure protection for the client, you begin practicing medical asepsis by limiting jewelry to only a wedding band and perhaps small earrings for pierced ears when administering client care. Fingernails are short and in good repair. Your hair is off your collar and under control to prevent contaminating sterile fields and falling into client’s food or wounds. While providing client care, the following principles should be kept in mind:

- Linen rooms or carts are considered clean; therefore linen not used for client care cannot be returned.
- Utility rooms are designated as areas for clean and dirty supplies. Cross-contamination must be avoided by not placing articles in the wrong area.
- Linen and articles are carried away from your uniform and are not held close to your body.
- Articles dropped on the floor are considered contaminated and must be discarded appropriately. If linen is accidentally dropped on the floor, it is placed in a soiled linen hamper.
- Clients are to wear slippers or shoes when out of bed.
- Paper tissue is used for removing client’s secretions. Discard the tissue in the trash basket.
- Each client has his or her own supplies and equipment, which are not used by other clients. Sterilization or disinfection of equipment is carried out between use.
- Equipment is cleaned and rinsed with cold water to remove secretions or substances before being returned to the central supply area. Heat coagulates the substances and makes them more difficult to remove.
- Soap and water are considered the best cleansers because they help break down soil so it can be more readily removed. Detergents may be more effective in hard or cold water; however, tissue damage can result from their use. Germicides, when added to soap or detergent, increase the effectiveness of the cleansing agent.
- Friction is used to facilitate soil removal. A brush, sponge, or cloth may be used to produce the friction.
- When aseptic technique is used, cleaning is conducted from the cleanest to the least clean area. For example, always clean the incision area from the center of the incision to the periphery of the skin.
- If you are not feeling well, you should not report for clinical experience. If you are running a temperature or have a cold and a runny nose, call the appropriate person and report that you are ill.

Hand Hygiene

The single most effective medical aseptic practice is handwashing. When you first arrive at the nursing unit and before beginning nursing practice, you should complete a medical handwashing procedure. The important concept to remember is that you thoroughly soap and rinse your hands twice before providing any nursing care to the client. Hands are washed before all procedures and between clients. Alcohol-based hand rub is usually used between clients if hands are not dirty. The specific step-by-step handwashing procedure is covered in Chapter 14, Infection Control.

Clean, nonsterile gloves are worn when touching, or there is a potential for touching, blood, body fluids, secretions, excretions, and contaminated items. Gloves are discarded immediately after use in an appropriate container. Gloving decreases the risk of cross-contamination between clients and between clients and healthcare workers. Handwashing is completed before donning and after removal of gloves.

PROTOCOL FOR PROCEDURES

Each procedure in this textbook follows a basic protocol. To save space and prevent repetition, all steps in the protocol are frequently not outlined in detail for each procedure. Remember, however, that these steps are important and must be followed if complete and responsible nursing care is to be delivered to the client.

- Check physician’s orders.
- Check client care plan, clinical pathway, Kardex, or client computer plan of care, not room number.
- Identify client using two forms of identification (according to facility policy, and not only for medication administration).
- Introduce yourself to the client, if first time in room.
- Explain procedure to be done.
- Answer client’s questions and reinforce teaching.
- Perform hand hygiene using alcohol-based solution unless your hands are dirty; then use soap and water.
- Gather equipment and fill out charge slips.
- Take all of the required equipment and linens to the room.
- Provide privacy for the client by drawing curtain or screen around bed.
- Raise bed to HIGH position.
- Lower side rail nearest you.
- Drape client (if appropriate).
- Don gloves (if appropriate).

- Perform procedure according to protocol.
- Clean client as necessary.
- Remove drape and position client for comfort.
- Remove gloves.
- Raise side rail to UP position.
- Lower bed.
- Replace call bell.
- Pull back curtain or remove screen.
- Remove equipment and clean, dispose of, and disperse used equipment.
- Perform hand hygiene using alcohol-based solution unless your hands are dirty; then use soap and water.
- Document or chart findings.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- As an RN you will be held accountable and responsible for your actions. When delegating client care, you must know the healthcare worker's level of client care tasks that can be assigned to each category of worker. The Nurse Practice Act for both RN and LVN/PN must be adhered to when assigning client care. The skill level and scope of practice of unassisted licensed personnel must be evaluated before assigning client care.
- The RN must abide by and function within the American Nurses Association Code of Ethics for Nurses. The RN is responsible for the appropriate delegation of nursing tasks to others in order to provide safe, competent client care.
- Legal issues and regulations must be followed in order to establish appropriate client care standards when delegating to other healthcare workers. The RN has a responsibility for a level of performance that must be carried out and cannot be delegated, including healthcare teaching, initial assessment, and the administration of IV medications.
- The signing of a consent form for surgery or an invasive procedure may be delegated to the LVN/LPN, and in some facilities a ward clerk may obtain the consent. Informed consent is the responsibility of the physician; however, most facilities allow nurses and other healthcare workers to witness the client's signature on the consent form after an explanation has been provided by the physician. Some facilities require that a physician obtain

the signed consent form. The signature of the witness indicates only that he or she obtained the client's signature on the form. The RN is still responsible for ensuring that the client understands what the procedure is, including potential complications. If the client is unsure of the procedure, the physician needs to be notified to re-explain the procedure until the client understands.

Communication Matrix

- Each member of the nursing unit should be given appropriate directions on the tasks to be completed, keeping in mind the legal issues surrounding delegation. Assign only those tasks the healthcare worker is legally responsible to carry out.
- The RN must ensure that proper consent forms are signed by the client prior to invasive procedures or surgery. Even when the task of witnessing a consent form signing is delegated, the RN is responsible for ensuring it is completed and placed in the client's chart. Ask the witness to inform you when all paperwork is completed for the procedure in order for you to check the forms.
- Ensure that all healthcare workers are aware of DNR orders. Make sure the Kardex or plan of care adequately states the DNR order, and provide that information during report.
- Give specific directions to healthcare workers regarding the client information you wish reported and how you wish to receive it (i.e., written or verbal).
- Provide current information to healthcare workers in a timely manner as it impacts their care of the client (i.e., changes in activity or diet orders).
- Ensure that all forms of documentation are completed in a timely manner; if computerized charting is utilized in the facility, all healthcare workers have responsibility to complete particular forms.

CRITICAL THINKING Strategies

Scenario 1

As a new student you are going into the hospital to prepare for the clinical experience tomorrow morning. There are two stages of preparation. The first stage is obtaining all the necessary information you will need to provide safe care. The second stage is reviewing your textbooks and lecture notes to gain an understanding of the client's diagnosis, medications,

lab values, and diagnostic tests that will be done during his/her hospitalization.

- If you have only a limited time to review the client's chart, what sections of the chart will provide you with sufficient information to render you safe to care for the client?

- In preparing for clinical practice, what information is essential to review in addition to the data you have obtained from the clinical record? Where is the most appropriate place to find this information?
- List the priority interventions you will carry out within the first hour of the clinical experience. Explain the rationale for your answers.

Scenario 2

As a student nurse you have been assigned to complete an activity where you compare and contrast legal/ethical issues related to nursing practice. You are assigned to research the ANA Standards of Clinical Nursing Practice, The Nurse Practice Act in your state, and the Code of Academic and

Clinical Conduct from the National Student Nurses' Association, Inc.

- Briefly describe the primary purpose/function of each of these nursing regulations or guidelines.
- Select one of the above nursing regulations/guidelines and describe how the regulation/guideline will impact your role as a professional nurse.
- The National Student Nurses' Association developed the Code of Academic and Clinical Conduct. How do you plan to incorporate the code into your practice as a student nurse? How will this practice prepare you for the Registered Nurse profession?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. According to the American Nurses Association, nursing is best defined as a profession that
 1. Cares for clients in all types of settings.
 2. Protects, promotes, and optimizes health and abilities of clients.
 3. Provides client care as ordered by the physician.
 4. Assists clients in activities of daily living and prepares them for home care.
2. The National Student Association has formulated a code for nursing students. The most important rationale for adhering to this code is it
 1. Encompasses ethical principles that guide professional behavior.
 2. Governs nursing behavior in the clinical setting.
 3. Lets the student know what is acceptable behavior.
 4. Gives guidelines for administering medications.
3. Guidelines for clinical preparation include which of the following activities?
 1. Ensure your uniform is similar to the staff nurse uniform.
 2. Begin the nurse–client relationship using a more social communication to place the client at ease.
 3. Address the client by first name to make him or her feel comfortable.
 4. Listen to client's statements and feelings regarding their clinical manifestations because they are more familiar with their bodily functions.
4. The Nurse Practice Act regulates the practice of nursing in each state. Which skills and functions are included?

Select all that apply.

 1. Delegate registered nursing responsibilities to an LVN/LPN who has many years of practice.
 2. Instruct the CNA to obtain the vital signs and health history on a newly admitted client.
 3. Complete a client care plan on a newly admitted client.
 4. Refer a client to the discharge planning nurse.
 5. Administer IV medications ordered by the physician.
 6. Observe and document client's responses to medications and treatments.
5. The best statement regarding the Standards of Clinical Nursing Practice is that the standards
 1. Apply only to nurses in specialty practice or who function under a physician.
 2. Do not apply to nurses who are advance practice nurses as they are not accountable for maintaining the basic standards of clinical practice.
 3. Describe a competent level of professional nursing care and professional performance common to all categories of nurses.
 4. Apply to nurses employed in acute care and long-term care settings only.
6. The penalties for professional misconduct could include which of the following?

Select all that apply.

 1. Probation.
 2. Revocation of license.
 3. Imprisonment for practicing without a license.
 4. Compensation to facility for costs accrued from criminal act.
 5. Reprimand.
7. The nurse can be charged with gross negligence when
 1. There is an act that causes death of a client.
 2. The nurse demonstrates a reckless disregard for client safety.
 3. There is an improper use of restraints.
 4. The nurse refuses a client assignment before the shift begins.

8. Before providing client care, the nurse will
 1. Gather appropriate equipment.
 2. Ask the RN what order of care the client usually likes.
 3. Check the Kardex or computerized plan of care record to determine the order of care for the client.
 4. Identify the client by calling his/her name.
 9. When performing a basic nursing assessment, the nurse will
 1. Perform the assessment following morning care, after the client is more relaxed.
 2. Complete an assessment of the physiologic system most affected by the client's condition.
 3. Perform a brief overall system assessment, with a focus on the system most affected by the client's diagnosis.
 4. Complete an in-depth assessment at the end of each shift to provide client-centered information to the on-coming shift.
 10. Principles of medical asepsis include
 1. Placing soiled linen only on the bottom of the linen cart.
 2. Cleaning (with alcohol) equipment that has been dropped on the floor.
 3. Using equipment from another client providing it is cleaned with 2% chlorhexidine before and after use.
 4. Cleaning equipment with cold water before returning it to central supply according to facility policies.
-

2

Nursing Process and Critical Thinking

LEARNING OBJECTIVES

1. Define the term *critical thinking*.
2. Explain how critical thinking is used in each step of the nursing process.
3. Define the term *nursing process*.
4. Describe how the nursing process relates to nursing.
5. Discuss the term *assessment*, and describe how it influences the nursing process.
6. List the components of the assessment step.
7. Describe the primary purpose of the analysis phase of the nursing process.
8. Define outcome identification and planning, and give an example of this step in the nursing process.
9. Define what is meant by the implementation phase of the nursing process.
10. Explain evaluation and include your understanding of why it is an important step in the nursing process.
11. Define the term *nursing diagnosis*.
12. Differentiate nursing diagnosis from medical diagnosis.
13. Define NIC and NOC and their role in standardizing nursing language.
14. Compare and contrast the two-part and three-part Nursing Diagnosis Statement.
15. Define evidence-based nursing practice.
16. State two examples of nursing diagnoses.

NURSING PROCESS

Nursing process is a familiar term in nursing and is used as a way of organizing nursing actions in healthcare delivery. It is a systematic, problem-solving approach to client care. It is considered a critical thinking competency that assists the nurse to intervene in client care. The nurse's actions are based on reasoning and scientific knowledge. By definition, the term *process* refers to a series of actions that lead toward a particular result. When attached to nursing, the term *nursing process* becomes a general description of nursing: assessment, analysis/nursing diagnosis, planning, implementation, and evaluation. The nursing process is used to diagnose and treat human responses to health and illness (American Nurses Association, 1980). The nursing process provides an organized structure and framework for the delivery of nursing care in all settings. It provides the basis for critical thinking in nursing. Although the five steps can be described separately and in

logical order, in practice the steps overlap and events may not always occur in the order listed here. For purposes of understanding this process, however, it is appropriate to work through each phase in logical progression.

The five steps of the nursing process are presented, defined, and illustrated to assist you in understanding the importance of integrating this framework in your beginning mastery of nursing content. A model of each step will enable you to visualize how the individual components can be translated into direct nursing actions or behaviors.

Assessment

Assessment, the first step in the nursing process, refers to the establishment of a database for a specific client. Assessment requires skilled observation, reasoning, and a theoretical

Assessment

Gather data

Objective data

Subjective data

Verify data

Confirm observations

Organize data

Make inferences from data

Communicate data

Observe—Interview—Examine

Identify client needs

Be aware of staff reactions to client

Assess sources of data

Client history

Data from family

Client status—physical/emotional

Signs and symptoms

Test results and findings

Recall stored knowledge

knowledge base to gather and differentiate, verify and organize data, and document the findings. The nurse gathers information relevant to the client from a variety of sources and then assigns meaning to this data. Assessment is a critical phase because all the other steps in the process depend on the accuracy and reliability of the assessment. Assessment is based on concepts of physiology, pathophysiology, psychology, and social adjustment.

Assessment is also the initial step in critical thinking that leads to the appropriate nursing diagnosis.

Nursing Diagnosis

Nursing diagnosis is an integral component of the nursing process. Following the assessment step of the nursing process, a nursing diagnosis is formulated. Nursing diagnosis is the statement of a client problem derived from the systematic collection of data and its analysis. It is a clinical judgment about a designated client, family, or community that provides the basis for completion of the nursing process. Nursing diagnosis includes the etiology, when known, and relates directly to the defining characteristics. Nursing diagnosis provides the foundation for

Nursing Diagnosis

Analyze and synthesize collected data

Examine defining characteristics, both major and minor

Determine clusters of clues

Identify related factors

Identify potential nursing diagnoses

Develop nursing diagnosis appropriate to client problem

Planning

Identify short- and long-term goals and outcomes

Prioritize nursing diagnoses

Develop a plan based on goals and outcomes, including a teaching plan

Anticipate needs of client and family based on priorities

Select nursing behaviors needed to accomplish goals

Specify deadlines for completion of plan

Coordinate care and community resources

Consider contingencies for modifying plan

Record relevant information

each individual client's therapeutic plan of care, and once it is established, the nurse is accountable for actions that occur within the scope of this nursing diagnosis framework.

Nursing diagnosis is a clinical judgment about individual, family, or community responses to actual or potential health problems/life processes. Nursing diagnoses provide the basis for selection of nursing interventions to achieve outcomes for which the nurse is accountable (North American Nursing Diagnosis Association, 1997). The nurse must use critical thinking and decision-making skills when determining nursing diagnoses.

Outcome Identification and Planning

This phase refers to the identification of nursing actions that are strategies for achieving the goals or the desired outcome of nursing care. The planning and outcome phases are directly related to solving or alleviating the problems identified in the nursing diagnosis. The plan includes short- and long-term client-centered goals, strategies for goal outcome, and nursing measures for the delivery of care. During this phase, the nursing diagnoses are prioritized to meet the client's immediate needs.

Clients should be involved in the planning phase to ensure that the client's and the healthcare team members' goals are congruent. If they are not, goal achievement can be impaired. Planning focuses on the development of a plan of care individualized for a specific client.

Planning is based on the client's healthcare needs, selected goals, and strategies directed toward goal achievement. It is a plan of care in which the appropriate nursing actions and the client's desires are considered and chosen to achieve a goal.

Implementation

The fourth phase in the nursing process is the implementation, or intervention, phase. This phase refers to the priority nursing actions or interventions performed to accomplish a specified goal. It explicitly describes the action component of the nursing process. This phase involves initiating and completing those nursing actions necessary to accomplish the identified client goals and outcomes. Nursing actions must be appropriate, individualized for the client, and based on safe nursing practice; they should be formulated on scientific principles and derived from the problem-solving process. Finally, the

Implementation

Implement client care plan by giving direct care based on goals and outcomes

Perform actions and procedures in accordance with client needs

Counsel and teach client, family, or both

Use preventive, palliative, or emergency measures for client's welfare

Encourage independence and self-care

Motivate and maintain optimum wellness

Communicate appropriately to client and client's family

Record data

Continue assessment process

interventions must be congruent with the total medical as well as nursing treatment plan. Implementation of the plan involves giving direct care to the client to accomplish the specified goal.

Implementation is based on accurate and complete assessment, interpretation of data, identified client needs, goals and outcomes, analysis, nursing diagnosis, and strategies to achieve goals.

Evaluation

The final phase of the nursing process is evaluation. Evaluation is the examination of the outcome of nursing actions or the extent to which the expected outcomes or goals were achieved. Was the goal achieved? What parts of the goal were not achieved? Was client behavior modified? Evaluation is a necessary phase to complete the nursing process. It allows the nurse to continue to identify goals in the overall treatment plan and to alter the current plan to the client's needs.

Evaluation is based on the previous phases of the nursing process (assessment, analysis, outcomes and planning, and implementation). The evaluation phase completes the process and examines the outcome.

The nursing process has provided the framework for the immense amount of nursing content that is contained in this textbook. The rationale for choosing this framework is that it provides a way to organize and present nursing knowledge as well as being an essential component of providing quality client care.

Evaluation

Determine effects of nursing actions

Determine extent to which goals and outcomes were achieved

Examine appropriateness of nursing actions

Investigate effect and degree of compliance for client and family

Reassess care plan—judge if goal modification is necessary

Consider alternative nursing actions

Record client responses

CRITICAL THINKING

All nurses are required to use critical thinking skills as they provide nursing care for clients. Nurses are expected not only to master nursing content from many disciplines, but to think creatively, solve problems, communicate, and use reflective judgment in the practice of nursing. Though critical thinking involves problem solving and decision making, it is a more complex process involving higher-level thinking. It employs interpretation, analysis, evaluation, and inference. Critical thinking requires understanding abstract ideas, consideration of the context in which a situation exists, and openness to new ideas.

There is no single accepted definition, but many authors have defined critical thinking in terms that are relevant to nursing. The word *critical* is derived from the Greek word *kritikos*, meaning “critic.” To be critical means to ask questions, to analyze, to examine your own thinking and the thinking of others (Chaffee, 1994). Critical thinking focuses on judgment, and nurses must use reflective judgment because each clinical situation they encounter is different and unique. Effective critical thinking and problem solving actually depend on relevant knowledge and previous experience (Facione 1998; McKeachie, 1999). The definition of critical thinking by Scriven and Paul (1996) for the National Council for Excellence in Critical Thinking Instruction is widely accepted today by many in the field of education. “Critical thinking is an intellectually disciplined process of actively and skillfully conceptualizing, applying, analyzing, synthesizing, and/or evaluating information gathered from, or generated by observation, experience, reflection, reasoning, or communication, as a guide to belief and action.” To expand on this statement, critical thinking requires cognitive skills, the ability to ask pertinent questions, knowledge, and the ability to think clearly. As stated, an important aspect of critical thinking is also the ability to use reflection and language properly. Reflection is the action of thinking back or recalling an earlier clinical situation, remembering nursing actions that worked or didn't work, and determining whether this information is helpful in the current situation. The ability to use language is associated with the ability to think meaningfully. Thinking and language are closely related processes (Miller & Babcock, 1996). To become a critical thinker, the nurse must use language accurately. If nurses are unable to use appropriate terminology, communication with the client and other healthcare workers may be impaired. In addition to these skills, nurses need to be creative thinkers in order to develop appropriate plans of care for clients.

Critical thinking competencies are the cognitive processes a nurse uses to make judgments. Specific critical thinking competencies in clinical situations include diagnostic reasoning, clinical inferences, and clinical decision making. These competencies are used by many healthcare professionals. The nursing process is considered the specific critical thinking competency in nursing. Diagnostic reasoning is a series of clinical judgments made during and after data collection, resulting in an informal judgment or formal diagnosis (Carnevali & Thomas, 1993). The clinical decision-making process uses

reasoning to ensure that after evaluating all options available, the best are chosen to improve the client's health status.

Critical thinking skills assist the nurse to look at all aspects of a situation and then arrive at a conclusion. Critical thinkers identify and question assumptions, determine what is important in each situation, and examine each alternative before making an informed decision. When critical thinking is employed in a clinical situation, you would expect that one would examine ideas, beliefs, principles, assumptions, conclusions, statements, and inferences before coming to a conclusion and then making a decision. The conclusions and decisions made by nurses affect clients' lives; therefore, they must be guided by precise, disciplined thinking, which leads to accurate and complete data collection. While examining the situation, using these concepts, the nurse would also be using scientific reasoning, the nursing process, and decision-making processes.

NURSES ARE CRITICAL THINKERS

Nurses are required to be problem solvers and decision makers, to acquire nursing judgment skills, and to think critically in order to practice in today's nursing climate. Decision-making and problem-solving skills are necessary for managing and delivering client care. Both of these skills require critical thinking.

Watson and Glaser have described critical thinking as a process that defines a problem, selects pertinent information for a solution, recognizes stated and unstated assumptions, formulates and selects relevant hypotheses, draws conclusions, and judges the validity of inferences. The outcome of critical thinking is forming a conclusion and stating the justification for that conclusion. This is what differentiates critical thinking from usual thinking.

Nurses who are considered critical thinkers are those who use logic, creativity, and good communication and are flexible and competent in delivering client care. Additional attitudes attributed to nurses who are considered critical thinkers include open-mindedness, empathy, realism, and being a team player.

Nurses use critical thinking skills as they relate theory to practice, apply the nursing process in client care, and make critical clinical decisions. The ability to use critical thinking skills assists the nurse to recognize and analyze problems and to solve them using a systematic approach.

To acquire critical thinking skills, the nurse must first develop a sound theoretical knowledge base. This means studying the concepts appropriate to each clinical discipline (e.g., the pathophysiology related to the medical diagnosis or disease state; knowledge of pharmacology, growth and development, nutrition, and psychology; and client problem in each area of nursing practice). This knowledge is transferred to clinical situations by determining the appropriate nursing diagnosis in order to provide safe client care and make independent judgments. In addition to reflecting on previous knowledge, the nurse gains immeasurable experience in the identification of clients' problems with each clinical experience. Over time, the nurse is able to select the best solution for assisting clients to resume a healthy state.

Critical thinking is a process as well as a cognitive skill that is used to identify and define problems, assess clients, and evaluate their responses to treatment and care. Nurses select and classify data and organize it into clusters or patterns to formulate nursing diagnoses. Critical thinking is used when multiple nursing actions are considered and the most appropriate action is selected for each client problem. After the client intervention is carried out, the effectiveness of the intervention and client outcome is evaluated using critical thinking. It is easy to see from this statement that critical thinking is used throughout the steps of the nursing process.

You have used problem-solving methodologies throughout your education as you have faced everyday situations. The nursing process provides the basis for critical thinking in nursing when problem solving is required in client care. The following examples demonstrate how critical thinking is used throughout the five steps of the nursing process. When the steps are followed consistently and accuracy of the data is maintained, habits that promote critical thinking in nursing are developed.

Assessment in Critical Thinking

Identifying essential assessment data and where the data can be found requires critical thinking. Obtaining, classifying, and organizing data is a principal function of critical thinking.

A leading cause of error in making clinical judgments or decisions is the collection of inaccurate or incomplete data during the assessment phase. The data collection or assessment step of the nursing process assists the nurse to predict, detect, prevent, and control client problems. A nurse with good critical thinking skills develops a systematic approach to obtaining and validating data. This includes using all sources for data collection (i.e., reviewing the client's chart, asking pertinent questions, and completing the assessment in a systematic manner). If an assessment tool is used, ensure that thought goes into the way the data is recorded; don't just write information down in a rote manner. Review the assessment form to determine whether additional or more in-depth information is required based on the initial findings—this action involves critical thinking. Ask yourself, "Is this information relevant?" and "Do I need to assess anything else?" Listen to the client. Clients provide important subjective data to add to objective information. Once all of the data are collected, information should be validated to ensure that data are not missing and that existing data are correct. Data also need to be organized or categorized in a usable system. Clustering of similar information assists the nurse in forming a picture of the client's problems and strengths. Critical thinking is necessary to determine the significance of reported data, and clustering identifies whether patterns of behavior or responses exist. Clustering data helps determine relevant from irrelevant data as well as gaps in information. It also pinpoints cause-and-effect relationships. Once the clustering is completed, inferences may be formulated.

Nursing Diagnosis in Critical Thinking

A nursing diagnosis is the identification of a client problem. Before a nursing diagnosis is made, the nurse has critically analyzed, synthesized, clustered, and interpreted all the collected data. Use of critical thinking skills is essential in this step of

the nursing process. As you cluster data, you are applying the scientific principle of classifying information in order to determine whether relationships exist among the data and whether data are relevant or irrelevant in this situation. As information is clustered, inconsistencies among the collected data may prompt the nurse to look for additional assessment findings. Determining when additional information is needed for an accurate diagnosis prevents the nurse from making a very common critical thinking error—making a judgment based on incomplete information. It is important to recheck the client's records, asking additional questions of the client in order to obtain the necessary information needed to complete the appropriate nursing diagnosis. After the data are clustered, the nurse begins to organize defining characteristics into meaningful patterns. This is a major step toward identifying the client's problems. Usually, the presence of two to three defining characteristics validates the nursing diagnosis. The identification of this information assists the nurse in determining the appropriate nursing diagnosis. Identifying patterns requires critical thinking skills associated with a sound scientific knowledge base. The nurse must differentiate the normal from the abnormal findings, as well as the risk factors for abnormal patterns of functioning. Using a nursing diagnosis reference book will assist the nurse in clarifying data relevant to defining characteristics or risk factors related to the client's clinical manifestations.

During this step of the nursing process, actual client problems are identified, potential problems are predicted, and priorities are established. Establishing nursing diagnoses is an important independent action of the nurse; however, medical diagnoses must be considered as well. Nursing diagnoses cannot be treated in isolation. Collaborative problem identification and treatment with other healthcare workers form the basis of client care and contribute to a holistic approach to client care. Priorities of care are determined by the severity of the client's problems. These priorities are identified within the planning and intervention steps of the nursing process.

Planning in Critical Thinking and Outcome Identification

Long- and short-term goals are formulated after deliberating with the client, family, and other healthcare team members. Defining realistic goals that are acceptable to the client requires critical thinking. A prioritized plan of care is developed during this phase of the nursing process.

Determining outcomes (goals) and strategies for achieving goals are paramount to providing effective client care. Outcomes are time-specific as well as setting-specific. Long-term outcomes or goals are usually based on what is expected by the time of discharge from a nursing unit or a facility. In acute care facilities, short-term outcomes are based on time frames as short as by the end of the shift, within 24 hours, etc. The long-term goal or discharge expected outcome should be determined before other outcomes and interventions are initiated. When setting priorities for client problems, keep in mind that treating these problems must be addressed on the plan of care in order to achieve the client's discharge goal or outcome. There are two critical thinking skills inherent in this step. One is listing the

client problems and determining whether there are relationships between the problems, and the other is assigning the problems by highest priority. These critical thinking skills require sound scientific principles and scientific method, clinical judgment, reasoning skills, and goal-directed thinking.

When listing the actual and potential problems identified by the assessment data, identify which problems need immediate intervention and those that are underlying causes of the problems. Those situations identified as causing the problem must be assigned the highest priority. After listing the problems, determine whether there are relationships among the problems. If relationships exist, explore how one problem affects another. Maslow's Hierarchy of Human Needs is employed by many nurses to determine prioritization of problems. Maslow lists problems with survival needs (food, fluids, oxygen) as the highest priority. These needs must be addressed first in the plan of care for the client's well-being.

To write specific, realistic, client-centered outcomes, the problems must be stated clearly. Outcomes are derived directly from the problem statement, and the subject of the problem statement is the client. An example of a clear, client-centered outcome is "The client will ambulate the length of the hall before discharge." Remember, problem statements are written as nursing diagnoses. An example of a client outcome utilizing a nursing diagnosis is "The client will demonstrate accurate administration of insulin according to the guidelines established by the diabetic educator within 24 hours of admission." This outcome is directly related to a "Knowledge Deficit: Insulin Administration" nursing diagnosis. You will also notice there is a time-specific statement included within the outcome statement. This time frame assists the nurse to evaluate outcome achievement and the need to re-evaluate the plan of care.

Implementation in Critical Thinking

Nursing interventions are specific strategies developed to achieve positive client outcomes. These interventions are determined by using the critical thinking skills of generalizing, explaining, and predicting outcomes. After consideration of all identified possible actions, nursing interventions are implemented.

Identifying appropriate nursing actions is critical to the outcome of client care. Determining these actions requires critical thinking skills. These skills include the ability to identify specific actions, predict and monitor the client's response to the actions, and weigh risks and consequences of each action. Examining the risks and consequences of an action, a nurse is determining the most beneficial and least harmful approach to client care. When interventions are clearly delineated on the plan of care, the likelihood of the actions being carried out is enhanced. The more specific the intervention, the greater chance of outcome success. If increasing fluid intake is the intervention, specifics regarding fluid likes and dislikes of the client should be addressed. For example, "Client prefers noncarbonated beverages at room temperature." Another example of a specific intervention is "Ambulate the client after his bath, before lunch, and before dinner." This would be appropriate for the goal to ambulate the length of the hall by discharge. Putting times for interventions or distances for ambulation increases the likelihood of compliance with the intervention by all healthcare workers.

Evaluation in Critical Thinking

During the final phase of the nursing process, the nurse critically analyzes each of the client outcomes. If the client need (goal/objective) was not met, the plan is revised. Clearly documenting a comprehensive plan provides the basis for evaluation. Evaluating progress toward outcome achievement assists the nurse in evaluating the effectiveness of the plan. A critical thinking question during this phase of the nursing process is “How well did the client accomplish the goal?” The nurse might also ask “What could have been done differently?”

NURSING DIAGNOSIS

An important implication of nursing diagnosis is that it refers to a health problem or condition that nurses are legally licensed to treat. Establishment and acceptance of using nursing diagnoses will demonstrate recognition and legal sanction of nursing as a profession with its own body of knowledge, education, and experience.

Nursing diagnoses provide the basis for selection of nursing interventions to achieve outcomes for which the nurse is accountable. In 1987, the Center for Nursing Classification at the University of Iowa College of Nursing introduced the Nursing Interventions Classification (NIC) system and in 1991 the Nursing Outcomes Classification (NOC) system. These classification systems and NANDA were merged and formed the NNN Alliance International in 2001. NIC is a comprehensive list of nursing interventions that are grouped according to nursing activities. The NIC includes physiological and psychosocial interventions to treat and prevent illness and promote health for clients, families, and the community. NOC has developed a taxonomy of standardized outcomes to measure the effects of nursing interventions. These outcomes can be used in all settings and with all client populations. Nursing diagnosis textbooks are now integrating the three components. Each nursing diagnosis statement includes domains, classes, diagnosis, outcomes, and interventions. The nursing diagnoses are continually changing as the NANDA research continues. New diagnoses are introduced at each biennial meeting.

Nursing diagnosis will play a pivotal role when evidence-based, professionally led nursing care is more universally implemented in client care. Using standardized terminology, such as Nursing Diagnosis, Nursing Interventions Classifications (NIC), and Nursing Outcomes Classifications (NOC) as electronic client health records become a requirement, will allow for systematic collection of nursing data across all healthcare organizations. Collecting data in this manner provides for analysis and audit of a large volume of information at minimal cost. Standardized terminology more effectively meets client needs while ensuring client safety.

The term *nursing diagnosis* is not comparable to or the same as a medical diagnosis. The major difference between medical and nursing diagnoses is the focus on illness, injury, or disease by the physician. The nursing diagnosis focuses on the response to actual or potential health problems or life processes and the client’s responses to illness, change in lifestyle, etc. Medical diagnoses do not vary until treatment is completed, whereas the nursing diagnosis is fluid and changes as the

Comparison of Diagnoses

Medical	Nursing
Cancer of liver	Pain, acute
Heart failure	Fluid volume, excess
Chronic obstructive pulmonary disease	Breathing patterns, ineffective

client’s condition or response to treatment changes. Nursing diagnosis highlights critical thinking and decision making and provides a universal terminology that all nurses, irrespective of work site, can understand. Nursing diagnosis is derived from the assessment phase of the nursing process and is based on both subjective and objective data. As the database evolves, patterns of health problems emerge, and alterations from normal health states are identified. A nursing diagnosis is a concise label that describes the observed behavior of the client. The nursing diagnosis can be an actual or potential problem. The specific problem identified implies that the nurse is qualified and prepared to intervene and treat that condition. The nurse is not legally able to intervene and treat a medical diagnosis without specific physician’s orders. Thus the nurse is not able to intervene if the client has a diagnosis of, for example, *potential atelectasis* or *pneumonia*. This is a medical diagnosis, whereas *breathing pattern, ineffective*, is a nursing diagnosis, and nursing interventions can be instituted to assist the client.

Nursing diagnoses provide a written communication to all healthcare workers regarding the client’s status. The use of nursing diagnoses provides a vocabulary that is used to describe specific nursing practice, research, and education. It provides a method to synthesize and communicate nurses’ observations and judgments to all members of the healthcare team.

Types of Nursing Diagnoses

The North American Nursing Diagnosis Association (NANDA International) states that a nursing diagnosis can be written as an “actual” or as a “risk for” statement, “possible,” “syndrome,” or “wellness.”

Actual: The nurse has validated an actual nursing diagnosis using clinical judgment, and the client has presented with specific defining characteristics.

Risk for: Based on clinical judgment, the client is more vulnerable to develop the problem than others in similar circumstances. This may also be referred to as a “potential problem.”

Risk diagnoses include risk factors.

The term *possible diagnosis* is not considered a type of diagnosis. It is an option indicating some data are present to confirm the diagnosis, but the data are incomplete or insufficient. Writing a nursing diagnosis as “possible” alerts other nurses of your concern but there is insufficient data to support a specific diagnosis as yet. Further data collection is needed to confirm or deny the diagnosis.

The term *syndrome* is used when a cluster of specific nursing diagnoses is seen together. A *wellness* diagnosis describes a client at a low level of wellness. Many diagnoses are further

qualified by terms such as effective, ineffective, impaired, imbalanced, readiness for, disturbed, and decreased.

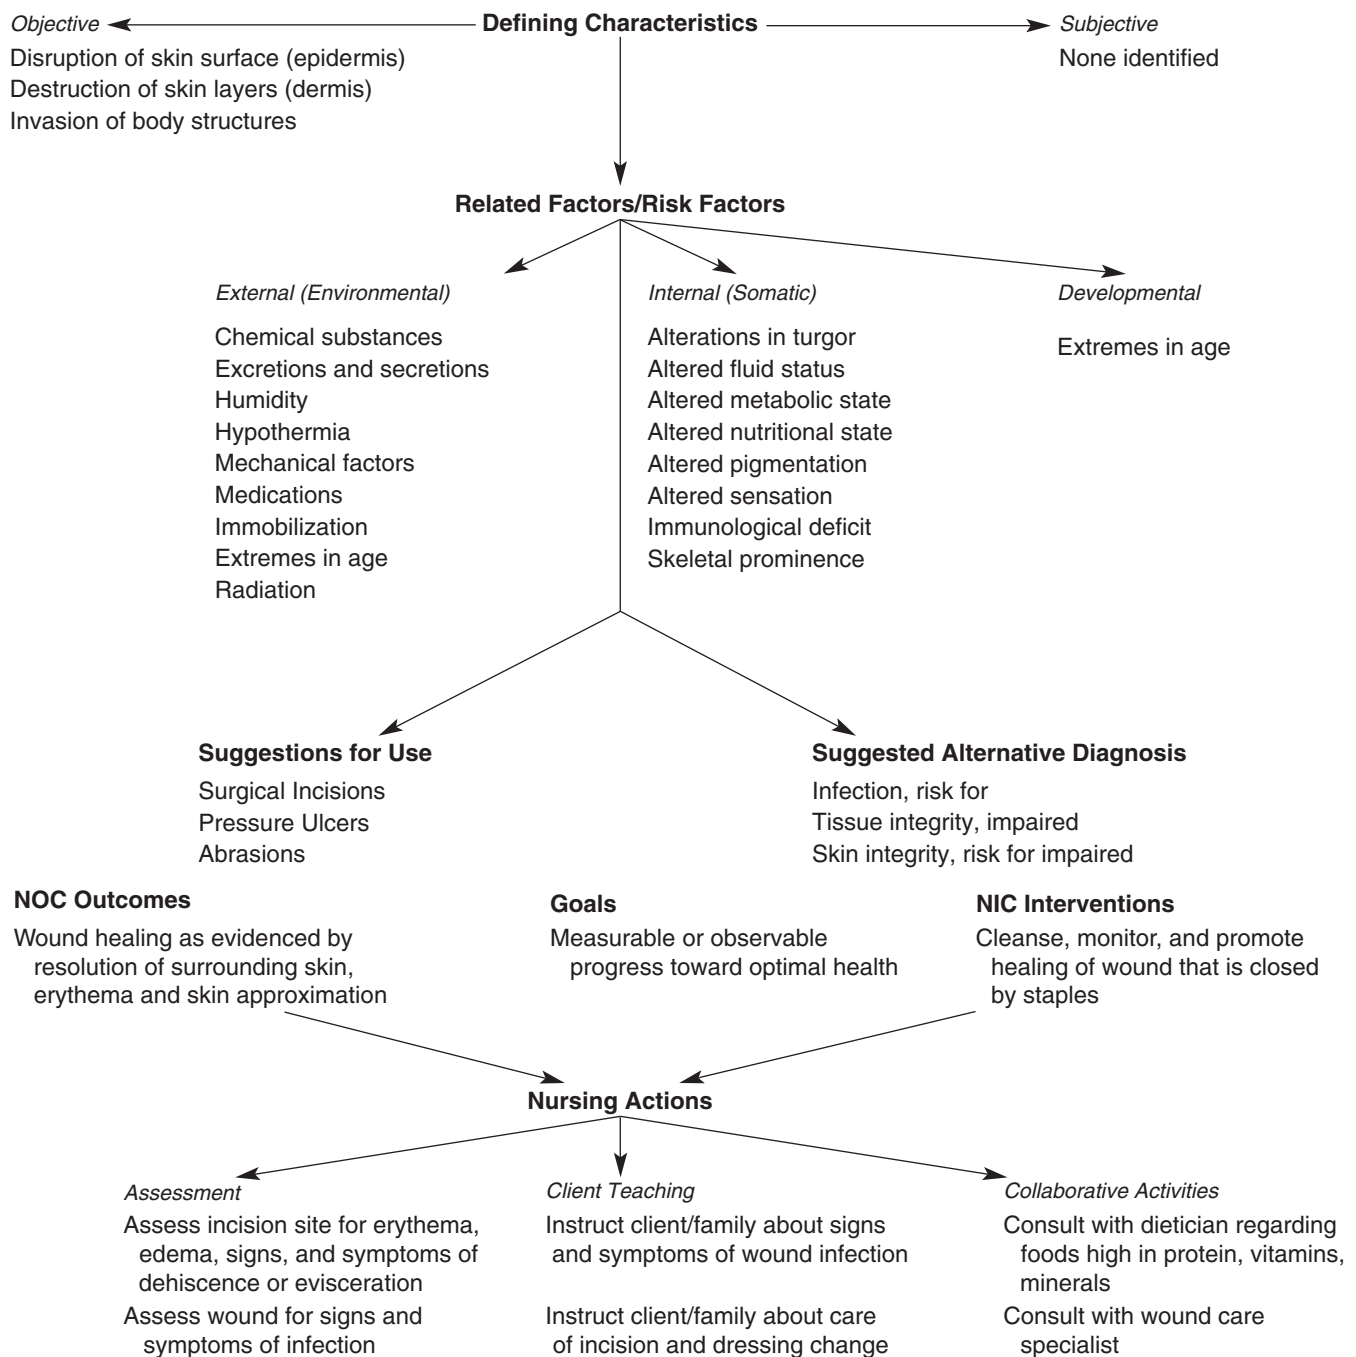

Diagnostic Statement

The diagnostic statement describes the health status of the client and the factors that have contributed to the status. These statements have been developed through research by NANDA and are termed *nursing diagnoses*. One hundred eighty-eight nursing

diagnoses were endorsed by NANDA International. For 2009 to 2011, there were 21 new diagnoses, 9 revisions, and 6 retired diagnoses, for a total of 203 nursing diagnoses. Because of the increased use of computers for documentation, a standardized language for describing client problems is mandatory. Nursing diagnosis provides the necessary terminology for use in a variety of clinical settings. NIC can be used both with a paper-based documentation system and electronic documentation system.

TABLE 2-1 Nursing Diagnosis: Impaired Skin Integrity

Definition: Altered epidermis and dermis

Source: NANDA International. (2008, November 10). *Nursing Diagnoses; Definitions and Classifications, 2009-2011*, 2nd ed. Oxford, United Kingdom:Wiley Blackwell.

TABLE 2-2 Nursing Diagnosis Care Plan Data

Each nursing diagnosis care plan includes the following data:

- Definition of the individual nursing diagnosis
- Defining characteristics as cues describing client behavior
 - a. Objective data, observed or gathered through other sources such as assessment findings by the nurse
 - b. Subjective data, verbalized by the client
 - c. Meaningful patterns that identify potential client problems
 - d. Two to three defining characteristics that verify an actual or potential nursing diagnosis
- Related factors or risk factors
 - a. “Related to” indicates what should change for the client to return to optimal health
 - b. Related factors are stated as: “related to,” “associated with,” or “contributing to” the diagnosis. They are classified as:
 1. Environmental (external) (e.g., hypothermia, moisture, physical immobilization)
 2. Somatic (internal) (e.g., alterations in fluid status, altered circulation)
 3. Developmental factors (e.g., extremes in age)
 - c. Risk factors lead to potential nursing diagnoses
- Suggestions for use: how to use the diagnosis appropriately or differentiating it from similar diagnosis
- Suggested alternative diagnosis
 - a. Similar diagnosis that can be considered when identifying client’s problems
 - b. Diagnosis that can be substituted for one that only partially matches client data
- NOC outcomes
 - a. Client outcomes that reflect client states or behaviors that nursing care can affect
 - b. Outcomes are not goals but can be used to set goals
- Goals and evaluation criteria
 - a. Goals represent measurable or observable criteria that represent whether the client problems have been resolved
 - b. Use NOC outcomes, indicators, and measuring scales to establish goals
 - c. Documented times and dates for meeting goals are stated
 - d. Documentation of progress toward meeting goals is set according to client’s condition and standards set by facility for documentation
- NIC Interventions
 - a. Guide for selecting appropriate interventions
 - b. Each intervention has a label name and a set of activities that are identified as steps to carry out the intervention
- Nursing activities are actions taken by the nurse related to the nursing diagnosis
 - a. Assessments
 - b. Nursing interventions
 - c. Client/family teaching
 - d. Collaborative activities with other healthcare team members

By 2010, the plan is that all healthcare events will be electronically recorded, and healthcare agencies will be required to submit the data to regional and national data banks according to the Department of Health and Human Services (DHHS). With the implementation of the electronic health records (EHRs), standardized nursing languages such as NANDA International (NANDA-I) will be used to provide a broad base of nursing knowledge at the point of care.

The 2009–2011 Taxonomy of Nursing Diagnosis, now Taxonomy II, is a classification in which the diagnostic data are grouped within the following concepts:

Health promotion
 Nutrition
 Elimination and exchange
 Activity/rest
 Perception/cognition

Self-perception
 Role relationship
 Sexuality
 Coping/stress tolerance
 Life principles
 Safety/protection
 Comfort
 Growth/development

Components of Nursing Diagnosis

There are basically two formats used to write the nursing diagnosis: the two-part statement and the three-part statement.

The two-part statement is the most common type of format used in practice. The first component is the *Diagnostic Label* or problem statement. This describes the client’s response to an actual or risk health problem. The second component,

An *Actual Nursing Diagnosis*, written as a three-part statement:

DIAGNOSTIC LABEL (Problem)	Transfer ability, impaired
CONTRIBUTING FACTORS (Etiology or Cause)	Related to inability to move left side
CLINICAL MANIFESTATIONS (Defining Characteristics)	Evidenced by flaccid paralysis of left side

A *Risk for Diagnosis*, written as a two-part statement, when there are no defining characteristics:

DIAGNOSTIC Label (Problem)	Walking, impaired
RISK FACTORS	Related to long leg cast secondary to fractured femur

Etiology, is the cause or contributing factor to the problem. The two components are linked by the “*related to (r/t)*” term.

The three-part statement includes the *Diagnostic Label*, *Etiology*, and the *Defining Characteristics*. Defining Characteristics are defined as signs and symptoms or clinical manifestations and subjective and objective data. The characteristics are linked to the other two components by the “*as evidenced by*” statement.

The accompanying box is an example of nursing diagnoses written in a two-part and three-part statement.

The PES framework is a commonly used approach or organizing framework developed by Marjory Gordon that uses the three-part diagnostic statement.

P refers to the *problem*, or state of health, of the individual, family, or community. This problem is expressed as clearly as possible; for example, Skin Integrity, Impaired.

E describes the *etiology*, or probable cause, of the health problem. This may refer to many factors that include client behaviors, environmental components, or the interaction of

both. The etiology is combined with the problem statement by using the words “related to,” for example, prolonged bed rest.

S signifies the relevant *signs and symptoms*—usually a summary of the objective assessment findings (signs) and subjective data reported by the client (symptoms). The phrase that connects this part of the statement is “as evidenced by”; for example, Impaired Skin Integrity, related to prolonged bed rest, as evidenced by a 2 × 2 cm circular red lesion or erythematous macules with moderate serosanguineous drainage.

Although there are several approaches to formulating a statement of nursing diagnosis, the PES system is used by many schools of nursing throughout the United States.

EVIDENCE-BASED PRACTICE

This term and use of evidence-based practice (EBP) is relatively new to the practice of nursing, even though nursing has recognized the importance of research as an essential basis for its development. Nurses should make clinical decisions using the best available research and other evidence that is reflected in approved policies, procedures, and clinical guidelines in a particular health-care agency. Using evidence-based data is critical in nursing to promote a consistent approach to client care that results in less care-quality variability. This is significant as nurses provide care in settings where a group of nurses provides the care to groups of clients. Other health-related disciplines have long relied on this type of empirical data when making clinical decisions.

Evidence-based nursing practice is defined as the application of the best available empirical evidence that applies recent research findings to clinical practice in order to aid clinical decision making.

Evidence-based nursing practice (EBNP) or evidence-based practice (EBP) is differentiated from research in several key ways. Basing nursing practice on evidence entails locating the latest research and other evidence, such as synthesizing results, and translating the evidence into a protocol or guideline that can be used to guide practice. Research is systematic investigation aimed at

Evidence-Based Research Project

When completing an evidence-based research project you need to complete the following steps:

Step 1: State the question you wish to study. It may be a simple question related to a standard nursing procedure that has been done a certain way for many years, or it may be a totally new way of completing a procedure.

Step 2: Gather the evidence (information). Do a literature search, use the Internet, and review medical and nursing studies reported in journals that relate to your subject of interest.

Step 3: Analyze and assess the evidence. Did it come from a valid source? Who did the study, and how was the study actually conducted?

Step 4: Based on research findings, conduct a pilot study to validate your hypothesis. Individuals can make changes in a pilot study, but for an institution to make changes, a plan must be developed, it must be based on research findings, and it must be formally implemented.

Step 5: Obtain feedback from individuals involved in the research. Monitor the research and identify the specific response(s) and alterations that have occurred in the practice setting as a result of the research findings.

Step 6: Analyze and report the outcome resulting from the research project. Reporting a change in practice that improves nursing procedures will encourage others to make changes in practice settings as well.

generating new knowledge or refining existing knowledge. EBNP and research involve some of the same tasks, but the purposes of the tasks differ in the way they achieve their goals. Research generates new knowledge, whereas EBNP applies the knowledge to practice.

The levels of evidence vary among researchers. Some researchers believe that the synthesis and use of scientific information comes from randomized clinical trials. Others look at the process more broadly and include information gleaned from case reports and expert opinion to guide healthcare decisions.

The University of Minnesota Evidence-Based Health Care Project concludes that evidence-based practice solves problems by carrying out four steps:

1. Identify issues or problems based on analysis of current nursing knowledge and practice.
2. Identify relevant research through literature search.
3. Evaluate research by using criteria that has scientific merit.
4. Select interventions by using the most valid evidence.

Nurses must recognize the importance of using research findings in clinical practice. It is paramount that nurses begin to not just read research articles but critically examine the content of the article and question current practice. Once research data are available, nursing must consider making changes in clinical practice based on the findings. In many facilities, this involves research teams that review current literature and then make appropriate recommendations for clinical practice. Unfortunately, very little is known about the best methods for implementing research evidence into nursing

practice. Evidence-based nursing will strengthen client outcomes, improve client safety, provide effective nursing practice, and increase nursing's credibility among other healthcare professionals and the general public. This should be considered another step in developing nursing's theory base.

One note of caution when you are reading about evidence-based practice: Do not confuse it with best practices. These terms are sometimes used interchangeably, but they do not mean the same thing. *Best practices* is a term used to describe nursing interventions that have proven effective in promoting positive client outcomes or in reducing overall costs to the client or facility. Best practices refers to nursing practices that are based on the "best evidence" available from nursing research. The goal of best practices is to apply the most recent, relevant, and helpful nursing interventions, based on research, in real-life practice. Although the two terms, best practices and EBP, are used interchangeably, the two are different in some respects. Best practice is a generic or general phrase for a process of infusing nursing practice with research-based knowledge. EBP emerges from evidence-based medicine (EBM). EBM is more rigorous and integrates individual clinical expertise with evidence from systematic research. Systematic reviews are more comprehensive in scope and quality of research, and they use mostly randomized clinical trials as the gold standard by which evidence is judged.

EBP highlights can be found throughout the book. EBP will provide you with a framework for determining the effectiveness of selected nursing skills and practice issues. As you proceed through your nursing program, you will be exposed to additional EBP research and its effect on clinical practice.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs, LVN/LPNs, and advanced nurse practitioners. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- The RN's responsibility when delegating client care tasks is to ensure that the care plan is followed for each client. Information contained on the care plan is reported to each healthcare worker assigned to client care.
- The RN is responsible for implementing the nursing process in all aspects of client care. LVN/LPNs may be assigned to carry out tasks within the nursing process, such as assessing clients after the initial assessment and executing interventions based on the client care plan. The RN, however, is ultimately responsible for client care, developing the plan of care, and ensuring that the plan is followed.
- The LVN/LPN may assist the RN in planning and updating the plan of care, but may not be responsible for this action.
- Assistive personnel, such as unlicensed assistive personnel (UAP) and CNAs, are delegated client tasks, but do

participate in the actual development of the plan of care. Their input is valuable and should be considered when changes in the plan of care are necessary.

- Critical thinking processes are used by all team members as they provide client care. The RN has a more expanded scientific knowledge base and experience in utilizing these skills to provide the leadership necessary for effective and safe client care. The RN must use these skills when assigning client care and delegating activities.

Communication Matrix

- The RN synthesizes client data and determines the most appropriate healthcare worker to provide care to each client in her/his assignment.
- Each healthcare worker is given a report on activities to be completed during the shift.
- Dissemination of client care information is based on the client's plan of care.
- Directions are given to all healthcare workers indicating the type of client information the nurse needs immediately and information that can be given during report times. For example, if a client has a fever, the RN may want to know the temperature as soon as it is obtained.

CRITICAL THINKING Strategies

Scenario 1

You have been assigned to care for Mr. Peters, a 76-year-old widower who was admitted with the diagnosis of heart failure. He has lived alone for the last 2 years since his wife died. His children live about 1 hour away and visit him once a month. The children ordered Meals on Wheels for him, but he refused to eat the food that was delivered. “I can do my own cooking, I am not an invalid,” was the answer when the nurse asked why he didn’t like the Meals on Wheels program. He had not seen the physician for at least 6 months. At the last visit, the physician prescribed a moderately low-sodium diet, Lasix 40 mg daily, Calan, and multiple vitamins. His admitting vital signs were BP 180/90, P 98, R 22. His weight indicated a gain of 10 pounds since the last visit. His physical assessment indicated rales in the lung bases, 3+ edema of the ankles, and difficulty breathing in the supine position, and with the least amount of exertion.

- How will you use the nursing process to determine an accurate assessment database?
- What information is missing that might be important to the nurse to assist in planning care for this client? What is the best approach for obtaining the information?
- Identify at least four nursing diagnoses that are relevant for this client’s plan of care. Write a two-part and a three-part diagnostic statement for each nursing diagnosis.

- Using a nursing diagnosis book, identify NIC and NOC statements for the four nursing diagnoses listed in question 3.
- Identify the priority nursing diagnosis, and provide the rationale for your decision.
- Develop a very brief nursing care plan using the nursing process format as outlined in the text.

Scenario 2

8 AM. You are assigned to a 22-year-old male client who was in a motorcycle accident yesterday. He sustained a compound fracture of the right fibula and tibia. He states his pain is 9/10 and it is throbbing. He is nauseated all the time. He is scheduled for surgery later in the day. You assess his wound area and notice there is a large amount of serosanguineous drainage in the dressing. You reinforce the dressing.

- Based on the information provided in the scenario, identify two nursing interventions.
- Determine priority nursing diagnoses and provide rationale for your decision.
- Using a nursing diagnosis textbook, develop a client care plan incorporating NIC and NOC data.

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

- Place the steps of the nursing process in sequence.
 - Evaluation
 - Planning
 - Implementation
 - Assessment
 - Nursing diagnosis
- Nurses who are considered critical thinkers exhibit which of the following attributes?

Select all that apply.

 - Possess good communication skills and are flexible.
 - Use logic and creativity.
 - Are structured in their delivery of nursing care.
 - Use a systematic method for providing care in the same order for each client.
- Which one of the following examples accurately describes a properly stated nursing diagnosis?
 - Poor airway exchange r/t mucus accumulation in the alveoli.
 - Client exhibits pain as a result of coughing as evidenced by grimacing.
 - Knowledge deficit r/t inadequate understanding of diabetes as evidenced by lack of regular blood glucose testing.
 - Pneumonia r/t inadequate ventilation during surgery.
- Select all of the following diagnoses that are considered a nursing, not a medical diagnosis.
 - Acute pain
 - Heart failure
 - Cancer of the liver
 - Ineffective breathing patterns
 - Pulmonary edema
 - Excess fluid volume
- Evidence-based nursing practice research is used to
 - Aid in clinical decision making.
 - Determine the most often used method to provide nursing care.
 - Develop new techniques for providing nursing care.
 - Differentiate nursing diagnosis from medical diagnosis.

6. The major role of assessment, the first step of the nursing process, is to
 1. Develop a nursing diagnosis after collecting client health data.
 2. Assess client and establish a database.
 3. Identify short- and long-term goals based on client's verbal statements regarding health needs.
 4. Assess sources of client data to determine whether accurate and before implementing client care.
 7. Client care planning effectively promotes compliance by:
 1. Ensuring all healthcare needs are identified.
 2. Developing the plan within 1 hour of admission.
 3. Involving the client and family with the healthcare team to develop congruent healthcare goals.
 4. Including a teaching plan as part of the overall short-term goals.
 8. During the implementation phase of the nursing process, the nurse
 1. Gathers all data and prioritizes client needs.
 2. Determines clusters of clues from collected data.
 3. Collects data and then provides education to client and/or family.
 4. Considers contingencies for modifying care plan.
 9. The implementation of Nursing Interventions Classification (NIC) with nursing diagnosis is primarily because
 1. The diagnosis is stated more clearly in nursing terminology.
 2. It is not easily confused with a medical diagnosis.
 3. It can only be used as a paper-based documentation system.
 4. It can be sent to national and regional databases.
 10. Delegation of responsibilities to other healthcare members can be completed in which one of the following situations?
 1. Ask the unlicensed assistive personnel to assist in the development of the client's plan of care.
 2. Assign the certified nursing assistants to clients who require completion of care plan goals before discharge.
 3. Ask the LVN (LPN) to assist in revising the care plan.
 4. Request that the LVN (LPN) complete the initial care plan after admitting the client.

Managing Client Care: Documentation and Delegation

LEARNING OBJECTIVES

1. Describe the components of the client care plan.
2. State the two types of client care plan.
3. Explain the method for individualizing the care plan when a standard care plan is used.
4. Define the term “client problem or need.”
5. State the most important reason for using nursing diagnosis in care planning.
6. Define the use of deadlines and checkpoints in the client care plan.
7. Compare and contrast a clinical pathway and a client care plan.
8. Explain at least three purposes of charting.
9. Describe at least three major components of accurate charting.
10. Complete a charting exercise in any of the charting systems using a simulated situation.
11. List the four items that should be charted for every client.
12. Define the terms “subjective data” and “objective data.”
13. Describe the legal ramifications for completing unusual occurrence reports.
14. Discuss specific client activities requiring consent forms.
15. Discuss the legal risks of computer charting.
16. Discuss the RN’s role in delegating client care.
17. Complete a data collection tool based on a clinical situation.
18. Develop a time-management worksheet for client care.

TERMINOLOGY

Acuity system a method for determining staffing requirements based on the assessment of client needs.

Care plan, client a plan of care, usually written, that meets the special needs of each client.

Charting process of recording information about a client concerning the progress of his or her disease and treatment.

Charting by exception documenting only exceptions to predetermined nursing standards in a narrative format.

Clinical pathways interdisciplinary client care plans using specific assessments, interventions, and outcomes for specified health-related conditions.

Computer-assisted charting client information is entered into the computer for storage and retrieval at a later time.

Delegation transferring to a competent individual the authority to perform a selected task in a selected situation.

EHR electronic health records.

Flow sheets client data are recorded or graphed to show patterns or alterations in findings.

Focus charting charting on one “focus” area. Using DAR format (data, action, response).

HIPAA health insurance portability and accountability act.

HITs health information technologies.

Kardex a convenient and readily accessible file of cards containing current client information.

Nursing process a set of actions that includes assessment, planning, intervention, and evaluation.

Problem-oriented medical record (POMR) a client record that is organized according to the person’s specific health problems.

Report to give an account of something that has been seen, heard, done, or considered.

SBAR a tool that standardizes a “hand-off communication” when one nurse turns a client over to another nurse; situation, background, assessment, and recommendations.

SOAP notes nursing notes organized consistently by what the client feels “subjectively,” what the nurse observes “objectively,” how the nurse “assesses” the situation, and what the nurse “plans.”

SOAPIE nursing notes similar to SOAP with additional data; implementation (i) and evaluation (e).

Source-oriented charting information in the chart is organized according to its source; for example, physician’s progress notes, nurses’ notes.

Systems charting charting or documentation relative to the assessment data obtained during the physical assessment of the client.

Unusual occurrence recording of an unusual happening or event that could affect client or staff safety; also commonly referred to as variance or incident report.

CLIENT CARE PLANS

Documentation is a major component of the nurse’s role. Importance is based on several factors: evaluation of planned client care, communication to other healthcare professionals, The Joint Commission and client safety regulations, reimbursement from the federal government, and legal implications. If a treatment, medication, or activity has not been documented in the chart, legally it is very difficult to prove that the client actually received the care. Contact with the client and care delivered to the client must be documented. One of the most useful tools to provide this care is the client care plan.

Client care plans are an integral part of providing nursing care. Without them, quality and consistency of client care may not be obtained. Client care plans provide a means of communication among nurses and other healthcare providers. The plan should serve as a focal point for client care assignments and reporting.

In earlier years, The Joint Commission required an individualized care plan be developed for each client. According to the guidelines from The Joint Commission, the client or family must be involved in the development of the care plan and it must be interdisciplinary. One reason the critical or clinical pathway (see explanation on page 36) is becoming more popular is the interdisciplinary approach involved in this system. Some facilities still use the standardized or individualized care plan. The only modification they need to make is to ensure that multidisciplinary planning and intervention are included in the care of each client. Documentation of client care must also be interdisciplinary.

Regardless of the type of care plan used, the following information should be included: client’s needs or problems, both actual and potential, expected outcomes or short-term goals; nursing interventions or actions; and discharge criteria or long-term goals.

Once the goals of client care are established, they are included in a multidisciplinary care plan. Each step in meeting these goals is detailed, including specific observations and how often the observations are made. Step-by-step directions are included for difficult problems, such as lengthy and involved dressing changes. Individualized client teaching programs are described on the care plan. As is evident, all of this information is essential in providing continuity of client care.

Types of Plans

Client care plans consist of two types: an individualized care plan, completely written by the nurse and other health team members for each specific client, and a standard client care plan (Form 3-A). Because of the time required to write individualized care plans, hospital nursing departments have developed preprinted standard care plans. These plans, based on the facility’s standards of nursing practice, are guidelines that outline the usual problems or needs. They contain a list of usual nursing actions or interventions and the standard expected outcomes for each problem. Advantages include standards of care; continuity of care, with all nurses providing the same level of care; decreased documentation time; and more accurate documentation. The major disadvantage is the risk that individualized client care may not be provided. The care plan becomes a part of the permanent client record.

Components of a Care Plan

Individualizing Care Plans All clients must have an individualized plan of care even though the standard care plan is used. To individualize the care plan, space is generally provided at the end of the preprinted form to allow the nurse to identify unusual problems or needs. Standard care plans are individualized by activating only those problems that pertain

CLIENT CARE PLAN

▲ Form 3-A. Preprinted standardized client care plan.

to a particular client. The nurse may add another problem to the bottom of the form to further individualize the care plan.

Initiating the Plan The client care plan is formulated after the assessment phase of the nursing process. The nurse, after completing the nursing history and assessment, determines whether a standard care plan is available for the client's medical diagnosis or if an individualized care plan must be written. If a standard care plan is available, the nurse need only circle, date, and initial the needs that are relevant for that client. When an individualized care plan is being written, the nurse translates the client's needs or problems into nursing diagnoses and enters the data into the computer or writes them on the care plan. Nursing diagnoses are the acceptable terminology for use on client care plans throughout the country. The terminology was established by the National Conference on Classification of Nursing Diagnosis, published for the first time in 1973.

Identifying Client Problems or Needs A client problem or need is a condition that requires assistance or intervention from a healthcare team member to return the client to a healthy state. The client problem is identified as any unmet

need. It can be as basic as the need for adequate comfort or nourishment to the more complex psychosocial needs.

On many care plans, problems are identified as either actual or potential. An actual problem is one that exists at that time. Interventions are planned to resolve or alter the problem. A potential problem describes a condition that frequently occurs with the client's diagnosis or health problem. An actual problem, for example, is a reddened coccyx related to urinary incontinence. Interventions are developed to treat the reddened area to prevent further breakdown or pressure ulcer formation. A potential problem, such as "ineffective breathing patterns related to acute pain" after gallbladder surgery, could affect any client with that condition. Interventions are planned to prevent the problem. Some potential problems are identified to assess more carefully for them. For example, a debilitated client with poor nutrition is assessed for possible wound infection.

Formulating Nursing Diagnoses Using a nursing diagnosis to state the client's real or potential problems takes the problem out of the realm of medical diagnosis. Nursing diagnosis does not focus on a problem or disease state but rather on a physical, psychological, or behavioral response.

Nursing diagnosis can change frequently as the client's health status changes and potential health problems become actual health problems. The nursing diagnosis approach, unlike the medical model or systems approach to care planning, allows for this flexibility in focus.

The use of nursing diagnosis in care planning is a universal method of communication to all health team members. When the diagnosis "Impaired Skin Integrity" is written, the entire health team knows that the client has a broken area on the skin with destruction of skin layers. The relationship of skin impairment to cause is usually stated as "Impaired Skin Integrity, *related to* prolonged immobility."

Expected Outcomes or Goals After the problems have been identified, the nurse sets goals or expected outcomes for client care that are congruent with the goals of the client or significant other. Client-centered goals should be clear, concise, realistic, and should identify specific observable and measurable behaviors. Expected outcomes or goals should indicate what is to be expected when the goal is achieved, by whom, when, to what degree of accuracy, and should be time-limited. The client care plan on page 34 shows several examples of a client-centered goal and the nursing interventions necessary to attain each goal.

Client care plans must include both short- and long-term goals. Long-term goals are frequently stated as discharge criteria and as such should be met before discharge, if possible. Short-term goals usually appear in the form of expected outcomes for each problem. They are designed as stepping stones to assist the client to meet discharge criteria or long-term goals. Some hospitals, particularly rehabilitation facilities, use short-term goals differently. They frequently set weekly steps or phases in the rehabilitative process that clients meet before the final expected outcome is achieved. For example, to meet the long-term goal of ambulation without use of devices, a short-term goal is to ambulate with a walker without assistance. These types of goals are prioritized and updated regularly.

Interventions After problems and expected outcomes are written on the care plan, the nurse determines appropriate nursing interventions that meet the goals of care. Interventions, if written properly, specify the exact nursing actions to be carried out or provide explicit instructions on how care is to be delivered. Time and frequency of the intervention should also be provided.

Checkpoints and Deadlines The standard care plan illustrated in this text includes checkpoint (CP) and deadline (DL) columns. The checkpoint indicates how often the action or intervention should be checked, observed, or carried out and therefore how often it should be charted. The deadline column indicates the time when the goal should be met or the action is no longer necessary. It is important to document the exact time and date when the nursing action should be completed to communicate this information to the entire nursing staff. On the sample client care plan on page 34, notice that item 1—Ineffective breathing pattern—should be alleviated by the third postoperative day, in this case, March 25 at 3:00 PM. The checkpoints are listed in sequence to meet the goal. For

the first 24 hours, the nursing interventions (1a through 1d) should be completed every 2 hours and then advanced to every 4 hours for the next 48 hours.

Updating Care Plans To ensure that client care plans are current and relevant, they should be reviewed on a daily basis and updated at least every 24 to 48 hours. There are several ways to update a care plan. Some facilities have spaces designated on the nursing Kardex or nurses' notes. In the figure, the update column is used when the original deadline is reached but the problem persists. A new deadline must then be established. If the ineffective breathing pattern exists beyond the third postoperative day, a new time frame for goal achievement is determined and documented in the update column.

Activating Care Plans When standard care plans are used, a systematic approach to activation and deactivation must be understood by all nursing personnel. As already stated, a common approach is to circle, date, and initial problems that are relevant for the individual client. Any problem that is not circled remains inactivated and should not be assessed, treated, or documented. From the example, you can see that the client has two of the problems listed, an ineffective breathing pattern and a knowledge deficit regarding discharge medication. Items 1 and 3 are circled. In the date column, date, time, and initials of the nurse activating the problem are entered. The second problem is not activated; therefore, a circle is not placed around the number.

Inactivating Care Plans To inactivate the problem, a single line through the problem or intervention with a black pen can be made. In the update/DC column, the date, time, and nurse's initials should be placed next to the crossed out, inactivated information. If only one of the interventions is not necessary, a line is drawn through that intervention and initials placed next to it in the initial column. The other interventions are left current and active.

Evaluating Care Plans The evaluation of how well the client care plan was individualized to meet the needs of the client is tested at discharge. If the care plan was appropriate, the discharge criteria are met. The nursing interventions and problems are then inactivated or discontinued. Frequently, there are clients who, on discharge, have not met the discharge criteria for various reasons. The documentation in the chart should reflect those problems that still exist, the extent to which the problem is being resolved, and additional information to indicate which plans were formulated for goal achievement.

Changing Care Plan Formats As computers are being used more commonly to document nursing care and workplace redesign is transforming how we deliver nursing care, the type and method of using the nursing care plan is changing. The Joint Commission's requirements are becoming more flexible and are allowing new ways to document client care. Critical paths, protocols, and standardized nursing care plans are used with or are replacing the more traditional care plans.

Computerized Client Care Plans The format used in computer software packages individualizes client care plans according to each health care facility's specifications. This type

of format is very popular now that computerized documentation systems have been implemented in many facilities. Preparation time for writing individualized care plans is decreased and standardized plans are developed and written by clinical experts. One disadvantage of this software is that nurses must carefully determine the relevance and appropriateness of the care plan for each individual client. The care plan for each client is generated by the computer each shift. Changes must be entered into the computer frequently to ensure the accuracy of the plan.

Critical Paths or Clinical Pathways

This type of documentation is used primarily with managed care delivery systems. In this system, traditional nursing care plans do not exist. A critical path or clinical pathway is a standardized multidisciplinary plan of care developed for clients with common or prevalent conditions (Form 3-B). It is a tool developed collaboratively by all health team members to facilitate achievement of client outcomes in a predictable and established time frame. The clinical pathways are used on each shift to direct and monitor client care. The plan indicates the actions and interventions achieved at designated times in

order to meet the criteria for reimbursable length of stay. For example, a client with a total hip replacement has a critical path that states time frames for out of bed, gait training, and ambulation listed under the physical activity section of the form. On the second postoperative day the client should move from bed to chair with assistance. Nursing diagnoses are not always incorporated in the critical path. Documentation of nursing activities completed in response to the critical path varies according to facility policies and guidelines. Some facilities initial each day's completed tasks on the critical path document, whereas others use flow charts and narrative charting.

If the client does not achieve the expected outcome in the specified time, a "variance" occurs, and an individual plan of care is developed that may then incorporate nursing diagnosis. For example, if a client is unable to ambulate by Day 3, a nursing diagnosis can be used to individualize the client's variance from the critical path expectations. An individualized care plan is initiated, and charting continues on the variance until it is resolved. The individualized section of the care path is usually found on the back of the form. In the sample "clinical pathway for operative hip," the form used to chart the variance is termed "multidisciplinary problem record." The problem is identified and listed as Problem 1. In the space provided

▲ Form 3-C. Sample of variance charting.

for the PROBLEM—a nursing diagnosis is used or a client problem is listed. Interventions are developed, and an evaluation section is added. All other documentation continues on the care path.

In addition to the pathway and multidisciplinary problem record, the more sophisticated clinical pathways also include an admitting assessment, nursing history including risk factors for falls and skin, nutrition risk evaluation, and social or cultural variables. An ongoing admission database is included in the packet. Also, this section contains a discharge planning risk assessment and multidisciplinary team conference section. Routine Assessment and Care Record frequently are included in this system of documentation.

There are several advantages for using critical or clinical pathways including continuity of care among all health care workers—discharge planning is begun on admission, and teaching plans are initiated early in the hospitalization. Clinical or critical pathways have been proven to reduce length of hospital stay, complications, and costs. Client satisfaction has also increased with the use of pathways.

Not all clients can be placed on pathways. For more complex clients, those requiring specialized care or clients experiencing complications, individualized care plans are more appropriate.

Protocols There are several uses for protocols within the various healthcare settings. Protocols can be used when specific equipment, such as a Roto Bed, is used in client care. They are also useful for specific nursing interventions such as administration of IV antifibrinolytic agents. In both of these situations, specific actions must be taken to ensure accurate and safe care of clients requiring these treatments. Using protocols in these situations promotes safety.

Protocols can be used in conjunction with standard care plans, individualized care plans, and critical paths. The use of protocols decreases the amount of documentation required on the care plan as actions and interventions are described in detail on the protocol.

In some areas of the hospital, protocols are used in place of care plans. This is particularly true in emergency departments,

outpatient surgery, labor and delivery, postanesthesia departments, and operating rooms. Protocols for client care in each of these areas are practical because clients have common needs. For example, clients in the postanesthesia area must have their respiratory status monitored, fluid balance maintained, and level of consciousness assessed. These clients must also meet certain criteria for discharge from the unit. There is no real requirement for an individualized plan of care for the clients in these settings. The time spent in these specialty areas is usually very limited and the service very specific.

CHARTING/DOCUMENTATION

Next to direct client care, charting is one of the nurse’s most important functions. Charting, the process of recording vital information, serves many important purposes:

- Charting communicates information, such as facts, figures, and observations, to other members of the client’s health-care team.
- Charting assists supervisory personnel to evaluate the staff’s performance on a day-by-day basis for specific clients.
- Charting provides a permanent record for future reference that may become a legal document in the event of litigation or prosecution.

Documentation—A Method of Communication

Complete and accurate documentation is essential to protect both the client and the nurse. In communicating your observations and actions, charting helps to ensure both quality and continuity of health care for your clients. Information recorded by you becomes a valuable database for nurses on subsequent shifts. Then, when you reassume responsibility for the client, you can determine what events occurred during prior time periods. Frequently, a client’s reaction time is nearly as important as the reaction itself; therefore, accuracy of time observations becomes an integral part of the charting process. In addition to the client’s attending physician, other personnel interested in

the chart may include the infection control nurse, discharge coordinator, utilization review personnel, or other hospital staff specialists who are checking on the client's progress or lack of positive reaction to treatment.

The client, as an individual, should receive individualized attention that focuses on his or her specific needs. As these needs are identified by each member of the healthcare team, they can be communicated to the others. Since nurses have the greatest amount of direct client contact, it is appropriate for the nurse to coordinate the important function of charting.

Charting provides one means for assessing the quality and effectiveness of nursing care. Nurse managers, team leaders, and supervisors use nurses' notes as a basis for staff evaluations. Because charts are documented descriptions of nursing actions, the quality of nursing care may be evaluated on the basis of the quality of charting notes.

Since charting describes nursing interventions and their outcomes, other healthcare personnel can determine whether subsequent treatment should be changed.

A client's record includes all charting and becomes part of a legal document. Should a client's hospital record be introduced in court, the notes become a legal record of the care provided by each healthcare provider. Legally, care that is not recorded is considered to be care that was not provided. It is necessary therefore to chart all care that you *do* provide, as well as any care that you *do not* provide.

The legal requirement for charting is found in state laws and professional requirements. For example, Title 22 of the California Code of Regulation states:

Nurses' notes which shall include but not be limited to the following: concise and accurate record of nursing care administered; record of pertinent observations including psychosocial and physical manifestations as well as incidents and unusual occurrences, and relevant nursing interpretation of such observations; name, dosage and time of administration of medications and treatment. Route of administration and site of injection shall be recorded if other than by oral administration; record of type of restraint and time of application and removal. The time of application and removal shall not be required for soft tie restraints used for support and protection of the patient.

In addition to the nurses' notes, Title 22 requires that a written client care plan must be a permanent part of the medical record.

There shall be a written patient care plan developed for each patient in coordination with the total health team. This plan shall include goals, problems/needs, and approach and shall be available to all members of the health team.

The Joint Commission also states its requirements for documentation in its nursing care standards. Examples of the documentation standards include an admission assessment performed and documented by a registered nurse that includes consideration of biophysical, psychosocial, environmental, self-care, educational, and discharge planning; nursing care based on identified nursing diagnoses or client care needs and client care standards; needs that are consistent with the therapies of other disciplines; interventions identified to meet the client's needs; the actual client care provided while hospitalized; educational

▲ Charting is completed immediately following client care, either at the bedside or nurses' station.

information provided; and the ability of the client or family to manage the continuing care on discharge.

Charting Format

The format of the chart, whether in the computer or on paper, varies from hospital to hospital. Most important is the content of the notes. First, your notes should describe the assessment that you completed at the beginning of your shift. This information provides a baseline for changes that may occur later in the client's condition. If there are no such changes, this fact should be entered as the final note. Some hospitals require that all parts of the assessment be documented; others require that only abnormalities be documented.

As your shift progresses, you should always include certain items in your notes, including changes in the client's medical, mental, or emotional condition. Nurses are well attuned to medical changes, such as shock, hemorrhage, or a change in level of consciousness; however, the nurse may overlook subtle emotional changes. Anger, depression, or joy should also be documented because these emotions often are indications of the client's response to the illness. Recording these changes is absolutely necessary if other nurses are to act appropriately during subsequent shifts. You should also chart if *no* changes occurred in the client's condition so that treatments can be modified as necessary. Normal aspects of the client's condition should be noted also.

New Trends

Meditech's Software Improves Quality of Care

Meditech's fully integrated Health Care Information System displays real-time client information so that all healthcare professionals, including ancillary departments, may access data at any time. Communication between providers appears instantly on the computer; for example, new physician's orders. This system also provides for sending alerts or messages throughout the organization.

Why Documentation Is So Important

It is the communication mode that nurses and other healthcare providers use to provide continuity of care and to deliver safe care.

It assists in maintaining The Joint Commission accreditation and reimbursement from Medicare.

It protects nurses legally when it verifies the care that has been delivered, demonstrating that the care has met professional standards.

Reactions to any unscheduled or PRN medications must be recorded. Because each medication is given to meet a specified need, the client's response or lack of response must be recorded to document whether the need was met. To complete this part of the entry, note the time the medication was given, the problem for which the medication was given, and the expected solution. For example: "7 AM. c/o moderate RUOQ abdominal incisional pain, '7' on pain scale. Roxanol, 30 mg, PO for pain." When the effects of the medication are known, write another note: "8 AM. States pain relieved."

Finally, it is important to record the client's response to teaching. These notes may describe return demonstrations, verbalization of learning, or resistance to instruction. Because most teaching takes place over a period of days, record both what you taught and how the client responded. Then other nurses will know whether to repeat the previous instructions, reinforce them, or start a new topic.

Frequently, repetitive aspects of nursing care, such as vital signs and intake and output, are recorded on flow sheets. If flow sheets are used, you need not repeat the same information in your notes. An exception is an abnormal measurement that is a part of a larger assessment. For example: "c/o sharp abd. pain. BP 78/50. P 136. Skin cold & diaphoretic. NG tube draining bright red bloody fluid with small clots. Reported to Dr. Jones."

Avoiding Legal Problems in Documentation

- Use facts. If you chart "physician notified," include time called, facts you gave, and his or her response.

Poor Documentation May Lead to Legal Problems

The client was admitted with a fractured right femur. Physician's orders were to turn the client every 2 hours. While hospitalized, the client developed several pressure ulcers, one severe enough to cause her right leg to be amputated. Examining the records, the court determined the client was turned 18 times and should have been turned 117 times. Most cases will be judged on the basis of "if it was not documented, it was not done." Good documentation is critical for the nurse's defense.

Source: Hurlock v. Parklane Medical Center (1985)

- Do not use pat phrases. Be specific and use individual assessment parameters. Do not chart global assessments such as "IV running."
- Be professional when you chart. Do not make interpretations; state what happened; for instance, "suggested to physician that client requires heart monitor" and physician responded "case does not warrant a monitor." If this client were later to be involved in a lawsuit, these notes indicate that the nurse was observant, alert, and aware that the client might be in danger.
- Do not use words such as *mistake* or *accident*; write specifically what incident occurred and what actions were taken.
- Do not use tentative or vague statements such as *appears* or *apparently*.
- Use correct language and medical terms. Do not use slang, pat phrases, or abbreviations that are not generally accepted.
- Use correct grammar and spelling.
- Do not chart for someone else.
- Do not chart ahead of time. Chart after the care is complete, but do not wait until the end of the shift.
- Do not alter a medical record. Draw a single line through an incorrect entry and initial and date the error.
- Write in late entries when you think about them; do not try to go back into earlier charting and insert the information. Label the information as "late entry" and put the time it actually happened in the entry.
- Countersign care given by assistive staff only if the facility allows you to countersign, and then do so only after you review the entry and are familiar with the care provided to the client.
- Chart potentially serious situations; include observations, reports to the physician and supervisor, and whether any action was taken. Be precise; add quotes or specific communication. This is the only kind of charting that holds up in court.
- Report problems to appropriate authorities, such as suspected child abuse to social services.
- Provide the best care you are capable of giving; then precisely chart your observations, interventions, and communications. This is the best deterrent to later legal problems.

Forensic Charting

The content of nurse's notes may affect the outcome of criminal investigations; when charting, especially in the ER, OR, or suspected assault cases, nurses must document exactly and carefully. Forensics is not only linked to criminal investigations; it is the connection between medical data and the legal process. Nurses must be aware that their documentation may be involved in a future legal case.

Charting Systems

The three main charting systems are *source-oriented*, *problem-oriented*, and *computer-assisted* charting. Two additional systems used are *focus charting* and *charting by exception*. *Source-oriented*

charting is so named because the information is organized and presented according to its source. For example, there are separate sections for doctors' progress notes, nurses' notes, and respiratory therapy notes. To obtain a complete "picture" of the client, one must read through all sections and piece together the separate bits of data. This may be a time-consuming process, and the result may not produce an accurate or complete assessment of the client. Narrative charting is found within this charting system.

A second system for chart organization is the *problem-oriented medical record*. In this system the chart is based on the problem list—all problems, present or potential, identified with that client. Using the problems as reference points, each person giving care charts progress notes on the same sheets. In this way assessment of a specific incident by everyone concerned (e.g., physician, RN, dietitian, enterostomal therapist)

is in the same location, and the client's overall picture can be easily seen.

The third method of organizing data is *computer-assisted charting* (see Electronic Charting, page 42). This type of charting constantly updates information from many sources. For example, physiologic measurements are recorded and updated on the computer terminal at least hourly. The information is easily retrievable by the nursing personnel as questions arise. Reference material for common nursing problems ensures quick reference and easily retrieved information to provide safe nursing care.

Focus Charting As the name implies, *focus charting* makes client needs or problems the focus of care in the progress notes. This method moves away from labeling client status a problem because it includes the client's condition, nursing diagnosis, signs or symptoms, or a significant client event or change in status (need for surgical intervention). The focus is not necessarily written as a nursing diagnosis. The progress notes are organized using the DAR format: data, action, and response. Data includes the information that supports the focus, action is the nursing intervention used to treat the problem, and response is how the client responds to the intervention and the outcome. The following is an example:

- D: Client found grimacing, hands clenched, and body rigid. Verbalized pain at 9 on pain scale.
- A: Administered 15 mg MS IV push. Called physician to request PCA for client.
- R: Pain moderately relieved after 35 minutes. Able to understand instruction in use of PCA.

Charting by Exception (CBE) is a system that focuses on significant findings or deviations from the norm. It reduces time spent documenting and reduces multiple data entries in the record. It uses flow sheets, protocols and standards of practice, nursing diagnosis, care plans, SOAP progress notes, and a nursing database. A nursing and physician order flow sheet is used to document physical assessments and implementation of physician and nursing orders as well as completion of nursing and physician orders. The form also contains the teaching record and discharge notes. Only changes or findings significantly different from the norm are documented. Nurses chart only when the client does not meet the predetermined standard or norm. All exceptions to the standards must be documented narratively. When nurses see entries in the chart, it alerts them that something unusual has occurred with the client. An additional advantage in CBE charting is that all flow sheets are kept at the bedside, which eliminates the need to transcribe information from a work sheet to the permanent record.

Some legal or reimbursement issues, such as admissibility in court, may be related to charting by exception. At this time, the rule "if it wasn't charted, it wasn't done" is still the prevailing attitude in legal issues.

Narrative Charting Another system of charting, now infrequently used, is source-oriented narrative charting. This form is based on chronology rather than systems.

When using narrative charting, an assessment should be performed at the beginning of the shift and as needed thereafter. When assessment is the initial entry in narrative charting, subsequent entries are more relevant and understandable. This combination of assessment and narrative charting is the best technique to ensure that adequate information about the client is recorded for all personnel who use nurses' notes.

There is a tendency for hospitals to move away from traditional narrative charting to focus on charting by exception. Because the client's chart is considered a legal document, it is important that nurses chart relevant, accurate, and appropriate information in a timely manner. The following rules involve the issues that become problematic if they are not done and may result in litigation.

Rules for Documenting Client Care

1. Document from first-hand knowledge—if you chart for other caregivers, you may have errors or inaccurate data. An exception to this rule is when you are responsible for charting for nonprofessional personnel.
2. Document clearly and legibly in black or blue ink, not felt pen or pencil.
3. Give clear, concise, and unambiguous information. Go back to the client to clarify or validate if information is incomplete. Avoid vague expressions or clichés in charting (i.e., slept well).
4. Select neutral terms or describe observed behaviors, rather than value judgments or generalizations. For example, rather than “client was drunk,” use “noted alcohol odor on breath and speech was slurred.”
5. Correct errors by drawing a single line through the error, write the words mistaken entry (ME) above it, and then initial the error. The error must be readable. Ink eradication, erasures, or use of occlusive materials is not acceptable. The word error is no longer advised because juries tend to associate the word error with an actual nursing care mistake.
6. Sign each entry with your first initial, last name, and status; for example, SN for student nurse, LVN for licensed vocational nurse, or RN for registered nurse. Script, not printing, is used for the signature. Each signature should appear at the right-hand margin of the nurses' notes.
7. Notes should appear on each succeeding line. Lines should not be omitted in the nurses' notes. A horizontal line is drawn to “fill up” a partial line. Continuous charting is done for each entry unless a time change occurs. You may or may not need a new line for each new idea or statement, depending on agency protocol.
8. The date is entered in the data column on the first line of every page of nurses' notes and whenever the date changes. Time is entered in the time column whenever a new time entry occurs. Do not put time changes in the text of the nurses' notes. If only one time is entered for block charting, enter the last time you were with the client.
9. Chart objective facts, not your interpretations. For example, chart “ate 100%,” not “good appetite.” If the client complains, place the complaint in quotation marks to indicate that it is his or her statement. For example, “c/o chest pain radiating down left arm.”
10. Refusal of medications and treatments must be documented. A circle is placed around the time the medication or treatment is to be given in the appropriate area of the chart. An explanation regarding the reason the medication was not given is entered in the nurses' notes.
11. Sign each entry before it is replaced in the chart rack. An entry is not to be left unsigned. If all the charting is completed for the shift at one time, a single signature is placed at the end of the charting.
12. Accuracy is important. Describe behaviors rather than feelings. This allows other health team members to determine the client's actual problems.
13. Chart only those abbreviations and symbols approved by the facility. Information can be misinterpreted or misleading when unfamiliar abbreviations are used. (See the listing at the end of Chapter 18 for examples of commonly used abbreviations.)
14. Spell correctly, using proper terminology and grammar.
15. Write legibly. If your writing is not legible, then print.
16. Do not use the word “client” in the chart. The chart belongs to that client.
17. Do not double chart. If something appears on a flow sheet, it does not need to appear on the nurses' narrative record unless there is an alteration from normal.
18. Do not squeeze information into a space because you forgot to chart it earlier. Add the information on the first available line. Write in the time the event occurred, not the time you entered the information. The words *late entry* can be inserted before the charting.
19. The following information should be charted.
 - a. Physician's visits.
 - b. Times the client leaves and returns to the unit, mode of transportation, and destination.
 - c. Medications (chart immediately after given). Include dosage, route of administration (if parenteral, where given), whether pain was relieved (if pain medication), and side effects.
 - d. Treatments (chart immediately after given).

A form of narrative charting is assessment–intervention–response (AIR). In the assessment (A) section of the chart, the nurse summarizes data and impressions of problems found via assessment. The intervention (I) section is for summaries

The Air Format

- A** Respirations 30 and labored. Rales bilateral in the bases.
- I** Deep breathing and coughing, incentive spirometer with Mucomyst. Up in chair.
- R** Respiration 24, decreased intensity of rales but still present.

Narrative Charting

Advantages

- Can be used in conjunction with flow sheets and other documentation systems
- Quick method of charting chronologic data
- Familiar method of charting
- Easy to use
- Used in all types of clinical settings

Disadvantages

- Lack of systematic structure leading to difficulty in determining data relationships
- Time-consuming
- Frequently lacks information on client care outcomes
- Difficult to monitor data for quality assurance
- Relevant information found in several areas in chart

about interventions based on assessment findings. The summary may include a condensed nursing care plan or plans for additional monitoring. The response (R) section focuses on the client's response to nursing interventions. Each assessment and intervention is labeled so that other nurses can chart pertinent responses. With appropriate flow sheets and the AIR method of narrative charting, client care is more clearly and concisely documented.

Informatics

The American Nurses Association in 2001 defined nursing informatics as “a specialty that integrates nursing science, computer science and information science to manage and communicate data, information and knowledge in nursing practice.” This new paradigm emphasizes content, structure, context, and the flow of information and technology. Research in the next decade will be based on an understanding of nursing informatics, intervention, and solution. In fact, the National League for Nursing (NLN) has stated that without curriculum reform, nurses will not be able to function in three critical areas: computer literacy, information literacy, and informatics.

Research in 2009 indicates that only 8% of the nation's 5,000 hospitals are currently using computer charting, although many are beginning to incorporate bar coding for medication administration. Approximately 25% of United States hospitals give their nurses hand-held devices for scanning bar codes for medication labels and client's wristbands to prevent medication mistakes. These numbers will increase, as there is a more determined effort to adhere to safety regulations.

Nurses are at the hub of client health information, so it is becoming more and more important for nurses to master technology. Nursing informatics is a specialty area in which nurses develop, customize, and evaluate various information technologies for adaptation to their particular facilities needs. Nurse informaticists' major responsibilities are to develop systems and act as communication liaisons for their care facility.

▲ RN informatics tech specialist helps to update and maintain the electronic database.

Electronic Charting

Many hospitals are integrating computer information systems as a way of improving client care and utilizing nurses' time more efficiently. Electronic information systems are moving documentation of client care from handwritten charting into the computer. With these systems, client data can be input and retrieved with the click of a mouse. Data can be input and a new assessment generated within minutes. These information computer systems not only improve client care, but also save nurses' time. Nursing organizations and accrediting agencies are placing more and more emphasis on electronic documentation.

Computer-assisted charting can be implemented by itself, or, as in most cases, it is a component of a facility medical information system. There are so many constraints on time and resources that this type of system is becoming a necessity for healthcare agencies today. Inaccurate documentation has a significant impact on quality of client care, costs, and revenues. Redundant information input wastes valuable nursing time. Missing or incomplete documentation is costly and frustrating. If supplies or treatments are not documented, payment cannot be obtained.

▲ Example of computer charting.

▲ Each nursing unit has several computer terminals for documentation.

Nursing information systems can manage clinical data in a variety of healthcare settings. These systems allow nurses to provide and access accurate and timely information. This type of charting allows the nurse to select content phrases on a screen that automatically builds a comprehensive record without inputting all the individual pieces of information.

Computer-assisted charting can be accomplished in a nurses' station or at the bedside. Most of the necessary documentation can be done at the bedside if the equipment is available. This includes vital signs, admission assessment, nursing assessment, intake and output records, client education records, and client care plans. Once the information is entered into the computer, it can be disseminated to different reports without the nurse's intervention. Some of the documentation systems offer packages, such as customized flow sheets for each nursing unit in the hospital, and individualized critical pathways for each service area in the facility. Laboratory results, respiratory therapy notes, and client care documentation are fully integrated into the electronic chart. Management reports can

also be generated through this type of system. Shift reports, client acuity, and client care plan variance can be generated in some systems.

Computer systems record, store, and retrieve many pieces of data about the client that must be communicated throughout the hospital for the client to receive optimal care. For example, when a client is admitted and the physician enters orders into the computer, many things automatically happen. The dietary department is notified of the diet needs, pharmacy is notified of medications and IVs that are ordered, CSR is notified of special equipment needs, and the laboratory is notified of required tests. It is no longer necessary for the nurse to make out and deliver requests to all these departments and then arrange for delivery or pick up of the desired items. Each nursing unit has

Electronic Health Records (EHRs) Being Implemented

The president, in 2005, announced that we were to have electronic health care records (EHRs) available by 2010. The initiative states that the United States should have a record interoperable database, while ensuring privacy and security. Interoperable EHRs would benefit both the clients and healthcare providers by eliminating redundancies, enabling access of medical records when clients are away from home, allowing biosurveillance of disease or tracking of disease movement (pandemic flu), and improving quality of care.

Despite this commitment, progress has been slow. One study showed only 17% to 24% of physicians in ambulatory facilities use EHRs to some extent. As benefits are becoming more and more obvious (improved safety, quality, and overall efficiency of care), more facilities are adopting EHRs.

▲ Sample—computer-generated client data.

several computer terminals, or the terminals may be at the bedside. Before accessing the terminal, the sign-on code must be entered. Each person accessing information must have their own sign-on code. This prevents unauthorized persons from accessing confidential information. After sending the code by pressing a SEND button, the nurse can select the section of the record needed. The cursor is pointed at the data category and after clicking, the selection comes up on the screen. The most common category selections are nurses' notes, physician orders, laboratory or x-ray reports, and client care plans.

Hospitals usually have programs that contain special matrices of "Nursing Retrieval Guide(s)." Once the retrieval guide appears on the screen, the nurse can choose the specific category of data needed. Much of the routine ordering and care a nurse gives can be charted rapidly and completely in a matter of seconds using this system.

When the nurse has completed the charting, the information is displayed. At this time the nurse can make corrections, additions, or deletions. If the data displayed are correct, the nurse enters the data and it becomes a permanent part of the

Innovation in Transcription Orders

El Camino Hospital in Mountain View, CA, was the first hospital in the world to use computerized physician order entry (CPOE). They began this innovative approach to transcription orders in 1971. Now, their 400 physicians prescribe everything electronically—from treatment orders to medications—using the windows system. A physician can enter orders from any computer and nurses view electronic orders in real time, regardless of when they were updated. The clinical nurse manager at El Camino says, “We don’t have transcription errors. Ever. It’s just something that doesn’t happen.” Because one of the major causes of errors in health care is transcription orders, this is a goal most hospitals would like to emulate.

Source: McPeck, P. (May, 2006). Beyond illegible scrawl: Computerized order entry. *Nurse Week*, California Edition, San Jose, CA.

computer record for that client, and a hard copy is printed out to be put in the chart.

When the client is to be discharged, the nursing discharge summary is completed. This shows not only the client’s physical condition, but also the status of client teaching and follow-up plans. Again, it is simply punched or tapped on the terminal and the data are displayed. This information and the client instruction sheet generated by the computer are sent home with the client.

In addition to making the charting of client care and the communication between departments much simpler and less time-consuming, the computer provides reference material for common nursing problems. For example, a matrix may show the signs and symptoms associated with diabetes mellitus. If the nurse is unsure of the signs and symptoms of the different forms of this disease, he or she can easily find them in the computer, and, if needed, this information can be printed out and put in the chart. In this way the nurse can be quickly updated about the client’s condition and thereby provide optimal care.

▲ Entry data becomes part of permanent record.

▲ Client data is entered into computer at nurse’s station.

As in many professions, use of the computer in nursing and medicine has become more common, and its possible uses are rapidly expanding. In the very near future, automated speech recognition will allow nurses to document into the computer by just speaking. Also, handwriting recognition programs are being tested and will soon be available. This will allow nurses to write, rather than type, information into a book-sized computer. If learning the skills of computer use is viewed as a challenge and the reward is more efficient nursing care and less time spent on paperwork, the learning time will have been well spent.

New software and high-tech equipment are also beginning to change client care. One example is the linking of ICU point-of-care to board-certified intensivist physicians and experienced critical care nurses. By providing remote care from a central location to several hospital ICUs, the level of care for critically ill clients will be substantially upgraded. For example, a study completed in 2004 in Norfolk, VA, noted a 27% reduction in mortality for ICU clients, a 17% reduction in length of stay, and savings of more than \$2,000 per client. This use of limited manpower can result in saving lives.

Health Information Technologies

Information technology is being integrated into the healthcare system. As evidence of this trend, President Bush in 2004 created a new position called the National Health Information Technology coordinator.

Bedside E-documentation Electronic charting is becoming more familiar in hospitals and clinics. Portable bedside and handheld computers have the following advantages:

- Data are entered into the client’s chart immediately.
- This method saves nurses’ time.
- Entry may be more accurate, because it is entered immediately after the intervention.
- Charges to the client are automatic.

▲ When the computer is at the bedside, charting can be completed immediately after client care.

There are disadvantages to using E-documentation. The computer may not be equipped for narrative charting, and if there is a central data bank, a computer problem could affect obtaining important client information.

At this time there are many issues with E-documentation, but for expediency (especially with the shortage of nurses), it will probably become a primary mode of client charting.

▲ Portable bedside computer unit facilitates client charting.

Technology at the Bedside The PDA (personal digital assistant) has the ability to share information with a host or central computer. Nurses can use the PDA as a clinical resource for medication doses and calculations, as well as drug side effects. This device can also be used to access diagnostic test results, evaluate lab tests, and review treatments and interventions. It may also assist the nurse to review medical

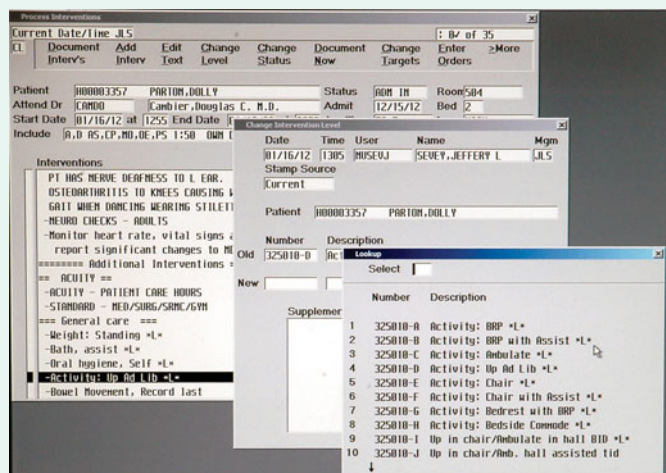

Electronic Charting

Advantages

- Minimizes errors when physicians enter orders into the computer
- Allows nurses to document more client details quickly and error correction is easier
- Provides more time to spend on direct client care
- Gives supporting healthcare providers more details about the client
- Provides templates for most conditions, problems, and associated outcomes; standardization is increased
- Protects against human error (i.e., IV pumps feed directly into the computer to monitor the medication rate)
- Provides interdisciplinary plans of care online and is upgraded each shift
- Compensates for messy, incomplete handwritten nurses' notes; quality of notes improves
- Offers instant information results from tests, lab work, x-rays, etc., and allows for instant data retrieval and access ability
- Gives new caregivers a quick and complete total picture of the client; medical management improves

Disadvantages

- Computer system is expensive to purchase and update
- "Downtime" or computer "crashes" can create problems of not receiving information or it is not charted on time

▲ Nurses may access specific categories of data for each client.

- Computer may increase charting time if number of terminals is insufficient
- Nurses rely on computers and don't question information when it may be wrong
- Unfamiliarity with computers (not enough experience in nursing school) may increase errors
- Health Insurance Portability and Accountability Act (HIPAA) and client confidentiality may be compromised; potential for unauthorized persons to access confidential records

EVIDENCE-BASED PRACTICE

Value of Using Computer Information Systems

A study conducted by David Wong, MD, at Long Beach VA Hospital showed that implementing information systems saved nurses an average of 1 hour per 12-hour shift in documentation time, thus freeing up more time for client care.

Source: Wong, D, M.D. (September 2004). *Nurse Week*, California Edition, San Jose, CA (nurseweek.com/news/archives (Sept. 2005)).

diagnoses and the steps of procedures. In addition, certified nurse assistants are using the PDA to record point-of-care at the bedside (for example, vital signs), which will be instantly transmitted to the RN. With all of these attributes, the PDA has the potential to improve nursing care, save nurses' time, and promote client safety.

HIPAA Guidelines for Using a PDA The HIPAA Privacy Rule establishes standards to protect the confidentiality of individually identifiable health information maintained or transmitted electronically. The security rule adopts standards for the security of electronic protected health information. This rule is comprehensive in that it includes 19 standards and 42 specifications. Healthcare providers must check with their employers to be sure that they are compliant in adhering to the electronic standards for security.

Protected Health Information (PHI) is a component of the HIPAA guidelines. It is recommended that the client's name or any identifying data not be input into the PDA. Personal demographics or client identifiers such as history, physical findings, data, and phone numbers must be input using passwords only. If identifying data must be input, the healthcare provider should use the "security" feature, which requires a password to enter the system.

High-Tech Innovations Improve Health Care

- The Vocera B2000 communication system is a small device worn around a nurse's neck that allows for two-way voice communication. This device enables nurses at the bedside to communicate instantly with each other and physicians. Because it is hands-free, the nurse can communicate

▲ Vocera communication system.

▲ PDA at bedside.

without stopping a procedure such as changing a sterile dressing. This device also saves time in locating another staff member or asking for assistance, as well as alerting the nurse to a client call or alarm.

- The AccuNurse is a wearable computer headset and speech recognition system. This system prioritizes interventions and enables nurses to dictate documentation into the electronic medical record. The software is a voice-activated system and can alert the nurse about a new order. Butler Memorial Hospital in Pennsylvania developed the system.
- A specialized PDA device for use at the client's bedside allows the nurse to scan the client's bar-coded identification and medications. The PDA displays all of the critical information, including the five rights of medication administration. This device also documents the medications given and alerts the nurse to adjunct information such as vital signs, pain level, and lab results. It includes a PDA reference based on McGraw-Hill Medical's *Pharmacotherapy Handbook* and is available as an electronic database that provides information on 82 topics and 140 diseases.
- Multimedia phones or iPhones are also being considered to assist nurses working at the bedside. Information and software can be downloaded to these devices to include such information as procedures, lab values, medication information, calculations, medical terminology, physician's preferences, and much more, including a rhythm strip comparing

▲ Robot delivering medication to a nurse assigned to the client.

the client's strip with a normal one. In fact, the application of the iPhone may be preferable to a computer because it allows the nurse to access information any time, any place, whereas the computer is at the client's bedside.

- Robots are another technological device becoming more and more available. Designed to take over certain clinical activities, they can save precious time, allowing the nurses to spend more time with the client. One example of robot use at a California hospital is as follows: A physician orders a new medication, and the robot in the pharmacy takes the medication directly to the specific nurse assigned to the client. The nurse then uses an ID smart card to access the drug. No other staff member can access the drug. Certain robots (e.g., the RD-7) are very versatile. They have telescopic vision and the technology to transfer vital information, such as a live image, a client's ECG tracings, urine output, heart sounds, etc. This aspect allows nurses off-site to teach, mentor, or help with client monitoring.
- PDAs, robots, telehealth devices, tablet computers, sub-notebook computers, wireless networks, and related software represent the current technology and will be the healthcare technology of the future.

Minimizing Legal Risks of Computer Charting

The American Nurses' Association, the American Medical Record Association, and the Canadian Nurses' Association offer guidelines and strategies for computer safety in charting.

- Your personal password or computer signature should not be given to anyone: neither another nurse on the unit, a float nurse, nor a physician. The hospital issues a short-term password with access to certain records for infrequent users.
- Do not leave a computer terminal unattended after you have logged on. Most computers do have a timing device that shuts down a terminal when it has not been used for a certain time.
- Computer entries are part of the client's permanent record and, as such, cannot be deleted. It is possible, however, to correct an error before the material has been stored. If the

Check out this "smart" room at El Camino Hospital in Mountain View, CA, which opened in November 2009. This high-tech room brings EHRs to the client's bedside and incorporates advanced technology for client care. For example, the nurse enters the client's room and sensors detect a presence. The client's health data are instantly displayed on a wall-mounted monitor listing allergies, risk factors, medications, tests or procedures scheduled, and any information that the nurse requires to care effectively for the client.

entry has already been moved to storage, handle the error by marking the entry "mistaken entry," add correct information, and date and initial the entry. If you record information in the wrong chart, write "mistaken entry," add "wrong chart," and sign off.

- Once information about a client is stored, it is difficult to delete accidentally. Do check that stored records have backup files. This is an important safety check. If you inadvertently delete a part of the permanent record (this is difficult to do, since the computer always asks if you are sure), type an explanation into the computer file with date, time, and your initials. Submit an explanation in writing to your supervisor.
- Do not leave computer information about a client displayed on a monitor where others have access to it. Also, do not leave printed files unattended. Keep a log that accounts for every copy of a computerized file that you have generated from the system.
- A positive diagnosis of human immunodeficiency virus (HIV) or hepatitis B virus (HBV) is part of the client's confidential record. Disclosure of this information to unauthorized people may have legal implications. If the diagnosis is entered as any other diagnosis, take steps to follow your hospital's confidentiality procedures. Check your state's special protocols for treatment of a client's HBV or HIV status.
- Computer entry errors are most common when using electronic documentation. In 2003, 15% of the errors reported involved the use of a computer system. Many of these (45%) occurred in the transcribing phase and involved the wrong dose/wrong quantity of a medication.

LEGAL FORMS OF DOCUMENTATION

Unusual Occurrence, Variance, or Incident Report

Unusual occurrence, also called incident report (IR), or unexpected occurrence, serves three main purposes: to help document quality of care, to identify areas where in-service education is needed, and to record the details of an incident for possible legal reference.

With some staff nurses, unusual occurrence forms have a poor reputation and, perhaps, with some justification. When something goes wrong and a nurse is told to “make out a report,” it is interpreted as a form of punishment.

Although these forms should be completed regularly with any unusual occurrence and may, on occasion, be used as a form of reprimand, they are no more nor less than what their title suggests: a report of an incident.

As a tool for documenting quality of care, unusual occurrences inform the quality assurance coordinator and the head nurse of areas of practice on the unit that need improvement. For example, there may be an increase in the number of clients who fell out of bed. Further research may show that because the census is up, the staff is very busy and is forgetting to reposition clients’ overbed tables. In their attempts to get water or tissues, for example, more clients are falling out of bed. The solution to the problem may be to speak with the staff regarding the consequences of this action, and as a group find a mutually acceptable way of preventing this type of incident from recurring.

Unusual occurrences also suggest and document the need for in-service education. For example, when an unusual number is written regarding a new piece of equipment, the head nurse may conclude that the staff, especially those on evening and night shifts, needs instruction on operating this equipment properly and effectively. Another example is IVs that are behind or ahead of schedule. This might indicate that the nurses do not know how to regulate the IV pump correctly. A solution to this problem is to conduct a series of classes for all shifts in which the operation of the IV pump is discussed and hands-on practice is given. Such classes could be given by someone in the hospital’s in-service education department or by a representative of the manufacturer of the IV pumps.

Unusual occurrences may also record the details of an occurrence for possible legal use. In some hospitals, unusual occurrences cover any situation that prevented the client from having a normal recovery. These incidents could include non-nursing actions such as returning to surgery for control of bleeding or having chest tubes inserted for a pneumothorax.

When completing an unusual occurrence with possible legal implications, it is doubly important to record all details of the incident. It is not easy to recall details of the care you gave a client 1 or 2 months ago. Frequently lawsuits are not filed for months or even years after an incident, so it is essential that you record important details promptly.

Information to record on the unusual occurrence includes general details of the incident, the client’s response, your action or reaction to the incident, and a list of other personnel who were aware of the details of the incident. Often there is space on the form to record the physician’s report of the

client’s condition after the incident. To fill in the section regarding the physician’s report, the nurse later copies the doctor’s progress notes from the chart onto the form. At no time is the unusual occurrences given to the physician. This is a written document between the hospital and its insurance carrier, not the physician.

On completion, unusual occurrences are forwarded to the unit manager or head nurse and then to nursing administration. Information from the report of interest to in-service education or quality assurance departments can be obtained at this time. Ultimately, the unusual occurrence is passed along to the hospital’s legal department to be retained indefinitely in the event that legal action is later initiated on behalf of the client.

Consent Forms

When an individual enters a hospital, some of his or her basic legal rights are affected. So that these rights are not violated, the client must give permission (consent) for all treatment. If consent is not obtained, the hospital, physician, or nurse may be charged with committing “battery” against the client. *Battery*, as defined by law, is an “offensive touching” of the client. This could include an injection or any breaking of the skin’s surface, use of x-rays, or insertion of tubes, for example.

Before you panic and attempt to get a consent signed for such a routine procedure as taking the client’s next blood pressure, you should know that routine nursing care is “consented to” when the client signs the “conditions of admissions” form. Also, certain procedures, such as injections, intubations, and dressings, are treatments ordered by the physician and agreed to by the client. If the client has listened to the explanation of a specific procedure and has agreed to allow the procedure to be carried out, he or she is giving implied consent; however, the client has the right to refuse any treatment, including changing his or her mind about a procedure previously agreed to. In that case the physician must be contacted regarding alternative actions.

When discussing the formal written or explicit consents, the two key nursing activities are obtaining and witnessing consent. Initiating consent is not a nursing function because it includes the explanation of what is to be done, the risks of the procedure to that client, alternative procedures, and probable outcomes. This information should be given by the doctor. The nurse may clarify the information to be sure the client understands.

The nurse’s role is to witness the signing of the consent. When the consent form is presented to the client, it should be explained, and the client should be encouraged to read it thoroughly before signing. Occasionally a nurse is asked to explain or expand the physician’s presentation. Acceptable practice is for the nurse to clarify, define a medical term, or add more details to the physician’s initial information. If the nurse feels that the client does not really understand what is going to occur, it is the nurse’s responsibility to notify the doctor to give further explanation before the client signs the consent. An easy way to determine what the client understands is to ask him or her to repeat the physician’s explanation. Under ordinary circumstances, only one witness to signing the consent is necessary. The witness does not have to be an RN, just someone over the age of 18 years.

Client Information

AUTHORIZATION FOR AND CONSENT TO SURGERY, ADMINISTRATION OF ANESTHETICS, SPECIAL DIAGNOSTIC OR THERAPEUTIC PROCEDURES

Date _____ Time _____

Your admitting physician is _____, M.D.

Your surgeon is _____, M.D.

- The hospital staff and facilities assist your physicians and surgeons in the performance of various surgical operations and other diagnostic and therapeutic procedures. These surgical operations and special diagnostic or therapeutic procedures all may involve calculated risks of complications, injury or even death, from both known and unknown causes and no warranty or guarantee has been made as to result or cure. Except in a case of emergency or exceptional circumstances, these operations and procedures are not performed upon clients unless and until the client has had an opportunity to discuss them with his/her physician. Each client has the right to consent to or to refuse any proposed operation or special procedure (based upon the description or explanation received).
- Your physicians and surgeons have determined that the operations or special procedures listed below may be beneficial in the diagnosis or treatment of your condition. Upon your authorization and consent, the operations or special procedures will be performed by your physicians and surgeons and their staff. The persons in attendance for the purpose of administering anesthesia or performing other specialized professional services, such as radiology, pathology and the like, are not the agents, servants or employees of the hospital or your physician or surgeon, but are independent contractors performing specialized services on your behalf and, as such, are your agents, servants, or employees. Any tissue or member severed in any operation will be disposed of in the discretion of the pathologist, except and those body parts specified as donor organs.
- Your signature opposite the operations or special procedures listed below constitutes your acknowledgement (a) that you have read and agreed to the foregoing, (b) that the operations or special procedures have been adequately explained to you by your attending physicians or surgeons and that you have all of the information that you desire, and (c) that you authorize and consent to the performance of the operations or special procedures.

(If client is a minor or unable to sign, complete the following): Client is a minor, is unable to sign because

Father Guardian

Mother Other person and relationship

▲ Form 3-G. Example of consent form.

There are many rules and regulations governing consents. If you have questions about them, consult the consent manual for your hospital, or a supervisory person. There are several important situations in which more information may be needed. One relates to the client's mental competency. Generally, the client must sign personally, and spouses are unable to sign for the client. Permanent incompetence usually involves legal action to assign someone else as conservator. Temporary incompetence may be the result of hospital treatments, such as drugs or anesthetics. When a narcotic or sedative has been given, at least 4 hours' elapsed time is recommended before the client is considered competent to sign a consent. A second situation concerns the client who is a minor. The age of consent varies by state and also according to specific situations, such as emancipation (being away from the family and self-supporting) and the type of medical problem (reportable diseases or pregnancy). An associated problem may arise when deciding who can legally sign for a minor.

REPORTING

A shift-to-shift report should be given not only from the Kardex but from the client care plan. There is no need to review particular procedures for such activities as dressing changes, when they are outlined on the care plan. A simple statement to the effect that the procedure is listed on the care plan is all that is necessary. This decreases both time and repetition of information.

To avoid confusion from shift to shift, specific times for treatments and for activities of daily living (ADLs) are indicated. For example, it is noted on the care plan that the client prefers his bath before 8 AM to avoid having to ask him every day when he wants his bath. This consistency promotes a feeling of confidence in the nursing staff and alleviates fear.

Intrashift Reports

Reporting your observations and interventions to other health team members is as essential as documenting them on the client's chart. Intrashift reports are usually verbal reports relayed to team members, team leaders, or charge nurses to keep them informed of changes in the client's conditions. Examples of findings that need to be communicated to other health team members include significant changes in vital signs, unusual responses to treatments, medications, or changes in the client's physical or emotional condition.

EVIDENCE-BASED PRACTICE

Interdisciplinary Collaboration

A 2004 study of the literature found positive outcomes from interdisciplinary collaboration. The most significant were coordination of care amongst clinical team members; improved efficiency and client outcomes; interdisciplinary communication, particularly with pharmacists; and reduced medication errors and adverse drug events.

Source: National Association for Healthcare Quality (2004, March-April). Patient safety: A case study in team building and interdisciplinary collaboration. www.nahq.org/Journal/ce/article_ID=171

Intershift Reports

Intershift reports disseminate client information between shifts. It may be accomplished through a verbal report or by tape recording the information. The intershift report should include the following data: client's name, room number, physician's name, diagnosis, and date of surgery when appropriate. In addition, report unusual findings based on the nursing assessment, response to treatments or medications, unusual occurrences, laboratory results, laboratory studies, tests to be completed on the next shift, and any physical or psychosocial problems that exist.

SBAR is a relatively new technique that nurses are using to focus communication relative to the client's condition. When the nurse is making an inter- or intrashift report, this technique includes the critical elements that must be transferred from one healthcare team to another: situation, background, assessment, and recommendations.

Physician/Advanced Practitioner Notification

Physicians should be notified whenever treatment or nursing care parameters are exceeded, significant alterations occur in physical assessment findings, or abnormal laboratory findings and test results are obtained.

Before calling the physician, have all data available to allow you to answer questions: current vital signs, laboratory results, when medications were given last, and so on. It is a good idea to have the entire chart with you.

When calling the physician, identify yourself by name, your status (RN or SN), nursing unit, and the client's name. State the exact reason you are calling. Give pertinent and succinct information.

Nurse Manager

Written or verbal reports are given to nurse managers, nursing supervisors, or clinical coordinators during each shift. The report includes information on all critically ill clients, those with unusual occurrences or complications, and clients with conditions that are difficult to manage. It is also a good idea to alert the supervisor to problems with families, physicians, or other health disciplines so she or he can assist you in the problem solving.

Client Care Conferences

Client care conferences and care plans play an integral role in planning and delivering health care for difficult or unusual problems. The client care conference can focus on developing the care plan or on identifying difficult problems. A conference can be scheduled to plan appropriate interventions and to inform all health team members of the goals for that client's care.

HEALTHCARE DELIVERY

Client Acuity Systems

State law, such as Title 22 of the California Code of Regulation, provides information on how staffing is determined in hospitals within that state. Title 22 states the following regulations regarding staffing.

There shall be a method for determining staffing requirements based on assessment of client needs. This assessment shall take into consideration at least the following:

1. The ability of the client to do self-care
2. Degree of illness
3. Requirements for special nursing activities
4. Skill level of personnel required in delivery care
5. Placement of the client in the nursing unit

There shall be documentation of the methodology used in making staffing determinations. Such documentation shall be part of the records of the nursing service and be available for review.

Various systems to determine staffing patterns have been used for many years. With the advent of diagnosis-related groups (DRGs), acuity systems for planning staffing needs are being used in many hospitals. This system forms the basis for client care delivery. Categories of nursing care are identified, and a numerical value is assigned to each category. These categories of care include areas such as ADLs, ambulation, client teaching, and medication administration. The numerical values assigned to each category are based on a point scale. For example, using a scale of 1 to 5, a score of 1 indicates the client can function independently in certain tasks; a score of 5 indicates complete dependency on a caregiver for that category.

The scores from all categories are totaled; this score is divided by the number of categories in the acuity system. The final score is designated as the client's acuity level, which is determined for each 8-hour shift. Every nursing unit has a pre-determined number of client care hours assigned for each acuity level. For example, a client acuity level of 4.0 on the day shift is allotted 2.8 hours of nursing care for that shift.

After all clients in the nursing unit are assigned an acuity level, the total client care acuity number is used to determine the number of nursing staff required for the next shift. Then, the acuity level of individual clients is used to plan care assignments for the staff. A nurse may be able to safely care for a total acuity of 16. This method seems equitable, since each staff member is assigned to clients based on acuity. Thus instead of assigning the nursing staff to clients based on room location or number of clients, the acuity level is used to allocate staff resources. Staffing patterns based on the acuity system have been found to be the most practical, equitable, and manageable.

Disease Management

A current trend in delivering health care specifies a goal of reducing complications associated with chronic diseases. Designed to incorporate healthcare interventions based on standard practice guidelines, this system is a cost-saving, empowering approach for clients.

It is a process that begins when the group paying for the health care identifies a client with a targeted chronic disease, including such diseases as cancer, chronic obstructive pulmonary disease (COPD), asthma, diabetes, or depression.

A nurse contacts the client, asks his permission to enter him in the program, and does an initial assessment. Following this, the nurse discusses recommended medical care to the client. The nurse then discusses lifestyle behaviors proven to

improve the chronic conditions. All are based on evidence-backed practice guidelines. Self-care efforts have proved to be significant in altering the course of the disease.

Most programs involve telephone communications from a registered nurse, although home visits may be arranged.

Clinical Alert

Studies show that 90 million U.S. citizens live with chronic diseases which are responsible for 7 out of 10 deaths in the United States.

DELEGATING CLIENT CARE

Client care assignments should be based on careful analysis of each client's needs and goals of care. The care plan may be consulted for an effective use of healthcare team members to their best advantage, as well as for the client's welfare. A client requiring extensive sterile dressing changes, frequent assessments, and IV medications is more appropriately assigned to a professional nurse. A client who is convalescing after a stroke and requires mainly bathing and ambulation assistance can usually be assigned to another member of the health team such as a nursing assistant.

In most healthcare facilities, delegating client care to healthcare workers has become a financially driven reality. RNs have less responsibility for actual direct care activities such as hygienic care, ambulation, and feeding. However, delegation of these tasks is under the jurisdiction of the RN. To delegate appropriate tasks, the nurse must be familiar with the Nurse Practice Act for RNs and Licensed Vocational Nurses (LVNs) in their state and with the hospital's job descriptions for each level of healthcare worker. More unlicensed assistive personnel (UAP) are being employed by facilities as a method of cost containment. The goal is still to deliver service to the clients. This classification of healthcare worker includes many titles, such as patient-focused care technician, patient care technician, UAP, and nurse assistant. This level of healthcare worker provides basic care functions and can be a help to the overburdened nurse. UAPs must receive training in the skills

▲ Client care assignments are delegated based on client acuity and competence of the healthcare worker.

they are to perform before client care is assigned. The usual tasks assigned to these workers are similar to those of certified nurse assistants (CNAs), with added responsibilities such as changing clean dressings or suctioning long-standing tracheostomies using clean technique. The RN is still responsible for the care that is provided by this category of healthcare worker. Because of this, many state boards of nursing have developed position statements and guidelines to help RNs delegate activities safely. Guidelines vary among states, so you need to check your state's guidelines. Also, there are general guidelines that should be followed regardless of the state in which you practice. According to the National Council of State Boards of Nursing (NCSBN), tasks that involve nursing judgment and the need to assess the client's responses to the care plan must not be delegated to any other level of worker than an RN. Any nursing intervention that requires independent, specialized nursing knowledge, skill, or judgment can only be delegated to an RN, according to the American Nurses Association. The hospital cannot expand the duties of healthcare workers beyond those legally allowed by the state. The hospital may, however, decrease their task levels and require certification or credentials for some tasks.

RN Delegation

Delegation is defined as “transferring to a competent individual the authority to perform a selected nursing task in a selected situation” (National Council of State Boards of Nursing). State licensing laws designate that nurses are legally accountable for quality of care and for direct client care. For example:

- RNs decide which tasks to delegate and under what circumstances.
- RNs must know what is safe delegation of nursing care tasks.
- RNs must supervise (monitor and evaluate) outcomes for all delegated tasks. The RN retains accountability for the delegation.

RNs must know the legal scope of practice of other licensed providers. They must also know competency of licensed and unlicensed personnel as well as the tasks which may be delegated.

- Some states identify tasks that may *not ever* be delegated (such as a sterile dressing to unlicensed personnel).
- RNs may *not* delegate assessment, evaluation, or nursing judgment functions.

RNs and LVNs must check with their own states' laws and regulations to determine which activities may *not* be performed by unlicensed assistive personnel (UAP).

Examples are as follows:

- Administration of medications or IV drugs.
- Venipuncture or intravenous therapy.
- Parenteral or tube feedings.
- Any invasive procedures such as NG tube insertion, catheters, or suctioning.

- Assessment of the client's condition.
- Educating client or family concerning healthcare problems.
- Reporting on laboratory tests.

RN Responsibilities That Cannot Be Delegated

- Data entry into client's charts for all unlicensed personnel to whom tasks are delegated.
- Initial health assessments (only by RN).
- Care plan objectives—checked by RN if completed by LVN.
- Review data obtained by other healthcare workers.
- Complete referral form for additional client services.
- Receive reports of client conditions and any unexpected findings from delegated activities.
- Identify parameters for which worker is to notify nurse.
- Carry out pain management activities (epidural narcotic analgesia done only by RN).
- Check advanced directives in client's chart.
- Organ donation—RN or LVN responsible for carrying out hospital policies.
- Complete discharge teaching plan.

Activities That May Be Delegated to LVN/PN The RN is legally responsible for client care. As such, the nurse must determine which task may be delegated. These decisions are based on the client's diagnosis, what the state allows the LVN to do, the amount of judgment and experience needed to complete the task, and whether the assistant is capable of performing and completing the task. Following are guidelines for delegation:

- While the RN initiates the care plan, the LVN may update the plan.
- After the RN completes the initial assessment, the LVN records assessment changes.
- The LVN may reinforce client teaching, but the RN must initiate the teaching and evaluate the results.
- LVNs, depending on the individual state standards, may or may not add medications to the IV. They may add vitamins and minerals in most states. After completing an IV course, LVNs may initiate IV therapy.

Delegation Regulations of Unlicensed Assistive Personnel (UAPs) and Certified Nurse Assistants (CNAs)

These terms refer to a group of workers who are trained and/or certified, but not licensed. These workers cannot be assigned tasks in lieu of a registered nurse. The nurse must determine which tasks may be performed by a UAP or CNA.

How to delegate to a UAP or CNA:

- The assistant's areas of competence must be judged against the specific needs of the client.
- The nurse must give specific instructions and do active monitoring during the assignment.
- Progress in client care through feedback and evaluation of outcomes should occur frequently.
- The nurse must be sure that the appropriate delegation is made: Can the assistant legally do this task, has the worker

been trained to perform this task, has the worker demonstrated that they can complete the task, and is the client response predictable?

- When performing the task, can the worker obtain the same result as the RN?

Duties Most Often Delegated to Unlicensed Assistive Personnel

- Taking vital signs and charting results
- Obtaining height and weight
- Repositioning a client or assisting a client to bed
- Bathing a client and making the bed
- Transferring a client between units
- Escorting a client out of the hospital
- Recording drainage from an NG tube
- Serving food trays and feeding a client
- Obtaining a specimen that is nonsterile and noninvasive
- Performing range-of-motion activities after instruction
- Initiating CPR after certification
- Working with a dying client
- Completing postmortem care

Standards of Competent Performance

- A registered nurse shall be considered competent when he/she consistently demonstrates the ability to transfer scientific knowledge from social, biological, and physical sciences in applying the nursing process.
- *Incompetence* means lacking possession of or failure to exercise that degree of learning, skill, care, and experience ordinarily possessed and exercised by a competent registered nurse.

Professional Functions of the RN (Denoted by State)

- Formulates a nursing diagnosis through observation of the client's physical condition and behavior, and through interpretation of information obtained from the client and others, including the health team.
- Formulates a care plan, in collaboration with the client, which ensures that nursing care services provide for the client's safety, comfort, hygiene, and protection, and for disease prevention and restorative measures.
- Performs skill essential to the kind of nursing action to be taken, explains the health treatment to the client and family, and teaches the client and family how to care for the client's health needs.
- Delegates tasks to subordinates based on the legal scope of practice of the subordinate and on the preparation and capability needed in the tasks to be delegated and effectively supervises nursing care being given by subordinates.
- Evaluates the effectiveness of the care plan through observation of the client's physical condition and behavior, signs, and symptoms through communication with the client and health team members and modifies the plan as needed.
- Acts as the client's advocate, as circumstances require, by initiating action to improve health care or change decisions

or activities that are against the interests or wishes of the client and by giving the client the opportunity to make informed decisions about health care before it is provided.

Parameters of Delegation

Many state boards of nursing have identified the parameters of delegation. Examples of these "Rights of Delegation" are:

Right Task—a task that can be legally delegated to an LVN/LPN, PCT, or UAP. Check the state nurse practice act to determine whether the caregiver is trained to perform the task. Judge whether the UAP or LVN is competent to perform the task.

Right Circumstances—the LVN, PCT, or UAP understands the elements of the procedure and the RN is assured that the UAP can perform the procedure safely in an appropriate setting. Caregiver is able to collect the right supplies to perform the procedure.

Right Person—the right person (RN or LVN) delegates the right task (legally can be delegated to a UAP) to the right person (legally can perform the task) on the right client (stable with predictable outcomes).

Right Communication—person delegating the task (RN or LVN) has described the task clearly, including directions, special steps of the task, and the expected outcomes. Then, the delegator must trust those they are delegating to, supporting the right to make certain decisions.

Right Supervisor—the RN or LVN delegating the activity answers the UAP's questions and is available to problem solve, if necessary.

STUDENT CLINICAL PLANNING

Preclinical Planning

To assist students with client care planning prior to clinical experience, many nursing programs have developed a Student Clinical Prep Form. This form helps focus the student's attention on the information necessary to ensure safe nursing practice. Most forms of this type, such as the example provided, include information related to the client's biographical data, history and physical assessment findings, medical diagnosis, nursing diagnosis, medications including IVs, and nursing interventions.

Time Management

Implementing time management techniques during your student clinical experience will assist you not only in organizing client care management, but also in completing your assignment efficiently. Some techniques you may find helpful are listed below.

- Design a time management work sheet you can follow.
- Collect the appropriate information you will require to identify client care tasks (e.g., RN report, care plan, Kardex, medication record).

STUDENT CLINICAL PREP FORM

IDENTIFYING DATA

Client Initials _____ Room # _____ Age _____ M _____ F _____ Date of Admission _____ Allergies _____

Cultural/Ethnic Background _____ Primary Language Spoken _____ Religious Preference _____

Occupation _____ Retired _____ Family/Living Arrangements _____

Admitting Diagnosis _____ Diagnostic Procedures (dates): _____

Brief History of Present Illness _____ Surgical Procedures (dates): _____

_____ Pertinent Lab Data: _____

▲ Form 3-I. Time management work sheet.

- Identify specific tasks of client care and the time frame needed for completion.
- Prioritize tasks included in the client care plan.
- Make an initial visit to assess your client's status.
- Revise priorities based on your assessment.
- Plan nursing interventions in sequence.
- Group and sequence client care activities for completion in the same time frame. Allocate sufficient time to complete client assignment.
- Consider client's wishes for completing nonpriority tasks, such as bathing and grooming.
- Identify tasks for which you will require assistance.
- Notify the appropriate colleague to assist you (e.g., ambulating your client).
- Identify and collect necessary equipment for task completion.
- Complete client care, implementing the prioritized plan of action (POA) using your time management work sheet.
- Allocate appropriate time to interact with your client.
- Mark off tasks on the time management sheet as you complete them, leaving a record for giving verbal report to the nurse when leaving the unit.
- Document client care as soon as feasible, or at least every 2 hours, on the appropriate records.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- The RN must complete the initial assessment, develop the client care plan, and develop the teaching plan. These activities cannot be delegated to any other healthcare team worker.
- Tasks that require judgment or the need to assess outcomes of the task may not be delegated to other healthcare team workers.
- Before delegating any client care to an LVN/LPN, review the Nurse Practice Act and the facility policies to determine which tasks may be delegated and which may not be delegated.
- Before delegating client care to Unlicensed Assistive Personnel (UAP), review the board of nursing (BRN) guidelines in your state as well as the facility policy governing their skill level. Remember the facility may decrease the level of responsibility for healthcare workers, but they cannot exceed the skill level outlined in Practice Acts or the BRN guidelines.
- When delegating client care, refer to the Kardex as well as the client care plan or critical pathway to determine the level of care required in order to appropriately assign the healthcare workers. Assign clients according to care needs, not location of rooms.

- Charting basic care modalities such as hygienic care can be assigned to CNAs and UAPs when flow sheets are used. These caregivers cannot be assigned to complete narrative charting.
- LVNs/LPNs are responsible for charting using all formats: narrative, flow sheets, problem-oriented, and computer-assisted charting.
- RNs are responsible for the data entry in charts for all unlicensed healthcare workers.

Communication Matrix

- Information relative to client care is provided both in written and verbal communication. Written information is found on the Kardex card, client care plan, or critical pathway. Verbal communication consists of the shift and team report and directions provided to the workers throughout the shift. When assigning client care to healthcare workers, the RN uses both communication processes. When directions are given to healthcare workers, the Kardex card and care plan or pathway is the foundation for client information. This information is provided in a verbal report at the beginning of the shift. Two-way communication is encouraged throughout the shift, as client's needs change or new orders are written for client care.
- Verbal reports can be given individually or to a group of healthcare workers. It depends on the type of healthcare delivery system that is employed in the facility.
- Specific information regarding client care must be provided to each healthcare worker. This information includes activity level, vital sign times, diet, ability to perform

- ADLs, procedures or treatments that will be conducted during the shift and the approximate time this will occur, specimens needing collection as well as any safety precautions necessary, visual and hearing deficits, dentures, and specific tasks to be completed by the healthcare worker.
- Communicate with all members of the healthcare team through the multidisciplinary care plan. Ensure they follow the plan of care and document to the care plan.
 - After receiving report from unlicensed health care workers, the RN must complete the charting except where flow sheets are used.
 - The RN is responsible for the accuracy of all documentation, including information contained in the flow sheet; therefore, it should be checked each shift.
 - Licensed nursing staff should review the documentation for the past 24 hours before beginning nursing care. The chart will provide details on the client's status, including assessment findings, response to pain medication, and client's response to treatments. Continuity of care can be provided when client information is known.
 - The RN should review necessary data, obtained by reading the chart, with the unlicensed personnel to provide for continuity of care.
 - RNs should review principles of charting with personnel if guidelines for charting are not being followed. The records are permanent and reflect the care provided the client while hospitalized. The chart can be subpoenaed if a lawsuit is filed.

CRITICAL THINKING Strategies

Scenario 1

Determine appropriate delegation of client activities for a staff team on a unit. This scenario does not take into consideration the acuity of the client, only the nursing tasks needed for the day shift. Each facility and state have differing policies regarding personnel; therefore, these policies need to be reviewed before this activity is completed.

The team consists of one RN, one LVN/LPN, and one UAP. There are 10 clients and 2 unoccupied beds. There is a charge nurse and ward clerk assigned to the nursing unit. There are two other teams, and these three teams make up the medical–surgical nursing unit.

- | | | | |
|---------|--|---------|--|
| RM 601A | Mr. Rodrigues, 98, admitted 24 hours earlier
Diagnosis: congestive heart failure
Bed rest, bed bath and assistance with oral hygiene, daily weight, I&O
Vital signs q 4 hrs., low sodium diet, restricted fluids to 1500mL
IV #2 1000mL D5/.2NS with 20mEq KCL at 50mL/hr—800mL remaining
IV medications: lasix 40mEq BID
Oral medications: Digoxin 0.25mg daily, vitamin supplement | | Ambulate ad lib, self-care
Oral medications for pain
IV discontinued at 8 AM
To be discharged today with discharge teaching |
| RM 601B | Mr. Jamisen, 69, admitted this AM
Diagnosis: coronary artery disease
Surgery at 10 AM: triple bypass—will go to ICU following surgery
Preop checklist and client teaching has been completed
Preop meds on call to OR
IV medications
IV #1 1000mL D5/.2NS at 75mL/hr | RM 602B | Not occupied |
| RM 602A | Mrs. Jones, 59, admitted 2 days ago
Diagnosis: cholelithiasis
Surgery 2 days ago: Laparoscopic cholecystectomy | RM 603A | Mrs. Henderson, 38, admitted yesterday
Diagnosis: metastatic cancer to the brain
CAT scan scheduled for 12 noon
IV #2 1000mL D5W with 20 mEq KCL at 50mL/hr
Assist with ADLs
Vital signs and neuro checks q 4 hrs, I&O
Oral medications for pain |
| | | RM 603B | Miss Johnson, 70, admitted 3 days ago
Diagnosis: pancreatic cancer with metastasis to the lungs
Chair TID, and ambulate to bathroom
Vital signs q 4 hrs
Spirometry q 4 hrs with RT
Deep breathing and coughing exercises q 4 hrs
Nasotracheal suction PRN
IV #5 1000mL D5W at 50 mL/hr
PCA pump for pain medication
Chemotherapy IV daily |
| | | RM 604A | Mr. Scott, 64, admitted this AM
Diagnosis: benign prostatic hypertrophy
Surgery for TURP at 1 PM—to return to the nursing unit
Needs preop teaching and a surgical checklist completed |
| | | RM 604B | Mr. Jackson, 37, admitted last night
Diagnosis: torn ACL
Surgery this AM at 7:30—will return to unit by 10:30 AM
CPM ordered postop |

- RM 605A Mrs. Price, 89, admitted 1 week ago
 Diagnosis: terminal heart failure, semi-comatose
 Complete ADLs, keep comfortable, turn q 2 hrs
 Vital signs q 8 hrs, I&O
 Foley catheter to drainage
 IV #8 D5/.45 NS with 40mEq KCL at KO rate
- RM 605B Not occupied
- RM 606A Mrs. Fellipe, 28, admitted last evening
 Diagnosis: gastroenteritis for past 4 days
 Ambulate to bathroom, chair as tolerated
 Independent in ADLs
 Vital signs q 4 hrs, NPO, I&O
 IV #3 1000mL NS with 40mEq KCL at 125mL/hr
- RM 606B Mrs. Blake, 48, admitted yesterday
 Diagnosis: sickle cell crisis
 Bed rest until pain subsides
 Vital signs q 4 hrs, I&O, diet as tolerated
 Oral medications: folic acid, nonsteroidal antiinflammatory drug
 Narcotic analgesic medication for pain
 IV #3 1000mL D5/.2NS with 40mEq KCL at 125mL/hr

- Determine the appropriate staff assignment for this client roster. What information do you need to complete this assignment?
- How would you as team leader make client assignments for each individual staff member?
- How do the theory of delegation and the facility/state policies of delegation impact on your assignment?
- What additional factors would you need to consider in making these assignments?

Scenario 2

You are assigned to provide nursing care for Mr. Fred Smith, 39 years of age. He is admitted to the hospital for severe dehydration due to the effects of chemotherapy. On your initial rounds at 7:30 AM, you find him sleeping. His respirations are

labored and stertorous. His color is ashen, eyes sunken, and skin dry. At 8 AM you enter the room and find him awake. He complains of being very thirsty and wants a glass of water. He cannot tolerate oral fluids and is receiving IV fluids with KCl added because of his nausea and vomiting on admission the day before. After taking his vital signs (T: 100.6; P: 100; R: 32) you give him his bath and make his bed. You notice he has reddened areas over his coccyx and on his elbows and heels, each area about the size of a quarter. His skin is dry and peeling. Drainage from his Foley catheter is a dark amber color with a very strong odor. You measure the urine at 8 AM. The total is 75 mL. The last output was measured at 6 AM.

- How would you chart the information obtained from the simulated situation? What would be appropriate forms to use?
- What assessment information (that you just charted) would require nursing interventions?
- If you were assigning this client to a team member, who would be most appropriate—RN, LVN/LPN, or CNA?

Scenario 3

As a new student, you are going into the hospital to prepare for the clinical experience tomorrow morning. There are two stages of preparation. The first stage is obtaining all the necessary information you will need to provide safe care. The second stage is reviewing your textbooks and lecture notes to gain an understanding of the client's diagnosis, medications, lab values, and diagnostic tests that will be done during his/her hospitalization.

- If you have only a limited time to review the client's chart, what sections of the chart will provide you with sufficient information to render you safe to care for the client?
- In preparing for clinical practice, what information is essential to review in addition to the data you have obtained from the clinical record? Where is the most appropriate place to find this information?
- List the priority interventions you will carry out within the first hour of the clinical experience. Explain the rationale for your answers.

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. Charting is an important nursing activity. The following is a list of functions that client charting fulfills.

Select all those that apply.

1. Communicates information to members of the health team.
2. Is a legal document.
3. Reminds nurse of the treatments to be performed for the client.

4. Assists supervisors to evaluate staff performance.
5. Provides a permanent client record.
6. Protects both client and nurse in terms of quality and continuity of health care.

2. Hospitals are rapidly adopting electronic charting programs that have many advantages. One of the disadvantages of using this system is it
 1. Allows nurse to document more client details quickly.

2. Encourages nurses to rely on the computer data without questioning the information.
 3. Gives the nurse more time to spend on client care.
 4. Offers instant test results and information.
3. The nurse finishes documenting a client's chart and notices that the information has been written in the wrong chart. The next action is to
 1. Notify the team leader to correct it.
 2. Completely cross out the writing so it is not visible.
 3. Line out the entry with a single line, write "error" above it, and initial the entry.
 4. Draw a red line through the incorrect entry, write "wrong entry" and initial.
 4. When completing an unusual occurrence (incident report), it is necessary to record
 1. Major details of the incident.
 2. Only the actual nursing interventions made.
 3. All of the details of the incident.
 4. General details with focus on client's reactions.
 5. Your hospital has implemented the use of standard clinical pathways as the major type of documentation. One of the advantages of this type of documentation is
 1. It allows for individual plans of care.
 2. There is continuity of care among all healthcare workers.
 3. It includes history, assessment, and risk factors.
 4. It allows for complex clients to receive specialized care.
 6. A bedridden Islamic client asks the nurse to bring a basin of water every morning and evening. The unit is understaffed and extremely busy. You will resolve this issue by
 1. Explaining to the client that you are too busy to bring him water today.
 2. Bringing him the water regardless of the busy schedule.
 3. Asking an unlicensed helper to explain the situation to him.
 4. Telling him that you will try to do it, but it may be late.
 7. When planning client care assignments in team nursing, the action that could lead to instability and inadequate care is
 1. Changing assignments frequently.
 2. Considering the job description of the team members.
 3. Considering the geographical location of the clients.
 4. Considering the acuity level of the clients.
 8. Which of the following actions will help a nurse manager to increase leadership skills through the process of delegation?
 1. Close supervision, thereby not allowing any errors.
 2. Clearly making all decisions about how a task is to be completed.
 3. Delegating responsibility in such a way that the worker is capable of handling responsibility.
 4. Delegating those tasks that are distasteful to the nurse manager.
 9. Witnessing a client sign a surgical consent form implies that the nurse
 1. Saw the client sign the consent form.
 2. Knows the client understands the proposed procedure.
 3. Believes the client to be competent.
 4. Believes the client is able to tolerate the procedure.
 10. Delegation is an important nursing function. Of the following statements, which one is incorrect?
 1. RNs decide which tasks to delegate.
 2. RNs must supervise outcomes for all delegated tasks.
 3. All nursing tasks may be delegated if an RN takes responsibility.
 4. RNs must know the legal scope of practice of other licensed providers.
-

4

Communication and Nurse–Client Relationship

LEARNING OBJECTIVES

1. Define the term *communication*.
2. Explain why communication is an important concept in nursing.
3. Describe what is meant by the term *confidentiality*.
4. Discuss four factors that affect communication.
5. List five examples of therapeutic communication.
6. List five examples of blocks to communication.
7. Explain why multicultural health care is important and discuss the term *cultural diversity*.
8. List three components of a cultural sensitivity assessment.
9. List two questions that would elicit information about the client's spiritual issues.
10. Demonstrate the steps for beginning a client interaction.
11. Explain why it is therapeutic to encourage the client to express feelings and thoughts.
12. Describe the phases of a nurse–client relationship.
13. List three components for maintaining a nurse–client relationship.
14. Describe the rationale for discussing termination at the beginning of the relationship.
15. Practice assisting a client to communicate with his/her physician.
16. List at least three cues you would observe if a client were depressed, anxious, or angry.
17. Discuss two interventions you would make if one of your assigned clients was depressed, anxious, or angry.

TERMINOLOGY

Acceptance favorable reception; basic acknowledgment.

Agitation excessive restlessness and increased mental and especially physical activity.

Anxiety a state of uneasiness and distress; diffuse apprehension.

Apprehension a fearful or uneasy anticipation of the future; dread.

Assistance aiding, helping, or giving support.

Attitude a state of mind or feeling with regard to some matter; disposition.

Behavior the actions or reactions of persons under specified circumstances.

Clarify to make clear or easier to understand.

Cliché stereotyped response; a trite or overused expression or idea.

Cognition the mental process or faculty by which knowledge is acquired.

Communication the exchange of thoughts, information, or messages.

Confusion disorder; jumble; distraction; bewilderment.

Congruence agreement; conformity.

Consent to agree; to be of the same mind.

Convey to communicate or make known; to impart.

Coping mechanism a means by which to adjust or adapt to disequilibrium; defense mechanism against anxiety.

Counseling to give support or to provide guidance.

Cultural diversity differences among people with respect to their values, beliefs, language, customs, and general patterns of behavior.

Cultural sensitivity being aware of and accepting diversity among people.

Depression a mental state characterized by dejection, lack of hope, and absence of cheerfulness.

Emotion any strong feeling, as of joy, hate, sorrow, love.

Empathy ability to readily comprehend the feelings, thoughts, and motives of another person.

Esteem to consider as of a certain value; regard; respect.

Ethnocentrism belief in the superiority of one's own ethnic group.

Evaluate to examine and judge; appraise.

Expression to manifest or communicate; make known.

Feedback the return of information to the place of origin.

“Hand-Off” Communication See SBAR definition.

Helping relationship an interaction of individuals that sets the climate for movement of the participants toward common goals.

HIPAA Health Insurance Portability and Accountability Act, enacted into law in 1996 to improve Medicare and Medicaid programs and efficiency of healthcare system.

Maladaptive inability to, or faulty adjustment or adaptation.

Multicultural health care a consideration of client's varying cultures (including beliefs, values, customs, traditions, language, etc.) when delivering health care.

Noncompliance failure or refusal to go along with a plan or program.

Nonverbal communication aspects of communication that are not content (such as body language or gestures) but still convey meaning.

Overdependence the state of needing or relying on someone or something too much.

Perception the process of receiving and interpreting sensory impressions.

Rapport a feeling of mutual trust experienced by persons in a satisfactory relationship.

Refer to send or direct someone for action or help.

Relationship an interaction of individuals over a period of time.

SBAR a tool that standardizes a “hand-off communication” when one nurse turns a client over to another nurse; situation, background, assessment, and recommendations.

Self-esteem a sense of pride in oneself; self-love.

Social involvement with communities and other persons.

Spiritual assessment assessing a client's religious or spiritual beliefs and values.

Support to lend strength or give assistance to.

Termination the end of something; a limit or boundary; conclusion or cessation.

Therapeutic having medicinal or healing properties; a healing agent.

Understanding to perceive and comprehend the nature and significance of; to know.

Validate to substantiate or verify.

Verbal communication the words, content, or information conveyed in the message.

COMMUNICATION

Communication is the process of sending and receiving messages by means of symbols, words, signs, gestures, or other actions. It is a multilevel process consisting of the content, or information, part of the message and the part that defines the meaning of the message. Messages sent and received define the relationship between people. From the point of view of a learned skill, communication is intended to accomplish a defined goal. It is the transmission of facts, feelings, and meaning through the communication process.

The communication process forms one of the primary bases for administering all skills. Without clear communication, the nurse cannot assess, administer, or evaluate his or her actions in performing the skill. The principles of therapeutic communication also form a basis for interviewing and counseling skills.

Communication is a vital element in nursing. Everything that occurs within the nurse–client interaction involves some form or mode of communication, whether it includes listening to an upset family member, assisting a client in health teaching, or performing a nursing procedure. Without communication, the nurse could not give nursing care.

The communication process includes both verbal and nonverbal expressions and is affected by the intrapersonal framework of the person, the relationship between the participants, and the purpose of the sender. The content of the message and the context also influence the communication process. The manner in which the message is sent and the effect on the receiver also play a role in the eventual outcome of the communication process. As you can see, the communication process can be very complex. As a beginning practitioner, however, the most important factor to remember is that *what* you say and *how* you say it have a very great influence on your client.

One of the most important skills you must master is to be able to talk therapeutically to clients and to be able to listen to them. Nurse–client communication is an intimate process of providing nursing care. In fact, the initial step in the nursing process—assessment—comprises observation, interview, and examination. The interview involves talking and listening to the client. Initially, it may be difficult for you to concentrate on both talking and listening, since you have not yet mastered the basic skills, such as a bed bath or taking vital signs. As you gain experience, however, these skills will become more familiar and you can focus on the communication–interaction process with the client.

Confidentiality (Client’s Right to Privacy)

Clients are protected by law (invasion of privacy) against unauthorized release of personal clinical data such as symptoms, diagnoses, and treatments. Confidential information may be released with the consent of the client. Information release is mandatory when ordered by the court or when a state statute requires reporting child abuse, communicable diseases, or other specific incidents.

Nurses, as well as other healthcare providers and their employers, may be held personally liable for invasion of privacy (as well as other torts) should litigation arise from the unauthorized release of client information. Nurses have a legal

and ethical responsibility to become familiar with their employers’ policies and procedures, as well as the new aspects of HIPAA, regarding production of client information.

Health Insurance Portability and Accountability Act (HIPAA)

This act, enacted into law in 1996 and phased in gradually, requires the Secretary of Health and Human Services to devise certain standards. This act improves the efficiency and effectiveness of Medicare and Medicaid programs, ensures continuing healthcare insurance if the client has had existing group insurance, and ensures the privacy of individual health information. One of the most important components of HIPAA is the privacy rule, which became effective in April 2003.

This act requires healthcare providers to protect clients against unauthorized disclosures of personal medical information. HIPAA requires client consent for any information dispersed to others. It states that clients must receive written notice of privacy practices and their rights. Clients may access personal medical records more freely than previously.

Guidelines That Influence Effective Communication

- A person cannot *not* communicate. This idea is basic to communication. We have an inherent need to communicate, whether it be verbal or nonverbal. Even silence is a form of communication.
- There is a content, or informational, value to messages sent and received that explains what the message is about and expresses how the sender regards the receiver.
- The message sent is not necessarily the meaning received.
- Messages contain overt and covert meanings. The sender is aware of the overt, or direct, meaning and may or may not be aware of the hidden, or covert, meaning.
- Communication becomes dysfunctional when a person does not assume responsibility for his or her communication. Dysfunctional communications result from failing to learn to communicate properly and leaving the responsibility for communicating to others.

Learning to talk with clients and listening to them is the beginning of a nurse–client relationship. Some of you come to nursing with many of these basic communication skills already mastered. Others experience shyness, hesitancy, and awkwardness in relating to clients. Try to keep in mind that you are being educated to be a professional person—a nurse—and as such you have a great deal to give to your clients. They will learn to respect your skill, value your presence, and depend on you when they are ill. One of the most rewarding aspects to nursing is experiencing a communication between you and your client. If you do feel shy or hesitant, remember that communication skills can be learned. Begin by practicing or role-playing with your classmates until you feel comfortable in the initial phases of a relationship.

All communication between nurse and client should be therapeutic, whether it involves obtaining information for an

assessment, interacting with the client during a bed bath, or doing client teaching. The difference between therapeutic communication and a therapeutic relationship is that a relationship has a beginning, middle, and end with specified goals for each phase. Therapeutic communication techniques should be used in all forms of communication.

Guidelines for Communicating With Clients

In establishing nurse–client communication, some basic guidelines should be remembered.

- Accept the client as a valued and worthwhile individual, for this acceptance is a prerequisite for a nurse–client relationship.
- Be aware of the total client, not just his or her physical needs. The client’s social, emotional, and spiritual needs are also important.
- Understand your own needs, feelings, and reactions so that they do not interfere with the therapeutic process with the client.
- Be prepared to feel some degree of emotional involvement with your client, evidencing caring and concern for his or her welfare. At the same time, however, it is necessary to maintain objectivity.
- Remember that the nurse–client interaction is a professional one. As such, you as the nurse possess the skills, abilities, and resources to relieve the other person’s pain and discomfort, and your client seeks comfort and assistance for alleviation of some existing problem.
- A nurse–client relationship does not require a long-term agreement or formal meetings between nurse and client to be effective. You may still meet the objectives of such a relationship in a short clinical experience.
- Take an active role and guide the conversation if the client is overly hesitant. For example, “I’m here to listen to any concerns you might have, Mr. Smith. You were mentioning having trouble understanding. ...”
- Give broad opening statements and ask open-ended questions to help the client describe what is happening to him or her. Pick up cues and follow through with the subject that the client introduces to provide continuity.
- Use body language to convey empathy, interest, and encouragement to facilitate communication.
- Use silence as a therapeutic tool, as it allows the client to pace and direct his or her own communications. Long periods of silence, however, may increase the client’s anxiety level, so use this technique wisely.

New Trends in Communication

Text messaging nurse to nurse or nurse to physician allows the person receiving the text to instantly learn the critical nature of the text. For example, texting “please review these critical lab values,” or “please call back STAT referencing client X.” This service enables a nurse to use only a name and web browser to locate the person who is receiving the text rather than taking time to look up a phone or pager number. A problem with

this system is that the nurse must document separately that a message was sent so that it goes into the client’s record.

A growing service called “pagerbox” is a Web site launched at Johns Hopkins University that allows a person to page a colleague using only the name and web browser and then confirm the page has been sent via a computer that is available. This system may well be adopted by other hospitals because it is so easy to use. (For more information, visit www.pagerbox.com.)

The Joint Commission Safety Goal 2: Improve Effectiveness of Caregiver Communication

The National Patient Safety Goals identified in 2003 by The Joint Commission (formerly JCAHO) are updated every year. One important safety goal targets good communication because poor communication between caregivers can cause errors and risk client safety. The Joint Commission, to improve the effectiveness of this goal, has identified four requirements that apply to nurses:

1. “Read back” or take three steps to verify a verbal telephone order or if the nurse is notified of a critical test result. In these situations, the nurse should write down the information, enter it into the computer, read it back to the person with whom the nurse is speaking, and then confirm what was read back.
2. Develop a list of abbreviations, acronyms, symbols, or dose designations that cannot be used in the facility because they are often misread or confused. (See list on page XX.)
3. Critical test results must be reported immediately. These are test results that are abnormal and for client safety may require an immediate intervention.
4. “Hand-off” communication means that a nurse must pass off crucial information about a client—status, their condition, recent changes, or ongoing treatment—to the next clinical caregiver. A tool available that standardizes hand-off is the SBAR technique. This is a technique that covers situation, background, assessment, and recommendations for the client that is being handed off.

“Hand-Off” Communication

“Hand-off” communication is a system or process that includes all relevant (especially critical elements) information about a client when one member of a healthcare team is “handing off” a client to another member. Using this technique increases client safety and implements a continuum of care.

SBAR is particularly important when you are handing off a client between preoperative and intraoperative areas. The transition of care must summarize critical client data, and SBAR provides a framework to accomplish this goal. Further, TJC’s universal protocol is now included in the 2009 Hospital National Patient Safety Goals, which state that there must be three aspects of this protocol:

- Active communication among all members of the surgical team.
- Involvement of the client or the client’s legal representative.
- Requirement for site marking and prevention of the wrong site, wrong procedure, and wrong person.

SBAR

The SBAR mnemonic communication technique is a standardized, focused method of communicating essential client information when members of the health team are transitioning from one member or team to another. This technique consists of four parts.

1. **Situation**—Identify yourself and the client and state the primary problem.
2. **Background**—Give the background of the client and be ready to answer any questions the other care provider may have.
3. **Assessment**—Give the essential assessment parameters of the client’s current state (for example, BP, P, R).
4. **Recommendations**—Make suggestions for continued care of the client in a priority framework.

Adhering to this format when one nurse is handing off a client to another caregiver will help to minimize safety risks for the client as well as assist the new health team members to give the best care possible. This method also provides a framework that directs a focus on a critical situation, if present, so that an immediate intervention may be made.

Source: Amato-Vealey, E. J., Barba, M. P., & Vealey, R. J. (2008, November). Hand-off communication: A requisite for perioperative patient safety. *AORN Journal*, 88(5), 763–770.

THERAPEUTIC COMMUNICATION TECHNIQUES

Communication includes the totality of the human person and reflects what is happening within and outside of us. Body sensations, thoughts, feelings, emotions, ideas, perceptions, judgments, previous experiences, and memories are all part of how and what we communicate. Effective, functional communication only occurs when what is happening within is congruent with what we share with the outside. It is important to be a therapeutic as well as a functional communicator and not to disturb the communication process by using nontherapeutic techniques or blocks to communication.

Therapeutic communication techniques assist the flow of communication and always focus on the client. Nontherapeutic communication techniques block or hinder communication and generally focus on the nurse and meet the nurse’s needs. The major therapeutic and nontherapeutic techniques are listed below.

Acknowledgment Acknowledging the client without inserting your own values or judgments. Acknowledgment

EVIDENCE-BASED PRACTICE

Results of the Harvard Medical Practice study revealed that poor communication is the most frequently cited cause of sentinel or adverse events. Using the SBAR technique will reduce errors and increase client safety.

Source: Brennan, T. A., Leape, L. L., Laird, N. M., Hebert, L., Localio, A. R., Lawthers, A. G., . . . Hiatt, H. H. (2004). Incidence of adverse events and negligence in hospitalized patients: Results of the Harvard Medical Practice Study I. 1991. *Quality & Safety in Health Care*, 13(2), 145–151.

▲ Therapeutic communication implies the nurse is focusing on the client. Here we see an example of nontherapeutic communication.

may be simple and with or without understanding, verbal or nonverbal.

Example: In the response “I hear what you’re saying,” the nurse acknowledges a statement without agreeing with it.

Example: “Yes, go on.” “Uh huh.”

Clarification Clarifying the client’s message. Check out or make clear either the intent or hidden meaning of the message, or determine if the message sent was the message received.

Example: “I don’t understand. Can you say it in a different way?”

Example: “Are you saying . . .” (Repeat meaning of client’s message as understood by you.)

Feedback Using feedback to relay to the client the effect of his or her words. This method helps keep the client on course or alters the course. It involves acknowledging, validating, clarifying, extending, and altering.

Example: “You changed the bag on your colostomy very well.”

Example: “When you say that, it makes me feel uncomfortable.” (If the client is making personal comments about the nurse.)

Focus Focusing or refocusing on the client’s statement. Pick up on central topics or “cues” given by the client.

Example: “You were telling me how hard it is to talk to your doctor.”

Example: “You said the Doppler test tomorrow is frightening.”

Incomplete Sentences Encouraging the client to continue.

Example: “Then your life is . . .”

Listening Consciously receiving the client’s message.

Example: Listening eagerly, actively, responsively, and seriously.

Minimum Verbal Activity Keeping your own verbalization minimal and letting the client lead the conversation.

Example: “You feel . . . ?” “Go on.”

Mutual Fit or Congruence Creating harmony of verbal and nonverbal messages.

Example: A client is crying, and the nurse says, “I’ll sit with you awhile,” and puts his or her hand on the client’s shoulder.

Example: A client tells the nurse he or she feels fine, but the client’s body language indicates that he or she is in pain. “You say you feel fine, but you look like you are in pain.”

Nonverbal Encouragement Using body language to communicate interest, attention, understanding, support, caring, and listening to promote data gathering.

Example: The nurse nods appropriately as the client talks.

Example: The nurse leans forward.

Open-Ended Questions Asking questions that cannot be answered with a simple “yes” or “no” or “maybe.” Generally ask questions requiring an answer of several words to broaden conversational opportunities and to help the client communicate.

Example: “How is your PCA working?” rather than “Is the pain gone?”

Reflection Identifying and sending back a message acknowledging the feeling or repeating the last few words the client said. (Conveys acceptance and great understanding.)

Example: “. . . distrust your diagnosis?”

Restatement Repeating the client’s statement as encouragement for him or her to continue.

Example: “You said that you can’t bear to look at your stoma.”

Validation Verifying the accuracy of the sender’s message.

Example: “Yes, it is confusing when so many staff are in the room.”

BLOCKS TO COMMUNICATION

Changing the Subject Introducing new topics inappropriately, a pattern that may indicate anxiety.

Example: The client is crying and discussing his or her fear of surgery when the nurse asks, “How many children do you have?”

▲ Within the interpersonal framework, nurses share part of who they are with the client.

False Reassurance Using clichés, pat answers, “cheery” words, advice, and “comforting” statements in an attempt to reassure the client. Most of what is called “reassurance” is really false reassurance.

Example: “It’s going to be all right.”

Example: “Don’t worry. This pain medication always works.”

Giving Advice Telling the client what to do. Giving your opinion or making decisions for the client implies he or she cannot handle his or her own life decisions and that you are accepting responsibility for him or her.

Example: “If I were you. . . .”

Example: “You should try some alternative treatments.”

Incongruence Sending verbal and nonverbal messages that contradict one another; two or more messages, sent via different levels, seriously contradicting one another. The contradiction may be between the verbal/nonverbal content or time/space content.

Example: “I’d like to talk to you” (but I’m just too busy), said while nurse is turning away from the client.

Assumptions Making an assumption about the meaning of someone else’s behavior that is not validated by the other person.

Example: The nurse finds the suicidal patient smiling and tells the staff he’s in a cheerful mood and much better.

Invalidation Ignoring or denying another person’s presence, thoughts, or feelings.

Example: Client: “Hi, how are you?” Nurse: “I can’t talk now, I’m on my way to lunch.”

Overloading Talking rapidly, changing subjects, and giving more information than can be absorbed at one time.

Example: “I see you’re 48 years old and were admitted yesterday. Have you had a physical assessment? Where do you come from?”

Social Response Responding in a way that focuses attention on the nurse instead of the client.

Example: “This sunshine is good for my roses. I have a beautiful rose garden.”

Underloading Remaining silent and unresponsive, not picking up cues, and failing to give feedback.

Example: Nurse asking, “I hope your pain is better” as he or she smiles and walks away.

Value Judgments Giving one’s own opinion, moralizing, or implying one’s own values by using words such as *nice*, *good*, *bad*, *right*, *wrong*, *should*, and *ought*.

Example: “I think he’s a very good doctor.”

Example: “I think it’s good that you decided to have the blood transfusion.”

MULTICULTURAL HEALTH CARE

As we move into the 21st century, there are demographic shifts occurring that will change the direction of health care. The last census showed that over 29% of the population is comprised of people of color, and 12% are of Hispanic or

Spanish origin. The total foreign-born population in 2000 was over 20 million, or over 12% of the total population, and 14 million Americans did not speak English. This trend can be expected to increase as the new census statistics are tallied. In fact, those groups that were minority may now be classified as majority.

Because of this change in the United States population demographics, there are emerging barriers to health care for many groups of people. Perhaps the greatest barrier is language, and since communication is an essential component of providing nursing care, it is important to consider language under the topic of communication. Other barriers may be living in urban, poor neighborhoods; poor prevention practices such as poor nutrition; and beliefs that affect how certain cultural groups understand illness and respond to treatment. Perhaps the greatest barrier for many ethnic groups is poverty. Those in the lower socioeconomic group have reduced access to health care, including health insurance, availability and location of health facilities, transportation, and so on.

Cultural Awareness

It is important for nurses to understand the impact of various cultures on healthcare practices if they are to become culturally competent. As more and more people immigrate to this country, nurses will be faced with cultural diversity problems in administering health care. Cultural diversity implies the range of differences in values, beliefs, customs, folklore, traditions, language, and patterns of behavior for the various cultural groups. For example, people from different cultures define personal space differently. Some may prefer closer personal contact, while others are offended by a person moving into their personal space. The nurse needs to be aware that personal space is related to culture, gender, and group behavior. Because all of these aspects potentially affect how an individual experiences, copes with, and responds to illness, nurses must be aware of these cultural differences.

Cultural Sensitivity

Nurses must become sensitive to people from cultures other than their own if they are to meet the needs of their clients. People from different cultures may have different beliefs and values about illness and treatment and different health practices and patterns of behavior. In order to treat the client holistically, the nurse should be aware of these differences and be able to incorporate them into the individual client's plan of care. For example, if a client is Native American and this person believes in and values shamanic healers, the nurse could formulate a plan that includes a healer visiting the client. This addition to the care plan could occur without interfering with the Western approach, in which the primary provider would be a physician.

Diversity in Health Care

Diversity is a key to delivering competent and safe nursing care because U.S. population projections beyond 2007 show that Hispanics, Asian Americans, and African Americans will

Cultural Assessment

When completing a total assessment on a client, the individual cultural components that are important to include are:

- Cultural background and orientation
- Communication patterns (based on culture)
- Nutritional practices
- Family relationships
- Beliefs and perceptions relating to health, illness, and treatment modalities
- Values relating to health practices
- Education
- Issues affecting the delivery of health care

outnumber whites. These diverse cultural groups will present all healthcare workers with a challenge: a challenge to make appropriate ethical decisions based on the unique cultural values, beliefs, and practices of each group.

Diversity awareness can be viewed in three parts: how people are different, recognizing the unique needs of others, and sensitivity (recognizing personal biases) so that they do not interfere with giving professional and safe nursing care.

Spiritual Assessment

When you are completing a total client assessment, it is important to include a spiritual assessment. This need not be invasive or intrusive. The purpose of such an assessment is to open the channels of communication so that the client will feel comfortable in discussing spiritual issues. If the client experiences no opening from the nurse, he or she may conclude that the nurse does not wish to discuss spirituality; therefore, just asking a few pertinent questions during a general assessment may accomplish the goal of opening communication.

RELATIONSHIP THERAPY

Nurses are given the unique opportunity to share part of who they are with others who have asked directly or indirectly for assistance. It is within this interpersonal framework that the nurse–client relationship begins to develop and take on its individual characteristics.

Both individuals bring into the relationship their thoughts, feelings, sense of self or self-worth, behavior patterns, abilities to adapt and cope, belief systems, and points of view about life and how they interact with it. Within all these complex variables, there is a commonly shared point at which the nurse–client relationship begins.

This relationship may be defined as the interaction between the nurse and a client with shared therapeutic goals and objectives. Characteristics of the relationship include acceptance, honesty, understanding, and empathy of the nurse

▲ Relationship therapy includes bringing the family together to discuss client care needs.

toward the client who is willingly or unwillingly seeking help. Generally, it is important for the nurse to view the client as a unique individual who is responsible for his or her own feelings, actions, and behaviors and who is an active participant in a healthcare program. The relationship is more effective if the client shows a willingness to accept responsibility and actively participates in the therapeutic relationship. This is not always possible, and the nurse must begin the relationship by accepting the level at which the client is able to participate. This, at times, is a difficult and frustrating process. The goal of relationship therapy is to assist the client to identify and meet his or her own needs. The nurse may assist the client in reaching the goals by demonstrating acceptance so that the client may experience the feeling of being accepted as an individual; by developing mutual trust through consistent, congruent nursing behaviors; by providing corrective emotional experiences to increase self-esteem; and finally by creating a safe, supportive environment. Some degree of emotional involvement and honest, open communication is essential throughout the relationship. The nurse must encourage the client to express his or her feelings, concerns, expectations, fears, and the like within safe limits.

Relationship Principles

Principles underlying a helping relationship include:

- Awareness of the total client, including emotional, physical, cultural, and spiritual needs.
- Some degree of emotional involvement while maintaining objectivity.
- The setting of appropriate limits and consistency in behavior while caring for the client.
- Open, honest, clear communication.
- Encouragement of the expression of feelings.
- Focus on “here and now.”

Dangers to the relationship include overemotional involvement and judgmental attitudes on the part of the nurse and the staff.

Phases in Nurse–Client Relationship Therapy

There are three phases in a traditional nurse–client relationship.

Initiation, or Orientation, Phase In the initial interaction with the client, you introduce yourself and establish the boundaries of the relationship. It is also the phase in which you identify problems, expectations, and relevant issues (cultural and spiritual) that need to be addressed during the relationship. It is at this stage in the relationship that you would identify any impairments, such as hearing, speaking, developmental, or psychological, that must be taken into account so that adjustments in the relationship may be made.

Continuation, or Active Working, Phase This is the phase in which you would develop a working relationship, and in conjunction with meeting the client’s needs, begin resolving the client’s problems: for example, working with the client to handle his pain; teaching the client to care for a new device, such as a colostomy; or implementing a plan to increase the client’s independent functioning.

Termination Phase At this final phase, when the client is soon to be discharged; you would follow the plan that you began when the client was admitted: for example, anticipate problems the client will face when he goes home; complete discharge planning and teaching; deal with client’s fears about being on his own after leaving the hospital.

CULTURAL AWARENESS

One way to become culturally competent is to learn the language that a majority of your clients speak—this will give you insight into the culture and help you recognize individual cultural impediments to the client’s receiving health care.

Source: Gaskill, M. (2002, May 6). Just say the words. *NurseWeek*: Santa Clara, CA.

Reference for Hispanics Because Hispanics are now the largest minority group in the United States, nurses should be aware of references that help to facilitate communication with this group. One such reference is *Procedures of Critical Care* by Judith Ann Lewis, Spanish edition. Physical examination is one topic covered in this text. Using this book will assist the nurse to help the client understand the procedures and treatments he or she receives while hospitalized.

Source: Kleinpell, R. M., Vazquez, M. G., Gailani, K. (2000, April). Translating Spanish: A brief guide for intensive care and acute care nurses. *Critical Care Nurse*, 20(2), 100–104.

TABLE 4-1 Religious Diversity Considerations for Client Care

Religious Orientation	Baptism	Death Rituals	Health Crisis	Diet
Adventist	Opposed to infant baptism	No last rites	Communion or baptism may be desirable	No alcohol, coffee, tea, or any narcotic
Baptist	Opposed to infant baptism	Clergy supports and counsels	Some believe in healing and laying on of hands. Some sects resist medical help	Condemn alcohol. Some do not allow coffee and tea
Islam	No baptism	Prescribed procedures by family for washing body and shrouding after death	No faith healing Ritual washing after prayers every day	Prohibit alcohol and pork
Buddhist	Rites are given after child is mature	Send for Buddhist priest Last rite chanting	Family should request priest to be notified	Alcohol and drugs discouraged; some are vegetarian
Christian Scientist	No baptism	No last rites No autopsy	Deny the existence of health crises Many refuse all medical help, blood transfusions, or drugs	Alcohol, coffee, and tobacco viewed as drugs and not allowed
Episcopalian	Infant baptism mandatory	Last rites not essential for all members	Medical treatment acceptable	Some do not eat meat on Fridays
Jehovah's Witness	No infant baptism	No last rites	Opposed to blood transfusions	Do not eat anything to which blood has been added
Judaism	No baptism but ritual circumcision on eighth day after birth	Ritual washing of body of death	All ill people seek medical care Treatment supersedes dietary restrictions	Orthodox observe kosher dietary laws, which prohibit pork, shellfish, and the eating of meat and milk products at the same time
Methodist	Baptism encouraged	No last rites	Medical treatment acceptable	No restrictions
Mormon	Baptism eight years or older	Baptism for the dead can be done by proxy	Do not prohibit medical treatment, although they believe in divine healing	Do not allow alcohol, caffeine, tobacco, tea, and coffee
Roman Catholic	Infant baptism mandatory	Last rites required	Sacrament of the sick	Most ill people are exempt from fasting

Note: There may exist circumstances that require a court order to supervise religious practices (e.g., a blood transfusion to save the life of a child).

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to include in a client care plan when the components are related to establishing and maintaining a nurse–client relationship.

NURSING DIAGNOSIS	RELATED FACTORS
Impaired Communication Verbal	Psychologic barrier, inability to speak dominant language, impaired cognitive function, lack of privacy
Powerlessness	Perceived lack of control resulting in dissatisfaction
Impaired Social Interaction	Lack of motivation, anxiety, depression, lack of self-esteem, disorganized thinking, delusions, hallucinations
Social Isolation	Hospitalization, terminal illness
Disturbed Thought Processes	Depression, anxiety, fear of unknown, emotional trauma, unclear communication, negative response from others

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. Remember to wash your hands or use antibacterial gel before and after each and every client contact.

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to TJC standards.

Therapeutic Communication

Nursing Process Data

ASSESSMENT Data Base

- Determine client's ability to process information at the cognitive level.
- Assess mental status data to establish baseline for intervention.
- Assess client's ability to communicate on a verbal level.
- Observe what is happening with the client here and now.
- Identify client's developmental level so interaction expectations will be realistic.
- Assess client's anxiety level because anxiety interferes with communication.
- Assess client's cultural background.
- Teaching Clients to Communicate With Their Physicians
- Assessing Cultural Preferences
- Assessing Spiritual Issues
- Assisting a Client to Describe Personal Experiences
- Encouraging a Client to Express Needs, Feelings, and Thoughts
- Using Communication to Increase a Client's Sense of Self-Worth

PLANNING Objectives

- To assist client to meet his or her own needs
- To assist client to experience the feeling of being accepted
- To increase client's self-esteem
- To provide a supportive environment for change
- To institute therapeutic rather than casual or non-goal-oriented communication
- To affect or influence the client's physical, emotional, and social environment
- To be sensitive to client's cultural orientation

IMPLEMENTATION Procedures

- Introducing Yourself to a Client72
- Beginning a Client Interaction72
- Teaching Clients to Communicate With Their Physicians72
- Assessing Cultural Preferences73
- Assessing Spiritual Issues73
- Assisting a Client to Describe Personal Experiences73
- Encouraging a Client to Express Needs, Feelings, and Thoughts74
- Using Communication to Increase a Client's Sense of Self-Worth74

EVALUATION Expected Outcomes

- Client develops the ability to assess and meet his or her own needs.
- Communication becomes clearer, more explicit, and centered on problem areas.
- A supportive environment is created so that the client can reduce the level of anxiety and experience change.
- Cultural diversity is accepted by the healthcare team.
- Cultural preferences and spiritual issues are addressed.
- Clients are able to communicate effectively with their physicians.

- **Critical Thinking Application**75
 - Expected Outcomes75
 - Unexpected Outcomes75
 - Alternative Actions75

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Introducing Yourself to a Client

Procedure

1. Obtain client assignment.
2. Read chart and review physician's orders.
3. Check client care plan.
4. Clarify any questions about client assignment.
5. Proceed to client's room and check client ID.
6. Introduce yourself to the client. (Example: "Good morning, Mr. Jones. My name is Miss Barnes. I am a student nurse from the Bellington School of Nursing, and I will be caring for you today.")
7. If the client is blind, introduce yourself as you come into the room: Tell exactly what you are doing and when you are leaving. ► **Rationale:** Blind clients become anxious when they hear someone enter the room who does not speak.
8. Begin to establish a nurse–client relationship using clear, open communication.

Beginning a Client Interaction

Procedure

1. Following introduction (at which time you call the client by name and tell the client your name), relate purpose of interaction.
2. Tell client specifically what you will be doing in terms of his or her care.
3. Ask if the client understands or has any questions.
4. Encourage client to describe how he or she is feeling at the time (especially focusing on the pain level).
5. Encourage client to participate in his or her care—both verbally and nonverbally.
6. Pay attention to communication as well as the procedure you are administering. ► **Rationale:** Often, your best data base is drawn from observation.
7. Assess nonverbal behavior and determine if it fits (is congruent) with verbal communication, especially when you are evaluating pain level.
8. Complete communication by asking client for feedback.
9. Complete interaction by telling client when you will return.
10. Follow through on agreed-upon meeting time to build client trust.

▲ When interacting with a client, the nurse includes friends as an important element in client's support system.

Teaching Clients to Communicate With Their Physicians

Procedure

1. Practice with client how to formulate and verbalize direct (vs. indirect) questions.
2. Role-play with client how to extract the specific information they wish to receive from the physician. ► **Rationale:** Receiving the information will increase client satisfaction and lower anxiety.
3. Verify directly (clarify) the information the client receives from the physician. ► **Rationale:** This will decrease client's anger and anxiety.
4. Assist client to ask about functional status of the disease and symptoms. ► **Rationale:** Increases client's sense of control over their condition.
5. Assist client to ask the physician purpose and expected outcomes of treatments. ► **Rationale:** Increases adherence and compliance to treatment.

Beginning in 2006, The Joint Commission requires hospitals to document client's language and communication needs in the medical record. The Joint Commission is implementing this because research shows that differences in language and culture can have a major impact on quality and safety in client care.

EVIDENCE-BASED PRACTICE

Teaching Clients to Communicate With Physicians

This study reviewed communication training interventions for 1,665 clients to determine the effectiveness of teaching clients how to communicate with doctors. The results indicated that clients who received this training asked more questions, had a

significant increase in direct (vs. indirect) questions to the physician, and received more information. The author's conclusions were that training clients to communicate with their doctors showed improvements in a variety of outcomes.

Source: Cegala, D. J., Miser, W. F. (2002). The other half of the whole: Teaching patients to communicate with physicians. *Family Medicine*, 34(15), 344–352.

Assessing Cultural Preferences

Procedure

1. Review client history related to cultural orientation to determine if adequate information pertaining to cultural preferences is included. ► **Rationale:** A complete history will detail cultural diversity patterns.
 - a. Ethnic heritage and language.
 - b. Family organization and role of members.
 - c. Dietary practices and knowledge about nutrition.
 - d. Education, formal and informal.
 - e. Healthcare practices and beliefs.
2. Introduce self to client and identify client.
3. Determine client's perception of illness based on cultural beliefs.
4. Validate verbal and nonverbal communication from client based on cultural understanding. ► **Rationale:** When the client's cultural background is different from the nurse's, communication problems may result.
5. Consider using an interpreter if communication seems unclear. ► **Rationale:** An interpreter will facilitate communication and reduce stress on the client.
6. Examine expectations of health care based on the client's cultural influences. ► **Rationale:** Health care should be congruent with the client's expectations or a positive outcome of treatment may be in jeopardy.

Assessing Spiritual Issues

Procedure

1. Ask the client relevant questions concerning spiritual issues. ► **Rationale:** If the nurse never opens this subject, the client will not feel free to discuss spiritual issues.
 - a. Do you have a spiritual component in your life?
 - b. If so, how will this help you during your illness?
 - c. Is there any particular person or spiritual advisor that you would like me to contact for you?
 - d. Is there anything that I (as your nurse) can do to support your spiritual beliefs?
2. "Are there any spiritual issues that you would like to discuss? If so, let's arrange a time to talk about these issues." ► **Rationale:** This approach will open communication and notify the client that you are willing to discuss these issues.

Communicating With the Hearing Impaired

If your client is hearing impaired, it is very important to establish a method of communication (pen and pencil, sign language, speaking loudly and clearly). Other factors to take into consideration when communicating with the hearing impaired are to pay attention to the client's nonverbal cues, decrease background noise such as television, and always face the client when speaking. It is also important to check with the family regarding how they communicate with the client. Finally, it may be necessary to contact the appropriate department resource person for this type of disability.

Assisting a Client to Describe Personal Experiences

Procedure

1. Encourage client to describe his or her perceptions and feelings.
2. Focus on communication as well as body reactions.
3. Don't dominate the conversation. ► **Rationale:** The less you say, the more you encourage spontaneity and verbalization from the client.
4. Assist client to clarify feelings.
5. Maintain an accepting, nonjudgmental attitude. ► **Rationale:** Making value judgments, even nonverbal ones, negatively affects the nurse–client relationship.
6. Give broad opening statements, and ask open-ended questions. ► **Rationale:** This open approach enables the client to describe what is happening.

Encouraging a Client to Express Needs, Feelings, and Thoughts

Procedure

1. Focus on feelings rather than superficial topics during interactions.
2. Assist client to identify thoughts and feelings.
3. Pick up on verbal cues, leads, and signals from the client.
4. Convey attitude of acceptance and empathy toward the client. ▶ **Rationale:** Being aware of your own feelings and attitudes and separating them from the client's contributes to acceptance.
5. Note what is said as well as what is not said.
6. Assist the client to become aware of differences between behavior, feelings, and thoughts.
7. Give honest, nonjudgmental feedback to the client.

Using Communication to Increase a Client's Sense of Self-Worth

Procedure

1. Use body language as well as verbal communication to convey empathy. ▶ **Rationale:** Sitting down at the client's bedside or not acting as if you are in a hurry encourages communication.
2. Respect the client's need for emotional privacy, but be available to the client.
3. Encourage the client to apply the problem-solving approach to different situations.
4. Be nonjudgmental (see example of making judgmental responses).
5. Mutually identify goals to meet the client's individual needs.
6. Keep all agreements with the client.
7. Become the client's advocate.
8. Give the client positive feedback when appropriate.

DOCUMENTATION for Therapeutic Communication

- Identification of client needs
- Explicit goals of interaction
- Communication patterns of client
- Emotional state of client
- Expressed feelings and thoughts if relevant
- Cultural issues if relevant
- Spiritual issues if relevant

TABLE 4-2 Communication Deficits and Interventions

Deficit	Intervention
Language/Culture	Determine client's level of fluency in English and understanding Use an interpreter or translator Pay attention to nonverbal communication Learn client's cultural values Be aware of client's cultural preferences that may affect etiquette (personal space, use of touch, eye contact) Avoid jargon or slang—select words you use carefully
Sensory—Hearing, Seeing	Speak slowly, clearly, and directly to the client; do not use a loud voice Use gestures to clarify or drawings to illustrate Describe carefully the care you are giving to the client Provide alternate means of communication: writing pad, gestures, etc. Work out a code with client for answers to basic questions; for example, "Are you in pain? For yes, blink once."

TABLE 4-2 Communication Deficits and Interventions (Continued)

Deficit	Intervention
Cognitive	<p>Orient to reality frequently (day, year, etc.)</p> <p>Use the same staff as much as possible</p> <p>Introduce self repeatedly, explain simply aspects of care</p> <p>Speak in clear, simple sentences</p>
Verbal Communication	<p>Speak directly to clients and treat them with dignity and respect even if they are nonverbal</p> <p>Ask specific questions that require a yes or no, not an open-ended question</p> <p>Recognize a client's facial expressions as well as their gestures</p> <p>If a client's behavior changes drastically, look for an acute illness, such as an infection</p> <p>Try flash cards or a chalkboard for a response</p> <p>Use nonverbal techniques yourself, such as touch</p> <p>Include client in the conversation even though there is no response</p>

Legal Considerations

A neonate receiving an IV in his right foot showed discoloration and edema at the injection site. The infiltration was noted on a transfer sheet as the baby was being transferred to another unit. It was not noted in the medical record. When the parents questioned the injury, they

were told that it was just a "blister." In time, the infiltration led to scarring and loss of motion. The nurse who originally noted the infiltration was sued.

This is an example of poor or inadequate communication when "handing-off" a client.

CRITICAL THINKING Application

Expected Outcomes

- Client develops the ability to assess and meet his or her own needs.
- Communication becomes clearer, more explicit, and centered on problem areas.
- A supportive environment is created so that the client can reduce the level of anxiety and experience change.
- Cultural diversity is accepted by the healthcare team.
- Cultural preferences and spiritual issues are addressed.
- Clients are able to communicate effectively with their physicians.

Unexpected Outcomes

Therapeutic communication is not achieved.

Client's demanding behavior interferes with the therapeutic communication process.

Cultural preferences/issues were not recognized, so communication was hindered.

Spiritual issues were not discussed until the client asked for a priest or minister.

Client remains uncomfortable in talking to physician.

Alternative Actions

- Eliminate blocks to communication from interaction style. If a block does occur, recognize it. Move to correct communication by using therapeutic modes of communication.
- Evaluate your own process of communication during and after interaction.
- If client needs to verbalize and you cannot help him or her do so, contact another nurse or the social worker.
- Do not ignore demands; they will only increase in intensity.
- Attempt to determine causal factors of behavior, such as high anxiety level.
- Set limits to response patterns when client is demanding. Control own feelings of anger and irritation.
- Teach alternative means to getting needs met.
- Complete a cultural assessment before revising a plan of care.
- Bring in a translator to converse with the client to establish baseline communication.
- Evaluate values, beliefs, preferences, and expectations related to health care.
- At this time, assess the client's spiritual beliefs and ask if there is any way you can assist him/her in this area.
- Continue to work with client by role-playing with nurse taking role of physician.
- Be present when client is questioning physician and give support.

Chapter 4

UNIT 2

Nurse–Client Relationship

Nursing Process Data

ASSESSMENT Data Base

- Determine the purpose of establishing a nurse–client relationship.
- Consider the overall condition of client to determine if he or she can benefit from a nurse–client relationship.
 - A specific relationship could feed into secondary gains of attention.
 - An individual with chronic organic brain disorder cannot benefit from a relationship per se.
- Identify client expectations of a therapeutic relationship to determine if you can meet these needs.
- Examine your own feelings and expectations to evaluate potential effect on such a relationship.

PLANNING Objectives

- To provide an environment in which client can feel secure enough to alter behavior patterns
- To allow a client to experience a positive, satisfying relationship
- To enable client to test more adaptive ways to handle anxiety
- To provide a climate conducive to raising the client’s self-esteem
- To allocate enough time to complete planned process of interaction
- To terminate relationship successfully

IMPLEMENTATION Procedures

- Initiating a Nurse–Client Relationship 77
- Facilitating a Nurse–Client Relationship 77
- Terminating a Nurse–Client Relationship 78

EVALUATION Expected Outcomes

- Principles of therapeutic communication are used.
- Boundaries of professional relationship are maintained.
- The appropriate environment for interaction is established.
- Termination of the relationship is completed successfully.

Critical Thinking Application 78

- Expected Outcomes 78
- Unexpected Outcomes 78
- Alternative Actions 78

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Initiating a Nurse–Client Relationship

Procedure

1. Read client's chart and be familiar with history, medications, etc.
2. Identify client with at least one form of client ID.
3. Perform hand hygiene.
4. Approach client and introduce self.
5. Assess client's symptoms and problems, and communicate a willingness to help alleviate these discomforts.
6. Establish a beginning relationship. ► **Rationale:** Open, honest, congruent communication and consistent behavior help lay the groundwork for trust in a relationship.
7. Establish mutual goals as a basis for the relationship. ► **Rationale:** Goals mutually set and agreed on are more easily accepted by both parties in the relationship.
8. Be consistent in your behavior; do what you say you will do, and only make promises you are willing to keep. ► **Rationale:** The most important element is the beginning of trust. Without trust the nurse–client relationship is ineffective.
9. Encourage client's participation in his or her care. ► **Rationale:** This focus enhances compliance to treatment.
10. Approach client in a warm, accepting manner during interactions. ► **Rationale:** The client may interpret a cool, aloof manner as lack of interest.

▲ Initiating a relationship is an important component of client care.

Facilitating a Nurse–Client Relationship

Procedure

1. Assume the role of facilitator in the relationship.
2. Accept client as having value and worth as an individual. ► **Rationale:** Basic acceptance is a fundamental prerequisite of a relationship.
3. Provide a safe environment conducive to client's willingness to share.
4. Maintain the relationship on a professional level. ► **Rationale:** Responding on a professional rather than a social level defines the relationship.
5. Keep interaction reality-oriented, that is, in the here and now. ► **Rationale:** Discussion of past or future experiences does not contribute to a change in behavior now.
6. Listen actively; that is, respond to the client's cues.
7. Use nonverbal communication to support and encourage client.
 - a. Recognize meaning and purpose of nonverbal communication, especially in assessing pain.
 - b. Keep verbal and nonverbal communication congruent.
8. Focus content and direction of conversation on client's cues, not on social or superficial topics.
9. Interact on client's intellectual, developmental, and emotional level.
10. Focus on "how," "what," "when," "where," and "who" rather than "why." ► **Rationale:** Asking "why" places the client on the defensive because it requires justification of behavior.

▲ Communication to and from the client can be verbal as well as written.

11. Teach client problem solving to correct maladaptive patterns.
12. Assist client to identify, express, and cope with feelings.
13. Help client develop alternative coping mechanisms that are more adaptive.
14. Recognize a high level of anxiety, and assist client to deal with it.

Terminating a Nurse–Client Relationship

Procedure

1. Work closely with the client in discharge planning and in planning the termination of the relationship from its beginning. ► **Rationale:** This approach promotes the client's independence and increases his or her sense of self-esteem.
2. Anticipate problems of termination and plan for their resolution. • **Rationale:** Saying goodbye is often uncomfortable and difficult for both the client and the nurse.
3. Be aware that the client's behavior may reflect fear that he or she can't cope at home, overdependence, depression, and withdrawal. ► **Rationale:** Allowing this behavior to be expressed helps the client to work it through.
4. Do not terminate the relationship too abruptly or allow it to persist beyond the client's needs.
5. Complete a satisfactory termination of the relationship. ► **Rationale:** This enables the client to move on.

DOCUMENTATION for Nurse–Client Relationship

- Primary goals of nurse–client relationship and identified client needs
- Ongoing process of relationship therapy, including client's expressed feelings, thoughts, and so forth
- Client's behavior and changes in behavior, both positive and negative
- Cues to other team members on how best to relate to this particular client
- Elements of discharge planning

CRITICAL THINKING Application

Expected Outcomes

- Principles of therapeutic communication are used.
- Boundaries of professional relationship are maintained.
- The appropriate environment for interaction is established.
- Termination of the relationship is completed successfully.

Unexpected Outcomes

Client refuses to participate in a nurse–client relationship.

Alternative Actions

- Comply with client's request, and do not force or impose relationship therapy.
- Continue to offer relationship therapy at intervals.
- Suggest that another team member attempt to establish a relationship.

Nurse–client relationship frequently degenerates into a social conversation.

- Reevaluate the goals for the relationship, and remind client of terms originally established.
- Set firm limits, and continually reexamine progress.

Termination of the nurse–client relationship is not successful.

- Reexamine the process of termination (termination should begin at the beginning of the relationship).
- Devote more interaction time to this aspect of the relationship.
- Attempt to elicit feelings about termination from the client as well as examining your own feelings.

Nurse–client relationship cannot be established due to cultural differences.

- Allow the client's behavior to be expressed without making value judgments, and assist the client to discuss his or her feelings.
- The nurse may make a special effort to understand the cultural preferences of the client.
- Consider finding another nurse to establish the relationship—one with a similar background.

Nursing Process Data

ASSESSMENT Data Base

- Observe for behaviors that do not fit expected reactions to illness or hospitalization.

Depression: *verbal cues* (expressing feelings of sadness, hopelessness, helplessness); *physical cues* (loss of motivation, vegetative, frequent crying episodes, bodily complaints, psychomotor retardation, weight loss); *emotional cues* (low self-esteem, preoccupation with inner thoughts, thoughts of suicide).

Anxiety: *psychological symptoms* (confusion, dread, agitation, difficulty making decisions, rumination); *physical symptoms* (tremors, dyspnea, palpitations, tachycardia, sweating, sleep disturbance); stages of anxiety (mild, moderate to severe).

Aggression/anger: *verbal expressions* (voicing anger in loud voice, yelling, cursing); *physically acting out* (clenching fists, throwing objects, refusing treatments, threatening actions).

Denial: *Verbal expressions* (expressing denial of the client's condition or diagnosis).

PLANNING Objectives

- To recognize client's behavior that fits special situations of depression, anxiety, anger, or denial
- To intervene therapeutically when special circumstances exist
- To provide a supportive climate for the client to work through feelings of depression, anxiety, or anger
- To assist client to develop more adaptive ways of handling feelings

Communication in Special Situations: Depression, Anxiety, Anger, and Denial

IMPLEMENTATION Procures

- Communicating With a Depressed Client80
- Communicating With an Anxious Client80
- Communicating With an Aggressive or Angry Client . . .80
- Communicating With a Client in Denial81

EVALUATION Expected Outcomes

- Client's unhealthy responses were recognized and identified, and planned interventions were made.
- Verbal, physical, and emotional cues indicating depression, anxiety, anger, or denial decreased.
- Nurse's therapeutic interventions resulted in more adaptive behaviors. Clients developed new coping mechanisms to handle feelings.

Critical Thinking Application82

- Expected Outcomes82
- Unexpected Outcome82
- Alternative Actions82

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Communicating With a Depressed Client

Procedure

1. Identify cues that client is depressed (see assessment cues).
2. Establish a nurse–client relationship. ► **Rationale:** A relationship provides the framework for therapeutic intervention.
3. Ask if client is feeling “down,” sad, or upset. ► **Rationale:** The answer will validate nurse’s perceptions or behavioral cues.
4. Remain with client, but it is not useful to encourage client to talk at length about feeling depressed; he/she will become even more depressed as conversation progresses. ► **Rationale:** Depression is best handled by mobilizing client, not talking.
5. Respond to client by suggesting activity, exercise, involvement with another client. ► **Rationale:** Activity lifts mood and focus outside client’s feelings and decreases depression.
6. Give client positive feedback for decisions, actions, and independent behavior. ► **Rationale:** Depressed clients have difficulty in making decisions.
7. Convey to client you care by spending time talking or participating in activities. ► **Rationale:** Knowing someone cares helps to lift depression.
8. Focus away from somatic complaints. ► **Rationale:** Depressed people often focus on somatic problems, but discussing them only increases depression.
9. Assess if client is considering suicide and intervene appropriately.

Communicating With an Anxious Client

Procedure

1. Identify cues that client is anxious (see assessment) and degree of anxiety manifested.
2. Establish nurse–client relationship. ► **Rationale:** Anxious clients may have difficulty relating to others.
3. Identify anxiety in self and maintain a calm, quiet approach. ► **Rationale:** Anxiety in the nurse will be transmitted to the client.
4. Assist client to identify anxiety and describe feelings and reactions. ► **Rationale:** Identifying presence and/or source will help to relieve anxiety.
5. Provide physical outlet for anxiety if possible (i.e., pacing).
6. Remain with anxious client, answering questions, supporting, etc. ► **Rationale:** This will help to prevent anxiety escalating, especially if client is in critical condition.
7. Provide structured, nonstimulating environment. Give clear, firm directions and information.

Communicating With an Aggressive or Angry Client

Procedure

1. Observe client for cues of anger or aggression getting out of control (see assessment).
2. Intervene immediately when loss of control is imminent.
3. Use a nonthreatening approach to client. ► **Rationale:** This approach will help to defuse situation.
4. Set firm limits and give specific expectations concerning behavior.
5. Avoid engaging in arguments or provoking client.
6. Calm client so that he/she may regain control.
7. Use problem-solving focus. ► **Rationale:** Discussion of feelings, examining causal factors and client’s response will help to defuse situation.
8. Responses to verbally abusive behavior: do not respond in kind; do not take abuse personally; do not reject client; help client calm down by remaining calm, give feedback concerning your response to comments, and teach alternative ways for client to express feelings.

Communicating With a Client in Denial

Procedure

1. Establish a relationship with the client while determining that the client is using the coping mechanism of denial—that is, denying the diagnosis or condition.
2. Do NOT confront client that he/she is in denial. ► **Rationale:** This is a protective defense mechanism the client needs at this time.

3. Be aware that denial may be a phase the client will pass through and eventually be able to cope with reality of the condition.
4. Discuss client's condition honestly and the options for treatment. ► **Rationale:** This focus may enable client to move more rapidly through the denial phase.
5. Offer to spend time with the client and respond to cues that he/she is ready to discuss feelings, but do not force client to confront issues before he/she is ready.

Denial is a defense mechanism whereby the ego protects itself from pain or conflict by denying reality. Elisabeth Kübler-Ross first identified denial as the first stage of the dying process, when the client is stunned at the knowledge, and handles it by denying the reality.

DOCUMENTATION for Communication in Special Situations

- Description of specific cues of client's behavior evidencing depression, anxiety, or anger
- Interventions completed and client's response
- Instructions for other team members on how best to relate to client

CRITICAL THINKING Application

Expected Outcomes

- Client's unhealthy responses were recognized and identified, and planned interventions were made.
- Verbal, physical, and emotional cues indicating depression, anxiety, or anger decreased.
- Nurse's therapeutic interventions resulted in more adaptive behavior.
- Client developed new coping mechanisms to handle feelings.

Unexpected Outcomes

Client remains depressed, anxious or angry; interventions do not bring about change in behavior.

Client has thoughts of suicide and is identified as a suicide risk.

Client remains angry and abusive to staff and others.

Alternative Actions

- Transfer to another nurse to work with client or request mental health consultant.
- Place client on suicide precautions.
- Try to change source of anger or aggressive behavior by identifying source, changing staff, relocating client to another room or private room.

GERONTOLOGIC Considerations

Physical Changes That Affect Communication

- Hearing changes (e.g., presbycusis, tympanic membrane atrophy, and distorted sounds) may make communication difficult. The nurse must speak clearly, loudly, and in view of the client. Use simple sentences and request feedback to validate understanding.
- Visual changes, such as presbyopia, and pupil, cornea, and lens impairment may diminish visualization. The nurse should be aware of eye changes and check that client sees clearly enough to perform required activities.

Psychosocial Changes That Affect Communication

- Relationships change with age. There is a loss of nurturing functions within the family. The nurse may need to perform this function with the elderly.
- Role changes within and outside the family occur—loss of spouse and loss of support systems. Elderly may require more support from caregivers.
- Elderly have fears of physical dependency, chronic illness, and loneliness. Caregiver may need to address these fears and work with client through communication and relationship to reduce them.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state’s regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- Evaluation of cultural diversity and spiritual issues should be completed by either the RN or LVN, not by a nursing assistant (NA).
- A full history should be completed by the RN or LVN.
- Care plan objectives relating to communication, spiritual issues, and cultural differences should be completed by the RN or checked by the RN if completed by the LVN.

Communication Matrix

- All staff caring for the client from a different cultural heritage should be informed of special needs of the client based on cultural diversity theory.
- The unit manager should include special needs of the client based on communication patterns and cultural background when making staff assignments. (For example, is there a nurse from the same cultural background or who speaks the same language as the client who can be assigned to that client’s care?)
- Assign a nurse who is comfortable dealing with spiritual issues if the initial assessment indicates the client wishes to discuss these issues.

CRITICAL THINKING Strategies

Scenario 1

A 25-year-old male comes to the emergency department. He has a bleeding wound on his arm, and he refuses surgical intervention when told he must remove his clothes and jewelry.

1. What effect would this client response have on the initial nursing plan of care?
2. What is your understanding of this client response? What are some questions you might ask the client?
3. Describe the strategies and goals you would devise to solve this problem.
4. Describe the measures you would implement to resolve this situation.

Scenario 2

A client has just been admitted with a diagnosis of rectal cancer. He is scheduled for surgery the next day. When you are completing an assessment and you ask about spiritual beliefs, the client says, “I’m a washed-out Catholic and I don’t think I’m going to live, so what’s the sense in talking about it?”

1. What would be the consequence of not responding to the client’s comments about spiritual beliefs?
2. How would the goals of establishing a nurse–client relationship and assessing spiritual beliefs overlap in this situation?
3. Describe the actions you would take to engage this client in a discussion about these issues.

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. Which intervention is most useful when communicating with an aphasic client?
 1. Use correct medical terminology when teaching or explaining.
 2. Ask open-ended questions to obtain information.
 3. Repeat the same word until the client understands.
 4. Provide frequent praise and encouragement.
2. A psychiatric client rapidly improves and is scheduled to be discharged tomorrow.

Which of the following responses demonstrates that the nurse has a good understanding of termination of a relationship?

1. “You have worked really hard the last three weeks. Good-bye and good luck.”
2. “Stop by and let us know how things are going.”
3. “You’ve done some good work here. I hope you are able follow through with it.”
4. “Good bye and good luck. Hopefully, we won’t be seeing you here again.”

3. One characteristic of a nurse–client relationship is that it is a professional one. This implies that the nurse
 1. Should be primarily concerned with implementing the policies of the hospital.
 2. Views the client’s needs as her/his primary concern.
 3. Maintains a distance between self and client.
 4. Establishes boundaries, formulates goals, and maintains the boundaries of a professional relationship.
 4. One day a client with terminal cancer says to the nurse, “Well, I’ve given up all hope. I know I’m going to die soon.” The most therapeutic response is to say
 1. “Now, one should never give up hope. We are finding new cures all the time.”
 2. “We should talk about dying.”
 3. “You’ve given up all hope?”
 4. “Your doctor will be here soon. Why don’t you talk to him about your feelings?”
 5. Which of the following statements would be best to stimulate conversation with a client about his or her social history?
 1. “Are you married?”
 2. “Do you have any children?”
 3. “Tell me about your family.”
 4. “Is your role in the family important?”
 6. A client is admitted to CCU with a diagnosis of anterior myocardial infarction. Shortly after admission, he states: “I might as well have died because now I won’t be able to do anything.” The most appropriate response by the nurse is
 1. “Don’t worry, everything will turn out all right.”
 2. “What do you mean, not able to do anything?”
 3. “Take one day at a time and it will all work out.”
 4. “You shouldn’t be thinking like this because you are doing well now.”
 7. A male client is becoming increasingly angry and verbally abusive. The appropriate intervention is to
 1. Send the client back to his room.
 2. Ask the physician for an order for restraints.
 3. Summon assistance from a male staff member.
 4. Set firm limits on the abusive behavior.
 8. Which of the following components would you include in a cultural assessment?

Select all that apply.

 1. Cultural background.
 2. Nutritional practices.
 3. Beliefs and perceptions of health.
 4. Age of the client.
 5. Belief in God.
 6. Communication patterns.
 7. Health practices including alternative.
 9. A client you are assigned to care for has impaired hearing. The most effective way to communicate with this client is to
 1. Use a writing pad and gestures.
 2. Speak clearly and slowly.
 3. Use nonverbal communication.
 4. Describe loudly and carefully what you are doing.
 10. The highest priority in a nursing intervention when caring for a client who is depressed is to
 1. Form a good nurse–client relationship.
 2. Encourage the client to talk about his feelings of depression.
 3. Suggest that the client do an activity.
 4. Assess the client frequently for potential suicide.
-

5

Admission, Transfer, and Discharge

LEARNING OBJECTIVES

1. Explain the steps of admitting a client to the hospital.
2. List client data that are included in documentation when admitting a client to the hospital, including the plan of care, goals, and outcome criteria.
3. Describe the disposition process for safeguarding client's valuables.
4. State what is meant by advance directives.
5. List documents that may be included in the client's admission record (Patient's Bill of Rights, Advance Directives, DNAR, etc.).
6. Propose two solutions for clients who are unable to adapt to the hospital environment.
7. Identify essential "hand-off" information to be communicated when client care is transferred to another caregiver, setting, or home.
8. Describe the process and rationale for medication reconciliation across the continuum of care.
9. Outline steps for transferring a client to another unit within the hospital or to the home.
10. Discuss discharge procedures when a client leaves the hospital.
11. Describe expected outcomes for clients being discharged from the hospital, including meeting criteria in the initial plan of care.
12. Complete discharge documentation including client's achievement of criteria established in the initial plan of care.
13. Describe three solutions for clients leaving the hospital against medical advice.
14. Outline discharge procedures that must be completed when a client leaves the hospital against medical advice.

TERMINOLOGY

Adaptation ability to adjust to a change in environment.

Admit the process of signing a client into the hospital.

Ambulatory able to walk, or not confined to bed.

Assessment critical evaluation of information; the first step in the nursing process.

Behavior a person's total activity—actions or reactions, especially conduct that can be observed.

Caring thoughtful attentiveness accompanied by responsibility.

Client Care Plan a plan for care of a specific client or one designed especially for one client.

Comfort to ease physically; relieve, as of pain.

Communication transmission of knowledge, information, or messages to another person.

Diagnostic test a test used to determine a diagnosis or to determine the cause and nature of a pathological condition.

Disability a disabled state or condition; incapacity.

Discharge to let go, as in discharging a client from the hospital.

DMEe durable medical equipment.

DRG diagnosis-related group. A system to classify all types of clients to determine how much Medicare pays the hospital, since clients within each category are similar clinically and are expected to use the same level of hospital resources.

Empathy the vicarious experience of another's situation.

Home care assistance nursing care given in the client's home.

Ident-A-Band a band, usually worn on a client's wrist, with the client's name and medical record number.

Limitation the state of being limited or restricted.

Maladaptation inability to adjust to a change in environment.

Potential possible but not yet realized.

Procedure a particular way of accomplishing a desired result.

Reconcile to resolve discrepancies.

Stress a state of agitation that renders the body out of balance.

Supervise to direct or inspect performance; to oversee.

Termination the spatial or temporal end of something; a limit or boundary.

Therapeutic having healing or curative powers.

Transfer to convey or shift from one person or place to another.

Transition the process or an instance of changing from one form, state, activity, or place to another.

Verbalize to express in words (written or spoken).

Volunteer a person who performs or gives his or her services of his or her own free will.

ADMISSION, TRANSFER, AND DISCHARGE

Admission to the hospital can be a positive event if handled with attention and empathy. On the other hand, it can be a negative experience if it is impersonal or mechanized.

Impressions formed by clients during the admission process can affect their attitude toward and ability to adapt to their total hospital experience, so the nurse should consider this an important aspect of client care.

Admission to the Hospital

The process of admitting a client to a healthcare facility varies among institutions, such as nursing homes, clinics, and hospitals. Regardless of the size or type of facility, the admission process assists in the provision of safe, effective care. Because the nurse–client relationship begins with admission, the nurse should have a thorough understanding of the standard admission process for the particular facility.

Clients who present to the emergency department (ED) are stabilized, then discharged, or admitted to the hospital by a general practitioner or specialist who writes, faxes, or telephones admitting orders. In some cases, the nurse calls the admitting physician for these orders.

Admission Protocol

- Advance directives are made available to clients.
- The *Client's Bill of Rights* is presented to each client.
- The admission assessment is completed by a registered nurse within a specified time after admission.
- All clients must be clearly identified by a legible identification band.
- When consent forms are required (for invasive procedures), they must be signed by an adult or guardian who is mentally competent. The adult must give voluntary consent, understand the risks and benefits of the treatment, and have the opportunity to ask questions.

Initial laboratory procedures and x-rays (according to client's DRG admitting diagnosis, surgeon, or anesthesiologist's orders) are usually completed before admission. The client may be provided a copy and/or explanation of an admission plan outlining the client's projected clinical course. Preadmission instructions discourage the client from bringing valuables to the hospital.

If a client enters the hospital in an emergency situation, he or she may feel insecure or fearful because there has been little time to make plans concerning family, travel, finances, or employment. When a client enters the hospital for elective treatment or surgery, both the nurse and client have more time for orientation and preparation for the hospital experience. The initial contact with the nurse leaves a lasting impression, so it should be conducted in an unrushed, organized, and respectful manner.

When the elective client arrives at the hospital, the first contact is usually with the admitting receptionist, who assigns a hospital number and interviews the client. If preadmission forms were mailed to the client, the information is verified by the receptionist at this time; otherwise, the client must answer questions about age, address, financial or insurance status, next of kin, religion, employment, and consent for treatment. If the client cannot answer these questions because of age or condition, a relative usually gives the information. A parent or guardian must do this for a child. At this time, the client receives an identification bracelet or Ident-A-Band. This bracelet includes the client's name, hospital number, and admitting physician's name.

Admission to the Nursing Unit

When admission to the hospital is complete, the client is either directed to the nursing unit or escorted by a volunteer. The client may be met by a staff nurse assigned to admission for that day or by a delegate who will orient the client to the unit and obtain baseline assessment data. Within a specific

time, a professional nurse performs a more thorough history and physical assessment, determines a priority of needs, and initiates an individualized plan of care.

The client is informed about telephone use, clergy availability, recreational area and lounge use, mealtimes, visiting hours, and other hospital schedules. Some hospitals have printed booklets describing this information. The client is also familiarized with the immediate environment, including the space for belongings, the bathroom, and operation of the nurse call system inside the bathroom. The nurse also demonstrates operation of the bedside nurse call system, television, radio, and bed controls. The more information the client receives, the more control he or she has over the environment.

Clients are discouraged from bringing items of monetary or sentimental value to the hospital (e.g., money, credit cards, jewelry, photographs, documents). If they are brought, the client may send them home with a family member or friend or place them in the agency vault per security personnel, or the client may retain them, assuming total responsibility and signing a "Release from Responsibility" form. Valuables retained in the agency vault are inventoried and witnessed, and the client is given a receipt. Safeguarded items may be withdrawn from the vault upon presentation of the receipt and completion of the "Request for Release of Valuables" form. Prosthetic devices such as hearing aids, dentures, and glasses are also considered to be valuables, but these are retained by the client.

Upon admission, a comprehensive list of the client's home medications is obtained (prescribed, OTC medications, and supplements), including route, dose, and frequency of use. A list of allergies to foods, drugs, devices, and materials is also obtained. The physician then orders continuation or discontinuation of

▲ Client may be admitted to the hospital in a wheelchair.

▲ Vital signs are obtained during the admission procedure.

home medications during hospitalization. If the client brings medications or supplements to the hospital, they should be verified by the hospital pharmacist, then placed in the client's medication drawer or sent home (according to agency policy). No medication should be kept at the client's bedside unless there is a specific physician's order that it be placed there.

In some circumstances, upon a physician's order, a client's labeled and pharmacist-verified home medication may be stored in the client's medication drawer and then administered by nursing staff in lieu of a hospital-dispensed preparation. In this case, the medication administration record (MAR) reflects that the client supplies the particular medication and the hospital does not charge for dispensing it.

Because clients may not be sure of their role while in the hospital, many hospitals have adopted versions of the American Hospital Association's *Client's Bill of Rights* (see The Client's Bill of Rights, Chapter 1, page 8). This bill includes the client's rights to obtain information about the client's illness or injury, to refuse medication or treatment, to participate in his or her own care, to know the rationale and risks of the treatment, and to receive courteous care.

The *Patient Self-Determination Act* requires all Medicare and Medicaid recipient hospitals to provide clients with information regarding their rights to reject medical treatment and to complete advance directives. An advance directive is a document the client creates that reflects goals, values, and preferences for health care. A "Living Will" specifies medical treatments the client wants or does not want at the end of life (e.g., feeding tube, mechanical ventilation). Another form of advance directive is the "Durable Power of Attorney," which designates an individual to make decisions for the client when the client is unable to make them for himself or herself. These documents vary from state to state. Copies of advance directives are placed in the client's chart. Additionally, many states mandate that an agency inquire about a client's requests concerning resuscitation. Competent clients who have been informed about their diagnosis and prognosis may be asked to execute a "Do Not Attempt Resuscitation" directive at the time of admission. Following such a request, the physician attaches an order to the client's record, and the order is then reevaluated according to agency policy. (See Chapter 1 for more information about advance directives, living wills, and durable power of attorney.)

Transfer to Another Unit

When a client is admitted through the ED, the nurse must carefully review the ED record for any treatment or diagnostic

"Hand-Off" Process

Each healthcare facility must define and implement a consistent process by which relevant details about client care are communicated among hospital personnel throughout the continuum of care. This process must allow opportunity for clarifying information in a time frame that is consistent with safe care for the patient

Source: The Joint Commission National Patient Safety Goals. NPSG. 02-05-10 (www.jointcommission.org).

test the client has received, as these may indicate the need for follow-up assessment or intervention. Similarly, when the client returns from x-ray or other procedures, the nurse considers intervening events (e.g., medications administered) that may influence care decisions. This information, as well as any special instructions for client care, is included on the "hand-off" communication form.

Clients are frequently transferred from one unit to another within the same facility as their condition fluctuates. When a client is moved, all records, charts, medications, MAR, belongings, and personal hygiene and special equipment are transferred with him or her. A complete hand-off report is given to the receiving unit's nursing staff. The new unit's receiving nurse has an obligation to validate all information relayed about the client, to perform an independent client history and physical assessment, and to handle the client's transfer as a "new admission" to the receiving unit. The client also has a right to receive an orientation to the new setting just like that provided in the previous setting. Sometimes clients are transferred within the same unit (e.g., from a semiprivate to a private room or vice versa) for various reasons. While these transfers are readily accomplished within a short time frame, communication about such transactions may be delayed, and confusion about a client's identification or location may result in the client's injury. Always ensure that the client's chart reflects the client's current room number and that all departments participating in the client's care are informed about the client's transfer to a new room number.

A client's transfer to another facility, and sometimes to another unit within the same facility, closes the current hospital record just as if it were a "discharge." A new record is established when the client arrives at the new receiving unit (equivalent to a new hospital admission). In these circumstances, a copy of the client's records may or may not accompany the client; therefore, a thorough report of the client's pretransfer hospital course and current health status must be thoroughly communicated to receiving personnel in order to facilitate continuity of care.

Discharge From the Hospital

From the time of admission, healthcare team conferences help to identify ongoing needs and to make arrangements for the client's reintegration into the community setting. This discharge planning process takes into consideration the physical, emotional, and psychosocial needs of the client, family, and caregiver. Sometimes hospitalization introduces the client to a lifelong need to chronically adapt to declining physical health and to chronically affiliate with the healthcare system. The nurse must be empathetic to the client's response at discharge and approach the client with all possible options for continued care, educational and financial resources, and any other services to assist the client to adapt to a chronic situation. The final responsibilities of the discharge process are to terminate the nurse-client relationship and evaluate the discharge process.

Discharge Against Medical Advice (AMA)

If, for a variety of reasons, a client decides to leave the hospital against medical advice (AMA), it is imperative that the nurse notify the physician, especially if the client is still undergoing

diagnosis and ongoing treatment. Most hospitals have AMA protocols that include a mental status evaluation and possible psychiatric consult or detention proceedings.

A competent client, of course, has the right to refuse treatment, but the nurse must still advocate for the client by attempting to determine the reason for the client's decision to leave and explaining that diagnosis and/or treatment have not been completed. An AMA discharge form should be signed by the client and witnessed. This form usually includes follow-up instructions, prescriptions, and documentation that there may be negative consequences of premature discharge.

See Chapter 6 (Client Education and Discharge Planning) for further information on discharging clients to home or another healthcare facility.

ADAPTATION TO HOME CARE

The home healthcare industry has experienced drastically reduced payments and fewer reimbursable visits as a result of the Balanced Budget Act of 1997. Now home healthcare agencies are required to complete data collection information forms. The Outcome and Assessment Information Set (OASIS) was instituted in February 1999, and the newest form, OASIS C, was implemented in January 2010. (See Chapter 6, page 116, for additional information on OASIS C).

The OASIS items were designed to enable systematic measurement of client home healthcare outcomes, with appropriate adjustment for client risk factors affecting those outcomes. The items have specific definitions used to measure changes in client's health status between two or more time points.

OASIS addresses sociodemographic, environmental, support system, health status, functional status, and health service utilization characteristics of the client. Data are collected at the start of care, 60 days after initial care, and at discharge. Additional data are collected if the client has a significant change in condition that requires emergent hospitalization.

In addition to measuring client outcomes, OASIS data have the following uses:

- Client assessment and care planning for individual adult clients
- Agency reports on various client characteristics such as demographic, health, or functional status at the start of care
- Internal Home Health Agency (HHA) performance improvement

The information collected through OASIS is much more comprehensive, particularly in the area of the client's health history.

Legal Issues in Home Care

Home health nurses are at risk for potential legal liability. Nurses work alone in the home care setting and do not have the advantage of calling on a colleague to collaborate on a client situation. This situation leaves the nurse vulnerable to legal risks. Home health nurses must be extremely skilled in handling equipment of all types, as well as performing specialized procedures without the assistance of another nurse. It is critical that

these nurses attend workshops, keep abreast of new equipment and procedures, and continue to read nursing journals on a regular basis. If home equipment is not functioning properly, the nurse should inform the client, call the medical equipment provider, fill out an incident report, and not use the equipment.

Home health nurses are also responsible for care provided by unlicensed personnel and LVN/LPNs. It is the responsibility of the nurse to know the competence level of the staff, evaluate their skill level, provide in-service instruction on new equipment or skills, and instruct them only within their specific scope of practice.

It is extremely important to maintain open communication with physicians and professionals in other disciplines providing care to clients in the caseload. Cell phones and e-mail allow for quick response time and improved communication.

Another legal issue is the need for appropriate client documentation that supports the need for home care services. If documentation is not accurate, timely, and complete, the client's reimbursement may be denied. This can lead to hours of time attempting to recover the costs of service, or it could lead to legal repercussions. Maintaining appropriate client records protects the nurse, client, and agency in cases under investigation. Writing legibly, using correct grammar and English, and being succinct and descriptive provide a good legal stance if necessary. Writing notes at the time care is delivered is essential so that information is not forgotten. Many agencies have documentation forms on a computer, so the nurse can enter data as he or she provides care.

The purpose of the unit "Admission to Home Care" in this chapter is to present clinical skills appropriate for the home setting. Many of these skills are exactly the same as those presented in other sections of this book. Some skills require minor change for adaptation to the home environment.

The use of the nursing process is just as important in home care as it is in the hospital. Nursing care plans are required by Medicare regulations and are also used as a justification for skilled nursing services by private insurers. Information regarding admission to home care is presented in the nursing process format to assist in organizing nursing actions and evaluating health care.

Plan of Treatment

A plan of care for home health care based on previous hospitalization admission findings. Centers for Medicare and Medicaid Services (the federal office that administers the Medicare program) requires that all agencies certified to provide home health care to Medicare clients complete the OASIS forms and the home health certification and plan of treatment form (form CMS-485) within 7 days. These forms must be completed on admission to home health care and signed by a physician. The plan of treatment is effective for 60 days. If the client's condition changes, an updated plan must be signed and submitted to the Medicare office every 60 days.

In addition to form CMS-485 and the OASIS forms, the documentation includes the home care agency's admission worksheet, nursing care plan, medication profile, plan of treatment, and consent for admission and service.

Documentation

Charting must follow the nursing care plan and cover the areas listed in the OASIS C documentation system. OASIS C is an assessment instrument used to collect specific information when a person is receiving Medicaid or Medicare and requires the services of a home health agency. OASIS C is a key component of Medicare's partnership with the home care industry to foster and monitor client outcomes and assist with quality improvement. Oasis C data items include sociodemographic, environmental, support system, health status, and functional status attributes of adult clients. Information gathered in the OASIS C form is forwarded to the state, where it goes to the Centers for Medicare and Medicaid Services. There, the information is used for reimbursement purposes for the specific home health agency. This prospective payment system went into effect in October 2000. Several forms must be completed for each client.

An in-depth assessment identifies areas in which client status differs from optimal health or functional status and is used as the basis of client care planning. Many agencies use standardized care plans and individualize them for each client.

Since interventions are implemented by the client, family, and part-time caregivers, all are involved in the treatment plan. The nurse or the case manager is responsible to coordinate and evaluate the care. The physical therapist can assume the role of case manager when the client is receiving rehabilitation services only.

Because home health aides provide care without direct daily supervision of a nurse, agencies usually hire only experienced nursing assistants (in most states, those who have worked in a hospital or nursing home). Home health aide certification is voluntary in some states and required in others. In many states, the training is completed after nursing assistants have obtained a CNA certificate.

Medicare requires the nurse to make a home visit at least every 14 days to reassess client and family needs and to revise the care plan. One visit each month is to discuss the treatment plan with the family. The nurse also accompanies the home health aide once a month for a supervised visit.

Home health nurses must meet the national standards of care as published by the American Nurses Association. The best preparation for home health nursing continues to be a sound base of nursing skills coupled with a broad knowledge of agency procedures and protocols.

CULTURAL AWARENESS

With the increasing number of clients from culturally diverse backgrounds, it is imperative that nurses be culturally sensitive. Cultural generalizations should only be utilized as a starting point, since differences exist within each culture and among individuals.

Several areas where cultural diversity is common include handshakes, use of eye contact, violation of personal space, facial expressions, and gestures.

The American healthcare system emphasizes medical science and care, informed consent, self-care, advance directives, and risk management. In contrast, clients of other cultures may prefer to rely on faith in God, beliefs, hope, and acceptance of fate as their primary coping mechanisms. A medical interpreter's assistance may be sought to help bridge these two sets of values and to help the client understand the hospitalization experience. The nurse should be aware of different cultural responses to Western protocols (e.g., Chinese-Americans believe the number 4 is unlucky because it sounds like the Chinese word for death; if possible, do not assign 4 as a room number).

Source: Pagana, KD (2009, July). Mind your manners multiculturally. Nurseweek: Mountain West, 18–22.

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to include in a client care plan when the components are related to admission, transfer, and discharge of a client.

NURSING DIAGNOSIS	RELATED FACTORS
Anxiety	Actual or perceived threat to self-concept, threat to biologic integrity, unfamiliar environment and treatments, change in socioeconomic status
Fear	Known or unknown outcome of hospitalization, medical or surgical diagnosis, and treatments
Grieving	Loss of function, change in lifestyle, lack of social support system, change in social role or economic status
Ineffective Health Maintenance	System impairment, surgery, musculoskeletal impairment, visual disorders, external devices
Powerlessness	Actual or perceived lack of control over situation, imposed regimens, lack of privacy
Social Isolation	Hospitalization, chemical dependency, altered appearance

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. Remember to wash your hands or use antibacterial gel before and after each and every client contact.

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Chapter 5

UNIT 1

Admission and Transfer

Nursing Process Data

ASSESSMENT Data Base

- Determine client's understanding of reason for hospitalization
- Observe and record client's physical, emotional, and mental status.
- Observe and record client's ability to adapt to the hospital environment.
- Observe for disabilities or limitations.
- Obtain a list of medications client is currently taking (prescribed, OTC, and supplemental), including dose, route, and frequency of use.
- Identify any food, drug, device, or device material allergies.
- Assess the client's level of comfort.
- Assess client for potential discharge needs.
- Assess condition prior to transfer.
- Obtain a thorough "hand off" report of client's progress and status at shift report, when receiving from another unit, or when returning from any test or procedure.

PLANNING Objectives

- To obtain a preliminary nursing history/assessment
- To assist client to adapt to hospital environment with minimal distress
- To encourage the client to participate in his or her own plan of care
- To provide a comfortable and aesthetically pleasing environment for the client
- To provide the client with some control over his or her immediate environment
- To provide the client with an opportunity to verbalize his or her feelings about hospitalization
- To facilitate safe and individualized continuity of care at all transition points throughout the continuum of care.

IMPLEMENTATION Procedures

- Admitting a Client 91
- Transferring a Client 93

EVALUATION Expected Outcomes

- Client adapts to hospital environment.
- Client participates in the individualized plan of care.
- Client understands rationale for and accepts transfer to a new care unit.
- Client is transferred to new unit without complication.

Critical Thinking Application 94

- Expected Outcomes 94
- Unexpected Outcomes 94
- Alternative Actions 94

Pearson Nursing Student Resources

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Admitting a Client

Equipment

- Admission kit with personal hygiene articles (if indicated)
- Hospital gown
- Thermometer
- Blood pressure cuff and stethoscope (or automated unit)
- Hospital Nursing History and Assessment form
- Client's chart or access to electronic documentation
- Labeled containers for client's dentures, etc.

Procedure

1. Refer to client's chart to determine reason for hospitalization and note any orders to be initiated immediately (e.g., oxygen administration). ► **Rationale:** Timely initiation of tests or treatments reduces hospitalization time and costs.
2. Notify physician of client's admission and obtain orders if not already done.
3. Check client's Ident-A-Band and have client state name and date of birth (according to agency policy).
4. Introduce yourself to the client and begin to establish a therapeutic nurse–client relationship.
5. Orient client to hospital room, various controls, and routines. ► **Rationale:** Reduces anxiety about hospitalization.
6. Provide labeled container for client's prosthetic items (e.g., dentures).
7. Assist client to don hospital gown.
8. Perform preliminary nursing assessment (may be obtained by a delegate).
9. Obtain client's health history and complete the physical assessment (performed by the professional nurse).
10. Complete score assessments for fall and pressure ulcer risk status.
11. Obtain a complete list of medications client is currently taking (prescribed, OTC, and supplements) including dose, route, and frequency. ► **Rationale:** The physician reconciles this list by continuing or discontinuing each medication and by ordering new ones.
12. Place allergy and other alert bands on client's wrist if indicated.
13. Initiate client's care plan: Identify individual client's problem areas and needs.
14. Reassess client's level of comfort and ability to adapt to hospitalization.
15. Complete client teaching for all unfamiliar procedures or interventions.
16. Document information on appropriate forms in chart.

Clinical Alert

The Joint Commission Performance Measurement Initiative requires that all clients admitted with a diagnosis of myocardial infarction, community-acquired pneumonia, or heart failure be assessed for tobacco dependence and that smoking cessation advice/counseling be provided.

Source: www.jointcommission.org

Obtaining a Health History

- Past medical history or health problems, including those for which client was not hospitalized
- Signs and symptoms of current problems according to client's perceptions
- Client's knowledge of illness (understanding of present illness) and expectations of care
- Lifestyle patterns: diet, elimination pattern, exercise, habits (i.e., smoking, alcohol intake), sleep patterns
- Relationships and social support systems; emergency contacts
- Values, beliefs, religious or spiritual practices
- History of food, drug, device, or device materials allergies and nature of reaction
- Medications (prescribed and OTC) and supplemental products including dose, route, and frequency used
- Risk analysis for discharge (anticipated needs)
- Special data base for elderly client: level of independence, ability to complete activities of daily living (ADLs), side effects of medications, history of recent loss of loved one, management of chronic conditions

CONFIDENTIAL INFORMATION

CONFIDENTIAL INFORMATION

Sample nursing history assessment form (b). ►

Transferring a Client

Equipment

- Wheelchair or gurney
- Covering for client
- Client's records, chart MAR, and care plan
- Client's valuables receipt
- Special equipment (e.g., walker)
- Personal belongings

Procedure

1. Verify physician's order if needed. ► **Rationale:** Physicians order client transfers from and to hospital units. They do not always order transfers within a unit.
2. Contact admitting office to arrange for transfer.
3. Communicate with transfer unit to determine the best time for transferring client.
4. Identify client and inform client of impending transfer. ► **Rationale:** Discussing the rationale for transfer facilitates adjustment to the new unit.
5. Gather equipment, belongings, and records.
6. Obtain necessary staff assistance for transfer.
7. Transfer client to wheelchair or gurney unless client is remaining in bed for the transfer. Use protective belts and rails as indicated.
8. Cover client to provide warmth and to avoid exposure during transfer.
9. Notify receiving nurse when you arrive on the unit.
10. Introduce client to new staff who will be caring for the client that day.
11. Give complete report to staff, using the client care plan medication reconciliation list, MAR and Kardex. Give information concerning client's current status, individualized care needs (e.g., bed alarm), client problems/alerts, and when next medications or treatments are due. Note any completed or pending test results. If necessary, give phone report to receiving nurse. ► **Rationale:** Complete "Hand-Off" communication maintains continuity of care after transfer and promotes client safety.
12. Notify physician when client's transfer is completed.

▲ Clients may be admitted or transferred on a gurney.

13. Notify appropriate departments (dietary, pharmacy) as required by hospital protocol when transfer is completed.
14. Notify x-ray and laboratory if tests were scheduled or results are pending.

Clinical Alert

Healthcare facilities must accurately and completely reconcile medications and other treatments at every transition of care: change in setting, service, practitioner, or level of care (National Patient Safety Goal # 8). Reconciliation at every transition point helps avoid medication errors such as omissions, duplications, dosing errors, or drug interactions.

Source: www.jointcommission.org

Clinical Alert

When a client is moved to another bed or room within the same unit, make certain the room/bed number is changed on the client's chart, MAR, and all other documents at the time the client is transferred. All appropriate departments must receive transfer notification.

DOCUMENTATION for Admitting and Transferring

- Admission procedures/orientation provided
- Adaptation to hospitalization
- Client's health history and physical assessment including risk assessment scores
- Individualized care plan and progress toward goal achievement.
- Client-signed documents added to the chart (e.g., advance directive)
- Inventory and dispensation of client's valuables and home medications
- Transfer time, destination, mode of transfer, transporter's name, and client's status
- Name of receiving unit's staff to whom report was given

Legal Considerations

Misidentification of Clients Does Not Ordinarily Occur in Absence of Negligence

This client underwent an apparently uncomplicated hysterectomy. She was placed in Bed B of a semiprivate room to recover.

Several hours later, the client occupying Bed A in the same room was moved elsewhere in the facility, but hospital staff failed to note the move in its records. Two shifts of nurses also failed to note the move.

The next day, the nurses on the unit directed the orderly to the room to find the woman who had previously been in Bed A to transport her to the lab for an ultrasound.

The hysterectomy client in Bed B, who wore a traditional hospital ID bracelet and whose name was posted on her bed, protested that she had just come from surgery, had been instructed not to move without direction, and that she knew of no scheduled test. Nevertheless, the orderly persisted without checking the client's identity.

The client testified that she felt excruciating pain and nearly passed out, but the orderly proceeded to take her to the lab. The lab commenced the procedure, and after client complaints, finally determined her true identity and returned her to her room, but failed to notify the attending nurse of the mistake.

The client suffered an incisional dehiscence and hernia, necessitating further surgery. Based on evidence at trial, the jury found the hospital had a "lackadaisical attitude" toward client identification procedures, evincing a "reckless and wanton disregard of the rights of the client." Potentially, this would allow an award of punitive damages in excess of actual damages determined.

Source: *Scribner v. Hillcrest Medical Center* (1992).

CRITICAL THINKING Application

Expected Outcomes

- Client adapts to hospital environment.
- Client participates in the individualized plan of care.

- Client understands rationale for and accepts transfer to a new care unit.
- Client is transferred to new unit without complication.

Unexpected Outcomes

Client has difficulty adapting to hospital environment.

Alternative Actions

- Assess physiologic, emotional, or cultural basis for difficulty.
- Consult case manager, interpreter, clergy, or other assistant to facilitate client's adaptation.
- Understand client's cultural acceptance of fate and fear that the diagnosis actually caused the disease process.
- Explore client's concept of hot/cold balance; assist in meal planning accordingly.
- Emphasize essentials of care and discharge planning as many feel the hospital is a place to die.
- Be flexible regarding timing of meals and other aspects of care as much as feasible.

Foreign client appears depressed, refuses to participate in the plan of care.

- Orient client to new setting and elicit client's perception of reason for transfer.
- Correct misperceptions regarding transfer and continuity of care.
- Explain that transfer decision is based on client's clinical progress and that new unit will be appropriate to provide client's current care needs.

Client is anxious about transfer.

- Check with transferring unit for retained items.
- Check with security personnel for client's registered items.
- File a variance report if belongings are not located.

Upon transfer, client's personal belongings are lost.

Height and Weight

Nursing Process Data

ASSESSMENT Data Base

- Check the need for daily or weekly body weight measurements.
- Determine appropriate method for obtaining client's weight (standing scale, bed scale).
- Determine client's ability to stand for height measurement.
- Obtain previous height and weight measurements to compare with expected norms or to establish a base for identifying trends.

PLANNING Objectives

- To identify excess or deficit of fluid balance
- To establish baseline data to monitor response to drug therapy (e.g., diuretic)
- To determine weight-based drug dosages
- To determine nutritional status in relation to body requirements (see Chapter 19)

IMPLEMENTATION Procedures

- Measuring Height and Weight96

EVALUATION Expected Outcomes

- Height and weight are obtained and recorded.
- Client's weight, depending on disease state and therapy, shows expected losses, gains, or stabilization.

Critical Thinking Application98

- Expected Outcomes98
- Unexpected Outcomes98
- Alternative Actions98

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Measuring Height and Weight

Equipment

- Balance beam scale (for clients who are able to stand without assistance)
- Bed scale (for clients who are confined to bed or who are unable to stand) or
- Bed scale (built into the bed)
- Floor scale (for clients in wheelchairs)
- Paper towel

Preparation

1. Perform hand hygiene and check client ID.
2. Weigh client in the morning before breakfast. Ask client to void before weighing.
3. Use the same scale each time you weigh the client.
 - ▶ **Rationale:** For consistency in weight from day to day, keep variables the same as possible.
4. Make sure the client wears the same type of clothing (e.g., gown or robe) for each weighing.

5. If bedscale is used, account for weight of linens, etc.
 - ▶ **Rationale:** Extraneous variables, such as linens, extra pillows, etc., result in inaccurate client measurements.
6. Change wet gown or heavily saturated dressings before weighing the client.

Procedure

1. Transport client to scale or bring scale to bedside.
2. Balance scale so that weight is accurate. (See Table 5-1 for desirable weight based on sex and height.)
3. Place a clean paper towel on scale and ask client to remove shoes.
4. Assist client to stand on scale.
5. Move weights until the weight bar is level or balanced.
6. Record weight on appropriate record.
7. Ask client to face front so back is toward scale's balancing bar.
8. Instruct client to stand erect.

▲ Weigh client in the morning, before eating or drinking, using the same scale each time.

▲ Instruct client to stand erect to measure height.

▲ Scales accommodate wheelchairs for weighing clients.

▲ Bed scale is used to weigh clients who are on complete bed rest. Note: See Chapter 6 for specialty beds that include scale capability.

9. Place L-shaped sliding height bar on top of client's head.
10. Read client's height as measured.
11. Record height on appropriate record.
12. Discard paper towel (if used) and assist client back to room.
13. Perform hand hygiene.

TABLE 5-1 Weight Chart (Desirable Weights in Pounds, According to Frame—in Indoor Clothing)

WOMEN Height		Small Frame	Medium Frame	Large Frame	MEN Height		Small Frame	Medium Frame	Large Frame
Feet	Inches	Pounds	Pounds	Pounds	Feet	Inches	Pounds	Pounds	Pounds

6	2	N/A	N/A	N/A	6	2	156–167	162–180	173–194
6	3	N/A	N/A	N/A	6	3	160–171	167–185	178–199
6	4	N/A	N/A	N/A	6	4	164–175	172–190	182–204

Height is in feet and inches, including shoes. Weight is in pounds, including indoor clothing. Assumption: Male indoor clothing with shoes weighed seven pounds. Female clothing with shoes weighed four pounds. Identify clothes client wore for accurate weight. For girls between 18 and 25, subtract 1 pound for each year under 25. Source: Blue Cross/Blue Shield of Delaware, 1997; American Heart Association. NOTE: See Chapter 19, Nutritional Management, for body mass index table.

DOCUMENTATION for Height and Weight

- Time of day height and weight were measured
 - Client's height and weight measurement recorded on client's chart and MAR
 - Type and identifying number of scale used for weighing
 - Weight of any attached equipment shoes or clothing that adds to client's actual weight
-

CRITICAL THINKING Application

Expected Outcomes

- Height and weight are obtained and recorded.

- Client's weight shows expected losses, gains, or stabilization.

Unexpected Outcomes

Client cannot be weighed accurately because of attached mechanical devices.

Alternative Actions

- Analyze unexpected weight loss or gain by assessing other factors, such as fluid intake and urinary output, presence of edema, lung sounds.
- Remove attached device momentarily to obtain accurate weight.

Client's weight varies more than expected from one day to the next.

- Check time of day weight was measured.
 - Check if same scale was used for both weighings.
 - For equipment reliability, check client's weight with another scale and compare findings.
 - Check what clothing or linen was on the client when weighed on both days.
 - Check MAR for medications that alter fluid balance (e.g., diuretics).
 - Check I & O record for sources of fluid loss or gain.
-

Discharge

Nursing Process Data

ASSESSMENT Data Base

- Verify order for client’s discharge.
- Identify discharge destination (home, rehabilitation unit, etc.).
- Assess client’s feelings about discharge.
- Review care plan to determine client’s progress toward goal achievement during hospitalization.
- Identify client’s teaching needs for discharge and report findings to multidisciplinary team.
- Assess for any unaddressed need for healthcare assistance in the home.
- Determine that discharge needs have been addressed by case manager, dietitian, occupational or physical therapist, social worker, or other specialist.
- Verify that client is ready for discharge.
- Try to determine reason for client’s intent to leave the hospital against medical advice.

PLANNING Objectives

- To collaborate with the multidisciplinary team
- To prepare client for discharge and complete discharge planning
- To assist in the discharge of a client whose condition necessitates lifestyle changes or care at another facility
- To allow the client to verbalize feelings about discharge and to identify the client’s strengths and needs
- To inform client of risks involved in leaving the hospital against medical advice (AMA)

IMPLEMENTATION Procedures

- Discharging a Client100
- Discharging a Client Against Medical Advice (AMA)101

EVALUATION Expected Outcomes

- Client understands discharge process and is not exhibiting anxiety.
- Client remains in the hospital until discharged by the physician.

Critical Thinking Application101

- Expected Outcomes101
- Unexpected Outcomes101
- Alternative Actions101

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Discharging a Client

Equipment

- Client's record
- Hospital Discharge Instructions form
- Copy of discharge medication order list and any new physician's written prescription
- Educational pamphlets/instructions
- Telephone numbers and information regarding follow-up appointments or special referrals
- Adaptive aids (e.g., walker, toilet seat extender) needed on discharge (may be dispensed by the hospital)
- Client's home medications retained, hospital dispensed liquids, MDIs (metered dose inhalers), if continuation is prescribed.
- Materials for dressing changes (if indicated), antiembolic stockings, or any additional items previously dispensed for individual client use
- Transport vehicle for discharge

Preparation

1. Determine that physician's discharge orders have been written.
2. Notify client's interdisciplinary team of discharge order.

▲ Clients are discharged in a wheelchair for their safety.

3. Along with care team, determine that client is ready for discharge.
4. Ensure that all laboratory work, x-rays, treatments, and procedures are completed before discharge.
5. Determine that client understands instructions for self-care, including medications and follow-up arrangements.
6. Complete client teaching if applicable. (See Chapter 6.)
7. Notify client's caregiver to arrange transportation.
8. Obtain adaptive aids or other supplies that can be dispensed by the hospital (e.g., dressings, potty extender).
9. Provide opportunities for client to discuss impending discharge.

Procedure

1. Identify client.
2. Review details of discharge with client (see Discharge Planning unit in Chapter 6).
3. At discharge, the client's list of medications received during hospitalization is reconciled by the physician and prescriptions are written for new medications to be taken if indicated. The physician should document reasons for discontinuing or omitting certain medications upon discharge from the hospital, such as a beta-blocker and aspirin for the post-myocardial infarction client.
4. Review any teaching and answer questions about medications, diet, bathing, any activity restrictions (e.g., lifting, sexual activity, driving), physical/wound care, use of special equipment or supplies, and follow-up appointments.
5. Explain how to recognize complications and what to do if they occur.
6. Complete written instructions on Discharge Instructions form using lay terminology that client can understand.
7. Have client sign Discharge Instructions form and provide the client with a copy.
8. Place copy of client's signed Discharge Instructions form and discharge medication order list on client's chart.
9. Assist client to retrieve safeguarded valuables per hospital policy.
10. Terminate relationship with client. ► **Rationale:** Providing an opportunity for the client to express feelings and impressions contributes to a positive termination.
11. Follow hospital procedure for client discharge, including time and method of leaving hospital unit.
12. Document time and method of client's discharge, destination, individual accompanying, and any supplies, prescriptions, and forms sent with client.
13. Notify appropriate departments of client's discharge.

Discharging a Client Against Medical Advice (AMA)

Equipment

- Client's record
- Form for discharge against medical advice (AMA)

Procedure

1. Immediately notify physician and nurse manager if client insists on leaving the hospital prematurely.
 - **Rationale:** If the nurse judges that the client is endangered by leaving AMA, the physician should be notified immediately.
2. Ascertain why the client wants to leave the hospital prematurely.
3. Explain reasons that continued hospital care is necessary (e.g., diagnosis, treatment).
4. Explain risks of leaving hospital AMA (e.g., incomplete testing or treatment).
5. Inform client that some insurance companies may not pay for hospitalization if the client leaves AMA. Refer client to his or her insurance plan.
6. Request client to sign the AMA form if he/she still insists on leaving AMA. The nurse witnesses and cosigns the document.
 - **Rationale:** This form states that the hospital is relieved from responsibility for any ill effects which may result from AMA discharge.
7. Place signed AMA form in client's record and provide a copy to the client along with prescriptions, self-care and follow-up instructions, etc.
8. *If the client refuses to sign the AMA form*, note this on the form, have it witnessed, notify appropriate hospital personnel, and file a variance report.
 - **Rationale:** This fulfills legal requirements if the client insists on discharge AMA without signing form.
9. Document client's verbatim statement in nurses' notes indicating reason for leaving.
10. The client is not escorted by hospital personnel, but leaves the hospital on his own or with family or friends whose names should be documented on the client's chart.
11. Notify client's caregiver and hospital security if there is concern for the client's welfare or safety.
12. Notify appropriate people when the client leaves (physician, case manager, nursing supervisor, risk management personnel).

Clinical Alert

Refer to agency standard operating procedures (SOPs) for specific instructions related to client admission, transfer, or discharge.

DOCUMENTATION for Discharging a Client

- Day-to-day preparatory activities for discharge such as teaching, return demonstrations
- List Copy of Discharge Instructions form, discharge medication order list, and client teaching/instructions provided
- Discharge data (time, destination, how discharged, and accompanied by whom)
- Client's own medications, physician-written prescriptions, special equipment taken home by client
- Discharge criteria not met and reason criteria were not met as identified on client's care plan
- Client's signed Release from Responsibility for Discharge (AMA) form, instructions provided, name of individual accompanying client out of the hospital, and client's telephone number and address for follow-up call or visit by social worker
- Individuals notified of client's discharge AMA

CRITICAL THINKING Application

Expected Outcomes

- Client understands discharge process and is not exhibiting anxiety.
- Client remains in the hospital until discharged by the physician.

Unexpected Outcomes

Client is anxious about discharge to an extended care unit.

Client wants to leave the hospital AMA.

Alternative Actions

- Reinforce physician/hospital's recommendation for extended care.
- Provide time for client and caregiver to recognize that the goal is to increase client's strength and independence.
- Attempt to identify client's reasons for wanting to leave AMA.
- Notify client's physician.

Unexpected Outcomes

Alternative Actions

- Consult hospital policy and procedures regarding AMA before releasing client.
 - Negotiate possible alternative to leaving hospital (e.g., child care arrangements, employment concerns).
 - Encourage discussion about risk of leaving/benefits of remaining hospitalized.
 - Notify charge nurse, or supervisor, case manager and social worker, or clergy to discuss situation with client.
 - In case of a minor or mentally incompetent client, contact hospital attorney ASAP.
 - Have client sign hospital AMA form.
 - If client will not sign AMA form, have another nurse witness refusal, and chart details of discharge.
-

Admission to Home Care

Nursing Process Data

ASSESSMENT Data Base

- Assess client’s financial eligibility for home care service.
- Observe client’s physical, emotional, and intellectual status.
- Observe client’s ability to adapt to the home setting.
- Assess the client’s level of comfort.
- Determine client’s understanding of the health status and any limitations.
- Assess home condition and safety factors prior to client returning home.
- Examine equipment for safety features.
- Assess nurse’s safety for making home visits.

PLANNING Objectives

- To assist client to adapt to home care with minimal distress
- To encourage client and family to participate in the plan of care
- To provide a comfortable and safe environment for the client
- To maximize client’s outcomes after discharge from hospital
- To provide the necessary and appropriate home care treatment modalities
- To provide a safe environment for the nurse

IMPLEMENTATION Procedures

- Nurse’s Role in Home Care104
- Identifying Eligibility for Medicare Reimbursement104
- Completing Admission Documentation105
- Maintaining Nurse’s Safety106
- Assessing for Elder Abuse107

Note: See Chapter 7 for Safety Interventions for Home Care

EVALUATION Expected Outcomes

- Client adapts to home setting with minimal difficulties.
- Client and family participate in the plan of care.
- Safe environment is provided for client.
- Nurse’s safety is maintained during home visits.

Critical Thinking Application107

- Expected Outcomes107
- Unexpected Outcomes107
- Alternative Actions107

 and Skill Checklists

Nurse's Role in Home Care

Equipment

- Discharge Planning Records
- OASIS C Forms
- H485 Forms
- Consent Forms
- Agency Forms

Preparation

1. Obtain appropriate documents from healthcare facility.
 - a. History and physical examination
 - b. Diagnosis
 - c. Treatments
 - d. Medications
 - e. Subjective and objective discharge notes.
 - f. Physical or occupational therapy during home care.
 - g. Hospital follow-up care appointments.
 - h. Caregiver status (i.e., family member or home health aide).
2. Obtain all OASIS C documents to be completed during initial visit.
3. Contact discharge planner at facility to determine date, time of discharge, method of transfer to home, and availability of health caregiver when client reaches home.
4. Contact client, health caregiver, or family to arrange time for initial visit.

Procedure

1. Introduce self to client, family, and health caregiver.
2. Describe services that will be provided, including time frames and use of ancillary personnel, including role of each member of the health team.
3. Assess home for safety issues (see Chapter 7).
4. Determine client's eligibility for services.
5. Complete OASIS C forms and CMS-485 forms, in addition to relevant forms based on assessment (pressure ulcer forms, mental status, sensory status, etc.). Develop client care plan.
6. Review client's or caregiver's responsibility for care during absence of agency staff.
7. Provide telephone numbers for agency, emergency services, and, if appropriate, the RN (will vary among agencies).
8. Review medication names, doses, and time of administration and side effects that should be reported to the physician.
9. Review and have client or caregiver demonstrate any treatments that will be completed when agency personnel are not in home.
10. Develop a nurses' worksheet and care plan to be reviewed each visit. ► **Rationale:** To ensure all activities have been completed and documented.

NOTE: Worksheet to include assessment findings, flow sheets (ADLs, pain assessment, medications, etc.), vital signs, education provided, IVs. Care plan update.

Identifying Eligibility for Medicare Reimbursement

Procedure

1. Complete OASIS C forms.
 - a. Integrate information with CMS-485 data.
 - b. Complete all sections of document. ► **Rationale:** Denial of service can result if documentation incomplete.
 - c. Complete forms within 7 days.
 - d. Ensure information from forms is transcribed accurately onto CMS-485 forms. ► **Rationale:** To prevent denial of service.
2. Check required criteria for Medicare coverage eligibility. ► **Rationale:** This prevents administering care for which reimbursement will not be received.
3. Identify client as homebound.
 - a. Client's condition severely restricts leaving the home.
 - b. Leaving the home requires considerable effort and assistance of another person.
 - c. Special transportation is necessary.
 - d. Absences from the home are infrequent and short.
4. Check that home service is considered skilled. To be skilled, service must be under the supervision of a registered nurse or a physical therapist.
 - a. Registered nurse performs specific functions:
 - Client teaching
 - Dressings or irrigations
 - Catheterization
 - Parenteral therapies
 - Medication administration and teaching
 - b. Physical therapist performs certain functions:
 - Gait training
 - Therapeutic exercises
 - Ultrasound, diathermy, TENS
 - Restorative therapy
 - c. Speech therapist performs certain functions:
 - Therapy for clients with certain diagnoses (e.g., cerebrovascular accident, laryngectomy)
 - Selected diagnostic and evaluative services
5. Provide supplemental services from home health aide, social worker, or occupational therapist; care is reimbursed by Medicare only when one of the three skilled services is required.
 - a. Supplemental services may be obtained even if one of the skilled services is not needed; however, Medicare does not reimburse, and client is responsible for payment.

Clinical Alert

The Outcome and Assessment Information Set (OASIS-B1) and the Discharge Form in the OASIS paperwork is more extensive than previously gathered information on documentation forms. Be careful to complete all sections of the form.

- b. Home health aide services are reimbursable only if plan of care is established and supervised by registered nurse. Personal care (activities of daily living [ADLs]) Light housekeeping (e.g., food preparation, client's laundry) Selected semiskilled care (e.g., passive range-of-motion exercises)
 - c. Social worker. Interventions must contribute significantly to the improvement of the client's medical condition. Indication that social, environmental, or family conditions inhibit progress of recovery from medical condition.
 - d. Occupational therapy. Design maintenance program. Teach compensatory techniques and ADLs. Design self-help devices to assist with ADLs. Provide restorative therapy.
6. Provide care that is part-time and intermittent.
- a. Care must be episodic or acute and not chronic.
 - b. Medically predictable recurring need for care must be present.
 - c. Knowledge that condition will improve in a limited time frame.
 - d. Frequency of service ranges from daily to every 90 days, depending on individual client's need.
7. Check that plan of treatment is authorized by physician and recertified every 60 days.
- a. Centers for Medicare and Medicaid Services form (CMS-485) is standardized for plan of treatment.

Guidelines for Home Care

- Take as little with you into the home as possible.
- Use appropriate nursing protocols in home setting.
- Perform hand hygiene on entering and leaving home.
- Maintain clean technique in the home.
- Know CDC infection control guidelines.
- Review state and federal guidelines and protocol for reimbursement.

This form is used by all home health agencies for Medicare clients.

- b. Form must include:
 - Identifying data
 - Diagnosis (ICD-9CM)
 - Start of care
 - Types of services required and frequency
 - Functional limitations
 - Activities permitted
 - Safety measures
 - Treatments
 - Medications
 - Mental status
 - Nutritional status and diet orders
 - Medical supplies and DME
 - Goals and discharge plans
 - Significant clinical findings
 - Prognosis
 - Physician's name, address, signature
 - Certification of homebound status
8. Assess that care is medically reasonable and necessary.
- a. Entire plan of care must correlate with client's medical problems and client's clinical status.
 - b. Each service's goals (client outcomes) must be clearly stated and realistic for the client.

Completing Admission Documentation

Procedure

1. Complete all sections of the OASIS C document.
 - a. Demographic data: address, referring physician, payment source, etc.
 - b. Present history.
 - c. Present illness.
 - d. Living arrangements.
 - e. Supportive assistance.
 - f. Physical assessment/review of systems.
 - g. ADLs.
 - h. Medications.
 - i. Equipment management.
 - j. Homebound status.
 - k. Therapy modalities required.
 - l. Unmet needs.
 - m. Lack of Knowledge section.
 - n. Treatment/Procedures Performed.
 - o. Response to Teaching/Training Performed.
 - p. Patient Rights and Responsibilities.
 - q. Coordination of Patient Services.
 - r. Discharge Planning.
2. Signed consent forms.
 - a. IV therapy.
 - b. Consent for treatment.
 - c. Consent for service
3. Signed HIPAA form.
4. Signed Advance Directive document.
5. Signed Patient's Bill of Rights document.

6. Billing Data Base.
7. Discipline Specific Evaluation, if therapy was instituted.
8. Plan of Care.
9. CMS-485 Worksheet.
10. Aide Assignment and Duties, if appropriate.
11. Physician Plan of Care.
12. Home Health Plan of Care.
13. Nurses' Notes as necessary.
14. Identify if prehospital "Do Not Resuscitate" form has been signed.

Maintaining Nurse's Safety

Procedure

1. Evaluate safety of nurse before the visit.
 - a. Call the client before the visit to determine convenient time.
 - b. Confirm directions to home.
 - c. Determine whether household pets are present; if so, ask that they be secured during visit.
 - d. Check neighborhood to determine need for assistance from police to make home visit.
2. Wear identifying name badge. Most agencies request that the nurse wear a lab coat.
3. Wear flat shoes to allow you to walk quickly or to run if necessary.
4. Maintain personal safety while traveling in the car.
 - a. Keep car in good working order and stocked with necessary equipment.
 - b. Keep gas tank at least half full at all times.
 - c. Obtain automobile club membership for emergency use.
 - **Rationale:** To call for assistance with car problems.
 - d. Keep a windshield cover with CALL POLICE sign available. ► **Rationale:** To alert neighbors you need immediate assistance.
 - e. Have car phone available and charged at all times.
 - f. Keep blanket in car. ► **Rationale:** To keep warm in the winter if you need to wait for assistance.
 - g. Keep thermos of water in car at all times. ► **Rationale:** In case you need to wait for assistance in hot weather.
 - h. Keep doors locked and windows up at all times.
 - i. Park in full view of neighbors, preferably directly in front of home.
 - j. Lock all personal items in the car trunk before leaving home or office.
 - k. Keep all equipment in the car trunk.
 - l. Restock the nurses' bag before the visits for the day. Keep nurses' bag on front seat.
 - m. Keep change in car for phone calls if necessary.
 - n. Place all valuable objects out of direct sight in car (i.e., laptop computers, phone). Place these under the seat if possible. ► **Rationale:** To prevent car break-in and theft.
5. Maintain personal safety while walking on the street.
 - a. Keep one arm and hand free when walking from car to house.
 - b. Walk directly to client's residence.
 - c. When approaching a group of strangers, cross the street or walkway, if appropriate.
 - d. When leaving a residence, keep keys in your hand with the pointed end of the key facing outward. ► **Rationale:** The keys can be used as a weapon if necessary.
 - e. Carry a chemical spray and whistle within easy reach.

Clinical Alert

If your safety is in jeopardy, use one of the following defensive strategies: *Scream* or yell *FIRE* or *STRANGER*. Kick the person in the shin or groin. Bite or scratch the person. Use chemical spray or blow a whistle. If you feel your personal safety is in question, do not make a visit or stay in the residence.

NOTE: Attendance at a class is necessary before it is legal to carry a chemical spray such as Mace.

6. Maintain personal safety when making home visit.
 - a. Use common walkways or hallways. Do not park behind a building or in a dark area.
 - b. Knock on the door and wait for permission to enter.
 - c. Keep a clear pathway to the door if the situation is potentially unsafe.
 - d. Observe home environment for safety hazards (i.e., weapons).
 - e. Make a joint visit with another agency staff member or ask for an escort if there is a potentially unsafe situation.
 - f. Call for police support if the visit is essential and the situation is unsafe. ► **Rationale:** There may be times when a visit is essential, but it is unsafe for one individual to make a visit.
 - g. Make a visit in the morning when good visual support exists if neighborhood is unsafe.
 - h. Close the case if the nurse feels the situation is unsafe and there are no alternative actions that can guarantee nurse's safety.

Assessing for Elder Abuse

Procedure

1. Assess client for indications of neglect: failure to provide adequate food, clothing, medical assistance, or assistance with ADLs. Check body for signs of cleanliness. Determine whether emotional abuse is present. Ask about threats, intimidation, or isolation.
2. Identify whether financial abuse has occurred, such as misuse of finances or property.
3. Assess for signs of physical abuse: signs of restraining; hitting, biting, burning; black and blue marks on trunk, abdomen, buttocks, upper thighs; scars; and abrasions. Bilateral bruises or parallel injuries may indicate forceful restraining; shaking may cause parallel injuries of upper arms. Accidental injuries affect knees, back of hands, forehead, and elbows.
4. Assess for signs of malnourishment or dehydration.
5. Check skin for pressure ulcers.
6. Assess for signs of sprains or dislocations from pulling or pushing the client.
7. Ask about visits to the hospital ER. Ask why client sought medical care, how much time elapsed between injury and visit to ER.
8. Assess for signs of emotional abuse. Observe if client is fearful of strangers, becomes quiet when caregiver enters room, craves attention and socialization.

Questions to Ask If Suspicion of Abuse

- Who cares for you at home?
- Did someone hurt you?
- Are you happy with where you live?
- Tell me about your daily routine.
- Who assists you with ADLs?
- Do you feel safe living here?
- Who manages your money?
- How did the injury (or bruises) occur?
- Did you receive medical attention?
- Has this type of injury happened before?

DOCUMENTATION for Admission to Home Care

- Complete all required forms, i.e., OASIS C, CMS-485, agency-specific forms
- Safety issues occurring within house
- Mental status of client and ability to care for self
- Teaching activities for client or caregiver
- Nursing care plan update
- Medication side effects and referral to physician
- Changes in client status
- Notification of physician

CRITICAL THINKING Applications

Expected Outcomes

- Client is acclimated to home environment and is able to provide care after a period of support from agency staff.
- Client is provided appropriate home care modalities.

Unexpected Outcomes

Client is noncompliant with treatments, safety procedures, and taking medications at home.

- Safe environment provides for client safety in home.
- Nurse's safety is maintained during home visit.

Alternative Actions

- Explain rationale for following home care plan.
- Discuss reason with client, caregiver, and family members to determine whether change in plan would increase compliance.
- Remind client that if he or she refuses to follow plan, he or she will be taken off services.
- Document appropriately on all forms indicating noncompliance issues.
- Notify physician.

GERONTOLOGIC Considerations

U.S. Demographics Affect Hospital Admissions

- The average life expectancy has increased.
- The number of elderly will double by 2020.
- Healthcare services are used by the elderly more than any other age group.
- Three of four elderly people die of heart disease, cancer, or stroke.

Elderly Clients Admitted to the Hospital Require Special Consideration

- Fatigue and pain may be pronounced; admission procedures may need to be altered.

- Repeated orientation may be indicated due to short-term memory deficit, confusion, sensory impairment.
- Special problems associated with age must be anticipated and nursing care planned appropriately (e.g., risk for falls).

Elderly Clients Admitted to Home Care Require Special Consideration

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- Delegation for the admission of a new client may be divided into three task areas:
 1. A CNA may assist the client into bed, place client's personal items in a designated area, describe the room environment including the use of telephone, television, and nurse summon controls, visiting hours, mealtimes, and other hospital routines. The CNA may also take vital signs and obtain height and weight measurements.
 2. The LVN/LPN may complete a health history form, obtain admission data required by the hospital, witness consent forms, and complete the same tasks identified above.
 3. The RN is responsible for the complete health history and reviewing the data obtained by other health care workers, initiating the client care plan (nursing diagnosis, goals, and interventions), and beginning the discharge plan in collaboration with the healthcare team.
- An LVN/LPN may complete discharge teaching following the established discharge teaching plan.
- Escorting a client out of the hospital can be delegated to a volunteer, CNA, or LVN/LPN. Many facilities have escort services that utilize volunteers.

Communication Matrix

- Clients being admitted to the hospital are usually frightened and unsure of the events that will take place. It is important to communicate their needs to and collaborate with all staff members involved in the client's care. This will provide a team approach for comprehensive care.
- A complete report on the newly admitted client must be given to all team members. If an LVN/LPN or CNA assisted in the admission process, he or she must provide immediate feedback to the RN manager regarding their findings.
- The client Kardex and Medication Reconciliation List must be completed in a timely manner to facilitate safe and effective care. It is often the responsibility of the unit secretary to process orders and initiate the documentation; however, it is the responsibility of the RN to check the processing and documents for accuracy and completeness.
- A client care plan must be established within a designated time frame. The time is determined by the facility in accordance with The Joint Commission guidelines.
- "Hand-Off" shift report must contain a brief history: reason for admission, overview of the client's assessment, current status, and any special needs. Diet, specific treatments, procedures, test results or those pending, and any alerts (e.g., DNAR, isolation) should be included. The hand-off process (including audio-taped reports) must allow opportunity for asking and receiving answers to questions relevant to safe client care.

CRITICAL THINKING Strategies

Scenario 1

Mr. Moore has been told by his cardiologist that his coronary arteriogram indicates he has three-vessel disease and he is a candidate for coronary artery bypass surgery. The surgery is scheduled and Mr. Moore is welcomed at the facility's

preadmission testing unit 1 week before admission for preliminary blood work and preoperative instructions. At this time he receives information about his expected clinical course, which includes a multidisciplinary Plan of Care.

1. What is the advantage of providing the client with information this far in advance of surgery?
2. What is included in the Plan of Care?
3. Who participates in the development of the Plan of Care?
4. How does the Plan of Care facilitate the client's admission, transfer, and discharge processes? Are there drawbacks?

Scenario 2

Marilyn James, age 45, has been admitted to the hospital for incision and drainage of a wound infection following knee surgery she had 3 weeks ago. Her therapy now requires 2 more weeks of hospitalization for twice-daily intravenous antibiotic therapy.

After the first day of antibiotic therapy, she says she's going to leave the hospital AMA without completing the recommended course of treatment. She "wasn't prepared for prolonged hospitalization" and has to go home to care for her 3-year-old granddaughter and elderly mother who live with her.

1. What right does a client have to leave the agency prematurely, AMA?
2. What should the nurse's initial response to this client be?
3. How can the nurse advocate for this client?
4. What are the usual procedures involved in discharging a client AMA?
5. How is this process documented in the client's record?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. DNR decisions are made by the
 1. Client's family.
 2. Advance Directive counselor.
 3. Client.
 4. Client's physician.
2. Who is responsible for inquiring if the client has an Advance Directive?
 1. The hospital chaplain.
 2. The admitting nurse.
 3. The hospital attorney.
 4. The client's physician.
3. During the admission process, the client receives an identification bracelet (Ident-A-Band)
 1. Before arriving on the nursing unit.
 2. Upon arrival to the nursing unit.
 3. After the initial assessment has been completed.
 4. Upon receipt of admitting physician's orders.
4. The Ident-A-Band contains the client's name as well as this information

Select all that apply.

 1. Client's room number.
 2. Admitting physician's name.
 3. Client's date of birth.
 4. Client's hospital number.
5. During the admission process, the client is oriented to the hospital unit, including use of various control systems. The purpose of this orientation is to
 1. Save time for the nursing staff.
 2. Provide client control over the environment.
 3. Release the hospital from liability in case the client falls.
 4. Prevent the client's abuse of expensive equipment.
6. This information should be included in the client's orientation to the hospital environment

Select all that apply.

 1. Meal times.
 2. Use of emergency call system.
 3. Roommate's name.
 4. Use of nurse call system.
 5. Physician visit times.
7. Mr. Jones has been admitted to your unit with a diagnosis of "Rule Out MI" (myocardial infarction). The Joint Commission requires that this client be assessed for and counseled about
 1. Smoking.
 2. Diet.
 3. Exercise.
 4. Stress.
8. The client's body mass index (BMI) is calculated using the client's
 1. Age and waist measurement.
 2. Age and weight.
 3. Height and weight.
 4. Sex and waist measurement.
9. Serious injuries can occur when clients are transferred from one hospital unit or one bed to another because of
 1. Client misidentification.
 2. Loss of personal items.
 3. Delays in medication administration.
 4. Falls during transport.
10. When a client intends to leave the hospital prematurely, against medical advice, the nurse should first
 1. Have the client sign the hospital AMA form.
 2. Try to identify the reasons why the client wants to leave AMA.
 3. Notify the client's physician.
 4. Inform the client about risks of leaving AMA.

6

Client Education and Discharge Planning

LEARNING OBJECTIVES

1. Define the process of client education.
2. Discuss the meaning of the term *learning theory*.
3. Outline the process of collecting client data to determine learning needs.
4. Explain the application of the nursing process to client education.
5. List two factors to consider when determining an appropriate teaching strategy.
6. List and describe two specific teaching strategies appropriate for clients and families.
7. Define cultural competence.
8. Identify assessments to determine readiness to learn.
9. Discuss the application of Adult Learning Principles (Knowles) to client education.
10. Identify one strategy to determine readability level of written material.
11. Describe how to develop an evaluation tool.
12. Discuss the meaning of the term *discharge planning*.
13. List three risk factors that require discharge planning.
14. Identify the steps necessary to complete a discharge summary.
15. Describe documents required to accompany client to home.
16. Identify appropriate referral for Home Health Team.

TERMINOLOGY

Assessment the first step in identifying client's knowledge base is to set meaningful learning goals and strategies.

Client education the process of influencing behavior and teaching the client self-care techniques so that he or she can resume responsibility for certain aspects of health care following discharge from the health facility.

Compliance follow-through on advice and direction by medical personnel to promote wellness and rehabilitation.

Comprehensive health care a total system of health care that takes the whole person into account.

Counseling giving support or providing guidance.

Culture a way of living, thinking, and behaving. It is learned within the family and guides the way we solve problems in our daily lives.

Cultural competence a set of congruent behaviors, attitudes, and policies that enables nurses and other healthcare workers to work effectively in a cross-cultural situation.

Diagnosis-related groups (DRGs) categorization of disease diagnoses that standardizes the reimbursement of government funds for number of days in the hospital.

Discharge to release from care; done by a physician, nurse, or medical care facility.

Discharge planning systematic process of planning for client care following discharge; includes client needs, goals of care, and strategies for implementation.

Evaluation tool a test, questionnaire, or direct observation that evaluates the effectiveness of the teaching.

Helping relationship an interaction of individuals that sets the climate for movement of the participants toward common goals.

Home care assistance nursing care provided by licensed and unlicensed personnel in the client's home setting.

Learning The process of conceptual change, within the framework of the client's perceptions, that leads to modifications in behavior.

Maladaptive inability to, or faulty adjustment or adaptation.

Readiness to learn a component of the learning process; referring to the psychologic state of being open and accepting of new information and the learning process.

Relationship an interaction of individuals over time.

Resistance inability to listen and participate in discussion of health behavioral changes.

Support to lend strength or give assistance to.

Termination the end of something; a limit or boundary; conclusion or cessation.

Therapeutic having medicinal or healing properties; a healing agent.

Transfer to convey or shift from one person or place to another.

Transition the process or an instance of changing from one form, state, activity, or place to another.

Transitional care the process of facilitating the transition or move between hospital and home to maintain continuity of health care.

Understanding to perceive and comprehend the nature and significance of, to know.

Validate to substantiate or verify.

CLIENT EDUCATION

Historically, client education has been one of the most important responsibilities of the professional nurse. With advances in medical science and an increasing number of clients with progressive chronic illness, the role of client education can directly affect the client's health, adaptation to illness, and recovery. While a segment of healthcare consumers are more informed and active in making healthcare decisions, there still remain those who lack "health literacy," or lack the ability to read, comprehend, and act on medical information. These factors contribute to the increasingly difficult task of providing appropriate and comprehensive client education. In addition, the influx of clients from various diverse cultures, different languages, availability of educational materials written at appropriate readability levels and/or languages, lack of time, and shorter hospital stays present challenges for nursing.

The purpose of client and family education is for them to gain knowledge, skills, and behavior changes necessary to meet the client's healthcare needs. Client education should be individualized, specific, and understandable. Clients have a right

Challenges to Providing Client Education

- Various cultures
- Various languages
- Lack of time
- Lack of reimbursement
- Lack of appropriate readable materials
- Lack of literacy appropriate materials
- Lack of training in providing client education and/or the development of materials

to know about their illness, medications, and any procedures being performed. Client education is an expected standard for nursing practice.

The Joint Commission (formerly JCAHO) has mandated that client and family education be part of comprehensive care and devised Patient and Family Education (PFE) Standards for accredited agencies.

The Joint Commission set the following goals for client and family teaching:

- Client participation and decision making about health care options
- Increased potential to follow the healthcare plans
- Development of self-care skills
- Improved client/family coping
- Increased participation in continuing care
- Adopting a healthy lifestyle

The Joint Commission reviews for evidence of three major processes involved in client education: the hospital's internal focus on education, direct education of the client and family, and evaluation of how well the education program achieves the identified goals. The Joint Commission stresses the need for a multidisciplinary approach to planning and implementing client education. Because nurses are the principal providers of care and have legal responsibility for client education, as outlined in each state's Nurse Practice Act and emphasized in documents published by the American Nurses Association and many specialty associations, they usually provide the leadership role in directing the educational plan for the client and family. Nurses provide the communication link between the multidisciplinary team members to ensure the client's goals are met in a timely manner.

The cultural beliefs and practices of the client have a major influence on healthcare behaviors, beliefs, and willingness to learn. Client education must be sensitive to these beliefs. For example, if teaching a Chinese diabetic, the nurse must consider the food the client likes to eat, as well as the social values. Eating may not be merely for nutrients, but also a gesture of politeness and social interaction. It is important that nurses gain an awareness of the various cultures in order to provide *culturally competent* care.

The goal of client and family education is to promote optimal client health. To achieve this goal, clients and families must learn in a way that is meaningful and acceptable to their concept of self and in relationship to the illness. Thus learning is a process of conceptual change within the framework of the client's perceptions that leads to behavioral change.

To be effective and facilitate the teaching/learning process, the nurse must utilize excellent listening and communication skills to establish rapport. Determining learning needs, preferred learning style, and learning readiness are all requirements included in the The Joint Commission's Standards for Patient & Family Education. Once a client has received a new diagnosis or new information about his/her condition, the nurse must assess three areas: (1) what they already know, (2) what they need to know and, (3) how best to assist with learning. Clients need to be able to identify and understand what the illness is, effects of the treatment, whether it is acute or chronic, and short- and long-term care needs and outcomes. Discussing possible outcomes of the illness will help the client accept the condition, be open for new ideas or teaching, and be motivated to learn and make appropriate health behavior changes. The client must recognize any gaps in knowledge and misconceptions and then assimilate new information for possible actions. When the client and family assist in goal setting and the information is presented based on their preferences, learning becomes more meaningful.

The client education plan is a component of the total nursing care plan, which is part of the nursing process. Thus the same principles of the nursing process apply to client education: assess the learning needs, and plan appropriate teaching, implementation, and evaluation. Client education, when viewed as a process rather than the simple action of imparting information, helps the client to actively participate in his or her health plan for wellness. Individualized to the specific client needs and included as part of a total care plan, client education contributes to continuity of care following discharge.

Principles of Client Education

Malcolm Knowles, author of *The Modern Practice of Adult Education*, discusses strategies for adult learning. He suggests that adult learning and readiness to learn are influenced by developmental tasks. Knowles formulated what he called the "Adult Learning Principles," which include the following:

- Adults learn best when there is a perceived need. In order for learning to occur, the client must understand why they need to know about a subject. Therefore, the nurse must ensure that the client understands the underlying health issue that is to be prevented or the illness that is to be resolved before teaching.
- Teaching plan is considered part of client care plan.
- Teaching of adults should progress from the known to the unknown. Assess what they already know; don't reteach the things they already know.
- Teaching of adults should progress from the simpler concepts to more complex topics.
- Adults learn best using active participation. Asking the client to restate what has been discussed will encourage learning and provide for clarification.
- Adults require opportunities to practice new skills. When acquiring new manual skills, such as drawing up or injecting insulin, it is essential that the client be allowed to practice the skill. It is important to observe a return demonstration in order to evaluate the effectiveness of the teaching.
- Adults need behavior reinforced. An example of reinforcing behavior would be to allow the client to draw up and give their insulin each time it is required.
- Immediate feedback and correction of misconceptions increases learning.

Similar to Knowles's principles of adult learning, simplicity and reinforcement are essential in providing client education. An understanding of these principles is essential for individuals who teach adults in the healthcare setting.

Resistance to Change

Most nurses recognize that the client may resist learning and cannot be forced to learn; the nurse can only assist the client, encourage him or her, and facilitate learning. To master information, the client must have internalized some form of motivation to learn; for example, the client realizes that to adequately control diabetes and feel better, he or she must understand the relationship of insulin and food to body needs.

Tips to Facilitate Client-Focused Education

- Get to know the client, his/her knowledge level, perception, current practices, and preferences.
- Determine client's goals and readiness to learn, and individualize ways to achieve goals.
- Take into account client's goals, learning style, special skills, cultural beliefs, and developmental level.
- Utilize simple language and interact at client's level with empathy and concern.
- Utilize a variety of materials and methods that encourage active learning and participation.
- Plan for right time and right place to maximize client and family learning.
- Follow up at another time to clarify information and reassess learning.

Many clients appear to resist change, even when changing would result in a positive outcome. When this occurs, the process of learning is blocked. As a nurse educator, you are functioning as an agent of change, and dealing with resistance to change is a necessary task. There are several reasons underlying resistance; one of the most common is that change is frightening, even when a person consciously wishes to alter his or her behavior. If a person perceives change as a possible threat, he or she may resist. Another cause of resistance is inaccurately perceiving the reason for or effect of change. Other sources of resistance include psychologic inflexibility, cultural practices, inability to tolerate change, and not believing that change will have a positive effect.

The nurse is both an educator and an agent of change. If the client resists change (the teaching process), attempting to identify the reason for that resistance and altering the teaching approach accordingly may assist the nurse to accomplish the goals of client education.

Barriers to Change	Nursing Approaches
Perceived threat or fear of change	Identify specific fears or threats and impart accurate information that may reduce fears. Focus on the positive outcome of change.
Inaccurate perceptions of effect of change	Clarify client perceptions. Impart accurate information, and discuss results of behavior change.
Disagreement that change is positive	Work to agree on mutual goals and demonstrate positive outcomes so client views change as positive rather than negative.
Psychologic resistance or perceived loss of freedoms or behaviors	Focus on discussion of client's perceived loss of freedom and demonstrate willingness to alter plan or adapt to client's needs.
Inability to tolerate change	Recognize that low tolerance is often caused by fear—allaying fear through developing trust, being supportive when client attempts to change, and giving positive feedback decreases fear of change.

Client education is more than imparting information to a client; it is the process of influencing behavior. As such, it needs to be directed toward the client's thinking to facilitate meaningful behavioral changes. When goals are mutually agreed on and clearly stated, the learner understands what is expected, the nurse understands his or her role and can evaluate it, and the results can more easily be measured. Because of the need to control costs and the current practice of discharging clients earlier, a more extensive teaching plan must be developed and implemented.

Readiness to Learn

Assessing the client's readiness to learn is an essential component of client education. Readiness to learn can be limited by physical and psychosocial demands caused by illness, such as pain and fatigue. For many clients, the post-acute or recovery phase and desire to return to normalcy act as an incentive to learning.

Methods of Teaching

The methods of client teaching may include:

- One-to-one education: most common methodology used in hospitals, clinics, and physician offices.
- Group teaching: most often utilizes videotapes or similar technology, such as CDs or DVDs.
- Computer-aided instruction: used in clinics, hospitals, and physician offices or for client to learn at home.
- Internet: can increase client's understanding of symptoms, conditions, and treatments—key to Internet use is choosing appropriate health Web sites.

Regardless of the methodology chosen, selection of educational materials and resources should be appropriate for age, developmental level, cognitive level, culture, and language.

DISCHARGE PLANNING

Recent changes in healthcare delivery systems, as an attempt to contain rapidly rising costs, have altered client care. The number of hospital days for clients in acute care hospitals has decreased; frequently, these clients are discharged still requiring care; and this care is frequently delivered in the home setting. Most clients, especially those who are high risk, benefit from the process of discharge planning. Discharge planning is defined as the systematic process of planning for client care after discharge from the hospital. The emphasis and goal of discharge planning are to meet client needs through continuity of care—from an acute care setting to a discharge facility.

To comply with The Joint Commission requirements related to discharge planning, initial assessment at admission, ongoing assessments, and referrals must be documented.

When the client is admitted and the care plan formulated, discharge planning should be initiated. The process includes an assessment of the client and family's anticipated needs; physical, emotional, and psychosocial status; home environment; and family and community resources. Two common assessment instruments measuring physical and cognitive function are frequently given to at-risk clients at the time of admission. The Lawton IADL and Katz ADL

scales provide information useful when developing the discharge plans.

Comparison of the two scales:

Activities of Daily Living	Instrumental Activities of Daily Living
(Katz ADL)	(Lawton IADL)
Feeding	Using the telephone
Continence	Shopping
Transferring	Preparing food
Toileting	Housekeeping
Dressing	Doing laundry
Bathing	Using transportation
	Handling medications
	Handling finances

Source: Graf, C. (2008, April). The Lawton instrumental activities of daily living scale. *American Journal of Nursing*, 108(4), 52–62.

Discharge planning requires a multidisciplinary approach with participation by all members of the healthcare team, including the client and family. Many of the larger hospitals have discharge planners or coordinators, who orchestrate the discharge planning. This is especially important when the client is considered high risk. The nursing staff still play a major role in assessing discharge needs and preparing the client and caregivers to assume responsibility for care after hospital discharge. With the assistance of social workers or community-based nurses, the nurse identifies and anticipates client needs and formulates a plan for meeting these needs after discharge from the hospital.

Discharge Planning: High-Risk Clients

- Elderly
- Multisystem disease process
- Major surgical procedure
- Chronic or terminal illness
- Emotional or mental instability
- Inadequate or inappropriate living arrangement
- Lack of transportation
- Financial insecurity
- Unsafe features in the home

Successful discharge planning includes:

1. A transitional plan of care from the acute care setting to home or another healthcare facility.
2. Appropriate teaching for family and client in self-care.
3. Knowledge and skills necessary for self-care and emergency procedures.
4. Appropriate agencies involved in transition to the home care setting.

A new approach to discharge planning is transitional care using transition specialists. This category of practitioner was implemented to facilitate the transition from hospital (where discharge planning is initiated) to recovery (in the home). The transition specialist meets with the family and client in the acute setting, begins discharge planning, and usually makes a home visit before the client is discharged. After discharge to the home, this specialist is available to the client and family.

The Joint Commission Standards for Client Education

- Hospital plans for and supports the provision and coordination of client education activities.
- Hospital identifies and provides the resources necessary for achieving educational objectives.
- Education process is coordinated among appropriate staff or disciplines who are providing care or services.
- Client receives education and training specific to the client's assessed needs, abilities, learning preferences, and readiness to learn as appropriate to the care and services provided by the hospital.
- Client is educated, based on assessed needs, about how to safely and effectively use medications according to law and regulation and the hospital's scope of services, as appropriate.
- Client is educated about nutrition interventions, modified diets, or oral health, when applicable.
- Hospital ensures client is educated about how to safely and effectively use medical equipment or supplies, as appropriate.
- Client is educated about pain and managing pain as part of treatment, as appropriate.
- Client is educated about habilitation or rehabilitation techniques to help him or her become more functionally independent, as appropriate.
- Client is educated about other available resources, and when necessary, how to obtain further care, services, or treatment to meet his or her identified needs.
- Education includes information about client's responsibilities in his or her care.
- Education includes self-care activities, as appropriate.
- Discharge instructions are given to client and those responsible for providing continuing care.
- Academic education is provided for a hospitalized child or adolescent, either directly by the hospital or through other arrangements, when appropriate.

Federal Requirements for Discharge Planning Process

- Hospitals must identify at an early stage of hospitalization all Medicare clients who are likely to suffer adverse health consequences on discharge if there is no planning.
- The hospital must provide a discharge planning evaluation.
- A registered nurse, social worker, or other qualified person must develop or supervise development of the evaluation.
- Discharge planning must include an evaluation of the likelihood of needing posthospital services and of the availability of the services.
- The evaluation must include the client’s capacity for self-care or the possibility of the client being cared for in the environment from which the client entered the hospital.
- The evaluation must be completed on a timely basis so that appropriate arrangements for posthospital care are made before discharge.
- The discharge planning evaluation must be in the client’s medical record.

This type of transitional care and coordination has proven to be cost-effective and has improved the quality of client care.

Communication between the client, family, and healthcare agencies is essential for effective discharge planning. According to HIPAA, discussing client information with the family

members or friends is only permitted if it directly affects them and the client agrees. The information reflecting client approval needs to be documented in the client’s record. Family members involved in discharge planning are helpful, as they can inform the healthcare team about cultural traditions, financial issues, unsafe living conditions, and support for the client at home. The nurse establishes a dialogue between these various people and coordinates the discharge plan before the client leaves the hospital. When referrals to other agencies are necessary, these are initiated before the client is discharged. The nurse, if there is no discharge planner available, is responsible for coordinating such referrals—including signed physician’s orders for specific care, treatments, or medications.

ADAPTATION TO HOME CARE

Home Care Definition

The term *home health care* refers to all services that promote, maintain, or restore physical, social, or emotional health to clients in the home setting. Home care is provided in the individual’s residence. For a smooth transition from hospital to home, the home care coordinator communicates with the family members and the home health nurse. Home care is also provided to clients in long-term care or residential care facilities in which there are no or limited staff members.

A variety of health workers are needed to provide comprehensive home care services to clients and families. Table 6-1 presents an overview of healthcare providers and their major responsibilities. The list and responsibilities are not inclusive; consult an additional home care reference for more detailed information.

TABLE 6-1 Home Health Team

Healthcare Provider	Major Responsibilities
Registered Nurse	Performs as a case manager. Initiates physician-ordered plan of care; performs assessment, planning, and interventions for needed home care skills and teaching. Assists in evaluating treatment regimens for all services.
Home Care Aide	Performs hygienic care, skin care, exercise, ambulation, dressing, and elimination skills. Some may prepare and serve meals. Assists in maintaining a clean, safe, client environment (e.g., client’s bedroom).
Homemaker	Maintains the home environment, shops for and prepares meals, transports client, and runs errands.
Social Worker	Assists in planning for home care needs, instructs in use of social and community services and resources. Provides information relative to long-term planning and respite care in the home.
Physical Therapist	Evaluates environment in preparation for client’s return home. Assists with safety adaptations for the home, instructs in exercise program, gait training, and use of special adaptive equipment.
Occupational Therapist	Instructs in activities of daily living, grooming, upper extremity strengthening, function activities, and use of adaptive equipment.
Speech Therapist	Evaluates swallowing and chewing ability; memory; assists with increasing communication techniques for client, family, and healthcare provider; and provides speech reeducation program.
Registered Dietician	Evaluates and provides for nutritional needs of client. Plans and instructs in appropriate diet.
Physician	Prescribes medical plan of treatment. Writes specific prescriptions for medications, diet, supplies, nursing interventions, and therapist parameters.
Licensed Vocational Nurse	Provides skilled nursing care similar to a Home Care Aide under RN supervision. They are not used by all agencies because of limited independent activities allowed.

Referral to Home Care

It is necessary for nurses in all settings to be aware of the referral process and the type of client who should be referred for home care services. Although most home care clients have been hospitalized, it is not a prerequisite for service. Physicians, individual clients, families, residential care administrators, and friends may refer a client by calling a home health agency and requesting service. A physician's approval is needed for reimbursement. An evaluation visit is made by the RN or PT, who act as case managers, to determine if service is needed, and if so, an appropriate plan of care is established. Speech therapists are not allowed to do initial evaluations in California and in most other states.

Most hospitals have a designated protocol for making referrals, which is described in the hospital policy manual. In most hospitals it is the discharge planner, case manager, or social worker who makes the referral. The nurse may alert the appropriate person to the client's need for home care. It is essential that the nurse provide complete and thorough information about the client's condition, including physical and psychosocial needs. This information is documented on a standard referral form or on an official form from the Department of Health and Human Services and sent to the home health agency. Accurate information and orders are needed to facilitate a smooth transition from hospital to home. Incomplete or inadequate communication could mean a lapse in service and inadequate care for the client.

All age groups use home health services. The criteria for referral depends on various factors, such as client need, agency protocol, and insurance criteria. Since the elderly on Medicare represent the largest segment of the population using home care services, it is important that all nurses know Medicare eligibility criteria for home visits. This ensures that accurate information is given to the client and family. In addition to eligibility criteria, many regulations govern the type and frequency of care. Since these regulations are subject to change and interpretation by the fiscal intermediaries who administer Medicare insurance, frequent review of Medicare regulations should be done. Eligibility for another funding agency, Medicaid, differs from state to state. It is the nurse's responsibility to be familiar with these policies. Each individual insurance company reimburses for services at different rates and for different levels of service. Each insurance plan needs to be reviewed to determine reimbursement.

Transition From Hospital to Home

A smooth transition from hospital to home depends on an appropriate discharge plan. The shorter duration in hospital stay requires a thorough, efficient discharge plan that must be initiated at the time of hospital admission. Identifying the client's needs and resources before planning for discharge results in a realistic plan. Since any illness causes additional stress in the family and necessitates an adaptive coping response, the needs of the family or significant other must be included in the teaching and discharge plan. Discharge planning is completed during meetings of the interdisciplinary healthcare team. A representative member of each discipline discusses the client's progress and individual needs for discharge. In addition, accurate and comprehensive documentation must accompany the physician's plan of treatment to ensure a smooth transition. A description of the

client at discharge should be provided; include physical assessment findings, ability to assist in ADLs, adaptive devices needed for care, and a brief summary of hospitalization. These data greatly assist in the transition from hospital to home.

Home Health Care Changes

Home health care, a rapidly growing field of health care, has developed in response to recent changes in political and social forces in the United States. These changes have demanded that nurses expand their knowledge about home care and acquire skills needed to provide safe, competent care to clients in the home setting.

Several factors have contributed to the emergence of home health care as a primary delivery system. The fastest growing segment of the American population is 85 years of age or older. The elderly constitute the largest proportion of population currently using home healthcare services. Nine percent of those 65 to 74 years of age and 25% of those 75 years and older require some type of home care service. Many younger clients are receiving home care visits as a direct result of early discharge from hospitals. Home care visits are funded by private insurance companies and are a cost-effective measure for providing nursing care.

Another factor is the changing structure and role of the American family. Traditionally, women have provided health care for the family members at home. With more women working outside the home, the demand for home health services has increased.

Political factors have had an effect on healthcare delivery patterns. A cost-containment measure initiated by the federal government in 1983 to curb rising costs of hospitalized Medicare clients drastically altered the extent of care administered in the hospital setting. A prospective payment system (DRGs), rather than a retrospective payment system, was implemented. This resulted in shorter hospital stays for Medicare clients. With the shorter stays came a dramatic increase in the need for professional services to care for high-acuity clients in the home. Additional types of services have also had to be added to the home care system to meet the needs of these clients. Even more changes occurred with healthcare reform in the 1990s. Health maintenance organizations (HMOs) and reimbursement policies directly affected the home healthcare agencies.

Documentation using Outcome and Assessment Information Set (OASIS) is regulated by the Health Care Financing Administration. The OASIS system was developed by The Center for Health Policy Research in Denver, Colorado. Oasis C has added 30 process measures that will affect outcomes. The new client assessment information was also used to develop a prospective payment system for home health agencies, which went into effect October 2000. Home visits for maternity clients and children under 18 do not require completion of these forms.

Client Teaching

Client teaching is an essential component of both hospital and home care. Since clients are discharged earlier and with a higher acuity level, the client and his or her family are expected to accept more responsibility for follow-up care. It is essential for client teaching to begin in the hospital and provide a

description of the disease or condition and the treatment regimen. The client and family should be instructed in skills and treatments necessary to restore health and prevent other illness or complications. The home health nurse builds on the teaching plan, with the main emphasis on adapting care in the home environment. Continuity of care depends on comprehensive communication between the discharging and home care agencies.

Adapting Care to the Home Setting

The client is often a passive recipient of care in the hospital. In the home setting, on the other hand, the client is in control—it is his or her environment. That is, the environment is determined by the client and family according to their needs, desires, values, and resources. The nurse is a guest in this environment, which requires flexibility in adapting to a variety of situations.

In the hospital, equipment is readily available. Nurses perform procedures or treatments and provide 24-hour-a-day coverage of nursing care. In the home, equipment must be ordered or improvised, and the emphasis is on teaching the client or caregiver self-care activities. The home care nurse must become very creative in adapting and improvising equipment and techniques.

When a client referral is received by a home health agency, a nurse or physical therapist makes an initial admission visit. This visit includes a thorough assessment of the client, family, and home environment. The home environment is evaluated for safety, and the client and family are assessed for knowledge of safety and emergency procedures. Assessment of the client includes physical, emotional, psychologic, and economic status. The home is assessed for any adaptations that must be made to enable the client to function optimally in his or her environment. Family members are assessed for understanding of the client's illness or needs; cultural, ethnic, and health beliefs and values; ability to cope with the current situation; the physical, emotional, and spiritual needs of family members; financial resources; and knowledge of how to use community resources. A complete list of assessment parameters for each of these areas is included on the initial assessment form.

CULTURAL AWARENESS

The Developmental Disabilities and Bill of Rights Act of 2000 defined culturally competent services as services that are (a) provided in a manner responsive to the beliefs, interpersonal styles, attitudes, language, and behaviors of individuals; and (b) provided in a manner that demonstrates respect for individual dignity, personal preference, and cultural differences.

It is essential to remember that all client teaching plans and strategies must consider cultural aspects in the planning phase. Cultural differences affect client's open-mindedness to client education and their willingness to listen to the teaching and then be compliant with the changes that need to occur. Cultural differences affect client's attitudes about illness, healthcare workers, and treatment modalities. The Joint Commission has mandated that there must be greater awareness of diversity, attention to the needs of special populations, and staff training to meet their needs.

When taking cultural competence into account, nurses should consider the following to make client teaching more effective:

- Be aware of own cultural biases and prejudices.
- Become familiar with the core cultural values of client groups.
- Whenever possible, use a translator to convey information.

All cultures have health beliefs about illness: what causes it and what cures it, as well as who they will allow to treat them. It is important for nurses to understand each culture's differences, as it will impact the client teaching process. Table 6-2 summarizes cultural beliefs that may have an effect on health care and client teaching.

Included in the discharge plan is a discharge summary. This summary includes an overall review of hospitalization activities and the client's learning needs. There is a statement indicating how well the learning needs have been met, the client teaching completed, short- and long-term goals of care, referrals made, and coordinated care plan to be implemented after discharge.

Since 1988, hospitals have been mandated by federal requirements to provide a discharge planning process for all Medicare clients. These same requirements now apply to all clients within hospitals in the United States.

TABLE 6-2 Cultural Beliefs Affecting Client Teaching

Ethnic Group	Cultural Beliefs
Asian/Pacific Islander	Extended family has large influence on client. Older family members are honored and respected, and their authority is unquestioned. Oldest male is decision maker and spokesman. Strong emphasis on avoiding conflict and direct confrontation. Respect authority and do not disagree with healthcare recommendations—but they may not follow recommendations.
Chinese	Chinese clients will not discuss symptoms of mental illness or depression because they believe this behavior reflects on family; therefore, it may produce shame and guilt. Use herbalists, spiritual healers, and physicians for care.
Japanese	Believe physical contact with blood, skin diseases, and corpses will cause illness. Believe improper care of the body, including poor diet and lack of sleep, causes illness.

(Continued)

TABLE 6-2 Cultural Beliefs Affecting Client Teaching (Continued)

Ethnic Group	Cultural Beliefs
	Believe in healers, herbalists, and physicians for healing, and energy can be restored with acupuncture and acupressure. Use group decision making for health concerns.
Hindu and Muslim	Indians and Pakistanis do not acknowledge a diagnosis of severe emotional illness or mental retardation because it reduces the chance of other family members getting married.
Vietnamese	Vietnamese accept mental health counseling and interventions, particularly when they have established trust with the healthcare worker.
Hispanic	Older family members are consulted on issues involving health and illness. Patriarchal family—men make decisions for family. Illness is viewed as God's will or divine punishment resulting from sinful behavior. Prefer to use home remedies and consult folk healers known as <i>curanderos</i> rather than traditional Western healthcare providers.
African American	Family and church oriented. Extensive extended family bonds. Key family member is consulted for important health-related decisions. Illness is a punishment from God for wrongdoing, or is due to voodoo, spirits, or demons. Health prevention is through good diet, herbs, rest, cleanliness, and laxatives to clean the system. Wear copper and silver bracelets to prevent illness.
Native American	Oriented to the present. Value cooperation. Value family and spiritual beliefs. Strong ties to family and tribe. Believe state of health exists when client lives in total harmony with nature. Illness is viewed as an imbalance between the ill person and natural or supernatural forces. Use medicine man or woman known as a shaman. Illness is prevented through elaborate religious rituals.

NURSING DIAGNOSES

The following nursing diagnoses are appropriate to include in a client care plan when the components are related to establishing and maintaining a client teaching and discharge planning.

NURSING DIAGNOSIS	RELATED FACTORS
Impaired Communication Verbal	Cognitive impairment, auditory impairment, language barrier
Denial	Attempt to disavow need to alter lifestyle by avoiding client teaching
Ineffective Health Maintenance	Cultural and religious beliefs, information misinterpretation, lack of education, lack of motivation, inadequate healthcare services
Deficient Knowledge	Inadequate understanding of condition, misinformation, language differences
Noncompliance	Impaired ability to perform tasks, poor self-esteem, lack of motivation
Relocation Stress Syndrome	Changes associated with transfer between facilities or facility and home, effects of losses associated with moving, stress in family members
Ineffective Role Performance	Change in self-perception of role; change in others' perception of role as a result of an altered health status, which leads to denial of learning need

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. Remember to wash your hands or use antibacterial gel before and after each and every client contact.

IDENTIFY CLIENT Before every procedure, check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Client Education

Nursing Process Data

ASSESSMENT Data Base

- Assess high-risk criteria for client education.
- Determine the need for client teaching program.
- Identify client learning style and preferences.
- Assess knowledge and skill level of client.
- Assess motivation to learn.
- Assess readiness to learn.
- Identify physical or emotional barriers that may affect client's ability to participate in teaching plan.
- Identify health beliefs and practices.
- Assess developmental and educational level of client.
- Determine appropriate methodology for client teaching sessions.
- Identify appropriate adjunctive materials, such as audiovisual aids, to enhance learning process.
- Assess appropriate setting for the individual client.
- Determine family members or significant others who will be involved in client education.

PLANNING Objectives

- To develop a plan using the nursing process framework and adult learning principles
- To determine learning needs and establish learning objectives
- To select appropriate teaching strategies
- To increase client's knowledge to promote compliance with health regimen
- To encourage client participation in goal selection and implementation program
- To encourage client to acknowledge individual responsibility for health behaviors and health status
- To improve client's ability to make informed decisions affecting health status
- To facilitate behavioral changes that are conducive to optimum health status
- To provide continuity of care when the client is moving from one healthcare setting to another

IMPLEMENTATION Procedures

- Collecting Data and Establishing Rapport 120
- Determining Readiness to Learn 121
- Assessing Learning Needs 121
- Determining Appropriate Teaching Strategy 123
- Selecting the Educational Setting 124
- Implementing the Teaching Strategy 125
- Evaluating Teaching/Learning Outcomes 126

EVALUATION Expected Outcomes

- Client's knowledge regarding his or her health status has increased.
- Client's ability to make informed and effective health-related decisions, based on accurate information and awareness of self, has improved.
- Effective use of the healthcare delivery system has been promoted.
- Continuity of care and information exchange has occurred between health agencies or between the hospital and client's home and family.
- The nurse has evaluated his or her teaching effectiveness and revised the plan, teaching style, and content as necessary.
- Increased compliance to medical regimen as demonstrated by client's ability to manage condition/disease process.

Critical Thinking Application 127

- Expected Outcomes 127
- Unexpected Outcomes 127
- Alternative Actions 127

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Collecting Data and Establishing Rapport

Equipment

- Client teaching plan
- Room or suitable setting to complete assessment
- Adjunct materials, such as audiovisual equipment, charts, and illustrations
- Written materials, such as outlines or other handouts
- Equipment for demonstration and return demonstration
- Documentation forms: Kardex, client's chart, electronic forms

Preparation

1. Develop a client teaching plan utilizing the following information: assessment findings, expected learning outcomes, teaching strategies, teaching materials, education methods.
 - a. Use adult (and/or age-appropriate) learning principles.
 - b. Use communication and interpersonal relationship skills. ► **Rationale:** To encourage client's participation in the plan.
 - c. Use a nonjudgmental approach. ► **Rationale:** A nonjudgmental attitude assists client to be honest with feelings.
 1. Use "how" questions to facilitate communication. ► **Rationale:** "How" is more effective than "why" in a question, as "why" tends to set up a defensive reaction to the question.
 2. Use verbal and nonverbal behavior and congruency of behavior to build relationship with the client.

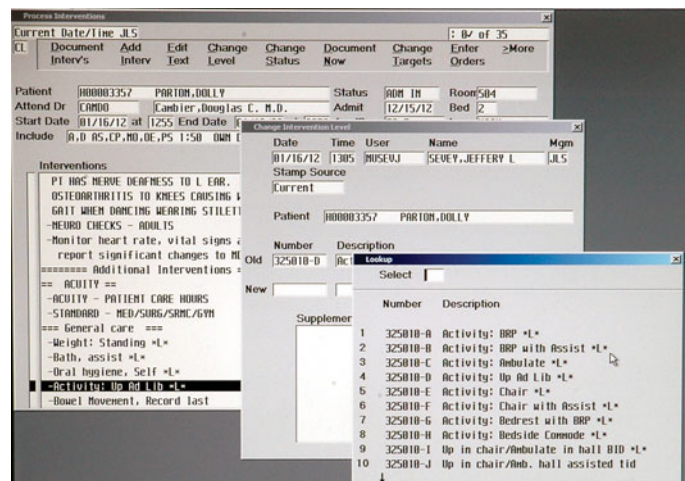

▲ When collecting data to determine learning needs and strategies, use age-appropriate materials.

- d. Use assessment (observation) skills. ► **Rationale:** To establish a baseline for client teaching.
 - e. Request demonstration of a skill previously learned or currently used (e.g., giving self an insulin injection). ► **Rationale:** Client's ability to demonstrate skill assists you to evaluate ability to perform, as well as mastery of previous teaching principles.
2. Develop an evaluation plan that determines extent of client learning goals.

Procedure

1. Identify personal characteristics.
 - a. Age, sex, developmental level.
 - b. Educational level.
 - c. Marital status.
 - d. Family composition and living situation.
 - e. Ethnic group and cultural practices pertinent to language skill and preference.
2. Identify resources available; both personal and community.
3. Identify values and attitudes toward self and others having his or her particular disease or condition.
4. Assess baseline knowledge—anatomy and physiology (normal and disease-related) and the disease process—by asking specific questions.
5. Assess current knowledge and ability to perform specific skills.
6. Assess patterns of coping.
 - a. Past experiences of self and others in relation to the disease.
 - b. Perception by client of how ill he or she is at this time.
 - c. Reactions to stress and ways of managing anxiety.
 - d. Current level of self-management.
 - e. Willingness of client to change behavior.

▲ Obtain data from Client Profile to prepare teaching plan.

Determining Readiness to Learn

Procedure

1. Determine client's physiologic readiness.
 - a. Degree of physical comfort of client (level of pain), level of alertness, ability to concentrate, degree of interest.
 - b. Acuteness of the illness and its influence on client's ability to learn.
 - c. Environmental factors that may affect client's degree of readiness.
 - d. Safety issues and need for supervision.
2. Evaluate client's psychologic readiness.
 - a. State of client's feelings and their influence on receptivity to learning. ► **Rationale:** An angry and hostile client is not going to absorb information until his or her anger is acknowledged or worked through.
 - b. Psychologic barriers (for example, the presence of denial) and their influence on the learning process.
 - c. Client's intellectual capacity and level of comprehension.
3. Assess client's willingness to make changes and be compliant with the teaching plan.
4. Assess family's ability and willingness to participate in teaching.
 - a. Determine willingness to participate in actual hospital instruction.
 - b. Determine cognitive ability to understand instruction.
 - c. Evaluate the extent of time and active participation of the family during instruction.
 - d. Assess the interaction of the client and family during client teaching. ► **Rationale:** This will provide data on potential compliance and noncompliance issues related to the teaching plan.
5. Assess the extent of support and actual care the family members will provide for the client at home. ► **Rationale:** This will determine the extent of the instruction necessary for the family.

Clinical Alert

The Joint Commission's Standards for Patient and Family Education require that client's learning needs, preferred learning styles, literacy level, educational level, language spoken and understood, and learning readiness are assessed.

Assessing Learning Needs

Procedure

1. Assess if client has learning needs related to diagnosis, hospitalization, surgical procedures, or treatments.
 - a. Ask specific questions relative to what physician has told client related to specific learning need(s).
 - b. Ask client what he/she is most interested in learning about specific learning need(s).
 - c. Ask client to tell you in his/her own words what they know about specific learning need(s).
2. Interview client to determine what his/her daily life is like. ► **Rationale:** The information will assist you in determining impact of changes in client's lifestyle brought on by illness or condition. This will help you determine how to approach the teaching plan.
 - a. Ask client to describe his/her usual daily routine.
 - b. Determine whether anything has changed with this pattern since illness began.
 - c. Describe hobbies or sports activities in which client participates.
 - d. Describe normal workday and what activities are involved with employment, if still working.
 - e. Discuss usual family responsibilities. Will the family be involved with his/her care?
3. Determine client's age and developmental level. ► **Rationale:** Knowing client's developmental level is necessary to provide the most effective teaching strategies.
4. Determine client's learning style. ► **Rationale:** This will assist in matching the most appropriate teaching strategy for client education.
 - a. Ask questions related to what time of day he/she learns best.
 - b. Determine whether he/she learns best by reading, listening, hands-on learning, or a combination of styles.
 - c. Use a commercial learning style inventory, if available.

▲ Include family in teaching, particularly if they will play a role in caring for client.

5. Complete a cultural assessment. ▶ **Rationale:** To develop a culturally responsive teaching plan based on client's beliefs.
 - a. Determine client's belief about illness.
 - b. Determine how strong the client's belief system is relative to his/her traditional culture.
 - c. Determine whether he/she uses folk medicine practices and uses a traditional healer. Clients from Asia, Africa, and South America are more likely to maintain this cultural component of their former country.
 - d. Identify whether traditional dietary habits are practiced in the home. If so, these should be included in the teaching plan, particularly nutritional counseling.
6. Determine client's educational and literacy levels.

▶ **Rationale:** Clients may seem disinterested in learning when in fact they do not understand what is being said and are embarrassed to ask. This can lead to missed physician appointments, noncompliance with treatment or medication usage, and even disability.

 - a. Determine client's reading level by measuring his/her reading and comprehension skills.
 - b. Use a test of reading and comprehension to obtain a client profile before beginning teaching process.

▶ **Rationale:** To determine most appropriate written material for client.
7. Assess client's ability to speak and read English.
 - a. Determine whether client requires an interpreter during assessment of learning needs and teaching process.
 - b. Ensure that words you use in client's language are correct for the situation.
 - c. Do not use slang that could be misunderstood.
 - d. Use simple words and phrases to allow interpreter to relate the intent of your statement.
8. Use assessment data and assessment instrument to jointly determine client's learning needs: educational, physical, psychosocial, and financial needs.
9. Formulate needs as goals.
10. Prioritize learning needs or goals.
11. Review with client alternative resources available to accomplish goals.
12. Determine ability of facility, family, staff, or multidisciplinary team to meet goals or learning needs.
13. Identify potential barriers to learning.
 - a. Physical: visual or auditory, pain level, literacy level, reading level.
 - b. Emotional barriers: stress or anxiety, inability to focus on information.
 - c. Language or culture: ability to understand and speak English, beliefs about health, folk practices, or communication style differences.
14. Obtain verbal or written contract with client for educational program.
15. Refer client to other resources or agencies when appropriate.

Clinical Alert

Agencies contract with telephone language lines to provide interpreter services. These services are available through AT&T Language Line Services and Pacific Interpreters Inc. on a 24-hour basis and in over 140 languages.

Family Assessment is an integral part of planning an effective teaching plan if family members will be affected by, or part of, the care of the client. Include the following information in the assessment:

- Which family members will be involved with care of client?
- Has client approved that family members be given confidential medical information?
- Can family members provide necessary care or will additional support be necessary?
- Does home environment support client's care needs?
- Are any changes to home necessary to provide a safe environment?
- Do family members speak English and have basic literacy skills?
- Are there any cultural belief conflicts that could inhibit adequate care in home?
- Do family members interact in a supportive manner with the client?
- What do family members know about the client's condition? Do they need additional teaching?

Determining Reading Grade Level

Readability Formulas

The Fry Formula assesses three samples of 100 words from different parts of a written handout and is useful to determine client's reading grade level. The Simplified Measure of Gobbledygook (SMOG) formula is very similar. The Fry Formula plots the average number of syllables and average number of sentences on a graph that then shows grade level. The SMOG formula also measures the number of syllables in a particular sample of written material, which is then converted by a chart that determines reading grade level.

The Rapid Estimation of Adult Literacy in Medicine (REALM) reading test can be easily administered in a few minutes. This test provides the reading grade level for clients who read below ninth-grade level. Words the client reads are all common health terms. The client reads as many words as he/she can correctly pronounce. A chart is used to convert raw scores obtained from word reading into a reading grade estimate.

Determining Appropriate Teaching Strategy

Procedure

1. Consider the following factors when determining appropriate strategy:
 - a. Input from client about how he or she learns best.
 - b. Specific task or nature of the content to be transmitted and how it is best learned.
 - c. Client attention span and retention ability.
 - d. Reading level of client.
 - e. Teaching materials and resources available. Electronic material is available for client education; it is used particularly for medications, diagnostic tests, and diagnoses.
 - f. Time, availability, skills, and abilities of staff; appropriate use of paraprofessional and professional staff.
 - g. Participation by members of other healthcare disciplines as part of a team.
 - h. Determination of most appropriate time for teaching.
 2. Use appropriate reading material for individual client.
 - a. Determine reading level of written material.
 - b. Use a readability formula to determine most appropriate written information for client.
 - c. Use brochures, handouts, and written material written at a sixth-grade level if client has low literacy skills.
 - ▶ **Rationale:** Seventy-five percent of the adults in the United States should be able to read the material.
 - d. Use short, common words in written material.
 - ▶ **Rationale:** Medical terminology may be misunderstood.
 - e. Make sentences 10 words or less and written in active voice.
 - f. Make paragraphs short with one focus.
 - g. Use large type (fonts) and lowercase letters.
 - ▶ **Rationale:** Large font size is easier for clients with visual impairments or elderly clients, and lowercase letters are easier to read.
 - h. Use diagrams and photos whenever possible to make a point.
 - i. Set realistic goals and only one or two objectives for each teaching session.
 - ▶ **Rationale:** Overloading client with information will not allow him/her to master information necessary for compliance.
 - j. Ensure client completes a return demonstration, if appropriate.
 - ▶ **Rationale:** This assists you to determine the extent to which client understands information presented. The greater the understanding and ability to perform a particular skill, the greater the compliance to treatment.
3. Determine which type of teaching strategy will be effective in a given situation.
 - a. Group process: use of principles from group dynamics, mental health, or other related fields to enhance learning or behavior changes in a small group setting.
 - b. Lecture–discussion: presentation of content in a didactic fashion with opportunity for questions and interaction during or at the conclusion of the presentation.
 - c. Demonstration–return demonstration: demonstration (videotape) by the instructor with practice by the learner and return demonstration of mastery of the skill.
 - d. Role playing: assumption of roles by various participants or learners for the purpose of clarifying various aspects of a situation.
 - e. Games: structured (age-appropriate) game situation with rules designed for the learner to accomplish specific educational objectives.

▲ Determine which teaching strategy will be most effective for client.

Components of a Teaching Plan

- Client learning needs
- Expected learning outcomes
- Teaching content organized from simple to complex
- Teaching methods and tools
- Barriers to learning and readiness to learn
- Evaluation tools

EVIDENCE-BASED PRACTICE**Silent Clients**

A qualitative study in Finland (N = 38 patients, N = 19 nurses) found that 18 clients who were identified as aloof or silent spoke little about themselves and followed the lead of the nurse. The nurse often used communication techniques that did not facilitate communication and were nontherapeutic. The study concluded that client's quietness or silence in client education settings "was complex, supported by the hospital's institutional standard, nurses' lack of expertise, and client's restrictive and face-saving speech." This underscores the necessity that client education be client focused, based on client's knowledge, experience, and preferences, rather than comply to a preset standardized, structured format.

Source: Kettunen, T., Poskiparta, M., Liimatainen, L., Sjögren, A., & Karhila, P. (2001, May). Taciturn patients in health counseling at a hospital: passive recipients or active participators? *Qualitative Health Research*, 11(3), 399–422. From Mynatt, S. (2002, January). Patient taciturnity in health counselling was understood in terms of 4 participation frames. *Evidence-Based Nursing*, 5(1), 30.

4. Select appropriate teaching adjuncts based on developmental level, learning style, and reading literacy.

◀ After selecting the appropriate setting, choose the teaching adjuncts.

▲ Client education using computerized program assists nurse in providing information that is relevant to client's needs.

- a. Videotape or videocassette programs.
 - b. Films; slide and tape presentations.
 - c. Diagrams, charts, and illustrations.
 - d. Programmed instruction materials, i.e., computer/Internet.
 - e. Books.
 - f. Pamphlets and other written handouts.
5. Provide language-specific material for non-English-speaking clients.
 - a. Photos.
 - b. Models of specific body parts.
 - c. Audio tapes in specific language.

Selecting the Educational Setting**Procedure**

1. Choose an appropriate setting based on selected teaching strategy and available facility space.
2. Evaluate types of setting most appropriate to individual client and family learning needs.
3. Consider an informal setting.
 - a. Spontaneous teaching interactions between nurse and client can occur at any time in any setting.
 - b. Usually no formal plan or evaluation tool is used.
4. Consider a formal setting.
 - a. Teaching is carried out in a specified area of the facility such as an in-service classroom.
 - b. Teaching can occur independently, such as with audiovisual programmed instruction modules, or in a group setting.
 - c. Formal plan for the teaching program includes written goals, objectives, teaching strategies, content, and evaluation method.

▲ Preoperative teaching using computerized module.

Implementing the Teaching Strategy

Procedure

1. Gather teaching materials appropriate for client's learning needs and teaching strategy.
2. Sit with client in designated setting, and establish a warm and accepting relationship. ► **Rationale:** This is conducive to teaching and assists client in learning.
3. Specify previously established mutual goals and behavioral objectives of the program. ► **Rationale:** Mutually agreed-on goals promote acceptance of teaching strategy by the client.
4. Clarify or reclarify contract, agreements, or expected outcomes with individual or group. ► **Rationale:** Beginning at the level of understanding of person or group facilitates the process.
5. Assess teaching situation for any modifications needed and adjust plans accordingly.
6. Teach content or components of the plan to client. ► **Rationale:** Sticking to the plan and not deviating or going off on a tangent reinforces your commitment to help client master the content.
7. Use appropriate communication skills throughout session. **Rationale:** Therapeutic communication techniques enhance learning environment.
8. Request feedback (evaluation interchange) during teaching process. **Rationale:** Feedback lets you know how client is understanding content and allows for modification as indicated.
9. Plan for short teaching sessions on a frequent basis.
10. Adhere to agreed-upon starting and ending times; negotiate any changes. ► **Rationale:** This encourages client to trust you.
11. Provide closure to teaching situation by summarizing and reiterating agreements made, actions to be taken, or subsequent events to follow.
12. Provide positive reinforcement if not done previously. ► **Rationale:** This approach increases self-esteem and encourages learning in client.
13. Terminate teaching session by establishing time for next client contact.
14. Do post-assessment of your own participation, and plan for corrections and improvements in presentation. ► **Rationale:** Ongoing evaluation assists in final step of nursing process evaluation.
15. Reinforce teaching throughout hospitalization.
 - a. Use return demonstration of skills frequently throughout hospital stay.
 - b. Review teaching content through use of videotapes and reading material.
 - c. Provide positive reinforcement for changes in behavior.
 - d. Discuss teaching content and written information by asking pertinent questions and providing answers to client's questions.
16. Send teaching plan and written materials home with client and family. Computer-generated written material (medications, tests, diagnosis, etc.) should be discussed verbally, in addition to providing written material.
17. Place copy of written instructions in chart for documentation. Instructions must be signed by client. This stays in chart.
18. Provide copy of teaching plan and written material to home health agency if referral has been made for visiting nurse. ► **Rationale:** This promotes consistency in information dissemination and reinforces teaching provided to client while hospitalized.
19. Document your teaching on specific client teaching forms, or electronic forms.

Documentation should include:

 - a. Educational assessment/comprehension level.
 - b. Knowledge and skill level of learning need(s).
 - c. Motivational level (interaction during teaching session).
 - d. Learning barriers (language, speech, vision, hearing).
 - e. Overall goal achievement.

▲ Demonstration is an important component of teaching strategy.

EVIDENCE-BASED PRACTICE

Computer-Generated Client Education

Computer-generated client education has been studied several times. Leaffer and Gonda found that clients taught how to use the Internet to retrieve health information were still using it 90 days later, and 66% of them were taking the information they found on the Internet to their healthcare providers when they had a scheduled visit. More than 50% of the clients stated that using the Internet made them feel more knowledgeable, and thus they were more satisfied with the treatment they received.

Source: Leaffer, T., & Gonda, B. (2000). The Internet: An underutilized tool in patient education. *Computer Nursing*, 18, 47–52. http://www.medscape.com/viewarticle/478283_print

Baker et al. surveyed 4,764 individuals, and the results indicated that 40% stated they had used the Internet for information or advice about health or health care during the last year. Sixty-seven percent stated that using the Internet improved their understanding of symptoms, conditions, or treatments.

Source: Baker, L., Wagner, T. H., Singer, S., & Bundorf, M. K. (2003). Use of the Internet and e-mail for health care information: results from a national survey. *JAMA*, 289(18), 2400–2406.

Evaluating Teaching/Learning Outcomes

Procedure

1. After demonstrating skill(s), ask client to complete a return demonstration. Evaluate client's ability to perform tasks.
2. Ask client and/or family to explain demonstration using own words.
3. Ask client and/or family specific questions regarding information provided. ► **Rationale:** To determine necessity of reinforcing or reteaching information.
4. Develop a simple pre- and posttest to determine client's knowledge base.
5. Develop hypothetical situations for client to problem solve. ► **Rationale:** This will help determine client's understanding of disease or condition.
6. Use an evaluation tool, if appropriate. ► **Rationale:** Evaluating with a specific tool focuses the evaluation phase better.

▲ Request a return demonstration to evaluate client understanding.

BARRIERS TO LEARNING CODES		NEEDS CODES		TEACHING METHOD CODES		EVALUATION CODES

Comments (include Date/Time and Initials):

INITIALS	SIGNATURE/TITLE	DEPT.	INITIALS	SIGNATURE/TITLE	DEPT.

▲ Multidisciplinary teaching record.

- a. Evaluate forms, format, and types of tools available for evaluation.
 1. Pretest–posttest: measures changes in areas such as knowledge level, attitudes, and values.
 2. Questionnaire: completed by client to report attitudes, certain behaviors, and, most frequently, level of satisfaction with the teaching program.
 3. Physiologic tracers: determined before teaching episode to be the criterion of measurement of success

- (e.g., changes in blood pressure values after teaching program for hypertensive clients).
4. Direct observation of behavior changes: report of level of performance during return demonstrations.

- b. Choose an evaluative tool based on goals and objectives of the teaching program. ► **Rationale:** The purpose is to achieve goals, thus evaluative tool should be based on goals.

DOCUMENTATION for Client Education

- Client's learning needs
- Client's learning objectives and goals set by client and staff
- Topics or subjects covered as a part of client education process, such as medications, procedures, dietary plan, activity restrictions, or follow-up care
- Teaching strategies used
- Degree of client's participation in the teaching activity
- Client's reading level
- Client's learning style preference
- Progress in meeting the expected outcomes of teaching
- Client's emotional response to the learning process
- Information or equipment sent home with client
- Client's developmental level

CRITICAL THINKING Application

Expected Outcomes

- Client's knowledge regarding his or her health status has increased.
- Client's ability to make informed and effective health-related decisions, based on accurate information and awareness of self, has improved.
- Effective use of the healthcare delivery system has been promoted.

- Continuity of care and information exchange has occurred between health agencies or between the hospital and client's home and family.
- The nurse has evaluated his or her teaching effectiveness and revised the plan, teaching style, and content as necessary.
- Increased compliance to medical regimen as demonstrated by client's ability to manage condition/disease process.

Unexpected Outcomes

Client's health status or treatment compliance has not improved as a result of the teaching program.

Alternative Actions

- Reevaluate nursing care plan according to the nursing process.
- Reassess client for barriers to learning.
- Assess client's reading and developmental levels.
- Reevaluate testing tool.
- Review client's learning style preference.
- Determine readability level of written material.
- Problem solve with client as to next step to take.
- Request assistance from in-service consultant for determining which aspects of the teaching program were not successful and why.
- Assist in revising parts of the program and restructure for individual client needs.

Client is hostile to teaching program.

- Attempt to determine underlying reason for hostility.
- Terminate this session of teaching program, but tell client you will return tomorrow or at a later time.
- Bring another nurse along to assist you in teaching as well as to help you evaluate reason for hostility.

Client's ability to make informed and effective health-related decisions, based on accurate information and awareness of self, has not improved.

- Assist client to take realistic responsibility for ineffective decisions without guilt and shame attached.
- Assist client to identify those areas in which he or she is willing to make changes and support development of a plan of action.
- Refer to other resources such as groups with like conditions (e.g., cancer, diabetes).

(Continued)

Unexpected Outcomes

Client is unable to understand client teaching due to language barrier.

Alternative Actions

- Identify a volunteer or family member who can be used as an interpreter.
 - Use the AT&T Language Line.
 - Obtain teaching material in client's native language.
 - Use photos or models, or make drawings that depict task to be performed.
-

Discharge Planning

Nursing Process Data

ASSESSMENT Data Base

- Determine client discharge planning needs.
- Determine if client is in a high-risk category.
- Assess special needs of client for individualized planning.
- Assess need for multidisciplinary healthcare workers.
- Determine information needed for compiling discharge summary.

PLANNING Objectives

- To complete a discharge risk factor assessment when admitting a client
- To determine healthcare workers needed for discharge planning
- To make appropriate referrals for client discharge
- To complete discharge teaching
- To develop a discharge plan
- To complete a discharge summary

IMPLEMENTATION Procedures

- Preparing a Client for Discharge130
- Completing a Discharge Summary131

EVALUATION Expected Outcomes

- Client's discharge plan is initiated upon admission.
- Client's discharge teaching is completed before discharge.
- Client's plan for discharge is based on identified long-term goals.

Critical Thinking Application132

- Expected Outcomes132
- Unexpected Outcomes132
- Alternative Actions132

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Preparing a Client for Discharge

Procedure

1. Obtain admission history, physical, and hospital progress notes.
2. Determine risk factors for discharge planning at time of admission.
3. Refer high-risk clients to discharge coordinator or social service department, if appropriate.
4. Develop discharge plan (if not already completed) including short- and long-term goals in conjunction with physician and client. Plan components should include:
 - a. Diet.
 - b. Medications.
 - c. Treatments.
 - d. Physical activity limitations.
 - e. Signs and symptoms to report.
 - f. Follow-up medical care.
 - g. Equipment.
 - h. Appropriate community resources.
5. Evaluate degree to which client education plan was implemented; reinforce aspects that were incomplete or refer to home agency.
6. Identify need for follow-up care after discharge in conjunction with physician.
7. Make appropriate agency referrals.
8. Complete a discharge referral form, and communicate directly with referral agency about client.

NOTE: Healthcare agency may prefer their own discharge form to be completed rather than documentation in the nurses' notes.

9. Develop written discharge instructions for client and family, including medication administration times, dose, and side effects; treatments to be carried out at home for in a facility, potential side effects or complications from treatments or surgery; when to notify physician regarding symptoms; etc.
10. Update client care plan, and send copy to referral agency.
11. Send client teaching plan and materials to referral agency. ► **Rationale:** To maintain consistency in client teaching.
12. Document discharge summary.

▲ Discharge teaching is an important component of the discharge plan.

DISCHARGE PLAN		Medicare No. _____

▲ Sample discharge plan form.

Completing a Discharge Summary

Procedure

1. Document a complete physical and psychosocial assessment at time of discharge.
2. Review vital sign ranges, and state latest vital signs.
3. Identify activity level of client.
4. Describe use of adaptive devices or equipment needs.
5. Review client teaching plan. Provide explanation of areas where teaching was adequate and where additional reinforcement is required.
6. Identify prescribed medications, dosage, and administration times. Provide information on client's knowledge of medication.
7. Describe goal achievement based on client care plan. Describe action taken if goal not achieved.
8. Identify referral agencies contacted.
9. Provide information regarding instructions on physician office visits, appointments to healthcare agencies, or support services.
10. Describe client's condition at time of discharge.
11. Document discharge instructions provided to client and family.

▲ Computer programs provide discharge teaching that is accurate and inclusive.

12. Describe method of discharge (e.g., wheelchair) and person accompanying client at discharge.
13. State means of discharge transportation (e.g., private car, ambulance).
14. Specify discharge facility where client is going.

NOTE: Many facilities have developed forms that combine discharge summaries and client instructions.

DOCUMENTATION for Discharge Planning

- Discharge teaching completed, and additional teaching need(s) necessary after discharge
- Discharge plan completed, including risk factors, short- and long-term goals, and degree to which plan was implemented
- Summary of client care during hospitalization, client interventions provided
- Need for follow-up after discharge
- Referral agencies contacted
- Discharge summary form completed; discharge instructions including medications, treatments, etc.
- Client's condition at time of discharge
- Date, time, location, and mode of discharge

Legal Considerations

Lawsuit Regarding Follow-Up Discharge Teaching: *Roberts v. Sisters of St. Francis Health Services (1990)*

A 3-year-old presented to the emergency room with an upper respiratory infection. The child was discharged home in the care of her mother. The nurse gave both verbal and written instructions, including a pretyped instruction, for treating a fever. The child's condition worsened a few days later and the mother brought the child to another hospital, where the child subsequently died from meningitis.

The mother brought a lawsuit against the first hospital for failure to provide adequate instructions upon discharge. The suit contended the nurse was negligent for not providing written follow-up instructions to see another physician and not warning the mother to observe

for symptoms of meningitis. The court found in favor of the nurse stating she was not negligent and that she provided written instructions for fever treatment and other instructions. The court held that the mother was negligent for not seeking help when the child needed additional care.

Based on this court ruling, remember to give both written instructions and verbal explanations. Written client teaching sheets should be used to reinforce, not replace, discharge teaching. It is recommended that this type of information (teaching sheets) should be written at the sixth-grade reading level. Non-English-speaking clients should have instructions translated into the client's primary language.

CRITICAL THINKING Application

Expected Outcomes

- Client's discharge plan is initiated upon admission.
- Client's discharge teaching is completed before discharge.

Unexpected Outcomes

Client is discharged before discharge plan is completed.

Discharge plan does not contain adequate data.

Goals of discharge plan were not accomplished.

Discharge referral plan is not implemented and client receives no referral notice before discharge.

- Client's plan for discharge is based on identified long-term goals.

Alternative Actions

- Continue to complete discharge plan, and send to referral agency.
- Verbally communicate to referral agency and discuss discharge needs of client.
- Reassess parameters of a discharge plan, and revise accordingly.
- Elicit assistance from another nurse or supervisor to revise discharge plan.
- Attempt to assess reason goals were not met.
- Reformulate or revise goals so that they are mutually agreed on and more realistic.
- Request assistance from expert healthcare workers or in-service consultant.
- Attempt to contact other referral agencies to provide continuity of care for client.
- Notify physician and discharge coordinator (if available) of necessity of providing follow-through care after discharge.

GERONTOLOGIC Considerations

Teaching Strategies

Memory changes occur with the elderly population.

- There is better short-term memory with auditory rather than visual presentation of information.
- Structure should be brief and simple.
- Repetition is important.
- Older clients learn better by doing, using multiple senses, than by reading instructions.
- Memory is better for things considered important.
- Clients remember best what is told *first*.
- Declining mentation is not inevitable with aging, but some memory loss is usual.

Retention facts that underlie teaching strategies. People remember:

- 5% to 10% of what they read.
- 10% to 20% of what they hear.
- 30% to 50% of what they hear and verbalize.
- 70% of what they verbalize and write.
- 90% of what they say as they perform a task.

Interventions for teaching the elderly

- Speak distinctly and sit close to learner.
- Face the learner so that lip reading can supplement hearing.
- Use visual aids and verbal teaching.
- Decrease extraneous noise.
- Use printed materials with large type and high contrast.
- Limit use of blue, green, and violet illustrations. Use red.

- Avoid totally dark room for audiovisual presentations.
- Increase time allowed for psychomotor skills, and allow time for repetition.
- Slow the pace of presentation.
- Give small amounts of information at one time.
- Use analogies and examples to explain information. Mnemonic devices are helpful to compensate for imperfect memory.
- Establish attainable short-term goals.
- Encourage participation in goal setting and planning.
- Integrate new behaviors with previously learned ones.
- Focus on problem solving, not just delivery of facts.
- Apply teaching to present situation.
- Bolster self-esteem and self-confidence in self-care.
- Stress the “why” of what is presented.
- Recognize that the elderly client may prefer to be alone when learning.
- Make follow-up phone calls, if indicated, to check on the client, reinforce teaching, or to clarify any misunderstanding.

Discharge Planning

A discharge plan for the elderly contains some of the same components as a plan for a younger adult; at every step in the plan, however, the coordinator must remember that this is an elderly person and he or she must be evaluated for the ability and resources to manage at home. Include family and/or

caregiver in discharge planning. This is especially so if the elderly person lives alone or with another elderly person. Following are several issues that the discharge planner must consider when formulating the plan:

- Was the person functioning independently at home before hospitalization, and is it realistic to expect him/her to do so again?
 - Does this person have capable family or friend resources to assist with functioning in the home (in addition to the necessary professional resources)?
 - What is the baseline health status of the person (assuming he/she recovers from the current hospitalization), and does this status allow for independent functioning after hospitalization?
 - What are the long-term financial resources of the elderly person and do special measures need to be initiated for coverage?
 - If the elderly person cannot return to the facility he or she was in before hospitalization, what special arrangements need to be made?
- Special considerations the discharge planner must take into account when coordinating a plan for an elderly individual. For example:
 1. Does the person have a hearing or visual impairment that interferes with learning?
 2. Does the teaching need to be done in written form (not just verbal)?
 3. Would a return demonstration of care procedures by the home health nurse be beneficial after the client has returned home?
 4. Will the anxiety level of the client to be discharged interfere with understanding and learning?
 5. Is the health status of the client a way of gaining attention? If so, this need should be separated from the needs of self-care after discharge. It is important to convey this need to the follow-up caregiver.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- RNs must develop the teaching and discharge plans based on the assessment of client needs. The Nurse Practice Act sets the standards for who assesses and plans client care. Multidisciplinary team input is critical and a major component of both plans. The nurse is usually the coordinator of most client care plans and teaching plans.
- Once the teaching and discharge plans have been developed, other members of the healthcare team may participate in implementing them.
- LVN/LPNs follow the guidelines established in the teaching plans. They can assist with the discharge plans; however, an RN must write the discharge referral summary and communicate with the referring agency.

Communication Matrix

- The teaching plan should be developed in concert with the client and family. Mutually acceptable goals should be established with realistic time frames.
- The teaching plan is initiated early in the hospitalization. It must be written because it is a permanent part of the client record. It is updated as goals are achieved.
- Team members are kept apprised of the progress toward meeting the teaching goals by updates during shift report.
- Client information is disseminated between referral agencies and the hospital through a written discharge summary and/or referral sheet. The data in the summary includes pertinent information on the hospitalization and the condition at discharge, the medications and treatments the client is to continue to take, and specific equipment required for client care.

CRITICAL THINKING Strategies

Scenario 1

Mr. John Johanson, age 58, was admitted to the medical unit with a diagnosis of heart failure. He is African American, 5'7", and weighs 260 pounds. He is a cross-country truck driver. He lives alone when not working. He usually watches TV and eats fast foods or frozen dinners. This is his second hospital admission in the last month. His vital signs are BP 230/108, P 108

and irregular, R 36. He has bibasilar rales and a 3+ pitting edema of the lower extremities. His point of maximal impulse (PMI) is at the sixth intercostal space (ICS), midaxillary line. He states he is short of breath and has had difficulty ambulating the last few days. He states he has tried to lose weight but even after dieting he gains more weight back. When asked about his

smoking habits, he states he knows he is not supposed to smoke and he has tried to stop, but with his work it is too difficult because he is alone so much. He states he is on blood pressure drugs, but unsure of the name.

1. Identify the current nursing diagnoses by priority and provide rationale for answers.
2. From these data, identify the teaching needs by priority and develop a teaching plan for Mr. Johanson.
3. Are there any cultural considerations that need to be taken into account when considering his teaching plan? If so, identify actions you will take relative to the cultural considerations.
4. Briefly outline how you will determine when it is appropriate to initiate the teaching plan.
5. Describe the discharge plan you might develop for Mr. Johanson.

Scenario 2

A very young mother brings a 6-month-old child to the emergency room and tells the triage nurse that she doesn't know what is wrong her child, but she doesn't seem to be "normal."

The child is assessed by the pediatrician and the child is admitted for further testing. The pediatrician's admitting diagnosis is *failure to thrive*. The child's weight is only 5 pounds over what it was at birth (7lb 2 oz), and the child is still not turning over from back to front. As the admitting nurse, you need to begin the discharge plan and the teaching plan. Based on the limited information from the physician and the admitting diagnosis, complete the following scenario.

1. What information will you need to obtain before you can plan for discharge?
2. What information is necessary to obtain before you can develop a teaching plan?
3. What approach will you take with the mother in order to obtain the necessary information for both the discharge and teaching plan?
4. Describe the nurse's role in client teaching for this mother.

NCLEX[®] Review Questions

Unless otherwise specified, choose only one (1) answer.

1. The healthcare team member (HCT) who assumes the leadership role in directing the educational plan for the client and/or family is usually the
 1. Physician.
 2. HCT member whose role represents the greatest teaching need requiring education.
 3. Discharge planner.
 4. Nurse.
2. Clients at high risk for discharge, usually requiring specific instructions, include those who are/have
 1. Living alone.
 2. Multisystem issues.
 3. Small children.
 4. A job requiring them to return to work immediately.
3. Data for which one of the personal characteristics below is least necessary to obtain when planning for client teaching?
 1. Educational level.
 2. Family composition and living situations.
 3. Ethnic group.
 4. Employment/occupation.
4. It is imperative the client's family participate in teaching activities. What actions would *not* be used to determine their ability and willingness to participate?
 1. Assess cognitive ability to understand instruction.
 2. Assess how attentive they are to the client and how often they visit.
 3. Evaluate extent of time and active participation of family during instruction.
 4. Evaluate interactions between client and family.
5. You have been assigned to develop a teaching plan for a client being discharged after a laparoscopic procedure for gallbladder removal. Your priority intervention is to
 1. Assess the home environment for specialized equipment needs.
 2. Determine when the client plans to return to work.
 3. Determine who will be at home with the client after discharge.
 4. Assess the client's usual lifestyle and daily activities.
6. You are developing the strategy for an initial teaching plan for a 24-year-old client admitted with newly diagnosed acute leukemia. Which one of the factors would *not* be taken into consideration as you develop the initial teaching plan?
 1. Attention span and retention ability.
 2. Reading level.
 3. Input from client on how he/she learns best.
 4. Support for client at home.
7. Nurses evaluate the effectiveness of the teaching strategies by

Select all that apply.

 1. Asking the client to do a return demonstration of the skill being discussed.
 2. Having the client take a posttest of the teaching content.

3. Asking pertinent questions relative to the teaching content.
 4. Summarizing the teaching content they presented.
 5. Clarifying misinformation after each teaching session.
8. A client becomes very agitated and hostile when you approach him to begin client teaching for discharge. Which one of the actions would *not* be an appropriate action by the nurse?
1. Begin the teaching and explain you are required to complete the teaching.
 2. Attempt to determine the reason for the agitation and hostility.
 3. Do not begin the teaching program but explain that you will return later.
 4. Ask another nurse to assist you in assessing the reason why the client is refusing the teaching.
9. Documentation for discharge includes which of the following statements?
- Select all that apply.**
1. Summarize vital signs during hospitalization and include latest vital signs.
 2. Describe the activity level of the client during hospitalization.
 3. Summarize the teaching plan and client's response to teaching.
 4. Summarize nursing interventions provided during hospitalization.
 5. Provide intake and output findings during hospitalization.
10. Gerontologic considerations for client education should include which one of the following concepts for older clients? They
1. Learn best through reading material.
 2. Remember 30% to 50% of what they read.
 3. Need extraneous noises decreased while teaching is being presented.
 4. Learn best in group settings.
-

Safe Client Environment and Restraints

LEARNING OBJECTIVES

1. Define the term *adaptation*.
2. Describe three characteristics that influence adaptation.
3. Outline four sociocultural dimensions of environmental adaptation.
4. State two nursing diagnoses relevant to maintaining a safe environment.
5. Outline the objectives for providing a safe environment.
6. Identify clients who are at high risk for falls.
7. List and briefly describe at least four guidelines for using restraints to prevent mechanical injuries.
8. Describe nursing actions for clients with seizure activity.
9. List the guidelines for providing safety when clients are receiving radioactive materials.
10. Demonstrate two methods of client evacuation when a fire occurs in a nursing unit.
11. Demonstrate the application of wrist restraints.
12. Demonstrate the application of a torso/belt restraint.
13. List the components that should be included when charting for application of restraints.
14. Describe The Joint Commission Standards for restraint use.
15. Describe the Home Assessment Checklist.

TERMINOLOGY

Adaptation ability of an organism to adjust to a change in environment.

Ambiance the pervading atmosphere of the surrounding environment.

Ambulation to move from place to place by walking.

Aseptic sterile; a condition free from bacteria and infection.

Assessment critical evaluation of information; the first step in the nursing process.

Behavior a person's total activity—actions or reactions; especially conduct that can be observed.

Centers for Medicare and Medical Services (CMS) previously named Health Care Financing Administration (HCFA).

Chemical restraint use of a sedating psychotropic drug to manage or control behavior.

Comprehensive health care a total system of health care that takes the whole person into account.

Contaminated waste radioactive waste, which, if improperly disposed of, may be harmful or cause a radiation hazard.

Decibel a unit for measuring difference in acoustic signals; a unit of intensity and volume of sound.

Ecosystem the biologic and physical dimensions of the environment that refers to all living and nonliving elements.

Epidemiologist one who studies the causes, distribution, and frequency of disease outbreaks in a human community.

Homeostasis a state of equilibrium of the internal environment.

Hospital acquired infection (HAI) (formerly termed nosocomial) infection or disease originating in a hospital.

Hygiene pertinent to a state of health and its preservation.

Limitation the state of being limited or restricted.

Licensed independent practitioner (LIP) an individual licensed by the state or institution who is permitted to provide and monitor conscious sedation to clients and order restraints or seclusion. This practitioner is either a

physician, dentist, advanced nurse practitioner, or physician's assistant.

Maladaptation inability of an organism to adjust to a change in environment.

Mechanical restraint containment of a person in a chair or bed to provide safety.

Nosocomial formerly used term for infection or disease originating in a hospital (now called hospital acquired infection).

Physical restraint any manual method or physical or mechanical device that restricts freedom of movement or normal access to one's body, material, or equipment, attached to or adjacent to the client's body that he/she cannot easily remove. Holding a client in a manner that restricts his/her movement.

Physiologic in accord with or characteristic of the normal functioning of a living organism.

Psycho prefix referring to the mind or mental processes of an individual.

Psychosocial a term that refers both to psychologic and social factors.

Restraint any involuntary method (chemical or physical) of restricting an individual's freedom or movement, physical activity, or normal access to the body.

Seclusion the isolation of a client in a special room to decrease stimuli that might be causing or exacerbating the client's emotional distress, free from objects that could cause the client harm.

Sentinel event any unexpected occurrence involving death or serious physical or psychological injury or the risk thereof.

Sociocultural a term that refers both to society and culture.

Stress any emotional, physical, social, economic, or other factor that requires a response or change.

Supervise to direct or inspect performance; to oversee.

Therapeutic having healing or curative powers.

Thermal pertaining to using, producing, or caused by heat.

ORIENTATION TO THE CLIENT ENVIRONMENT

Maintaining Homeostasis

As a nurse, one of your primary responsibilities is to make sure your clients have a safe and comfortable healthcare environment. It is your responsibility to help clients adapt to this environment as well as to their health care in general.

From a holistic view, the term *environment* can generally be explained as the total of all conditions and influences, both external and internal, that affect the life and development of an organism. As human beings we are constantly exposed to changing physical, biologic, and social conditions. To survive, we continually assess our relationship to our changing

surroundings. We also learn how to make adjustments that help us control and improve our environment. This complex process is called *adaptation*.

Adaptation includes psychologic and physiologic adjustments. People in most situations are able to control or adapt to their immediate surroundings. Although no two people respond to the environment in exactly the same way, common principles related to adaptation can be found in all human beings:

- All adaptations are attempts to maintain optimum physical and chemical states, or homeostasis.
- Individuals retain their own identity and uniqueness regardless of the degree of adaptation required.
- Adaptation affects all aspects of human existence.

- Human beings have limits in the process and degree of their adaptation.
- Adaptation is measured in relationship to time.
- Adaptive responses to the environment may or may not be adequate or appropriate.
- Adaptive attempts may be stressful.
- The degree and process of adaptation varies from individual to individual.
- Adaptation is an ongoing process about which the individual may be consciously or unconsciously aware.

Each of us adjusts to our immediate environment in a way that is unique to us. When this environment changes suddenly, for instance when we are hospitalized, we may not be able to adapt independently to our immediate surroundings safely and comfortably. It is at this point that assistance must be provided.

CHARACTERISTICS THAT INFLUENCE ADAPTATION

The characteristics that make all people unique also provide information about the process of adaptation to the environment. These factors must be considered when assessing clients' needs and abilities to safely adjust to their immediate surroundings.

Age

A client's age is a critical factor in the assessment process. Because terms such as *elderly* and *young* can be interpreted in many different ways, the nurse may need to look at the client's developmental stage (physical and mental growth) rather than at the client's chronologic age.

As people develop, sensory receptors help process day-to-day events. Human beings learn how to protect themselves and how to adjust to changing needs through experiencing these events. During the learning process, young children may require entirely different protection than teenagers. Even a 30-year-old man who has learned through experience how to protect himself in a routine environment may not have adequate skills in an unfamiliar atmosphere.

The older adult often requires special assistance. Sensory and motor changes, such as slowness of movement, postural instability, decreased vision or hearing, and even diminished acuity for taste and touch, are not uncommon. These changes can result in an altered ability to sense and adapt to harmful environmental stimuli. The older person may not see or hear an approaching car, detect the taste of spoiling food, or move quickly enough to avoid falling.

Mental Status

The ability to perceive and react to environmental stimuli is closely related to mental status. Adapting to a new or different environment requires learning through experience and possessing a cognitive awareness of the immediate surroundings. Making adjustments to the environment requires stimuli to travel over the sensory pathways of nerves to the central nervous system. To respond to stimuli, such as avoiding a burn

from a hot object, motor neurons carry impulses to muscles to cause an involuntary reflex action, such as withdrawing the hand from hot water. Sensory impulses traveling to the cerebral cortex of the brain inform the person that this stimulus is potentially harmful. Voluntary movement then provides additional adaptation.

Consciousness is the state in which individuals are aware of themselves and their relationship to their surroundings. Unconsciousness indicates a lack of awareness and inability to cognitively respond to the environment. Levels of consciousness range from fully conscious to nonresponsive. Difficulty in adapting to the immediate environment due to alterations in mental status can manifest itself in a variety of ways:

- Confused clients often view their environment in a distorted way. This condition can lead to extreme behavioral changes, injury, or combativeness.
- Neurologically injured clients may have decreased perception of stimuli such as heat, cold, pain, or friction. In extreme cases, they may have no perception of any stimuli.
- Paralysis inhibits movement and is accompanied by a loss of position sense (dangling limbs or poor body alignment).
- Alterations in communication, sight, or hearing are barriers to identifying hazards and sharing fears or concerns with others.
- Fluctuating levels of consciousness create difficulty in promoting self-care and self-image.

Continuous assessment of changes in the client's ability to relate and adapt to the environment is essential. Ability to adapt influences the type and amount of assistance the client needs, especially while in less than familiar surroundings.

States of Illness

Illness or injury causes a person to focus more intensely on himself or herself. The very nature of disease or trauma requires the individual to use physical and mental energy to adapt to the situation and to become more egocentric. A client often cannot perform even the simplest daily activity. Fatigue or pain may render clients helpless. Assistance with activities, such as bathing, eating, skin care, and elimination, may be necessary.

Some medications produce such side effects as drowsiness, which prevent the individual from adequately assessing the environment. Perceptions may be distorted, and the client is more vulnerable to hazards.

Emotional stress and anxiety can occur in mild to acute degrees. Although mild anxiety very often increases perceptual awareness, acute anxiety reduces perceptual awareness.

Because an individual is able to focus only on a specific amount of stimuli at one time, additional stimuli that may be equally important are not perceived. Potential environmental dangers are not processed. The client whose energy is focused on pain may not even hear instructions from the nurse. Depressed clients also require assistance. Depression often results in slower than normal responses to stimuli. Alcohol, a central nervous system depressant, also causes dull, slow reactions to stimuli.

When pain, anxiety, illness, injury, weakness, medications, or even lack of sleep cause a decrease in sensory acuity, awareness of potential hazards is altered. The client may not be able to make the necessary biologic, physical, or emotional adjustments to adapt to the immediate environment. Any of these conditions necessitates immediate assessment and action.

PHYSICAL AND BIOLOGICAL DIMENSIONS

The influences that make up an environment include the basic categories of biological and physical conditions, and the third dimension termed sociocultural. The biological dimensions of our environment covered in this section include all living things, such as plants, animals, and microorganisms. Water, oxygen, sunlight, organic compounds, and other components in which living things exist and develop make up the physical dimensions of an environment.

As the nurse becomes more aware of the factors that affect environmental adaptation, a safe and comfortable atmosphere for the clients becomes a greater challenge. As you assess your clients and help them adapt to the environment of a health-care facility, you should consider the following essential elements: space, lighting, humidity, temperature, ventilation, sound levels, surfaces and equipment, safety, food and water, and waste disposal.

Adequate Space

Everyone needs space in which to grow and develop. This space may consist of a room or an area as small as a shelf or corner. No matter what form space takes, individuals need to feel they have control over it—that they can arrange it or decorate it to their liking.

Providing space for clients encourages stimulation and experimentation. Toddlers need the space of an area like a recreation room for discovery and motor skills, since playtime is their primary source of development. Adults often enjoy the social activities of a lounge but may also require well-defined personal areas, even if these areas are as simple as a bedside table or a bulletin board.

▲ Provide a comfortable environment with space for personal effects.

Natural and Artificial Light

Light, like space, is necessary for growth and development. The production of vitamin D, a critical component of bone metabolism, occurs from ultraviolet radiation on the skin. Natural light also assists in wound healing. In a hospital setting, natural light can be used to decrease feelings of isolation and to encourage clients to continue their normal routine.

Whether natural or artificial, adequate light is essential for the preservation of sight, for safety, and for accurate assessments and nursing care. Because eye strain, as well as nervousness and fatigue, can result from improper lighting, care should be taken to avoid glare, sharp contrast, and flickering lights. Night lights promote safety and orientation for the elderly.

Humidity and Temperature

The ability to adapt to changes in humidity or temperature is directly related to comfort. Most people in this country are comfortable at a room temperature of between 18.3° and 25°C (65°–77°F) with the humidity at 30% to 60%. People in other cultures function equally well at lower or higher readings.

Conditions that may inhibit a person's ability to adjust to high temperatures include excessive physical work, dehydration, extremes in age (the very young and very old), decreased physical fitness, and inappropriate clothing. An individual who has difficulty adapting to high temperatures may experience a rapid rise in pulse rate, cramps, nausea, and vomiting. Severe inability to adapt to heat can result in heat stroke and death.

An individual who has difficulty adapting to lower temperatures may experience a change in behavior, depressed vital signs, and eventual unconsciousness. Hypothermia, or abnormally low body temperature, occurs when there is an imbalance between heat loss and heat production.

Extremes of heat or cold increase the incidence of infection and add to discomfort. Temperatures in healthcare institutions can be regulated with air conditioners and dehumidifiers, although care should be taken to avoid drafts and excessive dryness.

▲ A pleasant environment promotes a sense of well-being.

Ventilation

Particular attention should be given to assessing the movement of air within a client's immediate environment. An adequately ventilated room should contain a comfortable amount of moisture; be free of irritating pollutants, odors, or noxious fumes; and be at a tolerable temperature.

Adequate ventilation is especially important when more than one client is in a room. Other areas requiring optimum ventilation are operating rooms, delivery rooms, nurseries, isolation rooms, and sterile supply rooms.

A properly functioning ventilation system reduces airborne contaminants by regulating the amount of air movement within an enclosed area. When ventilation cannot be maintained by using doors and windows, mechanical devices, such as fans or air conditioners, may be used.

Clients requiring airborne isolation are placed in private rooms where the ventilation system is a directional air flow negative-pressure ventilation system. Six to 12 air exchanges per hour occur with this system.

Comfortable Sound Levels

Noise can be defined as any undesirable sound. The intensity and kind of noise that is comfortable is highly individual and related to past experiences. A businessman who lives on a busy street in a city may not adjust well to the quiet he may experience at night in a hospital room. On the other hand, a farmer from a rural community may be disturbed by the slightest sound. Infants often sleep peacefully in an atmosphere of loud noise and activity.

Decibel is the unit for measuring the intensity of noise. At close range, noise produced from heavy traffic, for example, has a decibel measure of 90, whereas a whisper at 3 feet has an intensity of 20 decibels.

At certain levels noise is considered hazardous. Temporary or permanent hearing loss or damage can occur when noise is present for a prolonged time at intensities over 90 decibels. Other effects of sustained loud noise are muscle tension, increased blood pressure, blood vessel constriction, pallor, increased secretion of the adrenal hormone, and nervous tension.

The pitch, quality, and duration of noise may also affect the client's environment. Unwanted sounds produced by sirens, traffic, and aircraft are often beyond the control of the nurse. But noise within a hospital setting, such as television, call systems, careless handling of dishes and other equipment, visitors, excessive conversation at the nurses' station, and some care-related sounds (e.g., beeping monitors), can be controlled.

Nursing personnel should always be aware of the noise level and its effects on the clients' well-being. Very ill individuals are often more sensitive to excessive or meaningless stimuli. Certain sounds can be reassuring because they represent activity or assistance to the client.

Furniture: Bed Safety

Today, most healthcare facilities are designed to be attractive, orderly, efficient, and clean. Since a person's outlook is strongly influenced by the surroundings, careful attention to appearance and cleanliness can assist with adjustment to the healthcare

environment. Although it is essential to assess the routines and standards of cleanliness of each client, the nurse may also have to teach the client how to organize and clean up. In some cases, instruction to the client may be critical to maintaining or improving a healthcare condition.

The standards and routine cleaning procedures of the hospital are generally not a nursing function now because hospital house-keeping has become a specialized occupation. Maintaining an organized, clean environment, however, requires coordination by all healthcare providers.

Furnishings should be arranged to be physically safe, comfortable, aesthetically appealing for the client, and easily cleaned. Adequate cleaning of the room should be done at a time of day that is coordinated with the client's needs so that the resulting sense of security adds to the client's ability to adapt adequately to the surroundings. The ambiance of the room and a sense of order contribute to the client's sense of well-being.

Hospital beds are adjustable in height from the floor; when the bed is in LOW position, the client can more easily and safely get in or out of it; when it is in HIGH position, the nursing staff can more efficiently render care. The head and sometimes the knee areas of the bed can be elevated; this is accomplished by electric controls. The electric controls are found on the foot, the side of the bed, or on the side rails. When placed at the side, the client can more easily control bed positions. Bed wheels are equipped with locks and kept in locked position.

For many years, side rails have provided what everyone thought was safe nursing care, protecting clients from injury as a result of falling out of bed. Changes have occurred in both long-term care and acute-care settings regarding the use of side rails. The Center for Medicare and Medicaid Services (CMS, formerly called Health Care Financing Administration, HCFA) and the Food and Drug Administration (FDA) have established guidelines that decrease the routine use of side rails. There is still controversy over the safety of side rails. Appropriately placed half-rails function as assistive devices, helping clients transfer from bed to chair or wheelchair. The HCFA believed that regardless of whether side rails were used as restrictive or assistive devices, risk of client entrapment in the side rails overshadows the potential benefit. Elderly clients and those with altered mental status are at high risk for injury when side rails are routinely used.

▲ Half-length side rails can be requested by clients to use as an assistive device.

The HCFA stated that a half- or quarter-length upper side rail is not considered a restraint if the client uses it as an aid for moving in and out of bed. A full-length or four half-length rails are not considered restraints if the client requests them in order to feel more secure and if he is able to lower them by himself before getting into or out of bed.

Nurses must assess appropriateness for side rail use for each client and inform both client and family of benefits and risks for their use. These assessments must be completed according to hospital policies and procedures to ensure that client is not at risk for injury if they are in use.

The overbed table is adjustable in height and slides over the bed to provide space for self-care activities or additional working surface for the nurse. The overbed table may also be used when the client sits in a chair. Small bed trays are sometimes convenient when the overbed table cannot be used.

The bedside table, similar to a nightstand, holds the client's personal possessions in drawers. A cabinet section in the table can be used to store bathing or toiletry equipment, and the top provides space for the client's familiar items, such as pictures or books.

A chair with firm back and arm supports should always be a part of the client's furnishings. Chairs should be made of durable, easily cleanable materials, such as plastic or Naugahyde. The client should be instructed to avoid contact between skin surfaces and the chair when sitting in a chair. A small towel or blanket can be placed under the client for this purpose.

A signaling system is also essential for the client to call for assistance. A signaling system may be an intercom, buzzer, electric light, or handbell. Whatever device is available must be within the client's reach and ability to use.

▲ Ensure that call light or other summoning device is within easy reach of client to provide access to nursing staff.

Food and Water

Fresh, nourishing food and clean water are vital to recovering and maintaining health and must be planned for and provided in appropriate amounts in healthcare facilities. A client's well-being can be positively affected by the ingestion of the correct number of calories, fat, proteins, carbohydrates, minerals, vitamins, and water, but it is well known that many people have nutritional habits that can negatively affect their well-being. A careful nutritional assessment is a critical step in helping the client adjust to the environment.

Hazardous Products and Waste Management

All waste products, whether contaminated equipment, blood or body fluid, waste, garbage, soiled dressings, refuse, or hazardous products, must be handled and disposed of in a way that prevents risk for injury or illness.

Nurses must be aware of potential dangers to themselves as well as to their clients when handling and disposing of hazardous materials. Just a few of the hazardous chemicals that nurses and other healthcare workers may be exposed to include disinfectants, such as isopropyl alcohol and iodine; sterilizing agents, such as formaldehyde and ethylene oxide; and anesthetic waste gases, such as nitrous oxide and Fluothane. Antineoplastic agents used in cancer treatment may also pose a hazard even when proper prevention policies and procedures are in place. All healthcare agencies have specific guidelines regarding the handling and disposal of such materials. For example, unit Material Safety Data Sheets provide information about area-specific chemical hazards and precautionary measures. Each toxic agent sheet (Material Safety Data Sheet) in the facility details information on the chemical's makeup, its health effects, exposure information, and emergency care procedures. These are available and accessible to the staff.

The U.S. Public Health Service, Centers for Disease Control and Prevention, the Environmental Protection Agency, the Occupational Health and Safety Administration (OSHA), the American Hospital Association, and state departments of health are some of the agencies that prepare guidelines for the handling and disposal of biohazards and dangerous products. Familiarity with general and unit-specific hazards and adherence to recommended standards for their control is essential for safe nursing practice. OSHA requires hospitals to educate employees about chemical hazards and to train them in safety precautions before they work in an area where toxic agents are used. Most hospitals require annual hazardous chemical training as part of their required staff development and training updates. (Refer to Chapter 14, Infection Control, for more details in handling hazardous material.)

In many healthcare facilities, a position of infection control nurse has been created to gather data on the type and frequency of various infections found in the hospital. These data help the infection control nurse to locate the source of the problem, predict its spread, and identify the best method of preventing its recurrence. Many of the hospital-acquired infections (HAIs, formerly called nosocomial) can be traced to inadvertent transmission by care providers. Each nurse plays a

significant role in establishing a safe environment for the client by using standard precautions in client care and by handling and disposing of biohazards appropriately. The infection control nurse plays a major role in identifying the “no pay” adverse events in the hospital acquired conditions. The 10 identified events listed by Centers for Medicare and Medicaid Services (CMS) will not be reimbursed by Medicare-Medicaid. (See Chapter 14, Infection Control.)

SOCIOCULTURAL DIMENSIONS

The first two dimensions of the environment, the biologic and physical, or ecosystem, refer to all living and nonliving elements. The third dimension of an environment is sociocultural, which includes both past and present influences from the people and the culture surrounding the individual. Customs, religious and legal systems, and economic and political beliefs are all part of this environment. This dimension also involves responses and adjustments to the ideals, concepts, beliefs, activities, and pressure of various groups, such as social clubs, peer groups, or colleagues.

Organization of Time

How clients perceive and deal with time and the passing of time depends on their age, immediate situation, culture, and past experiences, as well as their present physical and emotional condition. To a mother waiting for her child to return from surgery, hours seem like days. Small children generally do not have a well-developed sense of time. A 3-year-old may act out feelings of abandonment when separated from a parent for just a few minutes. In an intensive care unit, time can be severely disrupted, since healthcare activities continue around the clock. The ability to organize time is a critical element in adaptation. Helping clients assess and plan their time is one of the most important ways you can help them cope with their new surroundings.

Privacy

Many people who enter a healthcare facility fear exposure and loss of identity. Providing privacy for a client is more than a luxury or a mere courtesy. It is necessary and vitally important to the individual's attitude toward health care.

Clients should be given as much privacy as possible. Most individuals give clues to the nurse about the degree of privacy they need. The client's culture, past experience, values, and age should all be considered when planning for privacy.

Hospital routines should be planned to promote privacy. If an embarrassing or upsetting situation occurs, the feelings of the client must be protected. People require time and space to think, organize, and reflect. Privacy is necessary for human development, even at home. In the hospital, privacy is critical to the client's attitude and well-being.

Privacy can be promoted by drawing curtains or screens. Doors and window shades may also be used. Signs stating “Do Not Enter Without Checking at Desk” posted on room entrances give the client a sense of security from disturbances. This is especially important during physical examinations,

▲ Clients should be given as much privacy as possible by drawing curtains or using screens.

personal care, or emotional upset. Knocking or asking for permission to enter the client's room or area promotes mutual respect and enhances a sense of emotional space.

Privacy also extends beyond the physical need of the individual. Health status, conversation, and records are privileged information. Since the privacy rule, a part of HIPAA, went into effect on April 2003, this has greatly increased the confidentiality of client's information. A more trusting, therapeutic relationship evolves if the client understands that confidences shared with nurses are used appropriately.

Individualized Care

Providing an environment that is comfortable, safe, and individualized to meet the specific needs of a client is a challenging task. The client's ability to adapt to the immediate environment can either improve or interfere with his or her well-being. To assist the client in adjusting to the environment, a careful assessment of the situation should always include the person's usual routines, self-care abilities, cultural beliefs, current perceptions, and past experiences. To promote the best adaptation to a different environment, encourage as much independence as possible with each client. You may be required to use your resourcefulness, imagination, and ingenuity to assist the client through difficult periods. Ongoing assessment and open communication between client and staff is essential if positive adaptation is to occur.

Hospitalized clients also need emotional space. This form of space is that psychological area where the person can experience a sense of self. This is particularly difficult to achieve in a hospital setting when caregivers exercise control over many of the activities of daily living. It is important that the staff be aware of this psychological need so that they can provide adequate privacy, quiet, and freedom of choice over all of the areas that the client can control. The staff must also be aware that the client rarely needs to relinquish total responsibility for his or her care.

▲ Providing an environment that is both safe and individualized is a challenging task for the nursing staff.

Information and Teaching

The amount of information the client has about the environment and immediate situation directly affects his or her ability to adjust safely and comfortably. When the individual is given information and explanation about strange equipment, diagnostic procedures, or unfamiliar healthcare personnel, fears and feelings of helplessness can be reduced and a shared sense of responsibility enhanced. The client becomes more capable of asking questions and expressing concerns if prepared for unfamiliar occurrences.

Providing the client and his or her family, if appropriate, with information about the client's environment is the responsibility of the nurse. As more people assume the role of consumers of health care, there is more demand for knowledge about aspects of health care. Including the client in planning and caring for himself or herself promotes a sense of responsibility, independence, and self-respect.

Teaching the client about various aspects of health care is one method of information sharing. Over the years, the focus has changed from the professional staff doing everything for the client to helping the client be more independent. This change enables the client to adapt to the environment with guided assistance from nurses. As the client learns about his or her own health care and becomes involved in meeting his or

her particular needs, a sense of trust, responsibility, and usefulness develops.

A SAFE ENVIRONMENT

The Joint Commission and CMS are taking the lead in attempting to ensure that Americans are better protected from unsafe health care. Nurses are expected to carry a major responsibility in preventing medical errors, as they are the managers of client care. The Joint Commission is committed to improving safety for clients and residents in healthcare organizations. About 50% of The Joint Commission standards are directly related to safety. The Joint Commission has standards that address restraints and seclusion, environment of care (fire drills, medical equipment monitoring), physical environment, and infection control policies, to name only a few.

The mission statement indicates it is continuously trying to improve the safety and quality of care provided to the public through its accreditation standards. In 2009 the new National Patient Safety Goals (NPSGs) were published by TJC. Among the goals are using at least two client identifiers (not the room number) when administering medications; implementation of a Universal Protocol for Preventing Wrong Site, Wrong Procedure, Wrong Person Surgery; standardizing a list of abbreviations, acronyms, and symbols used for medication administration and physician orders; and reducing the risk of client falls by implementing a fall reduction program and then evaluating the program. In 2010 the National Patient Standards have decreased from the 2009 NPSGs of 20. The missing goals have now become "Standards of Care" (see Table 7-1, NPSGs). Table 7-1 outlines the client/patient safety goals that directly affect hospitals.

SENTINEL EVENTS

One of the policies implemented by The Joint Commission in 1996 addressed sentinel events. This policy ensured that healthcare organizations identified sentinel events and took action to prevent their recurrence. These events include an unexpected death or serious physical or psychological injury. Serious injuries such as the loss of limb or function were included in this policy. All sentinel events are to be documented, and this documentation is forwarded to TJC. A total of 6,780 (4,590 in hospital) events have been reported to TJC since the initiation of data collection through the first quarter of 2010. Of these, 67% resulted in client death, 9% resulted in loss of function, and 24% resulted from other causes. These figures include sentinel events in hospitals, home care, emergency rooms, psychiatric care setting, etc.

It is assumed that 50% of more than 5,000 to 6,000 hospitals in the United States have experienced a sentinel event in the past 10 years. Unfortunately, not all sentinel events are reported. Approximately 67.7% of all reported events occur in general hospitals. When a sentinel event occurs, the facility must conduct what is termed a root cause analysis and must develop an action plan within 45 days of the facility becoming aware of the event. A root cause analysis examines the reasons the error occurred and suggests changes to the

TABLE 7-1 National Patient Safety Goals 2010

Goal 1—Improve the accuracy of patient identification.

- Use of Two Patient Identifiers When Administering Medications, Blood and Blood Products (NPSG.01.01.01)
- Eliminating Transfusion Errors (NPSG.01.03.01)

Goal 2—Improve the effectiveness of communication among caregivers.

- Timely Reporting of Critical Tests and Critical Results (NPSG.02.03.01)

Goal 3—Improve the safety of using medications.

- Labeling Medications (NPSG.03.04.01)
- Reducing Harm from Anticoagulation Therapy (NPSG.03.05.01)

Goal 7—Reduce the risk of healthcare-associated infections.

- Meeting Hand Hygiene Guidelines (NPSG.07.01.01)
- Preventing Multidrug-Resistant Organism Infections (NPSG.07.03.01)
- Preventing Central Line-Associated Blood Stream Infections (NPSG.07.04.01)
- Preventing Surgical Site Infections (NPSG.07.05.01)

Goal 8—Accurately and completely reconcile medications across the continuum of care.

Note: All requirements for Goal 8 are not in effect at this time.

- Comparing Current and Newly Ordered Medications (NPSG.08.01.01)
- Communicating Medications to the Next Provider (NPSG.08.02.01)
- Providing a Reconciled Medication List to the Patient (NPSG.08.03.01)
- Settings in Which Medications Are Minimally Used (NPSG.08.04.01)

Goal 9—Reduce the risk of patient harm resulting from falls. (NPSG.09.02.01)

Goal 14—Prevent health care-associated pressure ulcers (decubitus ulcers). (NPSG.14.01.01)

Goal 15—The organization identifies safety risks inherent in its patient population. Identifying Individuals at Risk for Suicide (NPSG.15.01.01)

NPSG goal numbers are current for 2010. Other goals not listed here (4, 5, 6, 10, 11, 12, 13, and 16) are not applicable for hospitals. Refer to www.jointcommission.org/PatientSafety/NationalPatientSafetyGoals for additional information.

In addition to the above goals, the Universal Protocol for Preventing Wrong Site, Wrong Procedure, and Wrong Person Surgery has been implemented to prevent surgical patient errors.

system that can prevent the incident from happening again in the future. Root causes of sentinel events indicate that communication is the primary reason leading to the sentinel event (66%). Client assessment errors are responsible for 42% of the events, and staffing issues account for 22% of the events.

“NEVER EVENTS”

The use of the term “Never Events” was first discussed in 2001 by the National Quality Forum (NQF). Since the inception, the term has expanded to include 28 events grouped into six categories (Surgical, Product or Device, Client Protection,

The Joint Commission Sentinel Events

According to TJC, the following events are considered sentinel events.

- Incidents that involve unexpected death or serious injury or the risk of death and serious injury that is not related to the natural course of the client’s condition.
- Any of the following incidents, even if the outcome was not death or serious injury:
 1. Suicide of a client receiving around-the-clock care.
 2. Unanticipated death of a full-term infant, weighing more than 2,500 g, unrelated to congenital conditions.
 3. Infant abduction or discharge to the wrong family.
 4. Intrapartum maternal death.
 5. Medication error resulting in major permanent loss of function or death.
 6. Client fall resulting in permanent loss of function or death.
 7. Rape.
 8. Hemolytic transfusion reaction involving administration of blood or blood products having major blood group incompatibilities.
 9. Surgery on the wrong client or body part.
 10. Assault, homicide, or other crime resulting in permanent loss of function or death.
 11. Any unauthorized departure of client from an around-the-clock care setting resulting in temporally related death or major permanent loss of function.

TABLE 7-2 Root Causes of Sentinel Events

Communication	66%
Orientation/training	57%
Client assessment	42%
Staffing	22%
Availability of information	20%
Competency/credentialing	20%
Procedural compliance	19%
Environmental safety/security	17%
Leadership	13%
Continuum of care	13%
Care planning	12%
Organization culture	10%

All categories 1995–2005; 3,548 total reported events.

Care Management, Environmental, and Criminal) that can lead to serious error, indicating a problem with the safety of a health facility. It has been estimated that medical errors cost from \$17 million to \$29 million annually and account for 2.4 million additional hospital days (Haberly, 2009).

As of October 2008, the CMS has ceased reimbursing hospitals for costs associated with specific events, such as serious hospital-acquired pressure ulcers it considers preventable. In fall 2009, 20 states had plans to deny payment for some of the “Never Events.” Studies have indicated that 30% to 40% of clients receive care inconsistent with scientific evidence. It is estimated that implementation of evidence-based practice will result in increased client outcomes during hospitalization.

Providing a safe environment involves a number of people, including the client, visitors, and healthcare providers. Providing protection from hazardous situations and education about safety precautions is one of your most important responsibilities as a nurse.

TABLE 7-3 “Never Events”

1. Artificial insemination with the wrong donor sperm or donor egg
2. Unintended retention of a foreign object in a patient after surgery or other procedure
3. Surgery performed on the wrong patient
4. Wrong surgical procedure performed on a patient
5. Intraoperative or immediately postoperative death in an ASA class I patient (ASA is a physical status classification system; ASA I indicates the client is considered normal and healthy)
6. Infant discharged to the wrong person
7. Patient suicide, or attempted suicide resulting in serious disability, while being cared for in a healthcare facility
8. Maternal death or serious disability associated with labor or delivery in a low-risk pregnancy while being cared for in a healthcare facility
9. Stage 3 or 4 pressure ulcers acquired after admission to a healthcare facility
10. Any incident in which a line designated for oxygen or other gas to be delivered to a patient contains the wrong gas or is contaminated by toxic substances
11. Any instance of care ordered by or provided by someone impersonating a physician, nurse, pharmacist, or other licensed healthcare provider
12. Abduction of a patient of any age
13. Sexual assault on a patient within or on the grounds of the healthcare facility
14. Death or significant injury of a patient or staff member resulting from a physical assault (i.e., battery) that occurs within or on the grounds of the healthcare facility
15. Patient death, or serious disability associated with:
 - Patient elopement (disappearance)
 - Medication error
 - Hemolytic reaction due to the administration of ABO/HLA-incompatible blood or blood products
 - Electric shock or elective cardioversion while being cared for in a healthcare facility
 - A fall
 - Use of contaminated drugs, devices, or biologics provided by the healthcare facility
 - Use or function of a device in patient care in which the device is used or functions other than as intended
 - Intravascular air embolism that occurs while being cared for in a healthcare facility
 - Hypoglycemia, the onset of which occurs while the patient is being cared for in a healthcare facility
 - Kernicterus associated with failure to identify and treat hyperbilirubinemia in neonates
 - Spinal manipulative therapy
 - Burn incurred from any source while being cared for in a healthcare facility
 - Use of restraints or bedrails while being cared for in a healthcare facility

▲ Providing a safe environment involves instructing the client, family, and visitors in safety measures.

Clients who are moved from their usual environment into one that is unfamiliar and often frightening may act in ways that are very different from their usual behavior. A threatening situation can interfere with the individual's adaptation to the immediate surroundings.

The design and decor of the client's room must satisfy two needs: comfort and safety. Tasteful, unobtrusive colors help to normalize the hospital room. Interesting color combinations and patterns generally appeal more to the senses than do the traditional white or green choices. Pictures, flowers, cards, colorful linens, and curtains can add variety and familiarity to a room.

Safety Precautions

The client's age and health status influence the specific safety precautions that need to be taken to provide a safe environment. For example, infants require constant supervision, since they may attempt to put anything in their mouths or noses.

Preschool-aged children can be taught more detailed aspects of safety. Fire precautions and guidelines for bathing should be stressed.

Elementary school-aged children can usually protect themselves from hazards. They do, however, require instruction on how to operate mechanical equipment as well as information about fires and emergency exits.

All hospitals in the United States are required to be smoke-free facilities. Teenagers, adolescents, and adults should be given instruction about nonsmoking, the use of special equipment, and emergency exits. In addition, general information regarding their safety during hospitalization should be explained.

Smoking Policies

The Joint Commission standards require hospital smoking policies be disseminated and enforced throughout hospital buildings.

- Directives on smoking policy should be conveyed to each client on admission.
- Smoking is prohibited throughout the hospital.
- A physician may write orders for an exception to this policy for an individual client.
- A designated smoking area may be made available for family or visitors. (See Chapter 30 for safety measures for clients receiving oxygen therapy.)

Client Falls

Falling is a common cause of morbidity and the leading cause of nonfatal injuries and trauma-related hospitalization. Falls account for 70% of accidental deaths among individuals 75 or older. Complications that occur from falls include soft tissue injury, bone fractures, and the fear of falling again. More than 90% of hip fractures result from falls, most occurring in individuals over 70 years of age.

It is estimated that one-third of individuals over 65 years of age and more than half of individuals over 80 years of age will fall at least one time per year. Nearly 70% of all emergency room visits by individuals older than 75 years are directly related to falls. More than 60% of the falls occur in the home. Fall-related injuries account for 6% of all medical expenditures for persons 65 years and older. It has been shown that most of the falls in the hospital have occurred from or near the client's bed. Other common areas where falls occur include the bathroom and corridor. Even though much research has been done on falls and fall prevention, it is still a major problem for healthcare organizations. Clients at risk for falls include those with impaired mental status due to confusion, disorientation,

▲ Rails next to the toilet assist in preventing client falls.

▲ Shower chairs provide for client safety.

▲ Safety features such as handrail on bathtubs assist in preventing client falls.

impaired memory, and inability to understand and those taking medications such as sedatives, tranquilizers, antihypertensives, and beta-blockers. In addition to physical injury, falls result in substantial psychological and social consequences, such as anxiety, loss of independence, and increased rate of nursing home placements.

A fall risk assessment is now part of the admission assessment of all clients. If the client is at high risk for falling, appropriate interventions are implemented immediately. (See Fall Risk Assessment Form, page 153.)

Elderly adults are especially at risk for injury from falls. Decreased sensory acuity, decreased balance and postural instability, acute confusion, or chronic physical problems such as arthritis contribute to the high risk for falls among the elderly. Specialized safety equipment, such as toilet and bathtub railing and modified seats, are often used in geriatric units to decrease risk of injury during bathroom use.

It is sometimes difficult to balance the need for client safety with that for autonomy. Surveillance by agency personnel or

family members, use of alarm systems, or special monitoring devices provide alternatives to use of restraints in promoting client safety.

Use of Restraints

Restraints are defined as any physical or chemical means used to restrict a client's movement or activity or access to their body.

For many years, restraining a client or placing a client in seclusion was considered a method to protect the client or the staff from injury. After much research into the subject, it has been determined that use of restraints is very problematic and actually leads to severe client injury and even death.

Because of client injury or potential injury from use of restraints or seclusion, both The Joint Commission and the CMS, formerly Health Care Financing Administration (HCFA), have developed regulations regarding use of restraints in acute care, long-term care, and psychiatric settings. The standards require that the facility exhaust all reasonable alternatives before a client is placed in restraints or seclusion. CMS standards used in long-term and psychiatric settings are more stringent than those of The Joint Commission. A licensed independent practitioner (LIP) is permitted by the state and hospital to order a restraint or seclusion. CMS requires that restraints can only be implemented with an order from a physician or LIP. An LIP must evaluate the client in person as soon as possible after implementation of restraints. In long-term care facilities, restraints may be used only to ensure physical safety of the resident or other residents and can only be applied after a written order by the physician. Orders for restraints can be written for up to 4 hours for an adult. The order can be renewed every 4 hours, up to a total of 24 hours. The Joint Commission allows that after an assessment by an RN, restraints may be implemented, and then the physician must be contacted within a specified time frame. Each facility determines the time frame for rewriting restraint orders. Continued use of restraints must be reevaluated every 4 hours for clients over 18 years of age, every 2 hours for clients 9 to 17 years of age, and every hour for children under 9 years. No standing orders or PRN orders are allowed for restraints. Facilities may choose to be more restrictive, but they cannot be less restrictive in the time frame for renewal of orders.

Documentation of the client's symptoms that lead to the implementation of restraints must be both subjective and objective and derived from a clinical evaluation. All less restrictive interventions utilized must be documented as well. Before caring for a client requiring behavioral seclusion or restraints, review facility policies, as they do vary from policies in an acute hospital.

When restraints are employed, they must be an appropriate method of restraint and be used in the least restrictive manner. The family, significant other, or guardian must be informed immediately when restraints are required. Many hospitals use "sitters" in place of restraints for clients whenever possible. Family members may be called on to sit with the client as well.

Devices and immobilization that are considered protective interventions but not "restraint" interventions include arm boards for IV stabilization, procedural immobilization such as the temporary use of soft restraints to prevent a client from interfering with a related treatment, or soft restraints and tabletop chairs that are used as a temporary preventative measure.

Restraint Guidelines

Review hospital policy for the use of restraints. Requires a physician's order.

Use restraints for the client's protection and to prevent injury only if all other less restrictive measures are not effective.

- Use the least amount of restraint possible. A torso belt is least restrictive, limb restraint is more restrictive, and chemical (medication) is most restrictive.
- Allow clients as much freedom of movement as possible. Use slip knots for quick release. Do not use square knots or bows.
- Always explain the purpose of the restraint to the client and family. Afford as much dignity to the client as possible.
- Remember that restraints can cause emotional, mental, and physical deterioration and increase the risk of injury if falls occur.
- Remember that circulation and skin integrity can be affected by restraints.
- Special precautions should be taken for adult females in restraints to protect breast tissue.

- Clients must be observed every 15 minutes.
- Release restraints every 2 hours for at least 5 minutes to inspect tissues and provide joint range of motion and position change to prevent circulatory impairment. When a client is combative, release only one restraint at a time.
- Assess and provide for client's fluid and elimination needs, pain management, and position change every 2 hours.
- Pad bony prominences, such as wrists and ankles, beneath a restraint.
- Attempt to make restraints as inconspicuous as possible for the sake of the client's relatives and friends, who may be upset by seeing restraints.
- Clearly document rationale and precautions taken for client safety.
- Notify family, significant other, or guardian if restraints are necessary.
- Enlist support of family members or significant other to sit with client rather than implement restraints.

ADAPTATION TO HOME CARE

The home environment should be evaluated for safety issues before the client is discharged from the hospital. The National Home Care Patient Safety Goals should be followed at home in order to improve the client's safety while recuperating. The following eight safety goals should be discussed with the client, family, and healthcare provider.

1. Identify patients correctly.

Use at least two ways to identify patients. Use the patient's name and date of birth. Ask the patient and staff questions to make sure that the treatment being done is the correct one. Make sure that the treatment will be done at the correct place on the patient's body.

2. Improve staff communication.

- Read back spoken or phone orders to the person who gave the order.
- Create a list of abbreviations and symbols that are not to be used.
- Quickly get important test results to the right staff person. Create steps for staff to follow when sending patients to the next caregiver. Make sure there is time to ask and answer questions.

3. Use medicines safely.

- Create a list of medicines with names that look alike or sound alike. Update the list every year.
- Take extra care with patients who take medicines to thin their blood.

4. Prevent infection.

- Use the hand-cleaning guidelines from the World Health Organization or Centers for Disease Control and Prevention.
 - Report death or injury to patients from infections that happen in healthcare organizations.
 - Use proven guidelines to prevent infection of the blood.
- ### 5. Check patient medicines.
- Ensure that it is OK for the patient to take any new medicines with their current medicines.
 - Provide a list of patient's medicines to their next caregiver. Give the list to the patient's regular doctor before the patient goes home.
 - Give a list of the patient's medicines to the patient and their family before they go home. Explain the list. Some patients may get medicine in small amounts for a short time. Make sure that it is OK for those patients to take those medicines with their current medicines.
- ### 6. Prevent patients from falling.
- Determine which patients are most likely to fall. Take action to prevent falls in these patients.
- ### 7. Help patients to be involved in their care.
- Tell each patient and their family how to report their complaints about safety.
- ### 8. Identify safety risks.
- Find out if there are any risks for patients who are getting oxygen; for example, fires in the patient's home.

NOTE: For complete description of Home Care National Patient Safety Goals, refer to list available on The Joint Commission Web site (http://www.jointcommission.org/PatientSafety/NationalPatientSafetyGoals/08_ome_npsgs.htm).

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to include in a client care plan when the components are related to maintaining a safe environment.

NURSING DIAGNOSIS	RELATED FACTORS
Injury, Risk for	Motor, sensory, or cognitive alterations; elimination urgency; bleeding tendency; physiologic instability due to medications, aging, illness, environmental hazards
Disturbed Sensory Perception (Specify)	Medications, decreased sensory acuity, altered level of consciousness, mental status changes, environmental conditions
Impaired Tissue Integrity	Chemical, thermal, or mechanical factors, decreased mobility, nutritional deficiency
Self-Mutilation, Risk for	Labile behavior, depression, guilt, inadequate coping, loss of control over problem-solving situations

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. *Remember to wash your hands or use antibacterial gel before and after each and every client contact.*

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Chapter 7

UNIT 1

A Safe Environment

Nursing Process Data

ASSESSMENT Data Base

- Identify client's age, previous or chronic sensory impairments, previous level of mobility, ambulatory aids used, and general health history.
- Assess the client's reliability as an accurate health historian.
- Identify any alteration of sensory or motor abilities or emotional adaptation due to illness, injury, or hospitalization.
- Observe and record client's present level of consciousness, orientation, mobility, and any sensory or motor restrictions.
- Evaluate client's ability to comprehend instruction about how to use potentially dangerous equipment.
- Evaluate client's ability to make judgments.
- Assess need for specific precautions to promote a safe environment.
- Assess type of fire extinguisher needed for specific types of fires or use ABC extinguisher.
- Assess the need for protection while administering care to clients with radioactive implant.
- Assess prodromal signs and symptoms (aura) for potential seizure activity.
- Assess home for environmental safety.

PLANNING Objectives

- To provide protection when states of illness decrease the individual's ability to receive and interpret environmental stimuli
- To assist client to interpret environmental stimuli relevant to his or her safety
- To determine safety equipment necessary to promote a safe environment
- To place all personal articles and call light within easy reach of client
- To enhance degrees of mobility in a safe environment
- To determine that all electrical equipment is intact and operated safely
- To determine the protective devices needed when caring for clients receiving radioactive material
- To provide a safe environment for a client with seizure activity
- To determine that home environment is safe

IMPLEMENTATION Procedures

- Preventing Client Falls 151
 - For High-Risk Client 151
- Preventing Thermal/Electrical Injuries 154
- Providing Safety for Clients During a Fire. 155
- Providing Safety for Clients Receiving Radioactive Materials. 156
- Providing Safety for Clients With Seizure Activity . . . 157
- Assessing Home for Safe Environment 157

EVALUATION Expected Outcomes

- Client's environment is safe from potential mechanical, chemical, and fire or electrical hazards.
- All personal articles and call light are within easy reach of the client.
- All electrical equipment is intact and operated safely.
- If oxygen is used, appropriate safety measures are in effect.
- Personnel are protected from radioactive material.
- Client is free of injury after seizure.
- Client does not experience sequelae from seizure activity.

Critical Thinking Application 159

- Expected Outcomes 159
- Unexpected Outcomes. 159
- Alternative Actions 159

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Preventing Client Falls

Equipment

- Side rails, handrails
- Alarm systems
- Restraints
- Locks for movable equipment, such as beds, wheelchairs, and gurneys

Procedure

1. Assess all clients for risk factors for falls.
2. Complete a comprehensive interview to determine potential for falls. Determine how many falls the client experienced in the last 6 months. Ask how they fall, backward or forward? Determine if medications are taken correctly and any dietary supplements the client is taking. Discuss client's diet: What foods and fluids do they eat and drink?
3. Determine psychosocial status. ► **Rationale:** To gain insight into how the client will react to necessary changes in their daily routine or changes in their house necessary to prevent falls.
4. Orient new clients to their surroundings, including use of call light.
5. Instruct ambulatory client in use of toilet and shower controls and emergency signals in bathroom.
6. Determine client's ability to safely use mobility aids.
7. Place bed in low position when you are not providing direct client care.
8. Determine appropriateness for side rail use.
9. Keep half side rails up for all heavily sedated, elderly, confused, and immediate postsurgical clients according to hospital policy.
10. Place articles such as call light, cups, and water within the client's reach.
11. Pad bed rails for client with high risk for seizures.
12. Remind client and hospital personnel to lock beds, wheelchairs, and gurneys and to release the lock only after client is secure for transport.
13. Tell clients who are weak, sedated, in pain, or who have had surgery to ask for assistance before getting out of bed.
14. Use two staff to transport client on gurney or wheelchair when nonattached equipment, such as chest-tube system or IV poles, must accompany client in transport.
15. Respond to client's summons as soon as possible.
16. Make sure floors are free of debris that might cause clients to slip and fall. Spilled liquids should be wiped up immediately. Encourage housekeepers to use signs for slippery areas.
17. Check to see that client's unit and hallway are neat and free of hazardous obstacles, such as foot stools, electrical cords, or shoes.

Assess Clients for Risk Factors for Falls

- Adverse reaction to medications
- Alterations in vision
- Weakness and decreased physical functioning
- Altered mental acuity or confusion
- Neurological conditions (i.e., paralysis, stroke)
- Agitation
- Environmental hazards
- Difficulties with elimination
- Unsafe footwear and/or foot problems
- Orthostatic hypotension
- Reaching for articles out of the way
- Elderly clients
- Chronic health problems
- Alcohol consumption
- Pain
- Cardiovascular alterations

Source: Gustafson, S. (2007, December). Assess for fall risk, intervene—and bump up patient safety. *Nursing*, 37, 24–25.

For the High-Risk Client

Clinical Alert Risk Factors for Falls

There is a tendency for multiple fallers to repeat the type and location of the fall on successive falls (e.g., use of commode). Studies have identified a variety of fall risk factors that have led to the development of a number of fall risk assessment tools. Clients at high risk for fall generally demonstrate more than one of the following:

- History of falls
- Advanced age
- Sensory or motor impairment
- Urgent need for elimination
- Postural blood pressure instability

18. Attend to acute changes in client's behavior (e.g., hallucinations, abrupt disorientation, or altered responses or cognitive impairment). Monitor client frequently.

19. Continuously orient the disoriented client.
20. Assess and respond to fluid and elimination needs every 2 hours.
21. Employ bed, chair, and wander alarms. Bed alarms involve placing a sensor on the client's bed. When a change in position or loss of contact with the sensor occurs, an alarm alerts the nurse. Ambualarm devices are placed on the client's leg and signal an alarm when the legs are in a dependent position, indicating the client is trying to get out of bed.
22. Apply hip protectors on clients at risk for a fractured hip if they fall (i.e., clients with osteoporosis). Soft foam pads are held in place at the hips with specially designed removable briefs.
23. Assign aides or elicit the assistance of sitters or family to monitor the high-risk client; make certain they inform you when they leave the client's side.
24. Relocate high-risk client to room near nurses' station.
25. Utilize a recliner chair for client safety.
26. Place absorbent pad next to bed. ▶ **Rationale:** Prevents severe injury if client falls out of bed.
27. Keep intercom open between client's room and nurses' station.
28. Obtain physician's specific orders if restraints are deemed absolutely necessary.

EVIDENCE-BASED PRACTICE

Do Side Rails Prevent Falls?

A New Zealand study of almost 2,000 clients tested a new policy of restricting side rails. The results revealed that even though the use of side rails decreased (from 29% to 7%), the mean fall rate remained the same (36.6 falls/100 admissions). However, the falls that did occur were less severe.

Source: Hanger, H. C., Ball, M. C., & Wood, L. A. (1999). An analysis of falls in the hospital: Can we do without bedrails? *Journal of the American Geriatric Society*, 47(5):529–531.

Clinical Alert

Methods to Prevent Falls

To prevent at-risk clients from falling out of bed, consider using one of the following interventions:

- Use a mattress with raised edges; use body-length pillows, rolled blankets, or “swimming noodles” (foam flotation aids) under mattress edges.
- Place mat on floor next to bed.
- Place client in a very low to ground bed (7 to 13 inches above floor).
- Use bed alert alarms.
- Use half or three-fourth length side rails.
- Identify high-risk clients and implement a plan of action to prevent falls.
- Place high-risk client near nurses' station.
- Monitor high-risk client frequently, make rounds every 1 to 2 hours.
- Educate staff in fall prevention programs.
- Decrease environmental risks, obstacles, and clutter.
- Implement grab bars in bathroom and stabilize beds.
- Support client's elimination needs.
- Monitor client's reaction to medications.
- Assist clients with mobility.
- Ensure client wears nonskid slippers.
- Monitor client's mental status.
- Institute interventions to prevent falls from bed.
- Use safety straps or seat belts when in wheelchairs or geri-chairs.
- Involve family members in client prevention program.

Risk Assessment Tools for Falls

- Falls Efficacy Scale—measures how confident the individual is when performing ADLs
- Balance Self-Perception Test
- Berg Balance Scale
- Tinetti Mobility Assessment
- The Mini Mental State Examination—for assessing cognition

Exit Alarms

Posture indicator:	Adhesive transmitter patch is applied to thigh and to a receiver alarm box. When client attempts to get up, alarm goes off.
Pressure release:	Pads, mats, or other devices are placed on the floor or chair. They sense changes in weight and pressure.
Pressure-sensitive:	Pad or mat placed on floor by bed or chair sounds when stepped on.
Clip-on alarms:	Alarms activated by pulling detachable tab from the unit, a small box attached to the bed, chair, or wheelchair. A clip is attached to client's clothes. When client gets up, tab detaches from box and sounds an alarm.

TABLE 7-4 Fall Risk Assessment Form (Required Form)

Fall Risk Assessment Form (REQUIRED FORM)			
Name _____		Date _____	Examiner _____
PARAMETER	SCORE	RESIDENT STATUS/CONDITION	
A. Level of Consciousness/Mental Status	0	ALERT (oriented X 3) OR COMATOSE

TABLE 7-5 Clinical Guidelines for the Prevention of Falls and Injuries in the Older Adult

- Brief assessment of all clients will identify those who should be referred for a comprehensive fall evaluation.
- Assessments may be done by all healthcare professionals.
- Because of the many factors associated with falls, one test cannot identify individuals at risk for falls. Several tests assessing for risk factors should be utilized.
- **Clients at risk for falls include older clients with:**
 - Medical needs who have experienced one or more falls
 - Reported recurrent falls
 - Abnormalities in gait and/or balance
- **Comprehensive clinical risk assessment usually consists of:**
 - A review of falls, history, and circumstances
 - Assessing home for hazards
 - Identifying medications routinely taken
 - Assessing gait, balance, mobility, and muscle weakness
 - Identifying risk for osteoporosis
 - Evaluating perceived functional ability and fear of falling
 - Assessing visual impairment and effects of corrective eyewear
 - Presence of urinary incontinence
 - Assessing acute and chronic health problems, joint function, and basic neurological function
- **Fall prevention:**
 - Utilize exercise programs
 - Implement behavior changes
 - Review medications
 - Treat contributing health conditions
 - Use assistive and protective devices
 - Modify house to prevent injury
 - Educate client and family in ways to prevent falls

Source: American Geriatrics Society. (2004). Guideline for the Prevention of Falls in Older Persons.

Preventing Thermal/Electrical Injuries

Equipment

Fire extinguishers

Procedure

1. Make sure that all electrical apparatuses are routinely checked and maintained. Look for safety inspection expiration dates on biomedical equipment.
2. Have all electrical appliances brought to the hospital by client (radios, electric razors, hair dryers, etc.) inspected by hospital maintenance staff. It is best to discourage use of nonhospital equipment.
3. Make sure water in the tub or shower is not more than 110°F (95°F for those with circulatory insufficiency).
4. When heating pads, sitz bath, or hot compresses are used, check the client frequently for redness. Maximum temperature should not exceed 105°F (95°F for those with circulatory insufficiency).
5. Hospitals do not allow smoking in the facility. There may be designated smoking areas outside the building. Inform clients and visitors about the hospital's smoking regulations. Do not allow confused, sedated, or severely incapacitated clients to smoke without direct supervision.
6. Store all combustible materials securely to prevent spontaneous combustion.
7. Make sure that all staff and employees participate in and understand fire safety measures, such as extinguishing fires and plan for evacuating clients.
8. Report and do not use any apparatus that produces a shock, has a broken plug or ground pin, or has a frayed cord.
9. Never apply direct heat (e.g., heating pad) to ischemic tissue—doing so increases the tissue's need for oxygen.
10. Turn equipment off before unplugging it. ► **Rationale:** This prevents sparks that can cause a fire.
11. Plug devices that require a high current (i.e., ventilators or radiant warmers) into separate outlets. ► **Rationale:** This prevents overloading the circuit that could lead to a fire.
12. Use only three-pronged grounded plugs.

Clinical Alert

The elderly, diabetic, or comatose client is especially vulnerable to thermal injuries.

Providing Safety for Clients During a Fire

Equipment

Appropriate extinguisher for fire:

- Water type
- Soda-acid type
- Foam type
- Dry chemical type
- ABC extinguisher

Procedure

1. Follow hospital policy and procedure for type of fire safety program and for ringing the fire alarm to summon help.
2. Remove all clients from the immediate area to a safe place. Be familiar with fire exits and agency evacuation plan.
3. To remove a client safely from the fire, use carrying method that is most comfortable for you and safe for client.
 - a. Place blanket (or bedspread) on floor. Lower client onto blanket. Lift up head end of blanket and drag client out of danger.
 - b. Use two-person swing method. Place client in sitting position. Form a seat by having two people clasp forearms or shoulders. Lift client into “seat” and carry out of danger.
4. Activate fire alarm.
5. Secure the burning area by closing all doors and windows.
6. Shut off all possible oxygen sources and electrical appliances in the fire area.
7. If possible, employ the appropriate extinguishing method without endangering yourself. Fire extinguishers should not be used directly on a person.
8. Be familiar with the different types of fire extinguishers and their location.

Class A

- a. Water-under-pressure type or soda-acid type.
- b. Use on cloth, wood, paper, plastic, rubber or leather.
- c. Never use on electrical or chemical fires due to danger of shock.

Class B

- a. Foam, dry chemical, carbon dioxide types.
- b. Use on fires such as gasoline, alcohol, acetone, oil, grease, or paint thinner and remover.
- c. Class A extinguisher is never used on class B fires.

Class C

- a. Dry chemical or carbon dioxide types.
- b. Use on electrical wiring, electrical equipment, or motors.
- c. Class A or class B extinguishers are never used on class C fires.

Class ABC combination

- a. Contains graphite.
 - b. Use on any type of fire.
 - c. Most common extinguisher in use.
9. Keep fire exits clear at all times.

▲ Become familiar with the location and use of fire extinguishers in the hospital.

Priorities for Fire Safety

- R Rescue and remove all clients in immediate danger
- A Activate fire alarm
- C Confine the fire; close doors, windows; turn off oxygen supplies and electrical equipment
- E Extinguish fire when possible

Providing Safety for Clients Receiving Radioactive Materials

Equipment

Protective shields for x-ray

Lead-shielded container if required

Film badge if required

Sign for client's door: "Caution, Radioactive Material"

General Guidelines for Radiation Precautions*

Radioactive Implant

- Care time not to exceed 15 minutes per employee per day.
- No pregnant woman or anyone under age 18 should enter room.
- No special handling of excreta other than standard precautions
- Bath usually omitted, client movement restricted.
- Visitors limited to 1 hour/day, keeping distance from client.
- All linens, gloves, trash, and dressings kept in room until cleared by radiation safety officer.

Systemic Radioactive Material

- No lab specimens to be taken without consent of radiation safety officer.
- Use disposable dietary tray.
- Handle all excreta and secretions with gloves.
- Have client use toilet—flushing twice.
- Shielding not needed.
- Visitors require special instructions.
- Keep gloves, dressings, linens, and trash in contaminated container.

*NOTE: See Institutional Policy for Specifics.

Procedure

1. Review these guidelines:
 - a. Determine type and amount of radiation used and its side effects and hazards.
 - b. Rotate care providers because increased time in the presence of a radioactive source increases exposure to radiation.
 - c. Use shields, such as lead walls or lead aprons, to protect from radioactive source.
 - d. Inform staff that exposure is greater the closer the person is to the radioactive source.
 - e. Store radioactive material in lead-shielded containers when not in use.
 - f. Issue monitoring badge to all who enter room to record exposure.
2. If nurse or family member is assisting with a radioactive procedure, they must put on a shield.
3. If a radioactive implant is used in a client, all nurses and visitors must be protected with a shield. Limit exposure with the client.
4. Keep track of how much time is spent in the presence of radioactive material. Check film badge frequently.
5. Constantly assess and support clients who are undergoing radiation therapy. Bed rest, isolation, and unpleasant side effects are sometimes common.

Clinical Alert

Pregnant nurses should check hospital policy regarding working with clients receiving radioactive materials.

▲ Badge worn when working with clients receiving radioactive material.

6. Follow guidelines for working with clients with unsealed sources of iodine-131.
 - a. Wear rubber gloves at all times when providing care.
 - b. Wash gloves before removing, and place in designated waste container.
 - c. Wash hands with soap and water after removing gloves.
 - d. Dispose of all bed linen in contaminated linen bag.
 - e. Wrap all nondisposable items that have come in contact with client's blood, saliva, or gastric juices in plastic bag. Send to appropriate hospital department for decontamination (usually nuclear medicine department).
 - f. Notify radiation safety officer (usually in radiology department) if clothes or shoes have been contaminated.
 - g. Instruct visitors and family member of no visitations for 24 hours.
7. If client is discharged immediately after radioactive iodine, provide client instructions.
 - a. Minimize contact (less than 3 feet or 0.6 meter for more than 1 hour each day) with everyone for the first 5 days, and with small children or pregnant women for 8 days.
 - b. Do not sit next to someone in an automobile for more than 1 hour.
 - c. Sleep in a separate room and use separate bath linen and laundry these and underclothing separately for 1 week.
 - d. Wash hands with soap and water every time the toilet is used.
 - e. Rinse the sink and tub thoroughly after using them.
 - f. Use separate eating utensils or disposable eating utensils. Wash eating utensils separately for 1 week. Do not prepare food for others.
 - g. Flush toilet 2 to 3 times after use for 2 weeks after discharge.
 - h. Males should sit when urinating to avoid splashing for 1 week.

Clinical Alert

Client Education After Receiving Radioactive Iodine

- Check with physician regarding guidelines
- Follow these guidelines, if approved by physician

Providing Safety for Clients With Seizure Activity

Equipment

- Oral airway
- Padding material for side rails
- Suction equipment and catheters
- Clean gloves

Preparation

1. Identify client at risk for seizure activity (e.g., clients with closed head injury, neurosurgical clients, meningitis, history of seizures).
2. Place suction equipment and catheters on bedside stand.
3. Tape oral airway to head of bed or place on wall.
4. Pad side rails with blankets or other heavy material.

Procedure

1. Determine type of seizure activity, if client has a previous history of seizures. ► **Rationale:** Assists in

determining potential type of seizure activity, client response, and presence of an aura.

2. Place client in side-lying position, with pillow at head of bed and side rails in raised position, if seizure activity is anticipated. ► **Rationale:** To protect client from injury.
3. When seizure activity begins, provide privacy; ensure bed is in low position and side rails are raised.
4. Maintain client in side-lying position with head flexed slightly forward. Do not restrain client or place anything in client's mouth. ► **Rationale:** To prevent injury to jaw or teeth. Flexed head will prevent tongue from occluding airway.
5. Remain with client during seizure to ensure airway is not occluded and client does not require suctioning.
6. Explain that client had a seizure when he/she is alert.
7. Remain with client after seizure to ensure he/she has an uneventful postictal period. Client usually sleeps for a period of time after seizure.
8. Document findings and notify physician of seizure.

Assessing Home for Safe Environment

Equipment

- Home Assessment Checklist
- Outcome and Assessment Information Act (OASIS-B1)

Procedure

1. Identify type of dwelling (i.e., client-owned, boarding home, rental, mobile home).
2. Identify water source.

3. Identify sewer source.
4. Identify type of plumbing available.
5. Determine if any pollutants are present in the environment.
6. Assess exterior of the home for:
 - a. Condition of sidewalks and steps.
 - b. Presence of railings on steps.
 - c. Barriers that prevent easy access to the home.
 - d. Adequacy of lighting.
 - e. Adequacy of roof and windows.
7. Assess interior of the home for:
 - a. Presence of scatter rugs or worn carpeting.
 - b. Uncluttered pathways throughout the house.
 - c. Adequacy of lighting.
 - d. Doorways wide enough to permit assistive devices.
 - e. Cleanliness of house.
 - f. Presence of insects, rodents, or infective agents.
 - g. Presence of functioning smoke detectors.
 - h. Adequate heating and cooling systems.
 - i. Presence of running water.
8. Determine whether hazardous materials are safely stored.
9. Assess for presence of lead-based paint.
10. Determine whether medications can be adequately stored out of reach of children and impaired individuals.
11. Assess stairway and halls for:
 - a. Adequacy of light.
 - b. Handrails that are securely fastened to wall.
 - c. Flooring in good repair.
 - d. Rugs or carpeting in good repair.
 - e. Light switches in easy reach and accessible at both ends of stairs or hallway.
12. Assess kitchen for:
 - a. Properly functioning stove.
 - b. Adequacy of light surrounding stove and sink.
 - c. Condition of small appliances.
 - d. Accessibility of appliances to clients in wheelchairs.
 - e. Adequacy of sewage disposal.
13. Assess bathroom for:
 - a. Skidproof strips or mat in tub or shower.
 - b. Handrails around toilet and tub or shower.
 - c. Accessibility of medicine cabinet.
 - d. Adequate space if wheelchairs or walkers are used.
 - e. Temperature of hot water from faucets in sink, tub, or shower.
14. Assess bedroom for:
 - a. Accessibility of closets and cabinets.
 - b. Ease in getting into and out of bed.
 - c. Adequate space, if commode or wheelchair is required.
 - d. Night light availability.
 - e. Accessibility of medications, water on night stand.
 - f. Calling system to alert healthcare provider.
 - g. Flooring in good repair and nonslippery surface.

DOCUMENTATION for Providing a Safe Environment

- Assessment notes
- Actual incidents involving mechanical, chemical, or thermal trauma
- Client education provided
- Safety devices used
- Behaviors occurring before, during, and after seizure activity
- Safety issues instituted for client receiving radioactive iodine
- Completion of home environment forms

Legal Considerations

Using Bed Alarms to Prevent Falls

Several small studies, with low numbers of clients, were conducted to determine whether use of bed alarms prevents falls. The conclusion indicated insufficient evidence regarding the effectiveness of bed alarms in preventing falls in elderly clients. Additional studies will need to be conducted to determine the usefulness of these devices in fall prevention.

Source: <http://www.injuryboard.com>, Using Bed Alarms to Prevent Falls.

Client Falls

Even though client falls are second only to medication errors in untoward events that happen to clients in hospitals, it does not mean that fault will be assessed against healthcare providers.

If it can be proven that the nursing staff used poor judgment in preventing client falls, liability will be assessed against the staff. A client was noted to be at high risk for falls but even with this data, was not placed on fall prevention interventions.*

In a second case, *Sullivan v. Edward Hospital, 2004*, the court found that the institution had taken appropriate measures to safeguard a client who fell and developed a subdural hematoma.**

Source: *Williams v. Covenant Medical Center, 2000. **Guido, G.W. (2006). *Legal and Ethical Issues in Nursing*, 4th ed. Upper Saddle River, NJ: Prentice Hall, 2006, p. 395.

CRITICAL THINKING Application

Expected Outcomes

- Client's environment is safe from potential mechanical, chemical, and fire or electrical hazards.
- All personal articles and call light are within easy reach of the client.
- All electrical equipment is intact and operated safely.

Unexpected Outcomes

The client, nurse, or visitor experiences an accident or injury related to mechanical, chemical, or thermal trauma.

Unfamiliarity with hospital fire and disaster protocol results in poor performance.

Radium implant becomes dislodged and falls out.

Spillage of excreta from client with systemic radioactive therapy.

- If oxygen is used, appropriate safety measures are in effect.
- Personnel are protected from radioactive material.
- Client is free of injury after seizure.
- Client does not experience sequelae from seizure activity.

Alternative Actions

- Provide immediate first aid or care.
- Assess vital signs and notify physician.
- Report the incident according to hospital procedure. Unusual occurrence forms are used to protect the injured individual, the nurse, and the hospital.
- Review safety procedures to ensure a safe environment.
- Report all malfunctioning equipment immediately to the proper department.
- Review protocols frequently to update knowledge base.
- Participate in fire and disaster drills to become familiar with protocols.
- Put on lead gloves, pick up radium with forceps, and place in lead-shielded container in client's room.
- Notify physician and hospital radiation safety officer immediately.
- Never touch radioactive source directly.
- Cover spillage with absorbent material and notify radiation safety officer.
- Wash with soap and water if skin is contaminated.

Chapter 7

UNIT 2

Restraints

Nursing Process Data

ASSESSMENT Data Base

- Assess client’s risk for falls on an ongoing basis.
- Assess need for fall prevention measures.
- Assess area under and surrounding a restraint to ensure it is not restrictive.
- Evaluate client’s response to restraint use.

PLANNING Objectives

- To identify clients who are at risk for injury
- To prevent a client from injuring himself/herself or others
- To employ fall prevention measures
- To obtain physician’s order for restraints if deemed absolutely necessary
- To apply restraints safely and effectively
- To restrain a child’s elbow to prevent the child from reaching an incision
- To promote client safety when ambulating or sitting in a chair

IMPLEMENTATION Procedures

- Managing Clients in Restraints 161
- Applying Torso/Belt Restraint 162
- Using Wrist Restraints 163
- Using Mitt Restraints 164
- Using Elbow Restraints 165
- Applying a Vest Restraint 165
 - For Client in Bed 165
 - For Client in Wheelchair 166
- Applying Mummy Restraints 168

EVALUATION Expected Outcomes

- Client is prevented from injuring himself (herself) or others.
- Restraints are applied appropriately.
- Client does not develop complications due to restraint use (e.g., agitation, pressure ulcers, circulatory disturbance).
- Child is prevented from reaching the incision site, IVs, or tubes.
- Client remains in restraints for a limited amount of time.
- Client does not experience complications as a result of restraint placement.
- Client does not endure undue psychological stress while being placed in restraints.

- **Critical Thinking Application** 170
 - Expected Outcomes 170
 - Unexpected Outcomes 170
 - Alternative Actions 170

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Managing Clients in Restraints

Equipment

Appropriate restraint, limb, torso, and vest

Preparation

1. Identify and evaluate if less restrictive measures have been explored before the client is placed in restraints.
2. Call physician or licensed independent practitioners (LIP) for restraint order before applying restraints. If restraints must be placed before the order is obtained, ensure the order is obtained within 1 hour for either a nonbehavioral health client or a behavioral health client. ► **Rationale:** Physician's order is required to apply restraints.

NOTE: Follow guidelines for obtaining restraint orders and updating orders according to hospital policy.

3. Ensure that a face-to-face assessment is completed on the client within 8 hours for a nonbehavioral health client and 1 hour for a behavioral (psychiatric) health client. ► **Rationale:** Frequent assessments prevent complications.
4. Ensure that restraint orders are renewed every 24 hours or sooner according to facility policy for nonbehavioral health clients or every 2 to 4 hours for behavioral health clients. Children from 12 to 17 must have orders renewed every 2 hours, for a maximum of 24 hours. ► **Rationale:** Restraints should be discontinued as soon as possible.
5. Establish and implement a plan of care for the client to eliminate the need for restraints.
6. Discuss the use of restraints with the client and family members. If possible, elicit the support of the family or use sitters to stay with the client rather than place the client in restraints.

Clinical Alert

Restraints are indicated only if there is no other viable option available to protect the client, and then they are implemented only when the client is assessed and evaluated by an appropriate licensed independent practitioner (LIP).

There are three types of restraints used in clinical practice:

1. **Chemical:** Sedating psychotropic drugs to manage or control behavior. Psychoactive medication used in this manner is an inappropriate use of medication.
2. **Physical:** Direct application of physical force to a client, without the client's permission, to restrict his or her freedom of movement.
3. **Seclusion:** Involuntary confinement of a client in a locked room. Physical force may be applied by individuals, mechanical devices, or a combination of any of them.

Source: The Joint Commission. (2000). www.thejointcommission.org.

Procedure

1. Gather appropriate restraint and perform hand hygiene.
2. Identify client using two identifiers and seek client's cooperation with restraint procedure, if possible.
3. Apply restraint according to manufacturer's specific directions.
4. Monitor and assess the client every 15 minutes, or according to facility policy.
5. Release restraint at least every 2 hours or sooner (The Joint Commission). ► **Rationale:** Releasing restraints allows the client to be provided with the following:
 - a. Toileting.
 - b. Fluids and food.
 - c. Hygiene care such as brushing teeth or washing face and hands.
 - d. Circulation checked; skin care provided.
 - e. Body alignment checked.
 - f. Range of motion to all joints, particularly those in restraints.

Clinical Alert

In acute medical and postsurgical care, a restraint may be necessary to ensure that an IV or tube feeding is not removed, or the client cannot be allowed out of bed after surgery. This type of medical restraint may be used temporarily to limit mobility or prevent injury to the client.

Additional types of activities that may constitute a restraint include:

- Tucking a client's sheet so tight that he/she cannot move.
 - Using a side rail to prevent a client from voluntarily getting out of bed.
 - Placing the client in a geri-chair with a table.
 - Placing a wheelchair-bound client so close to the wall that it prevents them from moving.
6. Avoid application of force on long bone joints and pad bony prominences beneath restraint. ► **Rationale:** Reduces pressure on skin.
 7. Take vital signs every 8 hours unless indicated more frequently.
 8. Bathe client every 24 hours or more often as needed.
 9. Do not interrupt the client's sleep unless indicated by his/her medical condition.
 10. Ensure that a new order and the physician or LIP completes a medical assessment every 24 hours.
 11. Obtain a physician's order and discontinue restraints as soon as it is clinically indicated.
 12. Document all assessments and findings on appropriate forms.

EVIDENCE-BASED PRACTICE**Effects of Restraints on Reducing Falls**

Studies have indicated that restraints do not reduce falls, prevent the removal of medical devices such as tracheostomy tubes or IVs, or increase client safety. Forty-seven percent of clients who fall are restrained, and 81% who remove their endotracheal tubes are restrained with wrist restraints. Restrained clients are eight times more likely to die during hospitalization. This is directly related not only to the use of restraints but to the fact they usually have IVs, dementia, or surgical intervention. The use of restraints or seclusion has led to more than 140 deaths in the past decade in behavioral health care facilities. Asphyxiation is the most common cause of restraint-related death when clients are trapped between the side rail and the mattress or bed frame.

Source: <http://www2.nursingspectrum.com> (Geriatric Anthology, 2005 Edition. Avelene Orhon. JECH.

TABLE 7-6 Methods to Decrease Use of Physical or Chemical Restraints

Environmental Alterations	Physiological Approaches
<ul style="list-style-type: none"> • Use alternatives such as wedge or roll cushions for positional support • Adjust lighting at night to decrease fear of unknown and facilitate vision of where bed is in room • Use rolled edge mattresses • Use low-level beds (7 to 13 in. from floor) • Place mats on floor in case of client fall • Use special beds • Place in special unit where client can be watched more carefully • Use sitters or family members • Use upper side rails only for aid in turning and moving 	<ul style="list-style-type: none"> • Potential complication assessment (i.e., increased temperature or hypoxia) • Pain relief • Comfort measures • Physical therapy/exercises
	Psychosocial Interventions
	<ul style="list-style-type: none"> • Identify and alter factors that are causing client anxiety, if possible • Talk with client • Involve client in activities that take his or her mind off what is happening • Encourage interaction with family members by phone if necessary

Applying Torso/Belt Restraint**Equipment**

Safety belt restraint (usually 2-in. soft webbing material) with waist and side belts (for bed)

Procedure

1. Check physician's order and client care plan for torso/belt restraint. Perform hand hygiene.
2. Obtain belt. Belts usually have a key-locked buckle.
 - ▶ **Rationale:** To prevent slipping and to provide a snug fit.
3. Identify client using two identifiers and explain necessity for safety belt to client and family.
4. Apply torso restraint as follows:
 - a. Slip waist belt through flat buckle, adjusting to client's size.
 - b. Snap hinged plate shut by hooking plain end of key over cross bar and lifting upward.
 - c. Attach side belts to bed frame in similar manner.
 - d. Release restraint by hooking green end of key over cross bar from below and pulling downward.
5. Document time, rationale, and type of safety belt used in nurses' notes, along with client monitoring, client response, frequency of care measures, and time and rationale for discontinuing restraint. Documentation must be done every 15 minutes.

▲ Some belts have a key-locked buckle to prevent slipping and to provide a snug fit.

EVIDENCE-BASED PRACTICE

Deaths Due to Use of Physical Restraint or Seclusion

A 50-state survey by the *Hartford Courant* in 1998 identified at least 142 deaths related to the use of physical restraint or seclusion since 1988. The true number of deaths is much higher since data regarding this type of information is not public information. According to statistical projections commissioned by the *Courant* and conducted by the Harvard Center for Risk Analysis, between 50 and 150 deaths occur every year across the country due to improper restraint procedures. Based on this data, it was felt there is a critical need for mandated monitoring of the use of restraints and seclusion.

Source: American Nurses Association. (2001). Position Statements: Reduction of Patient Restraint and Seclusion in Health Care Settings. www.nursingworld.org/EthicsHumanRights.

Using Wrist Restraints

Equipment

- Commercial cloth restraints with flannel padding
- Ace bandages of appropriate size for area to be immobilized
- Call bell for communication

Procedure

1. Attempt all other methods of client protection or less restrictive measures before applying restraints.
2. Check physician's order for wrist or ankle soft restraint. If necessary, place restraint on client, then phone physician or LIP for orders within 1 hour of application of restraint.

▲ First, apply padded portion of restraint around wrist or ankle.

▲ Secure restraint by pinching long-pronged adapter and inserting into buckle end of restraint.

3. Obtain soft restraints. Check correct size of restraints.
4. When applying restraint, place padded section over the wrist or ankle. Ensure restraint will not interfere with IVs or tubes.
5. Secure restraint by pinching long-pronged adapter and inserting into buckle end of restraint, or follow manufacturer's directions.
6. Slip two fingers under restraint. ► **Rationale:** This ensures it is not too tight and will not constrict blood flow.
7. Attach other end of restraint under movable portion of bed frame by using a half-bow knot. ► **Rationale:** This is a quick release knot and will untie quickly in an emergency.

Clinical Alert

Always keep scissors in easy access to facilitate cutting restraints in case of an emergency.

8. Release restraints every 2 hours. ► **Rationale:** Release is necessary to:
 - a. Check limb circulation and skin condition.
 - b. Provide extremity range of motion.
 - c. Change client's position.
 - d. Attend to elimination, fluid, or other needs.
9. Document use of and rationale for wrist restraints in nurses' notes. Identify all less restrictive actions tried before restraints.
10. Monitor client every 15 minutes. ► **Rationale:** Frequent monitoring prevents complications.

Clinical Alert

Limb, vest, and mitt restraints are considered a type II restraint. A type I restraint is a four-point locked restraint. Type I restraints are used primarily in psychiatric or emergency room settings.

If using any locked restraint, keep the key in client's room taped to the top of bed or near "stat" call button. It must be in sight and easily accessible in case of emergency.

Alternate Type of Soft Restraint

- Slide strap through slit in restraint.
- Tighten strap, leaving fingerbreadth space between restraint and client's limb.

▲ Secure restraint under moveable part of bed, using slipknot.

**Using Mitt Restraints****Equipment**

- Mitt restraint
- Gauze padding
- Call bell for communication

Procedure

1. Check physician's order, or after placing mitt restraint, phone physician or LIP for orders.
2. Determine whether less restrictive actions could be used.
3. Perform hand hygiene.
4. Obtain appropriate size mitt restraint and gauze padding, if needed.
5. Identify the client by checking two forms of identification.
6. Explain steps and purpose of procedure to family and client (to gain his or her cooperation) if client is able to understand.
7. Raise bed to high position.
8. Lower side rail as needed.
9. Check condition of skin and circulation in involved extremity.
10. Wrap fingers with gauze to absorb moisture and prevent abrasion, if necessary.
11. Apply mitt; secure wrist ties snugly, but maintain circulation by ensuring that two fingers can be slipped under the restraint.
12. For hand control, use slip knot to tie restraints to immovable part of bed frame, not to side rail.
13. Place call bell within access and monitor client every 15 minutes.
14. Remove mitt every 2 hours. ► **Rationale:** This is necessary to:
 - a. Check adequacy of circulation and skin condition.
 - b. Provide extremity range of motion.
 - c. Change client's position.
 - d. Provide for fluid.
15. Reapply mitt.
16. Raise bedrail and lower bed, according to facility policy.
17. Perform hand hygiene.
18. Chart on nurses' notes: client behavior necessitating restraint, all less restrictive actions taken, condition of skin, adequacy of circulation of involved extremity, time of mitt application, times of release and observed responses, and care needs met. Documentation must be done every 15 minutes.

Clinical Alert

Restraints are never used as a substitute for surveillance.

NOTE: In confused ambulatory clients, restraint use has been associated with increased falls.

Using Elbow Restraints

Equipment

- Elbow restraint
- Soft padding

Procedure

1. Check physician's order. This type of restraint, if used for medical procedures or to protect IVs, does not require specific restraint orders.
2. Obtain elbow restraints (many types are available).
3. Explain necessity of restraints to child's parents.
4. Place restraints over elbow of both arms. You may need to insert tongue blades into pockets of restraint.
5. Wrap restraints snugly around the arm. Secure by tying the restraints at the top. Many restraints have ties long enough to cross under the child's back and tie under the opposite arm.
6. For small infants and children, tie or pin restraints to their shirts.

▲ Elbow restraints prevent children from reaching equipment.

7. Release the restraints every 2 hours. ► **Rationale:** This allows for joint mobility.
8. Assess position of restraints, circulation, skin condition, and sensation every hour.
9. Provide diversionary activity for small child.
10. Encourage parents or hospital personnel to hold child to promote a feeling of security.
11. Document use of restraints in nurses' notes. Document release of restraints, skin, and circulatory condition. Documentation must be done every 15 minutes.

▲ Elbow restraints may be used to prevent child from reaching his or her face or head.

Applying a Vest Restraint

Equipment

- Safety vest
- Call bell for communication

Procedure

For Client in Bed

1. Check physician's order or apply vest and call physician or LIP within 1 hour for order.
2. Determine whether less restrictive actions could be used.
3. Explain necessity for jacket or vest restraint to client and family.
4. Place vest over gown.
5. Place safety vest on client so that closed side of vest is in back and front side of vest crosses over chest or according to manufacturer's directions. ► **Rationale:** This prevents choking if client slumps forward.
6. Bring strap through slit in front of the vest. ► **Rationale:** Criss-crossing vest in the back may cause serious injury.

Clinical Alert

The use of vest restraint has been associated with serious injury, including client suffocation. If your facility still uses this restraint, exercise extreme caution in applying restraint and monitor frequently.

▲ Vest restraint can be used for client on bed rest.

7. Tie straps to nonmovable upper section of bed frame using slipknot. ▶ **Rationale:** This position minimizes risk of inadvertent release, which may cause subsequent injury.
8. Observe client every 15 minutes to ensure proper fit of jacket.
9. Release vest restraint every 2 hours. Follow interventions for releasing restraints of all types.
10. Document use and rationale for restraint in nurses' notes every 15 minutes.
11. Document client assessment and attendance to fluid and elimination needs regularly.

For Client in Wheelchair

1. Place client in wheelchair with buttocks against chair back.
2. Place vest on client (zipper vest is best) place zipper to back of client. Zip vest from bottom to top. Ensure that there is adequate space between vest and client.

▲ Zip vest from bottom to top at client's back.

▲ Pull vest tails under armrests and cross tails in back of chair. Wrap tails around immovable kickspur.

▲ Tie each tail to kickspur using half-bow knot.

⚠ Check client every 15 minutes while in restraint.

- ▶ **Rationale:** To prevent constriction from vest that is too tight.
- 3. Pull straps at 45-degree angle to rear of seat and pull vest tails under armrests and cross tails in back of chair.
 - ▶ **Rationale:** Tying vest tails in back of chair prevents client from reaching the tails and untying the vest.
- 4. Wrap tails around immovable kickspur. ▶ **Rationale:** This anchors the tails and prevents client from slipping out of restraints.
- 5. Tie each tail to kickspur using half-bow knot.
 - ▶ **Rationale:** This type of knot is used because it can be quickly released if necessary.
- 6. Check client every 15 minutes to ensure vest is on correctly and client is not in compromising situation.
- 7. Document every 15 minutes according to policy.

Source: Health Resources Unlimited, LLC (2006, January).

Tying a Half-Bow Knot

1 Place restraint tie around wheelchair kickspur. Bring free end up, around, under, and over attached end of tie and pull tight.

2 Take free end over and under attached end of tie, but this time make half-bow loop.

3 Tighten free end of tie and bow until knot is secure.

▲ Pull end of tie and loosen first crossover tie in an emergency.

Clinical Alert

Alternate Method

Daisy chain tie is used as an alternate method to prevent tie from dangling to floor or to prevent client from releasing tie.

▲ Complete daisy chain.

▲ Tuck chain under mattress.

Applying Mummy Restraints**Equipment**

Blanket large enough to fit child, or sheet, if blanket not large enough for infant.

Procedure

1. Perform hand hygiene.
2. Place the blanket on a secure surface and fold down one corner until tip reaches the middle of the blanket.
3. Place the baby in a diagonal position with the head halfway off the folded edge of the blanket.
4. Bring one side of the blanket over the infant's arm and trunk, and tuck it under the other arm and around the back. Keep arms in natural position to the side.
5. Tuck the bottom part of the blanket up onto the infant's abdomen.
6. Fold the second side over the infant, and tuck it snugly around the body.
7. Use the restraint only until procedure is completed.

Mummy boards with Velcro straps are used more often in the hospital setting. A diaper or Chux is placed on the board, and the infant is placed on the board and secured with the Velcro straps.

▲ A mummy restraint is used when certain procedures are to be done.

Clinical Alert

Generally, restraint policies do not apply to:

- Restriction for security purposes.
- Procedure-related immobilization (e.g., for medical, surgical, or diagnostic procedure).
- Use of adaptive support devices (e.g., brace, orthopedic appliances).
- Use of medical protective devices (e.g., tabletop chairs, bed rails).
- Voluntary restraint (client consent).

DOCUMENTATION for Applying Restraints

- Description of specific behaviors leading to restraint.
- Note all less restrictive techniques used. If less restrictive techniques were not used, provide rationale.
- Extent to which client is able to cooperate with restraint procedure.
- Any injury to client or others.
- All observation data for entire time restraint is applied. Include skin integrity, neurovascular changes, etc.
- Client's behavior after and during time restraint is applied.
- Justification and reassessment for continued use of restraints.
- Document review of care plan for effectiveness or rationale for ineffectiveness of care plan.

Legal Considerations

Restraints: Swann v. Len-Care Rest Home Inc. (1997)

Family members requested the confused grandmother be restrained when they were not in attendance. The physician ordered the restraints and wrote a letter indicating he wanted the restraints placed when the client was alone. The client was left unattended and unrestrained, fell, and sustained a head injury. The family brought suit against

the facility. During the trial, it was noted this was the client's third fall while she was unrestrained. The court found for the plaintiff. To avoid liability, always follow hospital policies related to use of restraints.

Source: Health Resources Unlimited, LLC. January 2006.

CRITICAL THINKING Application

Expected Outcomes

- Client is prevented from injuring himself/herself or others.
- Restraints are applied appropriately.
- Client does not develop complications due to restraint use (e.g., agitation, pressure ulcers, circulatory disturbance).
- Child is prevented from reaching the incision site, IVs, or tubes.

Unexpected Outcomes

Skin abrasion, maceration, or rash occurs after application of restraints.

Impaired circulation or edema evidenced by change in color, sensation, movement, and blanching of nail beds.

Client unties restraints.

Client with history of falling has developed acute cognitive changes.

Child is able to reach incision site even with elbow restraints in place.

- Client remains in restraints for a limited amount of time.
- Client does not experience complications as a result of restraint placement.
- Client does not endure undue psychological stress while being placed in restraints.

Alternative Actions

- Reassess absolute need for restraint.
- Reassess application method.
- Increase padding of soft restraints before application.
- Keep restraints off as much as possible and have staff or family member stay with client.
- On observation of signs of neurovascular changes, immediately release restraints.
- Massage area gently to increase circulation.
- If extremity is edematous, elevate extremity above level of heart. Encourage range of motion.
- Request order for different type of restraint
- Camouflage restraint to decrease client's awareness.
- Reassess need for restraint.
- Exhaust alternative measures to promote safety.
- Anticipate and attend to client's needs.
- Alert all personnel that client is high risk for fall.
- Review medication regimen (e.g., Demerol and psychoactive drugs can cause acute confusion).
- Assess for physiologic causes (e.g., hypoxemia, infection, pain) and address alterations.
- Place bedside commode away from bed and remove all obstacles; provide good lighting as well as night light.
- Reduce environmental stimuli (e.g., television).
- Reorient client with each encounter.
- Move client for better surveillance.
- Employ monitoring alarm/device or engage family attendance.
- Request floor mattress or recliner chair.
- Make sure the elbow restraints are tight enough and extend over the elbow.
- Tie the one elbow restraint to the opposite elbow restraint by placing the tie under the child's back and securing the tie with the upper tie on the opposite restraint.
- Check that the restraint is large enough to completely immobilize the elbow. If not, obtain a larger size or use two restraints and tie them together securely.

GERONTOLOGIC Considerations

Safety Precautions for the Elderly

- Ensure sensory adaptive devices are used (glasses, hearing aid).
- Use one-half to three-quarter rails rather than full rails.
- Provide adequate lighting.
- Provide and encourage use of call bell/summons device.
- Assess fluid and elimination needs regularly.
- Promote activities of daily living and exercise to maintain muscle strength and flexibility.
- Assist client in ambulation if unsteady on feet.
- Heed client's summons promptly.

- Put necessary articles for personal hygiene and activities of daily living within easy reach.
- Provide nonslip mats and grab bars in bathtubs, showers, and near toilets.
- Use shower chair.
- Mop up spills promptly.
- Keep hallways clear of obstacles.
- Lock all equipment when not moving client.
- Provide handrails in hallways.
- Instruct in use of assistive devices when in use.
- Maintain a consistent environment: keep furniture in established places.

Preventing Thermal Injury

- Skin is fragile and prone to injury as client's age increases. Use thermal treatments with caution. Do not apply *direct* heat to areas with ischemic tissue.

- Check skin frequently when any type of heat therapy (e.g., Aqua K pad) is used.
- Check water temperature before placing client in bathtub (95°F for the elderly and those with peripheral circulation impairment).

Wandering-Client Management Plan

- Clients who are identified as potential wanderers from a facility or at risk for falls should wear a monitor device.
- Monitors come in various models, each one designed to identify clients who move away from a designated monitor zone.
- Clients need to be checked regularly to ensure the monitor is appropriately positioned and the alarm functions properly.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- Before nursing staff is assigned to care for clients requiring restraints, the team leader and/or charge nurse must ensure they have been properly educated in the legal requirements as well as in the application of restraints.
- All personnel must be aware of environmental and client risks for injury. Remind staff to notify RN of risks.

- Nurses must help identify clients at high risk for injury and must be familiar with agency plan/protocol for the prevention of injury.
- Nurses must individualize restraint implementation.

Communication Matrix

- Clients at high risk for injury: Report client risk behaviors, attempts to determine underlying cause, attempted alternative protective measures, and rationale for choice of restraint.
- Document type and time restraint initiated, regular monitoring, and client response. According to the FDA, approximately 20 clients die every year from protective restraints. It is critical to instruct all personnel (including CNAs and UAPs who may not administer the restraints, but give client care and therefore, observe restraint use) in the proper use of restraints.

CRITICAL THINKING Strategies

Scenario 1

As you enter Mrs. Lake's room, you find her with one leg over the side rail, making attempts to get out of bed unassisted. Mrs. Lake is an 82-year-old client with a history of heart failure (HF). When you question what she is doing, she tells you, "I need to go to the bathroom." She also tells you she is sure her dog needs to be let out because she hasn't been able to get out of the bed all morning. This is your second day

caring for Mrs. Lake. Your initial assessment on admission 2 days ago included her being oriented to person, place, time, and thing. The night shift reported off saying she was disoriented all night.

1. What is your first nursing action? Provide rationale for your response.

2. What additional priority nursing actions are justified for Mrs. Lake?
3. What additional information do you need to gather to determine the next step in her plan of care?
4. If, in the assessment completed by the RN, it is determined she needs to be closely monitored for possible falls, what interventions, by priority, will you implement?
5. Identify the legal requirements that must be implemented when a client is placed in restraints.
6. Identify other least restrictive measures that can be utilized before restraints are applied.

Scenario 2

A 75-year-old female was admitted to the hospital after sustaining a fractured hip after a fall on the sidewalk in front of her house. The admission nurse calls the unit to apprise them of the new admission. The nurse explains that the client is not sure what day it is nor where she is at the moment. She did sustain a cut on her forehead in the fall, requiring five

stitches. You have been assigned to admit the client when she arrives on the unit.

1. Identify the priority assessment you will complete at the time of admission.
2. Describe the environmental alterations that can be initiated to prevent injury to the client.
3. Considering the fall, determine what assessment findings you will evaluate in the initial assessment.
4. Describe two priority nursing interventions that will be included in the client care plan for this client.
5. The client has surgery the next day and returns to the nursing unit. The client comes back with two IVs, hip dressings with a drain, and O₂ per nasal cannula. The client responds to painful stimuli but is not fully awake. Determine the appropriate safety interventions that will be employed to prevent injury to the client as she awakens.

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. Which one of the following factors is not considered a characteristic that promotes adaptation to the environment?
 1. Environmental influences.
 2. Age.
 3. Mental status.
 4. State of illness.
2. The primary root cause of a sentinel event is:
 1. Poor staffing ratio.
 2. Errors in procedure.
 3. Inaccurate client assessment.
 4. Communication.
3. A client has an order for application of wrist restraints as a result of exhibiting confusion. How often in hours must a renewal order be written?
 1. 2.
 2. 4.
 3. 8.
 4. 24.
4. Restraint guidelines include which of the following?
 1. Client must be observed every 2 hours while in restraints.
 2. Wrist restraints must be the first type of restraints used before proceeding to other types of restraints.
 3. Slip knots or the daisy chain is used for securing restraints to the bed frame.
 4. Use of restraints is encouraged to replace sitters for clients at risk for falls.
5. You are preparing to care for a client with a radioactive implant. The most important client care principle is to
 1. Keep soiled dressings, gloves, and linens in contaminated container in the room.
 2. Assist client to sit at edge of bed to participate in bathing.
 3. Increase time available for client care; provide care by standing at head or foot of bed.
 4. Instruct visitors to limit visits to no more than 4 hours each day.
6. The priority nursing intervention when a client has a seizure is to
 1. Turn client on abdomen to prevent tongue from occluding airway.
 2. Insert tongue blade to side of mouth to prevent tongue from falling back.
 3. Place vest restraint on client after initial seizure activity to prevent client from falling out of bed.
 4. Stay with client during postictal state to ensure client has an uneventful recovery.
7. In case of fire in the nursing unit, the priority intervention is to
 1. Extinguish fire, if possible.
 2. Close doors and windows of clients' rooms.
 3. Remove clients from immediate danger.
 4. Activate the fire alarm.

8. The client teaching plan for an 88-year-old female client who is being discharged to home includes all but which one of the following safety precautions?
 1. Explain to client that he/she needs to be on bedrest until lower extremity strength and flexibility returns.
 2. Place essential articles for personal hygiene near the bed.
 3. Install grab bars in tubs and near the toilet.
 4. Use a shower chair when bathing the client in the shower.
 9. You assess a client for potential falls and determine that an environmental alteration could be used to prevent the need for restraints. This type of alteration would include
 1. Placing a rolled-edge mattress on the bed.
 2. Placing client in a room near nurses' desk for easy observation.
 3. Using a geri-chair and placing client near the nurses' desk.
 4. Placing bed in low position, with two upper side rails in the "up" position.
 10. The client is being positioned in a wheelchair with an order for a Posey vest to prevent him from falling out of the chair. Which actions should be taken by the nurses to secure the vest on the client?

Select all that apply.

 1. Place vest on client with the zipper in front.
 2. Place vest tails under arm rests and cross tails in back of chair.
 3. Tie vest tails using a daisy chain and anchoring on kickspur of the wheelchair.
 4. Tie each tail to the kickspur using a half-knot.
-

Bathing, Bedmaking, and Maintaining Skin Integrity

LEARNING OBJECTIVES

1. Compare and contrast the steps in making an occupied and unoccupied bed.
2. Demonstrate the skill of folding a mitered corner.
3. Outline the steps in bathing a bedridden adult client.
4. Differentiate between bathing a bedridden client and a critically ill client.
5. Compare and contrast the differences in bathing an infant, a child, and an adult client.
6. State the advantages of using a commercial bathing system.
7. Describe the assessment modalities completed while bathing a client.
8. Outline the steps in providing morning care.
9. Describe the skin assessment steps that must be completed on a daily basis.
10. Outline the steps in providing foot care.
11. Describe the changes in skin that occur with aging and appropriate nursing interventions to prevent a skin tear.
12. Describe briefly the components of evening care.
13. Define the three back care strokes and their use in back care.
14. Complete client charting for evening care on nurses' notes.
15. Write three nursing diagnoses appropriate for providing basic hygienic care to clients.

TERMINOLOGY

Bedmaking

Closed bed a bed not being used by a client; the linens are left to cover the bed.

Occupied bed the client remains in the bed while it is being made.

Open bed a bed being used by a client; the linens are fan-folded down.

Unoccupied bed the client is out of the bed while it is being made.

Equipment Used With Beds

Aside from the standard types of equipment used on the basic hospital bed, specialized equipment can be added to meet the client's healthcare needs.

Balkan overbed frame an overhead bar used to support a trapeze, or a series of pulleys and weights used for traction equipment.

Footboard usually a solid support placed on the bed where the soles of the feet touch. It is secured to the mattress or bed frame. Footboards are used to prevent permanent plantar flexion (footdrop) and to exercise leg muscles. The footboard may also have side supports to help maintain proper alignment of feet.

Sheets for Bedmaking

Fitted sheets sheets that have elastic at each corner.

Drawsheets sheets made of fabric or waterproof material that are placed across the shoulder-to-knee area of the bed and tucked in on the sides.

Full sheets regular full-length flat sheets that can be used as the top and/or bottom sheet.

Incontinent pads large cloth or disposable pads that can be placed under the buttocks area, head, drains, or any place where excess moisture or fluid may collect on the bed.

Pull sheets sheets placed across the shoulder-to-knee area of the bed. The sides are not tucked under the mattress. The sheet is kept wrinkle-free and folded under the client. Pull sheets are used to lift the client in the bed.

Levels of Personal Care

Complete or total care the client requires total assistance from the nurse because he or she is able to do little or nothing for him or herself. Complete bathing, skin care, oral care, nail and hair care, care of the feet, eyes, ears, and nose, and a total bed linen change are usually provided.

Early morning care or AM care given by the night shift or day shift nurses and may include bathing the hands and face, use of the bedpan, urinal, or bedside commode, oral care, and other preparations before breakfast.

Evening care (H.S. care, hour of sleep care) evening care is usually provided to prepare the client for a relaxing,

uninterrupted period of sleep. Activities may include oral care, partial bathing, skin care, a soothing back massage, straightening or changing the bed linen, and offering the bedpan or urinal. The client should also be assessed for the need of food, drink, or medication before sleep.

Preoperative care clients who will be undergoing surgery or diagnostic tests may be required to bathe the evening before. Partial bathing is sometimes allowed in the morning if time permits. If the client is not allowed to have anything by mouth, care must be taken not to allow swallowing of water or dentifrice while providing oral care. The client is usually given a clean gown. All dentures, hairpins, makeup, nail polish, contact lenses, and jewelry are removed. Valuables are locked up. The client is encouraged to void before leaving for the operating room.

Partial care the client performs as much of his or her own care as possible. The nurse completes the remaining care.

Independent care the client is able to complete his or her own care. The nurse provides the client with any needed equipment.

Skin Care

Acne skin condition due to irritation and infection of the sebaceous glands.

Blanching a whitish hue to an area of the skin when pressure is applied.

Echymosis collection of blood underneath skin surface; bruise.

Emollient soothing, softening agent applied to body surfaces.

Epidermis superficial, or top, layer of skin.

Erythema redness of skin associated with rashes, inflammation, infections, allergic responses, or congestion of the capillaries.

Hyperemia influx of blood into an area causing redness to the skin.

Ischemia decreased, insufficient blood supply to body area.

Lesion an area of broken skin as a result of trauma or a pathologic interruption of tissue.

Necrosis cellular death resulting from decreased blood flow to tissue.

Pediculosis infestation of lice.

Pediculus capitis head lice.

Pediculus corporis body lice.

Pediculus pubis crab lice or pubic lice.

Petechiae pinpoint reddish spots.

Pressure ulcer an area of cellular necrosis due to decreased circulation.

Purpura reddish purple area.

Shearing force layers of skin moving on each other.

Skin tear traumatic wound resulting from separation of the epidermis from the dermis.

Turgor the degree of elasticity of the skin.

Back Care

Effleurage long stroking motions of the hands up and down the back. Hands do not leave the skin surface. Pressure is light.

Petrissage pinching of the skin, subcutaneous tissue, and muscle as you move up and down the client's back.

Tapotement alternate striking of fleshy part of hands on client's back as you move up and down the back.

Foot Care

Athlete's foot irritation characterized by itching, burning skin; caused by an easily transmitted fungus.

GENERAL TERMINOLOGY

Assessment the collection, verification, organization, interpretation, and documentation of client data; the first step in the nursing process.

Complete bath all areas of the body are bathed. This bath can be done completely by the nurse or by the client.

Cyanosis blueness of the skin related to decreased oxygenation of the blood.

Dermis layer of skin below the epidermis containing blood and lymphatic vessels, nerves, nerve endings, glands, and hair follicles.

Epidermis superficial, avascular layer of skin primarily used for protection.

Excreta waste matter; materials cast out by the body.

Fissure a groove, slit, or natural division; ulcer or crack-like sore.

Flush a redness of the face and neck due to dilation of the capillaries.

Hypoallergenic against allergy, as hypoallergenic tape.

Incurvate curved, especially inward.

Inflammation swelling, pain, heat, and redness of tissue.

Intervention the act of coming between, so as to hinder or modify.

Jaundice yellowish appearance caused by deposition of bile pigment in the skin.

Calluses thickened epidermis over area of pressure.

Corns high calluses caused by pressure on toes, joints, or bony prominences.

Cracks and fissures between toes this problem can occur anyplace on feet, often on heels; often occurs as a result of excessively dry skin.

Decreased circulation to the feet a problem that is often caused by diabetes, vascular diseases, or the constriction of major vessels to the lower extremities.

Incurvated or ingrown toenails the corners of the nail tend to press into skin, causing pain, ulceration, and infection.

Plantar warts virus manifested as a deep, often painful wart on the soles of the feet.

Mucosa mucous membrane lining passages and cavities communicating with the air.

Pallor paleness; absence of skin coloration.

Partial bath certain parts of the body are bathed such as the face, hands, underarms, back, and perineal area. Another definition of a partial bath is a bath that occurs when the nurse bathes areas which the client cannot reach and the client washes all other areas.

Pigment any normal or abnormal coloring of the skin.

Plaque a patch on the skin or on a mucous surface.

Pressure point area for exerting pressure to control bleeding; an area of skin that can become injured with pressure, especially over bony prominences.

Sensory deprivation enforced absence of usual and accustomed sensory stimuli.

Sensory overload too much stimuli for the senses to adjust to at once.

Therapeutic bath baths requiring a physician's order used for specific conditions. The order should include type of bath, water temperature, solution to be used, and frequency.

Ulcer an open sore or lesion of the skin or mucous membrane of the body.

BASIC HEALTH CARE

Clients enter the hospital environment for a variety of reasons requiring immediate care, or because the physician has recommended diagnostic procedures or surgery. The latter is commonly referred to as an *elective admission*. Whatever the reason, the client must rapidly alter everyday routines and activities of daily living. The client may be concerned about his or her health and well-being and may experience varying degrees of anxiety as a reaction to unfamiliar procedures, hospital personnel, or the hospital environment itself.

After the client has been admitted to the healthcare unit, many independent actions, such as bathing, personal hygiene,

and general care, may be curtailed by the nature of the illness and confinement. The client may require assistance with even the simplest of actions. Without therapeutic intervention, the total adaptation process may be put in jeopardy as additional physical problems occur. Knowing when and how to intervene and performing such skills as bedmaking, bathing, and personal hygiene facilitate the client's process of adapting to the health-care environment.

When the client is confined to bed even for a short time, comfort is essential in order to promote rest and sleep. To prevent skin irritation and breakdown, beds must be kept clean and free of debris and wrinkles. The bed needs to be straightened frequently throughout the day to accomplish this. If the

client is to remain in bed for an extended time, all care and daily routines are directed from bed. It becomes the center of activity.

Types of Beds

There are many different types of beds and related equipment available to meet the special healthcare needs of individual clients.

The hospital bed is a standard twin-size bed in a frame that allows for different positions to facilitate care and comfort for the client. The height, head, and foot positions in most beds are electrically operated to assist both the client and the nursing staff. The nurse instructs the client in the proper use of bed controls and in bed positions that could be helpful or dangerous for the client.

Support Surfaces

Support surfaces such as mattress overlays filled with foam, gel, or water are commonly used as the first line of defense against skin breakdown. These surfaces prevent pressure on bony prominences, thus reducing pressure ulcer incidence. They are cost-effective surfaces that prevent pressure ulcers in clients who are classified as low risk. These surfaces can also be used to treat those clients who already have pressure ulcers. (See Chapter 25 for pressure ulcer care.)

Foam overlay (Care-Gard, Geo-Matt) support surfaces are used for prevention in low-risk clients. The foam pads are ventilated for moisture control and have an antishearing surface. Foam mattresses (Comfortline Ultimate, basic PRIMA, and SimpliMATT) can be placed on top of existing mattresses. An alternating therapy system mattress can also be used as a replacement for the mattress (DUO DETEQ, TRINOVA®). A third type of support system, the continuous airflow system (ACUCAIR), is also placed over an existing mattress. It keeps skin dry with the continuous airflow and moisture control feature. It also reduces friction and shear. This system is portable and easily transported and placed on the existing mattress.

Specialty Beds

New types of specialty beds are used to provide care to clients at risk for developing skin breakdown and pressure ulcers. Clients most susceptible to these conditions (where a specialty bed is critical) include spinal cord injury clients or those who need frequent turning and are difficult to move, such as CVA clients.

Specialty beds replace the entire hospital bed and are classified as air fluidized, low air-loss, kinetic therapy, and critical care therapy. High air-loss beds are used for clients with stage III and IV pressure ulcers. These beds have antifriction/shear surfaces and built-in scales. Low air-loss beds are used for clients who are difficult to reposition or when moving is contraindicated. Air-filled beds are used for clients who require minimal movement. It makes turning easy and facilitates drainage.

There are two additional types of specialty beds used as preventative or treatment measures for clients having special needs. The first type, the kinetic bed (TotalCare, SpO₂RT, and

RotoRest®) is used to provide continuous passive motion or oscillation for clients with unstable spines. The second type of bed, the bariatric bed (Magnum II®, Burke®, BariMaxx II®), is used with obese clients. These beds have a special feature that allows clients to be weighed in the bed, and it can also be converted into a chair.

Bathing

Routine bathing is an essential component of daily care. It is essential to prevent body odor, because excessive perspiration interacts with bacteria to cause odor. Dead skin cells can lead to infection if impaired skin integrity occurs. Excessive bathing, on the other hand, can increase the risk for impaired skin integrity in elderly clients. In the elderly, the skin may become dry and cracked due to a natural decrease in the production of moisturizing oils, which can lead to infection.

Bathing promotes a feeling of self-worth by improving the person's appearance. Relaxation and improved circulation are benefits of bathing and play a therapeutic role in the care of clients on bedrest. The apocrine glands, found in the axillae and pubic areas, produce sweat, which leads to odor. Therefore, thorough bathing should be provided to these areas.

In addition to the therapeutic effects, the bath affords the nurse time to communicate with and assess the client. Assessment of skin conditions, mobility, and self-care deficits can be detected while bathing the client.

In addition to the basin, wash cloth and soap bathing procedure, there are several types of commercial body cleansing systems currently used in hospitals and other healthcare facilities. The systems are a body bath, shampoo, and a perineal care package. The bath system uses disposable washcloths to cleanse the client. This type of system cleans, moisturizes, conditions, and protects the skin; therefore, it is a good alternative for elderly clients or clients with sensitive skin. The system contains ingredients that are hypoallergenic and bactericidal.

Bathing is accomplished in a variety of ways, according to the client's needs, condition, and personal habits. Bathing is necessary to cleanse the skin and to promote circulation. Baths may also be used as a treatment to promote healing for a client with burns. Various types of bathing include:

- **Complete bed bath:** The client, who is usually totally dependent, is bathed in bed by the nurse due to physical or mental incapacity. The client is encouraged to complete as much of his or her bath as possible.
- **Partial bath:** Face, axilla, hands, back, and genital area are bathed. Partial bath may be completed by client or nurse.
- **Therapeutic bath:** This bath is used as part of a treatment regimen for specific conditions, such as skin disorders, burns, high body temperature, and muscular injuries. Medicinal substances, such as oatmeal, Aveeno, and cornstarch, may be included in the bath water. Therapeutic baths require physician's orders.
- **Shower:** Preferred method of bathing if client is ambulatory or can be transported to use a shower chair.

- **Tub bath:** Used by ambulatory clients as well as those who must be assisted by a device such as the Hoyer lift.
- **Cooling bath:** The client is placed in a tub of tepid water to reduce body temperature.

Skin Conditions

The skin is the largest organ of the body. Skin is exposed to environmental risks as well as physical and mechanical injury. Skin is composed of the epidermis (outer layer) and the dermis (inner layer). The skin provides protection, thermoregulation, excretion, metabolism, sensation, and communication for the body.

Skin types, colors, textures, and condition are as different and unique as each person. The condition of a client's skin is determined by his or her health status, age, activity level, and environmental exposure. For example, the skin of an infant is often more sensitive and delicate than that of an adult because it has not been exposed to many environmental elements. Most infants cannot tolerate strong soaps and lotions and must be handled gently to avoid trauma. Adolescents are affected by acne and have areas of increased oil secretion. Adults may have drier skin, especially as they age. Older adults cannot always tolerate harsh soaps because their skin is more delicate. They require less frequent bathing and more lubrication with oil-rich creams and lotions.

According to Payne and Martin (1998), the classification of skin tears is a traumatic wound usually occurring on the extremities of elderly clients as a result of friction, or shearing and friction forces, resulting in separation of the epidermis from the dermis. This occurs more frequently with elderly clients as a result of changes in their skin with aging. The epidermis

gradually thins as a result of loss in dermal thickness and becomes more susceptible to mild mechanical trauma. In addition, the skin loses its elasticity as elastin fibers decrease. This leads to a less effective barrier against fluid loss, bruising, and infection. Impaired thermoregulation leads to decreased tactile sensitivity and pain perception. Blood vessels become thin and fragile, which presents as purpura or the appearance of little hemorrhages under the skin. Skin tears often occur at the site where purpura is present. Skin tears are more prevalent on the arms and hands, but can occur anywhere on the body. A skin tear on the back or buttocks is often mistaken for a pressure ulcer; however, the etiology of a skin tear is different.

Maintaining skin integrity is an integral part of providing nursing care; being aware of the client's skin condition and alterations in the integrity is a critical aspect of providing total client care. The feet are especially susceptible to discomfort, trauma, and infection due to the amount of stress they must endure as well as to their distance from main blood supplies. Many conditions can be avoided if proper foot care is taken.

CULTURAL AWARENESS

When providing hygienic care for clients, the nurse needs to assess the client's usual pattern of bathing, hygienic products usually used, and cultural rituals and beliefs.

Modesty and bathing rituals and beliefs must be considered in caring for clients. For example, some cultures and religions do not allow members of the opposite sex to see them from the waist to the knees (Gypsy culture, Southeast Asian cultures). Hispanic women have a strong sense of modesty and do not want healthcare workers to see them unclothed.

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to include in a client care plan when the components are related to basic care of the client.

NURSING DIAGNOSIS	RELATED FACTORS
Activity Intolerance	Prolonged bed rest, surgery, pain, treatment schedule, weakness, fatigue
Ineffective Health Maintenance	Ineffective coping, lack of motivation, motor impairment, lack of financial resources
Impaired Bed Mobility	Unable to ambulate, difficulty moving into or out of bed. Lack of coordination, motor impairment, visual disorders, surgery, muscle weakness, pain
Impaired Skin Integrity	Surgery, immobility, prolonged bed rest, mechanical factors (shearing force, pressure)

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. *Remember to wash your hands or use antibacterial gel before and after each and every client contact.*

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. *These actions prevent errors and conform to The Joint Commission standards.*

Bedmaking

Nursing Process Data

ASSESSMENT Data Base

- Assess the client's need to have linen changed.
- Determine whether the client's present condition permits a change of bed linen.
- Determine how many and what type of linens are required.
- Check client's unit for available linens.
- Determine client's prescribed level of activity and any special precautions in movement.
- Assess client's ability to get out of bed during linen change.

PLANNING Objectives

- To provide a clean, comfortable sleeping and resting environment for the client
- To eliminate irritants to skin by providing wrinkle-free sheets and blankets
- To avoid client exertion, do not move client more than necessary when making an occupied bed (Do not move client more than necessary)
- To enhance client's self-image by providing a clean, neat, and comfortable bed
- To properly dispose of soiled linens and prevent cross-contamination
- To correctly align clients to assist in promoting a physically and emotionally safe and comfortable position
- To prevent stress to the nurse's back or limbs during procedure

IMPLEMENTATION Procedures

- Folding a Mitered Corner 180
- Changing a Pillowcase 180
- Making an Unoccupied/Surgical Bed 180
- Changing an Occupied Bed 183

EVALUATION Expected Outcomes

- Bed remains clean, dry, and free of wrinkles.
- Client's skin is intact, and free of irritation.
- Nurse does not experience stress on back or joints during bathing and bedmaking.

Critical Thinking Application 185

- Expected Outcomes 185
- Unexpected Outcomes 185
- Alternative Actions 185

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Folding a Mitered Corner

Equipment

Same as for an unoccupied bed

Procedure

1. Tuck sheet tightly and smoothly under mattress at top or bottom of the bed depending on where mitered corner is needed.
2. Grasp edge of sheet with hand and bring sheet onto mattress so that edge forms a right angle.
3. Tuck lower edge of sheet under mattress.
4. Place finger on sheet where it meets mattress and lower top of sheet over finger. ► **Rationale:** This action makes the mitered corner neat, tight, and secure.
5. Remove finger without disturbing folds.
6. Tuck sheet securely under mattress.

▲ Mitered corners keep bed linens tight and wrinkle-free.

Changing a Pillowcase

Equipment

Clean pillowcase

Procedure

1. Perform hand hygiene.
2. Pick up center of closed end of pillowcase.
3. Continue to firmly grip end of pillowcase; then with other hand, gather pillowcase from open end and fold back (inside-out) over closed end.
4. Pick up center of one end of pillow with the hand holding the gathered pillowcase.
5. Invert pillow so pillowcase drapes down over pillow.
6. Pull pillowcase over pillow with other hand. Do not place pillow or case under arm, chin, or in teeth. ► **Rationale:** Contamination occurs from using these methods.
7. Adjust pillow corners in pillowcase by placing hand between case and pillow. Do not shake the pillow to position it in its case.

▲ Pick up center of one end of pillow with the hand holding the gathered pillowcase and pull case over pillow with the other hand.

Making an Unoccupied/Surgical Bed

Equipment

Chair or table

Linen hamper

Linens (in order of use):

Top sheet

Mattress pad, optional

Bottom sheet

Drawsheet

Incontinent pad, if needed

Top sheet

Blanket

Bedspread

Pillowcase

Clean gloves, as needed

NOTE: Whenever possible, make an unoccupied bed rather than occupied. This is physically less stressful for both the client and the nurse.

Preparation

1. Gather clean linen and hamper and bring to room.
2. Explain need for client to be out of bed during procedure.
3. Perform hand hygiene. Don gloves if needed. ► **Rationale:** Linens may be contaminated from urine, stool, or drainage.
4. Assist client out of bed and into chair.
5. Arrange second chair and hamper conveniently for use.
6. Place linen on chair; ensure chair is clean. ► **Rationale:** This action provides a clean surface and promotes infection control.
7. Place clean linen on chair in order of use; pillow case at bottom.
8. Detach call signal from bed linen.
9. Adjust bed to a comfortable working height and use body mechanics principles.

▲ Tuck drawsheet in tightly over bottom sheet.

▲ Unfold top sheet to cover mattress.

▲ Smooth linen before mitering corners.

▲ Form triangle and tuck in linen.

▲ Pull down top linen while holding corner.

▲ Fold cuff of sheet over spread.

▲ Fold sheet over spread and leave cuff.

▲ Pleat top linen to allow space for feet.

▲ Fanfold linen to foot of bed.

Procedure

1. Lower both side rails and place bed in flat position.
2. Remove spread and blanket. If they are to be reused, fold them and place on the chair.
3. Loosen linen on all sides, including head and foot of the bed.
4. Remove top, draw, and bottom sheet, and place in soiled linen hamper. ► **Rationale:** Never place dirty linen on the floor as cross-contamination occurs from this action.
5. Push mattress to head of bed. Center the mattress if necessary.
6. If mattress pad is not changed, smooth out wrinkles and recenter pad on the bed surface. ► **Rationale:** Wrinkles can cause skin abrasions if skin is compromised by age, disease, or malnutrition.
7. Make up one side of the bed, then move to the other side of bed and make it. ► **Rationale:** This step saves time and expenditure of nurse's energy.
8. Place fitted bottom sheet on mattress, and continue making bed at Step 13. If using a flat bottom sheet, place the center fold of the sheet in the middle of the mattress with the end of the sheet even with the end of the mattress.
9. Unfold the bottom sheet, and cover the mattress.
10. Tuck the top of the sheet under the head of the bed.
11. Miter the corner of the bottom sheet at the head of the bed. (See procedure for mitered corner.)
► **Rationale:** A mitered corner is tighter and less likely to come apart.
12. Tuck the remaining side of the bottom sheet well under the mattress.
13. If the client needs a drawsheet, place the drawsheet on the bed and open drawsheet. Tuck the sheet under the mattress. Smooth out wrinkles.
 - a. If a pull sheet is needed, fold drawsheet in half or quarters. Position sheet in middle of bed. ► **Rationale:** Pull sheets are used with heavy or difficult-to-move clients.
 - b. If absorbent pad is needed, center it on bed over draw or pull sheet.
14. Move to the other side of the bed. Pull linen toward you and straighten out linen.
15. Tuck the top of the sheet under the head of the bed if using a flat sheet.
16. Miter the corner of the bottom sheet at the head of the bed if not using a fitted sheet.
17. Tuck remaining bottom sheet well under the mattress. Gather sheet into your hand, lean away from the bed, and pull sheet downward. Tuck sheet under mattress.
18. If drawsheet is used, tighten and tuck the same as bottom sheet.
19. Straighten out absorbent pad and pull sheet if used.
20. Place top sheet, blanket, and spread full length on top of bed.
21. Leave a cuff of top sheet and spread at the head of the bed. Fold back top sheet and spread to form 5 inch cuff.
► **Rationale:** This prevents client's face from rubbing against blanket.
22. Tuck sheet, spread, and blanket well under foot of mattress, one side at a time.
23. Miter corners at the foot of the bed, one side at a time.
24. Make a small pleat or slightly loosen linen to allow room for client's feet. ► **Rationale:** To prevents friction and pressure on feet and toes.
25. Fanfold linen to foot of bed. ► **Rationale:** To facilitate client getting into bed.
26. Change pillowcase. See skill "Changing a Pillowcase."
27. Return bed to lowest position. Reattach call signal to linens.

▲ Keep linen hamper covered to prevent spread of microorganisms. Position hamper outside client's room for easy access.

28. Pull side rail up on side farthest from client.
 - ▶ **Rationale:** To allow client to position self in bed.
29. If the bed is unassigned, leave top linen pulled up, covering the bed.
30. Dispose of soiled linen in dirty utility room or hamper.
31. Perform hand hygiene.

NOTE: Some facilities use individualized plastic bags to transfer linens to dirty utility room.

Principles of Medical Asepsis

- Place dirty linen in hamper.
- Do not place dirty linen on floor.
- Discard all unused linen from client area.
- Do not transfer linen from one client area to another.
- Do not allow dirty linen to touch uniform.
- Perform hand hygiene.

Changing an Occupied Bed

Equipment

- Chair or table
- Soiled linen hamper
- Linens (in order of use):
 - Bath blanket or top sheet
 - Mattress pad, optional
 - Bottom sheet
 - Cloth drawsheet
- Incontinent pad, if needed
- Top sheet
- Blanket
- Bedspread
- Pillowcase
- Clean gloves, if indicated

Preparation

1. Talk with the client and explain how he or she can be involved in the procedure.
2. Explain the sequence for the procedure.
3. Arrange furniture and equipment (e.g., soiled linen hamper and chair) for convenience of use.
4. Perform hand hygiene and then collect the clean linen.

5. Place linen on chair; ensure that chair is clean.
6. Detach call signal from linens.
7. Provide for privacy for the client.
8. Adjust the bed to a comfortable working height with side rails up. Help client into a supine position.
9. Don gloves if bed linen is soiled with body fluids.

Procedure

1. Lower side rail on your side of the bed, but make sure side rail on opposite side is in UP position. ▶ **Rationale:** This ensures client safety as client rolls to edge of bed.
2. Loosen top linens.
3. Remove spread, sheet, and blanket at the same time the bath blanket is pulled over client. Top sheet may be used in place of bath blankets in some facilities. ▶ **Rationale:** Blanket keeps client warm during bed change. If they are to be reused, fold them and place on the chair.
4. Place top sheet in soiled linen hamper, unless being used to cover client during bedmaking.
5. Push mattress to head of bed. Center the mattress if necessary.
6. Assist client to the side of the bed, place in side-lying position facing away from you as near the far side rail as possible.

▲ Place center of sheet in middle of bed.

▲ Tighten bottom sheet under mattress.

▲ Place drawsheet in middle of bed.

▲ Assist client to roll over to side of bed toward you.

7. Loosen bottom linens on your side of the bed.
8. Fold or roll dirty linen under or as close as possible to client. ► **Rationale:** To keep soiled linen contained and away from client's skin.
9. Smooth out wrinkles and recenter pad on the bed surface if mattress pad is used but not changed. ► **Rationale:** Wrinkles may cause skin irritation.
10. Place clean bottom sheet on mattress with client on the opposite side of the bed. Place the center fold of the sheet in the middle of the mattress with the end of the sheet even with the end of the mattress.
11. Unfold the bottom sheet and cover the mattress. Make sure the clean bottom sheet is underneath any used linen. ► **Rationale:** This keeps the clean linen uncontaminated.
12. Tuck the top of the sheet under the head of the bed, or position fitted sheet around corner of mattress.
13. Miter the corner of the bottom sheet at the head of the bed if flat sheet is used.
14. Tuck the remaining bottom sheet well under the mattress from head to foot.
15. Center drawsheet on the bed, if the client requires a drawsheet, and fanfold half of the sheet under the client. Tuck side of the sheet under the mattress. Smooth out wrinkles.
 - a. Fold drawsheet in half or quarters if a pull sheet is needed. Position sheet in middle of bed. Fanfold half of the pull sheet under client, from client's shoulders to knees.
 - b. Fanfold absorbent pad and center it on bed under client's buttocks. Place the pad, absorbent side up and plastic side down, close to the client. ► **Rationale:** This position makes it easy to pull through to the other side of the bed.
16. Help the client roll over to the other side of the bed.
17. Tell the client why there is a hump of linen in the center of the bed. Ensure client comfort (i.e., reposition pillows).

▲ Move to other side of bed, and pull linen toward you.

18. Raise the side rail. Move to other side of bed.
19. Move linens to the other side of the bed, by gently pulling linens toward you.
20. Lower side rail, and loosen bottom sheets.
21. Pull dirty linen to side of bed and roll into a bundle at the foot of the bed or place linen in linen hamper. ► **Rationale:** This reduces the spread of microorganisms.
22. Never place dirty linen on the floor. ► **Rationale:** Cross-contamination occurs from this action.
23. Pull clean linen across mattress and straighten under client.
24. Miter the top corner of the flat bottom sheet or tuck fitted sheet over mattress edge.
25. Gather bottom sheet into your hand, lean away from the bed, and pull linens downward at an angle. Tuck remaining bottom sheet well under the mattress. If drawsheet is used, tighten and tuck it in the same way.
26. Help the client into a supine position and adjust the pillow.
27. Place top sheet, blanket, and spread over the client. Leave at least a 6-inch cuff of top sheet at the head of the bed.
28. Remove bath blanket, and straighten top sheet and blanket.
29. Miter corners at foot of bed.
30. Pull up all layers of linen at client's toes. Make a small pleat. ► **Rationale:** This allows room for client's feet and prevents sheets from rubbing on client's toes.
31. Raise side rail.
32. Remove pillow from bed, and change pillowcase.
33. Return bed to lowest position. Reattach call signal to linens.
34. Position client for comfort.
35. Dispose of soiled laundry.
36. Remove gloves, if used, and perform hand hygiene.

EVIDENCE-BASED PRACTICE

To reduce or eliminate the risk for pressure ulcers, research recommends limiting the layers of linen on which a client lies. Use only the minimum amount of bed linens needed for the specific client's needs or condition.

Source: Gibbons, W., Shanks, H. T., Kleinhelter, P., Jones, P. (2006). Eliminating facility-acquired pressure ulcers at Ascension Health. *The Joint Commission Journal on Quality and Patient Safety*, 32(9), 488–496.

DOCUMENTATION for Bedmaking

- Specific linens or equipment that cause discomfort for the client
- Special requirements for linens (e.g., certain detergents or elimination of starch)
- Use of pull sheets, incontinent pads, or specified ways to keep bed dry
- Addition or removal of linen to adjust for accurate client weight, if using bed scale

CRITICAL THINKING Application

Expected Outcomes

- Bed remains clean, dry, and free of wrinkles.
- Client's skin is intact and free of irritation.

Unexpected Outcomes

Client refuses to have bed made.

Cross-contamination occurs from improper linen disposal.

Client's skin becomes irritated from linen or begins to break down.

The nurse feels stress on back during bedmaking.

- Nurse does not experience stress on back during bathing and bedmaking.

Alternative Actions

- Assess reason for refusal. Client may be in pain or does not want to be disturbed.
- Offer to make the bed at a later time.
- Change only the pillowcase and drawsheet, if client allows.
- Beds do not need to be changed unless soiled or damp, so allow client's independence if possible.
- Provide adequate linen hampers for the nursing personnel.
- Attend in-service education programs on infection control.
- Obtain hypoallergenic linen.
- Place therapeutic mattress under client.
- Provide skin care with appropriate lotion.
- Make sure bed is positioned for comfort of the nurse. High position is generally used.
- If client is heavy, ask for assistance with bedmaking, especially in moving side to side.
- Use full sheet or Booster Lift for turning.
- Attend in-service classes on preventing back strain.
- Use body mechanics principles during bedmaking procedure.
- Use assistive devices for large clients, as available.

Chapter 8

UNIT 2

Bath Care

Nursing Process Data

ASSESSMENT Data Base

- Assess client's need for bathing and other personal hygiene activities.
- Check client's activity order. Note special precautions related to movement or exercise.
- Assess client's ability to perform his or her own care and determine how much assistance he or she needs.
- Discuss client's preferences for the bathing procedure, bath, and personal articles.
- Check client's room for availability of bathing articles and linens.
- Assess client's skin (see Unit 3 on Skin Integrity).

PLANNING Objectives

- To decrease the possibility of infection by removing transient bacteria, excessive debris, secretions, and perspiration from the skin
- To eliminate odors and rid body of microorganisms
- To promote circulation
- To maintain muscle tone through active or passive movement during bathing
- To alternate points of pressure on the body by changing client's position during the bath
- To provide comfort for the client
- To assess the client's overall status, skin condition, level of mobility, comfort

IMPLEMENTATION Procedures

- Providing Morning Care 187
- Bathing an Adult Client 187
 - For Female Client 190
 - For Male Client 190
- Providing Foot Care 190
- Bathing a Client in Tub or Shower 191
- Bathing Using Disposable System 191
- Bathing an Infant 192
- Bathing in a Hydraulic Bathtub Chair 193

EVALUATION Expected Outcomes

- Client's skin is free of excessive perspiration, secretions, and offensive odors.
- Client feels comfortable and does not experience itching or irritation.
- Client's skin is moist and free of itching sensation.
- Client is able to take bath or shower without excessive fatigue or anxiety.
- Client is able to bathe self using disposable cleansing system.

- **Critical Thinking Application** 194
 - Expected Outcomes 194
 - Unexpected Outcomes 194
 - Alternative Actions 194

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Providing Morning Care

Equipment

- Basin of warm water
- Soap
- Towel and washcloth
- Emesis basin
- Toothbrush and paste
- Bedpan or urinal
- Toilet tissue
- Clean gloves

Preparation

1. Determine whether client wishes morning care. ►
Rationale: Morning care is provided to “freshen” the client in preparation for breakfast, physicians’ visits, and procedures occurring before bathing.
2. Perform hand hygiene. ► **Rationale:** When providing morning care to several clients, it is important to perform hand hygiene between clients so that microorganisms are not transmitted from one client to another.
3. Gather equipment and take it to client’s room.
4. Identify client using two indicators.

5. Explain that early morning care is available while client remains in bed. If client is able, assist him or her to the bathroom.
6. Provide privacy.

Procedure

1. Perform hand hygiene.
2. Offer bedpan or urinal and assist client as needed. Don gloves when giving client bedpan or urinal.
3. Move bed to comfortable working height and lower side rail.
4. Put equipment on over-bed table within reach. Place towel under client’s chin. ► **Rationale:** To keep gown and linens dry.
5. Wash client’s face and hands or assist as needed. Dry face and hands.
6. Offer oral hygiene. Assist as needed. Gloves should be worn if client needs assistance with oral hygiene.
7. Hold emesis basin so client can rinse after brushing teeth.
8. Assist client to comfortable position.
9. Reposition bed, and replace side rails.
10. Remove equipment and draw curtains.
11. Remove gloves, if used.
12. Perform hand hygiene.

Bathing an Adult Client

Equipment

- Basin or sink with warm water (110°–115°F)
- Soap and soap dish
- Personal articles (i.e., deodorant, powder, lotions)
- Laundry hamper
- Two to three towels and several washcloths
- Gloves if appropriate
- Bath blanket
- Pajamas or hospital gown
- Table for bathing equipment
- Shaving equipment for male clients

NOTE: Use a new cloth for each section of the body to prevent cross-contamination.

Preparation

1. Provide a comfortable room environment (i.e., comfortable temperature, lighting).
2. Identify client; talk with client about plan for bathing to meet personal care needs.

3. Encourage client to bathe himself or herself. ► **Rationale:** To increase independence, promote exercise and a sense of self-worth.
4. Explain any unfamiliar methods or procedures regarding bathing.
5. Perform hand hygiene.
6. Collect necessary equipment, and place articles within reach on over-bed table.
7. Ask the client if he or she needs to void or defecate before starting the bath. ► **Rationale:** Warm water of the bath and movement can stimulate the client to void.
8. Position the bed at a comfortable working height.
9. Ensure privacy.

Procedure

1. Place bath blanket over client and over top linen. Loosen top linen at edges and foot of bed.
 - a. Ask client to grasp and hold top edge of bath blanket to keep it in place while you pull linen to foot of bed.
 - b. Remove dirty top linen from under bath blanket, starting at client’s shoulders and rolling linen down

EVIDENCE-BASED PRACTICE

Bed Bath or Disposable Bed Bath

Very few studies have been published on the effect that bed baths or tub baths have on client comfort or healing. One study by Dunn et al. (2002) stated that there was a high level of stress for clients receiving tub baths with the diagnosis of dementia. A study by Collins and Hampton (2003) indicated only that the bed bath was more costly than the disposable bed bath. There is a school of thought that indicates bed baths should be eliminated as part of nursing care, particularly since the average length of hospital stay is so short; however, there is insufficient evidence-based data to support this decision.

Source: Dunn, J. C., Thiru-Chelvam, B., & Beck, C. H. (2002). Bathing, pleasure or pain? *Journal of Gerontologic Nursing*, 28, 6.

Collins, F., & Hampton, S. (2003). The cost-effective use of BagBath: a new concept in patient hygiene. *The British Journal of Nursing*, 12, 984.

Moore, K. (2005). Does “arriving” mean we give up the bed bath? *Journal of Wound, Ostomy and Continence Nursing*, 32(5), 285–286.

toward the client's feet. If bath blanket is not available, use top sheet.

- c. Place dirty linen in laundry hamper.
2. Help client to the side of the bed closest to you. Keep the side rail on the far side of the bed in the UP position.
3. Remove client's gown. Most gowns have snaps and can be taken off without disturbing IVs or other tubes. Place gown in laundry bag. Keep client covered with bath blanket. ► **Rationale:** To protect client's modesty and keep client warm during bathing.
4. Remove pillow if client can tolerate.
5. Place towel under client's head.
6. Don clean gloves if risk of exposure to body fluids when bathing client. ► **Rationale:** To maintain Standard Precautions.
7. Make a mitt with a washcloth. Fold washcloth around your hand as illustrated. ► **Rationale:** This prevents wet ends of cloth from annoying client.
8. Bathe client's face. ► **Rationale:** Begin bath at cleanest area and work downward toward feet.
 - a. Wash around client's eyes, using clear water. With one edge of washcloth, wipe from the inner canthus

toward the outer canthus. ► **Rationale:** This prevents secretions from entering the lacrimal duct. Using a different section of the washcloth, repeat procedure on other eye. Dry thoroughly.

- b. Wash, rinse, and dry client's forehead, cheeks, nose, and area around lips. Use soap with client's permission.
 - c. Wash, rinse, and dry area behind and around the client's ears.
 - d. Wash, rinse, and dry client's neck.
9. Remove towel from under client's head.
 10. Use a clean washcloth for each section of the body. Bathe client's upper body and extremities. Place towel under area to be bathed.
 - a. Wash both arms by elevating client's arm and holding client's wrist. Use long, firm strokes from the wrist toward the shoulder, including the axillary area. ► **Rationale:** Movement distal to proximal increases venous return and promotes circulation.
 - b. Wash, rinse, and dry client's axillae. Apply deodorant and powder if desired.
 - c. Wash client's hands by soaking them in the basin or with a washcloth. Nails can be cleaned now or after the bath.
 - d. Keeping chest covered with the towel, wash, rinse, and thoroughly dry client's chest, especially under breasts. (Apply powder or cornstarch under breasts if desired.)
 11. Bathe client's abdomen. Using a towel over chest area and bath blanket, cover areas you are not bathing. Wash, rinse, and dry abdomen and umbilicus. Replace bath blanket over client's upper body and abdomen.
 12. Bathe client's legs and feet. Place towel under leg to be bathed. Drape other leg, hip, and genital area with the bath blanket.
 - a. Carefully place bath basin on the towel near the client's foot, with knee bent.
 - b. With one arm under the client's leg, grasp the client's foot and bend knee. Place foot in basin of water.
 - c. Bathe client's leg, moving toward hip with long, firm strokes. Rinse and dry client's leg. ► **Rationale:** This promotes circulation.

▲ Wrap one edge of cloth around palm and fingers.

▲ Wrap cloth around hand and anchor with thumb.

▲ Tuck far edge of cloth under edge in palm of hand.

▲ Remove top linen and replace with bath blanket.

▲ Remove gown while covering client with bath blanket.

▲ Wash eyes first, from inner to outer canthus.

▲ Wash hands by soaking them in a basin.

▲ Support wrist when washing client's arm.

▲ Keep client covered with towel during bath.

▲ Wash client's legs and feet for a total bed bath.

▲ Place client's feet in basin while bathing.

- d. Wash client's foot with washcloth. Rinse and dry foot and area between toes thoroughly.
 - e. Carefully move basin to other side of bed, and repeat procedure for client's other leg and foot.
13. Change bath water. Raise side rails when refilling basin.
 - ▶ **Rationale:** This ensures client safety. Check the water temperature before continuing with the bath.
 14. During the bath, continuously assess the client's skin and musculoskeletal system. Careful attention should be paid to the verbal statements and nonverbal expressions. ▶ **Rationale:** This data yields information about client's overall condition.
 15. Help client turn to a side-lying or prone position. Place towel under area to be bathed. Cover client with a bath blanket.
 16. Wash, rinse, and dry client's back, moving from the shoulders to the buttocks. ▶ **Rationale:** Move from clean to dirty area on body.

Clinical Alert

Bathe lower extremities gently if client is at high risk for deep vein thrombosis. DO NOT rub legs. This action could dislodge a clot.

17. Provide back massage now or after completion of bath. (For procedure, see Providing Back Care.)
18. Bathe client's genital area if client is unable to do this by self. Cover all body parts except area to be bathed. Place towel under client's hips.

For Female Client

- a. Bathe perineum from pubis to rectum. ▶ **Rationale:** This prevents contamination from the rectal area to the urethra.

- b. Use separate areas of the washcloth for each stroke.
- c. Discard soiled washcloths as needed.
- d. Clean the labia majora by separating the labia and clean between the majora and labia minora.
- e. Wash, rinse, and dry the clitoris, urethral meatus, and vaginal orifice.
- f. Ensure all folds of skin are thoroughly dry.

For Male Client

- a. Place a towel under the penis.
 - b. Hold the penis by the shaft. If the client is uncircumcised, retract the foreskin before washing if it retracts easily. ▶ **Rationale:** This will allow removal of smegma that may have collected, thus decreasing chance of infection.
 - c. Using a circular motion, wash, rinse, and dry the meatus of the penis and glans in an outward direction.
 - d. Gently replace foreskin to its original position.
 - e. Cleanse the shaft of the penis moving from the tip to the base of the penis.
 - f. Wash, rinse, and pat the scrotum dry, especially the posterior rugae.
19. Remove gloves and place in receptacle.
 20. Assist client to dress in a clean hospital gown or pajamas.
 21. Clean and store bath equipment. Dispose of dirty linen.
 22. Proceed with any other personal hygiene activities as needed.
 23. Replace call light, lower bed, and place side rails in UP position before leaving client.
 24. Remove gloves, if used, and perform hand hygiene.

Providing Foot Care

Equipment

- Basin of warm water
- Soap or emollient agent
- Washcloth
- Two towels
- Nail file, emery board, pick, or orangewood stick
- Skin care lotion or lanolin
- Clean gloves (use if risk of contacting body fluids)

Preparation

1. Determine foot care needs based on client's condition and assessment data.
2. Check physician's orders and client care plan.
3. Collect necessary equipment.
4. Help client into a chair in a comfortable sitting position if possible.

▲ Place towel on floor in front of client and place feet in basin for soaking.

5. Discuss procedure with client.
6. Perform hand hygiene.

Procedure

1. Place towel or bath mat on floor in front of client.
2. Place basin of warm water on towel.
3. Help client place feet in basin.
4. Add emollient agent to water, if desired.
5. Assist client with other personal hygiene activities while feet are soaking. Let feet soak for 10 minutes.
6. Using a washcloth, gently wash client's feet with soap and water.
7. Dry each foot thoroughly with a second towel. Dry between each toe.
8. Using nail clippers, cut straight across the nails.
▶ **Rationale:** Prevents trauma to surrounding tissue.
9. Clean underneath and on sides of nails using a file or orangewood stick.
10. If necessary, push back cuticles using an orangewood stick. Smooth rough edges with an emery board.
11. Apply lotion to entire foot focusing on callused or dry areas. If client's feet are cracking or excessively dry, instruct client to use a deep-penetrating moisturizer like shea butter.
12. Assist client in putting on clean socks and shoes or slippers.
13. Replace equipment.
14. Assist client to bed or position for comfort in chair.
15. Perform hand hygiene.

Bathing a Client in Tub or Shower

Equipment

- Two towels and washcloth
- Soap
- Clean gown, robe, and slippers

Preparation

1. Identify client; perform hand hygiene.
2. Assess client's ability to tolerate tub or shower.
3. Cover all tubings and dressings with plastic covering and instruct client to minimize getting these areas wet.
4. Ensure that tub or shower and equipment is cleansed per agency policy. ▶ **Rationale:** To prevent spread of microorganisms.
5. Place a rubber mat or towel on floor. Use shower chair if indicated. ▶ **Rationale:** To prevent client slipping and ensure safety.
6. Fill tub or adjust shower with warm water (temperature if tested 105°–110°F).

Procedure

1. Assist client into tub or shower. Use hydraulic bathtub chair if necessary (see procedure for Bathing in a Hydraulic Bathtub Chair).
2. Show client how to call for help when needed.
3. Provide client privacy. Assist client with washing back, lower legs, or feet, as needed.
4. Assist client with putting on clean gown, robe, and transporting back to room.
5. Clean shower or tub area and dispose of dirty linen.
6. Perform hand hygiene.

Bathing Using Disposable System

Equipment

- Commercial cleansing system
- Bath blanket
- Clean gown
- Disposable bag
- Clean gloves, if appropriate

Preparation

1. Obtain package with cleansing cloths. Cloths are premoistened with an aloe and vitamin E formula.
▶ **Rationale:** The cleansing cloths are less drying as they maintain the skin at pH of 4.7–4.9.
2. Heat package in microwave for no more than 45 seconds. Check temperature before applying to skin.
▶ **Rationale:** Increased time could lead to excessive heat and burning of the skin. The commercial system can be used at room temperature.
3. Explain procedure to client. ▶ **Rationale:** This procedure may be new to the client and an explanation is needed to ensure client understands the difference between a bed bath and a bath using a cleansing system. The client may not think he has had a complete bath but only “a sponge bath.”
4. Perform hand hygiene.
5. Don gloves if there is a risk of contact with body secretions.
6. Replace top linen and gown with bath blanket or top sheet if bath blanket not available.

Procedure

1. Open package and remove one cloth at a time.
2. Remove bath blanket at each site when cleansing with cloth.
3. Replace bath blanket when cloth removed. ▶ **Rationale:** To prevent client chilling.

▲ Place package containing cleansing cloths in microwave to warm, according to directions (usually no more than 45 seconds).

▲ Each towel is used once and discarded.

4. Use a new cloth for each section of the body as follows:
 - a. Face, neck, and chest
 - b. Right arm and axilla
 - c. Left arm and axilla
 - d. Perineum
 - e. Right leg
 - f. Left leg
 - g. Back
 - h. Buttocks
5. Discard cloth after cleansing each area. Do not flush down toilet. Rinsing is not required with this system. Replace bath blanket or sheet over each part of the body after it has been cleaned. ► **Rationale:** To prevent the client from becoming chilled.
6. Place clean gown on client.
7. Place client in comfortable position.
8. Discard cloths in appropriate receptacle.
9. Perform hand hygiene.
10. Document bath on flow sheet or nurses' notes.

EVIDENCE-BASED PRACTICE

Bath Basins as Potential Sources of Infection

A recent study (2009) conducted at three acute care hospitals examined 92 bath basins from three intensive care units. Sterile culture sponges were used to obtain samples from the basins. Some form of bacteria grew in 98% of the samples. The organisms with the highest positive rates of growth were enterococci (54%), gram-negative organisms (32%), *staphylococcus aureus* (23%), vancomycin-resistant enterococci (13%), and methicillin-resistant *staphylococcus aureus* (8%). The conclusion of the study indicated that bath basins are a reservoir for bacteria and may be a source of transmission of hospital-acquired infections.

Using a prepackaged bath indicated that microbial counts were significantly lower than basin baths. The study concluded that using a disposable bath is more efficacious for bathing, particularly for high-risk clients.

Source: Johnson, D., Lineweaver, L., & Maze, L. M. (2009). Patient's bath basins as potential sources of infection: a multicenter sampling study. *American Journal of Critical Care*, 18(1), 31–40.

Bathing an Infant

Equipment

- Tub or basin filled with warm water (100°F)
- Two towels
- Washcloth
- Suction bulb
- Mild soap
- Cotton balls
- Blanket
- Clean clothing
- Clean gloves, if indicated

Preparation

1. Provide a comfortable room environment (i.e., comfortable temperature, lighting).

2. Check client ID.
3. Perform hand hygiene.
4. Collect necessary equipment, and place articles within reach.
5. Position the bed at a comfortable working height.
6. Place towel, laid out in diamond fashion, on bed next to basin.
7. Don gloves if there is a risk of exposure to body secretions.

Procedure

1. Test water temperature with your wrist or elbow.
2. Lift infant using football hold.

Some facilities use disposable cleansing systems to bathe neonates and infants. There are four infant-size washcloths for infants up to 25 pounds. The bathing procedure is the same for infants and adults.

3. Remove all clothing except shirt and diaper.
4. Cover infant with towel or blanket. Never let go of the infant during the bath. ► **Rationale:** This is a safety intervention to prevent falls or other injury.
5. Clean infant's eyes using a cotton ball moistened with water. Wipe from inner to outer canthus, using a new cotton ball for each eye. ► **Rationale:** This procedure prevents water and particles from entering the lacrimal duct.

Clinical Alert

Discharge from the eyes may be present for 2 to 3 days due to prophylactic eyedrops administered at birth.

6. Make a mitt with the washcloth.
7. Wash infant's face with water.
8. Suction nose, if necessary, by compressing suction bulb before placing it in nostril. ► **Rationale:** This prevents aspiration of moisture. Gently release bulb after it is placed in nostril.
9. Wash infant's ears and neck, paying attention to folds; dry all areas thoroughly. Use mild soap and rinse.
10. Remove shirt or gown.
11. Remove diaper by picking up infant's ankles in your hand.

12. Pick up infant and place feet first into basin or tub. Immerse infant in tub of water only after umbilical cord has healed. Pick up infant by placing your hand and arm around infant, cradling the infant's head and neck in your elbow. Grasp the infant's thigh with your hand. ► **Rationale:** The umbilical cord is kept dry to prevent infection.
13. Wash and rinse the infant's body, especially the skin folds.
14. Wash infant's genitalia.
 - a. For a female infant: Separate labia and with a cotton ball moistened with soap and water, cleanse downward once on each side. Use a new piece of cotton on each side.
 - b. For an uncircumcised male infant: Do not force foreskin back. Gently cleanse the exposed surface with a cotton ball moistened with soap and water.
 - c. For a circumcised male infant: Gently cleanse with plain water.
15. Wrap the infant in a towel and use a football hold when washing an infant's head. Soap your own hands and wash infant's hair and scalp, paying attention to the nape of the neck and using a circular motion. Rinse hair and scalp thoroughly. ► **Rationale:** Football hold is the most secure for active infants.
16. Place infant on a clean, dry towel with head facing the top corner and wrap infant.
17. Use the corner of the towel to dry infant's head with gentle, yet firm, circular movements.
18. Replace infant's diaper and redress in a new gown or shirt.
19. Provide comfort by holding the infant for a time after the bath procedure.
20. Perform hand hygiene.

Bathing in a Hydraulic Bathtub Chair

Equipment

- Two towels and washcloth
- Soap
- Clean gown, robe, and slippers

Procedure

1. Check client's ID using two identifiers; perform hand hygiene.
2. Bring client to tub room in wheelchair.

▲ Check that water temperature is not above 105° For safety.

3. Fill tub with water and check temperature. ► **Rationale:** Temperature must not be more than 105°F or client may burn skin.
4. Release chair to lowest point beside tub, and place towel on floor under chair.
5. Move client into bathtub chair, and attach seat belt.
6. Swing chair into position over tub.
7. Direct client to move legs down, then lower chair into low position in the tub filled with water.
8. When client is finished bathing, reverse chair out of tub.
9. Assist client to towel dry.
10. Put clean gown, robe, and slippers on client and transport to room.
11. Transfer client to wheelchair.
12. Assist client to settle comfortably in bed.
13. Perform hand hygiene.

▲ Attach seat belt before swinging chair over the tub.

▲ Support client in chair as chair is swung over tub.

▲ Lower chair into tub filled with water.

DOCUMENTATION for Bath Care

- Client's overall ability to participate in own care
- Type of bath given (i.e., complete or partial) and by whom (e.g., client, nurse, family member)
- Condition of client's skin and any interventions provided for the skin (e.g., lotion, massage)
- Client's educational needs regarding hygienic care
- Information shared with client or family
- Infant bath demonstration to parents with return demonstration

CRITICAL THINKING Application

Expected Outcomes

- Client's skin is free of excessive perspiration, secretions, and offensive odors.
- Client feels comfortable and does not experience itching or irritation.
- Client's skin is moist and free of itching sensation.

- Client is able to take bath or shower without excessive fatigue or anxiety.
- Client is able to bathe self using disposable cleansing system.

Unexpected Outcomes

Client is unwilling to accept a complete bed bath.

Alternative Actions

- Respect client's wishes and take other opportunities for assessment.
- Have client wash hands, face, and genitals. You should wash back and give back care. Re-explain the purpose of the bath to the client and request client participation.

Client is too shy to allow bath.

- Respect client's privacy and only wash areas client wishes you to do.
- Give assistance so client can bathe himself or herself.
- Allow spouse or parent to give bath if this is more acceptable to client.

Client complains of dry, itching skin after the bath.

- Assess for cause of itching.
- Ask physician for an order for special lotion.
- Do not use soap for the bath.

Skin Integrity

Nursing Process Data

ASSESSMENT Data Base

- Assess for signs of skin breakdown or the eruption of lesions.
- Assess color of skin.
- Assess color of mucous membranes.
- Check for alterations in skin turgor.
- Assess for complaints of itching, tingling, or numbness.
- Assess texture of skin.
- Assess general hygienic state.
- Observe skin for increased or decreased pigmentation and discoloration.
- Assess client's condition to determine appropriate support surface or specialty bed.

PLANNING Objectives

- To maintain intact skin
- To recognize a break in skin integrity
- To avoid introduction of pathogens through break in skin
- To prevent skin breakdown from pressure points or strain
- To prevent excessive dryness, flaking, itching, or burning
- To use support surface or specialty bed to prevent or treat altered skin integrity

IMPLEMENTATION Procedures

- Monitoring Skin Condition 196
- Preventing Skin Breakdown 197
- Preventing Skin Tears 198
- Managing Skin Tears 199

EVALUATION Expected Outcomes

- Client's skin is intact.
- Client's skin does not show evidence of dryness, flaking, itching, or burning.
- Client is comfortable with no complaints of pain or discomfort.

Critical Thinking Application 201

- Expected Outcomes 201
- Unexpected Outcomes 201
- Alternative Actions 201

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Monitoring Skin Condition

Equipment

- Artificial light for observation if natural light is not available
- Bath blanket
- Gown
- Clean gloves, if indicated

Procedure

1. Perform hand hygiene.
2. Check two client identifiers and explain monitoring process to client.
3. Provide privacy for client.
4. Remove linens and gown if necessary. Cover client with bath blanket.
5. Compare color of client's skin with normal range of color within the individual's race. Observe for pallor (white color), flushing (red color), jaundice (yellow color), ashen (gray color), or cyanosis (blue color).
6. Place the back of your fingers or hand on client's skin to check temperature. Consider the temperature of the room and of your hands. ► **Rationale:** The back of the hand is more sensitive to changes in temperature than the palm.
7. Correlate abnormalities in skin color with changes in skin temperature. ► **Rationale:** Skin temperature reflects blood circulation in the dermis layer.
8. Observe for areas of excessive dryness, moisture, wrinkling, flaking, and general texture of skin.
9. Gently pick up a small section of the skin with your thumb and finger. Observe for ease of movement and speed of return to original position to check for skin turgor. ► **Rationale:** Degree of hydration is reflected in the skin turgor or elasticity of the skin.
10. Press your finger firmly against client's skin for several seconds (especially ankle area). After removing your finger, observe for lasting impression or indentation. ► **Rationale:** This identifies the severity of pitting edema. It is based on a 4-point scale: +1 (slight) to +4 (very marked).
11. When checking skin temperature and texture, note the client's response to heat, cold, gentle touch, and pressure.
12. Observe the amount of oil, moisture, and dirt on the skin surface. ► **Rationale:** Degree of moisture or dryness may indicate disease states or hydration status.
13. Note presence of strong body odor or odor in the skin folds.
14. Observe for areas of broken skin (lesions) or ulcers. If present, wear gloves. Check if lesions are present over entire body or if they are localized to a specific area.
15. Check for skin discolorations (e.g., ecchymosis, petechiae, purpura, erythema, and altered pigmentation). ► **Rationale:** These signs may indicate generalized disease states, such as leukemia, vitamin deficiency, or hemophilia.
16. Ensure client is resettled comfortably.
17. Perform hand hygiene.
18. Document findings in chart.

▲ Compare color of client's skin with normal range of color within the individual's race.

▲ Gently pick up a small section of skin with your thumb and finger to check for skin turgor.

▲ Place back of your fingers or hand on client's skin to check temperature.

▲ Press your finger firmly against client's skin for several seconds to check for pitting edema.

TABLE 8-1 Potential Skin Problems

Skin Condition	Problem	Nursing Responsibility
Xeroderma, or dry skin	If skin is extremely dry, it could crack and become infected. May cause pruritus.	Maintain skin integrity. Bathe less frequently. Relieve discomfort. Use emollient or moisturizing lotion after bathing. Encourage nutritious diet. Increase fluid intake. Maintain cool, humid environment.
Skin rash or contact dermatitis. May be allergic or nonallergic reaction; may have exudate.	Erythema, flat or raised eruptions, and inflammation. Could cause pruritus, discomfort, and infection if scratched.	Avoid soap and heat, and rubbing area. Bathe area: may use antiseptic soap with orders. Apply ordered lotion or spray (steroids) to prevent itching. Use cool, wet dressing. If exudate present, check bed linens and client's gown, change if moist.
Abrasions	Break in skin integrity could result in infection. Healing may be prolonged due to age (poor circulation, etc.).	Wash abrasions with soap and water. Apply lotion as ordered.
Fungal skin infection	Fungal skin infection: common in diabetics, those on antibiotics or immunosuppressive therapy, those who are incontinent.	Apply topical antifungal medication as ordered. Dry skin folds well before applying antifungal medication. Apply medication sparingly to prevent skin from becoming too moist. Keep incontinent clients dry and provide good perineal care. Avoid using plastic pants or liners next to client's skin. Use nonocclusive dressings if needed.
Yeast skin infection	Seen with prolonged antibiotic use and in skin folds.	Cleanse and dry skin folds, apply medicated lotion or cream as ordered.

Preventing Skin Breakdown

Equipment

- Skin lotion
- Pressure-relieving mattress
- Clean gloves if open lesions are present

Procedure

1. Perform hand hygiene.
2. Check two client identifiers.
3. Provide for client privacy.
4. Inspect skin daily; observe the client's most vulnerable body surfaces for ischemia, hyperemia, or broken areas.
5. Change the client's body position at least once every 2 hours to rotate weight-bearing areas. Use turning techniques. ► **Rationale:** To minimize skin injury caused by friction and shear forces. Observe all vulnerable areas at this time. Include right and left lateral, prone, supine, and swimming-type positioning if possible.

6. Massage client's skin and pressure-prone areas, if skin is not reddened, when client changes position.
 - ▶ **Rationale:** Massage increases risk of breakdown in clients with reddened areas over bony prominences.
7. Lubricate dry, unbroken skin to prevent breakdown.

NOTE: Products used to prevent skin breakdown and treat impaired skin integrity are selected based on client's skin type, product application, cost, and desired outcome.

8. Apply lotion to bedridden client's sacrum, elbows, and heels several times during the day.
9. Cleanse skin with warm water and a mild pH-balanced cleansing agent, then apply moisturizers and a barrier cream as ordered.
10. Protect healthy skin from drainage secretions.
11. Use protective padding on heels and elbows if needed.
12. Keep linens clean, dry, and wrinkle-free.

13. Minimize the layers between the client and mattress.
 - ▶ **Rationale:** Allows for proper functioning of pressure relief mattresses.
14. Encourage active exercise or range-of-motion exercise.
15. Encourage client to eat a well-balanced diet with protein-rich foods and adequate fluids.
16. Teach client and family how to prevent pressure areas and pressure ulcer formation.
17. Perform hand hygiene.
18. Document findings in chart.

Clinical Alert

Current guidelines from the U.S. Department of Health and Human Services advocate no skin massage on reddened skin or skin that has a potential for breakdown because massage causes friction and shearing.

▲ Observe client's most vulnerable body surfaces for ischemia, hyperemia, or broken skin.

▲ Lubricate dry, unbroken skin to prevent breakdown.

▲ High-risk, obese clients should be placed on a bariatric bed such as the BariMaxx II® or Magnum®.

Preventing Skin Tears

Equipment

- Lift or turning sheet or booster lift device
- Padding for bedrails, or other equipment
- Pillows and blankets
- Paper tape
- Moisturizing agent for skin
- Clean gloves as needed

Preparation

1. Identify clients at risk for developing skin tears.
 - ▶ **Rationale:** To identify clients at risk and then determine appropriate preventative measures. Clients at risk include those on bedrest, those with purpura or ecchymosis, paper-thin skin such as geriatric clients, those on long-term steroid use, or those with poor vision resulting in accidental bumping into objects.

2. Identify the category of skin tear, if present. ▶ **Rationale:** To determine correct nursing action to be completed.
3. Perform hand hygiene before providing client care.

Procedure

1. Check two client identifiers.
2. Use lift sheet or the Booster lift device when moving clients at risk for developing skin tears. ▶ **Rationale:** This will assist in preventing tears resulting from friction or shearing.
3. Remove tape from dressings carefully; use only paper or nonadherent dressing for at-risk clients, if possible.

Clinical Alert

Ensure that all healthcare workers are aware of proper handling of elderly clients with fragile skin. Slight friction and shearing can create a skin tear when turning or lifting these clients.

4. Assist clients with ambulation if unsteady gait. Remove objects in pathway. ► **Rationale:** To prevent client from bumping into objects, causing bruises, cuts or skin tears, from falling.
5. Ensure clients use glasses, if necessary, when ambulating or transferring into chair. ► **Rationale:** To prevent falling or unsteady gait due to impaired vision leading to potential skin tears from falls.
6. Place padding on beds, wheelchairs, or equipment. ► **Rationale:** To prevent client from rubbing on hard surfaces and causing bruising.
7. Don gloves and apply moisturizing agent to dry skin to keep moist.
8. Remove gloves and place in appropriate receptacle.
9. Perform hand hygiene.
10. Document findings in chart.

Payne–Martin Classification System for Skin Tears

Category I: skin tears without tissue loss

Linear type: epidermis and dermis pulled apart

Flap type: epidermal flap completely covers dermis to within 1 mm of the wound margin

Category II: skin tears with partial tissue loss

Scant tissue loss type: 25% or less of epidermal flap lost

Moderate to large tissue loss type: more than 25% epidermal flap lost

Category III: skin tears with complete tissue loss, no epidermal flap

Source: Fleck, C. (2007). Preventing and treating skin tears. *Advances in Skin and Wound Care: The Journal for Preventing and Healing*, 20(6), 315–321.
Payne, R. L., & Martin, M. L. (1993). Defining and classifying skin tears: need for a common language. *Ostomy Wound Management*, 39(5), 16–26.

Managing Skin Tears

Equipment

- Saline
- Nontoxic wound cleanser
- Moist wound dressing (e.g., Hydrogel, foam, petrolatum ointment)
- Nonadherent dressings
- Tegaderm
- Gauze
- Clean gloves

Procedure

1. Perform hand hygiene.
2. Check two client identifiers.
3. Don clean gloves.
4. Remove old dressing, being careful to not cause additional skin damage. Moisten dressing with saline before removing if dressing sticks to skin.
5. Assess for signs of infection.
6. Cleanse skin tear with saline or nontoxic wound cleanser. Be careful not to put pressure on skin as you are cleaning. ► **Rationale:** To prevent additional pain and trauma to skin.
7. Place Tegaderm or clear adherent dressing over tear site.
8. Change dressings according to hospital policy.
9. Remove gloves and place in appropriate receptacle.
10. Perform hand hygiene.
11. Document findings in chart.

DOCUMENTATION for Skin Integrity

- Client's skin condition: odor, temperature, turgor, sensation, cleanliness, integrity
- Client's mobility
- Turning frequency and client positioning
- Type of care given (e.g., massage, bathing)
- Client's complaints about skin or pressure ulcer
- Time and method used to obtain wound specimen
- Type of lesion, rashes and bruises; state location, size, shape, color
- Alterations in sensation in skin lesion area
- Skin or body odor
- Presence of skin tear and assessment findings
- Treatment given for skin tear

Support Surfaces and Specialty Beds

▲ First Step Plus, an overlay mattress from KCI.

▲ Total Care SpO₂RT® Pulmonary Therapy System (Hill-Rom).

▲ KinAir IV®, a low air-pressure bed from KCI.

▲ BariMaxx II®, a bariatric pressure bed from KCI.

▲ FluidAir Elite®, air-fluidized therapy from KCI.

▲ RotoRest® Delta Kinetic®, a kinetic bed from KCI.

TABLE 8-2 Therapeutic Beds

Type of Bed	Client Recommendations
Air fluidized and low air-loss	High risk for skin breakdown
KinAir IV® (KCI)	Obese clients
Clinitron Rite Hite® (Hill-Rom)	Skin grafts, flaps All four stages of pressure ulcers Wound healing
Air-fluidized	Severe skin disorders
Clinitron II® (Hill-Rom)	Pressure ulcers
Fluid Air Elite® (KCI)	Burns
Low air-loss	Massive edema
KinAir Med Surg® (KCI)	Critical care
Flexicair Eclipse® (Hill-Rom)	Pneumonia or other pulmonary problems with compromised skin integrity
Kinetic therapy	Obese—850–1,000 lbs.
Bariatric Client Care Systems	Difficult to move out of bed
MAGNUM II® (Hill Rom)	Assistance to place in a sitting position
BariAir® (KCI)	Difficult to move due to obesity
BariMaxx® II (KCI)	Difficult to move due to obesity
Critical care therapy	Pulmonary condition related to immobility (pneumonia), COPD
TriaDyne Proventa® (KCL)	Skin complications related to bed rest
SpO ₂ RT® (Hill Rom)	Spinal cord-injured, requiring skeletal traction
RotoRest Delta® (KCI) Kinetic	Spinal cord-injured, at risk for respiratory complications

CRITICAL THINKING Application

Expected Outcomes

- Client's skin is intact.
- Client's skin does not show evidence of dryness, flaking, itching, or burning.
- Client is comfortable with no complaints of pain or discomfort.

Unexpected Outcomes

Skin is erythematous but remains intact.

Client cannot be positioned in a manner to avoid erythematous areas entirely.

Skin integrity is interrupted, even with skin care.

Skin tear occurs.

Alternative Actions

- Monitor fluid balance and nutritional status.
- Obtain pressure-relieving mattress.
- Turn client every 2 hours.
- Ambulate if able.
- Turn at least every hour.
- Do not turn on erythematous site.
- Use protocol for stage 1 ulcer treatment on affected area.
- Place support mattress on bed.
- Use aseptic technique in treating area to prevent spread of bacteria and promote wound healing.
- Use appropriate skin care products.
- Place support mattress on bed.
- If skin is sensitive and breakdown occurs over large area, the use of a Clinitron unit or air-fluidized bed might be indicated (Table 8-2).

Chapter 8

UNIT 4

Evening Care

Nursing Process Data

ASSESSMENT Data Base

- Review client's usual routines before sleep.
 - Usual time of sleep and length of sleeping period
 - Personal hygiene routines
 - Temperature of room and number of blankets
 - Anticipated elimination needs
 - Religious or meditation needs
- Assess client's understanding and acceptance of safety precautions, such as use of side rails.
- Assess client's needs for comfort and security.
 - Dressings
 - Medication
 - Linen change or adjustment
 - Positioning
 - Television, radio, light
 - Communication needs
- Assess physical and emotional status during evening care.
- Assess condition of back, especially bony prominences.

PLANNING Objectives

- To encourage a period of comfortable, uninterrupted rest
- To evaluate the client's present health status
- To make observations about the client's physical and emotional status
- To provide time for the client and nurse to review the day's events
- To provide time for the client to communicate needs and questions regarding health care
- To provide the client with a clean, secure environment in which to sleep

IMPLEMENTATION Procedures

- Providing Evening Care 203
- Providing Back Care 203

EVALUATION Expected Outcomes

- Client states he/she is comfortable and ready for sleep after evening care.
- Client states that back care has decreased muscle tension and improved comfort level.

Critical Thinking Application 205

- Expected Outcomes 205
- Unexpected Outcomes 205
- Alternative Actions 205

Prepare for success with NCLEX[®]-style practice questions
and Skill Checklists

Providing Evening Care

Equipment

- Disposable cleansing cloth system or towels, washcloth, basin with water and soap
- Clean linens if needed
- Dental care items (i.e., toothbrush, dentifrice, denture cup)
- Emesis basin, cup
- Fresh pitcher of water if allowed
- Skin care lotion if desired
- Personal care items (e.g., deodorant, skin moisturizers)
- Bedpan, urinal, toilet paper
- Miscellaneous supplies as needed (e.g., dressing, special equipment)
- Clean gloves, if indicated

Preparation

1. Perform hand hygiene.
2. Check two client identifiers.
3. Explain the needs and benefits of evening care; discuss how the client can be involved.
4. Collect and arrange equipment.
5. Adjust the bed to a comfortable working height, and assist the client into a comfortable position.
6. Ensure privacy.
7. Don gloves if indicated.

Procedure

1. Assess for pain. Medicate as necessary.
2. Offer bedpan or urinal if client is unable to use bathroom. Assist with handwashing.
3. If client needs or requests a bath, provide assistance as needed.

4. Assist with mouth and dental care as needed.
5. Remove equipment, extra linens, and pillows if possible. Remove sequential compression devices, ace wraps, and binders.
6. Change dressings, if necessary. Perform any required procedural techniques.
7. Wash face, hands, and back. Provide back massage.
8. Assist with combing or brushing hair if desired.
9. Replace sequential compression devices, stockings, and binders.
10. Replace soiled linen, or straighten and tuck remaining linen. Fluff pillow and turn cool side next to client.
11. Straighten top linens. Provide additional blankets if desired.
12. Remove any unnecessary equipment. Place call signal and water (if allowed) within client's reach.
13. Administer sleeping medication if ordered and client requests.
14. Assist client into a comfortable position.
15. Ensure that the client's environment is safe and comfortable.
16. Remove gloves, if used.
17. Raise upper side rails, place bed in LOW position, and turn lighting to low.

NOTE: Side rails are now considered restraints by the Centers for Medicare and Medicaid Services and the Food and Drug Administration. Check with your facility about agency policies on use of side rails.

18. Perform hand hygiene.
19. Document evening care provided.

Providing Back Care

Equipment

- Disposable cleansing cloth system or
- Basin of warm water, washcloth, towel, soap
- Skin care lotion
- Clean gloves if indicated

Procedure

1. Perform hand hygiene.
2. Check two client identifiers.
3. Explain the purpose of a back rub, and ask client if he or she would like one.
4. Provide privacy.
5. Assess for pain.
6. Warm lotion by holding bottle under water.
7. Raise bed to comfortable height for you, and assist the client into a comfortable prone or semiprone

position. Keep farthest side rail in UP position. Placing pillow below breasts may increase comfort for female clients.

8. Don gloves if necessary.
9. Drape bed clothes for warmth, and untie the client's gown. Cleanse back with disposable cleansing cloth or washcloth with soap.
10. Place lotion on your hands and rub hands together to warm lotion.
11. Once you place your hands on a client's back to begin a back rub, your hands should remain in constant skin contact with the client until back rub is complete.
 - **Rationale:** To prevent "tickling" sensation.
12. Repeatedly move your hands up on either side of the client's spine, across shoulders, and down the lateral aspects of the back using the effleurage stroke, applying firm and steady pressure.

▲ Cleanse back using a disposable cleansing cloth before beginning back rub.

▲ Without lifting hands from skin surface, massage in continuous motion.

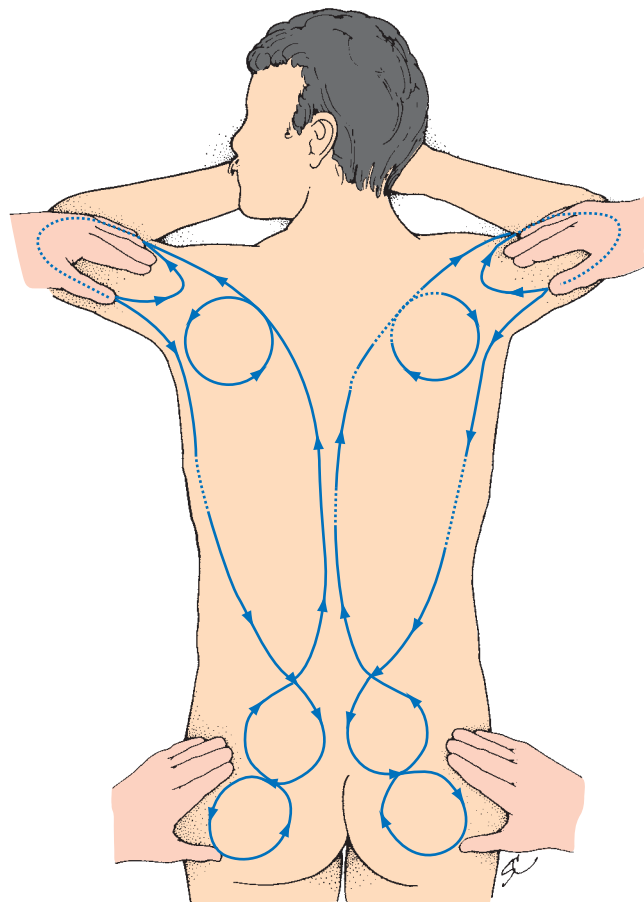

▲ The petrissage, or kneading stroke, is issued over the shoulders and along back.

▲ The tapotement stroke stimulates the skin as the hands move up and down the back. The kidneys area should be avoided.

13. Move your hands down the center of the client's back to sacral area.
14. Massage with a figure-eight motion from the sacrum out over each buttock.
15. Finally, rub lightly up and down the back a few strokes before lifting hands from client's back.
16. Throughout back rub, assess skin for color, turgor, skin breakdown.
17. When percussion is desired, the back and buttocks can be lightly struck with the fleshy sides of your hands, called tapotement. Using an alternating rhythm, move up and down the back several times, avoiding the kidney area. In addition, kneading can be accomplished by picking up the skin between the thumb and fingers as you move up the back. This movement is called petrissage.
18. Close client's gown, pull up bedcovers, and assist client to change position if desired. Place top half of side rails in UP position. (See Chapter 7 regarding use of side rails.) Place bed in LOW position.
19. Remove gloves, if used.
20. Return lotion to the proper area.
21. Perform hand hygiene.
22. Document care provided.

▲ Maintain constant skin contact during care by moving hands in figure-eight motion from shoulder to buttocks and back.

DOCUMENTATION for Evening Care

- Client's level of comfort or discomfort
- Type of care given (i.e., back care, evening care)
- Any significant complaints
- Nature of client teaching if done
- Medication required for discomfort or sleep
- Client's physical and emotional status after evening care completed

CRITICAL THINKING Application

Expected Outcomes

- Client states he/she is comfortable and ready for sleep after evening care.
- Client states that back care has decreased muscle tension, improved comfort level, and increased feelings of relaxation.

Unexpected Outcomes

Client refuses back care because he/she does not want to be touched.

Client refuses back care because he or she thinks you are too busy or disinterested.

Client is unable to sleep even after evening care is given.

Alternative Actions

- Tell client that if he or she cannot accept back care as part of the therapeutic regimen, you will stop.
- Make sure you offer the back care in an unhurried and meaningful manner. Do not allow the client to misinterpret your offer for care.
- Return to client and offer back care later in the evening.
- Encourage verbalization of feelings, fears, etc.
- Check to see if sleeping medication can be given.
- Provide additional back care.

GERONTOLOGIC Considerations

Factors That Can Increase Risk of Skin Breakdown and Delay Wound Healing

- Inadequate nutritional intake.
- Compromised immune system.
- Compromised circulatory and respiratory systems.
- Poor hydration.
- Decreased mobility and activity.

Skin Changes With Age

- Delayed cellular migration and proliferation.
- Skin is less effective as barrier and slow to heal.
- There is increased vulnerability to trauma.
- There is less ability to retain water.
- Geriatric skin is dry (osteotosis) due to decreased endocrine secretion and loss of elastin. This can cause pruritus, which could lead to skin ulceration.
- Increased skin susceptibility to shearing stress leading to blister formation and skin tears.
- There is increased vascular fragility.

The Skin of the Elderly Should Be Assessed

- Decreased temperature, degree of moisture, dryness resulting from decreased dermal vascularity.
- Skin not intact, open lesions, tears, pressure ulcers as a result of increased skin fragility.
- Decreased turgor, dehydration as a result of decreased oil and sweat glands.
- Pigmentation alterations, potential cancer.
- Pruritus—dry skin most common cause because of decreased oil and sweat glands.
- Bruises, tears, scars from increased skin fragility.

Bathing Adaptations to Minimize Dryness

- Have client take complete bath only twice a week.
- Use superfatted or mild soap or lotions to aid in moisturizing.
- Use tepid, not hot, water.
- Apply emollient (lanolin) to skin after bathing.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- All personnel interacting with clients must report any client risk behaviors or signs or symptoms that are unusual or new. Since activities of bathing or bedmaking have predictable outcomes and do not require nursing judgment, they are usually delegated to CNAs or UAPs. When these activities of daily living are delegated to a CNA or unlicensed personnel, the professional nurse remains responsible for total client care and should receive a complete report from the staff member assigned to the client.

- Even though unlicensed personnel are qualified to complete many tasks that involve activities of daily living, if the client is critically ill or unstable, the RN or LVN/LPN should be assigned to such a client. The professional nurse is responsible for assessing the client's total condition, thereby avoiding complications caused by missed assessment parameters.

Communication Matrix

- CNAs and UAPs must report any unusual or unanticipated signs or symptoms or risk behaviors to the RN or LVN/LPN responsible for the client's care. This report should include mental status as well as previously unreported physical signs and symptoms observed during the interaction period.
- Clients with alterations in skin integrity may be referred to the wound care specialist if the facility has one on staff.

CRITICAL THINKING Strategies

Scenario 1

An 89-year-old male was admitted earlier today, and you were assigned to admit him and provide nursing care for the remainder of the shift (4 hours). His admitting diagnosis is dehydration due to prolonged nausea and vomiting. He lives with his 88-year-old wife. They have some home health care twice a week, and a nursing assistant assists them with bathing and personal hygienic care. He is usually very active, walking, gardening, and attending church every week.

Your nursing history indicates he has not been out of bed for 3 days. He was unable to get to the bathroom and used a urinal, which proved to be difficult for him to manage and he spilled some urine each time he used it. He has not had a bath for 4 days and has also not brushed or cleaned his dentures.

1. Considering the client's issues related to bathing and bedmaking, what is your priority assessment after completing the initial assessment? Provide the rationale for your answer.
2. What information would you place on his plan of care to prevent skin breakdown? List the risk factors the client most likely exhibited.
3. Outline the nursing interventions that will be incorporated in his plan of care for the pressure ulcer.

4. What would you consider priority for his bathing needs? Provide the rationale for your answer.
5. Identify the major preventative measures to prevent skin breakdown or tears that will need to be discussed with the nursing assistant who will continue to care for him when he returns home.

Scenario 2

The client develops a skin tear on the greater trochanter the second day after admission. Refer to Scenario 1 for data.

1. In addition to risk factors identified in Scenario 1, describe additional risk factors that can cause skin tears.
2. Describe nursing interventions that can be used to treat the skin tear.
3. Describe nursing actions you will use when applying a dressing for the skin tear.
4. Explain how skin changes with age and how that leads to skin tears.
5. Are there any bathing changes that will need to be carried out during the time the treatment for the skin tear is being carried out?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. Which one of the following statements is correct relative to making an occupied bed?
 1. The bed is made by tucking the sheet under the mattress starting at the head of the bed, then pulling the sheet down to the foot of the bed.
 2. One side of the bed is completed first, then the client is moved to that side of the bed while the second side is completed.
 3. Making a bed with the client in the bed consists of changing the drawsheet and pillowcase.
 4. Unoccupied bed changes are completed only when the bed is soiled; then the bed is changed by rolling up

- the soiled part of the sheet and having the client move to the opposite side of the bed.
2. You are preparing to complete a bed bath for an elderly client who is experiencing difficulty when moving in and out of bed. Place in order the sequence you will use for bathing the client.
 1. Legs
 2. Arms
 3. Abdomen
 4. Back
 5. Face
 3. While assessing the skin of an elderly client, you notice the skin is very dry. The most appropriate intervention is to
 1. Use any fragrant soap when washing the skin.
 2. Bathe the client daily using only lukewarm water and mild soap.
 3. Apply generous amounts of oil-rich cream to the skin.
 4. Have the client only take showers to prevent build-up of soap on the skin.
 4. A physician's order must be obtained before you perform which one of the following nursing interventions?
 1. Cooling bath using tepid water.
 2. Tub bath requiring the use of a hydraulic bathtub chair.
 3. Bath using Aveeno or cornstarch.
 4. Partial bath including washing the genitalia.
 5. A client's diagnosis is heart failure. He has difficulty breathing when he experiences too much activity. The most appropriate intervention for bathing the client is
 1. The nurse gives him a bed bath.
 2. He is placed in a shower chair, wheeled to the shower, and the nurse showers him.
 3. He is assisted to the side of the bed and instructed to complete a partial bath.
 4. He assists with washing his face and hands if he is able to tolerate the activity.
 6. The protocol for client care on the unit where you are gaining clinical practice includes providing morning care to all bedridden clients. This activity includes **Select all that apply.**
 1. Offering oral hygiene.
 2. Providing a wash cloth and assisting the client with washing his/her face and hands.
 3. Changing the drawsheet and pillowcase.
 4. Providing back care.
 7. A major advantage of using a disposable bathing system for bathing a client that it
 1. Is less expensive than using regular linen.
 2. Is warmed to provide a soothing effect for the skin.
 3. Maintains a pH of 4.7 to 4.9 and is less drying.
 4. Prevents the spread of infection among clients.
 8. The first step in bathing an infant is to
 1. Wash the infant's hair and scalp.
 2. Place the baby into the bathtub and wash the face, neck, and ears.
 3. Cleanse the eyes using a moistened cotton ball.
 4. Lower the baby into the bathtub and wash the abdomen, arms, and legs before washing the genitalia.
 9. As part of your morning assessment, you are going to check the client's skin condition for signs of hydration. The most appropriate method to check for hydration is to:
 1. Place the back of your fingers or hand on the client's skin to check for resilience.
 2. Gently pick up a small section of the skin with your thumb and forefinger and observe for speed of return to original position.
 3. Firmly press your finger against the client's skin for several seconds and observe for blanching of skin.
 4. Observe for color change in skin of hands.
 10. You are working the afternoon shift and the day nurse asks you to carefully assess an elderly client because she thinks she may have the beginning of a skin tear. You complete the assessment as soon as you are out of report. Your findings are a Category I flap type skin tear on the right arm. The most appropriate nursing action is to
 1. Cleanse the tear with a Betadine swab, and press the tear back onto the skin.
 2. Place Tegaderm or adherent dressing over tear.
 3. Place dry 4" × 4" dressing over tear and tape securely.
 4. Apply a moist dressing over the tear and immobilize the arm to prevent excess movement.
-

9

Personal Hygiene

LEARNING OBJECTIVES

1. Discuss oral hygiene needs of clients.
2. Outline the procedure for flossing teeth.
3. Compare and contrast oral hygiene for clients with natural teeth and dentures.
4. Demonstrate safety awareness when providing oral care for unconscious clients.
5. Identify the appropriate method of hair care according to client's condition.
6. Outline the steps for shaving a male client.
7. Describe procedure for removing lice and nits from hair and other body areas.
8. State the rationale for preventing prolonged scalp contact with solutions used to treat pediculosis.
9. Demonstrate proper draping technique for female clients.
10. Demonstrate the skill of placing a bedpan for a bedridden client.
11. Describe the steps in providing perineal care for male and female clients.
12. Describe nursing actions necessary to care for clients with contact lenses.
13. State two suggested solutions when hearing is not improved after cleaning a hearing aid.
14. State at least two nursing diagnoses pertinent to clients requiring assistance with personal hygiene.

TERMINOLOGY

- Abrasion** the scraping away of a portion of skin or of a mucous membrane as a result of injury.
- Adaptation** an alteration or adjustment by which an individual can improve his or her relationship to the environment.
- Antibacterial** any substance that fights against or suppresses the growth of bacteria.
- Anticoagulant** any substance that suppresses or counteracts coagulation of blood.
- Aspiration** to withdraw fluid that has collected in an area to obtain a specimen.
- Canthus** the angle at either end of the slit between the eyelids.
- Capillary** minute blood vessel joining arterioles and venules; carries blood, forming the capillary system.
- Congenital** present at birth, as a congenital anomaly or defect.
- Cornea** the clear, transparent anterior portion of the fibrous coat of the eye.
- Debilitated** to become feeble; tired; loss of strength.
- Decalcification** the act of removing calcium, the basic component of bones and teeth.
- Decubitus** old term for pressure ulcer.
- Dental plaque** a thin film on the teeth made up of mucin and colloidal material found in saliva.
- Edema** a local or generalized condition in which there is excess fluid in the tissues.
- Emesis** vomiting.
- Epidermis** the outer layer of skin.
- Eversion** a turning outwards.
- Excoriation** an injury to a surface of the body cavity caused by trauma.
- Expectoration** expulsion of mucus or phlegm from the throat or lungs.
- Fissure** a groove, slit, or natural division; ulcer or crack-like sore.
- Floss** a waxed or unwaxed tape or thread used to clean between teeth.
- Fungus** a vegetable cellular organism that subsists on organic matter.
- Genitals** organs of generation; reproductive organs.
- Hemorrhage** abnormal internal or external discharge of blood.
- Holistic** the philosophy that an individual must be looked at as a whole rather than a sum of the parts.
- Hygiene** the study and observance of health rules.
- Hypoallergenic** having a lowered potential for producing an allergic reaction.
- Impetigo** inflammatory skin disease marked by isolated pustules that rupture and become crusted.
- Incontinent** inability to retain urine or feces through loss of sphincter control.
- Intervention** the act of coming between, so as to hinder or modify.
- Irritation** a source of annoyance; incipient inflammation, soreness or roughness, or irritability of a body part.
- Labia** the lips of the vulva.
- Lesion** an injury or wound; a single infected patch in a skin disease.
- Metabolism** the sum of all physical and chemical changes that take place within an organism; all energy and material transformations that occur within living cells.
- Microorganism** a minute living body such as a bacterium or protozoon not perceptible to the naked eye.
- Mucosa** mucous membrane lining passages and cavities communicating with the air.
- Nasolacrimal** pertaining to the nose and lacrimal apparatus.
- Nits** lice eggs.
- Ophthalmic solution** solution designed especially for the eyes.
- Oral** concerning the mouth.
- Palate** the roof of the mouth.
- Parotid gland** either of the largest of the paired salivary glands, located below and in front of each ear.
- Pediculosis** infestation with lice.
- Periodontal disease** chronic bacterial infection of the tissues surrounding the teeth.
- Perineum** the external region between the vulva and anus in a female or between the scrotum and anus in a male.
- Plaque** a patch on the skin or on a mucous surface; a blood platelet.
- Pressure point** area for exerting pressure to control bleeding; an area of skin that can become irritated with pressure, especially over bony prominences.
- Sclera** the tough, white, fibrous outer envelope of tissue covering all of the eyeball except the cornea.
- Semi-Fowler's position** semisitting position.
- Systemic** pertaining to the whole body rather than to one of its parts.
- Thrush** fungus infection of mouth or throat, especially in infants and young children and in clients with AIDS.
- Ulcer** an open sore or lesion of the skin or mucous membrane of the body.
- Urethra** canal for the discharge of urine extending from the bladder to the outside.
- Vascular** pertinent to or composed of blood vessels.

HYGIENIC CARE

Unfamiliar or life-threatening conditions affect the client's adaptation to the healthcare system. A holistic approach on the part of the nurse provides individualized care and assists the client to adapt. Basic hygiene care is an integral part of the total treatment program. Together with its role in enhancing the client's adaptation to the hospital environment and sense of self-worth, it provides an opportunity for the nurse to do a total assessment and evaluation. This time also allows for establishing a working relationship with the client and offers an opportunity to reduce stress by discussing fears and concerns about being in the hospital or the care being received.

The manner in which hygienic care is provided by nursing staff influences the client's perception of the staff. If care is administered in a professional and efficient manner, the client's confidence in the healthcare system is increased. The need to provide personal hygiene depends on each client's physical state and ability to care effectively for himself or herself. Your first responsibility is to assess the client's level of ability. After gathering this data, you should assist the client as necessary, providing any assistance or teaching he or she may require.

Oral Hygiene

The condition of the oral cavity has a direct influence on an individual's overall state of health. Dental diseases require a "host" (the tooth and gum), an "agent" (plaque), and an "environment" (e.g., the presence of saliva and food). When plaque comes in contact with bacterial enzymes, carbohydrates, and acids, cavitation begins as the enamel of the tooth is decalcified. As long as food and plaque remain in the oral cavity, the possibility of dental decay increases. In the hospital the incidence of caries (cavities) can be decreased by using a dentifrice containing fluoride, proper brushing and flossing, and adequate nutrition. Clients at risk for poor oral hygiene include those who are NPO, mouth breathers, and those with oral surgery.

Oral hygiene is a challenge for clients in long-term care settings. It is one of the most important interventions that nurses need to provide for these clients. Evidence links poor oral hygiene to serious systemic illnesses, including diabetes, stroke, hypertension, myocardial infarction, and aspiration pneumonia.

Hair Care

The appearance and condition of a client's hair may reflect his or her general physical and emotional status, individuality and feelings of worth, and the ability to care for him or herself. When complex medical care is required during illness or trauma, hair care is often neglected.

Hair care is an important aspect of regular hygiene. To prevent damage to the hair, scalp, and surrounding skin, and to promote the client's sense of well-being, you should assess the condition of a client's hair. Based on the assessment, provide hair and scalp care, shampooing, and shaving, and intervene to correct special problems.

Pediculosis

Pediculosis is one of the major health problems in school-age children and easily spreads to family members and friends. The use of terminology varies related to the life cycle of the louse. According to biologists, the life cycle of the head louse includes:

Adult Louse: wingless, flat insect about the size of a sesame seed, parasitic on warm blood.

Eggs: head louse eggs are also called nits: cemented firmly to hair shaft and take 6 to 9 days to hatch; nit shells remain on hair shaft.

Nymphs: immature louse released when egg hatches; looks like an adult head louse, but the size of a pinhead; takes 7 to 8 days to become an adult.

Perineal and Genital Care

The perineum consists of the area between the thighs and from the anterior pelvis to the anus. This area contains organs and structures related to sexual functioning, reproduction, and elimination.

Hygienic care involves cleaning the perineum and genitalia to prevent bacterial growth, which can rapidly increase in this warm, dark, moist environment. Perineal care is often provided as a routine part of bathing but may be required more frequently to prevent skin irritation, infection, discomfort, or odor.

All clients are susceptible to perineal irritation or infection. Clients who are especially vulnerable are those who are immobilized, incontinent, debilitated, postsurgical, or comatose; those who have indwelling catheters; those who have metabolic and fluid balance disorders; or those who require systemic medications.

Eye Care

The usual eye care provided for hospitalized clients is for the comatose client and the client with contact lenses. Several types of contact lenses are used by clients. The older, hard lenses were the first on the market and were made of solid plastic. They were easy to keep clean because they did not absorb proteins from the eye. They do inhibit oxygenation of the cornea; therefore, they must not be worn for long periods of time.

Soft lenses, the most popular of the lenses, allow more oxygenation of the cornea, but require care because they are less durable and carry a risk of contamination from collection of bacteria, dirt, and chemicals. Extended-wear lenses, another type of soft contact lenses, are worn for a number of days (usually up to 7) without being removed. The Food and Drug Administration (FDA) has approved the use of continuous 30-day lenses. It is recommended that the lenses be removed every 30 days, cleaned, disinfected, and replaced or discarded. Lenses should not be replaced for 24 hours to allow the eye to rest. There are reported side effects with these lenses, including conjunctivitis, dry eyes, and mild burning or stinging. Some clients use disposable extended-wear lenses. These are considered one-time-only contacts and are discarded, not cleaned, after they are removed.

Individuals who wear contact lenses must be aware of environmental contaminants such as dust, smoke, and sprays because they can irritate the eyes. Certain drugs cause a decrease in the eye fluid on which the contact lens floats and can lead to irritation of the eye. Common drugs that can lead to this problem include antihistamines, birth control pills, and alcohol. Clients who use eye cosmetics must apply the makeup before they insert the contact lenses so makeup will not adhere on the lenses.

CULTURAL AWARENESS

- Cultures define cleanliness in different ways. Western cultures, because of the abundance of detergents and washing machines, value clean clothes. Some underdeveloped countries have limited access to fresh water and therefore may not wash clothes as frequently.
- Anglo-Americans are fastidious about body cleanliness and the absence of body odor. The use of perfumes, deodorants, and aftershave lotions is a major part of their hygienic care. In some cultures, natural body odor is thought to have sex appeal.
- Some cultures incorporate the participation of family members to provide personal care, particularly assistance with using a bedpan or bedside commode, to maintain modesty. Puerto Ricans, African-Americans, and clients of Arab descent should be questioned regarding their preferences for assistance with personal care.

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to include in a client care plan when a client is admitted and requires basic hygiene care.

NURSING DIAGNOSIS	RELATED FACTORS
Deficient Knowledge	Misinformation or lack of information, impaired cognitive function, lack of motivation
Noncompliance	Inability to perform tasks, disability, impaired memory
Impaired Oral Mucous Membrane	Inadequate oral hygiene, chemotherapy, malnutrition, dehydration, infection, mechanical trauma
Bathing Self-Care Deficit	Impaired motor or cognitive function, pain, disease condition, surgery
Situational Low Self-Esteem	Impaired motor or cognitive function, chronic illness, chronic pain

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. Remember to wash your hands or use antibacterial gel before and after each and every client contact.

IDENTIFY CLIENT Before every procedure, check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Chapter 9

UNIT 1

Oral Hygiene

Nursing Process Data

ASSESSMENT Data Base

- Assess whether client wears dentures.
- Evaluate client's knowledge of oral hygiene techniques.
- Assess condition of client's oral cavity, teeth, gums, and mouth.
- Assess for color, lesions, tenderness, inflammation, intactness of teeth, and degree of moisture or dryness of the oral cavity.
- Observe external and internal lips.
- Assess palate (roof and floor of mouth), and inspect under tongue.
- Assess entire oral mucosa, noting inside of the cheek.
- Observe tongue. Note tip, sides, back position, and underside.
- Evaluate condition of gums and teeth.
- Assess condition of throat as client says "Ah."
- If dentures or orthodontic appliances are used, observe relationship of the appliances to client's oral cavity (i.e., fit, irritation, condition of dentures).

PLANNING Objectives

- To remove plaque and bacteria-producing agents from oral cavity
- To allow nurse to assess client's oral health status, knowledge, and routines of oral care
- To decrease possibility of irritation or infection of oral cavity
- To remove unpleasant tastes and odors from oral cavity
- To provide comfort for client
- To provide client teaching when appropriate
- To assess hydration status

IMPLEMENTATION Procedures

- Providing Oral Hygiene 213
- Providing Denture Care 215
- Providing Oral Care for Unconscious Clients 215

EVALUATION Expected Outcomes

- The oral health status of client has been assessed and documented by nurse.
- Oral hygiene care is provided without complications.
- Plaque and bacteria-producing agents are removed.

Critical Thinking Application 217

- Expected Outcomes 217
- Unexpected Outcomes 217
- Alternative Actions 217

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Providing Oral Hygiene

Equipment

- Toothbrush: small enough to reach back teeth; soft and rounded with nonfrayed rows of nylon bristles
- Dentifrice: client's choice, preferably one containing fluoride; special paste for dentures
- Cup of water
- Emesis basin or sink
- Dental floss: regular or fine, waxed or unwaxed, depending on client's needs
- Tissues or towel
- Mouthwash if desired
- Clean gloves

Preparation

1. Perform hand hygiene.
2. Collect necessary equipment.
3. Check two forms of client ID and introduce yourself.
4. Assist client to sink or provide privacy if care is to be given in bed.
5. Help client into a comfortable semi-Fowler's position or a sitting position. Assist client with the arrangement of equipment if necessary.
6. Don clean gloves.
7. Inspect surface of mouth for any abnormalities.
 - a. Inspect surface of mouth, especially buccal mucosa (it should be pink, smooth, and moist), for any abnormalities. ► **Rationale:** Alterations from normal may indicate presence of disease states such as measles, mumps, or Addison's disease.
 - b. Examine condition of teeth and gums. Be alert to changes in gums. ► **Rationale:** Gingival hypertrophy, crevices between teeth and gums, pockets of debris, and bleeding with slight pressure are indicative of gingivitis.
 - c. Ask client about usual oral care routines.

▲ Inspect surface of mouth abnormalities.

▲ Providing oral hygiene is an essential component of client care.

8. Elicit any concerns, comments, or questions client may have about his or her oral health status.
9. Determine oral hygiene needs based on findings.
10. Assess client's need for teaching. Consider educational level, physical, emotional and mental state, previous experiences, and cultural differences.
11. Assess client's physical condition. Consider diagnoses, lab reports, treatments, fluid status, drugs, diet, and level of comfort or pain.
12. Assess client's ability to care for himself or herself.

Procedure

1. Perform hand hygiene and don clean gloves.
2. Request that client open mouth wide and hold emesis basin under chin.
3. Instruct client to complete following steps or provide the care yourself. Direct the bristles of the toothbrush toward the gum line for all areas to be brushed.
 - **Rationale:** Action removes food particles from gum line and stimulates the gums.

▲ Assist client to rinse mouth with water.

The American Academy of Periodontology estimates that at least half of noninstitutional individuals age 55 and older have periodontitis and that almost 25% ages 65 and older have lost all of their teeth. Periodontal disease affects glycemic controls in diabetic clients. There is also a significantly higher incidence of cardiovascular complications as a result of periodontal disease.

4. Keep the brush positioned over only two or three teeth at a time. Use small rotating movements to cover the outside surfaces of all teeth.
5. Clean the inner surfaces of all back teeth, using the brushing method described above.
6. Use a firm back-and-forth motion to clean the flat chewing surfaces.
7. Use the bristles on the end of the toothbrush and rotate the brush back and forth across the teeth to clean the inner surfaces of the front teeth.
8. Lightly brush all areas of the tongue—this improves the breath. Be careful not to stimulate gag reflex.
9. Rinse the client's mouth thoroughly with water.
10. Inspect oral cavity, and repeat brushing if necessary.
11. Floss thoroughly, using approximately 12 inches of floss loosely wrapped around one finger of each of your hands. Flossing removes plaque from between teeth.
12. Instruct or assist client to complete the following steps.
 - a. Wrap one length of floss loosely around index fingers of both hands.
 - b. Hold floss taut between two hands, and gently pull back and forth between each tooth.
 - c. Move floss up and down sides of teeth to clean plaque. Go as near gum line as possible without injury to gum. Pull floss back and forth gently, working back toward the biting surface of each tooth. Repeat other

▲ Instruct client to floss to prevent build-up of plaque and food particles between the teeth.

EVIDENCE-BASED PRACTICE

In a longitudinal study of more than 600 individuals with type 2 diabetes, those with severe periodontal disease had 3.2 times the risk of death from ischemic heart disease and diabetic nephropathy than those with little or no periodontal disease.

Source: Saremi, A., Nelson, R. G., Tulloch-Reid, M., Hanson, R. L., Sievers, M. L., Taylor, G. W., ... Knowler, W. C. (2005). Periodontal disease and mortality in type 2 diabetes. *Diabetic Care*, 28(1), 27–32.

edge of each tooth, using a new section of floss.

► **Rationale:** Overly vigorous flossing can damage gums.

- d. Floss each tooth several times until all particles of food are removed.
13. Assist client to rinse mouth and expectorate into emesis basin.

Client Teaching

Begin teaching client about oral care during your initial assessment. Focus teaching on oral health needs and care. You may want to incorporate the following techniques:

- A demonstration and return demonstration to illustrate correct dental care techniques.
 - Disclosure tablets or solution that temporarily stains dental plaque pink. This technique helps the client to see where plaque appears on the teeth. After applying tablets or solution, ask the client to brush and floss until plaque is removed.
14. Wipe off client's mouth and chin.
 15. Wash client's toothbrush, rinse, and put the toothbrush and paste away and return additional equipment to the appropriate area.
 16. Remove gloves and place in appropriate receptacle.
 17. Perform hand hygiene.
 18. Check to see that client is comfortable.

Sonic Toothbrush

Many dentists and dental hygienists recommend the use of a sonic toothbrush, especially for clients with plaque formation, stains, and periodontal pockets. The usual recommended time for brushing is 2 minutes twice a day. The toothbrush is charged by plugging the charger into the electrical outlet; therefore, electrical safety procedures must be followed. Do not store or place the charger where it can come in contact with water. Client instructions for using the toothbrush are printed on the owner's manual and must be clearly understood before attempting to use the toothbrush.

NOTE: If the client brings the toothbrush to the hospital, it is not necessary to charge it if hospitalization is less than 2 weeks. If hospitalization is beyond 2 weeks or the toothbrush needs charging, instruct the client's relatives to take the brush home and charge it. It is required by most hospitals that any electrical appliance brought into the hospital must be checked for safety by the hospital engineering department.

Providing Denture Care

Equipment

- Denture toothbrush
- Denture cup, labeled with client's name
- Emesis basin
- Cleanser or effervescent tablets for dentures
- Clean gloves
- Mouthwash, if desired
- Adhesive dental liner, optional

Procedure

1. Encourage client to use dentures. ► **Rationale:** Dentures improve speech, make eating easier, and improve the shape of the mouth, appearance, and self-image.
2. Perform hand hygiene and don gloves.
3. Help client remove dentures. If client is unable to do this, carefully place your finger on the edge of the upper denture. ► **Rationale:** This action breaks the seal at the roof of the mouth and allows the denture to easily slide out. Lower denture generally lifts out easily.
4. If client is unable to clean own dentures, place them in an unbreakable container. Either wash dentures over a basin or carry them to the sink. Place a towel or washcloth on the bottom of the sink. ► **Rationale:** To cushion the surface in case you accidentally drop a denture.
5. Hold one denture in your hand. With your other hand, use a toothbrush or special denture brush and a cleaning agent, such as a commercially prepared paste or solution, to brush the denture. Use the same brushing motion as with natural teeth.
6. Rinse denture thoroughly in cold water. ► **Rationale:** Hot water can damage dentures.
7. If dentures are to remain out of the mouth for a period of time, as at night, store them in a clearly labeled, unbreakable container of cold water.
8. If dentures are to be worn immediately, help client to rinse oral cavity with warm water or mouthwash.
9. You may also gently brush client's gums and tongue. ► **Rationale:** To remove bacteria and freshen breath.
10. Apply adhesive dental liner if client requests. ► **Rationale:** Holds dentures in place and provides cushion for more security and comfort.
11. Moisten dentures according to client's desire.
12. Help client replace dentures.
13. Clean denture cup and emesis basin and replace in client's bedside stand.
14. Remove gloves, and place in appropriate receptacle.
15. Perform hand hygiene.

▲ Hold dentures securely while brushing.

▲ Rinse dentures in cold water.

Providing Oral Care for Unconscious Clients

Equipment

- Foam toothette oral swabs
- Lubricant for lips
- Waterpik devices or brush
- Bulb syringe or suction equipment
- Tongue blades or bite block
- Clean gloves

Procedure

1. Gather equipment.
2. Perform hand hygiene and don gloves.
3. If possible, position client on side in a semi-Fowler's position. If this is not possible, turn client's head to the side. ► **Rationale:** Allows fluid to drain or be suctioned out of mouth and thus prevents aspiration.

▲ Use padded tongue blade when brushing teeth.

4. Place a bulb syringe or suctioning equipment nearby.
 - ▶ **Rationale:** Safety precaution to use for suctioning oral cavity as needed.
5. Insert bite block if necessary to keep mouth open while brushing.
6. Place a small amount of toothpaste on brush. Brush the external surfaces of the teeth in the routine manner, using less water on the brush. You may use a tongue blade to move the cheeks and lips. Do not put your fingers in the client's mouth. ▶ **Rationale:** This prevents accidental closing down on toothbrush and biting your finger.
7. To clean the inner surfaces of the teeth, use a padded tongue blade to separate the upper and lower sets of teeth, if bite block is not used. Brush the teeth and tongue in the usual manner.
8. Rinse the client's mouth carefully, using very small amounts of water that can be suctioned.
9. Remove bite block.
10. Lubricate client's lips with petroleum jelly.

▲ Rinse mouth using water-filled syringe.

11. Provide oral care frequently—as often as every 4 hours if necessary. ▶ **Rationale:** Oral care maintains adequate oral health.
12. Remove gloves and place in appropriate receptacle.
13. Perform hand hygiene.

NOTE: Foam toothettes can be moistened with water and used as a toothbrush.

Toothette swabs are indicated for the following client conditions: radiation therapy, chemotherapy, bone marrow transplant, immunosuppressed, on a ventilator, nutritionally depleted, or elderly. Toothettes improve the appearance of oral tissue (tongue, palate, lips). Toothbrushes are more effective in stimulating gingival tissue and removing debris from the teeth.

Source: DeWalt, E. M. (2003, January). Effect of timed hygiene measures on oral mucosa in a group of elderly subjects. *Journal of American Dental Association*, 134(1), 109–110.

DOCUMENTATION for Oral Hygiene

- Findings from assessment of mouth; condition of gums, mucous membranes, and teeth
- Assessment of client's oral hygiene needs
- Planning steps taken to meet client's oral hygiene needs
- Oral care provided or observed
- Effectiveness of oral care on client's teeth, gums, mucosa
- Client's reaction and level of comfort
- Client's level of participation in oral care
- Client's participation in nurse–client teaching

CRITICAL THINKING Application

Expected Outcomes

- The oral health status of client has been assessed and documented by nurse.

Unexpected Outcomes

Even with increased oral hygiene, client still has odorous breath.

Client complains of extreme oral mucosal irritation or sensitivity.

Vigorous flossing results in bleeding and sore gums.

Client needs care after oral surgery or oral trauma.

Normal stimulation and cleaning is not sufficient to remove debris and plaque for the unconscious client.

Parotid gland inflammation can occur with improper oral hygiene.

- Oral hygiene care is provided without complications.
- Plaque and bacteria-producing agents are removed.

Alternative Actions

- Use antiseptic mouthwash between oral hygiene care.
- Notify the physician, as this could be a symptom of systemic disease.
- Obtain dental consultation to check for presence of dental caries or gum disease.
- Examine client's nutritional intake. Absent nutrients or imbalanced intake of fats, protein, or carbohydrates can result in bad breath.
- Request physician's order for one of the following solutions:
 - Saline solutions: for soothing, cleansing rinses
 - Anesthetic solutions: to dull extreme pain in the oral cavity
 - Effervescent solutions (e.g., hydrogen peroxide or ginger ale) to loosen and remove debris from the mouth
 - Coating solutions (e.g., Maalox) to protect irritated surfaces
 - Antibacterial—antifungal rinses (e.g., nystatin [Mycostatin]) to prevent the spread of organisms that cause thrush
- Give client warm antiseptic mouthwash to relieve soreness.
- Investigate gum condition and refer for consultation.
- Oral care after surgery or trauma is always ordered by physician. No oral hygiene care should be attempted until physician has clearly defined the specific care.
- Suctioning equipment should always be present.
- Assessment of client's head, face, neck, and general status is critical at this time.
- Try flossing teeth to dislodge debris.
- Provide mouth care with toothbrush and dentifrice at least twice daily.
- Check with physician and order sonic toothbrush.
- Rinse mouth with mouthwash.
- Use swab to reach back in oral cavity along mandible to temporomandibular area.
- Floss teeth at least daily.

Chapter 9

UNIT 2

Hair Care

Nursing Process Data

ASSESSMENT Data Base

- Review general physical assessment findings.
- Elicit information regarding loss of hair, tenderness of scalp, or itching.
- Determine client's ability to perform own hair care.
- If unable to care for own hair find out who usually assists client.
- Observe client's hair and scalp, noting the following:
 - Texture
 - Color
 - Degree of thickness and hair distribution
 - Degree of gloss or shine
 - Dryness or oiliness
 - Areas of irritation, rash, or scaliness on the scalp or surrounding skin
 - Matting or snarls
 - Pediculosis (lice)
- Assess usual hair care routines, products, and appliances.
- Assess method for providing hair care (e.g., in bed, on gurney, in wheelchair).
- Determine client teaching needs regarding hair care.
- Assess need for frequency of shaving facial hair for male clients.

PLANNING Objectives

- To prevent irritation to the scalp and damage to the hair
- To help maintain or improve client's existing condition of hair and scalp
- To promote circulation to the hair follicle and growth of new hair
- To distribute oils along the hair shaft
- To remove facial hair for client comfort and self-esteem
- To promote self-esteem

IMPLEMENTATION Procedures

- Providing Hair Care 219
 - For Routine Hair Care 219
- Shampooing Hair 219
 - For Client on a Gurney 219
 - For Client Using a Disposable System 220
- Shaving a Client 220

EVALUATION Expected Outcomes

- Hair and scalp assessment are performed without complications.
- Appropriate method of hair care provided for client.
- Client's hair and scalp are clean, comfortable, and styled according to client's preference.
- Client is comfortable and rested after shampooing.
- Shaving is accomplished without skin nicks or discomfort.

- Critical Thinking Application** 221
- Expected Outcomes 221
 - Unexpected Outcomes 221
 - Alternative Actions 221

Pearson Nursing Student Resources

Find additional review materials at nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Providing Hair Care

Equipment

Blunt-ended comb or pick
Brush
Towel
Mirror
Hair care products and ornaments

Preparation

1. Determine client's hair care needs.
2. Perform hand hygiene.
3. Help client into a comfortable position to perform hair care.
4. Collect and assemble equipment.

Procedure

For Routine Hair Care

1. Place all hair care items within reach.
2. Place towel over client's shoulders.
3. Brush or comb client's hair from scalp to hair ends, using gentle, even strokes.
 - a. Tangled Hair: Use short gentle strokes. Work from end of hair shaft toward scalp. May use conditioner to make combing easier.
 - b. Curly hair: Use wet comb on wet hair (water or oil) for ease of combing.
4. Style hair in a manner suitable to client.
5. Replace hair care items in appropriate place and clean items as needed.
6. Perform hand hygiene.

Shampooing Hair

Equipment

Two bath towels
Washcloth
Large container for water
Shampoo
Conditioner, if desired
Hair dryer, if allowed by hospital
For Disposable System
Package containing shampoo cap
Face or bath towel
Hair care products, as requested by client
Comb and/or brush

NOTE: Ensure that electrical equipment is checked by maintenance department before using. ► **Rationale:** This confirms that equipment is grounded and mechanically safe.

Preparation

1. Determine client's hair care needs.
2. Perform hand hygiene.
3. Collect and assemble equipment.
4. Help client into a comfortable position to perform hair care.
5. Shampooing the hair can be accomplished in a variety of ways depending on the client's usual routine and physical condition. In many institutions, a physician's order is necessary before shampooing a client's hair.
6. If possible, the easiest way to shampoo is to assist the client while he or she is in the shower. Caution should be taken to prevent the client from becoming overly tired or weak while in the shower. (Use shower chair if necessary.)

Procedure

For Client on a Gurney

1. Have shampoo items readily available.
2. Position gurney with head end at sink.
3. Lock wheels on gurney. ► **Rationale:** This prevents the gurney from moving away from the sink.
4. Pad the edge of the sink with a towel or bath blanket.
5. Move the client's head just beyond the edge of the gurney. ► **Rationale:** To allow water to run off more easily.
6. Put a pillow or a rolled blanket under the client's shoulders. ► **Rationale:** To help elevate and extend the head.
7. Drape one towel over client's shoulders and around neck. Place another towel within reach.
8. Use a washcloth to protect client's eyes. Wet hair and gently make a lather with shampoo.
9. Rinse thoroughly and repeat if necessary.
10. Towel dry, add conditioner if desired, and rinse again.
11. Using a dry towel, pat hair dry, and wrap turban style to transport back to room.
12. Use hair dryer if available.
13. Style as desired.
14. Replace equipment.
15. Perform hand hygiene.

Clinical Alert

If the client is elderly, do not press the neck down on the edge of the sink—this position can diminish circulation to the brain and has been reported to be a possible cause of strokes.

▲ Shampoo system activated by microwave.

For Client Using Disposable System

1. Heat shampoo package in microwave for no more than 30 seconds.
2. Perform hand hygiene.
3. Open package and check temperature. ► **Rationale:** Clients react to heat at different temperatures; therefore, check the cap temperature with client before placing on client's head.
4. Place cap on head. Ensure that all hair is contained within the cap. For longer hair, place cap on top of head and then tuck all hair up inside cap.
5. Gently massage cap with hands, 1–2 minutes for short hair and 2–3 minutes for longer hair. ► **Rationale:** This

▲ Disposable cap can be used for clients on bed rest.

will assist in saturating the hair with the solution. There is no need to rinse hair after using solution.

6. Remove cap and place in appropriate receptacle.
7. Towel dry hair.
8. Complete hair care according to client's needs and desires.
9. Perform hand hygiene.

NOTE: Disposable hair care systems provide a quick and easy way to freshen client's hair with minimal client movement

Clinical Alert

If hair is tangled, the cap may need to stay on for longer period of time in order to saturate hair. If blood or other secretions are present on hair, they may need to be removed using the washcloths from the disposable bath system before attempting to shampoo the hair.

Shaving a Client

Equipment

- Safety or electric razor, specific to client's needs or wishes
- Shaving cream
- Aftershave lotion (optional)
- Two towels
- Basin of warm water

Preparation

1. Place client in sitting position.
2. Perform hand hygiene.
3. Place towel over chest and under chin.
4. Put up mirror on overbed table.
5. Determine how the client usually shaves (i.e., use of safety edge or electric razor; special products).
6. Check to see if the client has excessive bleeding tendencies due to pathologic conditions (hemophilia) or the use of specific medications (anticoagulants or large doses of aspirin). ► **Rationale:** If client is accidentally cut, it could lead to some loss of blood.

Clinical Alert

Only electric razors can be used to shave clients with excessive bleeding tendencies.

Procedure

1. If using a safety edge razor:
 - a. Don gloves and apply a warm, moist towel to soften the hair.
 - b. Apply a thick layer of soap or shaving cream to the shaving area.
 - c. Holding skin taut, use firm but small strokes in the direction of hair growth.
 - d. Gently remove soap or lather with a warm, damp towel. Inspect for areas you may have missed.
2. If using electric razor:
 - a. Use rotating motion of razor and start from lateral aspect of face and move toward chin and upper lip area.
 - b. Clean razor with brush or remove razor head and clean facial hair from head of razor.

3. Apply aftershave lotion or powder as desired.
4. Reposition client for comfort if needed.
5. Remove gloves and replace equipment.
6. Perform hand hygiene.

Clinical Alert

According to the hospital policy, be sure to have the electric razor checked for safety aspects. Some hospitals do not allow clients to use their own electric razors.

DOCUMENTATION for Hair Care

- Documentation of hair care assessment and needs
- Shampooing method, outcomes, problems encountered
- Client's tolerance to hair care
- Shaving completed; note specific type of razor
- Unusual bleeding from shaving

CRITICAL THINKING Application

Expected Outcomes

- Hair and scalp assessment performed without complications.
- Appropriate method of hair care was provided for client.
- Client's hair and scalp are clean, comfortable, and styled according to client's preference.
- Client is comfortable and rested after shampooing.
- Shaving is accomplished without skin nicks or discomfort.

Unexpected Outcomes

Extreme matting, snarling, blood, or nonremovable substances appear in client's hair.

Alternative Actions

- Never cut a client's hair unless it is absolutely necessary.
- Check hospital policy regarding hair cutting. It may not be allowed in some facilities.
- Apply alcohol to tangled hair or blood-soaked hair. Keep in place 5 minutes. Wash hair with shampoo to remove alcohol and blood.
- Secure permission of family or physician (if order required).
- Assess extent of cut, and place a clean towel on the area with pressure to stop bleeding.
- If cut appears to be more than a nick, report to physician and fill out unusual occurrence report.
- Place warm towels on area to be shaved for 15 minutes.
- Apply more shaving cream.
- Ensure that razor is sharp.

Client is cut during shaving procedure.

Shaving is difficult and painful for the client.

Chapter 9

UNIT 3

Pediculosis

Nursing Process Data

ASSESSMENT Data Base

- Observe head (scalp), body (nape of neck, behind ears, beard, eyebrows, arms, legs), and pubic areas for the following signs:
 - Small, hemorrhagic areas on the skin
 - Scratches on the skin
 - Habitual itching and scratching, feeling something crawling in hair
 - Insect-type bites or pustular eruptions behind the ears or hairline
 - Small, white dandruff-like particles
 - Gritty feel when running fingers through hair
- Assess client's personal hygiene, living conditions, contact or exposure to others with lice (e.g., school-aged children, sexual partners, siblings).

PLANNING Objectives

- To remove lice from client's hair and prevent further skin problems such as impetigo or infection
- To remove cause of itching and intense need to scratch scalp
- To control spread of lice to others

IMPLEMENTATION Procedures

- Identifying the Presence of Lice and Nits (Lice Eggs) . . . 223
- Removing Lice and Nits 223

EVALUATION Expected Outcomes

- Lice removed after treatment.
- Client verbalizes cause of problem and preventive measures.
- Client repeats back to nurse instructions for preventing lice infestation and indicates understanding of process.
- Client and family members remain free of lice infestation.

Critical Thinking Application 225

- Expected Outcomes 225
- Unexpected Outcomes 225
- Alternative Actions 225

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Identifying the Presence of Lice and Nits (Lice Eggs)

Equipment

- Bright lamp/light
- Magnifying glass
- Clean gloves
- Isolation bag
- Nit comb or tongue blade (2)

Procedure

NOTE: Louse becomes adult in 7 to 8 days. Each louse lays 4 to 8 eggs/day for the next 18 days, then dies (each louse lays 100–400 eggs). The nits/eggs hatch in 8 days. Adult lice can survive up to 55 hours without a host.

1. Perform hand hygiene. Don clean gloves.
2. Check two forms of client identifiers, introduce yourself, and explain procedure to client.
3. Position client so head or affected body area is well lighted by lamp.
4. Use fine-tooth louse comb after removing tangles and comb from roots to end. After each stroke, examine comb for live louse or a viable egg. Use magnifying glass to observe scalp and hair.
 - a. For live lice:
 - Gray-white to reddish brown in color
 - 2–4 mm long; 1 mm wide
 - b. For viable eggs or nymph:
 - Tiny and hard
 - Yellow to white oval, tear-drop-shaped capsules
 - Attached firmly to base of hair shaft (dandruff will fall from hair shaft when touched)
 - Nits hatch after 7–10 days
 - Nits within 6 mm of scalp are usually viable and indicate an active infestation
 - Easier to detect close behind the ears or at the nape of the neck
5. Identify lice or nits:
 - a. Fine-toothed louse comb: after removing tangles, comb from roots to end with the nit comb. After each stroke, examine comb carefully for signs of lice.
 - b. Nits present without lice does not indicate there is an active infestation. Assess further: previous treatment, timing, and distance from scalp.
 - c. Put hair strands between two tongue blades and scrape white specks. Determine whether they come off the shaft easily. Observe base of scalp carefully for tiny lice.

Removing Lice and Nits

Equipment

- Isolation bags (optional)
- Topical insecticide/pediculicides:
 - Permethrin (Nix®, RID)
 - Pyrethrin® (A-200, Pronto, Tisit)
 - Malathion (Ovice, by prescription)
 - Benzyl Alcohol (Ulesfia, by prescription)
- Clean linen
- Fine-tooth “nit” comb
- Disinfectant for comb
- Clean gloves
- Towels

Procedure

1. Determine whether client is allergic to ragweed or chrysanthemums. ► **Rationale:** Pyrethrin is obtained from these plants and cannot be used to treat lice if client has allergic reaction to them.

Clinical Alert

When using any of the lice treatment products, the nurse needs to check for allergies to ragweed or chrysanthemum flowers. Allergies to ragweed can cause breathing difficulties or an asthmatic attack. Allergies to chrysanthemums can cause pneumonia, muscle paralysis, or death due to respiratory failure.

2. Perform hand hygiene.
3. Don clean gloves. Gloves are used even when completing treatment at home.
4. Remove and bag client’s clothing and linens. Client’s clothes do not need to be bagged separately and placed in isolation bags if standard precautions are used.
5. Notify physician and other healthcare providers of lice infestation. Begin treatment as ordered by physician.
6. Follow manufacturer’s directions for product ordered.

▲ Use magnifying glass when inspecting for head lice.

7. Apply lotion, mousse, or gel to scalp and dry hair, beginning at the roots, and extend to the end of the hair shaft. If using shampoo before treatment, be sure to towel dry hair.
8. Leave product on hair for 10 minutes (leave Malathion longer, according to directions).
9. Rinse hair thoroughly.
10. Give client a towel to protect eyes and face while applying product and rinsing hair.
11. Comb out nits using a fine-tooth or lice/nit comb. Hair should remain slightly damp while removing nits. If hair dries during combing, dampen slightly with water. ► **Rationale:** Combing is the most important step in the process of lice removal, as eggs can be left behind and hatch at a later time.
12. Disinfect combs and brushes with the shampoo.
13. Remove gloves.
14. Perform hand hygiene.
15. Instruct client, parent, or significant other to check hair and use “nit comb” every 2 to 3 days until lice are gone and to check skin for removal of scabies. (Pruritus may last for 2 weeks after treatment.)
16. Wash clothes and linens that person has used within 48 hours before treatment. ► **Rationale:** head lice rarely survive more than 48 hours off the body.
17. Place stuffed toys in hot dryer or place in a plastic bag and seal for 2 to 4 weeks.
18. Instruct client or family to vacuum furniture and floors to rid house of lice. ► **Rationale:** Head lice need a human host and therefore do not survive long after falling off head.
19. Administer Bactrim if ordered (usually used with resistant cases). ► **Rationale:** used if multiple treatments have tried to rid hair of lice.
20. Inspect all family members using wet louse comb or magnifying glass in bright light for lice/nits (eggs). Look

▲ Examine hair closely for white nits on hair shaft.

for tiny nits near scalp, beginning at back of neck and behind ears. Examine small section of hair one at a time. Treat each member infested with lice using the same treatment plan.

21. Discuss the cause, treatment, and preventive measures regarding lice infestation with client and family.
22. Reinspect hair every 1 to 3 days for signs of reinfestation.
23. Apply second treatment within 7 to 10 days to kill any newly hatched lice.

NOTE: Nix is treatment of choice and is over-the-counter. Recommended by the American Academy of Pediatrics because of its efficacy and lack of toxicity.

Clinical Alert

- Do not use more than three applications in 2 weeks.
- Do not use cream rinse or conditioner shampoo before applying pediculicide treatment as it will interfere with the medication.

Clinical Alert

- Do not use near eyes, eyebrows, eyelids, inside nose, mouth, or vagina.
- If product gets into eyes, immediately flush eyes with water. If child swallows product, immediately contact a Poison Control Center for directions on care.
- Stop treatment immediately if client complains of breathing difficulties, eye irritation, or skin or scalp irritation.
- Adverse reactions and side effects may be more frequent and severe in younger clients. Consult with physician about treatment dose. Pediculicides are not effective on some resistant strains of lice.

Removing Nits From Hair

- Part hair into sections; start at top of head and do one section at a time.
- Lift a 1- to 2-inch-wide strand of hair. Place comb as close to scalp as possible and comb with a firm, even motion away from scalp.
- Pin back each strand of hair after combing.
- Clean comb often. Wipe nits away with tissue and discard into a plastic bag. Seal bag and discard to prevent lice from spreading.
- After combing, thoroughly recheck for lice/nits. Recomb as needed.
- Check every 1 to 3 days for missed lice.

Guidelines for Diagnosis and Treatment of Pediculosis Capitis in Children and Adults

Diagnosis:

- A live louse or nymph on the scalp or a viable egg is usually found within 1 cm of the scalp.
- Using a fine-tooth louse comb is four times more efficient than direct visualization and two times faster.

Treatment:

- Permethrin is the treatment of choice because of efficacy and lack of toxicity.
- Pyrethrin and Piperonyl butoxide are not ovicidal and application should be repeated in 7 days.
- Malathion lotion.
- Combing wet hair using a conditioner of choice and a louse comb is an alternative regimen and the treatment of choice for children younger than 2 years of age. When using this method, repeat combing needs to be done for the next 2 weeks on days 1, 5, 9, and 13 to break the life cycle.
- A combination of Permethrin and Bactrim should be reserved for cases not responsive to traditional pediculicides and those suspected to have lice-related resistance.

Source: Prepared by University of Texas, Austin (2008), and posted in the National Guideline Clearinghouse; reviewed 19 references, in addition to the 41 previously reviewed to formulate the 2002 guidelines.

DOCUMENTATION for Removing Lice

- Location of lice infestation
- Notification of physician and healthcare providers
- Medicated shampoo applied
- Side effects of medicated shampoo, if any
- Nursing interventions and the results obtained
- Client teaching activities

CRITICAL THINKING Application

Expected Outcomes

- Lice removed after treatment.
- Client verbalizes cause of problem and preventive measures.
- Client repeats back to nurse instructions for preventing lice infestation and indicates understanding of process.
- Client and family members remain free of lice infestation.

Unexpected Outcomes

Special shampoo is left on hair/scalp too long.

Other clients or staff become infested with lice.

Lice are not eliminated with treatment.

Alternative Actions

- Observe for irritation or burning after rinsing out the shampoo.
- If scalp is burned, notify physician for a medication order.
- Do not repeat treatment unless specifically ordered by physician.
- Isolate the client's linen and personal hair grooming equipment to prevent spread of lice.
- Instruct client or staff on use of medicated lotion, shampoo, or combination therapy.
- Repeat treatment using combination therapy as ordered by physician.
- Do not repeat treatment for 7 days.
- Utilize another type of insecticide or wet-combing method.

Chapter 9

UNIT 4

Bedpan, Urinal, and Commode

Nursing Process Data

ASSESSMENT Data Base

- Determine client's usual voiding pattern.
- Assess client's ability to assist with the procedure.

PLANNING Objectives

- To assist the client to void when on bed rest or unable to urinate
- To help client void 200 to 500 mL of urine without discomfort or difficulty

IMPLEMENTATION Procedures

- Using a Bedpan and Urinal 227
 - *For Using a Bedpan* 227
 - *For Using a Urinal* 227
- Assisting Client to Commode 228

EVALUATION Expected Outcomes

- Client voids 200 to 500 mL of urine without discomfort or difficulty.
- Bladder does not become distended.
- Genitourinary system is free of infection.
- Client transferred to commode for voiding.

Critical Thinking Application 229

- Expected Outcomes 229

Using a Bedpan and Urinal

Equipment

- Bedpan or urinal
- Toilet tissues
- Absorbent pad, if needed
- Clean gloves

Procedure

1. Perform hand hygiene and don gloves.
2. Obtain bedpan or urinal and warm pan or urinal by running warm water around the edges of the receptacle if cold. Fracture pan is used for clients in traction, body cast, or with casted extremities.
3. Provide privacy.
4. Place client in a supine position, if possible, or position on edge of bed or in a chair.
5. Instruct the client to sit on bedpan or place penis into urinal. If the client needs assistance, follow these steps:

For Using a Bedpan

- a. Place absorbent pad under hips, if needed.
- b. Raise the client's hips and slip your arm under the client or turn the client on his or her side. Roll the client onto the pan.
- c. Place a rolled towel or blanket under the client's sacrum.
 - ▶ **Rationale:** This provides comfort by padding the bony area.
- d. Elevate the head of the bed.

For Using a Urinal

- a. Place the base of the urinal flat on the bed between the client's thighs.
- b. Position the client's penis into opening of the urinal.

NOTE: It may be easier for clients to use a urinal if they sit on the edge of the bed.

▲ Urinal, bedpan, and fracture pan used for clients on bed rest.

6. Place the signal light or call bell and toilet tissue within easy reach.
7. When the client has voided, remove the bedpan or urinal and assist with wiping as necessary.
 - a. Remove bedpan by placing hand under small of back.
 - b. Assist client to lift buttocks off pan.
 - c. Remove pan by pulling toward edge of bed. Keep bedpan flat when moving. ▶ **Rationale:** To prevent spilling urine out of bedpan.
8. Provide an opportunity for the client to perform hand hygiene.
9. Reposition the client for comfort, pull back curtains.
10. Measure intake and output if required.
11. Empty bedpan or urinal, clean equipment, and return to proper area in client's room.
12. Remove gloves and perform hand hygiene.

▲ Turn client to side to position on bedpan.

▲ Roll client onto pan and make comfortable.

Assisting Client to Commode

Equipment

- Commode with locking wheels or rubber-tipped legs
- Toilet tissue
- Nurse's call bell
- Slippers
- Bath blanket

Procedure

1. Place commode at foot of bed. Be sure to lock wheels on commode if needed.
2. Place slippers on client.
3. Raise head of bed to facilitate moving client to edge of bed.
4. Move client to edge of bed and assist to a sitting position at edge of bed. Instruct client to place feet flat on floor.
5. Stand directly in front of client, blocking client's toes with your feet and client's knees with your knees.
 - ▶ **Rationale:** Prevents client from buckling knees.
6. Flex your knees.
7. Place your arms securely around client's waist. ▶ **Rationale:** Stabilizes client for transfer.
8. When starting to transfer, avoid bending at the waist.
 - ▶ **Rationale:** Prevents back strain.
9. Instruct client to push self off bed and support his/her own weight.
10. Straighten your knees and hips as you raise client to standing position.
11. Pivot client in front of commode. Instruct client to grasp arm rest on farthest side.
12. Lower client onto commode, using correct body mechanics (flexing your hip and knees but not your back) to ensure client is securely positioned on commode.
13. Place toilet tissue within easy reach.
14. Cover client with bath blanket for warmth and privacy.
15. Place call bell within easy access of client.
16. Provide privacy by closing curtains and shutting door.
17. Assist client to wipe self as necessary.

▲ Pivot with client and bend knees when seating client.

18. Assist client back to bed.
19. Empty and clean commode.
20. Perform hand hygiene.

DOCUMENTATION for Bedpan, Urinal, and Commode

- Amount, color, appearance, and odor of urine and feces
- Techniques effective in stimulating voiding
- Equipment used (e.g., commode, bedpan)
- Type of support needed for transfer to commode

CRITICAL THINKING Application

Expected Outcomes

- Client voids 200 to 500 mL of urine without discomfort or difficulty.
- Bladder does not become distended.

Unexpected Outcomes

Unable to turn and has difficulty raising hips

Unable to void on bedpan.

- Genitourinary system is free of infection.
- Client transferred to commode for voiding as soon as able.

Critical Thinking Options

- Use a fracture pan rather than a bedpan. Powder the fracture pan.
- Insert the fracture pan with the flat side toward the head, under the client's thighs.
- Assess reason for difficulty.
- Maintain complete privacy.
- Run water in sink.
- Massage the lower abdomen.
- Place a hot washcloth on the abdomen.
- Pour warm water over the perineum with client positioned on toilet or bedpan.
- Give client a sitz bath after obtaining an order.

Chapter 9

UNIT 5

Perineal and Genital Care

Nursing Process Data

ASSESSMENT Data Base

- Review client's general assessment data.
- Observe for signs of perineal itching, burning on urination, or skin irritation. Ask client if he or she experiences any of these problems.
- Assess client's ability to bathe himself or herself and to perform perineal care.
- While providing privacy, observe the perineal–genital area for abnormal secretions, ulcerations, skin excoriations and sensitivity, drainage (amount, consistency, odor, color), swelling, enlarged lymph glands, catheter patency, and comfort.
- Assess client's learning needs related to perineal and genital care.

PLANNING Objectives

- To decrease the growth of bacteria
- To remove excessive secretions
- To promote healing after surgery and vaginal deliveries
- To prevent the spread of microorganisms for clients with indwelling catheters
- To increase client comfort

IMPLEMENTATION Procedures

- Draping a Female Client 231
- Providing Female Perineal Care 231
- Providing Male Perineal Care 232
- Providing Incontinence Care. 233

EVALUATION Expected Outcomes

- Perineal care has been comfortably and effectively provided.
- Perineal area is clean, odor-free, and without irritation or discharge.
- Skin remains intact after perineal care.

Critical Thinking Application 234

- Expected Outcomes 234
- Unexpected Outcomes. 234
- Alternative Actions 234

Pearson Nursing Student Resources

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Draping a Female Client

Equipment

Bath blanket

Procedure

1. Bring bath blanket to bedside.
2. Identify client and explain procedure.
3. Provide privacy.
4. Perform hand hygiene.
5. Assess bladder for distention. ► **Rationale:** Offer bedpan before providing perineal care to prevent urge to urinate during perineal care.
6. Place bed in HIGH position, and lower side rail nearest you.
7. Place bath blanket over client's top linen so that one corner of the blanket is pointed toward the client's head to form a diamond shape over the client.
8. Instruct client to hold onto bath blanket. Fanfold linen to foot of bed.
9. Request that client flex knees and keep them apart with feet firmly on bed.
10. Wrap lateral corners of bath blanket around feet in a spiral fashion until they are completely covered.
11. The corner of the blanket between knees and extending over perineum can later be folded back over the abdomen.

Providing Female Perineal Care

Equipment

Bath blanket or sheet
Two to three bath towels or perineal cloths
Protective pad
Three washclothes
Clean gloves

Preparation

1. Check to see if specific physician orders are to be followed.
2. Talk with client about how she can perform care or assist with procedure. ► **Rationale:** This gives client a sense of control.
3. Collect and arrange necessary equipment. Warm disposable cloth package if using disposable system.
► **Rationale:** Warm cloth is more comfortable for client.
4. Provide privacy by closing door and pulling drapes.
5. Perform hand hygiene.
6. Position client in a comfortable position in bed. Head of bed can be elevated to low-Fowler's position. Drape according to procedure described above.
7. If possible, encourage the client to bend her knees and separate her legs. ► **Rationale:** The perineal area can be cleansed more efficiently in this position.

Procedure

1. Place a protective pad or towel under the client's hips.
► **Rationale:** Keeps the linen clean and dry.
2. Don gloves.
3. Lift corner of drape away from perineal area.
4. Place first washcloth into basin. Rub cloth with soap, wring out excess water or open disposable cloth package.
5. Fold washcloth into mitt or gather into palm of hand.
6. Separate labia with one hand to expose urethral and vaginal openings.

▲ Draping protects client's privacy when performing perineal care.

7. Wash labia minora, from front to back, in a downward motion on one side. ► **Rationale:** This promotes the principle of washing from a clean to a dirty area to prevent a urinary tract infection.

▲ Separate labia and expose urethral and vaginal areas.

▲ Use different section of washcloth for each area of perineum.

8. Take opposite end of washcloth and wash other side from top to bottom.
9. Do not replace washcloth in basin.
10. Place second washcloth in water and soap washcloth, wash labia majora from top to bottom. ► **Rationale:** Prevents contamination from previous cleansing area.
11. Take opposite side of washcloth and clean external labia (labia majora) and perineal area from front to back.
12. Wring out new washcloth and rinse perineum.

▲ Thoroughly pat dry perineal area.

13. Thoroughly pat dry perineal area. ► **Rationale:** Prevents moisture accumulation and potential fungal infections.
14. Use washcloth used for rinsing and clean around anal area. ► **Rationale:** Anal area is last to be washed to prevent cross-contamination.
15. Discard washcloths in appropriate receptacle.
16. Remove gloves.
17. Position client for comfort.
18. Perform hand hygiene.

Providing Male Perineal Care

Equipment

- Bath blanket or sheet
- Two bath towels
- Protective pad or plastic sheet
- Three washcloths
- Basin of warm water
- Clean gloves

Preparation

1. Collect and arrange necessary equipment.
2. Talk with client about how he can perform care or assist with procedure.
3. Ask client to attempt to empty bladder.
4. Provide privacy by closing door and pulling drapes.
5. Perform hand hygiene and don gloves.
6. Cover client with bath blanket or towel over abdomen and cover client's legs with sheet or towel, exposing genital area as little as possible. ► **Rationale:** This contributes to client's comfort and privacy.

Procedure

1. Place washcloth in basin. Apply soap to washcloth.
2. Wring washcloth out to remove excess water. ► **Rationale:** This will prevent the protective pad from getting too wet.

3. If the client has not been circumcised, retract his foreskin carefully to expose the glans penis.
4. Gently but securely hold the shaft of the penis in one hand.
5. Using a circular motion, start at the tip of the penis and wash downwards toward the shaft with soap and water. Do not repeat washing over an area without using a new washcloth. ► **Rationale:** This procedure prevents cross-contamination.

▲ Hold shaft of penis in one hand.

▲ Use circular motion, starting at tip of penis and wash toward shaft.

▲ Wash around scrotum using new washcloth.

6. Obtain new cloth.
7. Replace the foreskin over the glans penis and cleanse area.
8. Obtain new washcloth and wash around the scrotum using new washcloth.
9. Wash the anus last.
10. Use new washcloth and rinse the perineal area.
11. Dry all areas.
12. Remove articles and cover client.
13. Reposition client for comfort.
14. Place disposable cloth in garbage or washcloth in linen hamper.
15. Remove gloves, and place in appropriate receptacle.
16. Perform hand hygiene.

Commercial Perineal Care Washcloths for Incontinent Client

- Used for clients with urinary or fecal incontinence.
- Remove soiled gown and place in appropriate receptacle.
- Remove washcloth from tub and wash perineal area.
- Use new washcloth for each swipe: Wash from front (pubis) to back (anus), starting at middle of perineum and working outward.
- Discard washcloth into appropriate receptacle. Several washcloths can be used to clean client.
- Place tub cover over remaining cloths for use at a later time.
- Change bed if needed.
- Place new gown on client.

Providing Incontinence Care

Equipment

- Commercially prepared package with premoistened perineal washcloths
- Cleansing agent if needed
- Clean linen, gown as needed
- Clean gloves

Preparation

1. Provide privacy for client and explain what you will be doing.
2. Obtain package of three washcloths premoistened with 3% dimethicone, a transparent barrier that remains on the skin to protect it. ► **Rationale:** This protective barrier is less messy than zinc oxide or other petroleum-based barriers, and it seals out wetness on the perineum.

3. Place in microwave for 12 seconds. ► **Rationale:** Warming for a longer time can potentially burn the client's perineum. Washcloths may be used at room temperature.
4. Take warmed package to room.
5. Don clean gloves.

Procedure

1. Remove client's soiled gown and place in linen hamper. (Change gloves if they become contaminated.)
2. Open package.
3. Clean soiled area by cleansing from front to back for females and tip of penis down shaft for males. ► **Rationale:** Prevents contamination. The cloths provide moisturizing, deodorizing, and a barrier protection.

4. Use a different cloth for each area of the perineum.
5. Discard soiled washcloths and package in appropriate receptacle.
6. Place new gown on client and change linen as needed.
7. Place client in position of comfort.
8. Remove gloves and place in appropriate receptacle.
9. Perform hand hygiene.

DOCUMENTATION for Perineal and Genital Care

- Assessment and care needs for perineal hygiene
- Client's level of understanding and teaching needs
- Perineal care provided and outcomes of care
- Type, amount, consistency of discharge from perineal area
- Presence of lesions, ulcerations, or other skin lesions
- Response of client to procedure
- Incontinence, number of times, and interventions attempted to control incontinence

CRITICAL THINKING Application

Expected Outcomes

- Perineal care has been comfortably and effectively provided.
- Perineal area is clean and odor-free, and without irritation or discharge.
- Skin remains intact after perineal care.

Unexpected Outcomes

Client has foul odor even after perineal care.

Alternative Actions

- Obtain order for sitz bath.
- Request order for medicated solution.
- Request culture of discharge so the appropriate treatment can be instituted.

Client develops urinary tract infection.

- Instruct client on proper technique for perineal care.
- Instruct female clients to wash from anterior to posterior aspects of perineum, using different sections of cloth for each wipe.
- Instruct male clients to wash from urethral opening down the shaft of the penis.

Eye and Ear Care

Nursing Process Data

ASSESSMENT Data Base

- Assess whether client is using eyeglasses or contact lenses or is experiencing any eye problems.
- Observe client’s eyes for symmetry and clarity.
- Assess skin surrounding client’s eyes for excessive dryness, scaling, and irritation.
- Assess eyes for discomfort, irritation, edema, crustation, sties, and lesions.
- Assess client’s knowledge related to care of contact lenses.
- Observe client’s tear duct areas and sclera for inflammation and excessive tearing.
- Assess client’s pupils for response to light.
- Observe client’s eye movements or muscle action.
- Evaluate ability to hear and effectiveness of hearing aid.

PLANNING Objectives

- To ensure that eyes and surrounding skin areas are clear, comfortable, and free of crustation
- To improve or maintain the client’s vision
- To prevent irritation and infection
- To maintain or improve the client’s appearance and self-esteem
- To increase ability to hear

IMPLEMENTATION Procedures

- Providing Routine Eye Care 236
- Providing Eye Care for Comatose Client 236
- Removing and Cleaning Contact Lenses 236
- Cleaning and Checking a Hearing Aid 237

EVALUATION Expected Outcomes

- Eyes and surrounding area are clear and free of crustation.
- Vision is maintained or improved.
- Contact lenses are cleaned and replaced without difficulty.
- Hearing is improved after cleaning of hearing aid.

- Critical Thinking Application** 238
- Expected Outcomes 238
 - Unexpected Outcomes 238
 - Alternative Actions 238

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Providing Routine Eye Care

Equipment

- Small basin
- Water or normal saline solution
- Washcloth or cotton balls
- Clean gloves

Preparation

1. Determine client's eye care needs, and obtain physician's order if needed.
2. Explain necessity for and method of eye care to client. Discuss how client can assist you.
3. Collect necessary equipment.
4. Perform hand hygiene and don gloves.

Procedure

1. Use water or saline solution at room temperature.
2. Using the washcloth or cotton balls moistened in water or saline, gently wipe each eye from the inner to outer canthus. Use separate cotton ball or corner of washcloth for each eye. ► **Rationale:** To prevent cross-contamination from one eye to the other.
3. If crusting is present, gently place a warm, wet compress over eye(s) until crusting is loosened.
4. Dispose of used supplies and return basin to appropriate area.
5. Remove and discard gloves.
6. Perform hand hygiene.

Providing Eye Care for Comatose Client

Equipment

- Water or normal saline solution
- Washcloth, cotton balls, tissues
- Sterile lubricant or eye preparations if ordered by the physician
- Eye dropper or Asepto bulb syringe
- Eye pads or patches
- Clean gloves

Procedure

1. Perform hand hygiene and don clean gloves.
2. Cleanse the eyes using a moistened washcloth or cotton balls moistened in water or saline. Gently wipe each eye from inner to outer canthus. Use separate cotton ball or

corner of washcloth for each eye. ► **Rationale:** Wiping from inner canthus to outer prevents particles and fluid from entering nasolacrimal duct.

3. Use a dropper to instill a sterile ophthalmic solution (liquid tears, saline, methylcellulose) every 3 to 4 hours as ordered by physician. (See procedure for *Instilling Eyedrops* in Chapter 18, Medication Administration.) ► **Rationale:** To prevent corneal drying and ulceration.
4. Keep client's eyes closed if blink reflex is absent. If eye pads or patches are used, explain their purpose to client's family. Do not tape eyes shut. ► **Rationale:** Corneal abrasions and drying occur when eyes lose blink reflex.
5. Remove gloves and perform hand hygiene.
6. Remove patch and evaluate condition of eye every 4 hours.

Removing and Cleaning Contact Lenses

Equipment

- Towel
- Contact lens container
- Commercially prepared cleaning solution
- Commercially prepared disinfecting solution
- Commercially prepared rinsing and storing solution
- Enzymatic agent (protein remover)
- Clean gloves

Procedure

1. Place client in semi-Fowler's position and place a towel under the client's chin.
2. Perform hand hygiene and don gloves.

3. Place the tip of your thumb across the lower lid below its margin.
4. Place the tip of the forefinger of the same hand on the upper lid above its margin.
5. Spread eyelids apart as wide as possible and locate outer edges of soft lens which should appear as a rim around outer edge of iris.
6. Place thumb and forefinger directly on soft lens.
7. Gently remove soft lens from surface of eyeball by squeezing lens between thumb and fingertip. To remove rigid lens, place thumb on lower eyelid and index finger on upper lid. Press gently against eyeball to release suction; lens is released as eyelids meet lens edge. Catch lens in your hand. ► **Rationale:** Cornea is avascular and

Clinical Alert

- Extended-wear (overnight) contacts, rigid or soft, increase the risk of corneal ulcers, infection-caused eruptions on the cornea that can lead to blindness. Symptoms include visual changes, eye redness, eye discomfort or pain, and excessive tearing.
- Clean, rinse, and disinfect reusable lenses each time they are removed regardless of number of times each day. Always store lenses in storage solution, not water. Microorganisms from water can feed on corneal tissue.

use of contact lenses interrupts flow of oxygen into cornea. Removing lenses for a period of time allows oxygen to reach cornea and thus prevent corneal complications.

8. Release eyelids.
9. Place lens in palm of hand or place disposable lenses in trash. Some types of disposable lenses are cleaned and reused. Follow eye care specialist directions.
10. Place 2 to 3 drops of cleaning solution on lens.
11. Clean lens thoroughly by rubbing between fingertip and palm of hand for 20 to 30 seconds.
12. Rinse lens thoroughly with sterile saline solution or rinsing solution. Use only lens cleaning system recommended by ophthalmologist. Do not interchange cleaning solution systems.
13. Place lens in disinfecting solution according to physician directions. Time varies from hours to 1 full day. ► **Rationale:** This destroys microorganisms on lenses.
14. Rinse lens thoroughly with rinsing solution.

15. Repeat procedure on second lens.
16. Use enzyme tablet or solution according to physician orders, usually weekly. ► **Rationale:** This removes stubborn protein and lipids.
17. Clean lens container daily and leave open to dry. Replace as directed by physician, either weekly or monthly.
18. Remove gloves and perform hand hygiene.

NOTE: A suction cup can be placed gently against lens for easy removal of lens. Squeeze suction cup with dominant hand, place on lens, open finger slightly to create suction between lens and cup. Rock lens gently to remove it.

Client Teaching for Contact Lens Care

Instruct the client in the following safety issues:

- Notify physician immediately if eyes are red, not comfortable, or you can't see clearly.
- Use only rinsing solution, not saliva, to wet lenses.
- Use only commercially prepared saline solution or rinsing solution to cleanse lenses.
- Do not interchange types of lens cleaning systems.
- Maintain lens-care regimen prescribed by physician.
- Put on makeup before inserting lenses.
- Use appropriate type of lenses for their intended use. Do not use daily-wear lenses at night or disposable lenses more than once.
- Do not allow soft lenses to dry out.
- Contact lens wearers should be instructed to carry appropriate identification on type and care for specific lens he/she wears.

Cleaning and Checking a Hearing Aid

Equipment

- Soap
- Water
- Petroleum jelly
- Pipe cleaner
- Cotton-tipped applicator
- Hearing aid batteries
- Clean gloves

Procedure

1. Determine ability of client to perform all or part of cleaning procedure, and teach procedure when necessary. Have client remove hearing aid if able to do so.
2. Perform hand hygiene and don gloves.
3. Wipe casing with dry cloth.

Types of Hearing Aids

- **Analog:** Two types, conventional and programmed. Programmed aids adjust amplifier more precisely to match hearing loss and provide greater fitting flexibility.
- **Digital:** Continuous sound waves are broken into small, discrete bits of information, digitalizing the signal. Computer programs are written for each client's hearing loss.

NOTE: 75% of all hearing aids sold are digital.

4. Check batteries if hearing aid has not been functioning. Insert new batteries, matching positive (+) and negative (−) signs.
5. Before inserting ear mold, cleanse outer ear gently with cotton-tipped applicator.

6. Turn receiver switch to ON. Assist client to adjust volume control to desired level. If whistling or feedback noises occur, check for tightness of fit as ear mold probably has not been inserted properly or there is a buildup of ear wax.
7. Place hearing aid in labeled container when not in use and place in bedside stand.
8. Remove gloves.
9. Perform hand hygiene.

Client Teaching for Hearing Aids

- Replace batteries when needed.
- Turn hearing aid off when not in use.
- Clean hearing aids according to manufacturers directions.
- Refrain from using hairspray or other hair products.
- Keep hearing aids away from moisture and heat.

Source: National Institute on Deafness and Other Communication Disorders (NIDCD), <http://www.nidcd.nih.gov/health/hearingaid.asp>.

DOCUMENTATION for Eye and Ear Care

- Documentation of eye assessment and eye care needs
- Method and outcome of eye care provided
- Condition of eye and surrounding structure
- Client's response to client teaching regarding contact lenses
- Response to using hearing aid
- Improved hearing after cleaning hearing aid
- Client's ability to insert, remove, and clean hearing aid

CRITICAL THINKING Application

Expected Outcomes

- Eyes and surrounding area are clear and free of crusting.
- Vision is maintained or improved.
- Contact lenses are cleaned and replaced without difficulty.
- Hearing is improved after cleaning of hearing aid.

Unexpected Outcomes

Eyelids become crusted from exudate.

Alternative Actions

- Place warm, moist washcloth across eyes and leave in place for several minutes.
- Moisten cotton applicator stick with sterile saline and gently twist the applicator stick over crusted surface to assist in removing crust.

Wrong solution used on contact lens causes excessive tearing and burning sensation when lens is placed in eye.

- Immediately remove lens from eye and place in proper storage container.
- Immediately rinse client's eye with copious amounts of sterile water.
- Have client checked immediately by ophthalmologist for emergency care of potentially burned cornea.

Hearing did not improve with cleaning of hearing aid.

- Check if receiver switch is ON.
- Check if batteries are properly in place and that the poles match: positive (+) and negative (-).
- Recheck hearing aid with expert.

GERONTOLOGIC Considerations

Clients With Dentures Require Special Nursing Care

- Check for proper fit when replacing dentures. Ill-fitting dentures interfere with chewing and can lead to altered nutrition. Loss of teeth may limit meal planning and the nurse should assist the client to choose a balanced diet taking into account tooth loss.
- Monitor denture cleaning to ensure client has fresh-tasting mouth to encourage eating. Elderly clients have decreased

sensitivity to sweet, sour, salty, and bitter tastes; thus they may compensate by using extra salt. The nurse can counsel the client on alternative seasonings and request dietary consultation.

Fear of the unknown

- Any treatment or activity may be unfamiliar and frightening to the elderly.
- Explain each procedure before attempting it. Ask client to help when appropriate.

Self-Perception/Self-Concept

- Poor self-concept, depression, and negative feelings are common among elderly.
- Encourage personal hygiene activities to promote a more positive self-image.
- A positive body image is enhanced with good personal hygiene. Nursing care should focus on assisting the client to maintain good personal hygiene.
- Encourage elderly clients to have hair and nail care done frequently to increase self-esteem.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- The staffing patterns today often require that Certified Nursing Assistants (CNAs) or Unlicensed Assistive Personnel (UAPs) complete personal hygiene activities for most clients because these activities have a predictable outcome and do not require nursing judgment. However, performing these tasks for the client provides an excellent forum for client assessment. When the tasks are delegated to other personnel, the RN and LPN/LVNs responsible for client care must receive specific reports of the client's condition and any unexpected findings. The CNAs and UAPs should receive specific instructions regarding the condition of each client and what to observe for.

- The RN is responsible for assessing all clients because assessment responsibilities cannot be delegated.
- The team member delegating staff assignments should try to implement a staffing pattern that allows professional nurses to be assigned to complete general care, including personal hygiene activities, at least every other day so that important assessment parameters are not missed.
- Check facilities procedure manual for appropriate healthcare worker to remove and replace contact lenses.

Communication Matrix

- CNAs and UAPs should be educated, encouraged, and rewarded with positive feedback when they give excellent reports on the client for whom they have performed the tasks of personal hygiene. When the unit is extremely busy, this may be the major source of information the professional nurse receives about the client for whom he or she is legally responsible.

CRITICAL THINKING Strategies

Scenario 1

You have been assigned to two clients for the 7 AM to 12 noon clinical experience.

Client 1:

A 68-year-old female with a total hip replacement 2 days ago. Her past history indicates she had a cataract removed 2 months ago and had a lens fitted a week ago. She has developed a very uncomfortable incision site. It is red and tender to touch. Her dressings are somewhat moist without observable drainage on the dressings. Her vital signs indicate a temperature of 101°F, P 90, R 28 and unlabored. She tells you she doesn't feel like doing anything today.

Client 2:

An 80-year-old female with a fractured hip, unrepaired, admitted this morning from a local long-term care facility. She is in severe pain and requires pain medications every

4 hours. She is unable to use the patient-controlled analgesia (PCA) because she forgets how it works. Her physical assessment indicates her skin is reddened around the coccyx and very dry. She appears to be unkempt, and her hair is matted.

1. Based on the scenario, what is your first action after you hear report? Provide rationale for your answer.
2. Identify the assessment you will complete on each client. What information will you be gathering in order to make a decision on nursing care for the shift?
3. List, in priority, the nursing care you will provide for each client and provide rationale for your decision.
4. Which client will you assess first and why?
5. Which of the personal hygiene skills will you provide or can be delegated for each client? Will any adjustments need to be made in the skill in order to provide care for

the client? Please state the changes that will need to be made.

Scenario 2

You are working in a pediatric clinic when a mother brings her two preschool children into the clinic. She tells you she is not sure why her children keep scratching their scalps and have something that looks like dandruff. After examining the children's hair you determine they have lice. When the mother receives this information she starts crying and states, "I just knew that preschool was dirty. I should not have sent the children there."

1. What response will be appropriate to this statement?
2. After calming the mother down, how will you approach her to explain the treatment for lice?
3. You begin the explanation with a discussion of potential side effects. What will you tell her about the side effects?
4. Describe the skill of applying a treatment for lice.
5. While shampooing the hair, if the child starts crying and says her eyes are burning, what will you tell the mother to do?
6. Explain the most effective method for removing nits from the child's hair after the treatment.
7. The mother asks you if she needs to do the treatment once and then the lice will be gone. What is your response to her?
8. The mother wants to know if she and her husband can get the lice also. What is your response to her?
9. What is your best response to the mother's question on whether she needs to burn the sheets and children's clothes?

NCLEX[®] Review Questions

Unless otherwise specified, choose only one (1) answer.

1. You are assigned to provide hygienic care to an unconscious client. Your assessment indicates she needs good oral hygiene. The major safety action for this procedure is to
 1. Turn the client's head to the side.
 2. Keep a suction bulb or equipment at bedside.
 3. Use a tongue blade to keep the mouth open.
 4. Don clean gloves to prevent spread of bacteria.
2. A client has severely tangled hair. The best description on how to provide hair care for this client is to
 1. Brush or comb her hair from the scalp to hair ends.
 2. Apply small amount of oil to tangled areas of scalp before combing.
 3. Use a hair pick to untangle hair and then brush hair.
 4. Use short gentle strokes with a wide-toothed comb, starting at the end of hair shaft.
3. Which of the following statements is true regarding lice eggs? Lice eggs
 1. Are light brown, crawl, and feed on blood.
 2. Are yellow to white and attach to hair shaft.
 3. Hatch in 17 days after louse lays eggs.
 4. Have clawed legs that assist in jumping and hopping.
4. Identifying a live louse or nymph on the scalp is evidenced by nits/eggs located on the hair shaft
 1. Less than 1 cm from the scalp are usually not viable.
 2. Within 10 mm from the scalp are usually not viable.
 3. Within 6 mm are usually viable.
 4. Easily seen on the hair shaft are viable.
5. The primary intervention to prevent spread of lice or nits is to
 1. Discard all clothing and bedding used by client.
 2. Use one of the products to prevent lice on all family members at same time client is being treated.
 3. Launder all clothing and bedding in hot water, followed by drying using hot cycle of dryer.
 4. Observe family members for signs of nits near scalp; if present, use same treatment plan as client.
6. The client requires denture care but is unable to remove his dentures. When removing the dentures, the nurse will place his/her finger
 1. To the side of the lower denture and move it sideways to remove it.
 2. On the middle of the upper denture and ask the client to move it with his tongue.
 3. On the edge of the upper denture and gently break the suction.
 4. In the middle of the teeth on the lower denture and gently pull the denture upward to remove it.
7. When moving a client from the bed to the commode, the most appropriate movement to prevent client or nurse injury is to
 1. Instruct client to place hands around nurse's neck to stabilize stance when standing.
 2. Ensure the nurse bends back and squats when moving client out of bed.
 3. Stand in front of client, block client's toes with your feet and client's knees with your knees before starting to transfer.
 4. Maintain your hips and knees flexed when pivoting client to commode.

8. When providing male perineal care, it is important to remember
 1. That if the client is not circumcised, wash the penis carefully to prevent retraction of the foreskin.
 2. To wash the penis using a circular motion, starting at the base of the shaft and moving toward the tip.
 3. When washing the penis, do not wash over the same area without using a new cloth.
 4. To always wash the scrotum first before washing the perineum.
 9. Client teaching for individuals who wear contact lenses should include explaining that
 1. Daily wear lenses can be worn overnight; however, they need to be disposed of once they are removed.
 2. You can use tap water or rinsing solution to wet reusable contact lenses.
 3. You can use interchangeable types of lens cleaning solutions regardless of type of contact lenses.
 4. Soft contact lenses should not be allowed to dry out.
 10. A client asks you about caring for a hearing aid. Your response includes
Select all that apply.
 1. You need to turn off the hearing aids when not in use.
 2. Keep hearing aids away from moisture and heat.
 3. Newer hearing aids do not have batteries that require changing.
 4. Hairspray should not be used when wearing hearing aids.

10

Vital Signs

LEARNING OBJECTIVES

1. Identify the cardinal signs that reflect the body's physiologic status.
2. List three mechanisms that increase heat production.
3. Explain how disease alters the "set point" of the temperature-regulating center.
4. Define hypothermia and list the symptoms of this condition.
5. Differentiate between the oral, rectal, axillary, and tympanic methods of taking temperature.
6. Describe two nursing actions that can be performed when temperature is not within normal range.
7. Describe at least three different types of pulse characteristics.
8. Discuss the pulse, and indicate how it is an index of heart rate and rhythm.
9. Compare normal heart rate range for adults and children.
10. Identify the characteristics of peripheral pulses.
11. Explain why the blood pressure cuff should be the appropriate size for the client.
12. Define Korotkoff's sounds in terms of phases.
13. Identify four of the seven factors that affect blood pressure.
14. Demonstrate the method of palpating systolic arterial blood pressure.
15. Discuss conditions when vital signs may be delegated and when they would not be delegated.
16. Demonstrate the proper techniques for obtaining peripheral pulses.
17. Describe the most effective method of obtaining a respiratory rate.

TERMINOLOGY

General Terminology

- Antipyretic** an agent that reduces febrile temperatures.
- Apex** the pointed end of a cone-shaped part or organ (e.g., lower heart, upper lung).
- Arteriosclerosis** an arterial disease characterized by inelasticity and thickening of the vessel walls with lessened blood flow.
- Atherosclerosis** a form of arteriosclerosis in which there are localized accumulations of lipid-containing material within the internal surfaces of blood vessels.
- Atrial** pertaining to the atrium, the upper cardiac chamber that receives blood from the lungs and systemic circulation.
- Autoregulation** the intrinsic ability of an organ or tissue to maintain blood flow despite changes in arterial pressure.
- Axilla** armpit.
- Cardiac output** the amount of blood ejected by the heart or the stroke volume (SV) times the heart rate ($CO = SV \times HR$).
- Cardio** pertaining to the heart.
- Cardiogenic** having origin in the heart itself.
- Chemoreceptor** a sense organ or sensory nerve ending that is stimulated by and reacts to chemical stimuli.
- Contractility** having the ability to contract or shorten muscle tissue or cells.
- Core temperature** the body's interior deep tissue temperature (e.g., the abdominal cavity).
- Diastole** the period in which the heart dilates and fills with blood; the period of relaxation.
- Doppler** a type of ultrasound stethoscope or probe that uses an ultrasound beam to detect blood flow.
- Febrile** feverish, increased body temperature.
- Fibrillation** quivering, involuntary contraction of individual muscle fibers.
- Hypertension** blood pressure that is considered to be higher than the normal range.
- Hyperthermia** unusually high body temperature.
- Hypovolemia** abnormal increase in the volume of circulating body fluid.
- Hypotension** blood pressure that is lower than the normal range.
- Hypothalamus** the part of the brain that lies below the thalamus; it maintains or regulates body temperature, certain metabolic processes, and other autonomic activities.
- Hypothermia** a body temperature below the average normal range.
- Hypovolemia** diminished blood volume.
- Infarction** an area of tissue in an organ or part that undergoes necrosis after cessation of blood supply.
- Infrared scanner thermometer** a noncontact digital thermometer that measures a client's temperature without physical contact by using infrared technology.
- Ischemia** local and temporary hypoxia due to obstruction of the circulation to a part.
- Korotkoff's sounds** low-frequency sounds that are regarded by the American Heart Association as the best index of blood pressure in an adult—sounds are produced as a result of changes in blood flow through a compressed artery.
- mmHg** millimeters of mercury, used for measuring blood pressure.
- Myocardium** the middle muscle layer of the walls of the heart.
- Normotensive** a normal tone, tension or pressure, as in normal blood pressure.
- Palpate** to examine by touch; feel.
- Peripheral** pertinent to the periphery, away from the central structure.
- Peripheral vascular disease** indicates diseases of the arteries and veins of the extremities, especially those conditions that interfere with adequate flow of blood.
- Piloerection** hair standing on end when heat production is stimulated through vasoconstriction.
- Pyrogen** any substance that produces fever.
- Set point** the constant temperature that the hypothalamus (the body's thermostat) strives to maintain.
- Shock** state of inadequate tissue perfusion resulting from circulatory failure, precipitated by many factors and identified by various signs and symptoms.
- Sonorous** loud breathing.
- Sphygmomanometer** instrument for indirectly determining arterial blood pressure.

Stertorous loud, noisy breathing.

Thermoregulation the body's physiological function of heat regulation to maintain a constant internal body temperature.

Valsalva's maneuver attempt to forcibly exhale with the glottis, nose, and mouth closed, producing an increased intrathoracic pressure.

Vasoconstriction constriction of the blood vessels and stimulation of heat production.

Vasodilation dilation of blood vessels and the inhibition of heat production.

Pulse Terminology

Atrial fibrillation atrial arrhythmia characterized by rapid, random contractions of the atrial myocardium causing a rapid, irregular ventricular rate.

Bigeminal pulse a regularly irregular pulse where every second beat has a decreased amplitude.

Bradycardia a pulse rate below 60 BPM.

Bounding pulse pulse pressure is increased. It is felt as a slapping against the fingers because of the rapid upstroke and quick downstroke. It is seen in conditions of increased cardiac output, such as exercise, anxiety, alcoholic intake, and pregnancy. It is also noted in pathology with fever, anemia, hyperthyroidism, liver failure, complete heart block with bradycardia, and hypertension.

Normal pulse pulse is smooth and rounded and is felt as a sharp upstroke and gradual downstroke. Provides information about cardiac status and blood volume. Correlates with cardiac contraction.

PMI apical pulse or point of maximum impulse; palpated at fifth intercostal space, left midclavicular line. Pulse occurs with contraction of left ventricle.

Premature beats a pacemaker outside the sinus node fires earlier than the sinus node, the normal pacemaker of the heart. Since the beat is early, the stroke volume is less because the ventricles do not have time to fill. This condition causes a pause in rhythm, which may result in a pulse deficit.

Pulse deficit occurs when the heart rate counted at the apex by auscultation is greater than the heart rate counted by palpation of the radial pulse. The pulse wave is not transmitted to the periphery to produce a palpable radial pulse.

Pulsus alternans rhythm is regular but the amplitude alternates from beat to beat. May be related to left ventricular failure.

Pulsus paradoxus detected by blood pressure measurement. The disappearance of Korotkoff's sounds during inspiration phase of breathing, with sounds appearing throughout the respiratory cycle (during inspiration and exhalation) at a pressure 10 mmHg lower than heard during exhalation alone. This phenomenon occurs in COPD and with cardiac tamponade and should be further evaluated.

Pulse pressure the difference between systolic and diastolic pressure (about 30 to 40 points).

Sinus arrhythmia common in children and young adults. The rate accelerates with inspiration and slows with expiration.

Tachycardia heart rate greater than 100 beats/min.

Weak or thready pulse pulse pressure is diminished. It is smooth and rounded, but is felt as a gradual upstroke and prolonged downstroke. It is commonly seen in conditions resulting in decreased cardiac output, such as heart failure and shock, and with obstruction to left ventricular ejection, such as aortic stenosis.

VITAL SIGNS

Vital signs, also termed cardinal signs, reflect the body's physiologic status and provide information critical to evaluating homeostatic balance. Vital signs include four critical assessment areas: temperature, pulse, respiration, and blood pressure. The term *vital* is used because the information gathered is the clearest indicator of overall health status. These four signs form baseline assessment data necessary for ongoing evaluation of a client's condition. If the nurse has established the normal range for a client, deviations can be more easily recognized. Although not a cardinal sign, pain is considered the fifth vital sign and must be assessed at the same time as all other vital signs.

Routine vital signs (including pain assessment) are important to assess on every client. These parameters should be assessed by a staff member who is familiar with the client's health history so results can be evaluated against previous data. Vital signs should be taken at regular intervals, and serial readings are important with all vital signs. In fact, trends yield more information than singular readings. The more critical the client's condition, the more often these assessments need to be

taken and evaluated. They are not only indicators of a client's present condition, but are also cues to a positive or negative change in status.

Obtaining the total picture of a client's health status is a major objective of client care. Although vital signs yield important information in themselves, they gain even more relevance when compared with the client's diagnosis, laboratory tests, history, and records. The five vital signs are as follows:

1. **Temperature** represents the balance between heat gain and heat loss and is regulated in the hypothalamus of the brain. Variations in temperature indicate the health status of the body; thermostatic function may be altered by pyrogens, nervous system disease, or injury.
2. The **pulse** is an index of the heart's action; by evaluating its rate, rhythm, and volume, one can gain an overall impression of the heart's action.
3. **Respiration**, the act of bringing oxygen into the body and removing carbon dioxide, yields data on the client's entire breathing process. When the pattern of respiration is

altered, ongoing evaluation yields important clues to a client's changing condition.

4. **Blood pressure** readings provide information about the condition of the heart, the arteries and arterioles, vessel resistance, and the cardiac output. Serial readings provide the best indication of a client's cardiovascular status.
5. **Pain assessment** that is ongoing and constant is essential to maintain the client's homeostasis and quality of life. Pain assessment provides information on location, quality, and intensity, as well as outcomes of relief measures. (See Vital Sign Assessment Record.)

Factors Influencing Vital Signs

Factors that cause alterations in vital signs include age, gender, race, heredity, medications, lifestyle, environment, pain, exercise, anxiety, stress, metabolism, circadian rhythms, and hormones. The normal variations in vital signs may be caused by age, disease, trauma, etc. The most common alterations are listed below.

Age Age influences body temperature. Body temperature varies from 96.0° to 99.5°F in newborns and 96.8° to 98.3°F in elderly clients due to thermoregulation deficiencies in both age groups. Newborns have an immature thermoregulation mechanism that causes temperature fluctuations in response to the environment. Elderly clients have an ineffective thermoregulating system due to physiological changes of aging. These changes are related to

loss of subcutaneous fat, decreased sweat glands, reduced metabolism, and poor vasomotor control. Environmental conditions may also play a role in an elderly person's ability to effectively adapt body heat and cooling to changes in external temperature. Respirations vary according to age as well. Newborns have a respiratory range of 30 to 80 breaths/minute with an average rate of 32 breaths/minute. As age increases, respirations decrease; adults average 16 breaths/minute. The pulse rate also decreases with age. Newborns average 140 beats/min and adults average 80 beats/min. On the other hand, blood pressure may increase with age. The newborn's mean blood pressure is 65/42, while the normal adult client's blood pressure ranges from 120/80 to 100/60.

Gender Women experience greater temperature fluctuations than men, probably due to hormonal changes. Temperature variations occur during the menstrual cycle. During menopause, the instability of the vasomotor controls leads to periods of intense body heat and sweating.

Race and Heredity Studies have been mostly inconclusive as to race and heredity being related factors in vital signs alteration. Blood pressure alterations appear to be the main difference in vital signs, usually as a result of particular groups being more susceptible to hemodynamic alterations. African Americans are more prone to high blood pressure resulting from increased salt sensitivity or increased blood cholesterol levels.

Medications Some medications can directly or indirectly alter temperature, pulse, respirations, and blood pressure. For example, narcotic analgesics can depress the rate and depth of respirations and lower blood pressure.

Pain Acute pain leads to sympathetic stimulation, which in turn increases the heart rate, respiratory rate, and blood pressure. Chronic pain decreases the pulse rate as a response to parasympathetic stimulation and may decrease heart rate and respirations.

Circadian Rhythms Biologic rhythms, or biorhythms, control certain physiological patterns in conjunction with environmental factors. The most familiar biorhythm is the circadian rhythm that controls sleep patterns. These rhythms influence blood pressure (pressure is lowest in the morning and peaks in late afternoon and evening) and temperature (highest in the evening—8 PM to 12 midnight—and lowest in the early morning—4 to 6 AM).

TEMPERATURE

Temperature control of the body is a homeostatic function, regulated by a complex mechanism involving the hypothalamus. The temperature of the body's interior (core temperature) is maintained within ±1°F except in the case of febrile illness. The surface temperature of the skin and tissues immediately underlying the skin rises and falls with a change in temperature of the surrounding environment. Core temperature is maintained when heat production equals heat loss. The temperature regulating center in the hypothalamus keeps the core temperature constant. Temperature receptors, which

determine whether the body is too hot or too cold, relay signals to the hypothalamus.

Regulatory Mechanisms

When the body becomes overheated, heat-sensitive neurons stimulate sweat glands to secrete fluid. This enhances heat loss through evaporation. The vasoconstrictor mechanism of the skin vessels is reduced, thereby conducting heat from the core of the body to the body surface. Heat loss occurs through radiation, evaporation, and conduction.

When the body core is cooled below 98.6°F (37°C), heat conservation is affected. Intense vasoconstriction of the skin vessels results. There is also piloerection and a decrease in sweating to conserve heat. Heat production is stimulated by shivering and increased cellular metabolism.

The “set point” is the critical temperature level to which the regulatory mechanisms attempt to maintain the body’s core temperature. Above the set point, heat-losing mechanisms are brought into play, and below that level, heat-conserving and heat-producing mechanisms are set into action.

Disease can alter the set point of the temperature-regulating center to cause fever, a body temperature above normal. Inflammation, brain lesions, pyrogens from bacteria or viruses, or degenerating tissue (i.e., gangrenous areas or myocardial infarction) also increase the set point. Dehydration can cause fever due to lack of available fluid for perspiration and by increasing the set point, which brings more heat-conserving and heat-producing mechanisms into play. When the “thermostat” is suddenly set higher, the client complains of feeling cold, has cool extremities, shivers, and has piloerection. Hypoxia can occur due to increased oxygen use with the increased metabolism of heat production. When the thermostat returns to normal, heat-losing mechanisms again are activated. The client feels hot and starts perspiring. Other symptoms of fever the client may experience are perspiration over the body surface, body warm to touch, flushed face, feeling cold alternately with feeling hot, increased pulse and respirations, malaise and fatigue, parched lips and dry skin, and convulsions, especially with rapid temperature increase in children.

When the body temperature falls below the normal range, the client experiences hypothermia and complains of being cold, shivers, and has cool extremities. Hypothermia may be caused by accidental cold exposure, frostbite, or GI hemorrhage. Medically induced hypothermia is used for some cardiovascular and neurosurgical interventions. The ability of the hypothalamus to regulate body temperature is greatly impaired when the body temperature falls below 94°F (34.4°C) and is lost below 85°F (29.4°C). Cellular metabolism and heat production are also depressed by a low temperature.

Measuring Body Temperature

Oral or rectal temperatures reflect the body’s core temperature. Tympanic and axillary temperatures are somewhat variable but are clinically acceptable for tracking important changes. The normal range of an oral temperature is 97° to 99.5°F, or 36° to 37.5°C. Rectal temperatures are approximately 1°F higher, ear canal 0.5° higher, and axillary temperatures are 1°F lower than

Fever Signs

Fever is considered to be any abnormal elevation of body temperature (over 100.8°F). The most common signs and symptoms are:

- Perspiration over the body surface
- Body warm to the touch
- Chills and shivers
- Flushed face
- Client complaints of feeling alternately cold and hot
- Increased pulse and respirations
- Complaints of malaise and fatigue
- Parched lips and dry skin
- Convulsions, especially in children

oral readings. Body temperature may vary according to age (lower for the aged), time of day (lower in the morning and higher in the afternoon and evening), amount of exercise, or extremes in the environmental temperature.

The thermometer is the instrument used to measure body heat. Oral and rectal (also used for axillary temperature) thermometers in hospitals are commonly, as of 2002, digital, disposable, and electronic. Before 1998, when the American Hospital Association agreed to eliminate mercury from the healthcare environment, mercury thermometers were used in hospitals. The thermometer is marked in degrees and tenths of degrees with either a Fahrenheit or Celsius (centigrade) scale and a range of 93° to 108°F (34°–42.2°C).

Electronic thermometers are now widely used in hospitals. They have disposable covers, which promote infection control, and therefore should always be used. The electronic thermometer plugs into a receptacle and has a heat sensor that records the client’s core temperature in seconds. The ear canal provides another noninvasive site for temperature measurement using infrared thermometers.

Heat-sensitive tapes are also used to record temperature. A chemical strip tape is applied to the skin, and color changes indicate the temperature level. A continuous-reading wearable tape can be used for 2 days; the temperature is also read by a change in color. These tapes are both disposable and nonbreakable. They are most appropriate for use with small children and in situations when proper cleaning of the thermometer is difficult.

A new type of thermometer, the temporal artery (sensor touch by Exergen), is now being used in hospitals. It is more cost effective and more accurate than the ear thermometer. It takes 0.1 second to respond and automatically self-calibrates. This device is configured to give either oral or arterial temperatures.

PULSE

The pulse is an index of the heart’s rate and rhythm. The apical pulse rate is the number of heart beats per minute. With each beat, the heart’s left ventricle contracts and forces blood into the aorta. Closure of the heart valves creates the sounds

heard. The forceful ejection of blood by the left ventricle produces a wave that is transmitted through the arteries to the periphery of the body. The pulse is a transient expansion of peripheral arteries resulting from internal pressure changes. If cardiac output is reduced (such as with a premature or irregular heartbeat), the peripheral pulse is weak; if the radial pulse rate is less than the apical rate, the difference is called a *pulse deficit*. The pulse wave is influenced by the elasticity of the larger vessels, blood volume, blood viscosity, and arteriolar and capillary resistance.

Circulatory System Control

The circulatory system is under the dual control of the autonomic nervous system and autoregulation (at the microcirculation level). This dual control allows the circulatory system to vary blood flow to meet the body's requirements. Local control of blood flow is called autoregulation. Blood flow is adjusted according to oxygen need based on changing metabolic activity of different tissues.

The autonomic nervous system regulates circulation through the vasomotor center in the medulla oblongata. Stimulation of the sympathetic nervous system causes vasoconstriction, increased heart rate and cardiac contractility, and a resulting increase in blood pressure. On the other hand, sympathetic inhibition causes vasodilation, reduced heart rate, and a reduction in blood pressure.

Pressure receptors, called baroreceptors, located in the walls of the carotid sinus and arch of the aorta also influence the vasomotor center. Decreased circulating volume (as in hemorrhage) stimulates these receptors, which then transmit signals to the vasomotor center to stimulate the sympathetic nervous system. Resulting cardiovascular responses divert blood flow to vital organs.

Heart Rate and Rhythm

A normal adult heart rate is from 60 to 100 beats/min; the average rate is 72 beats/min. Rates are slightly faster in women and more rapid in children and infants (90–140 beats/min; Table 10-1). The resting heart rate usually does not change with age. Tachycardia is a pulse rate over 100 beats/min. Bradycardia is a pulse rate below 60 beats/min.

When taking a client's pulse, be aware that many pathologic conditions produce bradycardia. Among the most common

causes are decreased thyroid activity, hyperkalemia, cardiac conduction blocks, and increased intracranial pressure.

Tachycardia is associated with stressful conditions, hypoxia, exercise, and fever. Client conditions, such as congestive heart failure, hemorrhage and shock, dehydration, and anemia produce tachycardia as a compensatory response to poor tissue oxygenation.

Heart rhythm is the time interval between each heartbeat. Normally, the heart rhythm is regular, although slight irregularities do not necessarily indicate cardiac malfunction. An irregular cardiac rhythm, especially if sustained, requires cardiac evaluation because it may be indicative of cardiac disease.

Variance in heart rate, either increased or decreased, may be attributed to many factors, such as drug intake, lack of oxygen, loss of blood, exercise, and body temperature. When evaluating a pulse rate, it is important to ascertain the normal baseline for each client and then to determine variances from the normal for that particular client. The heart normally pumps about 5 L of blood through the body each minute. This cardiac output is calculated by multiplying the heart rate per minute by the stroke volume, the amount of blood ejected with one contraction. Increasing the heart rate is one of the first compensatory mechanisms the body employs to maintain cardiac output.

Evaluating Pulse Quality

The quality of the pulse is determined by the amount of blood pumped through the peripheral arteries. Normally, the amount of pumped blood remains fairly constant; when it varies, it is also indicative of cardiac malfunction. A so-called bounding pulse occurs when the nurse is able to feel the pulse by exerting only a slight pressure over the artery. If, by exerting pressure, the nurse cannot clearly determine the flow, the pulse is called weak or thready.

The arterial pulse can be felt over arteries that lie close to the body surface and over a bone or firm surface that can support the artery when pressure is applied. In adults and children older than age 3, the radial artery is palpated most frequently because it is the most accessible. The femoral and carotid arteries are used in cases of cardiac arrest to determine the adequacy of perfusion.

Peripheral pulses may be absent or weak. The amplitude of a pulse depends on the degree of filling in the artery during systole (ventricular contraction) and emptying during diastole

TABLE 10-1 Vital Sign Chart for Children

Age	Normal Pulse		Blood Pressure Average	Respiration Average
	Range	Average		
Newborn	110–180	140	90/55	30–50
1 year	80–150	120	90/60	20–40
2 years	80–130	110	95/60	20–30
4 years	80–120	100	99/65	20–25
6 years	75–115	100	100/56	20–25
8 years	70–110	90	105/56	15–20
10 years	70–110	90	110/58	15–20

(ventricular relaxation). It is important to note characteristics of peripheral pulses: 0 = absent; 1+ = weak; 2+ = diminished; 3+ = strong; and 4+ = full and bounding. (Use the system described in your hospital procedure manual.)

When peripheral pulses cannot be palpated, a Doppler ultrasound stethoscope is used by the nurse to confirm the presence or absence of the pulse. Even though the peripheral pulse is an indicator of cardiac function, it is not always an accurate indication of the force of cardiac contractions. If cardiac contractions are weak or ventricular filling is incomplete, the pulse is weak; however, in the case of aortic stenosis, the pulse may be weak in spite of forceful cardiac contraction.

The pulse should be taken frequently (every 15 minutes to 1–2 hours) on an acutely ill hospitalized client and less frequently (every 4–8 hours) on more stable hospitalized clients. Once a week or even once a month is adequate for clients in long-term care facilities. Do not wait until the next routinely scheduled time if the client develops unexpected symptoms or has experienced trauma.

RESPIRATION

Respiration is the process of bringing oxygen to body tissues and removing carbon dioxide. The lungs play a major role in this process. Another respiratory function is to maintain arterial blood homeostasis by maintaining the pH of the blood. The lungs accomplish this by the process of breathing.

Breathing consists of two phases, inspiration and expiration. Inspiration is an active process in which the diaphragm descends, the external intercostal muscles contract, and the chest expands to allow air to move into the tracheobronchial tree. Expiration is a passive process in which air flows out of the respiratory tree.

The respiratory center in the medulla of the brain and the level of carbon dioxide in the blood both control the rate and depth of breathing. Peripheral receptors in the carotid body and the aortic arch also respond to the level of oxygen in the blood. To some extent, respiration can be voluntarily controlled by holding the breath and hyperventilation. Talking, laughing, and crying also affect respiration.

The diaphragm and the intercostal muscles are the main muscles used for breathing. Other accessory muscles, such as the abdominal muscles, the sternocleidomastoid, the trapezius, and the scalene, can be used to assist with respiration if necessary.

Evaluating Respirations

The quality of breathing is important baseline information. Normal breathing, termed eupnea, is almost invisible, effortless, quiet, automatic, and regular. When the breathing pattern varies from normal, it needs to be evaluated thoroughly. For example, bronchial sounds heard over the large airways are fairly loud. There is normally a pause between inspiration and expiration. Softer sounds are heard over peripheral lung areas, and there are no pauses between inspiration, which is a long sound, and expiration, which is a short sound. If breathing is noisy, labored, or strained, an obstruction may be affecting the breathing pattern that could lead to major alterations in homeostasis.

In addition to evaluating the breathing pattern, it is also necessary to evaluate the rate and depth of breathing. The normal rate for a resting adult is 12 to 18 breaths per minute. A rate of 24 or above is considered tachypnea, and a rate of 10 or less is considered bradypnea. The rate for infants ranges from 20 to 30 breaths per minute and is often irregular. Older children average about 20 to 26. The ratio of pulse to breathing is usually 5:1 and remains fairly constant.

The depth of a person's breathing (tidal volume) is the amount of air that moves in and out with each breath. The tidal volume is 500 mL in the healthy adult. Alveolar air is only partially replenished by atmospheric air with each inspiratory phase. Approximately 350 mL (tidal volume minus dead space) of new air is exchanged with the functional residual capacity volume during each respiratory cycle. Accurate tidal volume can be measured by a spirometer, but an experienced nurse can judge the approximate depth by placing the back of the hand next to the client's nose and mouth and feeling the expired air. Another method of estimating volume capacity is to observe chest expansion and to check both sides of the thorax for symmetrical movement.

After assessing the pattern, rate, and depth of breathing, it is important to observe the physical characteristics of chest expansion. The chest normally expands symmetrically without rib flaring or retractions. In addition, observation of chest deformities should also be made, as all of these signs yield information about the respiratory process and overall health status of the client.

BLOOD PRESSURE

The heart generates pressure during the cardiac cycle to perfuse the organs of the body with blood. Blood flows from the heart to the arteries, into the capillaries and veins, and then flows back to the heart. Blood pressure in the arterial system varies with the cardiac cycle, reaching the highest level at the peak of systole and the lowest level at the end of diastole. The difference between the systolic and diastolic blood pressure is the pulse pressure, which is normally 30 to 50 points (mmHg).

There are seven major factors that affect blood pressure:

Cardiac Output The force of heart contractions (the amount of blood ejected by the heart) influences blood pressure, especially systolic pressure.

Peripheral Vascular Resistance Resistance to the flow of blood is due to resistant vessels under the influence of the autonomic nervous system. Peripheral vascular resistance is the most important determinant of diastolic pressure.

Elasticity and Distensibility of Arteries Elasticity refers to the action of the blood vessel walls to spring back after blood is ejected into them. When blood is ejected into the aorta and large arteries, the arterial vessel walls distend. Recoil during diastole propels blood through the arterial tree and maintains diastolic pressure. Both elasticity and distensibility decrease with age, resulting in increased systolic pressure and slightly increased diastolic pressure.

Blood Volume Increased blood volume causes an increase in both systolic and diastolic blood pressure, whereas decreased

blood volume causes the reverse effect. Hemorrhage decreases blood pressure, whereas overhydration from excessive blood transfusions may cause an increase in blood pressure.

Blood Viscosity Blood viscosity (thickness) influences blood flow velocity through the arterial tree. For example, increased viscosity, which occurs with polycythemia, increases resistance to blood flow, whereas decreased viscosity, resulting from anemia, decreases resistance.

Hormones and Enzymes These substances have an important influence on blood pressure. For example, epinephrine and norepinephrine produce a profound vasoconstrictor effect on peripheral blood vessels (mediators of the sympathetic nervous system). Aldosterone (released by the adrenal cortex), renin (released by the juxtaglomerular apparatus of the kidney), and angiotensin (activated by the renin response) also produce effects that raise blood pressure. Histamine and acetylcholine (a parasympathetic mediator) cause vasodilation, therefore lowering blood pressure.

Chemoreceptors Chemoreceptors in the aortic arch and carotid sinus also exert control over the blood pressure. They are sensitive to changes in PaO₂, PaCO₂, and pH. Decreased PaO₂ stimulates the chemoreceptors, which stimulate the vasomotor center. Increased PaCO₂ and decreased pH directly stimulate the vasomotor center, causing increased peripheral vascular resistance.

Measuring Blood Pressure

Measuring arterial blood pressure provides important information about the overall health status of the client. For example, the systolic pressure provides a database about the condition of the heart and great arteries. The diastolic pressure indicates arteriolar or peripheral vascular resistance. The pulse pressure, or difference between the systolic and diastolic pressure, provides information about cardiac function and blood volume. A single blood pressure reading, however, does not provide adequate data from which conclusions can be drawn about all of these factors. Rather, a series of blood pressure readings should be taken to establish a baseline for further evaluation.

The *indirect method* of taking a blood pressure using a recently calibrated aneroid manometer and a stethoscope is accurate for most clients. New electronic blood pressure devices constantly monitor systolic, diastolic, and mean readings at preset time intervals and are helpful to measure blood pressure trends in clients who are at risk for hyper- or hypotension. These devices also provide a printout if needed for documentation. If a stethoscope is unavailable or the brachial artery amplitude is decreased, the brachial or radial artery can be palpated as the blood pressure cuff is inflated to determine the systolic blood pressure (palpated pulse disappears at this point). Alternatively, an inflated blood pressure cuff may be slowly deflated and the point at which distal pulsation is first palpated reflects systolic blood pressure. Those who are severely hypotensive or hypertensive (hemodynamically unstable), have low blood volume, or are on rapid-acting intravenous vasoconstricting or vasodilating drugs should have blood pressure measured by direct (intraarterial) method. The *direct method* is

continuous and measures mean arterial pressures. A needle or catheter is inserted into the brachial, radial, or femoral artery. An oscilloscope displays arterial pressure waveforms.

Normal blood pressure in an adult varies between 100 and 120 systolic and 60 and 80 diastolic (See box on Blood Pressure Classification on page 273.) As blood moves toward smaller arteries and into arterioles, where it enters the capillaries, pressure falls to 35. It continues to fall as blood goes through the capillaries, where the flow is steady and not pulsatile. As blood moves into the venous system, pressure falls until it is the lowest in the venae cavae.

Blood pressures vary widely. A blood pressure of 100/60 may be normal for one person but may be hypotensive for another. Hypotension (90–100 systolic) in a healthy adult without other clinical symptoms is little reason for concern.

Blood pressure readings are recorded in association with Korotkoff's sounds. These sounds are described as "K" phases. The systolic, or first, pressure reading occurs with the advent of the first Korotkoff's sound. The systolic reading represents the maximal pressure in the aorta after contraction of the left ventricle and is heard as a faint tapping sound.

According to American Heart Association standards, the diastolic, or second, reading should be taken at the time of the last Korotkoff's sound (phase V) for adults. The diastolic reading represents the minimal pressure exerted against the arterial walls at all times. In children under age 13, pregnant women, and clients with high cardiac output or peripheral vasodilation, sounds are often heard to a level far below muffling and sometimes to levels near 0. In these individuals, muffling (phase IV) should be used to indicate diastolic pressure, but both muffling (phase IV) and disappearance (phase V) should be recorded (e.g., 110/80/20).

Frequency of blood pressure assessment should be individualized or as ordered. Blood pressure for an acutely ill client should be taken every 15 minutes to 1 to 2 hours and the blood pressure of more stabilized clients should be taken every 4 to 8 hours to once a day. Clients with severe hypotension or hypertension, with low blood volume, or those on vasoconstrictor or vasodilator drugs require checking every 5 to 15 minutes.

There are approximately 58 million Americans with hypertension, and only 25% are controlled to normotensive. Another 30% were not even aware they had the disease. High blood pressure is one of the leading risk factors for cardiovascular disease.

Currently there are five methods of lifestyle modification suggested for management of hypertension:

1. Weight reduction
2. Diet modification (one rich in fruits and vegetables, with a reduced amount of saturated and total fat)
3. Sodium reduction
4. Physical activity—regular aerobic exercise
5. Moderate alcohol intake

The other important method of reducing blood pressure is prescriptive medications, monitored by a physician.

PAIN

According to The Joint Commission, pain should be considered the fifth vital sign. Pain must be evaluated every time vital signs are taken, and it should be documented on the vital sign record. Refer to Chapter 16, Pain Management, for a more in-depth explanation of pain and the options available for pain management.

CULTURAL AWARENESS

Many cultures believe that certain substances protect one's health. For example, Italians, Greeks, and Native Americans believe that garlic or onions eaten raw or worn on the body will prevent an illness such as high blood pressure. If a client wishes to include these items in his or her diet or wear them, the nursing staff should respect this practice, since it is an important cultural tradition for many groups.

NURSING DIAGNOSES

The following nursing diagnoses are appropriate to use on client care plans when the components are related to vital signs.

NURSING DIAGNOSIS	RELATED FACTORS
Ineffective Airway Clearance	Obstruction of airway, increased secretions, fatigue
Ineffective Breathing Pattern	Change in rate, depth, or pattern of breathing that alters normal gas exchange
Decreased Cardiac Output	Hypovolemia, rapid pulse, changes in breathing patterns, alteration in heart rhythm or rate, or vascular tone
Deficient Fluid Volume	Excessive urinary output, abnormal fluid loss, infection, fever
Excess Fluid Volume	Decreased cardiac output, fluid retention, inflammatory process, low protein diet, increased fluid intake
Chronic Pain	Chronic disease conditions, tissue trauma, injury
Ineffective Thermoregulation	Disease, infection, drug reactions, or damage to the hypothalamic temperature regulating center; possibly dehydration
Ineffective Peripheral Tissue Perfusion	Vascular disorders, hypovolemia, medications, hypoxemia
Impaired Spontaneous Ventilation	Metabolic factors; respiratory muscle fatigue

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. *Remember to wash your hands or use antibacterial gel before and after each and every client contact.*

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Temperature

Nursing Process Data

ASSESSMENT Data Base

- Determine number of times temperature needs to be taken daily.
- Assess temperature in relationship to time of day and age of client.
- Compare temperature with other vital signs to establish baseline data.
- Determine the method most appropriate for obtaining temperature.

Oral Method

- Accurate method of determining body temperature
- Used only for alert and cooperative clients; not unconscious clients or those with active signs
- Not appropriate for use with tachypneic or mouth-breathing clients
- Not appropriate for clients with oral inflammatory processes or oral surgery
- Delivery of oxygen by nasal cannula does not affect oral temperature readings
- Determine client has not taken hot or cold liquids or smoked for 15 to 30 minutes before taking temperature orally

Rectal Method

- Appropriate for tachypneic, uncooperative, confused, or comatose clients or for clients on seizure precautions
- Used for clients with open-mouth breathing, such as those with nasal or oral intubation
- Appropriate for clients with wired jaws, facial fractures, or other abnormalities, or for clients with nasogastric tubes who cannot breathe easily with mouth closed
- Contraindicated for infants or clients who have had surgery involving the rectum

Axillary Method

- Least accurate, but safe
- Often used for infants and young children
- Used in recovery rooms to avoid turning clients
- Time-consuming

Electronic Thermometer

- Accurate for oral or rectal temperature measurement, but inaccurate for axillary temperature measurement
- Prevents infection between clients
- Time-efficient and easy to read

Infrared Ear Thermometer

- Measures body heat radiating from the tympanic membrane
- Noninvasive, safe, efficient
- Less sensitive in detecting fever in the very young child and infant

Infrared Scanner Thermometer

- Measures temperature without physical contact via infrared technology.
- Used for children or unconscious clients.

Heat Sensitive Tape

- Disposable and nonbreakable
- Appropriate for children when proper cleaning of thermometer is difficult

PLANNING Objectives

- To determine whether core temperature is within normal range
- To provide baseline data for further evaluation
- To determine alterations in disease conditions

IMPLEMENTATION Procedures

- Using a Digital Thermometer 253
 - For Oral Temperature 253
 - For Axillary Temperature 253
- Using an Electronic Thermometer 254
 - For Oral Temperature 254
 - For Rectal Temperature 254
- Measuring an Infant or Child's Temperature 255
 - For Oral Route 255
 - For Rectal Route 255
 - For Axillary Route 255
- Using an Infrared Thermometer for Tympanic Temperature 255
- Using an Infrared Scanner Thermometer 256
- Using a Heat-Sensitive Wearable Thermometer 257

EVALUATION Expected Outcomes

- Temperature is within normal range.
- Temperature readings are compared with age, time of day, and previous readings.
- Alterations in temperature are detected early and treatment begun.
- Appropriate method of temperature taking is determined for each client.
- Correct length of time is used for thermometer insertion to obtain an accurate reading.

Critical Thinking Application 258

- Expected Outcomes 258
- Unexpected Outcomes 258
- Alternative Actions 258

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Using a Digital Thermometer

Equipment

- Client's individual digital thermometer or if multiple client use, thermometer with disposable sheaths
- Gloves, if necessary

Procedure

1. Perform hand hygiene.
2. Don gloves if risk of contact with saliva.
3. Identify client with two forms of ID.

For Oral Temperature

- a. Wait 20 to 30 minutes to take oral temperature if client has been eating, drinking, chewing gum, smoking, or exercising. ► **Rationale:** These activities may alter the temperature.
- b. Place thermometer in client's mouth under front of tongue and along gum line. ► **Rationale:** Location ensures contact with large vessels under tongue.
- c. Have client hold lips closed and leave thermometer in place for 45 to 90 seconds. The alert sound will indicate

▲ Ask client to hold lips closed and leave thermometer in place 45–90 seconds.

- time. ► **Rationale:** Open-mouth breathing produces abnormally low readings.
- d. Remove thermometer and read temperature displayed in digital window.

For Axillary Temperature

- a. Assist client to comfortable position and expose axilla area.
 - b. Dry axilla if necessary. ► **Rationale:** A false low reading may result if axilla is moist.
 - c. Place thermometer in center of axilla and lower arm down across chest. ► **Rationale:** This position allows thermometer to be in contact with large vessels.
 - d. Leave in place 1 to 2 minutes. ► **Rationale:** Axilla temperature recordings take a longer time to register.
4. Record temperature noting route and return thermometer to its case at client's bedside stand.
 5. Perform hand hygiene.

TABLE 10-2 Comparing Centigrade and Fahrenheit Temperatures

Centigrade (C)	Fahrenheit (F)
36.0	96.8
36.5	97.7
37.0	98.6
37.5	99.5
38.0	100.4
38.3	101.0
39.0	102.2
39.5	103.1
40.0	104.0

To convert degrees F to degrees C, subtract 32, then divide by 1.8. To convert degrees C to degrees F, multiply by 1.8, then add 32.

▲ Place thermometer in client's mouth under tongue.

EVIDENCE-BASED PRACTICE

Reducing Mercury in Hospitals

A survey of American hospitals released in late September 2005 indicated that 97% of hospitals have taken steps to reduce or eliminate mercury. Seventy-two percent of hospitals have inventoried and replaced mercury-containing devices or labeled them for proper handling.

Source: Survey conducted by American Hospital Association, Health Care Without Harm, and U.S. Environmental Protection Agency.

Clinical Alert

Temperature varies with time of day: It is highest between 5 and 7 PM and lowest between 2 and 6 AM. This variation is termed *circadian thermal rhythm*. A consistent method of body temperature measurement should be used so that readings are comparable.

Mercury Thermometers

Mercury thermometers are no longer used in hospitals. In 2001, a U.S. senator introduced a comprehensive bill to totally eliminate and retire mercury because of its toxic effects on people and the environment.

Using an Electronic Thermometer

Equipment

- Electronic thermometer unit with digital readout and probe
- Disposable cover for thermometer
- Lubricant on tissue (for rectal temperature)
- Clean gloves

Procedure

1. Perform hand hygiene and don gloves, if necessary.
2. Remove thermometer from charger unit.
3. Place carrying strap around your neck or remove thermometer from rolling stand.
4. Grasp probe at top of stem using your thumb and forefinger. ► **Rationale:** Pressure on top releases the ejection button.
5. Firmly insert probe in disposable probe cover.
6. Identify client with two forms of ID.
7. Provide privacy for rectal temperature.

Clinical Alert

Temperature assessment is the single most important infection control monitoring criterion for HAIs (nosocomial infections) and fever of unknown origin.

For Oral Temperature

- a. Instruct client to open mouth. Slide probe under front of client's tongue and along the gum line in the sublingual pocket. ► **Rationale:** The larger blood vessels in the pocket more accurately reflect the core temperature.
- b. Instruct client to close lips (not teeth). Lips should close at the ridge on the probe cover.

For Rectal Temperature

- a. Don clean gloves. ► **Rationale:** Prevents exposure to feces.
- b. Position client on side facing away from you, separate buttocks, instruct client to take in a deep breath, and insert covered and lubricated probe $\frac{1}{4}$ to $1\frac{1}{2}$ in. (depending on client's age) through anal sphincter. ► **Rationale:** Taking in a deep breath relaxes the sphincter and the lubrication prevents tissue trauma.

▲ Electronic thermometer unit with digital probe.

- c. Position probe to side of rectum to ensure contact with tissue wall. ► **Rationale:** This ensures probe is in contact with large vessels of rectal wall.
8. Remove probe when audible signal occurs. Client's temperature is now registered on the dial.
9. Discard oral probe cover into trash by pushing ejection button.
 - a. Discard rectal probe cover, tissue, and gloves. ► **Rationale:** Proper disposal prevents transmission of microorganisms.
 - b. Wipe anal area to remove lubricant and stool.
10. Assist client to comfortable position.
11. Perform hand hygiene.
12. Record temperature, and then return probe to storage well. ► **Rationale:** This ensures that system is ready for next use.
13. Return thermometer unit to charging base. Ensure charging base is plugged into electric outlet.

Clinical Alert

The temperature of an unconscious client is never taken by mouth. The rectal, tympanic, or scanner method is preferred.

Clinical Alert

Only use client's own dedicated electronic thermometer (including rectal and oral) if diagnosis includes *Clostridium difficile*-associated diarrhea because of the potential for spreading the bacteria and increasing the risk of transmitting an HAI (nosocomial) to other clients.

▲ Cover probe of thermometer before taking temperature.

▲ Slide probe under front of tongue to sublingual pocket.

Measuring an Infant or Child's Temperature

Equipment

- Digital or electronic thermometer with disposable probe cover
- Water-soluble lubricant
- Gloves, if necessary

Procedure

1. Determine appropriate thermometer and route for child.
 - ▶ **Rationale:** Oral route is appropriate only for child over 3 years of age. Electronic, nonbreakable thermometer or scanner is preferred.
2. Perform hand hygiene and identify client with two forms of ID.
3. Explain procedure at child's level of understanding.
4. Remove probe from cover or attach probe tip to electronic thermometer.

▲ The new scanner method is often used for children who are unconscious, have seizures, or have a structural abnormality.

For Oral Route (only for child 3 years or older)

- a. Place probe under child's tongue, one side or the other.
- b. Have child close mouth and either hold thermometer in place or monitor while taking temperature.
- c. Leave digital thermometer in place for 45 to 90 seconds or remove electronic thermometer when audible signal occurs.

For Rectal Route

- a. Place infant or child in prone or side-lying position.
- b. Lubricate probe.
- c. Insert thermometer $\frac{1}{4}$ to $\frac{1}{2}$ in. into rectum for infant or $\frac{1}{2}$ to 1 in. for child and hold in place.
- d. Turn on scanner and follow directions.
- e. Remove probe when tone or beep is heard.

For Axillary Route

- a. Assist infant or child to a comfortable position and expose axilla.
- b. Dry axilla if necessary. ▶ **Rationale:** A moist axillary area can produce a false low reading.
- c. Place thermometer in center of axilla. Lower child's arm down and across the chest. ▶ **Rationale:** This position ensures that thermometer remains in contact with large vessels of axilla.
- d. Leave in place 1-2 minutes or until tone is heard.
 - ▶ **Rationale:** Axillary temperature recordings take longer to register than oral or rectal.
5. Read and record temperature; indicate method.
6. Discard probe cover into trash by pushing ejection button, or return digital thermometer into its case.

Using an Infrared Thermometer for Tympanic Temperature

Equipment

- Infrared thermometer unit
- Disposable probe cover

NOTE: A tympanic thermometer measures the infrared energy that naturally radiates from the tympanic membrane and surrounding tissues.

Procedure

1. Perform hand hygiene and identify client with two forms of ID.
2. Attach disposable cover centering probe on film and press firmly until backing frame of probe cover engages base of probe. ▶ **Rationale:** Cover protects client from transmission of microorganisms.
3. Turn the client's head to one side and stabilize the client's head.
4. Pull pinna upward and backward for an adult or down and backward for a child. ▶ **Rationale:** This procedure provides better access to the ear canal.
5. Center probe and gently advance into ear canal to make a firm seal, directing probe toward tympanic membrane. ▶ **Rationale:** Pressure close to the tympanic membrane seals ear canal and allows for accurate reading.
6. Press and hold temperature switch until green light flashes and temperature reading displays (approximately 3 seconds). ▶ **Rationale:** Method records core body temperature.
7. Remove thermometer. Discard probe cover.
8. Return thermometer to home base or storage unit for recharge.

▲ Position client so ear canal is easily seen and pull pinna back and up.

9. Keep lens clean using lint-free wipe or alcohol swab, then wipe dry. Do not use povidone-iodine (Betadine).
10. Perform hand hygiene.
11. May be used for clients over 3 months of age.

Clinical Alert

Do not use ear thermometer in infected or draining ear or if adjacent lesion or incision exists.

▲ Place probe in client's ear and advance into ear canal to make a firm seal.

EVIDENCE-BASED PRACTICE

Correct Technique for Taking a Tympanic Temperature

Studies on the correct technique for taking a tympanic temperature indicate that the ear tug (pulling the pinna upward and backward for an adult and down and backward for a child) is essential for an accurate reading. Eliminating this step will not allow the thermometer to be directly at the tympanic membrane.

Source: The Joanna Briggs Institute. (1999). Vital signs. *Best Practice*, 3(3), 5. http://www.joannabriggs.edu.au/pdf/BPISEng_3_3.pdf.

Using an Infrared Scanner Thermometer

Equipment

Scanner temperature thermometer

Procedure

1. Check orders for scanner device (may be used with children to check temperature without waking).
2. Press power button to turn device on. Check to see thermometer is in person mode (see symbol in window).
3. Press and hold scan button. "00" will be displayed.
4. Aim infrared lens at client's forehead, holding thermometer 2 to 3 in. away.
5. Release scan button and note reading that is displayed.
6. Clean device with antiseptic wipe.
7. Record temperature in record.

▲ Follow manufacturer's directions for scanner device.

▲ After releasing scan button, note reading in window.

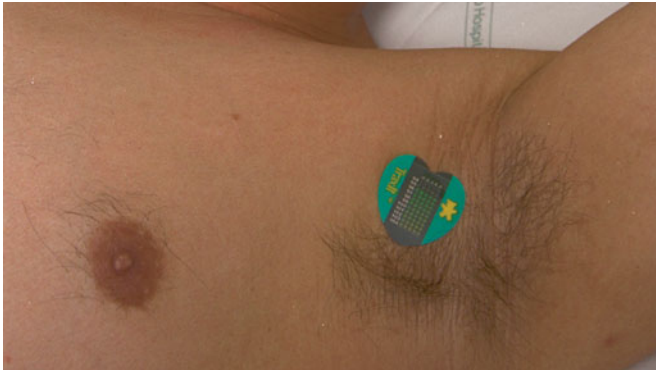

Using a Heat-Sensitive Wearable Thermometer

Equipment

Wearable thermometer (TraxIt), chemical strip tape or liquid crystal thermometer

Procedure

1. Check orders for continuous-reading thermometer and identify client with two forms of identification.
2. Dry forehead or axilla area, if necessary.

▲ Place Traxit®, a continuous-reading wearable thermometer, deep in the client's axilla.

3. Please strip on forehead or deep in client's axilla—may stay in place for two days.
4. Read correct temperature by checking color changes or dots that turn from green to black.
5. Record temperature on appropriate form or record.

▲ Liquid crystal thermometer is placed against lower forehead for 15 seconds.

DOCUMENTATION for Temperature

- Site designated: “O” (oral), “R” (rectal), “A” (axillary), or “T” (tympanic)
- Temperature recorded on temp sheet and graph
- Nursing interventions used for alterations in temperature
- Condition of skin related to alterations from normothermia (e.g., diaphoresis)
- Signs and symptoms associated with alterations in temperature (e.g., shivering, dehydration)

Legal Considerations

Nurse's Negligence

The client had transthoracic vagotomy after which the doctor ordered vital signs every 15 minutes \times 1 hour and every hour for 10 hours. Vital signs were recorded 4 times for 1 day. The next day the client's temperature was 102°F and it remained there until the next day when it was 105°F. The nurse administered aspirin

when it rose to 106°F. The nurse then contacted the doctor who found signs of serious wound infection. The client suffered organic brain syndrome as a direct result of the continued high temperature. The court found that the nurses breached standard of care when they failed to notify the doctor of the client's high temperature.

CRITICAL THINKING Application

Expected Outcomes

- Temperature is within normal range.
- Temperature readings are compared with age, time of day, and previous readings.
- Alterations in temperature are detected early and treatment begun.

Unexpected Outcomes

Fever develops.

Despite initial cooling measure, temperature remains elevated due to hypothalamus damage from brain disease or injury.

Temperature remains elevated because of bacterial-produced pyrogens.

Temperature remains subnormal.

Using a tympanic thermometer, client's temperature reading seems too low.

- Appropriate method of temperature taking is determined for each client.
- Correct length of time is used for thermometer insertion to obtain an accurate reading.

Alternative Actions

- Check possible sources of infection and take preventative measures.
- Notify physician.
- Employ cooling methods if temperature is dangerously high, such as tepid sponge bath, cool oral fluids, ice packs, or antipyretic drugs.
- Assess all vital signs.
- Notify physician and request cooling blanket.
- Monitor temperature every 15 to 30 minutes and record.
- Continue to administer antipyretic drugs as ordered.
- Check for order to obtain culture of possible sources of infection.
- Give antipyretic drugs as ordered.
- Decrease room temperature and remove excess covers.
- Give tepid sponge bath.
- Extreme low temperature can cause vasoconstriction; assess for blood clots.
- Institute measures to promote vasodilation (application of warmth).
- If extremity is ischemic, monitor that heat source does not exceed body temperature.
- Be sure client has been indoors for at least 10 minutes.
- Replace probe cover and retake temperature.
- Check that probe cover and lens are clean and intact.

Pulse Rate

Nursing Process Data

ASSESSMENT Data Base

- Assess appropriate site to obtain pulse.
- Check pulse with health status changes, as ordered by physician, or before administering certain medications.
- Assess for rate, rhythm, volume, and quality.
- Assess an apical pulse on clients with irregular rhythms or those on cardiac medications.
- Obtain baseline peripheral pulses with initial assessment or in any client going for cardiac or vascular surgery. Also obtain pulse for medical clients with diabetes, arterial occlusive diseases, atherosclerosis, or aneurysm, or any color or temperature changes in the periphery.
- Obtain an apical–radial pulse when deficits occur between apical and radial measurements.
- Assess the need to monitor pulses with an ultrasound or electronic device.

PLANNING Objectives

- To determine whether the pulse rate is within normal range and if the rhythm is regular
- To evaluate the quality (amount of blood pumped through peripheral arteries) of arterial pulses
- To determine whether peripheral pulses are equal in amplitude when compared with corresponding pulses
- To determine presence of peripheral pulses with ultrasound device when palpation is ineffective
- To monitor and evaluate changes in the client’s health status
- To determine apical pulse rate before heart medications are administered

IMPLEMENTATION Procedures

- Palpating a Radial Pulse 260
- Taking an Apical Pulse 261
- Taking an Apical–Radial Pulse 263
- Palpating a Peripheral Pulse 263
- Monitoring Peripheral Pulses With a Doppler Ultrasound Stethoscope 264
- Monitoring Pulse Oximetry 265

EVALUATION Expected Outcomes

- Pulse is palpated without difficulty.
- Pulse rate is within normal range and rhythm is regular.
- All peripheral pulses are equal in amplitude when compared with the corresponding pulse on the other side and when compared with the next proximal site.
- Apical pulse is easily detected and counted.

- Critical Thinking Application** 266
- Expected Outcomes 266
 - Unexpected Outcomes 266
 - Alternative Actions 266

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
and Skill Checklists

Palpating a Radial Pulse

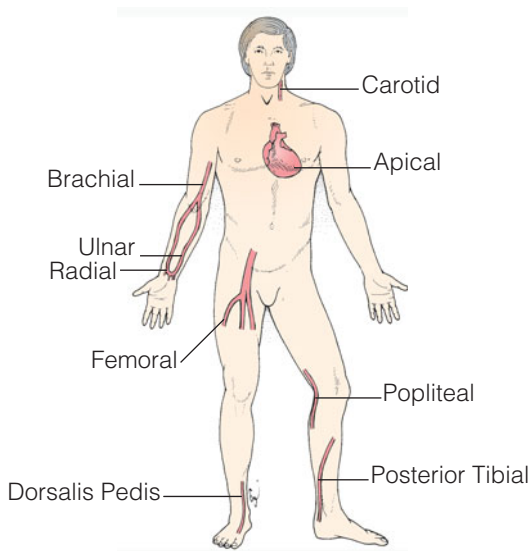

Equipment

Watch with sweep second hand or digital watch that indicates seconds.

NOTE: To assess a pulse correctly, the nurse's watch must have second-hand capability.

Procedure

1. Perform hand hygiene.
2. Check client identity with two forms of ID and place client in comfortable position.
3. Ask about activity level within last 15 minutes.
 - ▶ **Rationale:** Pulse rate increases with activity, then returns to preactivity rate.
4. Palpate arteries by using pads of the middle three fingers of your hand. ▶ **Rationale:** The nurse may feel own pulse if palpating with the thumb.
 - a. Radial artery is usually used because it lies close to the skin surface and is easily accessible at the wrist.
 - b. Press the artery against the bone or underlying firm surface to occlude vessel and then gradually release pressure. ▶ **Rationale:** Too much pressure obliterates the pulse.
 - c. Note pulse characteristics, i.e., quality (strength) of pulse. ▶ **Rationale:** Strength of the pulse is an indication of stroke volume or amplitude.
 - d. If pulse is difficult to palpate, try exerting more pressure on the most distal palpating finger. ▶ **Rationale:** This amplifies the pulse wave against the two more proximal palpating fingers.
5. Count pulse for 30 seconds, and multiply by two to obtain pulse rate. ▶ **Rationale:** This is sufficient time for rate determination if pulse rhythm is regular.

▲ Radial artery is the most commonly used site for determining pulse rate.

▲ Carotid artery is used when other sites are inaccessible or when there is a cardiac arrest to determine the adequacy of perfusion during CPR.

6. Count radial pulse for at least 1 minute if rhythm is irregular or difficult to count. ▶ **Rationale:** It may take a minute or so to detect the irregularity. This method assists you to count the pulse more accurately.
7. Check to see that client is comfortable.
8. Perform hand hygiene.
9. Record pulse rate, rhythm, and strength (volume).

TABLE 10-3 Pulse Quality

Pulse quality is determined by the amount of blood pumped through the peripheral arteries. The amount of pumped blood usually remains fairly constant; when it varies, it is also indicative of cardiac malfunction.

- **Bounding pulse:** Occurs when the nurse is able to feel the pulse by exerting only a slight pressure over the artery. May occur with increased stroke volume.
- **Weak or thready pulse:** Occurs if, by exerting firm pressure, the nurse cannot clearly determine the flow. May be associated with decreased stroke volume.
- **Pulsus alternans:** A regular pulse that the nurse feels as strong alternating with weak beats. May be related to left ventricular failure.
- **Bigeminal pulse:** Every second beat has a decreased amplitude. May be due to premature contractions.

Source: LeMone, P., & Burke, K. M. (2008). *Medical-Surgical Nursing: Critical Thinking in Clinical Care* (4th ed.). Upper Saddle River, NJ: Prentice Hall Health.

▲ Palpate radial pulse by using pads of middle three fingers, not thumb, for accurate results.

▲ Count pulse for at least 30 seconds and multiply by two to obtain pulse rate.

Pulse Characteristics

When counting the pulse rate, pay attention to:

- **Rate:** Average is 72 beats/min. The normal adult heart rate range is 60 to 100 beats/min. If pulse rate is below 60 or above 100 beats/min (outside the normal parameters), notify the physician.
- **Rhythm:** The pattern of beats, either regular or irregular.
- **Volume or amplitude:** The force of blood with each beat; can range from absent to bounding.
- **Symmetry:** Bilateral uniformity of pulse.

Palpate a Child's Pulse or Listen to the Heart

The best practice for taking a pulse for infants or children is to listen to the heart itself, rather than palpating the pulse—too much pressure may obliterate it and inadequate pressure may not detect it.

EVIDENCE-BASED PRACTICE

Pulse Rate Measurement

Studies have indicated that the accuracy of pulse rate measurement is influenced by the number of counted seconds (counting the pulse for 60 seconds is more accurate than 15 or 30 seconds). However, clinical significance of the result is not clear because in one study using a 15- or 30-second count was just as accurate as a 60-second count.

Source: The Joanna Briggs Institute. (1999). Vital signs. *Best Practice*, 3(3), 2. http://www.joannabriggs.edu.au/pdf/BPISEng_3_3.pdf Craven, R.F., Hinnle, C.J. (2006) *Fundamentals of Nursing Human Health and Function*, 5th ed. Philadelphia: Lippincott Williams and Wilkins.

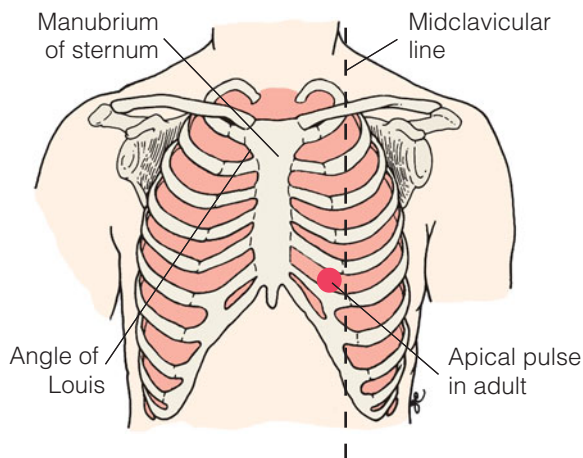

Taking an Apical Pulse

Equipment

Watch with sweep second hand
Stethoscope

Procedure

1. Gather equipment.
2. Perform hand hygiene.
3. Check two forms of client's ID. Provide privacy.
4. Explain procedure to client.
5. Place client in a supine position and expose chest area. If possible, stand at client's right side.
 - ▶ **Rationale:** Auscultation of heart sounds is often enhanced when examiner is at client's right side.
6. Locate the apical impulse, termed the point of maximal impulse (PMI), by palpating the angle of Louis just below the suprasternal notch. This is the angle between the manubrium, top of the sternum, and the body of the sternum.

▲ Apical pulse site in adult.

- a. Place your index finger just to the left of the client's sternum and palpate the second intercostal space.
 - b. Place your middle finger in the third intercostal space and continue palpating downward until you locate the apical impulse at the fifth intercostal space.
 - c. Move your index finger laterally along the fifth intercostal space to the midclavicular line (MCL).
7. Warm the stethoscope in the palm of your hand for 5 to 10 seconds. ► **Rationale:** Warming the stethoscope prevents startling the client.
 8. Count client's apical pulse.
 - a. Place diaphragm of stethoscope firmly over apical impulse site. ► **Rationale:** Heart sounds are high-pitched and most clearly heard with diaphragm of stethoscope.
 - b. Count the rate for 1 minute when taking an apical pulse. Count *lub-dub* sound as one beat. ► **Rationale:** More accurate readings are obtained over 1 minute, especially if pulse is irregular.

▲ Place middle finger in third intercostal space and continue to move downward to the fifth intercostal space.

▲ Move index finger along fifth intercostal space to midclavicular line.

▲ Accurate apical pulse is found in fifth intercostal space, left of sternum at midclavicular line, or at Erb's point.

- c. Determine if there is a regular pattern to any irregularity or if it is chaotically irregular. ► **Rationale:** This finding helps describe the rhythm disturbance.
9. Check to see that client is comfortable.
10. Perform hand hygiene and clean stethoscope, if necessary.
11. Record apical pulse rate, rhythm, and intensity.

EVIDENCED-BASED PRACTICE

Effect of Music on Vital Signs

The impact of music (Mendelson's classical violin) on vital signs was studied on a pulmonary medical unit. The results showed a trend toward a decrease in systolic and diastolic blood pressure as well as a decrease in heart rate.

Source: Burgner, K. (2005, June 27). Musical intervention. *Advance for Nurses*, 2, 21–23.

Taking an Apical–Radial Pulse

Equipment

- Watch with sweep second hand
- Stethoscope
- Another nurse to assist with procedure

NOTE: An experienced nurse may be able to assess apical and radial rates simultaneously without an assistant.

Procedure

1. Gather equipment.
2. Perform hand hygiene.
3. Check two forms of client's ID.
4. Provide privacy.
5. Explain procedure to client, especially if two nurses are taking the pulse. ► **Rationale:** Clients may be apprehensive when two nurses are at the bedside, so a full explanation helps allay fears.
6. Assist client to a supine position and expose chest area.

▲ Auscultate apical pulse and palpate radial pulse simultaneously, preferable using two nurses.

7. Place watch where clearly visible to both nurses. ► **Rationale:** Both nurses count pulse rates within the same time span, preferably using one watch.
8. Warm stethoscope in palm of your hand. ► **Rationale:** Prevents startling the client with cold stethoscope.
9. Locate radial pulse. The second nurse locates apical pulse at the fifth intercostal space left of sternum at the midclavicular line and firmly places diaphragm of stethoscope on the site. ► **Rationale:** Firm application helps transmit high-pitched heart sounds.
10. With assistant, select number on watch to start counting pulse (e.g., 12:00).
11. Signal to the other nurse with your hand when to start taking the pulse and when to stop. Both nurses simultaneously count pulse for 1 full minute.
12. Auscultate the apical pulse and palpate the radial pulse simultaneously (preferably using two nurses, one at each site).
 - a. Note a pulse deficit between apical and radial pulses when rhythm is irregular. ► **Rationale:** Atrial dysrhythmias and premature ventricular beats generally produce pulse deficits (apical greater than radial rate). A pulse deficit results from the ejection of a volume of blood that is too small to initiate a peripheral pulse wave.
 - b. If a significant pulse deficit is found, assess for other abnormal signs (BP).
 - c. Assess pulse volume by feeling the pressure of the beat. The quality is described as normal, weak, strong, or bounding.
13. Subtract radial rate from apical rate to obtain pulse deficit. ► **Rationale:** The pulse deficit represents the number of ineffective or nonperfused heartbeats.
14. Position client for comfort.
15. Perform hand hygiene.
16. Chart apical and radial rate and pulse deficit.

Palpating a Peripheral Pulse

Equipment

- Felt-tipped pen
- Watch with second hand

Procedure

1. Gather equipment.
2. Perform hand hygiene.
3. Check two forms of client ID.
4. Provide privacy. Explain procedure.
5. Place client in a supine position with relaxed legs.
6. Palpate peripheral pulses: radial, carotid (when other sites are inaccessible), brachial, femoral, popliteal, dorsalis pedis, posterior tibial. (For special cases, after carotid surgery, palpate temporal pulse also.)
7. Compare pulse sites bilaterally by palpating with pads of the middle three fingers of your hand.
8. Press artery against the bone or underlying firm structure to occlude vessel and then gradually release pressure.
9. Palpate weak pulses gently. ► **Rationale:** Too much pressure obliterates a weak pulse.
10. Assess if bilateral pulses are equal in amplitude (strength).

▲ Apply firm pressure against underlying structure, then release to find peripheral pulse.

- a. If pulse is not immediately palpable, examine adjacent area. ► **Rationale:** This action identifies where interruption or alteration in circulation occurs in an extremity.
 - b. Since pulse locations differ, mark pulse locations with felt-tipped pen, especially when they are difficult to palpate. ► **Rationale:** Marking site allows the next nurse to find location without spending extra time.
 - c. Compare presence and characteristic of peripheral pulses with previous findings. ► **Rationale:** This action allows early identification of alterations in peripheral circulation.
11. Check to see that client is comfortable.
 12. Wash your hands.
 13. Record pulse rate, rhythm, pattern, and volume.

Characteristics of Peripheral Pulses

Peripheral pulses may be absent or weak. The size (amplitude) of a pulse depends on the degree of filling of the artery during systole (ventricular contraction) and emptying during diastole (ventricular relaxation). The amplitude of a pulse is described as being large or small and determines the pulse pressure (the difference between systolic and diastolic pressure).

- 0 = Absent
- 1+ = Weak
- 2+ = Diminished
- 3+ = Strong
- 4+ = Full and bounding

Clinical Alert

If palpating the carotid pulse, avoid pressing on the carotid sinus in the upper neck area near the jaw. *Do not* palpate both carotids simultaneously because this decreases blood flow to the brain.

EVIDENCED-BASED PRACTICE

Determining Pulse Rate With a Doppler Device

Determining a pulse rate with a Doppler device is more accurate than palpation, which detects arterial wall expansion and retraction. The Doppler detects the motion of red blood cells and thus is more sensitive.

Source: Thomas, J., Feliciano, C. (July, 2003). Measuring blood pressure with a doppler device. *Nursing* 33(7): 52–53.

Monitoring Peripheral Pulses With a Doppler Ultrasound Stethoscope

Equipment

- Doppler ultrasound stethoscope or probe
- Conductive jelly (not K-Y)

Procedure

1. Gather equipment.
2. Perform hand hygiene.

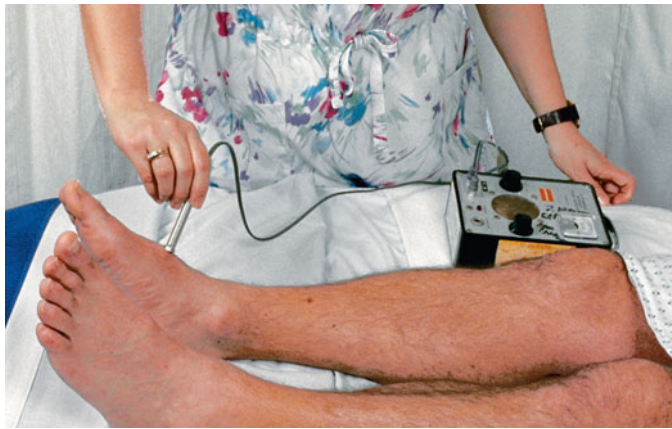

▲ Locate peripheral pulse with fingers before applying gel.

3. Check two forms of client ID; explain procedure.
4. Provide privacy.
5. Uncover extremity to be assessed.
6. Place extremity in a comfortable position.
7. Plug headset (stethoscope) into one of the two outlet

▲ Apply gel to skin to facilitate beam transmission.

▲ Hold probe against skin at 90° angle.

▲ Mark site where pulsations were heard.

jacks located next to the volume control. If not using stethoscope, plug probe into monitor.

8. Apply conductive gel to client's skin. ► **Rationale:** The ultrasound beam travels best through gel and requires an airtight seal between the probe and the skin.
9. Hold probe (at tapered end of plastic core) against skin at a 90° angle to the blood vessel being examined.
10. Turn on Doppler by pressing down the "ON" switch.
11. Move probe over site if pulse is not detected. Keep it in direct contact with skin, and adjust volume to detect blood flow. ► **Rationale:** This action should facilitate detection of whooshing pulse sounds.
12. Reapply new gel if pulse is still not detected and, with light pressure, place probe over site and turn switch ON. Increase volume control, or check if batteries are weak.
13. Mark site where pulsations were heard. ► **Rationale:** This facilitates future assessments.
14. Clean gel from skin and Doppler probe. Replace cover over extremity.
15. Position client for comfort.
16. Replace Doppler equipment to appropriate location.
17. Perform hand hygiene.

▲ Alternate equipment for Doppler probe. Skill steps are the same.

Monitoring Pulse Oximetry

NOTE: See Procedure in Chapter 30, Respiratory Care.

DOCUMENTATION for Taking a Pulse

- Type of pulse taken
- Rate, rhythm, intensity, and quality of pulse
- Pulse deficit, if any, present
- Characteristics of all peripheral pulses—use rating scale
- Use of Doppler stethoscope if needed
- Effects of nursing interventions or medical treatments on abnormal pulse rates or rhythms

CRITICAL THINKING Application

Expected Outcomes

- Pulse is palpated without difficulty.
- Pulse rate is within normal range and rhythm is regular.

Unexpected Outcomes

Apical, femoral, and carotid pulse is absent.

Abnormal heartbeats are present.

Tachycardia (pulse rate over 100 beats/min in adults or 140 in children)

Bradycardia (pulse rate less than 60 in adults or less than 70 in children)

Ectopic Beats (premature ventricular or atrial contractions)

Peripheral pulse is absent.

Loss of peripheral pulse.

Doppler stethoscope unable to detect sounds.

Client is in isolation and requires vascular assessment.

- All peripheral pulses are equal in amplitude when compared with the corresponding pulse on the other side and when compared with the next proximal site.
- Apical pulse is easily detected and counted.

Alternative Actions

- *Note:* For all unexpected outcomes, assess all vital signs and status of the client.
- Immediately call a Code.
- Initiate CPR immediately, and continue to assess the femoral or carotid pulse during resuscitation.
- For absent femoral pulse, assess for systemic circulation and presence of disorders affecting circulation to extremities.
- Use Doppler stethoscope to assess for presence of pulse.
- Relieve anxiety, fear, or stress through communication and pertinent information.
- If client has pain, relieve with change of position, back rub, and analgesic.
- Decrease heart rate by reducing an elevated temperature to normal.
- Take vital signs every 15 minutes to 2 hours until condition stabilizes and pulse rate is within normal limits.
- Determine significance of pulse rate as it affects blood pressure, sensorium, and client comfort.
- Reassess client for shock because a rise in pulse rate is one of the earliest signs of shock.
- Notify physician if persistent tachycardia continues or if there is a change in blood pressure.
- Determine whether tachycardia is normal for this client.
- Notify physician for electrocardiogram request to determine if heart block is present.
- If client is on digitalis, hold the drug, or on beta-blockers or other medications, notify physician.
- Have atropine and temporary pacemaker available for physician if pulse is consistently slow (less than 50) and client is not an athlete (who may well have a pulse less than 50).
- Continue monitoring pulse rate every 15 minutes to 2 hours until pulse is within normal limits.
- Relieve pain if irregularity is due to premature beats associated with pain.
- Administer oxygen if client has an order to do so.
- If associated with stimuli from noise, visitors, caffeinated beverages, or smoking, eliminate the cause of the stimulation.
- Notify physician to request a medical order for an electrocardiogram since premature beats in a client with myocardial infarction may be potentially harmful.
- Obtain order from physician to draw serum electrolytes, especially magnesium or potassium. Low levels can cause ectopic beats.
- Continue monitoring pulse rate every 15 minutes to 2 hours until irregularity is controlled.
- Assess for other signs and symptoms of circulatory impairment.
- Use a Doppler ultrasound and stethoscope to find pulse and report to physician.
- Check that conductive jelly is used because salt from K-Y Jelly can damage the probe.
- Check that batteries are less than 6 months old. The date should be indicated on all batteries.
- Use alkaline batteries; they last longer.
- Check that abnormal pressure is not applied, as this obliterates pulse.
- Clean with gas sterilization after discontinuing use of Doppler stethoscope.
- Do not clean with alcohol or autoclave.

Respirations

Nursing Process Data

ASSESSMENT Data Base

- Assess client's respiratory rate, depth, and rhythm.
- Note any abnormalities noted during inspection and palpation or by percussion and auscultation.
- Assess presence of dyspnea or cyanosis.
- Assess for presence of abnormal sounds, such as stertorous or sonorous breathing.
- Assess if accessory muscles are used for breathing.

PLANNING Objectives

- To note respiratory rate, rhythm, and depth
- To establish baseline information on admission to the unit
- To note labored, difficult, or noisy respirations or cyanosis
- To identify alterations in respiratory pattern resulting from disease condition
- To determine whether respiratory rate is within normal range compared with pulse and blood pressure readings

IMPLEMENTATION Procedures

- Obtaining the Respiratory Rate 268

EVALUATION Expected Outcomes

- Respiratory rate, rhythm, and depth are within normal limits.
- Baseline information upon admission is documented.
- Labored, difficult, or noisy respirations are evaluated.
- Alterations in respiratory patterns resulting from disease conditions are identified.

Critical Thinking Application 269

- Expected Outcomes 269
- Unexpected Outcomes 269
- Alternative Actions 269

Pearson Nursing Student Resources

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Obtaining the Respiratory Rate

Equipment

Watch with a second hand

Procedure

1. Perform hand hygiene.
2. Check two forms of client ID and explain procedure to client.
3. Check lighting to ensure it is adequate for procedure.
4. Maintain client's privacy.
5. Place hand on chest or observe chest rise and fall and count respirations.
6. Note relationship of inspiration to expiration. Note also depth and effort of breathing.
7. Count respirations for preferably 1 minute, or for 30 seconds and multiply by 2. ► **Rationale:** One full minute is more accurate for abnormal breathing patterns.
8. Perform hand hygiene.
9. Compare respiratory rate with previous recordings.
10. Record respiratory rate. Record if rhythm or depth altered from normal.

▲ Place hand on chest when respirations are difficult to count.

TABLE 10-4 Abnormal Breathing Patterns

Apnea	Absence of breathing.	
Biot's respirations	Abrupt interruptions between a faster, deeper respiratory rate.	
Bradypnea	Slow, regular respirations. Rate is below 10 per minute.	
Cheyne–Stokes	Periods of apnea appear throughout cycle. Respirations become deeper and faster than normal followed by a slower rate and progressing to periods of apnea lasting from 15 to 60 seconds.	
Hyperpnea	Abnormal increase in depth and rate.	
Kussmaul's respirations	Deep, gasping breathing. Attempt to blow off carbon dioxide as respiratory compensation for metabolic acidosis (e.g., diabetic ketoacidosis).	
Tachypnea	Respiratory rate increased above 24 breaths per minute. Rate remains regular but shallow in pattern.	

Normal Respiratory Rate

Adults: 12–20 per minute

Young children: 20–25 per minute

Infants: Up to 40 per minute

NOTE: One study found that counting respirations for 15 seconds versus a full minute produced a significant difference in the rate; thus the conclusion is respirations should be counted for a full minute.

DOCUMENTATION for Respiration

- Rate, depth, and rhythm of respirations
- Abnormal sounds associated with breathing
- Effectiveness of therapy if needed to correct respiratory problems
- Ratio of inspiration and expiration
- Alterations from baseline respiratory patterns

Legal Considerations

Failure to Assess and Monitor Vital Signs

A client entered the hospital with pain from a kidney stone. From 4:35 PM to 10:30 PM, he received three 5-mg doses of morphine, 1 mg of Dilaudid, and an additional 15 mg of morphine with 50 mg of Phenergan IV. At 1:05 AM, the night shift found the client in respiratory and cardiac arrest. He died shortly thereafter. After being transferred from the emergency department to a unit at 8:15 PM, the

client did not have his vital signs taken, even though hospital policy stated that after IV narcotic administration, the client must be monitored every hour for respiratory depression for 24 hours. The court found a breach of standard of care by the nurse's failure to assess, monitor, and document care of a client receiving narcotics.

Source: *McMinn v. Mount Carmel Health*, 1998.

CRITICAL THINKING Application

Expected Outcomes

- Respiratory rate, rhythm, and depth are within normal limits.
- Baseline information upon admission is documented.

Unexpected Outcomes

Apnea (absence of breathing) occurs, may be intermittent.

Tachypnea (rate faster than normal and more shallow >24) occurs.

Bradypnea (rate slower than normal <10) occurs.

Hyperpnea (increased depth of respiration) occurs.

Cheyne–Stokes respirations (respiratory cycle in which respirations increase in rate and depth, then decrease, followed by a period of apnea) occur.

Biot's (irregular pattern—slow and deep or rapid and shallow, followed by apnea) respirations occur.

Kussmaul's (deep and gasping breaths—more than 20 breaths/minute) respirations occur.

- Labored, difficult, or noisy respirations are evaluated.
- Alterations in respiratory patterns resulting from disease conditions are identified.

Alternative Actions

- *Note:* For all unexpected outcomes, assess client for all vital signs and comfort/condition.
- Begin artificial ventilation by mouth-to-mask, mouth-to-nose, or other airway adjunct method at the rate of 12 per minute for an adult or 20 per minute for a child.
- Summon help immediately; call a Code.
- Relieve anxiety, fear, and stress through communication and pertinent information.
- Relieve fever if that is the cause.
- Correct respiratory insufficiency with low-flow oxygen administration, good pulmonary toilet, and deep breathing and coughing exercises.
- A sleeping adult's respirations can be less than 10 per minute; if so, use other vital signs to check condition.
- If due to respiratory depressant drugs, such as opiates, barbiturates, and tranquilizers, be prepared to assist respirations or administer mouth-to-mask resuscitation.
- Administer oxygen at 4 to 6 L/min via nasal cannulae as ordered. If client has COPD use 2 L/min.
- Stimulate client to take breaths at least 10 times per minute.
- Rest after period of exertion.
- Relieve fear, anxiety, or stress.
- May be indicative of respiratory compensation for metabolic acidotic state (Kussmaul's pattern).
- Follow physician's orders to treat underlying disease state (e.g., heart failure, increased intracranial pressure).
- Monitor respirations every 15 minutes to hourly, depending on client's status.
- Be prepared to administer CPR if apnea occurs.
- Evaluate cause—one of the indicators that death is approaching.
- Assess for central nervous system (CNS) abnormalities (increased intracranial pressure, meningitis).
- Follow orders to treat for renal failure, septic shock, or diabetic ketoacidosis.

Chapter 10

UNIT 4

Blood Pressure

Nursing Process Data

ASSESSMENT Data Base

- Assess blood pressure initially and whenever client's status changes.
- Assess size of cuff needed for accurate reading.
- Assess the beginning and disappearance of Korotkoff's sounds during a blood pressure reading.
- Assess presence of factors that can alter blood pressure readings.
- Note any changes from prior assessments.

PLANNING Objectives

- To determine whether arterial blood pressure reading is within normal range for the individual client
- To assess condition of heart, arteries, blood vessel resistance, and stroke volume
- To establish a baseline for further evaluation
- To identify alterations in blood pressure resulting from a change in disease condition
- To correlate blood pressure readings with pulse and respirations

IMPLEMENTATION Procedures

- Measuring a Blood Pressure 271
- Palpating Systolic Arterial Blood Pressure 274
- Measuring Lower-Extremity Blood Pressure 275
- Measuring Blood Pressure by Flush Method in Small Infant 276
- Using a Continuous Noninvasive Monitoring Device 276

EVALUATION Expected Outcomes

- Blood pressure readings provide information regarding the overall health status of client.
- Major changes from prior assessments are documented.
- Accurate readings are taken by using correct cuff size and procedure.
- Beginning and disappearance of Korotkoff's sounds during a blood pressure reading are evaluated and documented.
- The presence of factors that can alter blood pressure readings is identified.

- **Critical Thinking Application** 278
- Expected Outcomes 278
- Unexpected Outcomes 278
- Alternative Actions 278

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX[®]-style practice questions and Skill Checklists

Measuring a Blood Pressure

Equipment

- Sphygmomanometer with proper size cuff
- Stethoscope
- Alcohol wipe

Procedure

1. Gather equipment. Clean stethoscope before use. Be sure the cuff is an appropriate size for the client.
 - ▶ **Rationale:** A cuff that is too narrow results in erroneously high readings; a cuff too large may result in false low readings.
2. Provide quiet environment.
3. Perform hand hygiene.
4. Check two forms of client ID.
5. Explain procedure to client. If client is a child, take blood pressure after the other vital signs.
 - ▶ **Rationale:** This intervention may upset the child and affect pulse and respirations.
6. Place client in relaxed reclining or sitting position. (Sitting position with feet on the floor is the preferred position.)
 - ▶ **Rationale:** Blood pressure can vary by position in certain persons.
7. Prepare client for blood pressure reading.
 - a. Assess whether client has smoked or exercised within last 15 minutes. Prepare client for blood pressure reading.
 - b. Allow client to rest several minutes before beginning a reading.
 - c. Client should be instructed not to cross legs or talk during the procedure.
 - ▶ **Rationale:** Client activities and a slouched position yield false high readings.
8. Expose upper part of client's arm and position it with palm upward, arm slightly flexed with the whole arm supported at heart level.
 - ▶ **Rationale:** If arm is below level of heart, the blood pressure reading is higher than normal, and if above the heart, is lower than normal.
9. Choose appropriate size cuff and wrap totally deflated cuff snugly and smoothly around upper part of arm (lower border of cuff 1 in. above antecubital space) with center of cuff bladder over brachial artery (pressure dial at zero).

Stethoscopes—Carriers of Bacterial Infection

A study conducted at the emergency department, Michigan State University, found that 89% of the stethoscopes grew staphylococci and 29% yielded *staphylococcus aureus*. When the stethoscope diaphragms were cleaned (using alcohol swabs), it resulted in immediate reduction in the bacterial count by 94%.

▲ Clean the bell/diaphragm of the stethoscope after taking client's blood pressure.

▲ Blood pressure cuffs are available in various sizes.

▲ Before starting procedure, explain steps to the client.

▲ Wrap blood pressure cuff snugly around upper arm.

10. Locate and palpate brachial artery with fingertips (medial aspect of antecubital fossa).
11. Position stethoscope ear pieces in ears. The ear pieces should tilt slightly forward. ► **Rationale:** Sounds are heard more clearly.
12. Ensure stethoscope hangs freely from ears. ► **Rationale:** Rubbing of stethoscope against an object can cause artifact and inaccurate readings.
13. Close valve on sphygmomanometer pump.
14. Inflate cuff rapidly (while palpating radial artery) to a level 30 mmHg above level at which radial pulsations are no longer felt. ► **Rationale:** This level ensures that

▲ Palpate brachial artery on medial antecubital fossa.

▲ Place stethoscope on medial antecubital fossa.

- cuff is inflated to a pressure exceeding the client's systolic pressure. Slow inflation can yield gaps in pressure readings.
15. Note level and rapidly deflate, waiting 60 seconds. ► **Rationale:** This is enough time for venous congestion to decrease.
16. Place bell (or diaphragm) of stethoscope lightly on the medial antecubital fossa where brachial artery pulsations are located and rapidly inflate cuff to 30 mmHg above point where radial pulse disappeared. ► **Rationale:** This pressure ensures that cuff is inflated to exceed client's systolic pressure.
17. Deflate cuff gradually at a constant rate by opening valve on pump (2–4 mmHg/sec) until the first Korotkoff's sound is heard. This is the systolic pressure, or phase I, of Korotkoff's sounds. ► **Rationale:** Slower or faster deflation yields false readings.
18. Read pressure on manometer at eye level. ► **Rationale:** This ensures accurate reading.
19. Continue to deflate cuff at a rate of 2 to 4 mmHg/sec. Do not reinflate without letting cuff totally deflate. ► **Rationale:** Reinflating cuff results in erroneously high readings.

▲ Bell of stethoscope

▲ Diaphragm of stethoscope.

▲ Read manometer at eye level.

20. Note point at which Korotkoff's sounds begin (phase I) and when they disappear completely (phase V). Disappearance of sounds (phase V) is regarded by the American Heart Association as the best index of diastolic blood pressure in individuals over age 13. If the child is younger than 12 years, the best indication of diastolic pressure is the distinct muffling of sounds at phase IV.

NOTE: Some facilities require that all five phases be recorded.

21. Do not leave cuff inflated for a prolonged period.
 ► **Rationale:** Leaving cuff inflated produces client discomfort.
22. Deflate cuff completely and wait at least 1 to 2 minutes before rechecking the blood pressure. ► **Rationale:** This allows time for blood vessels to return to normal.

NOTE: Check level of comfort of client and level of consciousness (as well as other vital signs) when evaluating blood pressure reading. If all signs and symptoms don't correlate, reevaluate blood pressure.

EVIDENCE-BASED PRACTICE

Forearm Blood Pressure

Statistical analysis has shown that blood pressure taken in the upper arm versus the forearm varies by 14 to 20 mmHg. The two pressures are therefore not interchangeable. If the appropriate size cuff is not available and the forearm has to be used, document the site used.

Source: Schell, K., Bradley, E., Bucher, L., Seckel, M., Lyons, D., Wakai, S., . . . Simpson, K. (2005). Clinical comparison of automatic, noninvasive blood pressure in the forearm and upper arm. *American Journal of Critical Care*, 14(3), 232–241.

Body Positioning Affects Blood Pressure

A study in an ambulatory cardiac clinic found that clients seated in proper position (in a chair with back support, feet on the floor and arms at heart level) had readings 12 to 14 percent lower than those who were seated on exam tables.

Source: Turner, M. (2008). University of Virginia Health System reported by the Academy of Medical-Surgical Nurses.

23. Remove cuff from client's arm.
24. Clean the diaphragm/bell and cuff with an approved antiseptic. If possible, each client should have a disposable

Clinical Alert

When a client moves from recumbent to standing position, systolic pressure can fall 10 to 15 mmHg and diastolic may rise by 5 mmHg.

Blood Pressure Cuff Sizes

- Standard (12–14 cm wide) for the average adult arm.
- Narrower cuff for infant, child, or adult with thin arms.
- For children (younger than 13 years) the bladder should be large enough to encircle the arm completely (100%).
- Wider cuff (18–22 cm) for client with obese arms or thigh pressure readings.

The cuff's inflatable bladder width should be 40% of the circumference of the limb on which it is used. The length of the bladder should be twice its width.

- blood pressure cuff. ► **Rationale:** Studies have shown that cuffs (as well as stethoscopes) can become contaminated.
25. Check that client is comfortable.
26. Compare blood pressure reading with previous recordings.
27. Perform hand hygiene.
28. Record blood pressure readings using two phases: 120/80 where 120 is the systolic (phase I) and 80 is the diastolic (phase V) pressure; or three phases: 130/110/80 where 130 is the systolic (phase I), 110 is the first diastolic (phase IV), and 80 is the second diastolic (phase V) pressure.
29. Repeat this procedure on the opposite arm if this is an initial reading. ► **Rationale:** Clients may have a difference of 10 points between the two arms. For ongoing monitoring, note that BP should be taken on the arm with the higher blood pressure.
- NOTE:** If there is more than 20 points difference, report to physician.

Blood Pressure Classification

Blood Pressure	Systolic	Diastolic
Normal	<120	
Pre high blood pressure	120–139	80–89
Stage I high blood pressure	140–159	90–99
Stage II high blood pressure	160 and higher	100 and higher

Source: National Heart, Lung, and Blood Institute, 2003.

Korotkoff's Sound Phases

Phase I: The pressure level at which the first faint, clear tapping sounds are heard. The sounds gradually increase in intensity as the cuff is deflated. This phase coincides with the reappearance of a palpable pulse (systolic sound).

Phase II: That time during cuff deflation when a murmur or swishing sounds are heard.

Phase III: The period during which sounds are crisper and increase in intensity.

Phase IV: That time when a distinct, abrupt, muffling of sound (usually of a soft, blowing quality) is heard (diastolic sound in children or physically active adults).

Phase V: That pressure level when the last sound is heard and after which all sound disappears (second diastolic sound).

In person with hypertension, an auscultatory gap may be present. This gap is an absence of sounds after the first Korotkoff's sounds appear and then the reappearance of the sounds at a lower level. This condition can be avoided if the brachial artery is palpated first and the cuff is inflated above the level where the pulsations disappear.

Source: American Heart Association.

Clinical Alert

The American Heart Association recommends routine use of the *bell* of the stethoscope for blood pressure (Korotkoff's sounds) auscultation. Studies indicate that when measuring the blood pressure, accuracy is much higher when using the bell (rather than the diaphragm) of the stethoscope.

Source: The Joanna Briggs Institute. (1999). Vital signs. *Best Practice*, 3(3), 3. http://www.joannabriggs.edu.au/pdf/BPISEng_3_3.pdf

Routinely, blood pressure for an acutely ill client should be taken every 1 to 2 hours, and blood pressure for more stabilized clients should be taken every 4 to 8 hours. Clients with severe hypotension or hypertension, with low blood volume, or on vasoconstrictor or vasodilator drugs may require checking every 15 minutes.

EVIDENCE-BASED PRACTICE

Body Position Influence on Blood Pressure

When the client's arm was placed above or below the level of the heart, BP changed by as much as 20 mmHg. Therefore, it is recommended that clients sit with their arm supported horizontally at heart level.

Studies showed that when hypertensive clients crossed their legs while having their BP taken, the systolic readings rose by 9.45 mmHg and the diastolic rose by 3.7 mmHg. Clients should have their feet on the floor during a BP measurement.

Sources: The Joanna Briggs Institute. (1999). Vital signs. *Best Practice*, 3(3), 3. http://www.joannabriggs.edu.au/pdf/BPISEng_3_3.pdf. Foster-Fitzpatrick, L., Ortiz, A., Sibilano, H., Marcantonio, R., & Braun, L. T. (1999). The effects of crossed leg on blood pressure measurement. *Nursing Research*, 48(2), 105–108.

Children's Blood Pressure

Children as young as 3 should have their blood pressure checked to identify possible heart disease. Children under age 3 can have their BP checked by palpation method. The normal systolic BP can be determined by using the formula $80 + 2 \times$ the child's age. A newborn's systolic BP ranges between 50 and 80 mmHg and diastolic between 25 and 55 mmHg.

Palpating Systolic Arterial Blood Pressure

Equipment

Sphygmomanometer with proper size cuff

Procedure

1. Gather equipment. Check that cuff is appropriate size for client. ► **Rationale:** A cuff that is too narrow results in erroneously high readings.
2. Perform hand hygiene.
3. Check two forms of client ID.
4. Explain procedure to client.
5. Place client in relaxed position and support arm at heart level.
6. Wrap cuff snugly and smoothly around the upper part of the arm (1 in. above antecubital space) with center of bladder over brachial artery.
7. Keep pressure level in cuff at zero.

▲ Palpate radial artery while inflating cuff and releasing pressure.

8. Locate radial artery pulsations on cuffed arm.
9. Inflate cuff rapidly (while palpating radial artery), to a level 30 mmHg above level at which radial artery pulsations are no longer felt. ► **Rationale:** This level

ensures that cuff is inflated to a pressure exceeding client's systolic pressure.

10. Continue to palpate artery and release pressure from cuff slowly (2–3 mmHg/sec). The first palpated beat is the systolic pressure. This should be the same point at which the last pulsation was felt during inflation of cuff.
11. Remove cuff and return equipment.
12. Perform hand hygiene.
13. Record systolic blood pressure reading as “palpated systolic pressure.”

Clinical Alert

- Avoid measuring blood pressure in an arm with extensive axillary node dissection (e.g., radical mastectomy) or an arteriovenous fistula (e.g., for dialysis).
- Ultrasound techniques such as using a Doppler stethoscope can be used to measure systolic blood pressure when auscultatory sounds are too faint to be heard.

Measuring Lower-Extremity Blood Pressure

Equipment

- Stethoscope
- Sphygmomanometer with standard or large-size cuff

Procedure

1. Gather equipment.
2. Perform hand hygiene.
3. Check two forms of client ID.
4. Explain procedure to client.
5. Wrap cuff snugly and smoothly around lower leg with cuff's distal edge at the malleolus.
6. Locate either the dorsalis pedis or posterior tibial artery pulsations.
7. Inflate cuff rapidly while palpating foot artery, to a level 30 mmHg above level at which artery pulsations are no longer felt.
8. Place bell (or diaphragm) of stethoscope quickly on pulse site.
9. Deflate cuff slowly (2–4 mmHg/sec) while auscultating sounds over the selected artery.
10. Remove cuff and return equipment.
11. Check to see that client is comfortable.
12. Record readings for first (systolic) and last (diastolic) sounds, noting site and client position.

For Alternative Methods

13. Measure blood pressure in thigh by using a large cuff with bladder placed over posterior mid-thigh and bottom edge above knee. ► **Rationale:** The cuff bladder

▲ Wrap cuff snugly around lower leg and locate dorsalis pedis.

must be directly over the posterior popliteal artery for accurate reading. Listen with stethoscope at popliteal fossa with client in prone position, or supine with knee flexed enough for stethoscope placement.

NOTE: The systolic pressure is 20 to 30 mmHg higher than in the brachial artery. The diastolic pressure is the same.

14. Measure blood pressure in forearm by placing appropriate size cuff around forearm 13 cm from elbow; listen for Korotkoff's sounds over radial artery at wrist.
15. Compare blood pressures measured indirectly in the arm, leg, and thigh to reveal similar values. Measurements may be difficult to obtain in clients with peripheral vascular disease.

Clinical Alert

Traditionally, vital signs provided the basis for assessing the need for and adequacy of sedation in critically ill clients. If the client is on drug therapy, vital signs may not always be a reliable indicator of sedation, because they do not directly reflect the level of consciousness.

Measuring Blood Pressure by Flush Method in Small Infant

Equipment

Sphygmomanometer with appropriate cuff
Elastic bandage
Assistant for observing flush
Well-lighted room

Procedure

1. Gather equipment.
2. Perform hand hygiene.
3. Check two forms of client ID.
4. Wrap blood pressure cuff snugly and smoothly just above wrist or ankle.
5. Elevate extremity above heart level.
6. Wrap elastic bandage firmly around exposed hand or foot.
 - ▶ **Rationale:** Bandage compression empties the veins.
7. Lower extremity to heart level when compression is complete.
8. Inflate cuff rapidly to 200 mmHg.
9. Remove elastic bandage.
10. Deflate cuff slowly (not exceeding 5 mmHg/sec).
11. Instruct assistant to watch for appearance of flush in the extremity distal to cuff. ▶ **Rationale:** An assistant is necessary so that pressure at which flush appears can be precisely noted. This reading more clearly reflects the *mean* blood pressure than the systolic pressure.
12. Document that blood pressure was taken by flush method.

Clinical Alert

Flush pressures are taken on small infants or on adults when unable to auscultate or palpate blood pressure readings.

Using a Continuous Noninvasive Monitoring Device

Equipment

Blood pressure cuff
Display monitor
Readout paper for monitor

Procedure

1. Check two forms of client ID and perform hand hygiene.
2. Gather equipment. Select proper size blood pressure cuff. (Size should be two-thirds the size of upper arm.) Attach the cuff to the air hose by firmly pushing the valve from the cuff into the air hose and twisting to secure fit.
3. Squeeze the air from the cuff.
4. Wrap the cuff securely around the extremity (usually the arm).
 - a. Place cuff over brachial artery with lower edge 1 in. above antecubital fossa.
 - b. If skin is fragile, place single layer of cotton under cuff.
5. Turn power switch ON.

▲ Continuous monitoring of blood pressure is done by attaching cuff to display monitor.

6. Position the extremity at the level of the heart. ▶
Rationale: If arm is below heart level, reading will be higher than normal.
7. Set arterial pressure alarm limits by pushing *Alarm* to ON and set both HIGH and LOW parameters by depressing the *Alarm* button until the parameters read out on the digital display. ▶ **Rationale:** The alarm parameters provide a safety factor by alerting the nurse when the readings exceed the parameters.
8. Test time cycles by turning wheel (found above alarm button) to 1 minute and check for cycling effects. Then, to set automatic cycle time, move the wheel to desired time increments.
9. Press START button for approximately 4 seconds to activate printer for readout of blood pressure; press again to begin reading. Systolic, diastolic, mean arterial pressures, and heart rates can be monitored with this system.
10. Alternate extremities if device is used for a prolonged period of time.
11. Check position of cuff and skin under cuff frequently. ▶
Rationale: It is important to note bruises or skin trauma and to check if position of cuff has changed.
12. Perform hand hygiene.

New Trends—Electronic Stethoscope

A new electronic stethoscope is now available. It measures a client's blood pressure via Bluetooth-Enabled Cardioscan and sends the results directly into the client's computer record for immediate evaluation.

Source: Courtesy 3M® Littman®.

DOCUMENTATION for Blood Pressure

- Two phases of Korotkoff's sounds (e.g., 120/80) and site
- Three phases of Korotkoff's sounds (e.g., 130/110/80) and site
- Response to alternative nursing actions
- Response to position changes
- Document vital signs in chart, in addition to attaching digital read-outs

CRITICAL THINKING Application

Expected Outcomes

- Blood pressure readings provide information regarding the overall health status of the client.
- Major changes from prior assessments are documented.
- Accurate readings are taken by using the correct cuff size and procedure.
- Beginning and disappearance of Korotkoff's sounds during a blood pressure reading are evaluated and documented.
- The presence of factors that can alter blood pressure readings is identified.

Unexpected Outcomes

Blood pressure reading is abnormally high without apparent physiologic cause.

Alternative Actions

- Check if arm was unsupported.
- Check if cuff was too narrow.
- Check if cuff was not snug.
- Check if cuff was deflated too slowly or reinflated during deflation, causing venous engorgement and abnormally high diastolic readings.
- Ask if client has pain, was anxious (white coat syndrome), or had just exercised, eaten, or smoked. Recheck pressure as indicated.
- Check blood pressure on both arms. The normal difference from arm to arm is usually no more than 5 mmHg.
- Check if insufficient rest before assessment.

(continued)

Unexpected Outcomes

Blood pressure reading is very low and there are no significant clinical indicators.

Alternative Actions

- Assess if cuff is too wide.
- Check if client's arm was above heart level.
- Check if inflation was too slow. This reduces intensity of Korotkoff's sounds.
- Assess if Korotkoff's sounds were barely audible. Raise client's arm, and then recheck. Sounds should be louder.
- Identify if stethoscope was misplaced and was not on brachial artery.
- Take blood pressure 3 minutes after client rises from supine to standing if postural hypotension is suspected.

Hypotension (systolic pressure less than 90 mmHg) develops.

- Take all vital signs more frequently (every 15 minutes to 2 hours) until condition has stabilized.
- Place client in supine position with lower extremities elevated 45° and head on pillow.
- Assess cause of hypotension, and notify physician.
- Increase or administer fluids as ordered by physician.
- Observe postoperative clients for signs of bleeding.
- Administer oxygen.

Blood pressure cannot be measured on upper extremity due to casts or other causes of inaccessibility

- Use lower extremity to obtain blood pressures. Systolic pressure in thigh is usually 20 to 30 mmHg higher than in arms, but diastolic pressure is equivalent to arm readings.

Korotkoff's sounds cannot be heard due to hypotension.

- Use the palpation method or ultrasound technique. Client may be candidate for intraarterial (direct method) pressure monitoring.

Hypertension (blood pressure consistently over 140/90 mmHg) develops.

- For clients with severe, acute hypertension, take vital signs more frequently (every 15 minutes to 2 hours) until condition has stabilized.
- Notify physician.
- If client is anxious or excited, institute relaxation techniques to lower blood pressure.
- Allow client to rest after strenuous exercise.
- Relieve pain with reassurance, change of position, and analgesia as ordered by physician.
- For clients with essential hypertension, administer antihypertensive and diuretic drugs as ordered by the physician. Evaluate response by checking blood pressure in reclining, sitting, and standing position. Instruct client in diet therapy, such as low salt, low fat, and inclusion of vitamins and garlic.

Continuous BP monitoring system displays 00 instead of blood pressure reading. (00 indicates the unit is unable to determine parameters.)

- Check cuff placement and size to determine if appropriately placed.

Client's blood pressure continues to be high with a diagnosis of hypertension.

- Evaluate any medication client is taking, including antihypertensive agents.
- Teach client about lifestyle modifications as a cornerstone for managing hypertension.
 1. Lose excess weight.
 2. Maintain a low-fat diet with many fruits and vegetables.
 3. Limit alcohol intake.
 4. Stop smoking.
 5. Exercise regularly.
 6. Include extra minerals in diet: potassium, calcium, and magnesium.
 7. Reduce sodium intake and switch to sea salt.
 8. Practice stress-reducing exercises such as meditation, yoga, tai chi.

GERONTOLOGIC Considerations

Cardiac Status—Changes

- Changes in cardiovascular status with aging are often insidious and may become apparent when system is stressed and there is increased demand for cardiac output (which may occur with illness and hospitalization). Nursing care assessment should focus on client's cardiovascular status, even when diagnosis does not include a cardiac condition.
- Blood pressure measurement should take age into account. If client has severe joint stiffness, pseudohypertension may be present. If this is suspected, raise the cuff pressure above the systolic blood pressure and, if the radial pulse remains palpable, the reading may show 10 to 15 mmHg in error.
- Postural hypotension is common in the elderly (positional drop of less than 20 mmHg); nurses should take note when helping a client out of bed. Hypertension is also common in this age group.
- A rise in blood pressure may be associated with reduced cardiac output, vasoconstriction, increased blood volume, or fluid overload.
- Pulse changes, particularly an irregular pulse, can be related to hypoxia, airway obstruction, or electrolyte imbalance.
- The arteries in elderly clients may feel stiff and knotty due to decreased elasticity. Excessive pressure to site

when taking pulse may obliterate it. The normal rate is 60 to 90 beats/min.

- If pulses are not palpated, the Doppler may need to be used.

Respiratory Status—Changes

- Changes in the respiratory system may be subtle and gradual with the elderly: oxygen saturation is decreased to 93% to 94%; there is often poor cough response and incomplete lung expansion—all of which leads to increased risk of pulmonary infection when the elderly client is hospitalized.
- Slightly irregular breathing patterns are not unusual in the elderly.

Temperature—Changes

- With the elderly, temperature may be as low as 95°F. Because they may be easily dehydrated with increased temperature, nursing assessment should include baseline temperature at admission and continued monitoring during hospitalization.
- Elderly who have acute infections may have a subnormal temperature.
- Increased temperatures can lead to increased metabolism, thus increasing the body's demand for oxygen. This causes the heart to work harder.
- Oral temperatures are the preferred method for obtaining the elderly client's temperature.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LPN/LVNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- Taking vital signs for clients may be assigned to any healthcare worker provided they have been assessed for competency in the procedure. This includes LPN/LVN, CNA, UAP, and EMT.
- The registered nurse must identify parameters for which the healthcare worker is to notify the nurse (i.e., blood pressure above or below a certain reading, pulse rate, or irregular pulse).
- The nurse must provide detailed explanations and/or demonstrate alterations in the procedure or specific methods of obtaining the vital signs to CNA, UAP, or EMTs.
- Obtaining peripheral pulses by use of the Doppler is the responsibility of the RN or LPN/LVN. A CNA or UAP is not responsible for using the Doppler.

- The CNA or UAP may monitor blood pressure using the noninvasive monitoring device; however, the CNA or UAP is not responsible for initiating the procedure or setting the alarms.

Communication Matrix

- Directions must be given to healthcare workers on documentation procedures. Do they complete the graphic record, write the findings on a vital sign sheet at the nurses' desk, or give the results to the nurse?
- The registered nurse must evaluate all abnormal or changed vital signs identified by the healthcare workers. The nurse maintains total responsibility for client care even though someone else performs the task of taking the vital signs.
- The registered nurse must ensure that the healthcare workers know the parameters for reporting unusual vital signs. Periodic checks with the workers may be necessary.

CRITICAL THINKING Strategies

Scenario 1

Mr. Trager (age 92) has been admitted to your unit with a temperature of 103°F, BP 140/90, P 114, and R 30 and labored. He reports a history of 3 days of diarrhea and fever and asks you for something to drink.

- From your analysis of the admission data, determine the following:
 - Appropriate nursing diagnosis in priority for this client.
 - The metabolic effects of fever on pulse and respiration.
 - Age factors that contribute to the existing problem.
- What are the other assessment findings indicative of the diagnosis established from primary admitting data?
- Develop a plan of care for this client.
- Describe the evaluative outcomes for problem resolution.

Scenario 2

Mr. Sondheim is admitted to the hospital with unstable hypertension for evaluation. He has a family history of hypertension and heart disease. The nurse will complete a physical exam and a history.

- What information is missing in the family history that the nurse will want to elicit from the client?
- Which questions regarding lifestyle would be appropriate to ask?
- Which aspects of client teaching would the nurse want to cover before Mr. Sondheim is discharged?

Scenario 3

You are caring for a client, and when checking his vital signs, you are unable to palpate his radial pulse.

- What would be your follow-up intervention?
- When you still cannot find a pulse clear enough to document, what would be your next intervention?
- What parameters of the pulse will you pay attention to when assessing and recording a client's pulse?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

- During a shift assessment, the nurse notes that the client's peripheral pulses are absent. The next intervention would be to
 - Palpate the peripheral pulse.
 - Assess for other signs of circulatory impairment.
 - Notify the physician.
 - Administer O₂ as ordered.
- When a pulse deficit is detected in a client, the nurse would expect that the client is experiencing
 - Premature ventricular beats.
 - Bradycardia.
 - Tachycardia.
 - Heart block.
- A client's temperature remains elevated despite the administration of antipyretic drugs. The first intervention after determining this is to
 - Administer a cool bath.
 - Assess all remaining signs.
 - Request orders for a cooling blanket.
 - Obtain an order for a blood culture.
- Taking a client's blood pressure that has been within normal limits, the nurse gets a reading that is very low without any significant clinical indicators. The appropriate intervention is to
 - Assess if the BP cuff is too narrow.
 - Assess if the BP cuff is too wide.
 - Assess if the client's arm was positioned below heart level.
 - Notify the physician.
- Taking a client's blood pressure, the reading is very altered from previous readings recorded on his chart. The first intervention is to
 - Recheck the blood pressure with different equipment.
 - Notify the physician.
 - Validate the reading with another nurse.
 - Check the client's circulatory status.
- Which of the following breathing patterns of adults are abnormal?

Select all those that apply.

 - Apnea.
 - Rate of 12 to 20 per minute.

3. Hyperpnea.
 4. Biot's.
 5. Bradypnea.
7. Assessing a client newly admitted to the ER, an early sign of shock would be a
1. Pulse rate of 120.
 2. Blood pressure of 110/70.
 3. Respiratory rate of 24.
 4. Fever of 101 degrees F.
8. An accurate graph of blood pressure readings is very important for evaluation. For taking a blood pressure reading, the nurse should apply the cuff to the
1. Same arm, while the client is in the same position each time.
 2. Right arm, while the client is in a sitting position.
 3. Left arm, while the client is in a left lateral recumbent position.
 4. Left arm, while the client is in a supine position.
9. When using the tympanic route for taking a temperature, what is the rationale for directing the probe toward the tympanic membrane?
1. Pressure seals the ear canal.
 2. The probe will not record unless it is near the tympanic membrane.
 3. This method records the core temperature.
 4. This method provides better access to the ear canal.
10. The RN is in charge of the team assigned to care for six clients for morning shift. The staffing includes the RN, an LVN, and two Nursing Assistants. All clients need to have vital signs taken as part of their shift assessment. How will the RN best assign these duties?
1. The LVN should do all of the vital signs.
 2. The RN and LVN should split the vital signs.
 3. The RN should assign vital signs to the two Nursing Assistants.
 4. The RN should do all of the vital signs.
-

11

Physical Assessment

LEARNING OBJECTIVES

1. Outline the essential elements obtained from a health history.
2. List the four techniques of physical assessment.
3. Demonstrate six steps of the focus assessment.
4. Describe the abnormal manifestations associated with each specific body system for one client with whom you are familiar.
5. List four normal responses that determine the client's level of consciousness.
6. Describe four abnormal responses in pupil assessment.
7. State three assessment components of the skin.
8. Describe normal and abnormal lung sounds.
9. Describe the assessment techniques use in an abdominal assessment in sequential order.
10. Outline the steps of breast assessment.
11. Identify the four areas for heart sound auscultation.
12. List at least five essential elements included in a mental status assessment.
13. Compare and contrast three elements of the antepartum obstetrical assessment.
14. Relate the elements of a "9" score on the Apgar test.
15. Describe basic components of a pediatric physical assessment.

NCLEX® Review Questions	333

ASSESSMENT

Basic assessment discussed in this chapter can be performed in less than 10 minutes using a stethoscope, penlight, reflex hammer, your hands, and observational skills. Although you may not be able to perform assessment rapidly at first, you will have many opportunities to practice your skills, because every client should be assessed at least once a shift.

While interviewing the client, note such characteristics as hair, skin, posture, facial expression, and body language—in other words, the general appearance of the client. Then

proceed with a head-to-toe systems assessment using the four techniques of assessment: inspection, palpation, percussion, and auscultation. This IPPA sequence is used for all systems except for the abdominal assessment, which requires auscultation *before* palpation and percussion. Palpation and percussion are performed using fingers and hands to assess abnormalities of sound, such as vocal fremitus, enlarged organs, organ displacement, and chest expansion. Auscultation is accomplished by using a stethoscope to listen to breath, heart, and bowel sounds. Observe the client's response as each system is assessed.

Equipment

The stethoscope is the primary instrument used for assessment. Remember that any movement of the tubing or chest piece by clothing or hands can cause extraneous noise that obliterates the sounds you want to hear. The diaphragm piece should be applied firmly to the skin. It enhances high-pitched sounds (breath sounds, normal heart sounds, bowel sounds). The bell piece should be placed very lightly to pick up low-pitched sounds, such as vascular sounds and abnormal heart sounds. If the bell is pressed firmly, it stretches the skin and acts as a diaphragm. Other instruments used include the penlight, reflex hammer, ophthalmoscope, otoscope, and tuning fork.

HEALTH HISTORY

A total client assessment begins with a nursing health history. Using open-ended questions such as “Tell me about . . .,” collect data about past health conditions, current problems, and present needs. The information is obtained through objective (observed) and subjective (stated by client) data collection.

Information obtained from the interview and the physical assessment constitutes the basis for identifying nursing diagnoses and establishing the individualized client care plan. A complete health history includes the following elements:

- *Biographic information*: age, sex, educational level, marital status, living arrangements.
- *Chief complaint*: condition that brought client to healthcare facility; reason for visit; any recent changes.
- *Present health status or illness*: onset of the problem; clinical manifestations, including severity of symptoms; pain characteristics if present.
- *Health history*: general state of health, past illnesses, surgeries, hospitalizations, allergies, over the counter (OTC) medications, herbal supplements, current medications, and general habits such as smoking, alcohol consumption, or recreational drug use.

- *Family history*: age and health status of parents, siblings, and children; cause of death for immediate family members.
- *Psychosocial factors, lifestyles*: cultural beliefs that influence health management; religious or spiritual beliefs.
- *Nutrition*: dietary habits, preferences, or restrictions.
- *Domestic violence*: (The Joint Commission requirement).

NURSES' ROLE

The nurses' role in obtaining a health history and completing a physical assessment has expanded dramatically over the last 40 years. Today nurses must be adequately instructed to perform a total assessment, as well as a focus assessment, including the use of equipment, formerly the domain of physicians only. The skill of performing a physical assessment must be practiced repeatedly to acquire expertise.

EXAMINATION TECHNIQUES

Inspection

Observe the client while facing him or her in the bed or chair. Observe the client's skin color and texture; check for lesions and hair distribution. Look at overall body structure. If the client can be out of bed, observe gait and stance. Note all parts of the body as the examination proceeds. Inspection also evaluates verbal and behavioral responses and mental status.

Palpation

Obtain information by using the hands and fingers to palpate. A light or deep palpation depends on the area being palpated. The palmar surface of fingers and finger pads are used to determine position of the organs, size and consistency, fluid accumulation, pain, and masses. The ulnar surface of the hand is used to distinguish vibration and temperature. The moisture and warmth of the skin can also be determined during palpation.

▲ Inspection.

▲ Percussion.

▲ Palpation.

▲ Auscultation.

Percussion

With percussion, sound waves are produced by using the fingers as a hammer. Place the interphalangeal joint of the middle finger on the skin surface of the nondominant hand. Using the tip of the middle finger of the dominant hand, strike the placed finger. Vibration is produced by the impact of the fingers striking against underlying tissue. Sound or tone of the vibration is determined by body area or organ percussed. Normal lung areas

produce a resonance sound; liver sounds are dull, and a flat sound is heard over muscle.

Auscultation

Place the stethoscope on the client's bare skin to listen for the presence and characteristics of sound waves. The bell of the stethoscope is used to detect low-pitched sounds; the diaphragm detects high-pitched sounds. Note variations in intensity, pitch, duration, and quality.

Assessment: Focus (Shift)

A full, comprehensive physical assessment is completed upon admission. A focus assessment, also called a bedside or shift assessment, is performed at the beginning and ending of the shift and concentrates on vital assessment parameters; it tracks changes or problem-oriented assessments from shift-to-shift

and should take no more than 5 minutes to complete. Several activities in the assessment can be completed at the same time. Usually, it is individualized to fit the client's condition, diagnosis, and level of acuity.

▲ Step 1

Step 1

Evaluate the client's level of consciousness, eye contact and responsiveness, color and texture of the skin, and any IVs, dressings, or tubes visible. Ask appropriate questions to determine orientation to time and place. Establish the nurse–client relationship at this time.

▲ Step 2

Step 2

Assess vital signs. While taking the client's pulse, feel skin temperature and moisture. Check bilateral radial pulses. Observe for edema in face or neck. Individualize the assessment; for example, with a neurologic condition, check pupils.

▲ Step 3

Step 3

Remove client's gown or raise gown. Use stethoscope to listen to heart sounds, apical pulse and breath sounds bilaterally. Observe breathing patterns, symmetry of chest movement, shape of chest, and depth of respirations. Check for skin turgor.

▲ Step 4

Step 4

Auscultate abdomen for bowel sounds. Use palpation and percussion techniques only if appropriate to diagnosis. Palpate bladder if necessary (based on output). If catheter is in place, observe urinary output for color, odor, consistency, and amount.

▲ Step 5

Step 5

Assess lower extremities for warmth, color, moisture, presence of pedal or popliteal pulses, muscle tone, and sensation. Assess for pedal edema or general edema in the lower extremities. Check traction or casted areas for skin breakdown, alignment, and placement.

▲ Step 6

Step 6

Have client turn onto side or sit at edge of bed. Assess posterior lung fields and symmetry of chest movement with inspiration. Assess skin for pressure areas, particularly coccyx and heels when client returns to side-lying position. Evaluate client's ability to move in bed.

ASSESSMENT OF THE NERVOUS SYSTEM

- Level of Consciousness
 - Glasgow Coma Scale
 - Respiratory Assessment
 - Cranial Nerves
 - Spinal Nerves
- Pupil Assessment
- Motor Function Assessment
- Coordination Assessment
- Reflex Assessment
- Sensory Function
- Vital Signs

An understanding of the function of each lobe of the brain allows the nurse to be able to identify potential client problems when an injury occurs to that portion of the brain.

The brain comprises three segments: the brainstem, cerebrum, and the cerebellum. There are 12 cranial nerves, which are discussed later in this chapter, and 31 pairs of spinal nerves with dorsal and ventral roots.

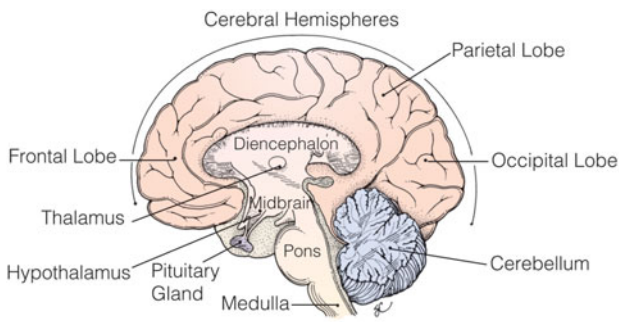

The brainstem is divided into four sections: The *diencephalon* comprises the thalamus, which screens and relays sensory impulses to the cortex, and the hypothalamus, which regulates the autonomic nervous system, stress response, sleep, appetite, body temperature, water balance, and emotions. The *midbrain* is

responsible for motor coordination and conjugate eye movements. The *pons* controls involuntary respiratory reflexes and contains projection tracts between the spinal cord, medulla, and brain. The *medulla* contains cardiac, respiratory, vomiting, and vasomotor centers. In addition, all afferent and efferent nerve tracts must pass between the spinal cord and brain through the medulla.

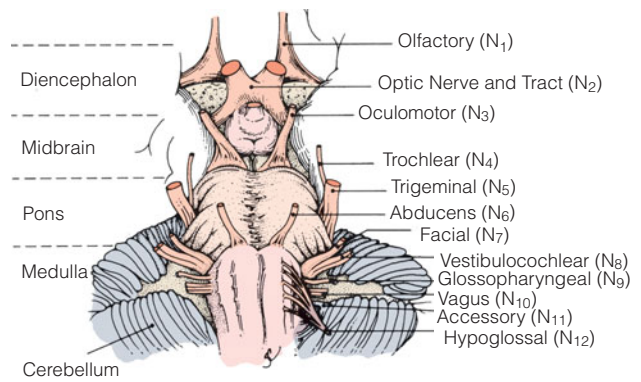

The cerebral hemispheres have an outer layer formed by cellular gray matter, called the cerebral cortex. The two cerebral hemispheres are divided into four major lobes. The frontal lobe controls emotions, judgments, motor function, and the motor speech area. The parietal lobe integrates general sensations; interprets pain, touch, and temperature; and governs discrimination. The temporal lobe contains the auditory center and sensory speech center. The occipital lobe controls the visual area. The cerebellum coordinates muscle movement, posture, equilibrium, and muscle tone.

The 12 cranial nerves are summarized in Table 11-2. The 2nd through 12th nerves arise from the brainstem. The cranial nerves are 12 pairs of parasympathetic nerves with their nuclei along the brainstem.

The neurologic examination begins with the initial contact with the client. Evaluation of verbal responses, movement, and sensation is carried out throughout the examination. In addition, functions of the cerebrum, cerebellum, cranial nerves, spinal cord, and peripheral nerves are assessed. The level of consciousness is the most sensitive and reliable index of cerebral function.

▲ Lobes of the brain.

▲ Brain segments and cranial nerves.

TABLE 11-1 Glasgow Coma Scale

A. Motor response.	Points
1. Obeys a simple command	6
2. Localizes painful stimuli; attempts to remove offending stimulus; lack of obedience	5
3. Withdrawn—moves purposelessly in response to pain	4
4. Abnormal flexion—decorticate posturing	3
5. Extensor response—decerebrate posturing	2
6. No motor response to pain	1
B. Verbal response.	Points
1. Oriented—to time, place, and person	5
2. Confused conversation; disorientation in <i>one</i> or more spheres	4
3. Inappropriate or disorganized use of words (cursing); lack of sustained conversation	3
4. Responds with incomprehensible sounds	2
5. No verbal response (Record T if an endotracheal or tracheostomy tube is in place)	1
C. Eye opening.	Points
1. Spontaneous when a person approaches	4
2. In response to speech	3
3. Only in response to pain	2
4. Eyes do not open, even to painful stimuli (Record C if eyes are closed by swelling)	1

NOTE: This scale is a tool for assessing a client’s response to stimuli. Scores range from 3 (deep coma) to 15 (normal). Add numbers to get a total score.

TABLE 11-2 Cranial Nerves and Their Function

Cranial Nerve	Function	Testing Cranial Nerves
I Olfactory	Sensory nerve	Recognizes odor in each nostril separately (e.g., coffee)
II Optic	Sensory nerve: conducts sensory information from the retina	Demonstrates visual acuity: can read newsprint
III Oculomotor	Motor nerve: controls four of the six extraocular muscles; raises eyelid and controls the constrictor pupillae and ciliary muscles of the eyeball	Responds to light: pupils constrict; moves eyes medially; elevates upper eyelid

TABLE 11-2 Cranial Nerves and Their Function (Continued)

Cranial Nerve	Function	Testing Cranial Nerves
IV Trochlear	Motor nerve: controls the superior oblique eye muscle	Move eyes to the right, up then down, and to the left
V Trigeminal	Mixed nerve with three sensory branches and one motor branch: the ophthalmic branch supplies the corneal reflex	Demonstrates normal facial sensation; clenches teeth with no lateral jaw deviation; blinks as wisp touched to cornea
VI Abducens	Motor nerve: controls the lateral rectus muscle of the eye	Moves eyes laterally
VII Facial	Mixed nerve: anterior tongue receives sensory supply, motor supply to glands of nose, palate lacrimal submaxillary, and sublingual; motor branch supplies hyoid elevators and muscles of expression and closes eyelid	Elevates eyebrows; puffs cheeks; recognizes tastes (sugar, salt)
VIII Acoustic	Sensory nerve with two divisions: hearing and semicircular canals	Hears whisper separately with each ear
IX Glossopharyngeal	Mixed nerve: motor innervates parotid gland; sensory innervates auditory tube and posterior portion of taste buds	Demonstrates gag reflex to tongue blade when touched to back of tongue
X Vagus	Mixed nerve: motor branches to the pharyngeal and laryngeal muscles and to the viscera of the thorax and abdomen; sensory portion supplies the pinna of the ear, thoracic, and abdominal viscera	Same as IX
XI Accessory	Motor nerve: innervates the sternocleidomastoid and trapezius muscles	Shrugs shoulders
XII Hypoglossal	Motor nerve: controls tongue muscles	Sticks tongue out in midline without deviation

Assessment: Neurologic

Assessment	Normal Responses	Abnormal Responses
Level of Consciousness		
Apply Glasgow Coma Scale Evaluate verbal responses and orientation If client seems awake and alert but does not respond properly, check to see if client is blind, deaf, or speaks another language	A score of 15 is evaluated as normal Alert Mood appropriate to situation Responds to verbal command Answers questions appropriately Speaks clearly Oriented to time, person, place, and purpose Recent and remote memory intact	A score under 15 is not normal; a comatose client is 7 or less Drowsy Difficult to awaken Unable to give date, month, place Irritable Memory defect Difficulty finding words Does not recognize family Does not respond to own name
Observe and test symmetry of motor responses on both sides of body	Eyes open Follows command to stick out tongue, squeeze fingers, move extremities	Eyes closed Does not follow directions to stick out tongue, squeeze fingers, or move extremities
Exert pressure on nailbed with pen Apply pressure to supraorbital ridge Pinch Achilles tendon Test each side independently	Responds to painful stimuli by reaching out or trying to stop pressure	Does not localize or withdraw from painful stimuli or withdraws abnormally Assumes <i>decorticate posturing</i> (legs extended; feet extended with plantar flexion; arms internally rotated and flexed on chest): may

(continued)

Assessment: Neurologic (Continued)

Assessment

Decorticate posturing—abnormal flexor posturing

Decerebrate posturing—abnormal extensor posturing

Abnormal Responses

be due to lesion of corticospinal tract near cerebral hemisphere
 Assumes *decerebrate posturing* (arms stiffly extended and hands turned outward and flexed; legs extended with plantar flexion): may be due to lesion in diencephalon, pons, or midbrain

Assumes *flaccid posturing* (no motor response): may be due to extreme brain injury to motor area of brain

Involuntary movements

Choreiform (jerky and quick):

present in Sydenham's chorea

Athetoid (twisting and slow):

present in cerebral palsy

Tremors: hyperthyroidism, cerebellar ataxia, parkinsonism

Spasms: cord-injured clients

Seizures: brain injury, heat stroke, electrolyte imbalance

Respiratory Assessment

Clients with neurologic damage are at risk for respiratory complications

Respirations are normal
 Oxygen levels are normal

Asterixis: metabolic encephalopathy due to liver or kidney failure

Respiratory complications may include traumatic or spinal cord injury

Cranial Nerves

See Table 11-2 for specific functions and testing.

Spinal Nerves

Thirty-one pairs of peripheral nerves that originate on the spinal cord from anterior roots. Each pair of spinal nerves is related to a specific region of the body.

▲ Spinal nerves.

Assessment	Normal Responses	Abnormal Responses
<p>Pupil Assessment Observe pupils using penlight and pupil gauge or an automated pupillometer <i>Size of pupils</i></p>	Diameter: 1.5–6 mm	<p>Unilateral dilation: sign of third cranial nerve involvement Bilateral dilation: sign of upper brainstem damage Unilateral dilation and nonreactive: sign of increased intracranial pressure (ICP) or ipsilateral oculomotor nerve (III) compression from tumor or injury</p>
<i>Shape of pupils</i>	Round and midposition	<p>Midposition and fixed: sign of midbrain involvement Pinpoint and fixed: sign of pontine involvement or opiate effect</p>
<i>Equality of pupils</i>	Equal	Unequal: sign that parasympathetic and sympathetic nervous systems are not in synchronization
Observe reaction to light by using penlight in darkened room	Pupil constricts promptly	Sluggish reaction or failure to react to light: early warning of deteriorating condition or elevated ICP
		
▲ Move light toward client's eye from side position.		
Open eyelid being tested; cover opposite eye		Light reflex is the most important sign differentiating structural (cranial involvement) from metabolic coma due to extracranial cause (e.g., diabetic coma), which does not alter light reflex
<p>Observe consensual light reflex Hold both eyelids open Shine light into one eye only Observe opposite eye</p>	Both pupils constrict	Pupil does not constrict: sign that connection between brainstem and pupils is not intact
Check accommodation (ability of lens to adjust to objects at varying distances)	Lens can adjust	When the lens thickens (often in the fifth decade of life) accommodation can be limited

(continued)

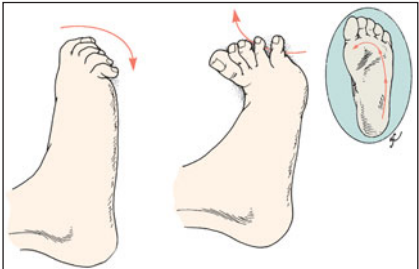

Assessment: Neurologic (Continued)

Assessment	Normal Responses	Abnormal Responses
<p>Motor Function Assessment Assess bilateral muscle strength Test hand grip by asking client to squeeze your fingers Rate muscle strength from 0 to 5, with 0 indicating no muscle contraction and 5 (normal) indicating full range of motion against gravity with full resistance</p>	Muscle strength is equal bilaterally	Absent or weak muscle function on one side may be sign of hemiplegia (paralysis of one side of the body); or hemiparesis (weakness on one side); paraplegia (paralysis of the legs or lower part of the body); tetraplegia or quadriplegia (paralysis of arms and legs)
<p>Test arm strength by asking client to close eyes and hold arms out in front with palms up</p>	Maintains position for 20–30 seconds	Cannot maintain position—down drifts one extremity
		
<p>▲ Test client's hand grip.</p>		
<p>Muscle Grading Scale Muscle Graduations</p>	<p>Description</p>	
5 – Normal	Complete range of motion against gravity with full resistance	
4 – Good	Complete range of motion against gravity with some resistance	
3 – Fair	Complete range of motion against gravity	
2 – Poor	Complete range of motion with gravity eliminated	
1 – Trace	Evidence of slight contractility, no joint motion	
0 – Zero	No evidence of contractility	
<p>Assess flexion and extension strength in extremities Stand in front of client, place your hand in front of client, and ask client to push your hand away</p>	Equal response in both arms	Unequal response in arms Asymmetrical response Inability to perform movements
<p>Place your hand on client's forearm and ask client to pull arm upward</p>		

Assessment	Normal Responses	Abnormal Responses
<p>Position client's leg with knee flexed and foot resting on bed; as you try to extend leg, ask client to keep foot down</p> <p>Place one hand on client's knee and one hand on client's ankle; ask client to straighten leg as you apply resistant force to knee and ankle</p>	Equal response in both legs	Unequal response in legs
<p>Assess muscle tone</p> <p>Flex and extend client's upper extremities to assess how well client resists your movements</p>	Client resistance is apparent	<p>Increased resistance: sign of increased muscle tone from muscle rigidity or spasticity in upper motor neuron (UMN) lesions; for example, as with cerebrovascular accident (CVA) and parkinsonism</p> <p>Decreased resistance to leg extension and arm flexion in UMN lesion (CVA)</p>
<p>Flex and extend client's lower extremities to assess resistance</p>		Weakness in lower motor neuron (LMN) and cerebellar lesion
Coordination Assessment		
<i>Hand coordination</i>		
<p>Ask client to pat both thighs as rapidly as possible</p> <p>Ask client to turn hands over and back in quick succession</p> <p>Ask client to touch thumb with each finger in rapid succession—repeat with other hand</p>	Client able to perform coordinated movements on request: hand, foot, hand and leg positioning	<p>Uncoordinated movements: may be due to cerebellum or basal ganglia involvement</p> <p>Clumsy movement with cerebellar involvement</p>
<i>Foot coordination</i>		
<p>Place your hands close to client's feet</p> <p>Ask client to tap your hands alternately with the balls of feet</p>		
<i>Hand positioning coordination</i>		
<p>With client's eyes open, extend your hand in front of client's face</p> <p>Ask client to touch nose with index finger several times in rapid succession</p> <p>Repeat test with client's eyes closed</p>		<p>Tremor as nose is approached indicates cerebellar involvement</p> <p>Inability to perform task with eyes closed: may be due to loss of positioning sense</p>
<i>Leg positioning coordination</i>		
<p>Ask client to put heel on opposite knee and to slide heel down leg to foot</p>		
Reflex Assessment		
<i>Blink reflex</i>		
<p>Hold client's eyelid open</p> <p>Approach client's eye unexpectedly from side of head</p> <p>Complete corneal touch</p>	Eyes close immediately	Absence of blink response; eyelid continuously in open position: due to fifth or seventh cranial nerve (pons) involvement; blindness
<i>Gag and swallow reflex</i>		
<p>Open client's mouth and hold tongue down with tongue blade</p> <p>Touch back of pharynx on each side with applicator stick</p>	Gag and swallow reflex present	Absence of gag and swallow reflex; inability to swallow food or liquid: due to ninth or 10th cranial nerve (medulla) involvement

(continued)

Assessment: Neurologic (Continued)

Assessment	Normal Responses	Abnormal Responses
<p>Plantar reflex</p> <p>Run top of pen along outer lateral aspect from heel to little toe of client's foot</p> <p>Continue tracing a line across ball of foot toward great toe</p>  <p>▲ Testing plantar reflex.</p> <p>Deep tendon reflex</p> <p>Ask client to relax</p> <p>Position limb to be assessed so that muscle is somewhat stretched</p> <p>Using reflex hammer, strike tendon quickly</p> <p>Assess according to scale</p>	<p>Toes are pointed down</p>  <p>▲ Normal plantar reflex.</p> <p>Biceps reflex: flexion at elbow and contracting of biceps muscle</p> <p>Triceps reflex: extension at elbow and contraction of triceps muscle</p> <p>Patellar reflex: extension of knee and contraction of quadriceps</p>	<p>Babinski response: great toe dorsiflexes; other toes fan on foot of paralyzed side in CVA, and bilaterally in spinal cord injury (SCI)</p>  <p>▲ Babinski response (abnormal).</p> <p>Absent or diminished: sign of cervical cord (C-5 or C-6) involvement</p> <p>Absent or diminished: C-7 or C-8 cord involvement</p> <p>Absent or diminished: L2-3 or L3-4 cord involvement</p>
<p>Grading Scale</p> <p>4+ Hyperactive or exaggerated</p> <p>3+ More brisk than usual but not indicative of disease state</p> <p>2+ Average or normal</p> <p>1+ Slightly diminished, low normal</p> <p>0 No response</p>		<p>Indicates upper motor neuron (UMN) lesion or SCI</p> <p>Seen with lower motor neuron (LMN) lesion</p>
<p>Sensory Function</p> <p>Assess superficial sensations</p> <p>Pain</p> <p>Ask client to close eyes</p> <p>Stroke or touch skin with cotton-tipped applicator, alternating cotton tip with wooden end</p> <p>Ask client to distinguish sharp and dull pain</p>	<p>Ability to distinguish between sharp and dull sensations</p>	<p>Alterations in pain or temperature sensations: indicate lesion in posterior horn of spinal cord or spinothalamic tract of cord</p>
<p>Temperature</p> <p>Fill two test tubes with water, one hot, one cold</p> <p>Ask client to close eyes and touch client's skin with test tubes</p>	<p>Ability to distinguish between hot and cold</p>	
<p>Touch</p> <p>Ask client to close eyes</p> <p>Stroke cotton wisp over client's skin</p>	<p>Ability to identify light touch— equal bilaterally</p>	<p>Anesthesia = loss of light touch</p> <p>Analgesia = absence of sense of pain</p> <p>Hypalgesia = decreased pain sensation</p> <p>Hyperalgesia = exaggerated sensitivity to pin prick (pain)</p>

Assessment	Normal Responses	Abnormal Responses
<p>Positioning Ask client to close eyes Grasp client's finger with your thumb and index finger Move client's finger up and down Ask client to identify direction finger is moving. Repeat with great toe.</p>	<p>Ability to identify position or mimic position with other hand</p>	<p>Inability to determine direction of movement: may be due to posterior column or peripheral nerve disease</p>
<p>Vital Signs Temperature Apical/radial pulses Respiration Blood pressure Assess temperature If client is semiresponsive or nonresponsive, take rectal, axillary, or tympanic temperature If rectal temperature is contraindicated or there are signs of increased ICP, use alternate method.</p>	<p>Ability to maintain normal body temperature (approximately 98.6°F, or 37°C)</p>	<p>Inability to maintain normal temperature: may be due to damage to hypothalamus No sweating below level of injury; due to spinal cord injury Hypothermia</p>
<p>Assess apical and radial pulses Note character of pulses Count heart rate Count radial pulse rate</p>	<p>Regular rhythm Rate 60–100 beats/min Apical and radial rates are equal</p>	<p>Fast heart rate due to decreased blood volume, arrhythmia, heart failure, fever, medulla dysfunction Irregular rhythm with premature beats due to hypoxia, cardiac irritability, or electrolyte imbalance Pulse deficit due to premature beats or ineffectual cardiac contraction.</p>
		
<p>▲ Assess client's apical pulse.</p>		
<p>Assess respiration Assess rate and pattern of breathing</p>	<p>Regular rate: 12–20 breaths per minute</p>	<p>Cheyne–Stokes (rhythmic increase in depth of breathing followed by period of apnea) may be due to deep cerebral or cerebellar lesion or condition altering cerebral perfusion Central neurogenic (sustained) hyperventilation due to upper brainstem involvement Ataxic (Biot's) breathing unpredictably irregular, due to lower brainstem involvement</p>
<p>Monitor arterial blood gases if signs of respiratory imbalances occur</p>	<p>pH: 7.35–7.45 PCO₂: 35–45 mmHg HCO₃: 22–26 mEq/L</p>	<p>Alterations in pH and PCO₂ values indicate respiratory imbalances: pH below 7.35 and PCO₂ above 45: sign of respiratory acidosis (hypoventilation) pH above 7.45 and PCO₂ below 35: sign of respiratory alkalosis (hyperventilation) HCO₃ above 26 indicates metabolic compensation for chronic respiratory acidosis (hypoventilation)</p>

(continued)

Assessment: Neurologic (Continued)

Assessment	Normal Responses	Abnormal Responses
<p>Assess blood pressure</p> <p>Position neurologic clients in low- to semi-Fowler's position</p>	<p>Normal pressure (range <120/<80)</p>	<p>Systolic blood pressure rises with diastolic pressure remaining same (widening pulse pressure): sign of increased intracranial pressure</p> <p>Blood pressure over 140/90 is a sign of stage 1 hypertension</p> <p>Blood pressure below 90/60 is a sign of hypotension</p>

Korotkoff's Sound Phases for Blood Pressure

Phase I: The pressure level at which the first faint, clear tapping sounds are heard. The sounds gradually increase in intensity as the cuff is deflated. This phase coincides with the reappearance of a palpable pulse (systolic sound).

Phase II: That time during cuff deflation when a murmur or swishing sounds are heard.

Phases III: The period during which sounds are crisper and increase in intensity.

Phase IV: That time when a distinct, abrupt, muffling of sound (usually of a soft, blowing quality) is heard (diastolic sound in children or physically active adults).

Phase V: That pressure level when the last sound is heard and after which all sound disappears (second diastolic sound).

Blood Pressure Classification

Blood Pressure	Systolic	Diastolic
Normal	<120	<80
Pre high blood pressure	120–139	80–89
Stage I high blood pressure	140–159	90–99
Stage II high blood pressure	160 and higher	100 and higher

ASSESSMENT OF THE HEAD AND NECK

- Eye Assessment
- Ear Assessment
- Nose Assessment

- Mouth and Lips Assessment
- Neck Assessment

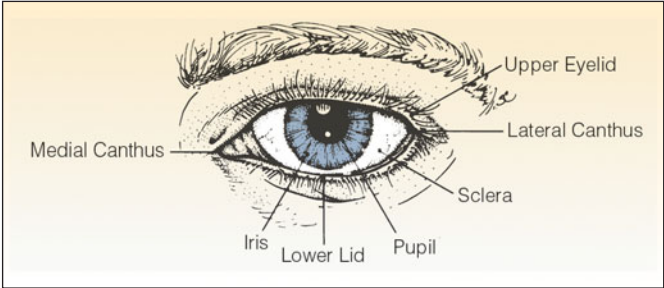

▲ Bones that form the skull.

The names of the regions of the head are derived from the bones that form the skull. Knowing the names of the bones and regions of the skull can assist in describing the location of the physical findings.

The size and shape of the head should be noted, as well as the placement of the eyes and facial structures. Note any lesions or discharge from the ears; if there are any lesions of the lips or mouth, assess further.

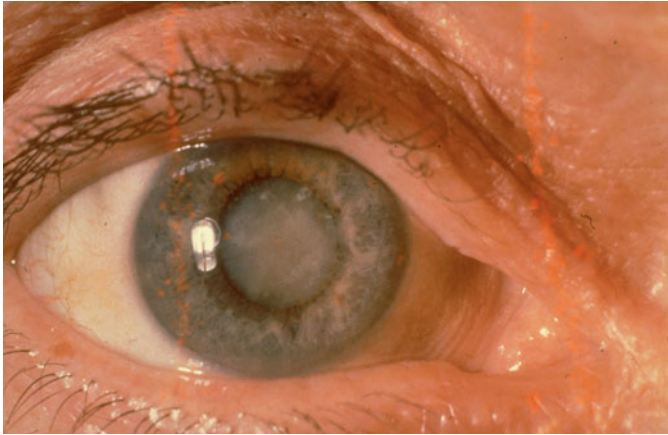

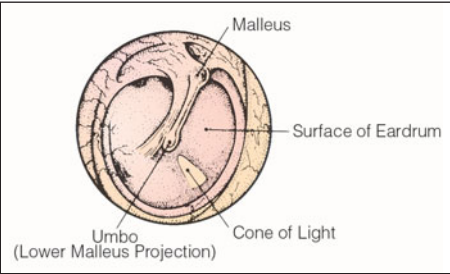

When palpating the neck, note the head position and neck muscles. Using your fingers, palpate the lymph nodes in the neck to determine swelling. Check the thyroid gland in the front of the neck, and if enlarged, note that this condition requires further assessment.

Assessment: Head and Neck

Assessment	Normal	Abnormal
Eye Assessment		
Note visual acuity by observing client performance of activities of daily living	Adequate performance of activities of daily living	Age-related macular degeneration (AMD)
Factors influencing visual acuity include client's previous status and age	Appropriate responses to environment	Hyperopia (farsightedness)
Note exact location, size, and color of any external lesions	No external lesions	Myopia (nearsightedness)
Palpate for mobility and firmness		Cataract (opacification of the lens)
		Enucleation (loss of an eye): may have prosthesis in place
		Circumocular ecchymosis: may be sign of basal skull fracture
		Xanthelasma (small, yellowish, well-circumscribed plaques): may appear on eyelids of clients with lipid disorders. <i>Example:</i> atherosclerosis
		
▲ Anatomy of the eye.		
Note equality of eyelid movement	Eyelids are equal in movement	Ptosis (paralytic drooping of the upper eyelid)
Note color, consistency, amount, and origin of discharge from eyes	No discharge	Sty or hordeolum
Note internal lesions	No internal lesions	Thick white discharge; may be due to conjunctivitis
Assess differences between pupil size and reaction	Both pupils are the same size	Conjunctival or ciliary injection (dilatation of the blood vessels)
Note presence of hemorrhage		Anisocoria (indicates unequal pupil size): may be indicative of neurologic trauma or deficit
		Corneal edema (very soft, movable mass that looks like raw egg white): frequently occurs in clients who have increased intracranial pressure
		Arcus senilis (partial or complete whitish circle near the outer edge of the cornea); usually due to aging; does not affect vision

(continued)

Assessment: Head and Neck (Continued)

Assessment	Normal	Abnormal
		
<p>▲ Assess pupil size and reaction.</p>		<p>▲ Cataract: Opacity of the crystalline lens.</p>
<p>Observe for opacity of lens— cataract</p>	<p>No opacity noted</p>	<p>Cataract present—one or both eyes</p>
Ear Assessment		
<p>Note auditory acuity by asking client to indicate if he or she hears normal sounds as you make them</p>	<p>Adequate responses to normal sounds Auditory changes due to aging</p>	<p>Deafness or impaired hearing; excess cerumen in auditory canal Abnormal sounds in the ears (ringing or buzzing) may be caused by ototoxic drugs</p>
<p>Note exact size, color, and location of any external lesions Palpate lesions for mobility and firmness</p>	<p>No external lesions</p>	<p>Battle’s sign (ecchymosis behind the ear): may be sign of basilar skull fracture</p>
<p>Examine tympanic membrane using an otoscope</p>	<p>Membrane intact, flat, gray, with no scarring</p>	<p>White patches show prior infections: yellow or red patches may be infection of middle ear Bulging membrane may indicate increased pressure in middle ear Depressed membrane may indicate vacuum due to blocked eustachian tube.</p>
		
<p>▲ Anatomy of the tympanic membrane (ear drum).</p>		
<p>Note color, quantity, and consistency of any discharge from the ears Test clear fluid for glucose using a Labstix</p>	<p>No discharge Wax buildup Glucose test negative</p>	<p>Redness, swelling, and pain may be signs of otitis externa Cerebrospinal fluid leak: may be due to head injury. If drainage is blood and CSF, it will develop a “halo” with a reddish area in the center surrounded by a whitish circle if placed on white material Perforation of tympanic membrane: serosanguineous or purulent drainage Glucose test of clear drainage is positive if CSF</p>

Assessment	Normal	Abnormal
------------	--------	----------

▲ Two techniques for positioning and inserting an otoscope into ear before viewing.

Nose Assessment

Note any **structural changes** in the nose by observing client breathing. Gently occlude one nostril at a time; ask client to breathe through the nonoccluded nostril.

Note color, quantity, and consistency of any **discharge** from the nose.

Regular breathing with mouth closed
Breathing through nonoccluded nostril

Minimal discharge

Breathing through the mouth only; furuncles may occlude breathing
Obstruction in the nose due to deviated nasal septum, swelling of the nasal turbinates, or excessive mucus secretions
Cerebrospinal fluid leak (fluid tests positive for glucose with Labstix)
Copious, watery-to-thick, mucopurulent discharge: may be due to acute rhinitis
Excessive buildup of mucous secretions

Mouth and Lip Assessment

Note size, color, and location of any **external lesions**.
Palpate for mobility and firmness.

Note size, color, and location of any **internal lesions**.
Palpate for mobility and firmness.

No external lesions

No internal lesions

Dehydrated mouth or lips
Fissures
Pressure sores
Necrosis
Candidiasis (a fungal infection indicated by adherent, white patches)

Neck Assessment

Note any **lesion or swelling** in the neck.
Ask client to relax and flex neck slightly.
Palpate the neck, using the pads of your fingers to move the skin and underlying tissues.

Occasional small, mobile, discrete, nontender lymph nodes

Enlarged tender immobile nodes

► Lymph nodes in the head and neck.

ASSESSMENT OF THE SKIN AND NAILS

Skin Assessment

Nail Assessment

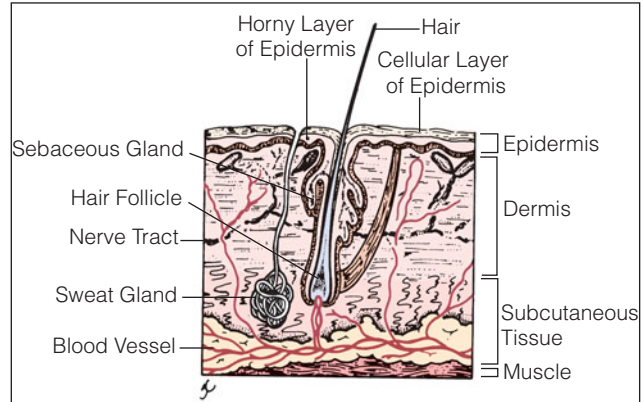

The skin is the body's first line of defense against disease and injury. It is made up of three layers: the epidermis, the dermis, and the subcutaneous tissues.

The epidermis is divided into two avascular, or bloodless, layers: an outer layer that consists of dead keratinized cells and an inner layer that consists of live cells where keratin and melanin are formed. The dermis contains blood vessels, connective tissue, sebaceous glands, and some of the hair follicles. The subcutaneous tissues contain the remainder of the hair follicles, fat, and the sweat glands.

Hair, nails, sweat glands, and sebaceous glands are appendages of the skin. There are two types of sweat glands: eccrine and apocrine. Eccrine glands are distributed over most of the body except for the palms and soles. These glands help control body temperature through their sweat production. The apocrine glands are found mainly in the axillary and genital areas and

are stimulated by emotional stress. Bacterial decomposition by apocrine sweat glands causes adult body odor.

The nail body is made up of dead keratinized cells. Nail production occurs at the nail root. Underlying vessels give the nail its pink color.

▲ Anatomy of the skin.

Assessment: Skin

Assessment	Normal	Abnormal
Note color of the skin by assessing the oral mucous membranes, the conjunctiva, and the nailbeds	Pink, tan, or brown, depending on the client's basic skin color Oral mucous membrane: moist, pink Conjunctiva: moist, pink Nailbeds: pink	Pallor (decrease in color) <i>Example:</i> anemia from acute blood loss (hemorrhage), renal failure, dietary deficiencies, or arterial insufficiency Jaundice (icterus): due to the presence of conjugated or unconjugated bilirubin in the blood and tissues; appears most frequently in the face and sclerae; seen best under natural light <i>Example:</i> liver disease Cyanosis (blue, blue-gray, or purple discoloration of the skin and mucous membranes): caused by hypoxia, a result of an increased amount of reduced hemoglobin Peripheral: seen in nailbeds and earlobes <i>Example:</i> vasoconstriction, venous insufficiency Central: seen in nailbeds, lips (circumoral), and oral mucosa Erythema (redness of the skin): caused by capillary congestion; occurs with inflammation or infection; usually a local finding
		
▲ Check quality of the skin.		

Assessment	Normal	Abnormal
Note pigmentation	Discolored spots may be due to normal aging	Hyperpigmentation (especially in skin creases) <i>Example:</i> use of oral contraceptives, pregnancy, Addison's disease, and hyperthyroidism
Note turgor and mobility	Smooth and elastic	Tight or stretched and difficult to move: due to local or generalized edema Wrinkled: due to dehydration or caused by rapid weight loss
Pinch skin over the sternum If the fold persists, skin turgor is poor	Resilient and supple	Thin and translucent (parchment) <i>Example:</i> chronic steroid use. Thin, shiny, and smooth with alopecia on lower extremities <i>Example:</i> chronic arterial insufficiency

Assess for **edema**

Press finger firmly for 5 seconds into skin on top of foot or inner ankle bone

Resilient and no depression remains after pressure released

Pitting edema: excess interstitial fluid
Example: congestive heart failure, renal failure, cirrhosis of the liver, venous stasis

▲ Check client for edema.

▲ Grading pitting edema.

Note **moistness** and **temperature** of the skin

Warm and dry

Warm (hot) and moist due to temperature elevation
Cool and moist (cold and clammy): may be due to shock states
Abnormally dry: may be due to dehydration, decreased sebaceous gland secretions, or the excessive use of soap

Assess for **sensation**—response to external stimuli

Feels touch, sensitive to heat and cold and pressure

Absence of touch or pain sensation
Example: spinal cord injury or nerve damage
Diminished heat and cold sensation
Example: peripheral vascular disease
Itching and tingling
Example: peripheral vascular disease, peripheral neuropathy, allergy

Note **lesions** on the skin
Physical characteristics include color, elevation, shape, mobility, and contents

No lesions present

Macules (flat localized changes in color)
Example: petechiae, first-degree burns, purpura
Papules, plaques, nodules (solid, elevated, varying in size)
Example: psoriasis, xanthomas
Cancerous lesions
Examples: Basal cell epithelioma—small, smooth papule with atrophic center

(continued)

Assessment: Skin (Continued)

Assessment	Normal	Abnormal
		<p>Melanoma—pigmented tumor; may arise from a blue-black mole</p> <p>Squamous cell—macules with indistinct margins; surface may be crusted</p> <p>Wheals (elevated, circumscribed, transient) <i>Example:</i> urticaria, insect bites</p> <p>Vesicles and bullae (clear, fluid-filled pockets between skin layers) <i>Example:</i> second-degree burns</p> <p>Pustules (vesicles or bullae filled with purulent exudate) <i>Example:</i> furuncles, acne</p>
Nail Assessment		
Note condition of the nails	Smooth transparent layer with white crescent called a lunula	<p>Clubbing occurs with hypoxia or decreased tissue perfusion, cirrhosis, and other conditions</p> <p>Spoon-shaped nails may indicate iron deficiency</p> <p>Thickened nails may relate to circulatory disorder</p> <p>Cracked, split, or broken nails may result from nutrient deficiencies</p>

ASSESSMENT OF THE CHEST, LUNGS, AND HEART

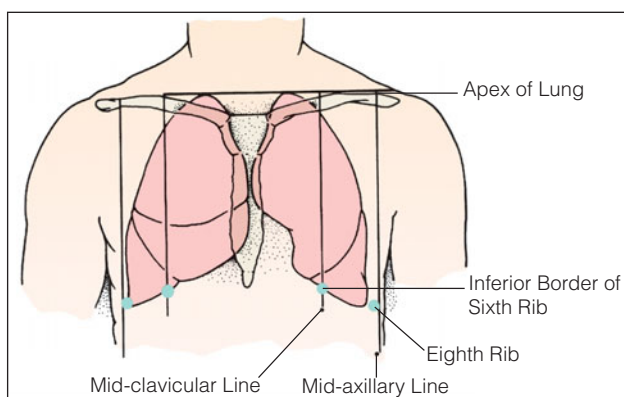

Chest Assessment

Lung/Respiratory (Breath Sounds) Assessment

Heart Assessment

The chest, or thorax area, extends from the base of the neck to the diaphragm. The overall shape of the thorax should be elliptical, although deformities such as barrel chest, pigeon chest, or funnel chest do occur. Total assessment includes the external aspect: The nurse should observe for movement, posture, shape, and symmetry, especially of the breast and axilla area, and the internal components of the lungs and the heart.

The lungs anteriorly extend from 2 to 4 cm above the inner third of the clavicle to the eighth rib at the midaxillary line and the sixth rib at the midclavicular line.

▲ Anterior anatomical relationship of lungs to skeletal structure.

Posteriorly the lungs extend from the third thoracic spinous process and descend to the 10th process or, on deep inspiration, to the 12th process.

Chest assessment begins with inspection, proceeds to palpation, and then to auscultation. Breath sounds of clients differ due to the depth of breathing, underlying disease, or obesity. Because of these differences, it is difficult to compare the breath sounds of one client with another. The basic principle to remember when auscultating the lungs is to do a comparison between the right and left lung. To make these comparisons, begin auscultating at the apices of one lung, alternating sides as you work down through both lungs. By comparing similar areas in both lungs, you can note changes and determine causes for these changes more easily.

Examination of the chest usually proceeds from posterior to anterior. For posterior assessment of the lungs, place the client in an upright sitting position with shoulders pulled forward. For anterior assessment, the client can be sitting or supine (especially if female). If the client is lying on his or her side, the lung closest to the bed is mechanically compressed, and true lung sounds cannot be heard.

Ask the client to breathe a little deeper than usual through the mouth. Breathing through the nose produces extra sounds that mask true lung sounds.

The heart is located directly behind the sternum, with the left ventricle projecting into the left chest. The heart is usually thought to be in the left chest for two reasons: the left ventricle produces the most movement (ventricular contraction), and three of the valve sound areas are located to the left of the sternum.

The action of the heart should be assessed both proximally and distally. Proximal assessment involves evaluating heart sounds, heart rate, and rhythm to obtain information about the

mechanical activity of the heart. Distal assessment involves evaluating the peripheral pulses to obtain information about the effectiveness of the heart's pumping action.

One method for assessing heart sounds is to start at the aortic area, moving slowly across to the pulmonic area, down to the tricuspid area, and over to the mitral area. This same general progression can also be used in reverse, starting at the mitral area and progressing up to the aortic area. Most clinicians begin the assessment at the mitral area, which is the point of maximum impulse and where the apical pulse is the loudest.

The most important point to remember in heart assessment is to use the same method every time, repeating the same steps in the same sequence. By using one systematic approach, you learn how to compare the different sounds more easily and not neglect to listen to all areas on the chest.

Breast assessment should include observing for lumps, drainage, dimpling of breast tissue, and presence of asymmetry. The client should also be asked if she has noted any recent changes.

Assessment: Chest

Assessment	Normal	Abnormal
Chest Assessment		
Note respiratory rate—increase may be due to fever, pain, anxiety	A normal or increased rate does not assume a normal tidal volume	Clients may have an increased rate to compensate for decreased tidal volume, but the resultant minute volume is still not sufficient. (Normal minute volume is 6–8 L/min.) Increased depth: due to neurologic disease, intracranial pressure (ICP) from trauma, drug overdose, exertion, fear, or anxiety Decreased depth: due to neurologic disease, ICP from trauma, drug overdose, respiratory disease, pneumothorax, or pain
Note the general appearance of the chest and movement when client breathes	Straight spine, level shoulders Relaxed breathing; rib cage moves symmetrically with respirations	Breathes sitting forward with arms on pillows or overbed table (present with emphysema) Uses accessory muscles (i.e., scalene, trapezius, sternocleidomastoid, pectoralis, or intercostal)
Note shape of chest	Anterior–posterior dimension is half of lateral dimension	Anterior–posterior dimension increased in emphysema (barrel chest) Deformities such as scoliosis (lateral curvature), kyphosis (forward curvature), or kyphoscoliosis
Note position of ribs	Ribs slant downward	Horizontal is common in COPD Bulging of interspaces during exhalation with retraction on inhalation (present with asthma and emphysema) Chest tilted to one side when client sits or stands: may be due to pain in ribs or chest wall or trauma (i.e., fractured ribs or surgery such as a thoracotomy)
Measure chest excursion for range and symmetry: place hands parallel to 10th rib (under scapulae) with thumbs beside spine. Bunch up fold of skin pushing thumbs medially. Ask client to inhale. For anterior assessment, place hands over lower thorax, push medially, then have client inhale. Note equidistant lateral movement of hands.	On inhalation, the thumbs move equidistant away from midline indicating equal expansion	Flail chest: occurs when four or more ribs are broken; area collapses inward during inhalations and outward on exhalation Asymmetrical (unequal) chest expansion occurs with pneumothorax, fractured ribs, atelectasis, or when client's chest splints due to pain

▲ Measure chest excursion while client takes deep breath.

(continued)

Assessment: Chest (Continued)

Assessment	Normal	Abnormal
<p>Tactile and Vocal Fremitus</p> <p>Tactile fremitus (vibrations felt on surface of chest as sound passes through tissue)</p> <p>Palpate upper thorax and ask client to say “ninety-nine”; vibrations detected as hands move down thorax</p>	<p>Varied because it depends on thickness of chest wall</p> 	<p>Decreased sounds: obesity, emphysema, pneumothorax, and possible</p> <p>Increased sounds: heard when lung is filled with fluid-consolidation (pneumonia) or tumors</p> <p>Absent sounds: atelectasis or pleural effusion</p> <p>Asymmetric sounds: abnormal</p> <p>Normal sounds: found with bronchitis or pulmonary edema</p>

▲ Palpation for tactile fremitus.

Lung/Respiratory Assessment

Complete a **general assessment** of the lungs

Respiratory rate

Respiratory depth or volume

Auscultation: note location and quality of **lung sounds**

Note presence of *adventitious (extra) sounds*, such as rales/crackles, wheezes, and rhonchi, or pleural friction rub

12–20 respirations/minute

Normal depth is equal to about 500 mL

No extra sounds heard—symmetrical areas should be the same in quality and intensity

Increased respiratory rate: may be due to increased metabolic needs (fever), mechanical injury, surgery, or trauma to chest wall

Discontinuous Sounds: *Crackles* (rales) are due to sudden opening of closed airways, indicating hypoventilation; usually heard as soft, high-pitched scratching sounds, like hair strands rubbing together at end of inspiration

Heard in dependent areas of bedridden clients or in early congestive heart failure. May be collapsed or fluid-filled alveoli. Simulate by rubbing hair together in front of your ear

Continuous Sounds:

Wheezes are produced by air passing through airways narrowed by edema, spasm or mucus; may be heard on inspiration but more often louder on expiration; high-pitched and musical

Rhonchi are low-pitched rumbling, coarse; sounds heard on inhalation and exhalation. Fluid-blocked airways—may be cleared with coughing.

Sibilant wheezes are high-pitched, musical sounds; may be caused by asthma, increased secretions, or edema

▲ Stethoscope placement sites for posterior (left) and anterior (right) auscultation of breath sounds. Follow arrows for sequence of examination.

Assessment	Normal	Abnormal
------------	--------	----------

▲ Listen to posterior breath sounds.

Evaluate **breath sounds**

Bronchovesicular breath sounds

Heard over the mainstem bronchi below the clavicles and adjacent to the sternum, between scapulae

Moderate to high pitch, with moderate amplitude
Hollow, muffled quality
Inspiration and expiration equal in duration

Bronchial or bronchovesicular sounds heard in the perimeter where vesicular sounds are expected indicate consolidation such as pneumonia. The client's spoken and whispered words are also clearly heard by the examiner over consolidated lung areas
Breath sounds may be absent over areas of atelectasis, pneumothorax, or pleural effusion

Vesicular (normal) breath sounds

Heard over lung parenchyma (heart will mask breath sounds on the left side)

Low to medium pitch, with low amplitude
Soft, whooshing quality

Lungs extend anteriorly to the sixth intercostal space

Inspiration two to three times longer than expiration

Bronchial breath sounds

Heard over the trachea above the sternal notch

High pitch and amplitude
Harsh, loud, tubular quality
Expiration longer than inspiration

Lungs extend posteriorly to T10 on expiration, to T12 on deep inspiration

Breath sounds are decreased (faint) with hypoventilation, early atelectasis, and COPD

Heart Assessment

Evaluate **atrioventricular heart sounds** (S_1 heart sound). Use diaphragm of stethoscope—best for picking up high-pitched sounds

S_1 (the first heart sound, a combination of the mitral and tricuspid closure) heard best over the mitral and tricuspid areas. S_1 louder than S_2 in this area

Heart sounds not heard in the area prescribed (e.g., with left ventricular hypertrophy, mitral sound moves laterally)

Mitral valve sounds

Heard best at left, fifth intercostal space at, or medial to, the midclavicular line

Tricuspid valve sounds

Heard best at fifth intercostal space, left sternal border

S_1 also heard at this area and is louder than S_2

Evaluate **semilunar heart sounds** (S_2 heart sounds)

S_2 (the second heart sound, a combination of the aortic and pulmonic closure): heard best over the aortic and pulmonic areas

Sounds altered with aortic stenosis (thrill) and hypertension (accentuated sound)

(continued)

Assessment: Chest (Continued)

Assessment	Normal	Abnormal
------------	--------	----------

▲ Auscultate heart sounds.

▲ S₁ heard best over mitral and tricuspid areas. S₂ heard best over aortic and pulmonic areas.

Aortic valve sounds

Heard best at second intercostal space, right sternal border

Pulmonic valve sounds

Heard best at second intercostal space, left sternal border

Evaluate presence of **diastolic heart sounds**

Use bell of stethoscope—best for picking up low-pitched sounds and gallops. Place lightly on chest with client in left side lying position.

S₃ (ventricular gallop)

Heard just after S₂, at the apex or at lower, left sternal border

S₄ (atrial gallop)

Heard just before S₁, at the apex or at lower, left sternal border; occurs when blood flow from atrial contraction meets increased resistance in ventricle

Assess for **heart murmurs**, heard between heart sounds

Produced by atypical flow of blood through the heart (e.g., irregularity or partial obstruction, increased flow in normal area, flow into dilated chamber, flow through abnormal passage); regurgitant flow Occurs during systole (between S₁ and S₂) or during diastole (between S₂ and S₁)

Evaluate the **apical pulse** when assessing for general heart rate and rhythm of contractions

Auscultate at the apex of the heart (left, fifth intercostal space at the midclavicular line)

Part of S₂ is louder than S₁ in this area. May be heard separately from aortic closure if client inhales deeply
Quiet and low-pitched

May be a physiologic finding in children and young adults
Abnormal finding in older clients

Normal finding in elderly

Faint sound
More common during systole
Often found in children and young adults

Regular rhythm
Heart rate: 60–100 beats/min

Moderate bradycardia common in well-trained athletes

Accentuated with pulmonary hypertension

Murmurs originating from stenotic valves

Almost always signifies heart failure in client over age 40

Heard in older individual with hypertension

Faint or loud enough to be heard without a stethoscope
Occurs during systole or diastole (diastolic murmurs are almost always pathologic)—found in older clients with heart disease or infants and children with congenital heart defects

Irregular rhythm (dysrhythmia) may be regularly irregular or irregularly irregular (i.e., atrial fibrillation)
Bradycardia (less than 60 beats/min)

Assessment	Normal	Abnormal
------------	--------	----------

Describing a Murmur

Murmurs are classified by timing and are heard between heart sounds:

Timing—When does it occur? Between systolic (S₁ and S₂) sounds or between diastolic (S₂ and S₁) sounds.

Location—Point where murmur is loudest.

Radiation—Where murmur starts (point of maximum intensity) and moves to surrounding areas.

Quality—Blowing, harsh, musical, or rumbling.

Pitch—High, low, medium.

Intensity—Grade 1, barely audible; to grade 6, audible with stethoscope just off client’s skin.

Pattern—Intensity over time; soft to loud/loud to soft.

Source: Smith, S. (2009). *Sandra Smith’s Review for NCLEX-RN*, 12th ed. Sudbury, MA: Jones & Bartlett Publishers, p. 216.

Palpate and view pulse on chest wall if client’s chest wall is thin enough	Mild tachycardia possible with stress, infection, or fever	Tachycardia (more than 100 beats/min)
Assess for irregular apical pulse		
With another nurse, take apical and radial pulses <i>simultaneously</i>	Equal apical and radial pulses = no pulse deficit	Fewer beats at the radial area may indicate an irregular apical pulse, producing ineffective pumping
Compare beats per minute for both pulses		
Auscultate apical pulse and compare to carotid pulse	Two pulses are synchronous	Apical pulse greater than carotid pulse indicates a pulse deficit

▲ Compare apical and carotid pulse to identify pulse deficit.

Palpate peripheral pulses *: radial, brachial, femoral, popliteal, dorsalis pedis, posterior tibial (For special cases, after carotid surgery, palpate temporal pulse also)	Easily palpated	Difficult to palpate
Guidelines for palpating peripheral pulses: If pulse is not immediately palpable, examine adjacent area—pulse locations differ with clients	Equally strong on both sides	Unequal pulses
Palpate weak pulses gently so that you do not obliterate pulse with too much pressure	Posterior tibial pulse usually weaker than femoral	Weak pulse
If you cannot differentiate your pulse from client’s pulse, check your radial or carotid pulse, or observe monitor pattern		Absent pulses
When peripheral pulses cannot be palpated, use a Doppler ultrasound stethoscope and grade according to scale		

▲ Palpate peripheral pulse, dorsalis pedis.

*See assessing peripheral pulses in Chapter 10, Vital Signs

ASSESSMENT OF THE ABDOMEN, SPLEEN, KIDNEY, LIVER, AND GENITOURINARY TRACT

- Abdomen Assessment
- Liver Assessment
- Spleen Assessment
- Urinary Tract Assessment
- Genital Assessment
- Breast Assessment
- Testicular Examination

The abdomen extends from the diaphragm to the pelvis. Generally speaking, there are two body systems present in this area: the gastrointestinal system and the genitourinary system.

The gastrointestinal system begins at the mouth and consists of the esophagus, stomach, the small and large intestines, and associated organs that include the liver, pancreas, and spleen.

The urinary tract consists of the kidneys, ureters, bladder, and the urethra. The urinary tract should be assessed frequently and accurately because changes in urine production reflect changes in other body systems.

The most common way to assess the urinary tract is to note the quantity and quality of the urinary output. Some medications

▲ Assessment requires knowledge of abdominal organ anatomy.

or foods produce unusual odors and colors in urine (e.g., sulfasalazine [Azulfidine] turns urine a yellow-orange color; asparagins gives urine a musty odor).

External male genitalia include the penis, the scrotum, and the testicles. External female genitalia include the vulva, the urethral orifice, and the vagina.

Assessment: Abdomen, Liver, Spleen, Kidney, and Genitourinary Tract

Assessment	Normal	Abnormal
<p>Abdomen Assessment</p> <p>Have client lie flat in bed At the client's abdominal level, inspect the general contour of the abdomen</p> <p>Inspect for bruising around umbilicus and over flanks Observe for scars, stretch marks, dilated veins, presence of hernia</p> <p>Assess circumference for intraabdominal hemorrhage or ascites by placing a tape measure around the largest circumference of the abdomen. Draw two lines around client's entire abdomen, one line at the top of the tape measure, one line at the bottom of the tape measure; perform measurement when client exhales</p> <p>Auscultate abdomen to assess presence and quality of bowel sounds</p>	<p>Abdomen flat from chest to pubis with concave indentation at umbilicus</p> <p>No change of skin color around umbilicus or flanks Correlate with health history</p> <p>No increase in abdominal circumference</p>	<p>Scaphoid (concave) abdominal contour: due to inadequate nutritional intake to meet caloric need or inadequate food absorption</p> <p>Distended abdomen: caused by gas and fluid accumulation due to lack of peristalsis, hemorrhage, or intestinal leakage after trauma (e.g., auto accident or surgery), or ascitic fluid (e.g., liver or cardiac failure)</p> <p>Acute abdomen</p> <p>Dilated veins caused by liver disease Bulge seen with defect in abdominal wall Abdominal circumference increases steadily within 1–2 hours</p>

▲ Auscultate abdomen for bowel sounds.

Note: After abdominal surgery, the return of GI function is determined by the (1) return of flatus, (2) bowel movement, (3) hunger, (4) no nausea or tolerance of oral feeding, (5) flat abdomen/nondistension, rather than the return of bowel sounds.

Assessment	Normal	Abnormal
Place diaphragm of stethoscope firmly on right lower quadrant and count sounds for 1 minute	Bowel sounds gurgle, about 5–30 per minute	Hyperactive bowel sounds: due to blood in GI tract, diarrhea, or to partial bowel obstruction (sounds become high-pitched and tinkling or come in “rushes,” followed by silence as obstruction progresses)
Listen at all quadrants, near the center, for several minutes if sounds not heard initially	Varying frequency of sounds with clients and time of day (i.e., more sounds right before and after eating) Decreased or absent bowel sounds after surgery After general anesthesia, normal sounds in 1–2 days After abdominal surgery, normal sounds in 3–5 days	Bowel sounds hypoactive, quiet, and infrequent: may be due to peritonitis, paralytic ileus, or no obvious cause Absent bowel sounds: may be due to complete bowel obstruction or systemic illness
Palpate abdomen lightly to determine area of tenderness. Palpate deeper to check abdominal muscles and organs beneath muscles. Assist client to relax, lie flat in bed, and flex knees. Have client mouth-breathe.	No tenderness, abdomen is relaxed.	Tenderness is present—hypersensitivity.
		
	▲ Palpate client’s abdomen.	
Place your hand flat on client’s abdomen, holding your four fingers together and depress ½ in. or 1 cm.	Soft, pliant musculature when relaxed	Rigid, tender muscles/pain produced with cough: may be due to presence of muscle spasm, inflammation, or infection (peritonitis)
Have client cough to determine any areas of abdominal tenderness	Cough does not produce pain in abdomen	
Begin palpation at the pubis, moving upward. Palpate any problem areas last to minimize effects of discomfort.	No bulges felt No masses felt	Pain or tenderness with quick release of pressure indicates rebound tenderness suggesting peritoneal inflammation
Palpate all quadrants of abdomen to assess organs contained in each quadrant		If hernia is suspected, have client raise head and shoulders and observe for abdominal bulge
Superficial palpation: use slight pressure only with your fingers extended		
Deep palpation: indent the abdominal wall 4–5 cm—may use one hand over the other to apply pressure	No masses felt	Masses felt with colon disease, vascular aneurysm, dilated bowel, distended bladder, or cancer

Liver Assessment

Palpate liver by placing left hand behind 11th and 12th ribs with right hand on right abdomen lateral to rectus muscle	Normal liver (difficult to palpate) may feel like sharp ridge with smooth surface	Tenderness may be due to inflammation (hepatitis) Enlarged liver with nontender edge may be due to cirrhosis
---	---	---

(continued)

Assessment: Abdomen, Liver, Spleen, Kidney, and Genitourinary Tract (Continued)

Assessment	Normal	Abnormal
------------	--------	----------

▲ Palpation of the liver.

Spleen Assessment

Standing on client's right side, palpate spleen. Place left hand under rib cage on left side and elevate rib cage. Press fingers of right hand into left costal margin area and ask client to take a deep breath. You should feel spleen move forward toward right hand.

A normal spleen is usually not palpable

Enlarged spleen (which can be palpated) occurs in acute infections such as mononucleosis

▲ Palpation of the spleen.

Urinary Tract Assessment

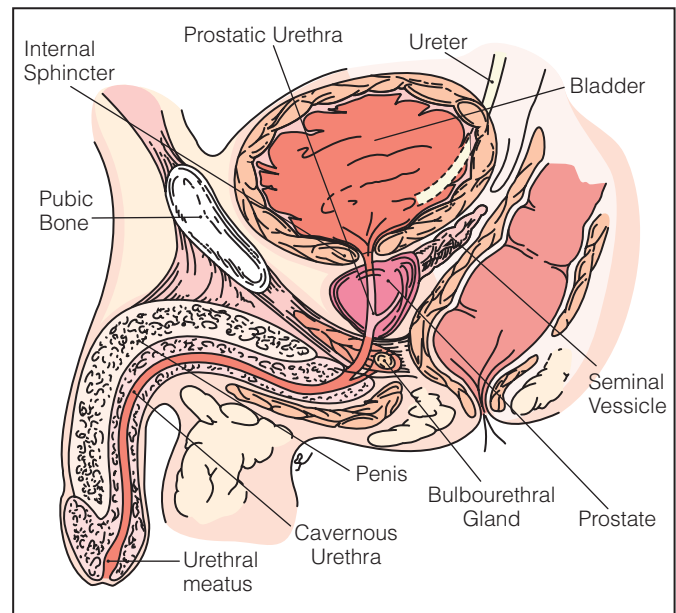

Assess the **external urethra**

Orifice is pink and moist; clear, minimal discharge

Burning or pain at urethral orifice: may indicate urinary infection

▲ Female genitourinary system.

▲ Male genitourinary system.

Assessment	Normal	Abnormal
Assess the quantity, color, odor, specific gravity, and pH of urine output	<p>Output: average 1,200–1,500 mL/24 hours, or 30–50 mL/hour—should equal oral and IV intake</p> <p>Clear, yellow-amber color (vegetarians may have slightly cloudy urine)</p> <p>Slight odor (ammonia-like odor indicates that specimen has been sitting for some time)</p> <p>Specific gravity: 1.003–1.030</p> <p>pH range from 4.5–7.5; average is 6–7</p>	<p>Increased output: may indicate increased intake, diuresis, potential diabetes mellitus, or inappropriate antidiuretic hormone (ADH) response (e.g., diabetes insipidus)</p> <p>Frequent small amounts of urine output indicate urinary retention or urinary tract infection</p> <p>Decreased output: may indicate dehydration, acute nephritis, cardiac disease, renal failure, or excess ADH response (e.g., head injury)</p> <p>Cloudy (<i>turbid</i>): may indicate possible urinary tract infection</p> <p>Dark amber: may indicate very concentrated urine due to dehydration</p> <p>Dark amber to green: may indicate hepatitis or obstructive jaundice</p> <p>Foul-smelling: may indicate urinary tract infection, drug or specific food ingestion (e.g., asparagus)</p> <p>Sweet odor: may indicate acetone from ketoacidosis (i.e., diabetes mellitus)</p> <p>Specific gravity of more than 1.030: indicates dehydration</p> <p>Constant specific gravity of 1.010, regardless of fluid intake: indicates renal failure</p> <p>Acidic pH—when below 6.0 may indicate starvation or acidosis</p> <p>Alkaline pH greater than 7.0: indicates metabolic alkalosis or alkaline ash diet (e.g., vegetarian)</p>
Assess for blood in urine using Hemastix or Labstix	No blood present	Smokey to mildly pink-tinged to grossly red-colored urine: indicates blood in urine
Palpate for bladder distention	Not normally palpated	Distended bladder (firm, round mass) accompanied by discomfort and urge to void: indicates urine retention (common following surgery, where catheter is not used)

Kidney Assessment

Assess (palpate) for kidney pain on either side of vertebrae column between last thoracic and third lumbar vertebrae

Use indirect percussion to further assess the kidneys

When palpated, client feels no pain

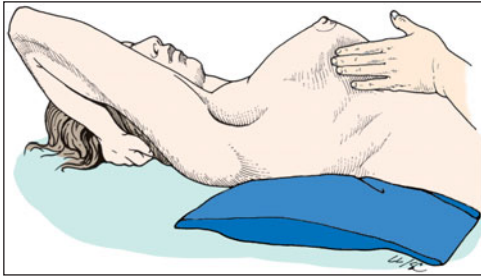

▲ Use of indirect percussion will identify pain.

Severe pain, discomfort, or tenderness in the flank region (below rib cage posteriorly and lateral to spine): indicates kidney infection, stones, or kidney disease. Kidney enlargement may indicate neoplasm or polycystic disease.

(continued)

Assessment: Abdomen, Liver, Spleen, Kidney, and Genitourinary Tract (Continued)

Assessment	Normal	Abnormal
Genital Assessment Male		
Visually examine the male genitalia	Clean	Unclean
Retract the foreskin of the uncircumcised penis to note cleanliness, any lesions , and discharge	No odor No lesions	Odor Lesions and discharge may indicate venereal disease or cancer
Lift scrotum to inspect for rash	No discharge Size of penis and scrotum vary	Oval and round, dark erosion: may indicate syphilitic chancre
Noting groin area, ask client to strain down	Urethra opens midline of the tip of the glans No bulges in groin area	Hypospadias: due to congenital displacement of the urethral meatus Bulge on straining seen with hernias Indurated nodule or ulcer: may indicate carcinoma
Testicular Examination		
Palpate scrotum, testes, and observe shape and contour.	Should be pear-shaped with left side lower than right; no masses; testes nontender, smooth, and solid	Swelling may indicate orchitis or scrotal edema; scrotal hernia or testicular torsion; varicocele
Observe for swelling, redness, and distended veins or lesions inguinal area.	Flat, no evidence of masses	Mass may be related to inguinal hernia or cancer
Using thumb and first two fingers, gently palpate each testicle for size, shape, and consistency	Two testicles in the scrotum No nodules felt, no swelling or tenderness	Mass in scrotum: indicates possible hernia, hydrocele, testicular tumor, or cyst Pain indicates inflammatory disease
Female		
Visually examine female genitalia	Clean No odor	Unclean Odor (musty with bacterial infection)
Assess for signs of sexual abuse	No signs	Bruises, welts, burns, unusual swelling
Assess for lesions or discharge or complaints of itching	Minimal, clear discharge Menstrual flow Lochia (normal discharge after delivery) No lesions No pruritus	Thick; thin, white, yellowish, or green discharge: may indicate trichomoniasis Thick, white, and curdy discharge with pruritus may indicate candidiasis Lesions: could indicate syphilitic chancre, herpes infection, venereal wart, or carcinoma of vulva
Breast Assessment		
Inspect size, symmetry , and contour of breasts, comparing one side with the other	Size varies with each client Breasts should be fairly equal in size and contour and symmetric in position	Masses, skin thickening, dimpling, or flattened areas: indicate possible cancer
Place client in sitting position Have client remove clothing from waist up Have client raise arms over her head		
Color, edema , and venous pattern of skin	Normal skin color with darker area surrounding nipples No edema or prominent vessels	Erythema: indicates infection or inflammatory carcinoma Edema or increased venous prominence: indicates carcinoma
Inspect size and shape of nipples Note direction in which they point, and any rashes or discharge	Simple inversion of nipples is common	Flattening, nipple retraction, or axis deviation of nipple points: may be due to fibrosis associated with cancer
To palpate breasts, position client supine or on side Place a pillow under the shoulder of the side being examined Using three fingers in a circular motion, compress breast tissue gently against chest wall		Ulcerations of nipples and areola: may be due to Paget's disease Discharge: may not be malignant but should be observed closely Mobile nodules may indicate cystic disease

Assessment	Normal	Abnormal
Systematically examine entire breast, top to bottom, moving medially to laterally into the axilla	Soft, elastic tissue with mobile nodules	Hard nodules fixed to skin or underlying tissue may indicate cancer When nodules are present: Describe location and quadrant of breast where found Note size in centimeters Describe consistency and shape Note tenderness and mobility of nodule in relationship to underlying tissue
		
▲ Examine breast tissue in circular movement.		
Palpate nipples		
Compress nipple and areola between thumb and index finger to inspect for discharge	No discharge or small amount of milky discharge in previously nursing mother	Bloody discharge: may indicate papilloma
Note elasticity	Elastic, no retraction of nipple	Loss of elasticity: indicates possible cancer
Observe for erection of nipple with palpation		Inversion, flattening, or retraction: may indicate cancer

MENTAL HEALTH ASSESSMENT

The mental assessment is completed throughout the physical assessment during the history taking. It is not generally considered a separate entity. Mood, memory, orientation, and thought processes can be evaluated while obtaining the health history. Nutritional preferences and restrictions can be determined as a part of a client care plan and may or may not be included in the general client assessment.

A spiritual assessment can be obtained as a part of the health history, although specific sociocultural beliefs may need to be ascertained separately. The purpose of a spiritual assessment is to facilitate the client adapting to the hospital environment and to help the staff understand stressors the client may be experiencing as a result of belief systems.*

The purpose of a mental status assessment is to evaluate the present state of psychologic functioning and to monitor safety needs of the client. It is not designed to make a diagnosis; rather it should yield data that contribute to the total picture of the client as he or she is functioning at the time the assessment is made.

The specific rationale for completing a mental status assessment is:

- To collect baseline data to aid in establishing the cause, diagnosis, and prognosis
- To evaluate the present state of psychologic functioning

NOTE: For more information on a spiritual–religious assessment, see Chapter 4.

- To evaluate changes in the individual’s emotional, intellectual, motor, and perceptual responses
- To determine the client’s ability to cope with the present situation
- To assess the need and availability of support systems
- To ascertain if some seemingly psychopathologic response is, in fact, a disorder of a sensory organ (i.e., a deaf person appearing hostile, depressed, or suspicious)
- To determine the guidelines of the treatment plan
- To document altered mental status for legal records

The initial factors that the nurse must consider in completing a mental status assessment are to correctly identify the client, the reason for admission, record of previous mental illness, present complaint, any personal history that is relevant (living arrangements, role in family, interactional experience, history of alcoholism, domestic violence), family history if appropriate, significant others and available support systems, assets, and interests.

The actual assessment process begins with an initial evaluation of the appropriateness of the client’s behavior and orientation to reality. The assessment continues by noting any abnormal behavior and ascertaining the client’s chief verbalized complaint. Finally, the evaluation determines if the client is in contact with reality enough to answer particular questions that further assess the client’s condition.

Assessment: Mental Status

Assessment	Normal	Abnormal
General Appearance, Manner, and Attitude		
Assess physical appearance	General body characteristics, energy level	Inappropriate physical appearance, high or low extremes of energy
Note grooming , mode of dress, and personal hygiene	Grooming and dress appropriate to situation, client's age, and social circumstance Clean	Poor grooming Inappropriate or bizarre dress or combination of clothes Unclean
Note posture Note speed, pressure, pace, quantity, volume, and diction of speech	Upright, straight, and appropriate Moderated speed, volume, and quantity Appropriate diction	Slumped, tipped, or stooped Tremors Accelerated or retarded speech and high quantity Poor or inappropriate diction
Note relevance, content, and organization of responses	Questions answered directly, accurately, and with relevance	Inappropriate responses, unorganized pattern of speech Tangential, circumstantial, or out-of-context replies
Expressive Aspects of Behavior		
Note general motor activity	Calm, ordered movement appropriate to situation	Overactive (e.g., restless, agitated, impulsive) Underactive (e.g., slow to initiate or execute actions)
Assess purposeful movements and gestures	Reasonably responsive with purposeful movements, appropriate gestures	Repetitious activities (e.g., rituals or compulsions)
Assess style of gait		Command automation Parkinsonian movements Ataxic, shuffling, off-balance gait
Consciousness		
Assess level of consciousness	Alert, attentive, and responsive Knowledgeable about time, place, and person	Disordered attention; distracted, cloudy consciousness Delirious Stuporous
Thought Processes and Perception		
Assess coherency, logic, and relevance of thought processes by asking questions about personal history (e.g., "Where were you born?" "What kind of work do you do?")	Clear, understandable responses to questions Attentiveness	Disoriented in time, place, person Disordered thought forms Autistic or dereistic (absorbed with self and withdrawn); abstract (absent-mindedness); concrete thinking (dogmatic, preaching)
Assess reality orientation : time, place, and person awareness	Orderly progression of thoughts based in reality Awareness of time, place, and person	Disorders of progression of thought; looseness, circumstantial, incoherent, irrelevant conversation, blocking Delusions of grandeur or persecution: neologisms, use of words whose meaning is known only to the client Echolalia (automatic repeating of questions) No awareness of day, time, place, or person

Assessment	Normal	Abnormal
Assess perceptions and reactions to personal experiences by asking questions, such as “How do you see yourself now that you are in the hospital?” “What do you think about when you’re in a situation like this?”	Thoughtful, clear responses expressed with understanding of self	Altered, narrowed, or expanded perception illusions Depersonalization
Thought Content and Mental Trend		
Assess degree of anxiety Ask questions to determine general themes that identify degree of anxiety (e.g., “How are you feeling right now?” “What kinds of things make you afraid?”)	Mild or 1+ level of anxiety in which individual is alert, motivated, and attentive	Moderate to severe (2+ to 4+) levels of anxiety
Assess ideation and concentration	Ideas based in reality Able to concentrate	Ideas of reference Hypochondria (abnormal concerns about health) Obsessional Phobias (irrational fears) Poor or shortened concentration
Mood or Affect		
Assess prevailing or variability in mood by observing behavior and asking questions, such as “How are you feeling right now?” Check for presence of abnormal euphoria	Appropriate, even mood without wide variations high to low	Cyclothymic mood swings; euphoria, elation, ecstasy, depressed, withdrawn
If you suspect depression , continue questioning to determine depth and significance of mood (e.g., “How badly do you feel?” “Have you ever thought of suicide?”)	May be sad or grieving but mood does not persist indefinitely	Flat or dampened responses Inappropriate responses Ambivalence
Memory		
Assess past and present memory and retention (ability to listen and respond with understanding or knowledge); ask client to repeat a phrase (e.g., an address)	Alert, accurate responses Able to complete digit span Past and present memory appropriate	Hyperamnesia (excessive loss of memory); amnesia; paramnesia (belief in events that never occurred) Preoccupied Unable to follow directions
Assess recall (recent and remote) by asking questions, such as “When is your birthday?” “What year were you born?” “How old are you?” “Who is the president of the United States now?”	Good recall of immediate and past events	Poor recall of immediate or past events
Judgment		
Assess judgment, decision-making ability , and interpretations by asking questions, such as “What should you do if you hear a siren while you’re driving?” “If you lost a library book, what would you do?”	Ability to make accurate decisions Realistic interpretation of events	Poor judgment, poor decision-making ability, poor choice Inappropriate interpretation of events or situations

(continued)

Assessment: Mental Status (Continued)

Assessment	Normal	Abnormal
Awareness		
Assess insight , the ability to understand the inner nature of events or problems, by asking questions, such as "If you saw someone dressed in a fur coat on a hot day, what would you think?"	Thoughtful responses indicating an understanding of the inner nature of an event or problem	Lack of insight or understanding of problems or situations Distorted view of situation
Intelligence		
Assess intelligence by asking client to define or use words in sentences (e.g., recede, join, plural)	Correct responses to majority of questions	Incorrect responses to majority of questions indicate possible severe psychiatric disorders
Assess fund of information by asking questions, such as "Who is president of the United States?" "Who was the president before him?" "When is Memorial Day?" "What is a thermometer?" (Consider client's cultural and educational background and his or her grasp of English)	Correct responses to majority of questions	Deteriorated or impaired cognitive processes
Sensory Ability		
Assess the five senses (i.e., vision, hearing, taste, feeling, and smell)	Able to perceive, hear, feel, touch appropriate to stimulus	Lack of response Suspicious, hostile, depressed Kinesthetic imbalance
Developmental Level		
Assess developmental level compared with normal	Behavior and thought processes appropriate to age level	Wide span between chronologic and developmental age Mentally retarded
Lifestyle Patterns		
Identify addictive patterns and effect on individual's overall health	Normal amount of alcohol ingested Smoking habits, number of years Prescriptive medications Adequate food intake for physical characteristics	High quantity of alcohol taken frequently Heavy smoker Addicted to illegal drugs Habitative medication; user of over-the-counter or legal medications Anorexic eating patterns Obese or overindulgence of food
Coping Devices		
Identify defense-coping mechanisms and their effect on individual	Conscious coping mechanisms used appropriately, such as compensation, fantasy, rationalization, suppression, sublimation, or displacement Mechanisms effective, appropriate, and useful	Unconscious mechanisms used frequently, such as repression, regression, projection, reaction formation, insulation, or denial Mechanisms inappropriate, ineffective, and not useful

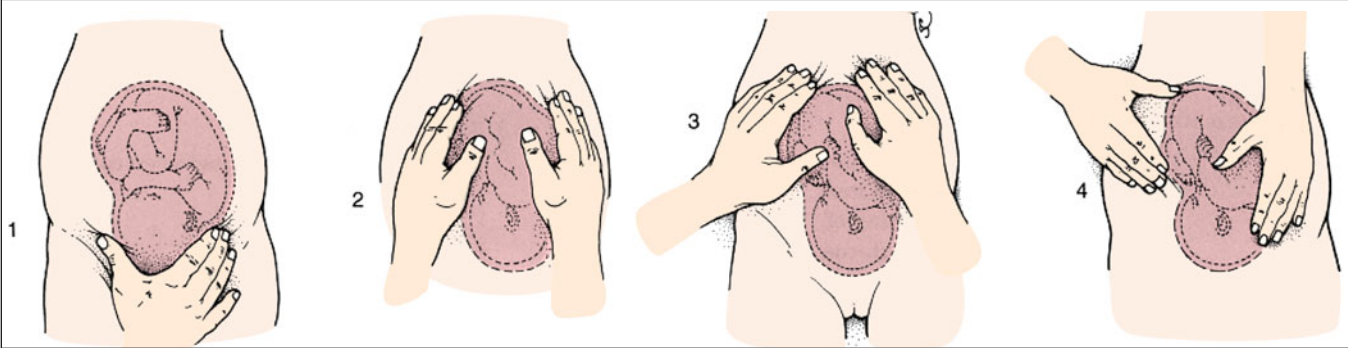

Assessment: Obstetrical

Assessment	Normal	Abnormal
Baseline Data		
Assess breasts and nipples		
Contour and size		
Presence of lumps	No lumps	Lumps
Secretions	Colostrum secretions in late first trimester or early second trimester	Secretions, other than colostrum
Assess abdomen		
Contour and size		
Changes in skin color	<i>Linea nigra</i> (black line of pregnancy along midline of abdomen) Primiparas: coincidentally with growth of fundus Multiparas: after 13–15 weeks' gestation	
<i>Striae</i> (reddish-purple lines)	On breasts, hips, and thighs during pregnancy After pregnancy, faint silvery-gray	
Scar, rashes, or other skin disturbances	Usually none present	
Fundal height in centimeters (fingerbreadths less accurate): measure from symphysis pubis to top of fundus	Fundus palpable just above symphysis at 8–10 weeks Halfway between symphysis and umbilicus at 16 weeks Umbilicus at 20–22 weeks	Large measurements: Expected date of confinement, or delivery (EDC) is incorrect; tumor; ascites; multiple pregnancy; polyhydramnios, hydatidiform mole Less than normal enlargement: fetal abnormality, oligohydramnios, placental dysmaturity, missed abortion, fetal death
Perineum: assess for scars, lesions, or discharge	None present	Rash, warts, discharge
Evaluate weight		
Take vital signs, blood pressure (BP), temperature, pulse, and respiration (TPR)	Vital signs normal	
Evaluate lab findings		
Urine: sugar, protein, albumin	Negative for sugar, protein, and albumin throughout pregnancy	Positive for sugar, protein, and/or albumin
Hematocrit (HCT)	38%–47%	
Hemoglobin (Hgb)	12–16 gm/dL	
Blood type and Rh factor		If Rh negative, father's blood should be typed If Rh positive, titers should be followed; possible RhoGAM at termination of pregnancy
Pap smear		
VD smears and screening		
Antepartum Assessment		
Evaluate weight to assess maternal health and nutritional status and growth of fetus	Minimum weight gain during pregnancy: 24 lb If underweight: gain 28–42 lb If obese: gain 15 lb or more Normal weight gain: 25–35 to 40 lb	Inadequate weight gain; possible maternal malnutrition Excessive weight gain: if sudden at onset, may indicate preeclampsia; if gradual and continual, may indicate overeating

(continued)

Assessment: Obstetrical (Continued)

Assessment	Normal	Abnormal
Evaluate blood pressure	Fairly constant with baseline data throughout pregnancy	Increased: possible anxiety (client should rest 20 to 30 minutes before you take BP again) Rise of 30/15 above baseline data: sign of preeclampsia Decreased: sign of supine hypotensive syndrome. If lying on back, turn client on left side and take BP again
Evaluate fundal height	Drop around 38th week: sign of fetus engaging in birth canal Primipara: sudden drop Multipara: slower, sometimes not until onset of labor	Large fundal growth: may indicate wrong dates, multiple pregnancy, hydatidiform mole, polyhydramnios, tumors Small fundal growth: may indicate fetal demise, fetal anomaly, retarded fetal growth, abnormal presentation or lie, decreased amniotic fluid
Determine fetal position , using Leopold's maneuvers . Complete external palpations of the abdomen to determine fetal position, lie, presentation, and engagement <i>First maneuver:</i> to determine part of fetus presenting into pelvis <i>Second maneuver:</i> to locate the back, arms, and legs: fetal heart heard best over fetal back	Vertex presentation	Breech presentation or transverse lie
 <p>▲ Steps of Leopold's maneuvers.</p>		
<i>Third maneuver:</i> to determine part of fetus in fundus <i>Fourth maneuver:</i> to determine degree of cephalic flexion and engagement		
Evaluate fetal heart rate by quadrant, location, and rate Check for presence of edema	120–160 beats/min In lower extremities toward end of pregnancy	>160 or <120: may indicate fetal distress. <i>Notify physician</i> In upper extremities and face: may indicate preeclampsia
Evaluate urine (clean catch midstream)	Negative for sugar, protein, and albumin	Positive for sugar: may indicate subclinical or gestational diabetes Positive for protein and/or albumin: may indicate preeclampsia
Evaluate levels of discomfort		

Assessment	Normal	Abnormal
<p>Intrapartum Assessment</p> <p>Assess for lightening and dropping (the descent of the presenting part into the pelvis)</p> <p>Check if mucous plug has been expelled from cervix</p> <p>Assess for “bloody show”</p> <p>Assess for ruptured membranes</p> <p>Time water breaks</p> <p>Color of amniotic fluid</p>	<p>Several days to 2 weeks before onset of labor</p> <p>Multipara: may not occur until onset of labor</p> <p>Relief of shortness of breath and increase in urinary frequency</p> <p>Usually expelled from cervix before onset of labor</p> <p>Clear, pinkish, or blood-tinged vaginal discharge that occurs as cervix begins to dilate and efface</p> <p>Before, during, or after onset of labor</p> <p>Clear, straw color</p>	<p>No lightening or dropping: may indicate disproportion between fetal presenting part and maternal pelvis</p> <p>Breech presentation: frank meconium or meconium staining</p> <p>Greenish-brown: indicates meconium has passed from fetus, possible fetal distress</p> <p>Yellow-stained: fetal hypoxia 36 hours or more before rupture of membrane or hemolytic disease</p>
<p>Quantity of amniotic fluid</p>	<p>Normal is 500–1,000 mL of amniotic fluid, rarely expelled at one time</p>	<p>Polyhydramnios—excessive amniotic fluid over 2,000 mL</p> <p>Observe newborn for congenital anomalies: craniospinal malformation, oro-gastrointestinal anomalies. Down’s syndrome, and congenital heart defects</p> <p>Oligohydramnios—minimal amniotic fluid, less than 500 mL</p> <p>Observe newborn for malformation of ear, genitourinary tract anomalies, and renal agenesis</p>
<p>Odor of fluid</p>	<p>No odor</p>	<p>Odor may indicate infection; deliver within 24 hours</p>
<p>Fetal heart rate</p>	<p>120–160 beats/min</p> <p>Regular rhythm</p>	<p>Decreased: indicates fetal distress with possible cord prolapse or cord compression</p> <p>Accelerated: initial sign of fetal hypoxia</p> <p>Absent: may indicate fetal demise</p>
<p>Labor and Delivery Assessment</p>		
<p>Evaluate Contractions</p> <p><i>Frequency:</i> from start of one contraction to start of next</p> <p><i>Duration:</i> from beginning of contraction to time uterus begins to relax</p> <p><i>Intensity</i> (strength of contraction): measured with monitoring device</p>	<p>3–5 minutes between contractions</p> <p>50–90 seconds</p> <p>Peak 25 mmHg</p> <p>End of labor may reach 50–75 mmHg</p>	<p>Irregular contractions with long intervals between: indicates false labor</p> <p>>90 seconds: uterine tetany; stop oxytocin if running</p> <p>>75 mmHg: uterine tetany or uterine rupture</p>
<p>First-Stage</p> <p><i>Latent phase</i> (0–4 cm dilation)</p>	<p>0–3 to 4 cm; average 6.4 hours</p>	<p>Prolonged time in any phase: may indicate poor fetal position, incomplete fetal flexion, cephalopelvic disproportion, or poor uterine contractions</p>

(continued)

Assessment: Obstetrical (Continued)

Assessment	Normal	Abnormal
<p><i>Active phase</i> (4–8 cm) <i>Transitional phase</i> (8–10 cm)</p>	Length of time varies—may be 1–2 hours	If total labor <3 hours: indicates precipitous labor, increasing risk of fetal complications, or maternal lacerations and tears
<p>Assess for bloody show Observe for presence of nausea or vomiting Assess perineum Evaluate urge to bear down</p>	Beginning to bulge	Often uncontrolled Multipara: can cause precipitous delivery “Panting” (can be controlled until safe delivery area established)
<p>Second stage (10 cm to delivery) Assess for presenting part</p>	<p>Primipara: up to 2 hours Multipara: several minutes to 2 hours Vertex with ROA or LOA presentation</p>	<p>>2 hours: increased risk of fetal brain damage and maternal exhaustion Occiput posterior, breech, face, or transverse lie</p>
<p>Assess caput (infant head) Multipara: move to delivery room when caput size of dime Primipara: move to delivery room when caput size of half dollar</p>	Visible when bearing down during contraction	“Crowns” in room other than delivery room: delivery imminent (do not move client)
<p>Assess fetal heart rate (FHR) Bradycardia, drop of 20 beats/min below base line (↓120 beats/min) Tachycardia, increase in FHR over 160 beats/min for 10 min</p>	120–160/min	<p>Decreased: may indicate supine hypotensive syndrome (turn client on side and take again) Hemorrhage (check for other signs of bleeding; notify physician) Increased or decreased: may indicate fetal distress secondary to cord progression or compression (place client in Trendelenburg or knee–chest position; give oxygen if necessary; inform physician)</p>
Evaluate fetal heart rate tracing	<p>Short-term variability is present Long-term variability ranges from 3–5 cycles/min</p>	<p>Absence of variability (no short term or long term present) Severe variable decelerations (fetal heart rate <70 for longer than 30–45 seconds with decreasing variability)</p>
Deceleration	Early deceleration (10–20 beat drop) Recovery when acme contraction passes—often not serious	Monitor closely—distinguish from decrease with hypertonic contraction; leads to fetal distress
<p>Variable deceleration; decrease in FHR, below 120/min Loss of beat-to-beat variation</p>	<p>Mild; may be within normal parameters—continue to monitor If continues less than 15 minutes, no problem apparent</p>	<p>Cord compression—may result in fetal difficulty Late deceleration pattern occurs—monitor for hypertonic contraction; leads to total distress.</p>
Evaluate breathing	Controlled with contractions	Heavy or excessive: may lead to hyperventilation and/or dehydration

Assessment	Normal	Abnormal
Evaluate pain and anxiety	Medication required after dilated 4–5 cm unless using natural childbirth methods	Severe pain early in first stage of labor: inadequate prenatal teaching, backache due to position in bed, uterine tetany
Third stage (from delivery of baby to delivery of placenta)	Placental separation occurs within 30 minutes (usually 3–5 min)	Failure of placental separation Abnormality of uterus or cervix, weak, ineffectual uterine contraction, tetanic contractions causing closure of cervix >3 hours: indicates retained placenta
Fourth stage (first hour postpartum)		Mother in unstable condition (hemorrhage usual cause) Highest risk of hemorrhage in first postpartum hour
<i>Temperature</i>	36.5°C–37.5°C	>37.5°C: may indicate infection Slight elevation: due to dehydration from mouth breathing and NPO
<i>Pulse</i>	Pulse: 60–100	Increased: may indicate pain or hemorrhage
<i>Respiration</i>	Respirations: 12–22	
<i>Blood pressure</i>	Blood pressure: 120–140/80	Increased: may indicate anxiety, pain, or post-eclamptic condition Decreased: hemorrhage
Postpartum Assessment		
Assess vital signs every 15 minutes for 1 hour, every 30 minutes for 1 hour, every hour for 4 hours, every 8 hours, and as needed	Pulse may be 45–60/min in stage 4 Pulse to normal range about third day	Decreased BP and increased pulse: probably postpartum hemorrhage Elevated temperature >38°C indicates possible infection Temperature elevates when lactation occurs
Assess fundus every 15 minutes for 1 hour, every 8 hours for 48 hours, then daily	Firm (like a grapefruit) in midline and at or slightly above umbilicus Return to prepregnant size in 6 weeks: descending at rate of 1 fingerbreadth/day	Boggy fundus: immediately massage gently until firm; report to physician and observe closely; empty bladder; medicate with oxytocin if ordered Fundus misplaced 1–2 fingerbreadths from midline: indicates full bladder (client must void or be catheterized)
Assess lochia every 15 minutes for 1 hour, every 8 hours for 48 hours, then daily	3 days postpartum: dark red (rubra) 4–10 days postpartum: clear pink (serosa) 10–21 days postpartum: white, yellow brown (alba)	Heavy, bright-red: indicates hemorrhage (massage fundus, give medication on order, notify physician) Spurts: may indicate cervical tear No lochia: may indicate clot occluding cervical opening (support fundus; express clot)
<i>Color</i>		
<i>Quantity</i>	Moderate amount, steadily decreases	Foul: may indicate infection
<i>Odor</i>	Minimal	
Assess breasts and nipples daily	Days 1–2: soft, intact, secreting colostrum Days 2–3: engorged, tender, full, tight, painful	Sore or cracked (clean and dry nipples; decrease breast-feeding time; apply breast shield between feeding)

(continued)

Assessment: Obstetrical (Continued)

Assessment	Normal	Abnormal
	Day 3+: secreting milk as baby sucks: common in multiparas	Milk does not “let down”: help client relax and decrease anxiety; give glass of wine or beer if not culturally, religiously, or otherwise contraindicated
Assess perineum daily	Episiotomy intact, no swelling, no discoloration	Swelling or bruising: may indicate hematoma
Assess bladder every 4 hours	Voiding regularly with no pain	Not voiding: bladder may be full and displaced to one side, leading to increased lochia (catheterization may be necessary)
Assess bowels	Spontaneous bowel movement 2–3 days after delivery	Fear associated with pain from hemorrhoids
Assess mother–infant bonding	Touching infant, talking to infant, talking about infant	Refuses to touch or hold infant
Evaluate Rh-negative status	Client does not require RhoGAM	RhoGAM administered
Maternal History: Definition of Terms		
<i>Abortion</i> : pregnancy loss before fetus is viable (usually <20 weeks or 500 g)	<i>Multigravida</i> : refers to second or any subsequent pregnancy	<i>Nullipara</i> : refers to female who has never carried pregnancy to viable age for fetus
<i>Gravida</i> : any pregnancy, including present one	<i>Para</i> : past pregnancies that continued to viable age (20 weeks); infants may be alive or dead at birth	<i>Multipara</i> : refers to female who has given birth to two or more viable infants; either alive or dead
<i>Primigravida</i> : refers to first-time pregnancy	<i>Primipara</i> : refers to female who has delivered first viable infant; born either alive or dead	

Assessment: Newborn

Assessment	Normal	Abnormal
Skin Assessment		
Note skin color, pigmentation, and lesions	Pink Mongolian spots	Cyanosis, pallor, beefy red Petechiae, ecchymoses, or purpuric spots: signs of possible hematologic disorder
	Capillary hemangiomas on face or neck	Café au lait spots (patches of brown discoloration): possible sign of congenital neurologic disorder Raised capillary hemangiomas on areas other than face or neck
	Localized edema in presenting part Cheesy white vernix Desquamation (peeling off)	Edema of peritoneal wall Poor skin turgor: indicates dehydration Yellow discolored vernix (meconium stained)

Assessment	Normal	Abnormal
	Milia (small white pustules over nose and chin) Jaundice after 24 hours; gone by second week	Impetigo neonatorum (small pustules with surrounding red areas) Jaundice at birth or within 12 hours Dermal sinuses (opening to brain) Holes along spinal column Low hairline posteriorly: possible chromosomal abnormality Sparse or spotty hair: congenital goiter or chromosomal abnormality
Note color of nails	Pink	Yellowing of nail beds (meconium stained)
Note muscle strength/tone	Strong, tremulous	Flaccid, convulsions Muscular twitching, hypertonicity
Head and Neck Assessment		
Note shape of head	Fontanels: anterior open until 18 months; posterior closed shortly after birth	Depressed fontanels indicate dehydration; closed or bulging indicate congenital anomalies; full or bulging indicate edema or increased ICP Cephalohematoma that crosses the midline Microcephaly and macrocephaly
Assess eyes	Slight edema of lids	Purulent discharge Lateral upward slope of eye with an inner epicanthal fold in infants not of Asian descent Exophthalmos (bulging of eyeball): may be congenital anomaly, sign of congenital glaucoma or thyroid abnormality Enophthalmos (recession of eyeball): may indicate damage to brain or cervical spine
	Pupils equal and reactive to light by 3 weeks of age Intermittent strabismus (occasional crossing of eyes) Conjunctival or scleral hemorrhages Symmetrical light reflex (light reflects off each eye in the same quadrant): sign of conjugate gaze	Constricted pupil, unilateral dilated fixed pupil, nystagmus (rhythmic nonpurposeful movement of eyeball): continuous strabismus Haziness of cornea Absence of red reflex; asymmetrical light reflex
Note placement of ears , shape and position The top of the ear should be on an imaginary line from the edge of the eye		Low-set ears: may indicate chromosomal or renal system abnormality
Assess nose Assess mouth	Discharge, sneezing Sucking, rooting reflexes Retention cysts Occasional vomiting	Thick, bloody nasal discharge Cleft lip, palate Flat, white nonremovable spots (thrush) Frequent vomiting: may indicate pyloric stenosis Vomitus with bile: fecal vomiting Profuse salivation: may indicate tracheoesophageal fistula

(continued)

Assessment: Newborn (Continued)

Assessment	Normal	Abnormal
Assess neck	Tonic neck reflex (Fencer's position)	Distended neck veins Fractured clavicle Unusually short neck Excess posterior cervical skin Resistance to neck flexion
Assess cry	Lusty cry	Weak, groaning cry: possible neurologic abnormality High-pitched cry: newborn drug withdrawal (may occur 6–12 months after birth); hoarse or crowing inspirations; catlike cry: possible neurologic or chromosomal abnormality
Chest and Lung Assessment		
Assess chest	Circular Enlargement of breasts Milky discharge from breasts	Depressed sternum Retractions, asymmetry of chest movements: indicates respiratory distress and possible pneumothorax
Assess respirations/lungs	Abdominal respirations Respiration rate: 30–50 Respiration movement irregular in rate and depth Resonant chest (hollow sound on percussion)	Thoracic breathing, unequal motion of chest, rapid gasping or grunting respirations, flaring nares Deep sighing respirations Grunt on expiration: possible respiratory distress Hyper-resonance of chest or decreased resonance
Heart Assessment		
Assess the rate, rhythm, and murmurs of the heart	Rate: 100–160 at birth; stabilizes at 120–140 Regular rhythm Murmurs: significance cannot usually be determined in newborn	Heart rate >200 or <100 Irregular rhythm Dextrocardia, enlarged heart
Abdomen and Gastrointestinal Tract Assessment		
Assess the abdomen	Prominent	Distention of abdominal veins: possible portal vein obstruction
Assess the gastrointestinal tract	Bowel sounds present Liver 2–3 cm below right costal margin Spleen tip palpable Umbilical cord with one vein and two arteries Soft granulation tissue at umbilicus	Visible peristaltic waves Increased pitch or frequency: intestinal obstruction Decreased sounds: paralytic ileus Distention of abdomen Enlarged liver or spleen Midline suprapubic mass: may indicate Hirschsprung's disease One artery present in umbilical cord: may indicate other anomalies Wet umbilical stump or fetid odor from stump
Genitourinary Tract Assessment		
Assess kidneys and bladder	May be able to palpate kidneys Bladder percussed 1–4 cm above symphysis pubis	Enlarged kidney Distended bladder; presence of any masses

Assessment	Normal	Abnormal
Assess the genitalia	Edema and bruising after delivery Unusually large clitoris in females a short time after birth Vaginal mucoid or bloody discharge may be present in the first week Inguinal hernia	Ambiguous genitalia (chromosomal abnormality)
Urethral orifice	Urethra opens on ventral surface of penile shaft	Hypospadias (urethra opens on the inferior surface of the penis) Epispadias (urethra opens on the dorsal surface of the penis) Ulceration of urethral orifice
Testes	Testes in scrotal sac or inguinal canal	Hydroceles in males
Spine and Extremities Assessment		
Assess the spine	Straight spine	Spina bifida, pilonidal sinus; scoliosis
Assess extremities	Soft click with thigh rotation	Asymmetry of movement Sharp click with thigh rotation: indicates possible congenital hip Uneven major gluteal folds: indicates possible congenital hip Polydactyly (extra digits on a hand or foot); syndactyly (webbing or fusion of fingers or toes)
Assess anus and rectum	Patent anus	Closed anus: no meconium

TABLE 11-3 Apgar Scoring

Sign	0	1	2
Heart rate	Absent	Slow (less than 100)	Over 100
Respiratory effort	Absent	Slow, irregular	Good, crying
Muscle tone	Flaccid	Some flexion of extremities	Active motion
Reflex irritability	No response	Cry	Vigorous cry
Color	Blue, pale	Body pink, extremities blue	Completely pink

APGAR scoring system is a method of evaluating a newborn's condition at 1 and 5 minutes after birth.

- Newborns who score 7–10 are considered free of immediate danger.
- Newborns who score 4–6 are moderately depressed.
- Newborns who score 0–3 are severely depressed.

Scores less than 7 at 5 minutes, repeat every 5 minutes for 20 minutes. Infant may be intubated unless 2 successive scores of 7 or more occur.

Assessment: Pediatric

Assessment	Normal	Abnormal
Measurements		
Measure height and weight and plot on a standardized growth chart	Height/weight proportional Sequential measurements: pattern follows normal growth curves	Height/weight below fifth percentile Sudden drop in percentile range of height and/or weight: possible sign of disease process or congenital problem Sudden and persistent increase (above 95th percentile)

(continued)

Assessment: Pediatric (Continued)

Assessment	Normal	Abnormal
Assess temperature (axillary or tympanic until 6 years of age)	Axillary 36.5°–37.5°C (97.7°F) Elevations after eating or playing not unusual Rectal 36.6°–37.2°C (97.8°F)	Temperature of 104°–105°F: corresponds roughly with 101°–102°F in an adult Large daily temperature variations Hypothermia: usually result of chilling
Measure circumference of head and chest		
Examine or check circumferences when child is less than 2 years old Compare measurements with standardized charts	Head at birth: about 2 cm greater than chest During first year: equalization of head and chest After 2 years: rapid growth of chest; slight increase in size of head	Increase in head circumference greater than 2.5 cm per month: sign of hydrocephalus
Assess pulse apically	Birth–1 year: 100–180 1 year: 80–150 2 years: 80–130 3 years: 80–120 Over 3 years: 70–110	Pulse over 180 <i>at rest</i> after first month of life: cardiac or respiratory condition Inability to palpate or very weak femoral and pedal pulses: possible coarctation of the aorta
Assess respirations	Birth: 30–50 6 years: 20–25 Puberty: 14–16 (Young children have abnormally high respiration rate with even slight excitement)	Consistent tachypnea: usually a sign of respiratory distress Respiratory rate over 100; lower respiratory tract obstruction Slow rate: may be sign of CNS depression
Assess blood pressure	Birth: 55–60/80–90 1 year: 90–60 Rise in both pressures: 2–3 points per year of age Adult level reached at puberty	Elevated blood pressure in upper extremities <i>and</i> decrease in lower extremities: coarctation of aorta Narrowed pulse pressure (normal or elevated diastolic with lowered systolic; less than 30 points difference between systolic and diastolic readings): possible sign of aortic or subaortic stenosis or hypothyroidism Widened pulse pressure: possible sign of hyperthyroidism
Appearance		
Observe general appearance	Alert, well-nourished, comfortable, responsive	Lethargic, uncomfortable, malnourished, gross anomalies, dull
Listen to voice and cry	Strong, lusty cry	Weak cry, low- or high-pitched cry: may indicate neurologic problem or chromosomal abnormality Stridor: possible upper airway edema or obstruction or hoarse cry
	Facial expression animated No indications of pain	Expressionless, unresponsive Doubling over, rubbing a body part, general fretfulness, irritability
Assess presence of odor	No odor	Musty odor: sign of phenylketonuria, diphtheria Odor of maple syrup: may be maple syrup urine disease Odor of sweaty feet: one type of acidemia Fishy odor: may be metabolic disorder Acetone odor: acidosis, particularly diabetic ketoacidosis

Assessment	Normal	Abnormal
Skin Assessment		
Assess pigmentation	Usually even Pigmented nevi common Large, flat, black and blue areas over sacrum, buttocks (mongolian spots)	Multiple cafe au lait spots: possible neurofibromatosis Cyanosis Jaundice Pallor
Assess lesions	Usually none Adolescence: acne	Erythematous lesions Multiple macules, papules, or vesicles Petechiae and ecchymoses: may indicate coagulation disorder
Assess signs/symptoms of abuse	None present	Hives (allergy) Subcutaneous nodules: may indicate juvenile rheumatoid arthritis Any unexplained bruises, welts, scars, burn marks, rope marks, failure to thrive, x-ray findings of multiple bone injuries, passive, noncommunicating child
Note consistency of skin	Good turgor Smooth and firm Check fontanel in infant	Poor turgor Dryness Edema Lack or excess of subcutaneous fat: sign of malnutrition or excess nutrition (obesity)
Assess nails	Nailbeds: normally pigmented Good nail growth	Cyanosis Pallor Capillary pulsations Pitting of the nails: possible sign of fungal disease or psoriasis Broad nailbeds: possible sign of Down's syndrome or other chromosomal abnormality
Assess hair (consistency appropriate to ethnic group)	No excessive breaking Consistent growth pattern	Dry, coarse, brittle hair: possible sign of hypothyroidism Alopecia (loss of hair): may be psychosomatic or due to drug therapy Unusual hairiness in places other than scalp, eyebrows, and lashes: may indicate hypothyroidism, vitamin A poisoning, chronic infections, reaction to Dilantin therapy Tufts of hair over spine or sacrum: may indicate site of spina bifida occulta or spina bifida Absence of the start of pubic hair during adolescence: possible hypothyroidism, hypopituitarism, gonadal deficiency, or Addison's disease
Assess lymph nodes	Nontender, movable, discrete nodes up to 3 mm in diameter in occipital, postauricular, parotid, submaxillary, sublingual, axillary, and epitrochlear nodes Up to 1 mm in diameter inguinal and cervical nodes	Tender or enlarged nodes: may be sign of systemic infection

(continued)

Assessment: Pediatric (Continued)

Assessment	Normal	Abnormal
Head and Neck Assessment		
Assess scalp	Usually without lesions	Ringworm, lice
Assess frontal and maxillary sinuses	Nontender	Tenderness: indicative of inflammatory process Seborrheic dermatitis
Assess face	Symmetrical movement	Asymmetry: signs of facial paralysis Twitching: could be due to psychosomatic causes; vitamin/mineral deficiency
Evaluate the eyes	With younger child, ability to focus and follow movement and to see objects placed a few feet away	Inability to follow movement or to see objects placed a few feet away
Gross screening of vision		
Snellen chart		
Sclerae	Completely white	Yellow sclera: sign of jaundice Blue sclera: may be normal or indicative of osteogenesis imperfecta
Placement in eye socket	Normally placed	Exophthalmos (protrusion of eyeball) Enophthalmos (deeply placed eyeball)
Iris	At rest: upper and lower margins of iris visible between the lids	Setting sun sign (iris appears to be beneath lower lid): if marked, may be sign of increased intracranial pressure or hydrocephalus
Movement	In newborn, intermittent strabismus or nystagmus	Fixed strabismus or intermittent strabismus continuing after 6 months of age: indication of muscle paralysis or weakness Involuntary, repetitive oscillations of one or both eyes: normal with <i>extreme</i> lateral gaze Nystagmus: may be cerebellar dysfunction indicative of use of certain drugs (anticonvulsants, barbiturates, alcohol)
Eyelids	Fully covers eye Fully raised on opening	Ptosis of eyelid: may be an early sign of a neurologic disorder Sty
Conjunctiva	Clear	Inflammation (conjunctivitis) Hemorrhage Stimson's lines (small red transverse lines on conjunctiva)
Cornea	Clear	Opacity: sign of ulceration Inflammation Redness
Discharge	Tears	Purulent discharges: note amount, color, consistency (bacterial conjunctivitis)
Pupils	Round, regular Clear, equal Brisk reaction to light Accommodation reflex (ability of lens to adjust to objects at different distances)	Sluggish or asymmetrical reaction to light: indicates intracranial disease Lack of accommodation reflex
Lens	Clear	Opacities (cataracts)

Assessment	Normal	Abnormal
Evaluate the ears Sinuses	No abnormality	Small holes or pits anterior to ear: may be superficial but could indicate the presence of a sinus leading into brain
Position	Top of ear above level of eye	Top of ear below level of eye: associated with some congenital defects
Discharge	None	Discharge: note color, odor, consistency, and amount
Hearing	In infant: turning to sound In older child: responds to whispered command	Diminished hearing in one or both ears
Assess the nose	No secretions Breathing through nose	Secretions: note characteristics Any unusual shape or flaring of nostrils Breathing through mouth
Assess the mouth	 Intact palate Teeth in good condition In older child presence of permanent teeth	Circumoral pallor: possible sign of cyanotic heart disease, scarlet fever, rheumatic fever, hypoglycemia; also seen in other febrile diseases Asymmetry of lips: seen in nerve paralysis Cleft palate Delayed appearance of deciduous teeth: may indicate cretinism, rickets, congenital syphilis, or Down's syndrome; may also be normal Poor tooth formation: may be seen with systemic diseases Green or black teeth: seen after iron ingestion or death of tooth Stained teeth: may be seen after prolonged use of tetracyclines
Assess the gums	Retention cysts in newborn	Inflammation, abnormal color, drooling, pus, tenderness Black line along gums: may indicate lead poisoning
Assess the tongue	Moves freely	Tremors on protrusion: may indicate chorea, hypothyroidism, cerebral palsy Protruding tongue—Down's syndrome White spots (thrush) Tongue-tie (frenulum) Strawberry tongue (scarlet fever)
Assess the throat	Pink, with conical, filiform nontender papillae Tonsils normally enlarged in childhood	White membrane over tonsils (diphtheria) White pus on sacs, erythema (bacterial pharyngitis), tender: vitamin deficiencies, anemia
Assess the larynx	Normal vocal tones	Hoarseness or stridor: possible upper respiratory tract obstruction

(continued)

Assessment: Pediatric (Continued)

Assessment	Normal	Abnormal
Assess the neck	Short in infancy Lengthens at 2–3 years Trachea slightly right of midline	Trachea deviated to left or right: may indicate shift with atelectasis
Thyroid	Not enlarged	Enlarged: may be due to hyperactive thyroid, malignancy, goiter
Movement	Full lateral and upward/downward motion	Limited movement with pain: may indicate meningeal irritation, lymph node enlargement, rheumatoid arthritis, or other diseases
Lungs and Thorax Assessment		
Assess the lungs	Normally clear and equal breath sounds bilaterally No retractions Symmetry of diaphragmatic movement	Presence of rhonchi, crackles, or wheezes Diminished breath sounds heard over parts of lung Mild to severe intercostal or sternal retractions indicative of respiratory distress Asymmetry of movement (phrenic nerve damage)
Assess the sputum	None or small amount of clear sputum in morning	Thick, tenacious sputum with foul odor Blood-tinged or green sputum
Assess the breasts	Slightly enlarged in infancy Generally slightly asymmetrical at puberty	Discharge or growth in male Masses (especially solid, fixed nonmobile) in older adolescent
Heart Assessment		
Assess heart sounds	S ₁ , S ₂ , S ₃	S ₄ indicates congestive heart failure
Assess femoral pulses	Strong	Weak
Note edema	None present	Edema—note location (initially periorbital) and duration, bulging fontanelles
Note clubbing of fingers	None present	Clubbing—congenital cyanotic heart defects; note location and duration
Note murmurs		Murmur grade 3 or higher is always abnormal No change in quality with positional changes
Note cyanosis	None normally present	Circumoral or peripheral cyanosis: indicates respiratory or cardiac disease (hypoxemia); congenital heart defects
Abdomen Assessment		
Assess skin condition	Soft	Hard, rigid, tender
Assess for peristaltic motion	Not visible	Visible peristalsis—may indicate pyloric stenosis (olive-shaped mass, palpable, in area of pylorus)

Assessment	Normal	Abnormal
Assess shape	“Pot-bellied” toddlers Slightly protuberant in standing adolescent	Large protruding abdomen: may indicate pancreatic fibrosis, hypokalemia, rickets, hypothyroidism, bowel obstruction, constipation, inguinal hernias, unilateral or bilateral: observe for reducibility
	Umbilical protrusion	Umbilical hernia
Genitourinary Tract Assessment		
Assess female genitalia		
Discharge	Mucoid, no odor	Foul or copious discharge; any bleeding before puberty
Assess male genitalia		
Presence of urethral orifice Urethral opening	Orifice on distal end of penis Normal size	Hypospadias or epispadias (urethral orifice along inferior or dorsal surface)
Foreskin	Covers glans completely	Stenosis of urethral opening Foreskin incompletely formed ventrally when hypospadias present
Placement of testes	Descended testes	Undescended testes Enlarged scrotum
Signs of abuse	No signs	Bruises, welts, swelling, discharge, bleeding
Assess urine output	Full, steady stream of urine	Urine with pus, blood, or odor (infection) Excessive urination or nocturia: possible sign of diabetes
Check anus and rectum	No masses or fissures present	Hemorrhoids, fissures, prolapse, pinworms Dark ring around rectal mucosa: may be sign of lead poisoning
Musculoskeletal Assessment		
Assess extremities		
	Coloration of fingers and toes consistent with rest of body	Cyanosis—indicates respiratory or cardiac disease, or hypothermia in newborn Clubbing of fingers and toes indicates cardiac or respiratory disease
	Quick capillary refill on blanching	Sluggish blood return on blanching indicates poor circulation
	Temperature same as rest of body	Temperature variation between extremities and rest of body indicates neurologic or vascular anomalies
	Presence of pedal pulses	Absence of pedal pulses indicates circulatory difficulties
	No pain or tenderness	Presence of localized or generalized pain
	Straight legs after 2 years of age	Any bowing after 2 years of age may be hereditary or indicate rickets
	Broad-based gait until 4 years of age; feet straight ahead afterwards	Scissoring gait indicates spastic cerebral palsy Persistence of broad-based gait after 4 years of age indicates possible abnormalities of legs and feet or balance disturbance Any limp or ataxia

(continued)

Assessment: Pediatric (Continued)

Assessment	Normal	Abnormal
Assess spine	No dimples Flexible	Presence of dimple or tufts of hair indicates possible spina bifida Limited flexion indicates central nervous system infections Hyperextension (opisthotonos) indicates brainstem irritation, hemorrhage, or intracranial infection
Have child bend forward at waist and check level of scapulae (scoliosis screening)	No lateral curvature or excessive anterior posterior curvature Scapulae at same height	Presence of lordosis (after age 2 years), kyphosis, or scoliosis
Assess hips		Asymmetrical thigh folds, clicks on adduction—hip dysplasia
Assess joints	Full range of motion without pain, edema, or tenderness	Pain, edema, or tenderness indicates tissue injury
Assess muscles	Good tone and purposeful movement Ability to perform motor skills approximate to development level	Decreased or increased tone Spasm or tremors may indicate cerebral palsy Atrophy or contractures

GERONTOLOGIC Considerations**Head and Neck and Neurologic System****Physiologic Changes With Age**

- Decreased speed of nerve conduction and delay in response and reaction time, especially with stress
- Diminution of sensory faculties; decreased vision, loss of hearing, diminished sense of smell and taste, greater sensitivity to temperature changes with low tolerance to cold
- Tooth loss
- Poor dentition, inadequate chewing, poor swallowing reflex
- Condition of teeth, gums, buccal cavity
- Periodontal disease

Taste sensation decreases.

- Chronic irritation of mucous membranes
- Atrophy of up to 80% of taste buds
- Loss of sensitivity of those on tip of tongue first: sweet and salt
- Loss of sensitivity of those on sides later: salt, sour, bitter

Assessment

- Facial symmetry
- Poor reflex reactions
- Level of alertness—presence of organic brain changes: memory impairment
- Motor function—strength

Skin**Physiologic Changes With Age**

Skin less effective as barrier:

- Decreased protection from trauma
- Less ability to retain water
- Decreased temperature regulation

Skin composition changes:

- Dryness (osteotosis) due to decreased endocrine secretion
- Loss of elastin
- Increased vascular fragility
- Thicker and more wrinkled on sun-exposed areas
- Melanocyte cluster pigmentation

Sweat glands:

- Decreased number and size
- Decreased function of sebaceous glands

Hair:

- General hair loss
- Decreased melanin production
- Facial hair increases in women

Nails:

- More brittle and thick

Assessment

Skin:

- Temperature, degree of moisture, dryness
- Intactness, open lesions, tears, decubiti
- Turgor, dehydration
- Pigmentation alterations, potential cancer
- Pruritus—dry skin most common cause
- Bruises, scars

Condition of nails (hard and brittle):

- Presence of fungus
- Overgrown or horny toenails, ingrown

Condition of hair

Infestations (scabies, lice)

Chest

Physiologic Changes With Age

Respiratory muscles lose strength and become rigid.

Ciliary activity decreases.

Lungs lose elasticity:

- Residual capacity increases.
- Larger on inspiration.
- Maximum breathing capacity decreases; depth of respirations decreases.
- Alveoli increase in size, reduce in number.
- Fewer capillaries at alveoli.
- Dilated and less elastic alveoli.

Gas exchange is reduced:

- Arterial blood oxygen PaO₂ decreases to 75 mmHg at age 70.
- Arterial blood carbon dioxide PaCO₂ unchanged.

Coughing ability is reduced—less sensitive mechanism.

More dependent on the diaphragm for breathing.

System less responsive to hypoxia and hypercardia.

Assessment

- Shape of chest excursion
- Lung and breath sounds
- Quality of cough, if present; sputum

Rib cage deformity

Dyspnea, hypoxia, and hypercarbia

Breast—size, symmetry, contour:

- Presence of lumps
- Size and shape of nipples

Heart

Physiologic Changes With Age

Mitral and aortic valves thicken and become rigid.

Cardiac output decreases 1% per year after age 20 due to decreased heart rate and stroke volume.

Vessels lose elasticity:

- Less effective peripheral oxygenation
- Position change from lying-to-sitting or sitting-to-standing can cause blood pressure to drop as much as 65 mmHg

Increased peripheral vessel resistance:

- Blood pressure increases: systolic may normally be 170 mmHg, diastolic may normally be 95 mmHg.
- Smooth muscle in arteries is less responsive.

Blood clotting increases.

Assessment

Heart sounds—murmurs

Peripheral circulation, color, warmth:

- Apical pulse
- Jugular vein distention

Orthostatic hypotension:

- Dizziness
- Fainting

Edema

Activity intolerance

Dyspnea

Transient ischemic attacks (TIAs)

Abdomen

Physiologic Changes With Age

Esophagus dilates, decreased motility.

Stomach:

- Hunger sensations decrease.
- Secretion of hydrochloric acid decreases.
- Emptying time decreases.

Peristalsis decreases and constipation is common.

Absorption function is impaired:

- Body absorbs less nutrients due to reduced intestinal blood flow and atrophy of cells on absorbing surfaces.
- Decrease in gastric enzymes affects absorption.

Hiatal hernia common (40%–60% of elderly).

Diverticulitis common (40% over age 70).

Liver:

- Fewer cells, with decreased storage capacity.
- Decreased blood flow.
- Enzymes decrease.
- Increased risk for drug toxicity.

Impaired pancreatic reserve.

Decreased glucose tolerance.

Assessment

- Indications of possible hiatal hernia.
- Bowel distention.
- Bowel sounds.

Genitourinary Tract

Physiologic Changes With Age

Kidneys:

- Smaller due to nephron atrophy.
- Renal blood flow decreases 50%.
- Glomerular filtration rate decreases 50%.
- Tubular function diminishes: less able to concentrate urine; lower specific gravity; proteinuria 1+ is common; blood urea nitrogen (BUN) increases 21 mg%.
- Renal threshold for glucose increases.

Bladder:

- Muscle weakens.
- Capacity decreases to 200 mL or less, causing frequency.
- Emptying is more difficult, causing increased retention.
- Increased risk of incontinence.

Prostate enlarges to some degree in 75% of men over age 65; hypertrophy.

Menopause occurs by mean age of 50.

Perineal muscle weakens.

Vulva atrophies.

Vagina:

- Mucous membrane becomes dryer.
- Elasticity of tissue decreases, so surface is smooth.
- Secretions become reduced, more alkaline.
- Flora changes.

Sexuality:

- Older people continue to be sexual beings with sexual needs.
- No particular age at which a person's sexual functioning ceases.
- Frequency of genital sexual behavior (intercourse) may tend to decline gradually in later years, but capacity for expression and enjoyment continues far into old age.

Assessment

- Condition of skin—dehydration
- Urinary output; blood in urine; color; specific gravity; prothrombin time (PT)
- Incontinence

- Bladder distention
- Genital assessment

Musculoskeletal System

Physiologic Changes With Age

Contractures:

- Muscles atrophy, regenerate slowly, strength diminishes.
- Tendons shrink and sclerose.

Range of motion of joints decreases:

- Lack of adequate joint motion, ankylosis
- Slight flexion of joints

Assessment

Mobility level:

- Ambulate with more difficulty.
- Limitation to movement.
- Muscle strength cramps.
- Gait becomes unsteady.
- Presence of kyphosis.
- Pain in joints.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- RNs must complete the admission assessment and document the findings. They cannot delegate this activity to anyone else on the team.
- LVN/LPNs may complete focus assessments each shift; however, any changes in assessment findings must be reported and verified with the RN.
- Unlicensed assistive personnel may not perform assessments on clients.

Communication Matrix

- Changes in assessment data identified in report or in the client's chart must be reported to the appropriate nurse assigned to complete the focus assessment.
- LVN/LPNs delegated the responsibility to complete focus assessments on clients must have clear direction on what is essential information to report back. Remind the LVN/LPN they must verify with the RN any changes identified in the assessment.
- Remind LVN/LPNs that if there are any questions on the client status as a result of their assessment, they must notify the RN immediately.

CRITICAL THINKING Strategies

Scenario 1

Mrs. Smiley has had a history of hypertension for several years. She has recently experienced an inability to use her right arm and leg and has lost ability to express herself. She has been admitted to your unit with the diagnosis of R/O left CVA (stroke) and has been placed on a continuous heparin IV drip.

1. Based on admitting data, make a judgment about what deviations from normal you would find in the physical examination.
2. List appropriate nursing diagnoses based on her physical state and immobility status (this affects virtually all systems).

3. In view of all these existing and potential problems, identify *priority* concerns (all are important concerns) for this client.
4. Develop a plan of care addressing these priority concerns.

Scenario 2

You are caring for a woman in labor and monitoring the fetal heart rate. You note that early deceleration has occurred (a 10- to 20-beat drop in the fetal heart rate).

1. From these symptoms, indicate your priority intervention.
2. What would you conclude about the viability of the fetus?
3. What does this change in condition of the fetus imply?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. The systematic approach the nurse should follow when auscultating a client's lungs is
 1. Anterior to posterior.
 2. Top to bottom.
 3. Posterior to lateral to anterior.
 4. Side to side.
2. The nurse suspects that a client has appendicitis. When assessing for rebound tenderness, the nurse should
 1. Perform this assessment first.
 2. Have the client take a deep breath.
 3. Palpate deeply with quick release of pressure.
 4. Have the client lie flat with legs extended.
3. A client comes into the clinic for evaluation of a burn injury from hot liquid. The lesions are flat and red. The nurse should document the presence of
 1. Macules.
 2. Wheals.
 3. Vesicles.
 4. Papules.
4. The nurse is assessing a client's deep tendon reflexes. When documenting a normal response, the nurse would chart
 1. +1.
 2. 0.
 3. +2.
 4. +4.
5. The cranial nerve that is assessed when testing for the "gag reflex" is the
 1. XI accessory.
 2. VII facial.
 3. IX glossopharyngeal.
 4. XII hypoglossal.
6. During a cardiac assessment, the S₁ heart sound can be heard best
 1. At the second intercostal space.
 2. By using the bell of the stethoscope.
 3. Over the aortic area.
 4. At the apex of the heart.
7. When assessing the lymph nodes in the neck, the nurse should instruct the client to
 1. Raise the chin.
 2. Lie in a supine position.
 3. Swallow a sip of water.
 4. Flex neck slightly.
8. Completing a physical assessment, the nurse is unable to palpate a peripheral pulse, the dorsalis pedis. The next intervention would be to
 1. Notify the physician.
 2. Examine the adjacent area.
 3. Obtain a new Doppler.
 4. Move on to the next area.
9. The urinary tract assessment includes checking the specific gravity of the client's urine to determine if it is within normal limits. The normal range of specific gravity is _____.
 1. How do you feel today?
 2. What work did you do 20 years ago?
 3. Who is the president of the United States?
 4. Tell me about why you are in the hospital.
10. Suspecting that the client you are assessing may be exhibiting cognitive decline or dementia, which of the following statements would be appropriate?
 1. How do you feel today?
 2. What work did you do 20 years ago?
 3. Who is the president of the United States?
 4. Tell me about why you are in the hospital.

12

Body Mechanics and Positioning

LEARNING OBJECTIVES

1. Discuss the primary function of the skeletal muscles, joints, and bones.
2. Describe nursing measures that assist in preserving joints, bones, and skeletal muscles
3. Describe the ANA Standards that promote safe handling of clients and prevention of injury to healthcare workers.
4. Describe a minimum of two principles of correct body mechanics.
5. State two expected outcomes of using proper body mechanics.
6. Discuss the objectives for moving and turning clients.
7. Compare and contrast the methods used in moving clients up in bed for a single nurse and when assistants are available.
8. Describe the position of the head of the bed in the four Fowler's positions.
9. Describe the correct placement of the canvas pieces when placing a client on the floor-based client lift.
10. Explain the rationale of assisted ambulation for clients.
11. Demonstrate the procedures for moving a client to the side of the bed and dangling a client.
12. Outline the steps in logrolling a client.
13. Describe requirements for lift team members.
14. List the pertinent data that should be charted when moving a client from the bed.
15. Write a client care plan using at least three nursing diagnoses for a client requiring moving and turning interventions.

TERMINOLOGY

Alignment referring to posture, the relationship of body parts to one another.

Ambulate walking; able to walk.

Appendicular skeleton composed of 126 bones, which include the shoulder girdle, arm bones, pelvic girdle, and leg bones.

Assistive equipment used to move clients without placing pressure on back and trunk.

Atrophy a wasting; decrease in size of an organ or tissue.

Axial skeleton includes the head and trunk, which form the central axis to which the appendicular skeleton is attached.

Balance client's ability to maintain equilibrium.

Base of support surface area on which an object rests (e.g., for a client lying in prone position, the base of support is the entire undersurface of the body).

Body mechanics movement of the body in a coordinated and efficient way so that proper balance, alignment, and conservation of energy is maintained.

Brachial plexus network of spinal nerves supplying arm, forearm, and hand.

Cartilage nonvascular, dense supporting connective tissue. Found in joints, thorax, larynx, trachea, nose, and ear.

Center of gravity midpoint or center of the body weight. In an adult it is the midpelvic cavity between the symphysis pubis and umbilicus.

Dangle to have a client sit on the edge of the bed with feet in a dependent position, flat on floor, if possible.

Dorsiflexion upward or backward flexion of a part of the body, such as the foot at the ankle.

Ergonomics physical stressors involving excessive force; i.e., lifting heavy objects or working in an awkward position.

Flexion the act or condition of being bent.

Footdrop a falling or dragging of the foot from paralysis of the flexors of the ankle.

Fowler's position head of bed is at a 45° angle; client's knees may or may not be flexed.

Gravity the force that pulls objects toward the earth's surface.

High-Fowler's position head of bed is at a 60° angle; often used to achieve maximum chest expansion.

Hoyer lift a mechanical device that enables one person to safely transfer a client from bed to chair.

Joint the portion of the body where two or more bones join together.

Leverage the use of a lever to apply force.

Ligament a band or sheet of strong fibrous connective tissue connecting the articular ends of bones serving to bind them together and to facilitate or limit motion.

Line of gravity an imaginary line that goes from the center of gravity to the base of support.

Manual client handling tasks such as lifting, transferring, and repositioning of clients without use of assistive devices.

Mobility state or quality of being mobile; facility of movement.

Musculo pertaining to muscles.

Musculoskeletal pertaining to the muscles and bones.

Orthosis use of external device or special equipment to stabilize or immobilize a body part, protect against injury, or assist with function.

Paralysis temporary or permanent loss of function, especially loss of sensation or voluntary motion.

Posture attitude or position of body.

Prone lying horizontal with face downward.

Reverse Trendelenburg's position mattress remains un bent, but head of bed is raised and foot is lowered.

Semi-Fowler's position head of bed is at a 30° angle; often used for clients with cardiac and respiratory problems.

Skeletal system system of separate bones (206) bound together by ligaments and responsible for supporting, moving, and giving shape to the body.

Sprain injury caused by wrenching or twisting of a joint that results in tearing or stretching of the associated ligaments.

Stable when the center of gravity is close to the base of support.

Strain injury caused by excessive force or stretching of muscles or tendons around the joint.

Trendelenburg's position mattress remains un bent but the head of the bed is lowered and the foot is raised. "Shock blocks" may be used under the legs of the bed to achieve this position.

Trochanter either of the two bony prominences below the neck of the femur.

MUSCULOSKELETAL SYSTEM

The musculoskeletal system protects the body, provides a structural framework, and allows the body to move. The primary structures in this system are muscles, bones, and joints.

Skeletal Muscles

Skeletal muscles move the bones around the joints by contracting and relaxing so that movement can take place. Each muscle consists of a body, or belly, and tendons, which connect the muscle to another muscle or to bone.

When skeletal muscles contract, they cause two bones to move around the joint between them. One of these bones tends to remain stationary while the other bone moves. The end of the muscle that attaches to the stationary bone is called the origin. The end of the muscle that attaches to the movable bone is called the insertion.

Muscles are designated flexors or extensors according to whether they flex the joint (decrease the angle between the bones) or extend the joint (increase the angle between the bones). For example, when the deltoid muscle contracts, it abducts the arm and raises it laterally to the horizontal position. The anterior fibers aid in flexion of the arm, and the posterior fibers aid in extension of the arm.

Joints

Joints are the places where bones meet. Their primary function is to provide motion and flexibility. Although the internal structure of joints varies, most joints are composed of ligaments, which bind the bones together, and cartilage, or tissue, which covers and cushions the ends of the bones.

Bones

Bones provide the major support for all the body organs. Bone is composed of an organic matrix, deposits of calcium salts, and bone cells. The organic matrix provides the framework and tensile strength for the bone. The calcium salts, which are about 75% of the bone, provide compressional strength by filling in the matrix. As a result, it is very difficult to damage a bone by twisting it or by applying direct pressure.

Bone cells include osteoblasts, osteocytes, and osteoclasts. Osteoblasts deposit the organic matrix; osteocytes and osteoclasts reabsorb this matrix. Because this process is usually in equilibrium, bone is deposited where it is needed in the skeletal system. If increased stress is placed on a bone, such as the stress of continued athletic activity, more bone is deposited. If there is no stress on a bone, as is often the case with clients on prolonged bedrest, part of the bone mass is reabsorbed, or lost.

SYSTEM ALTERATIONS

Alterations in mobility can result from problems in the musculoskeletal system, the nervous system, and the skin. A primary cause for alterations in muscles is inactivity. With forceful activity muscles increase in size. With inactivity muscles decrease in size and strength. When clients are in casts, in traction, on prolonged bedrest, or unable to exercise, their muscles become weak and atrophied.

Alterations in joints result when mobility is limited by changes in the adjacent tissues. When muscle movement decreases, the connective tissue in the joints, tendons, and ligaments becomes thickened and fibrotic.

Chronic flexion and hyperextension can also cause alterations in the joints. Chronic flexion can cause joints to become contracted in one position so that they are unmovable. Hyperextension occurs when joints are extended beyond their normal limits, which is usually 180°. The results of hyperextension are pain and discomfort to the client and abnormal stress on the ligaments and tendons of the joints.

TABLE 12-1 Pathophysiological Effects of Immobility

System Affected	Result
Cardiovascular	<ul style="list-style-type: none"> • Veins become engorged, leading to valve damage due to lack of muscular activity. • Increased risk of clot formation due to slowing of blood flow and inadequate circulation of blood to cells and tissues.
Heart Effects	<ul style="list-style-type: none"> • Valsalva maneuver, caused by holding the breath when trying to raise up in bed or when having a bowel movement, leads to increased workload on the heart. • Potential for blood pressure decrease causing orthostatic hypotension when standing; can lead to falls.
Respiratory	<ul style="list-style-type: none"> • Accumulation of thick secretions pooling in the lower respiratory structures, secondary to spinal positioning. • Prevents lung expansion, decreases movement of secretions in the airways, and decreases expectoration of secretions.
Gastrointestinal	<ul style="list-style-type: none"> • An indirect effect of immobility on the GI system occurs during the intake of nutrients, both food and water. • Decreased metabolic needs can cause anorexia. • Decreases in food intake lead to protein deficiency. • Constipation or diarrhea may occur due to fecal impaction, weakened muscle tone, and not feeling the urge to defecate.
Urinary	<ul style="list-style-type: none"> • Immobility causes the kidneys to force urine against gravity. • Sluggish flow leads to pooling of urine in the kidney and increases the risk of renal calculi and infection. • Loss of sphincter muscle tone can lead to urinary incontinence, resulting in losing the urge to void and increased urine dribbling.
Musculoskeletal	<ul style="list-style-type: none"> • Loss of muscle tone and deterioration of bone leads to weakness and stiffness. • Loss of elasticity and demineralization of bones leads to osteoporosis.

Alterations in bone are caused by disease processes, decalcification, and breaks caused by trauma or twisting. Encouraging clients to stand and to walk is important because the body functions best when it is in a vertical position. Physical activity forces muscles to move and increases blood flow, which improves metabolism and facilitates such body functions as gastrointestinal peristalsis.

Many body systems are affected by immobility. Even a few days of immobility can lead to alterations in many body systems. The following chart indicates a few of the systems affected and what occurs with immobility.

In addition to the system alterations, mental health can be affected. Alterations in mental health can range from depending upon others for care, loss of independence, isolation, and depression.

Nursing Measures

Nursing care measures to preserve the joints, bones, and skeletal muscles should be carried out for all clients who require bedrest. Positions in which clients are placed and methods of moving and turning should all be based on the principles of maintaining the musculoskeletal system in proper alignment. The nurse must also use good body mechanics when moving and turning clients to preserve her or his own musculoskeletal system from injury. These nursing measures are also performed by the home care providers.

In addition to paying attention to the body positioning and moving and turning, it is essential to:

- Perform range-of-motion exercises—maintain blood circulation and muscular activity, as well as promote oxygenation to the cells and tissues.
- Provide frequent turning and proper positioning—essential to prevent skin breakdown.
- Avoid using the Valsalva maneuver when turning or moving the client.
- Increase fluids to maintain blood flow, unless contraindicated by the client's condition.
- Instruct the client in coughing and deep-breathing exercises to prevent and remove secretions from the airways and promote oxygenation.
- Provide nutritious meals, especially high calcium for bone health.

BODY MECHANICS

Knowledge of a client's body and how it moves is important. Knowledge of your own body and what happens to it when you care for clients with altered mobility is also important. Before you lift or move a client, determine the causes and consequences of the client's illness and implement the use of Safe Patient Handling and Management Algorithms to determine the appropriate client moving/transfer protocols. These guidelines also indicate the equipment needed for safe client transfer/moving or the need for the lift team. This knowledge enables you to move the client without causing additional discomfort.

The most common client handling approaches used in the United States in the past included manual client lifting, education related to body mechanics, education in safe lifting techniques, and the use of back belts. There is strong evidence that each of these approaches is not effective in reducing caregiver injuries. Evidence-based practice indicates that use of client handling equipment/devices, client care ergonomic assessment protocols, "No Lift" policies, education of proper use of client handling equipment/devices, and client lift teams reduce injury to both clients and staff.

The physical environment of the healthcare setting and the aging of the nursing workforce also contribute to work-related injuries. The "tight quarters" and configuration of client rooms, nurses' work areas, and equipment can affect use of appropriate body mechanics as well as equipment for moving clients.

A well-designed client care environment assists the staff in using ergonomically sound procedures that improve client handling. The size of the hospital room determines the ability of the staff to use safe handling techniques. It is recommended that 6 feet be left between the door and client's bed to accommodate lifting equipment, such as a floor lift. Leaving 42 in. between the toilet and wall on one side will accommodate a lateral standing transfer. Doorways should be 36 to 43 in. wide to accommodate bariatric equipment.

Trying to lift or move too much weight forces you to use your body incorrectly and frequently causes injuries. The average weight of clients who require lifting is 169 lbs, but with the increasing rates of obesity, it will be changing. The National Institute for Occupational Safety and Health (NIOSH) states that the average worker should not lift more than 51 lb under controlled and limited circumstances. Incorrect lifting puts most of the pressure on the muscles of your lower back. Because these muscles are not strong enough to handle the stress, you can sustain severe injuries. If you do not follow guidelines for promoting proper body mechanics or using equipment, you are putting your own health and safety in jeopardy. It is advisable that healthcare workers do simple exercises to strengthen and stretch the abdominal muscles and muscles that support the back. This will assist in preventing back injuries.

Low back pain is an occupational hazard for many workers. Back injuries account for approximately 20% of all injuries and illnesses in the workplace.

Nursing personnel are among the most at risk for musculoskeletal disorders. Nurses ranked number six among occupations with a high risk of strains and sprains. The ANA research on the impact of musculoskeletal injury indicates 52% of nurses complain of chronic back pain and 30% of nurses who acquired back pain were required to leave work. Twelve percent of all nurses left the profession as a result of back pain. The majority of the injuries occur from manual client handling. Moving or lifting a client in bed precipitated 61% of low back pain episodes and 60% of lost workdays. Other movements, such as forward bending, twisting, and reaching when assisting clients with ADLs are associated factors in musculoskeletal disorders.

The Occupational Safety and Health Administration (OSHA) has developed the following lifting guidelines for healthcare workers to prevent injury to the client and the worker.

- Evaluate need for assistive devices or lift team.
- Never lift clients who have fallen if you are alone. Use team lifts or use mechanical assistance.
- Never transfer clients when off-balance.
- Lift loads close to the body.
- Limit number of allowed lifts per worker per day.
- Avoid heavy lifting, especially, with spine rotated.
- Complete training in “when and how” to use mechanical assistive devices.

Source: Occupational Safety and Health Administration. HealthCare Wide Hazards Module: Ergonomics. <http://www.osha.gov/SLTC/etools/hospital/hazards/ergo/ergo.html>.

Proper use of body mechanics helps prevent injuries to clients and all members of the health team. Guidelines that underlie the implementation of body mechanics include:

- Assume a proper stance before moving or turning clients.
- Distribute workload evenly before moving or turning clients.
- Establish a comfortable height when working with clients. Keep the client as close to your body as possible when moving.
- Push and pull objects when moving them to conserve energy.
- Use large muscles for lifting and moving, not back muscles. Move the hip and shoulders as one unit.
- Avoid leaning and stretching.
- Request assistance from others or use client-handling equipment/devices when working with heavy clients to avoid strain.
- Avoid twisting your body.
- Maintain low back in neutral position.

In addition to proper use of body mechanics, ergonomic protection and education programs must be implemented in all healthcare facilities to decrease risk factors related to back injuries. Whereas the use of body mechanics, equipment, and devices alone does not prevent back injuries and musculoskeletal disorders among nurses, together, appropriate use of body mechanics and a safe client handling or client care ergonomics program can decrease injuries in both number and severity.

ANA Promotes Safe Handling Legislation

The American Nurses Association (ANA) has been campaigning for the Federal Occupational Safety and Health Administration (OSHA) to develop standards to control ergonomic hazards in the workplace for the prevention of work-related musculoskeletal disorders. This regulation would

include stipulations requiring healthcare settings to use assistive lift and transfer equipment for client handling tasks and eliminate total manual client handling. Using assistive equipment and devices prevents injury such as falls and skin tears, especially in geriatric clients. Anxiety reduction and client comfort occurs during lifting, transferring, or repositioning and promotes confidence in the healthcare team. Assistive devices are selected based on the client’s ability to assist with moving and thus promotes client autonomy. In the absence of a national standard, the ANA established the Handle With Care national campaign in 2003 (www.NursingWorld.org/handlewithcare/). This proactive plan was developed to promote safe client handling and the prevention of musculoskeletal disorders among nurses.

As part of the campaign, the ANA fostered the development of client care ergonomics, programs that include the use of assistive client handling equipment and devices and the elimination of manual client handling. The ANA Handle With Care Recognition Program rewards and increases visibility of healthcare organizations that have made the commitment to and the investment in safe patient handling programs. The U.S. Senate Bill S1788 was introduced in October 2009 to establish a Safe-Client Handling and Prevention Standard. As of August 2010, the hearings have not yet been completed.

HOME CARE

Knowledge of body mechanics and how to use these principles when giving care is important to both the healthcare provider and the client. Correct use of body mechanics decreases the caregiver’s potential for injury and provides safety for the client. Recently, there has been an increase in the number of back injury accident claims among home healthcare providers. One reason for the increase is the improper use of body mechanics while performing skills in the home setting. Also, there may be no one to assist the care provider when lifting and turning clients in the home. The nurse may need to improvise, as the equipment may not be adequate or adjustable. More home care agencies assist clients in obtaining assistive devices. The purpose of this unit is to consider adaptations necessary for providing safe care to the client while using proper body mechanics. In the home setting, much of the care is given by the family; therefore, it is essential that they also be taught good body mechanics.

CULTURAL AWARENESS

Different cultures may have cultural variances regarding distance and space. When clients are being moved or transferred to a bed or gurney, the client is brought close to the nurse’s body. It is important to explain the transfer process to client, particularly Americans, Canadians, and British clients. They may be threatened by invasion of personal space and touch. Japanese, Arabs, and Latin Americans may not be as concerned about personal space.

NURSING DIAGNOSES

The following nursing diagnoses are appropriate to use on client care plans when the components are related to body mechanics.

NURSING DIAGNOSIS	RELATED FACTORS
Activity Intolerance	Impaired motor function, weakness, paralysis, or pain
Risk for Injury	Altered mobility, impaired sensory function, prolonged bedrest
Impaired Physical Mobility	Trauma or musculoskeletal impairment, surgical procedure, muscle weakness, pain, decreased strength
Impaired Transfer Ability	Weakness, flaccidity, amputation, decreased strength
Impaired Walking	Muscle weakness, impaired motor function, orthopedic surgery, or dysfunction
Ineffective Breathing Patterns	Musculoskeletal dysfunction; decreased energy
Ineffective Peripheral Tissue Perfusion	Mechanical reduction of venous and/or arterial blood flow

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. Remember to wash your hands or use antibacterial gel before and after each and every client contact.

IDENTIFY CLIENT Before every procedure, check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Chapter 12

UNIT 1

Proper Body Mechanics

Nursing Process Data

ASSESSMENT Data Base

- Evaluate personnel's knowledge of the principles of body mechanics.
- Evaluate personnel's knowledge of how to use correct muscle groups for specific activities.
- Assess knowledge and correct any misinformation about body alignment and how to maintain it with each position.
- Assess knowledge of physical science and application to balance and body alignment.
- Assess the competency of spinal cord and associated musculature.
- Assess the muscle mass of the long, thick, and strong muscles of the shoulders and thighs.

PLANNING Objectives

- To promote proper body mechanics while caring for clients
- To maintain good posture, thereby promoting optimum musculoskeletal balance
- To provide knowledge of the musculoskeletal system, body alignment, and balance in order to assist the nurse in caring for clients
- To correct body mechanics, promote health, enhance appearance, and assist body function

IMPLEMENTATION Procedures

- Performing Back Exercises 341
- Applying Body Mechanics 341
- Maintaining Proper Body Alignment 343
- Using Coordinated Movements 344
- Using Basic Principles 345

EVALUATION Expected Outcomes

- Correct body mechanics are used when preparing for and providing client care.
- Injuries are prevented to both the nurse and the client.
- Proper body mechanics facilitate client care.
- Clients and nurses are not injured when nursing care is provided.
- Center of gravity is maintained when lifting objects.
- Back care exercises promote back health.

- Critical Thinking Application** 346
- Expected Outcomes 346
 - Unexpected Outcomes 346
 - Alternative Actions 346

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Performing Back Exercises

Equipment

Small pillow

NOTE: This skill is for nurses to prevent back strain.

Procedure

- Complete the four exercises in order, and repeat 10 cycles. ► **Rationale:** to assist in strengthening stomach, buttocks, and thigh muscles and stretching lower back muscles to prevent back injuries.
- Complete pelvic tilt exercises.
 - Lie flat on your back with head on a small pillow or stand against a wall.
 - Bend knees and hips so feet are flat on the hard surface.
 - Push lower back onto floor or against wall (back needs to be flat).
 - Tighten abdominal muscles, then exhale.
 - Tighten gluteal muscles, then exhale.
 - Lift hips from floor, or away from wall, and tilt whole pelvis forward while maintaining back flat against hard surface. Hold position for count of 10.
 - Slowly relax.
- Complete 10 lumbar stretches to keep natural curves of spine in shape.
 - Lie flat on floor with head on pillow.
 - Bend knees and slowly bring them toward your chest. Place hand behind thigh to assist in bending knees.
 - Keep head on pillow, and elevate buttocks as high as possible off the floor. Keep knees as close to chest as possible.
 - Hold position, holding onto thighs and keeping knees to chest for count of 10.
- Complete hamstring stretches for 10 cycles to promote easy bending.
 - Lie on a hard surface with knees close to the chest in a relaxed position.
 - Slowly extend one leg toward ceiling, flex foot and push heel upward to feel hamstring muscles stretch. Hold position and count to 10. Bend leg and bring knee back toward chest.
 - Extend second leg while lowering first leg and complete step b.
 - Repeat exercise 10 times and then bring both knees toward chest, roll to one side, and take a standing position.
- Complete reverse sit-ups to strengthen abdominal muscles.
 - Sit on floor in upright position with knees bent.
 - Lock hands together behind head and hold arms out to side.
 - Slowly lean back 15 degrees while tightening stomach muscles. Hold position for count of at least 5.
 - Slowly lean back about 20 degrees, hold the position, and count to 10.
 - Slowly return to an upright position, Repeat exercises 10 cycles.

Clinical Alert

Stop exercises if you experience pain or if it gets more difficult with repetitions. Check with your physician before attempting exercises.

Applying Body Mechanics

Procedure

- Determine need for assistance in moving or turning a client following OSHA Lifting Guidelines. ► **Rationale:** Half of all back pain is associated with lifting or turning clients. The most common back injury is strain on the lumbar muscle group.
- Establish a firm base of support by placing both feet flat on the floor, with one foot slightly in front of the other.
 - Distribute weight evenly on both feet.
- Slightly bend both knees. ► **Rationale:** Allows strong muscles of legs to do the lifting.
- Hold abdomen firm and tuck buttocks in so that spine is in alignment. ► **Rationale:** This position protects the back.
- Hold head erect and secure firm stance.
- Use this stance as the basis for all actions in moving, turning, and lifting clients.
- Maintain weight to be lifted as close to your body as possible. ► **Rationale:** This position maintains the center of gravity and provides leverage that reduces lower back strain.
- Align the three natural curves in your back (cervical, thoracic, and lumbar). ► **Rationale:** Weight of client is evenly distributed throughout spine, lowering risk of back injury.
- Prevent twisting your body when moving the client. ► **Rationale:** This prevents injury to the back.

Clinical Alert

Proper body mechanics is a myth according to the American Nurses Association "Handle With Care" campaign. "Proper body mechanics" training does not translate well into nursing practice. Body mechanics methods primarily concentrate on the lower back for lifting and do not account for other vulnerable body parts involved in other types of client handling tasks, such as lateral transfers.

Guidelines on Prevention of Low Back Pain for Workers

- Physical exercise is recommended for prevention of low back pain. There is insufficient evidence to recommend for or against any specific type or intensity of exercises.
- Lumbar supports or back belts are not recommended.
- Shoe inserts/orthoses are not recommended. There is insufficient evidence to recommend for or against insoles, soft shoes, soft flooring, or antifatigue mats.
- Temporary modified work and ergonomic workplace adaptations can be recommended to facilitate early return to work for individuals with low back pain.
- There is insufficient consistent evidence to recommend physical ergonomic interventions alone for prevention of low back pain.
- Further research is necessary to determine appropriate prevention in low back pain. Future studies need to be high quality, using randomized controlled trials.

▲ Gait belts are routinely used to assist in manual transfer in most facilities.

▲ Manual transfers from bed to chair should be done only if client is able to stand.

▲ Use proper body mechanics whenever moving clients or objects.

EVIDENCE-BASED PRACTICE

Use of Back Brace to Prevent Back Injury

Two studies on prevention of low back pain using a back support differed in their conclusions. One study, Linton and van Tulder, researched the literature and found 27 investigations that were consistently negative about the use of back braces to prevent low back pain. There is strong evidence not only that they are ineffective in prevention, but that lumbar supports or back belts are no more beneficial than either no intervention or preventative interventions; in fact, they may be detrimental. The results of the Linton and van Tulder study were consistently negative about the use of lumbar supports. The study indicated that exercises, conversely, showed positive results in the randomized controlled trials, providing consistent evidence of their function in prevention.

The second study, conducted at the University of California, Los Angeles (UCLA), by Kraus, McArthur, and Samaniego, found the opposite results. The UCLA study “found compelling evidence that back support can play an important role in helping reduce back

injuries among workers who do a lot of lifting.” The study, completed in 1994 with 36,000 participants, indicated that low back injuries are reduced by one-third when workers wear a back support. This study recommends worker training and proper workplace ergonomics design and indicates that back supports should be part of an overall back injury prevention program.

The National Institute of Occupational Safety and Health (NIOSH) reviewed the scientific findings in the UCLA study and issued a report in 1994 that concluded the benefit of back supports remained unproven and did not recommend that they be used. A number of preventive measures have been introduced to prevent work-related back injuries. Training, job screening, and ergonomic modification are recommended by NIOSH, but objective evidence of their effectiveness alone or in combination has been elusive and subject to many issues and problems.

These study results have culminated in a recommendation by the European Guidelines for Prevention in Low Back Pain (November 2004) to promote prevention of low back pain using activity/exercise, ergonomics, and orthosis. Physical exercise has a positive effect in prevention of back pain. Various types of activities were reviewed, such as aerobic exercises, physiotherapy, and specific trunk muscle training. The researchers found no specific differences in pain intensity between these interventions. No studies indicated harmful effects of exercise or increased symptoms of pain.

Source: Linton, S. J., & van Tulder, M. W. (2001). Preventive interventions for back and neck problems: What is the evidence? *Spine*, 26(7), 778–787.

◀ Ensure that height of bed allows you to work without causing injury.

Maintaining Proper Body Alignment

Procedure

1. Begin with the proper stance established in the previous intervention.
2. Evaluate working height necessary to achieve objective.
 - a. Test parameters of possible heights (i.e., bed moves within an approximate range of 18 in. from floor).
 - b. Establish a comfortable height in which to work; usual height is between waist and lower level of hip joint.
3. Test that this level minimizes muscle strain by extending your arms and checking that your body maintains proper alignment.
4. If you need to work at a lower level, flex your knees.
 - ▶ **Rationale:** Bending over at the waist results in back strain.
5. Make accommodations for working at high surface levels.
 - ▶ **Rationale:** Reaching up may result in injury to the back through hyperextension of muscles.

▲ **Correct:** Keep body in correct alignment when turning and reaching for objects to prevent muscle strain or back injury.

▲ *Incorrect:* Do not use stretching or twisting movements when you reach for objects out of close proximity to your body.

▲ *Correct:* Work close to the body so that center of gravity is not misaligned.

6. Work close to your body so that your center of gravity is not misaligned and your muscles are not hyperextended.
 - ▶ **Rationale:** This prevents back strain.
7. Use your longest and strongest muscles (biceps, quadriceps, and gluteal) when moving and turning clients.
8. Whenever possible, roll, push, and pull objects instead of lifting.

▲ *Incorrect:* Bending over incorrectly could injure back muscles and cause undue strain.

Using Coordinated Movements

Procedure

1. Plan muscle movements to distribute workload before you actually begin turning, moving, or lifting clients.
 - a. Establish a clear plan of action before you begin to move.
 - b. Take a deep breath so oxygen is available for energy expenditure.
 - c. Tense antagonistic muscles (abdomen) to those you will be using (diaphragm) in preparation for the movement.

▲ *Correct:* Move muscles as a unit and in alignment rather than twisting.

- d. Release breath and mobilize major muscle groups (abdominal and gluteal) to do the work.
2. Move muscles in a smooth, coordinated manner.
 - ▶ **Rationale:** This avoids putting strain on one muscle and is more efficient.
3. Do not make jerky, uncoordinated movements. ▶ **Rationale:** This may cause injury or frighten the client.
4. When you are working with another staff member, coordinate plans and movements before implementing them.

▲ *Incorrect:* Do not twist or rotate upper body when working at lower surface levels.

Using Basic Principles

1. Move an object by pushing and pulling to expend minimal energy.
 - a. Stand close to the object.
 - b. Place yourself in proper body alignment stance.

▲ **Correct:** Keep body in proper alignment by bending knees and keeping back straight when lifting objects.

▲ **Incorrect:** Prevent injury to back muscles; for proper alignment, bend at knees and use leg muscles.

▲ **Correct:** Hold objects close to the body to prevent muscle strain and possible back injury.

▲ **Incorrect:** Holding objects away from the body may cause back strain or injury.

▲ **Correct:** When pushing an object, place yourself in proper body alignment.

▲ **Incorrect:** Standing away from object puts body out of proper alignment.

- c. Tense muscles, and prepare for movement.
- d. Pull toward you by leaning away from the object and letting arms, hips, and thighs (*not back*) do the work.
- e. Push away from you by leaning toward object, using body weight to add force.

2. When changing direction, use pivotal movement—moving muscles as a unit and in alignment, rather than rotating or twisting upper part of body.
3. When working at lower surface levels, do not stoop by bending over. Flex body at knees and, keeping back straight, use thigh and gluteal muscles to accomplish task.
4. Use muscles of arms and upper torso in an extended, coordinated movement parallel to body stance when reaching to prevent twisting or hyperextension of muscles.
5. Lift clients or objects with the maximum use of these body alignment principles:
 - a. Determine that the movement is within your capability to perform without injury.
 - b. Place yourself in proper body alignment stance.
 - c. Stand close to and grasp the object or person near the center of gravity.
 - d. Prepare muscles by taking a deep breath, and set muscles.
 - e. Lift object with arms or by stooping and using leg and thigh muscles.
- f. Carry object close to your body to prevent strain on your back.
- g. Take frequent rest periods to prevent additional strain.

The Veteran's Health Administration completed a literature review and determined that body mechanics training has proven to be ineffective.

1. Body mechanics training alone is not effective to prevent job-related injuries.
2. There is no evidence that back belts are effective in reducing risks to caregivers.
3. Literature does not support the myth that physically fit nurses are less likely to be injured.
4. The average worker should lift no more than 51 pounds and only under controlled circumstances.
5. The long-term benefits of proper equipment and mechanical lifts far outweigh the costs related to work-related injuries.
6. Staff will use the equipment when they are included in the decision-making process for purchasing new equipment.

Source: American Nurses Association. (2002). <http://www.NursingWorld.org>.

DOCUMENTATION for Body Mechanics

- Devices needed for turning and moving
- Number of personnel required for turning and moving
- Ways in which client assists in moving
- Special requirements of client for proper body alignment, such as support pillows
- Complete an unusual occurrence report for client or nurse injury during transfer or moving client. (Some facilities refer to this as a Safety Report or Incident Report.)

CRITICAL THINKING Application

Expected Outcomes

- Correct body mechanics are used when preparing for and providing client care.
- Injuries are prevented to both the nurse and the client.
- Proper body mechanics facilitate client care.
- Clients and nurses are not injured when nursing care is provided.
- Center of gravity is maintained when lifting objects.

Unexpected Outcomes

Incorrect body mechanics are used while giving client care.

Alternative Actions

- Identify areas of your body where you feel stress and strain.
- Evaluate the way you use body mechanics.
- Attend an in-service program on using body mechanics appropriately.
- Concentrate on how you are using your body when moving and turning clients.
- Position bed and equipment at a comfortable height and proximity to working area.
- Use your longest and strongest muscles to prevent injury.

Unexpected Outcomes

Nurse injures self while giving client care.

Alternative Actions

- Prevent future episodes of back pain by increasing physical activity and exercises, changing ergonomics, and evaluating use of orthosis.
- Report any back strain immediately to supervisor.
- Complete unusual occurrence form.
- Go to health service or emergency room for evaluation and immediate care.
- Evaluate any activities that led to injury to determine incorrect use of body mechanics.
- Prevent additional injury by obtaining assistance when needed.
- Use devices such as turning sheets or assistive devices to assist in turning difficult clients.

Nurse uses poor body mechanics and injures client.

- Assess the extent of client's injury.
- Notify client's physician.
- Complete unusual occurrence form.
- Carry out physician's orders for follow-up treatment.

Nurse is unable to obtain sufficient assistance with turning and moving clients.

- Place turning sheets on bed for all clients who are difficult to move.
- Use principles of leverage in moving clients.
- Until adequate staff is available, turn and position client from side to side at least every 2 hr.
- Use Hoyer Lift.

Number of client/healthcare worker injuries increases in nursing unit.

- Determine cause of injury and nursing units involved.
- Based on causes, compile a survey and walking rounds on all shifts and units to gather data regarding injury status. Look for trends and personnel behaviors.
- Form a safety committee made up of direct healthcare providers, nursing staff, management, and risk manager to determine causes and propose changes in patient handling.
- Study findings of surveys and unusual occurrence reports to determine appropriate prevention program.
- Determine appropriate equipment based on level of injury and dependency. Bring in vendors to demonstrate equipment based on findings.
- Complete in-service staff development program on proper use of equipment and safety principles before implementing program.
- Continue to keep detailed notes on client and/or staff injury reports after implementation of new protocols. Analyze data and compare with prior injury rates and types.

Source: American Nurses Association. (2006). Based on Preventing Back Injuries: Safe Patient Handling and Movement.

Chapter 12

UNIT 2

Moving and Turning Clients

Nursing Process Data

ASSESSMENT Data Base

- Observe the client and identify ways to improve the client's position and alignment.
- Determine the client's physical ability to assist with positioning.
- Assess appropriate mechanical device for moving clients requiring assistance.
- Note the presence of tubes and incisions that alter the positioning and alignment procedures.
- Assess joint mobility.
- Assess skin condition with each turn.

PLANNING Objectives

- To provide increased comfort
- To provide optimal lung excursion and ventilation
- To prevent contractures due to constant joint flexion
- To promote optimal joint movement
- To help maintain intact skin
- To prevent injury due to improper movement
- To move and transfer clients using mechanical devices

IMPLEMENTATION Procedures

- Assessing Clients for Safe Moving and Handling 350
- Placing a Trochanter Roll 351
- Turning to a Lateral Position 352
- Turning to a Prone Position 352
- Moving Client Up in Bed 353
- Using Posey Lift Assist II 354
- Moving Client With Assistance 354
- Logrolling the Client 355
- Transferring Client From Bed to Gurney 357
- Dangling at the Bedside 358
- Moving From Bed to Chair 359
- Using a Floor-Based (Sling) Lift 362
- Using a Hydraulic Lift 363
- Using a Footboard 364

EVALUATION Expected Outcomes

- Client's comfort is increased.
- Skin remains intact without evidence of breakdown as a result of moving and turning.
- Breathing is adequate and unlabored.
- Joint movement is maintained.
- Footdrop is prevented.
- Body alignment is maintained.
- Mechanical equipment and devices are used in client transfers and repositioning as needed.
- Client is moved safely using appropriate device.

- **Critical Thinking Application** 365
- Expected Outcomes 365
- Unexpected Outcomes 365
- Alternative Actions 365

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

TABLE 12-2 Bed Positions for Client Care

Positions	Placement	Use
High-Fowler's	Head of bed 60° angle	Thoracic surgery, severe respiratory conditions
Fowler's	Head of bed 45°–60° angle; hips may or may not be flexed	Postoperative, gastrointestinal conditions, promote lung expansion
Semi-Fowler's	Head of bed 30° angle	Cardiac, respiratory, neurosurgical conditions
Low-Fowler's	Head of bed 15° angle	Necessary degree elevation for ease of breathing, promotes skin integrity, client comfort
Knee-gatch	Lower section of bed (under knees) slightly bent	For client comfort; contraindicated for vascular disorders
Trendelenburg's	Head of bed lowered and foot raised	Percussion, vibration, and drainage (PVD) procedure; promotes venous return
Reverse Trendelenburg's	Bed frame is tilted up with foot of bed down	Gastric conditions, prevents esophageal reflux

▲ High-Fowler's position at 60° angle.

▲ Fowler's position at 45°–60° angle.

▲ Semi-Fowler's position at 30° angle.

▲ Low-Fowler's position at 15° angle.

▲ Reverse Trendelenburg position.

▲ Trendelenburg position.

▲ Elevated knee gatch.

Assessing Clients for Safe Moving and Handling

Equipment

Mechanical equipment or devices based on assessment of functional level.

Procedure

1. Perform hand hygiene.
2. Check if physician orders need to be obtained for client transfers or moving (joint replacement, spinal cord injury, or surgical procedure).
3. Use two indicators to identify client and introduce yourself.

4. Explain use of assessment criteria in preparation for safe moving and handling.
5. Complete check list or document findings in nurses' notes.
 - a. Identify client's level of assistance.
 - (1) Independent: able to perform task safely with or without staff assistance or assistive devices.
 - (2) Partial Assist: requires stand-by assistance, cueing, or lifting no more than 35 lb of client's weight by staff.
 - (3) Dependent: requires staff to lift more than 35 lb of client's weight or is unpredictable in amount of assistance needed. Assistive devices need to be utilized.

Assessment Criteria and Care Plan for Safe Patient Handling and Movement

A: ASSESSMENT CRITERIA

I. Patient's Level of Assistance:
 Independent — Patient performs task safely, with or without staff assistance, with or without assistive devices.
 Partial Assist — Patient requires no more help than stand-by, cueing, or coaching, or caregiver is required to lift no more than 35 lbs. of a patient's weight.
 Dependent — Patient requires nurse to lift more than 35 lbs. of the patient's weight, or is unpredictable in the amount of assistance offered. In this case assistive devices should be used.

An assessment should be made prior to each task if the patient has varying level of ability to assist due to medical reasons, fatigue, medications, etc. When in doubt, assume the patient cannot assist with the transfer/repositioning.

II. Weight Bearing Capability
 Full
 Partial
 None

III. Bi-Lateral Upper Extremity Strength
 Yes
 No

IV. Patient's level of cooperation and comprehension:
 Cooperative — may need prompting; able to follow simple commands.
 Unpredictable or varies (patient whose behavior changes frequently should be considered as "unpredictable"), not cooperative, or unable to follow simple commands.

V. Weight: _____ **Height:** _____
Body Mass Index (BMI) [needed if patient's weight is over 300]: _____
If BMI exceeds 50, institute Bariatric Algorithms

The presence of the following conditions are likely to affect the transfer/repositioning process and should be considered when identifying equipment and technique needed to move the patient.

VI. Check applicable conditions likely to affect transfer/repositioning techniques.

<input type="checkbox"/> Hip/Knee Replacements	<input type="checkbox"/> Postural Hypotension	<input type="checkbox"/> Amputation
<input type="checkbox"/> History of Falls	<input type="checkbox"/> Severe Osteoporosis	<input type="checkbox"/> Urinary/Fecal Stoma
<input type="checkbox"/> Paralysis/Paresis	<input type="checkbox"/> Splints/Traction	<input type="checkbox"/> Contractures/Spasms
<input type="checkbox"/> Unstable Spine	<input type="checkbox"/> Fractures	<input type="checkbox"/> Tubes (IV, Chest, etc.)
<input type="checkbox"/> Severe Edema	<input type="checkbox"/> Respiratory/Cardiac Compromise	<input type="checkbox"/> Severe Pain, Discomfort
<input type="checkbox"/> Very Fragile Skin	<input type="checkbox"/> Wounds Affecting Transfer/Positioning	

Comments: _____

B: CARE PLAN

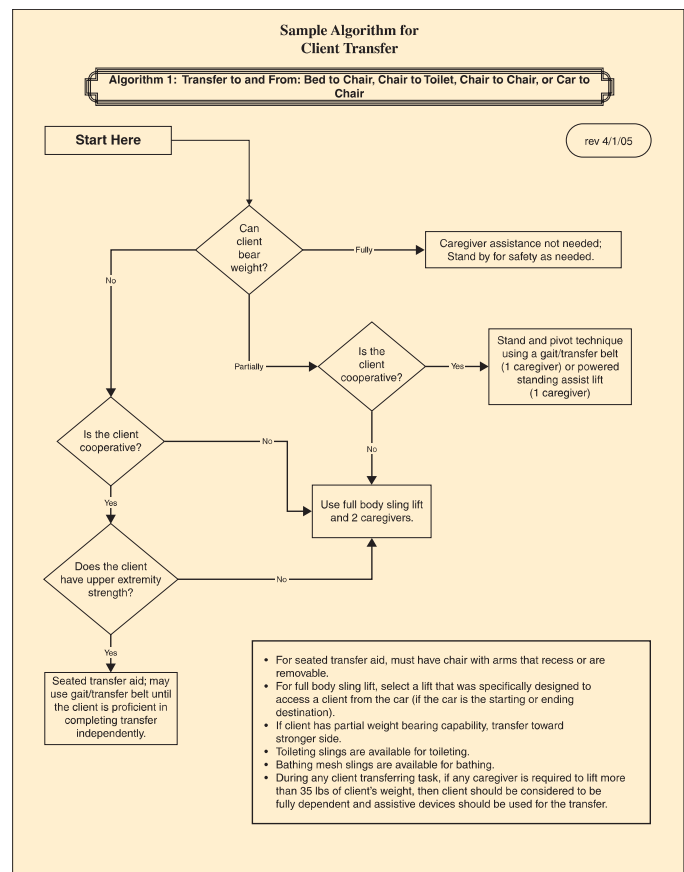

VH. Care Plan: Algorithm	Task	Equipment/ Assistive Device	# Staff
1	Transfer To and From: Bed to Chair, Chair to Toilet, Chair to Chair, or Car to Chair		
2	Lateral Transfer To and From: Bed to Stretcher, Trolley		
3	Transfer To and From: Chair to Stretcher, or Chair to Exam Table		
4	Reposition in Bed: Side-to-Side, Up in Bed		
5	Reposition in Chair: Wheelchair and Dependency Chair		
6	Transfer Patient Up from the Floor		
Bariatric 1	Bariatric Transfer To and From: Bed to Chair, Chair to Toilet, or Chair to Chair		
Bariatric 2	Bariatric Lateral Transfer To and From: Bed to Stretcher or Trolley		
Bariatric 3	Bariatric Reposition in Bed: Side-to-Side, Up in Bed		
Bariatric 4	Bariatric Reposition in Chair: Wheelchair, Chair or Dependency Chair		
Bariatric 5	Patent Handling Tasks Requiring Access to Body Parts (Limb, Abdominal Mass, Gluteal Area)		
Bariatric 6	Bariatric Transporting (Stretcher)		
Bariatric 7	Bariatric Toileting Tasks		

Sling Type (circle choice): Seated _____ Seated (Amputation) _____ Standing _____ Supine _____ Ambulation _____ Limb Support _____

Sling Size: _____

Signature: _____ Date: _____

*If patient's weight is over 300 pounds, the BMI is needed. For Online BMI table and calculator see: http://www.nhbi.nih.gov/guidelines/obesity/bmi_tbl.htm

- b. Weight-bearing capacity.
 - (1) Full.
 - (2) Partial.
 - (3) None.
- c. Evaluate bilateral upper-extremity strength.
- d. Determine client's ability to transfer weight, assist with repositioning of body before contractures occur.
- e. Client's level of cooperation and comprehension.
 - (1) Cooperative: may need prompting, able to follow simple commands.
 - (2) Unpredictable or varies: Client's behavior changes frequently, client is not cooperative or is unable to follow simple commands.
- f. Record client's:
 - (1) Height.
 - (2) Weight.
 - (3) Client more than 300 lb, must use Bariatric Algorithms for assistance.
- g. Identify client's physical condition, which will likely affect transfer/repositioning techniques (i.e., pin sites, surgical incision, fragile skin, fractures, presence of IVs and tubes, etc).

NOTE: See Sample Assessment Criteria and Care Plan for Safe Patient Handling and Movement and Algorithms. (Nelson, A. VISN 8 Patient Safety Center.)

6. Determine appropriate procedure for safe transfer; assistive devices, lift team, number of workers required for procedure for safe transfer.

Bariatric Considerations

Lifting and transferring bariatric clients has become a concern for healthcare providers. Approximately 5% to 10% of the general population is obese. When the body mass index (BMI) is greater than 38, special bariatric equipment is required. If the BMI is over 39, the client is considered morbidly obese.

Equipment may need to be ordered if not available in the facility. To ensure that appropriate equipment is available, the needs assessment should be part of the hospital admission assessment.

Frequently required equipment includes:

- Wider wheelchairs
- Wider beds
- Walkers
- Shower/commode chairs

7. Review algorithms or appropriate use of equipment and devices to determine equipment necessary to meet client's needs.
8. Complete care plan, identifying type of client transfers and specifics to be carried out during transfers.
9. Ensure all staff are properly instructed in techniques and equipment utilized as assistive devices. ► **Rationale:** promote safe handling of clients during transfer.

Placing a Trochanter Roll

Equipment

Bath blanket

Procedure

1. Perform hand hygiene, use two identifiers to identify client, and place client in supine or prone position.
2. Place folded bath blanket on bed next to client.
3. Extend blanket from greater trochanter to thigh or knee.

▲ Use trochanter rolls made from bath blankets to align client's hips.

Handroll Positioning

When positioning clients who are on long-term bedrest, all areas of the body must be considered. Handrolls made from folded washcloths rolled into a cone shape (or commercially available) may be used to position and maintain wrist and fingers in a functional position. The purpose is to prevent deformity and contractures.

4. Place blanket edge under leg and buttocks to anchor.
5. Roll bath blanket toward client by rolling it under.
6. Rotate affected leg to slight internal hip rotation.
 - ▶ **Rationale:** The purpose is to prevent external rotation of the head of the femur in the acetabulum.
7. Tighten the roll by tucking the roll under the hip joint.
8. Allow affected leg to rest against trochanter roll. Hip should be in normal alignment, not internally or externally rotated. Patella should be facing upward if client in supine position. ▶ **Rationale:** This is used most commonly for clients who have a muscle weakness or paralysis of that side of the body.

Turning to Lateral Position

Equipment

- Pillows for positioning
- Lateral-assist device or friction-reducing sheet (see Table 12-3)
- Drawsheet for trochanter roll

Procedure

1. Use two identifiers to identify client and perform hand hygiene.
2. Explain rationale for procedure to client.
3. Lower head of the bed completely or to a position as low as client can tolerate.
4. Elevate bed to a comfortable working height.
5. Move client to your side of bed. Put side rails up, and move to other side of bed. Use lateral-assist device or friction-reducing sheet if necessary.
6. Flex client's knees.

▲ Use pillows to support proper alignment.

Kinetic Bed Therapy

Kinetic bed therapy reduces the odds of developing HAI (nosocomial) pneumonia in mechanically ventilated clients. It has not shown a significant reduction in mortality, duration of mechanical ventilation, or length of ICU or hospital stays.

Source: Delaney, A., Gray, H., Laupland, K. B., & Zuege, D. J. (2006). Kinetic bed therapy to prevent nosocomial pneumonia in mechanically ventilated patients: A systematic review and meta-analysis. *Critical Care*, 10(3), R70.

7. Place one hand on client's hip and one hand on client's shoulder; roll onto side.
8. Position pillow to maintain proper alignment.
9. Be sure to position client's arms so they are not under the body.
10. Perform hand hygiene.

▲ Lateral (side-lying) position.

Turning to a Prone Position

Equipment

- Pillows for positioning
- Lateral-assist device or friction-reducing sheet

Procedure

1. Use two identifiers to identify client and perform hand hygiene.
2. Explain rationale for procedure to client.
3. Lower head of bed completely or to a position that is as low as client can tolerate.
4. Elevate bed to a comfortable working height.
5. Move client to side of bed away from side where he or she will finally be positioned. Use lateral-assist device or friction-reducing sheet if necessary.
6. Position pillows on side of bed for client's head, thorax, and feet.

- Roll client onto pillows, making sure that client's arms are not under his or her body.

▲ Supine position.

- Reposition pillows as necessary for client's comfort.
- Perform hand hygiene.

▲ Prone position.

Moving Client Up in Bed

Equipment

- Trapeze (optional)
- Friction-reducing sheet

Procedure

- Use two identifiers to identify client and perform hand hygiene.
- Explain rationale for procedure to client.
- Lower head of bed so that it is flat or as low as client can tolerate.
- Raise bed to a comfortable working height. ► **Rationale:** Allows nurse's center of gravity to assist in turning.
- Remove pillow and place it at head of bed. ► **Rationale:** This prevents striking client's head against bed.
- Place one arm under client's shoulders and other arm under client's thighs. Use this method of moving only if the client can assist with move.
- Flex your knees and hips. Move feet close to bed.
- Place your weight on your back foot.
- Instruct client to put arms across chest, bend legs, and put feet flat on the bed.

- Shift your weight from back to front foot as you lift client up in bed. ► **Rationale:** Shifting weight reduces force needed to move client up in bed.

▲ Encourage client to help when repositioning.

▲ Place one arm under shoulders and other under thighs.

▲ Maintain proper body alignment when moving client up in bed.

11. Ask client to push with feet as you move him/her.
12. Position client comfortably, replacing pillow and arranging bedding as necessary.
13. Perform hand hygiene.

NOTE: There are several other methods of moving a client up in bed—including using assist devices such as friction-reducing sheet or total lift devices for clients who are unable to assist with moving and turning.

EVIDENCE-BASED PRACTICE

Recommendations for Positioning

- Client experiences consolidated pneumonia in one lung: position good lung down to increase oxygenation.
- Progressive mobilization to dangling legs, standing, and walking are safe positions for intubated clients.
- Clients increase their oxygenation with head of bed elevated.
- Turning every 2 hr is not sufficient to prevent healthcare acquired pneumonia.
- Using kinetic and continuous lateral rotation therapy decreases risk of ventilator-acquired pneumonia (VAP) in clients on ventilators. Eighteen hours of rotation per day and early placement in kinetic bed are necessary to prevent VAP.
- Prone positioning improves oxygenation, but hasn't been shown to affect mortality rates.

Source: Rauon, C. A., Chulay, M., Bridges, E., Vollman, K. M., & Arbour, R. (2008). Seven evidence-based practice habits: Putting some sacred cows out to pasture. *Critical Care Nurse*, 28(2), 98–124.

Using Posey Lift Assist II

Equipment

- Posey Assist II
- Chair or wheelchair

NOTE: Posey Lift Assist is used for clients weighing up to 300 lb.

Procedure

1. Use two forms of identification to identify client
2. Introduce self and explain use of Posey Lift.
3. Inspect device for broken stitches; torn, cut, or frayed straps on fabric. ► **Rationale:** Ensure straps do not break and cause client to fall.

4. Stand in front of client, feet apart with broad base of support, one foot slightly ahead of other.
5. Keep back straight, bend hips and knees.
6. Place lift assist around client's lower back.
7. Firmly grasp handles of lift device.
8. Instruct client to lean forward and upward as you slowly stand upward. If client is weak at the knee, brace your knee against client's weak knee to stabilize as you assist client to standing position.
9. Assist client to pivot into chair. Gently lower client into chair.

Moving Client With Assistance

Equipment

- Friction-reducing sheet

Procedure

1. Use two identifiers to identify client and perform hand hygiene.
2. Explain rationale for procedure to client.
3. Lower head of bed so that it is flat or as low as client can tolerate.
4. Raise bed to a comfortable working height.
5. Remove pillow, and place it at head of bed. ► **Rationale:** To prevent head being bumped when moved.
6. Coordinate the movements of all nurses. ► **Rationale:** One nurse is responsible for stating when to move client, "on count of three."
7. Position client with two nurses or staff members.
 - a. Position one nurse on each side of client. Assume broad base of support; position front foot facing head of bed, body slightly turned toward head of bed.
 - b. Assist client to flex knees, if possible.
 - c. Each nurse firmly grasps sheet at level of client's upper back with one hand and at level of buttocks with other hand.
 - d. Each nurse places weight on back foot.
 - e. Then with one firm, coordinated, rocking movement (shifting weight from back to front foot), lift client toward head of bed.
 - f. Place client in a comfortable position.
8. Perform hand hygiene.

▲ Use friction-reducing sheet and shift weight from back to front leg when moving client up.

Clinical Alert

The ANA reports that an average healthcare worker should lift no more than 51 lb and only under very controlled circumstances. It is advisable to use lifting and transferring devices.

Logrolling the Client

Equipment

Pillows, towels, blankets for positioning
Turning sheet

Procedure

1. Check order for logrolling client and client care plan as to exactly why client needs to be logrolled.
2. Identify the client using two identifiers. Perform hand hygiene.
3. Obtain sufficient assistance to complete procedure with ease. Three nurses are preferable.
4. Place a pillow between the client's knees before moving the client. ► **Rationale:** To prevent adduction of hip. This will prevent spinal torque.
5. Position two nurses on side of bed to which client will be turned. Position third nurse on opposite side of bed.
6. Designate person at head of bed to be in charge of coordinating move.
7. Assume correct position for client move:
 - a. Nurse at head: one arm supports client's head, second arm supports shoulders and neck.
 - b. Second nurse: one hand grasps client's other shoulder, the other hand and arm around knee.
 - c. Third nurse: on the opposite side of the bed, nurse holds drawsheet firmly to support torso. ► **Rationale:** This maintains the body in alignment.
8. Instruct client to place arms across chest to keep body straight.
9. Assume broad stance with one foot ahead of the other and knees flexed.
10. Rock onto back foot, and use leg and arm muscles to move client in one coordinated movement when nurse

▲ Position nurses on each side of client.

▲ Maintain proper alignment while turning client.

at head of bed signals to move client. ► **Rationale:** To maintain proper alignment, all of the body parts must be moved at the same time. If not, injury to client's neck and spinal column may occur.

11. Maintain client's position in alignment with pillows, towels, or folded blankets.

▲ Maintain client's position with pillow support under client's back.

12. Change client's position frequently (minimum every 2 hr) according to physician's orders.

NOTE: It is recommended that a friction-reducing sheet be used instead of manual turning.

▲ After positioning pillow, allow client to lean back for support.

Client Lift Teams

A lift team consists of two physically fit individuals competent in lifting techniques, who work together to perform high-risk client transfers. The individuals on the team must have no prior history of a musculoskeletal injury and must depend on their physical strength and capabilities. They must have a physical examination and an x-ray of their spine, in addition to not having a history of back injury.

They are trained on the use of mechanical lifting devices. Several clinical trials have been conducted on the use of client lift teams. The outcomes indicated this intervention was effective in decreasing the loss of work days and compensable injury costs.

Source: Nelson, A., & Baptiste, A. S. (2004). Evidence-based practices for safe patient handling and movement. *The Online Journal of Issues in Nursing*, 9(3). Available at www.nursingworld.org/ojin. Accessed September 30, 2004.

EVIDENCE-BASED PRACTICE

Use of Draw Sheet for Moving Clients

Few evidence-based studies disagree that the critical task of repositioning a client in bed places caregivers at an increased risk of back injury due to high spinal loads. Although the two-person drawsheet method of repositioning clients has the lowest low-back disorder risk, spinal loads were still high, thus increasing the risk of a back injury.

Most low back injuries are not the result of a single exposure to a high load but repeated small loads (bending) or a sustained load (sitting). Low back pain is shown to result from repetitive motion and excessive loading.

Source: Marras, W. S., Davis, K. G., Kirking, B. C., & Bertsche, P. K. (1999). A comprehensive analysis of low-back disorder risk and spinal loading during transferring and repositioning of patients using different techniques. *Ergonomics*, 42(7), 904-926.

Transferring Client From Bed to Gurney

Equipment

- Transfer board: polyethylene board
about 18–22 in. wide by 72 in. long
- Sheets to cover board, gurney, and client
- Bath blanket (optional)
- Gurney, bed, or CT table

Procedure

1. Use two identifiers to identify the client and perform hand hygiene.
2. Introduce self and explain procedure to client and show client transfer board. ► **Rationale:** To allay client's fears of being dropped from board.
3. Cover client with sheet or bath blanket and cover board and gurney with sheets.
4. Position client on side of bed away from gurney in lateral position.
5. First nurse supports client while second nurse places board as close to client as possible. ► **Rationale:** This allows client to be positioned on entire board after turn.
6. Instruct client to turn onto back, directly onto board. Client may need assistance to turn.
7. Place both nurses on side of gurney or bed toward which client will be turned.
8. Assume appropriate body mechanics (broad base of support, one foot in front of the other, knees and hips flexed). Place weight on front foot.

▲ Move client to side of bed in lateral position and position transfer board.

▲ Use handholds on board to move client to gurney; maintain proper body mechanics.

▲ Two nurses move to transfer board side of gurney before moving client.

▲ Remove transfer board after centering client on gurney.

9. Transfer weight on count of three from front to back foot as you lift board and pull it toward you.
10. Center client on gurney or bed and remove board by pulling board out and up using handholds along edge of board and using good body mechanics.

11. Place side rails in UP position, or according to facility policy.

NOTE: Lateral-assist devices can be used to transfer clients from bed to gurney.

TABLE 12-3 Assistive Devices for Moving/Turning Clients

Equipment/Device	Use for Client Moving/Handling
Gait belt	Assists client to walk when he/she has leg strength, can cooperate, and requires minimal assistance.
Lateral-assist devices (roller boards, side boards, friction-reducing lateral-assist devices)	Assists clients in lateral transfers, bed-to-gurney, and reduces client-surface friction during transfers, thus preventing skin breakdown and client discomfort. Friction-reducing sheets are used to position clients in bed and in lateral transfers.
Electric beds	Assists clients in lateral transfers. Position the bed so transfer surface (gurney) slightly lower than bed to allow client to move onto new surface. Beds can be placed in high-Fowler's position to assist client into sitting position for easier transfer out of bed.
Nonmechanical sit-to-stand aids	Assists clients with some arm strength and weight-bearing ability and who can follow simple directions to move out of bed. Once client stands, pulling self up by holding onto bars, a seat flap is lowered, and the client can rest on the seat. Transfers to commodes, toilets, showers can be accomplished using this device.
Powered stand-assist device	Assists clients who can bear weight on at least one leg and can follow simple instructions. Client is instructed to place feet on footrest while a sling is placed under arms and around back. Legs are positioned against padded shin rest and client's hands are placed on handles. Machine will lift client to a standing position, once electronic hand control is pushed by nurse. Device can be used to transport client to bathroom or chair.
Powered full-body lifts	Assists clients who are unable to bear any weight. These lifts can also be used to pick clients off the floor after falls. Sling is placed under client, then attached to a positioning bar. Client is then lifted from bed or floor. These lifts are portable or ceiling mounted.

Dangling at the Bedside

Procedure

1. Use two identifiers to identify client and perform hand hygiene.
2. Introduce self and explain procedure to client.
3. Lower bed to lowest position.
4. Move client to edge of bed and instruct client to bend knees. **► Rationale:** This allows client to easily move legs and feet over side of bed onto floor.
5. Turn client onto side, keeping knees flexed, or place bed in Fowler's position (head elevated at 45° angle).
6. Stand at client's hip level. Assume broad base of support with forward foot closest to client. Flex your knees, hips, and ankles.
7. Place one of your arms under client's shoulders and other arm beneath client's thighs near knees. Instruct client to use arms to push shoulders up from bed. **► Rationale:** This prevents client falling backward onto bed.

▲ Move client to side of bed and instruct to flex knees.

▲ Turn client onto side, maintaining knees in flexed position.

△ Maintain broad base of support as you pivot client to sitting position.

8. Lift client's thighs slightly and pivot on balls of your feet as you move client into sitting position. Use gluteal, abdominal, leg, and arm muscles to move client.
9. Stand in front of client until client is stable in upright position. ► **Rationale:** Client may experience orthostatic hypotension if he/she has been on bedrest for a period of time.

△ Dangle client with feet flat on floor for several minutes before transferring to chair or ambulating.

10. Take vital signs, especially if this is first time client is dangled. ► **Rationale:** To determine if orthostatic hypotension is present.
11. Dangle client with feet flat on the floor for a few minutes before transferring to chair or ambulating. ► **Rationale:** When feet are on floor, it helps to prevent clot formation.

Moving From Bed to Chair

Equipment

- Chair
- Gait belt

Procedure

1. Use two identifiers to identify the client and perform hand hygiene.
2. Lock bed in place.
3. Place chair at head of bed. If using wheelchair, remove arm and foot closest to bed to facilitate transfer.
4. Lock chair wheels or have someone hold chair as you move client.
5. Follow steps 4–6 in skill *Dangling at the Bedside*.
6. Dangle client until he or she is stable.
7. Give client nonskid shoes or slippers.
8. Place gait belt around client's waist and move client to side of bed using gait belt for support. ► **Rationale:** Helps stabilize client to prevent falls during transfer to chair.
9. Stand as close to client as possible, place your foot closest to chair between client's feet.

△ When using wheelchair, remove arm and foot closest to bed for ease of transfer.

△ Pivot client to dangling position before placing feet on floor.

△ Move client to side of bed using gait belt for support.

▲ Stand with your foot between client's feet; assist client to standing position.

▲ Grasping gait belt for safe transfer, use leg muscles to pivot client into chair.

▲ Slowly lower client into chair while holding gait belt securely.

10. Bend your hips and knees, keeping back straight.
11. Rock client and, on count of three, assist client to standing position.
12. Grasp gait belt firmly for safe transfer while using leg muscles to pivot client to chair. Move your body in direction in which transfer is taking place.

13. Slowly lower client into chair.
14. Position client in chair to prevent pressure areas. If client has circulatory impairment, elevate legs while out of bed. ► **Rationale:** This promotes venous return.

NOTE: It is preferable to use the nonmechanical sit-to-stand aid for transferring clients out of bed unless they require minimal assistance.

Effectiveness of Safe Client Handling Using Assistive Equipment and Devices

Healthcare Staff Benefits

- Use of assistive client handling equipment and devices has made manual client handling unnecessary.
- New assistive devices control the ergonomic hazard associated with lifting and transferring clients, preventing injuries to staff.
- Injuries to nursing staff have decreased dramatically since the advent of the new devices and equipment, leading to cost savings for facilities for workers' compensation benefits.

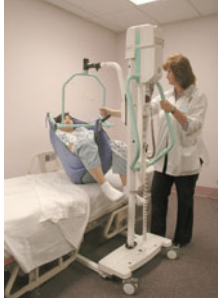

Client Benefits in Use of Assistive Devices and Equipment

- Reduction in client falls and skin tears as a result of the new equipment and devices.
- Clients feel more secure with transfer and ambulation with new equipment and devices.
- Client is more comfortable in moving and turning using the new devices and equipment.
- Client's dignity is protected by using assistive equipment and devices.
- Assistive devices and equipment are selected to match the client's ability to assist in own movement, allowing client more autonomy.

Criteria for Selection of Lifting and Transfer Devices

- Appropriate for task to be accomplished
- Safe and stable for client's caregiver
- Comfortable for client
- Can be managed with relative ease
- Maneuverable in confined work space
- Efficient use of time
- Minimal maintenance required
- Equipment storage requirements reasonable
- Adequate numbers of device available
- Cost effectiveness

TABLE 12-4 Safe Client Handling Devices

	Device	Use
	Gait belt	Assist client in walking if he/she has leg strength, can cooperate, and requires minimal assistance.
	Lateral assist device	Slide boards can be used to transfer clients from bed to gurney.
	Nonmechanical sit-to-stand aid	Used to assist clients who have some arm strength and some weight-bearing ability out of bed. Client pulls self up by holding onto bar. Unfold a seat flap and have client sit on seat.
	Friction-reducing sheet	Allows clients to be positioned in bed without causing shearing of the skin.
 	Powered full-body lift	Used for clients unable to bear weight. Clients can be moved out of bed or lifted off the floor after a fall. Ceiling-mounted lifts are also available.

NOTE: Follow manufacturer's directions for use of these assist devices.

Using a Floor-Based (Sling) Lift

Equipment

- Floor-based lift (such as a Hoyer)
- 2 canvas pieces: 1 large, 1 small
- 2 sets of canvas straps

Procedure

1. Check orders and client care plan. Determine that lift can safely move the weight of the client.
2. Use two identifiers to identify client and explain procedure to client. ► **Rationale:** Clients may be frightened by use of a mechanical device.
3. Perform hand hygiene.
4. Bring floor-based frame to bedside.
5. Provide privacy for client.
6. Lock wheels of bed.
7. Place client's chair by the bed. Allow adequate space to maneuver the lift.
8. Raise bed to HIGH position and adjust head and knee gatch so that mattress is flat.
9. Keep side rail on opposite side in UP position.
10. Roll client away from you.
11. Place lower edge of wide canvas piece under client's knees.
12. Place upper edge of narrow canvas piece under client's shoulders.
13. Raise side rail on your side of bed.
14. Move to opposite side of bed and lower side rail.
15. Roll client away from you to opposite side and straighten out canvas pieces. Turn client to supine position.
16. Place U base of frame under bed on side where chair is positioned.
17. Lock wheels of frame. Lower side rail.
18. Attach canvas straps from swivel bar to each canvas piece using hooks.
19. Place straps evenly on canvas pieces. Sling extends from shoulders to knees. ► **Rationale:** This supports client's weight equally.
20. Elevate head of bed.
21. Raise client by turning release knob clockwise to close pressure valve.
22. Pump lift handle until client is lifted clear of the bed.
23. Maneuver client over the chair.
24. Lower client by turning release knob *slowly* counterclockwise.
25. Guide client into chair.
26. Align client into chair.
27. Remove straps from bar and move lift out of the way.
28. Check for client's comfort in chair; place call bell close at hand.
29. Perform hand hygiene.
30. Return client to bed using reverse method.

▲ Place canvas piece under client from knees to shoulders.

▲ Raise client off bed by turning release knob clockwise.

▲ Use one nurse to stabilize client as second nurse guides client into chair.

Using a Hydraulic Lift

Equipment

- Sling
- Mechanical lift device
- Wheelchair

Preparation

1. Check physician's orders for type of assistive device ordered for client (check hospital's policy and procedure for available types of devices in facility).
2. Check equipment to ensure lift sling is intact (no frayed material or weak stitching; straps, hooks, and chains are intact), and mechanical lift device is functioning appropriately. Check manufacturer's instructions and safety precautions.
3. Use two forms of identifiers to identify client, introduce yourself to client, and explain how the hydraulic lift will transfer the client to the chair or wheelchair.

4. Complete an assessment to determine client's willingness and ability to assist with transfer.
5. Check client's weight. ► **Rationale:** Some lifts state a weight restriction. If over weight level, a bariatric hydraulic device will need to be ordered.
6. Bring equipment to room.
7. Perform hand hygiene.
8. Provide privacy.

Procedure

1. Place wheelchair close to head of bed, leaving space to maneuver lift between bed and wheelchair.
2. Ensure bed wheels are locked, flat, and in high position.
3. Roll client on side, and with client holding side rail, place sling under client.
4. Roll client to other side and pull sling through and straighten sling flat.

▲ Ceiling mounted lift device for client transfer.

▲ Turn client to side and pull sling under client.

▲ Position client in center of sling.

▲ Secure leg straps.

▲ Ensure that sling is securely attached to assist device.

▲ Move client directly over chair.

▲ Remove sling for client comfort.

5. Place client in supine position and place leg loops over thighs. Follow manufacturer's instructions to place loops correctly.
6. Roll lift under bed as far as possible. The lift arm should be over client if appropriately placed. Ensure lift base is wide open. ► **Rationale:** Provides stability for lift.
7. Attach sling straps to lift arm. If using hooks, they should be pointed away from client.
8. Elevate head of bed to place client in sitting position. Check manufacturer's instruction for client's hand placement.
9. Ensure wheelchair wheels are locked and client is instructed to remain very still during transfer.
 - **Rationale:** Maintain the lift's stability.
10. Slowly raise sling until buttocks is just above mattress.
 - **Rationale:** Self-leveling lift maintains client in sitting position.
11. Turn client to face second nurse who operates the lift. During turning, the client's legs are dangled off bed. Do not pull on client or the lift arm during this step of procedure.
12. Move lift away from bed by grasping steering bar and position client over wheelchair seat.
13. Slowly lower client onto wheelchair until he/she reaches a comfortable position.
14. Unhook sling from lift arm or remove chains or straps from sling. Keep sling in place under client. ► **Rationale:** Sling will be reattached to lift device to transfer back to bed.
15. Ensure client is positioned maintaining good body alignment.
16. Evaluate client's response to transfer and document findings.
17. Place overbed table near client. Place fluids, tissues, and personal items in easy reach.
18. Perform hand hygiene.

Using a Footboard

Equipment

Footboard

Procedure

1. Provide a footboard if client is unable to place feet in dorsal flexion or plantar flexion.
2. Cover footboard with a bath blanket to protect feet from rough surfaces.
3. Place footboard on bed in a place where client's feet can firmly rest on it without sliding down in bed.
4. Observe legs to ensure that they are not in a flexed position when feet are against the board.
5. Tuck top linen under mattress at foot of bed, and bring linen up over the footboard to the top of the bed. Do not drape top linen over footboard as it can easily be pulled off the bed.

6. Put feet and ankles through range-of-motion exercises every 4 hr for clients on prolonged bedrest.
7. Observe heels and ankles frequently for signs of breakdown.
8. Place pillow under client's calves (not under heels), allowing heels to be off mattress if skin breakdown is assessed.

NOTE: Clients are encouraged to wear high-top sneakers while on bedrest, along with the footboard. ► **Rationale:** Aids in preventing footdrop. Footboards are used to prevent plantar flexion. Extended periods of plantar flexion can lead to footdrop.

DOCUMENTATION for Moving and Turning Clients

- How often client is turned or moved
- Condition of skin and joint movement
- Unexpected problems with moving or positioning client and solutions to problems
- Client's acceptance of and feelings about the procedure
- Number of staff needed to complete the procedure
- Type of assistive devices needed from bed to chair, if appropriate
- Time client was in chair or dangling at bedside
- Use of a footboard or trochanter roll

Legal Considerations

Back Injuries From Lifting and Transferring

A suit was filed against a large nursing home chain by nursing assistants at five Pennsylvania nursing homes. The complaint with OSHA alleged they had suffered back injuries from lifting and transferring clients. After a 15-month investigation, OSHA issued citations against the nursing home for ergonomics violations under the "general duty" clause of the Occupational Safety and Health Act. The clause states that an employer must provide employees with a workplace free of recognized

Source: Mannix, R. (2002). Health Care Law.

hazards that are causing or likely to cause death or physical harm. OSHA argued that transferring clients exposed CNAs to serious injury to the upper back and upper extremities. OSHA settled with the nursing home chain. Under the terms of the settlement, the nursing home chain agreed to purchase mechanical lifting equipment at all facilities, nationwide, and to train all workers in the use of the equipment.

CRITICAL THINKING Application

Expected Outcomes

- Client's comfort is increased.
- Skin remains intact without evidence of breakdown as a result of moving and turning.
- Breathing is adequate and unlabored.
- Joint movement is maintained.

Unexpected Outcomes

Client unwilling to move due to fear of pain or discomfort.

Client unable to assist with movement.

Client unable to maintain any type of position without assistance.

Skin begins to break down.

Client frightened to use assistive device.

- Footdrop is prevented.
- Body alignment is maintained.
- Mechanical equipment and devices are used in client transfers and repositioning as needed.
- Client is moved safely using appropriate device.

Alternative Actions

- Explain rationale and need for the procedure more thoroughly.
- If possible, check if client can be medicated before the procedure.
- Obtain additional assistance to decrease client's apprehension.
- Use a friction-reducing sheet to provide more support for client.
- Obtain additional assistance to help with moving "dead" weight.
- Use trochanter roll to prevent external rotation of client's hip.
- Use foam bolsters to maintain side-lying positions.
- Use folded towels, blankets, or small pillows to position client's hands and arms to prevent dependent edema.
- Change client position every 2 hr.
- Request physician's order for therapeutic mattress or dressings for pressure ulcer(s) care.
- Explain use of equipment (i.e., comfort and safety in transferring).
- Demonstrate equipment before using.

Chapter 12

UNIT 3

Adaptations for Home Care

Nursing Process Data

ASSESSMENT Data Base

- Assess safety factors in home
- Check equipment for safety features
- Determine client's safety in home
- Determine caretaker's ability to provide client care and safety
- Determine need for additional client equipment to promote client and caregiver safety

PLANNING Objectives

- To provide a comfortable and safe client environment
- To ensure caregiver's safety while providing client care
- To provide necessary home care treatments utilizing appropriate safety equipment

IMPLEMENTATION Procedures

- Evaluating Client's Safety367
- Assessing Caregiver's Safety367

EVALUATION Expected Outcomes

- Safe environment is provided for client
- Healthcare worker's safety is maintained during home visit

Critical Thinking Application.....368

- Expected Outcomes368
- Unexpected Outcomes368
- Alternative Actions368

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Evaluating Client's Safety

Procedure

1. Evaluate client's cognitive abilities: level of consciousness, orientation, ability to make appropriate judgments, ability to follow commands and directions.
 - a. Knowledge of how to operate appliances (e.g., stoves and heaters).
 - b. History of alcohol or drug abuse.
 - c. Knowledge of medication times and doses to be taken.
 - d. Knowledge of how to call for help: physician, nurse, fire, police.
2. Evaluate client's sensory and motor function.
 - a. Hearing and vision acuity
 - b. Ability to ambulate with assistance
 - c. Need for assistive devices or support in ambulation
3. Determine client's ability to manage self-care.
 - a. Bathing, grooming, and dressing
 - b. Preparing food and feeding
 - c. Toileting
 - d. Housekeeping, shopping, transportation to physician and pharmacy
4. Assess if client needs alternatives to physical restraints.
 - a. Determine if environment needs to be modified by removing unsafe objects or barriers.
 - b. Remove wheels from chairs or bed.
 - c. Install bed check system or alarm device.
 - d. Decrease auditory and visual stimuli.
 - e. Place supplies close to bed or chair (e.g., tissues, water).
 - f. Develop routine for client.
5. Evaluate most effective type of restraint, if absolutely necessary.
 - a. Determine that less restrictive methods have been attempted.
 - b. Assess purpose of restraint to determine most appropriate type.
 - c. Obtain physician's order for restraint. Order must include reason, type, and time of restraints.
 - d. Obtain informed consent from client or guardian before applying.
 - e. Explain purpose of restraints to client and family members.
 - f. Ensure caregiver is instructed on use of restraints.
 - g. Evaluate effectiveness and continued need for restraints.
6. Determine client's financial support.
 - a. Determine healthcare insurance plan, workers' compensation, Medicare, Medicaid.
 - b. Determine need for social service intervention.

NOTE: The safety issues in the home are similar to the safety issues of hospitalized clients.

Assessing Caregiver's Safety

Procedure

1. Determine caregiver's cognitive function.
 - a. Ability to understand and carry out interventions
 - b. Ability to make safe decisions and judgments
 - c. Willingness to care for client
2. Determine caregiver's sensory and motor function.
 - a. Ability to hear client's needs
 - b. Visual acuity to read directions, medication labels
 - c. Ability to feel temperature changes (e.g., water for bathing)
3. Determine caregiver's motor function and strength.
 - a. Ability to assist client in transfer, moving, turning, and ADLs
 - b. Ability to provide treatments and care for client
 - c. Ability to prepare food and do housekeeping chores
 - d. Ability to do shopping and provide transportation for physician visits
4. Determine need for client care assistance with ADLs
 - a. Type of wheelchair, with or without removable arms
 - b. Shower chairs that fit over toilet or in shower
 - c. Toilet seat risers
5. Determine need for type of transfer assist devices for safe client handling.
 - a. Gait belts: provide secure grip without holding onto client's clothes or limbs. ► **Rationale:** Prevents caregiver strain as client weight is closer to caregiver and he/she can assume upright position.
 - b. Small slide/transfer board: used for seated lateral transfers, such as between bed and wheelchair or commode. ► **Rationale:** Caregiver does not need to manually lift client.
 - c. Turning discs: used to pivot seated clients who can bear weight and stand. The client is guided to a standing position without adjusting their feet. The client must be able to stand or the caregiver will have to exert excessive force in an awkward position.
 - d. Mechanical lift devices such as the Lean–Stand Assist Lift and Sling–Type Full Lift are used for clients who cannot support their own weight.
 - e. Repositioning devices: mechanically pull client up in bed without need for caregiver to assist client.
 - f. Trapeze lifts: a bar device suspended above the bed that allows clients to reposition. Client must have upper body muscle strength in order to reposition in bed.

DOCUMENTATION for Home Care

- Client's assessment findings determining ability to care for self and transfer from bed to wheelchair/chair
- Type of assistive devices used in moving and/or transferring client
- Client's ability to assist with transfer and repositioning
- Client's response to moving and repositioning

CRITICAL THINKING Application

Expected Outcomes

- Client is safely repositioned or transferred without injury to client or caregiver.
- Appropriate assistive devices are utilized to transfer client.
- Caregiver is able to manage turning, repositioning, and managing assistive devices.
- Appropriate body mechanisms are utilized by caregiver.

Unexpected Outcomes

Unable to transfer client from bed to wheelchair due to excess weight.

Injury occurs to client when caregiver attempts transfer to wheelchair.

Alternative Actions

- Determine if wheelchair without arms or transfer board can aid in transfer.
- Contact social services to obtain bariatric assist devices.
- Determine if other family members can assist with transfer.
- May need home health aide services to assist with transfer.
- Do not continue to reposition client, place in bed.
- Complete sensory, motor, and pain assessment.
- Notify physician.
- Document findings.

GERONTOLOGIC Considerations

Physiologic Age Changes in the Musculoskeletal System That Affect Nursing Care of the Elderly

- Contractures—muscles atrophy, regenerate slowly; tendons shrink and sclerose.
- Range of motion of joints decreases—lack of adequate joint motion, ankylosis.
- Mobility level is limited—muscle strength lessens and gait may be unsteady.
- Kyphosis occurs—cervical vertebrae may be flexed; intervertebral discs narrow.
- Bodies of thoracic vertebrae compress slowly with aging, leading to the hunchback appearance—loss of overall height results from disk shrinkage and kyphosis.
- Bone changes—loss of trabecular bones and bones become brittle.
- Osteoporosis occurs as a result of calcium loss from the bone and insufficient replacement.
- Osteoarthritis increases with age, equally affecting men and women. This condition results in physical stress on joints as a result of long-term mechanical, horizontal, chemical, and genetic factors.

Psychosocial and Physiological Changes in Elderly Who Are Immobilized

- At risk for confusion, depression, and disorientation—keep clock and calendar in room to help reorient to time and place.

- More susceptible to hazards of immobility—maintain own ADLs as much as possible and change position every 2 hr.

Aging and Changes in Ability to Maintain Activity Levels

- As aging occurs, there is a decrease in the rate or speed of activity.
- Loss of muscle mass interferes with activities that require strength such as bending down, dressing, and reaching for objects.
- Dexterity decreases, leading to a change in performing manipulative skills.

Nursing Care for Positioning Elderly Clients

- Ambulate within limitations of age.
- Alter position every 2 hr; align correctly.
- Prevent osteoporosis of long bones by providing exercises against resistance as ordered.
- Provide active and passive exercises—rest periods necessary and exercise paced throughout the day for the elderly.
- Provide range-of-motion exercises to all joints three times a day.
- Educate family that allowing the client to be sedentary is not helpful.
- Encourage walking, which is the best single exercise for the elderly.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- All levels of healthcare workers can be assigned to move and turn clients and provide assistance with transfers.
- Positioning clients in bed can be assigned to all levels of healthcare workers.
- Frequently, the physical therapist is assigned to work with postoperative clients or clients requiring special transfer techniques or ambulation until clients are released to nursing.
- Before assigning staff to logroll a client or use assistive devices for moving a client out of bed, ensure they have been properly instructed in the procedures and safety issues associated with these activities.

Communication Matrix

- The RN must give specific directions to the healthcare workers on appropriate positions for clients on bedrest or specifics on how to transfer clients to a chair or gurney.
- Before physical therapy releases clients to nursing for transfer or ambulation activities, the RN must obtain explicit information on the procedures to be used. This information must be written on the Kardex or computer record, as well as reviewed with all staff assigned to the client.
- A team conference may be necessary if special equipment or specific activities are required by a client. This conference ensures all staff will be given a demonstration and provided information necessary for safe client care.
- The RN must ensure that all new personnel are proficient in transfers, logrolling, and use of the assistive devices before assigning them to care for clients requiring these skills.
- It is crucial for safe client care that the RN monitors healthcare workers when they perform logrolling or use mechanical devices for transfer after the initial demonstration.

CRITICAL THINKING Strategies

Scenario 1

You are assigned to a medical unit where many of the clients require assistance moving in and out of bed. The following clients are assigned to you for care on the day shift.

- Onica Jones, 89-year-old (CVA) client who has weakness on the right side and is unable to communicate but seems to understand directions. She has been in the hospital for 4 days and will be transferred to an SNF this afternoon.
- James Metcalf, 60-year-old (MI) client who is about to be discharged. However, you notice he still has not been able to ambulate by himself.
- Madeline Oscar, 70-year-old client with Parkinson's disease and hospitalized for pneumonia. She was admitted last night. She has orders to be up in the chair BID.
- Joseph Nichols, 40-year-old client, hospitalized for possible kidney stones. He is in severe pain and the MD has ordered that he remain on bedrest until further orders.
 1. Which client will you assess first? Provide rationale for your answer.
 2. How will you determine the client's ability to assist with his or her own care and movement in bed?

3. For each client, identify the type of assistance he or she might need; provide rationale for your answer.
4. Describe the body mechanics you will use when moving clients; this will be based on the type of moving that will need to be performed for each of the four clients.

Scenario 2

You are assigned to care for a client who weighs 300 lb. The client was out of bed for lunch and now insists on getting back into bed. There are insufficient staff members available to help you. The client is able to weight bear but needs maximal assistance to stand.

1. Suggest creative resolutions to this problem.
2. Describe the procedure you will use to transfer the client from chair to bed.
3. If mechanical devices are not available, what action will you take?

NCLEX® Review Questions

Unless otherwise specified choose only one (1) answer.

1. The most effective method for teaching student nurses principles of moving clients is to discuss:
 1. Using a back brace when lifting clients.
 2. Instructions on safe lifting techniques using two to three nurses for heavy clients.
 3. Education related to body mechanics.
 4. Proper use of lift teams for moving clients.

2. According to the National Institute for Occupational Safety and Health (NIOSH), the average client weight that should be lifted by healthcare workers is _____ pounds.
 1. 51.
 2. 75.
 3. 100.
 4. 169.
3. Applying body mechanics includes which of the following principles? Select all that apply.
 1. Establish a base of support by placing the feet close together.
 2. Hold abdomen firm and bend at the waist when lifting client.
 3. Keep weight to be lifted as close to your body as possible when moving clients.
 4. Align three natural curves in your back when moving clients.
4. Maintaining proper body alignment is critical for nurses to prevent injuries when providing client care. Which of the following steps would *not* be included in teaching appropriate body alignment?
 1. The most comfortable height at which to provide client care is above the nurse's waist.
 2. Flex your knees if you need to work at lower than waist level.
 3. Triceps, quadriceps, and gluteal muscles are used when moving and turning clients.
 4. Push, pull, or roll objects instead of lifting whenever possible.
5. If you are injured while providing client care, it is important you immediately
 1. Complete an unusual occurrence (or incident report) form.
 2. Inform charge nurse you need to go home to rest and apply ice.
 3. Report the injury to your supervisor.
 4. Ask for a change in your assignment to prevent reinjury.
6. There is an order for a client to be placed in a low-Fowler's position. You will place the bed in a _____ degree position.
 1. 60.
 2. 45.
 3. 30.
 4. 15
7. During report the team leader stated, "the client needs to be turned to a lateral position every 2 hr." You recall the best way to turn the client is to
 1. Ask a second nurse to assist you in turning the client to his/her side.
 2. Ask the lift team to come every 2 hr to turn the client.
 3. Place a friction-reducing sheet under the client to assist in turning.
 4. Explain to the client that he/she needs to move up in bed before you can assist in turning the client to a lateral position.
8. A client is being moved from the bed to a gurney using a transfer board. The directions given the client include
 1. "You need to move toward the side of the bed nearest the gurney before being placed on the slide board."
 2. "Roll directly onto the transfer board and position yourself on your side."
 3. "The nurse will place the board close to you and you need to roll over the edge of the board onto the gurney while staying in a side-lying position."
 4. "Turn onto your back, directly onto the transfer board."
9. A client assessment indicates the client has some arm strength and weight-bearing ability and can follow simple directions to move out of bed. The most appropriate assistive device to move this client out of bed is the
 1. Powered full-body lift.
 2. Powered stand assist device.
 3. Nonmechanical sit-to-stand aid.
 4. Lateral assist device.
10. As part of a home care admission assessment, you need to determine a client's "Safe Handling and Movement" abilities. This assessment criteria includes:

Select all that apply.

 1. Weight-bearing capability.
 2. Client's level of cooperation and comprehension.
 3. Ability to assist in transfer.
 4. Need for assistive device.

Exercise and Ambulation

LEARNING OBJECTIVES

1. Define rehabilitative nursing.
2. Compare and contrast preservative and restorative methods of care.
3. Identify the joints and the type of movement they accommodate.
4. Compare and contrast passive and active range of motion exercises.
5. Demonstrate passive range-of-motion exercises using all muscle groups.
6. Explain the rationale of assisted ambulation for clients.
7. Complete a client teaching guide for clients requiring muscle-strengthening exercises.
8. Demonstrate the proper method for measuring crutches.
9. Compare and contrast the four crutch-walking gaits.
10. Demonstrate the four crutch-walking gaits.
11. List the components of crutch walking that require documentation.
12. Identify the steps in measuring a client for a cane.
13. Describe client instructions for using a cane.
14. Describe client instructions for using a walker.
15. Write three nursing diagnoses that are appropriate for clients requiring exercise and ambulation activities.
16. Describe safety steps necessary when home care client requests use of assistive devices.

TERMINOLOGY

Abduction movement of a bone away from the midline of the body or body part, as in raising the arm or spreading the fingers.

Adduction movement of a bone toward the midline of the body or part, as in lowering the arm from a raised position.

Alignment arranged in a straight line; position of body parts in relation to each other.

Ambulate walking; able to walk.

Antagonists muscles that exert an action opposing that of prime mover.

Atrophy a wasting or decrease in size of any organ or body part due to lack of nutrients or oxygen, causing death and reabsorption of cells.

Base of support foundation on which a person's body weight is supported.

Balance a result of body alignment that maintains equilibrium, coordination, and stability of the body in space.

Cardiovascular pertaining to heart and blood vessels.

Circumduction to revolve around an axis in such a way that the proximal end of a limb is fixed and the distal end traces a circle.

Contractility ability of muscle to shorten, tighten, and contract.

Dorsiflexion flexion of the foot at the ankle joint; the act of turning the foot and toes upward, as in standing on the heel.

Elasticity ability of strained muscle to regain original size and shape when applied force is removed.

Eversion turning outward; movement of the foot at the ankle joint so that the sole faces outward.

Excitability capacity of muscle to respond to stimulus without intervention of motor nerves.

Extensibility ability of muscle to stretch in response to applied force.

Extension a movement that increases the angle between two bones, straightening a joint.

Fibrous repair and replacement of inflamed tissues or organs by connective tissue.

Flaccidity decrease in muscle tone.

Flexion a movement that decreases the angle between two bones; the act of bending a joint.

Fracture any break or crack in a bone.

Hyperextension continuation of extension beyond the anatomic position, as in bending the head backward.

Hypertrophy increased muscle fiber leading to increased muscle shape and size.

Inversion turning inward; movement of the foot at the ankle joint so that the sole faces inward.

Ligament a band or sheet of strong fibrous connective tissue connecting the articular ends of bones serving to bind them together and to facilitate or limit motion.

Mobility state or quality of being mobile; facility of movement.

Musculoskeletal pertaining to the muscles and bones.

Paralysis temporary or permanent loss of function, especially loss of sensation or voluntary motion.

Plantar flexion extension of the foot at the ankle joint; the foot and toes are turned downward toward the sole of the foot, as in standing on tiptoe.

Posture attitude or position of body.

Prime movers muscles responsible for the essential movement of contraction.

Pronation rotation of the forearm so that the palm faces backward or downward; movement of the whole body so that the face and abdomen are downward.

Prone lying horizontal with face downward.

Protraction movement of the clavicle (collar bone) or mandible (lower jaw) forward on a plane parallel to the ground.

Proximal nearest the point of attachment or reference point.

Range-of-motion extent to which a joint can move through active or passive exercises.

Retraction movement of the clavicle or mandible backward on a plane parallel to the ground.

Rotation movement of a bone around its own axis, as in moving the head to indicate "no" or turning the palm of the hand up and then down.

Spasticity increase in muscle tension.

Sprain injury caused by wrenching or twisting of a joint that results in tearing or stretching of the associated ligaments.

Strain injury caused by excessive force or stretching of muscles or tendons around the joint.

Supination rotation of forearm so that the palm faces forward or upward; movement of the whole body so that the face and abdomen are upward.

Synergists muscles that enhance action of prime mover.

Tendons fibrous connective tissue serving for the attachment of muscles to bones and other parts.

Tonicity ability of muscle to maintain steady contraction, which determines its firmness.

Ulcer a lesion of the skin marked by inflammation, necrosis, and sloughing of damaged tissue.

REHABILITATION CONCEPTS

Rehabilitative nursing involves the prevention and correction of alterations in the musculoskeletal system. In fact, the definition of rehabilitative nursing is the process of restoring a person's ability to live and work in as normal a manner as possible. To assist clients to achieve and maintain optimal mobility, both preservative and restorative methods are used.

Preservative methods, such as exercises and assisted ambulation, include those interventions that are needed to help clients maintain their normal mobility. Because the changes that occur in the human body when a person is hospitalized are varied and subtle, preservative methods are used with every client. Restorative methods, such as crutch walking and splinting, are used with clients who have decreased mobility caused by such factors as debilitating illness or major surgery. The purpose for applying restorative methods is to assist the client in achieving the level of mobility he or she enjoyed before becoming ill.

The general goals for using these methods are to assist the client to strive for optimal function, to prevent further injury, and to restore the client's mobility to as close to normal function as possible. To achieve these goals of care, it is important for the nurse to accept the philosophy underlying rehabilitative nursing: that every illness is accompanied by the intrinsic threat of disability and that this part of total client care must begin with the initial client contact. Finally, it is important to accept that the principles of rehabilitation are basic to the care of all clients and that rehabilitation must be begun early in the client's hospitalization.

Being hospitalized and immobile seriously affects a person's body image, behavior, and overall adaptation and adjustment. The greater the disability, the more these aspects of a person's life are affected. The nurse's responsibility in providing total client care is to be aware of these responses and to take them into account when developing a client care plan.

MUSCULOSKELETAL SYSTEM

The musculoskeletal system is composed of bones, muscles, joints, cartilage, bursa, tendons, and ligaments. The bones form the infrastructure of the system. The ability of bones to provide weight bearing and mobility is in direct relationship to the size and shape of the bones.

Joints, in conjunction with muscles, provide motion and flexibility. Skeletal muscles are under voluntary control as a result of being innervated by somatic nerves. Muscles, through their ability to contract, convert energy into mechanical work, maintain body alignment, and cause movement.

The muscular system is a system of more than 600 fibers that are attached to bones. The system allows for body movement under the control of the voluntary nervous system. Muscles provide for body movement or locomotion, support the body, and perform several body functions, such as the partial production of heat. The fibers of the voluntary muscles are grouped together in a sheath of connective tissue. Each bundled group of muscle fibers is surrounded by a connective tissue sheath. The sheath tissue may be continuous with fibrous tissue that extends from the muscle as a tendon.

There are several properties of muscle fibers. The first is excitability, or the capacity of a muscle to respond to stimulus without intervention of the motor nerves. Another property is contractility, the ability of a muscle to shorten, tighten, or contract. Muscles are also able to maintain steady contraction (tonicity), stretch in response to applied force (extensibility), and regain their original size and shape when applied force is removed (elasticity).

Muscle Function

Skeletal muscles produce body movements by pulling on the bones. Bones serve as levers, and joints serve as fulcrums of these levers. Each muscle has a point of origin and a point of insertion that are usually attached to the bone. Muscles that move a body part usually do not extend over that part. These muscles usually perform with group action; some contract, and others relax. Prime movers are muscles responsible for the primary movement of contraction. Antagonists are muscles that exert an action opposing that of the prime movers. Synergists are muscles that enhance action of the prime mover. The accessory parts to muscles are the ligaments and the tendons.

JOINTS

A joint of the body is the point at which two or more bones join together. The function of a joint is skeletal flexibility and motion. Joints are classified according to structural variations that allow for different kinds of movements. There are three main types of classification: synarthrotic, amphiarthrotic, and diarthrotic joints.

Synarthrotic joints are immovable and include those areas where tissue grows between articulating surfaces, such as the suture lines of the skull. Amphiarthrotic joints have limited movement. Diarthrotic joints have two freely movable parts. This type of joint is a cavity enclosed by a capsule lined with synovial membrane, which secretes a lubricant. The following types of joint movement allow for structural variations:

- Hinge: allows single directional movement (elbow).
- Ball-and-socket: allows bending (hip).
- Saddle: allows multidirectional shifting (thumb).
- Pivot: allows rotary movement (neck, cervical spine).
- Gliding: allows limited sliding of bones against each other (wrist, ankle, vertebral joints).

Each of these types of joints have specific kinds of movements they can perform. These movements can be described in relationship to the three body planes: sagittal, transverse, and coronal. The sagittal plane divides the body into two portions with a straight vertical line between the two parts. The transverse plane divides the body into upper-lower portions with a horizontal line. The coronal plane divides the body into anterior-posterior portions at right angles to the sagittal plane. The joints accomplish a variety of movements that range from flexion-extension to rotation and circumduction. For definitions of joint movements through the planes of the body, refer to the following.

Joint Movements

Abduction: Movement of a bone away from the midline of the body or body part, as in raising the arm or spreading the fingers.

Adduction: Movement of a bone toward the midline of the body or part.

Circumduction: Movement of a bone in a circular direction so that the distal end scribes a circle while the proximal end remains stationary, as in “winding up” to throw a ball.

Extension: A movement that increases the angle between two bones, straightening a joint.

Eversion: Turning outward; movement of the foot at the ankle joint so that the sole faces outward.

Flexion: A movement that decreases the angle between two bones; the act of bending a joint.

Hyperextension: Continuation of extension beyond the anatomic position, as in bending the head backward.

Inversion: Turning inward; movement of the foot at the ankle joint so that the sole faces inward.

Pronation: Rotation of the forearm so that the palm faces backward or downward; movement of the whole body so that the face and abdomen are downward.

Protraction: Movement of the clavicle (collar bone) or mandible (lower jaw) forward on a plane parallel to the ground.

Retraction: Movement of the clavicle or mandible backward on a plane parallel to the ground.

Rotation: Movement of a bone around its own axis, as in moving the head to indicate “no” or turning the palm of the hand up and then down.

Supination: Rotation of forearm so that the palm faces forward or upward; movement of the whole body so that the face and abdomen are upward.

The 2008 Physical Activity Guidelines for America state that regular physical activity reduces the risk of many adverse health outcomes. Adults should avoid inactivity and participate in physical activity to gain some health benefit. There is a greater increase in health benefits as the amount of physical activity increases. All clients should be instructed to increase their physical activity if they are inactive. Elderly clients need to be encouraged to participate in regular physical activity, including aerobic muscle strengthening and flexibility activities. Balance training for elderly clients will decrease the risk of falls.

Resistive exercises, another rehabilitative measure, provide resistance in order to increase muscle power. These active exercises are performed by the individual working against resistance. Isometric or muscle-setting activities are similar to resistive exercises. These exercises maintain strength in a muscle when the joint is immobilized. They are performed by the individual without assistance.

Range-of-motion (ROM) exercises are the most common form of exercises for maintaining joint mobility and increasing maximal motion of a joint when the client is totally or partially immobilized. These exercises are completed by the nurse or physical therapist. The therapist puts an extremity through its full range so that the joint is moved through all the appropriate planes. Before beginning these exercises, it is important that the therapist and/or nurse assess the client’s condition and the baseline ROM capabilities, establish the extent of ROM to be carried out, and ensure that the client is comfortable. Be aware that clients might be fearful of this type of exercise and that a full explanation of what you are going to do is helpful to allay fears. Enlist the cooperation of the client for maximum benefit. Discontinue all range-of-motion exercises if the client complains of pain, for it is at this point that the exercises become counterproductive.

EXERCISE

Muscles that are not used become weak and shortened. During prolonged bedrest, strength and endurance decrease rapidly. Clients can regain muscle strength and mobility by practicing specific groups of exercises daily. Promoting exercise, both passive and active, is one of the most important nursing functions. The purpose of exercises is to promote proper alignment, prevent contractures, stimulate circulation, and prevent thrombophlebitis and pressure ulcers. Exercise reduces joint pain and stiffness and increases flexibility and endurance. Exercise also prevents edema of the extremities and promotes lung expansion.

The nurse both performs and teaches several types of exercises as a component of providing total client care. Passive exercises are carried out by the therapist or nurse without assistance from the client. These exercises enable the client to retain as much joint range of motion as possible, as well as stimulating circulation. Active exercises, although supervised by the nurse, are performed by the client. These exercises increase muscle strength when the client is partially immobile.

AMBULATION

Ambulation, or walking, is an important function that most of us accomplish automatically; that is, without thinking or conscious effort. When a person has been immobilized, confined to bed after surgery or an injury, or unable to ambulate, this seemingly simple activity can become a major hurdle to overcome. The longer a person is immobilized, the more difficult it is to regain ambulatory ability; likewise, the sooner a person begins to ambulate after being bedridden, the more easily he or she will regain preimmobilization status. Early ambulation decreases hospitalization time and prevents complications, such as paralytic ileus or thrombophlebitis.

The human body functions best when it is frequently placed in a vertical position. Ambulation improves physical and mental well-being. Ambulation increases muscle strength and joint mobility. It also increases respiratory exchange, gastrointestinal muscle tone, and circulation. Without stress on bones,

calcium deposits occur anywhere in the body, especially in damaged areas, and renal problems also increase from calcium-based calculi.

Balance, coordination, and good body alignment are aspects important to walking. One must be able to move forward and maintain an upright balance; use muscles, bones, and joints correctly for coordination; and keep the head erect and vertebral column fairly straight with feet and knee caps pointed forward in order to maintain good body alignment.

The major muscle groups used for walking are the thigh and leg muscles. If these muscles have not been used or exercised because the client has been in bed for a long period of time, ambulation must be accomplished step by step. Weak muscles cannot support a human frame for the mechanics of walking. It is important, then, to begin the process of ambulation by administering muscle-strengthening exercises. Several different types of exercises were described previously; however, the most important preambulatory preparation is quadriceps-setting and gluteal-setting exercises. Carried out several times a day, these exercises restore muscle strength and prepare the legs for weight bearing.

Before actually assisting the client to walk, explain precisely what you are going to do, and prepare the client by completing the ambulatory procedure in stages. For example, begin with the muscle-strengthening exercises. Then assist the client to sit up in bed to determine if he or she is experiencing vertigo. Have the client move to the side of the bed with legs down, and only when he or she is ready and feels comfortable in doing so, assist the client to stand beside the bed. You may decide to take the client's vital signs after dangling to determine if they are stable. Allow the client to remain there with the bed as support until he or she feels totally secure. Finally, and with the assistance of one or two nurses (depending on the assessment of the client's ability and readiness to ambulate), have the client walk by taking short steps and walking only as long as he or she can tolerate. Do this several times a day, and it will not be long before the client's legs are strengthened, and he or she can graduate to one assistant, a walker, or cane. Throughout this procedure, do not allow the client to lose confidence in the ability to walk or your ability to support and assist while regaining his or her independence of action.

ASSISTIVE DEVICES

A variety of assistive devices are available to give the client support when ambulating. Assistive devices are used to relieve the client's body weight to enable the client to ambulate. Canes relieve about 40% of the weight mainly attributable to the lower limb. Walkers and crutches allow for complete non-weight-bearing ambulation. Such devices may give the client confidence (especially important with the elderly), stability, support for a weak limb, or reduce the pressure on a limb. These devices may include canes (standard cane, T-handled cane, tripod cane, and quad cane) and walkers (standard, with wheels, or a hemi-walker). Crutches are another type of assistive device used to lessen or remove weight from one or both legs.

Crutches

Crutches are an aid to walking by providing support during ambulating when the lower extremities are unable to support the body weight. It is hoped that this situation is temporary, but even if it is permanent, crutches do allow independence of movement that otherwise could not occur.

There are three main types of crutches: the axillary (most common for short-term use), the Lofstrand, or Canadian (a forearm crutch with a metal band and handle), and the platform, for clients who are unable to use their wrists to bear weight.

Several safety factors should be taken into account before assisting the client to use crutches. The measurement should be 5 cm (2 in.) from the axillary fold to the crutch bar. The handpiece should be adjusted to allow 20° to 30° elbow flexion, and rubber suction tips should be placed on the bottom of the crutches. Finally, the client should be informed that while using crutches, one needs well-fitting shoes with non-slip soles.

The type of crutch used by the client depends on the ability to ambulate, the muscle strength needed for support, and the individual needs of the client.

Walkers

Walkers assist the client with balance and with walking. The client's arms are used to support all or part of the client's body and take weight off the lower limbs as he/she ambulates.

Walkers are a necessary assistive device for postoperative clients requiring help with ambulation. These clients include those with major spinal cord surgery or hip replacement surgery, or those who were/are debilitated from major surgery and are unsteady with ambulation.

Walkers are constructed with or without wheels, or platforms. Wheels are only on the front legs of the walker to prevent falls and possible injury. All walkers have rubber tips that must be observed frequently to ensure they are in good repair.

The height of the walker is adjusted by lowering or raising the legs of the extension piece to properly fit the client's height. The handles of the walker should be at the height of the client's wrist, with elbows slightly bent.

Canes

Canes are used to protect clients from falls. Clients who are unsteady, lose their balance, are weak, or have a leg(s) that cannot hold the client in the upright position are candidates for canes.

Using a cane affords the client the confidence to ambulate and maintain his/her independence. Canes, just like crutches, are measured for a proper fit. The cane is turned upside down with the handle on the floor and the rubber tip is removed. The client is instructed to stand with his/her arms at the sides of the body. The correct measurement is marked with the tip of the cane facing upward and at the level of the wrist. The cane is cut (if a wooden cane) 1/2 in. shorter than the mark. Aluminum canes can be adjusted within 1 in. of the desired height.

ADAPTATION TO HOME CARE

Knowledge of body mechanics and how to use these principles when giving care is important to both the healthcare provider and the client. Correct use of body mechanics decreases the caregiver's potential for injury and provides safety for the client. Recently, there has been an increase in the number of back injury accident claims among home healthcare providers. One reason for the increase is the improper use of body mechanics while performing skills in the home setting. Also,

there may be no one to assist the care provider when lifting and turning clients in the home. The nurse may need to improvise, as the equipment may not be adequate or adjustable. The purpose of this unit is to consider adaptations necessary for providing safe care to the client while using proper body mechanics. In the home setting, much of the care is given by the family; therefore, it is essential that they also be taught good body mechanics.

NURSING DIAGNOSES

The following nursing diagnoses are appropriate to use on client care plans when the components are related to exercise and ambulation needs of clients.

NURSING DIAGNOSIS	RELATED FACTORS
Activity Intolerance	Nutritional disorders, surgery, disease states, impaired motor function, pain
Impaired Home Maintenance	Chronic debilitating disease, lack of knowledge, insufficient funds, lack of support or community resources
Impaired Physical Mobility	Neuromuscular impairment, musculoskeletal impairment, surgical procedure, trauma
Acute Pain	Altered body function (muscle spasms or rigidity), musculoskeletal disorders, inflammation, immobility
Self-Care Deficit	Neuromuscular impairment, surgery, musculoskeletal impairment, visual disorders, external devices, decreased strength and endurance

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. *Remember to wash your hands or use antibacterial gel before and after each and every client contact.*

IDENTIFY CLIENT Before every procedure, check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Range of Motion

Nursing Process Data

ASSESSMENT Data Base

- Determine client’s physical ability to perform exercises (i.e., level of consciousness, presence of casts, traction).
- Ascertain client’s baseline level of joint movement and muscle strength.
- Note amount of spontaneous movement shown by the client.
- Assess client’s understanding of ROM exercises.

PLANNING Objectives

- To improve or maintain joint function
- To improve or maintain muscle tone and strength
- To enhance/mainstream soft tissue integrity
- To counteract effects of prolonged bedrest or immobilization
- To facilitate passive range of motion
- To prevent contractures
- To increase client comfort
- To prepare the client for ambulation

IMPLEMENTATION Procedures

- Performing Passive Range of Motion 378
- Teaching Active Range of Motion 382

EVALUATION Expected Outcomes

- Client improves range of motion and muscle tone after performing range-of-motion exercises.
- Client is able to progress through range-of-motion with minimal to no pain.
- Client is able to ambulate without difficulty following a period of bedrest.

Critical Thinking Application 382

- Expected Outcomes 382
- Unexpected Outcomes 382
- Alternative Actions 382

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Performing Passive Range of Motion

Equipment

Hospital bed

Procedure

1. Check physician's order to determine if passive range of motion can be performed (according to facility policy).
2. Explain procedure to client and caregiver who may be delivering range of motion at home.
3. Perform hand hygiene.
4. Check two forms of client ID and introduce yourself. Explain rationale for procedure to client.
5. Position client on his or her back with bed as flat as possible. Place bed in high position.
6. Expose limb to be exercised.
7. Put all joints through range of motion slowly and gently (Tables 13-1 and 13-2). Start at head.
8. Protect against gravity and detrimental movement when performing range-of-motion exercises.
9. Provide support above and below joint using a cradling support while performing the exercises.
10. Follow sequence of exercises for upper and lower body according to chart.
11. All joints should be put through five full-range-of-motion exercises to each joint at least twice daily.
12. Encourage client to do active exercises as soon as possible. ► **Rationale:** Passive exercises only help prevent contractures, but do not maintain muscle.
13. Discontinue exercises if client complains of pain or discomfort. ► **Rationale:** Range of motion exercises should be performed in pain-free movement.
14. Reassess client's ability to perform ROM exercises and adjust schedule accordingly.

TABLE 13-1 Range of Motion: Upper Body

	Neck	Shoulder	Elbow	Forearm	Wrist	Finger and Thumb
Flexion	Move head forward 90° with chin on chest	Raise arm 180° from side to above head	Bend elbow so arm moves up toward shoulder		Bend hand 90° toward inner arm	Make a fist so fingers are all bent inward
Extension	Move head up from chest 90° to erect position	Move arm to side of body	Straighten elbow and return to position		Move hand straight pointed out	Move fingers 90° to straight position
Hyper-extension	Move head backwards 90°	Move arm to back of body at 50° angle			Bend hand up and back 90° toward arm	Move fingers up toward back of hand
Abduction		Hold arm away from side 180° to above head			Bend wrist out away from arm	Spread fingers as much as possible
Adduction		Move arm from side across chest			Bend wrist inward toward radius	Move fingers and thumb together
External Rotation		Hold arm out to side with elbow bent 45°; move forward so palm faces forward				
Internal Rotation		Move arm to side at shoulder level with elbow bent 45°. Lower arm so palm faces back				
Rotation	Move head in circular motion—90° left, then 90° right					
Circumduction		Move arm in full circle				
Supination				Rotate forearm 90° so palm is up		
Pronation				Rotate forearm 90° so palm is down		

TABLE 13-2 Range of Motion: Lower Body

	Trunk	Hip	Knee	Ankle	Toes
Flexion	Bend forward 90°	Move leg forward and up 90°	Bend knee 90°; foot moves back and up		Point down 90°
Extension	Stand in straight position	Move leg in straight alignment with trunk	Move foot 90° with knee straight and leg in line with body		Straight out from foot
Hyperextension	Bend backward 30°	Move leg backward 50°			Point up 45°
Lateral Flexion	Bend to both sides 45°				
Internal Rotation		Turn leg and foot inward 90°			
External Rotation		Turn leg and foot outward 90°			
Circumduction		Move leg in circle 360°			
Abduction		Move leg away from body 45°			Spread apart 15°
Adduction		Move leg toward body 45°			Bring together in normal position
Rotation	Move in circle 360° from waist				
Plantar Flexion				Point toes downward	
Dorsiflexion				Point toes upward	
Eversion				Move sole of foot lateral to outside	
Inversion				Move sole of foot medial to inside	

NOTE: ROM exercises should be incorporated into ADL activities whenever possible.

▲ Flexion of neck—move head forward 90° with chin on chest.

▲ Extension of neck—move head up from chest 90°.

▲ Internal rotation of shoulder.

▲ External rotation of shoulder.

▲ Abduction of shoulder.

▲ Adduction of shoulder.

▲ Extension of elbow.

▲ Rotation of the wrist.

▲ Extension of finger joints.

▲ Adduction – abduction finger exercises.

▲ Rotate lower trunk outward 90°.

▲ Rotate lower trunk to other side 90°.

▲ Flex hip and knee.

▲ Straight leg raise.

▲ Abduction—Move leg away from the body.

▲ Adduction—Move leg toward midline of body.

▲ Plantar flexion—Move foot down and away from leg.

▲ Dorsiflexion—Move foot up and toward leg.

Teaching Active Range of Motion

Equipment

- Hospital bed
- Sturdy nonslip shoes or slippers

Procedure

1. Explain the rationale for the procedure to the client.
2. Demonstrate the exercises that the client should perform. (See *Performing Passive Range of Motion* for specific steps in exercises.)
3. Observe as the client performs the exercises.
4. Assist with the exercises as needed.
5. Correct any problems you notice in the client's performance.
6. Encourage client to perform as much of the exercises as possible.
7. Instruct client to do range-of-motion exercises every 4 hr, exercising all joints.
8. Move extremities through range of motion five cycles each procedure.

DOCUMENTATION for Range of Motion

ROM Exercises

- Amount of time needed to complete exercises
- Any changes in condition of joint or joint mobility
- Movements that caused unusual pain or discomfort
- Amount of client participation
- Specific joints put through range of motion
- Alterations in usual procedure
- Degree of mobility improvement after exercises

CRITICAL THINKING Application

Expected Outcomes

- Client improves range of motion and muscle tone after performing range-of-motion exercises.
- Client is able to progress through the range-of-motion exercises with minimal to no pain.
- Client is able to ambulate without difficulty after a period of bedrest.

Unexpected Outcomes

Client continues to lose mobility and strength despite nursing intervention.

Client experiences pain and discomfort during range-of-motion exercises.

Alternative Actions

- Discuss the need for additional measures to improve joint range with the health team.
- Refer client to physical therapist if range of motion only performed by nursing staff.
- Assess client for the need to use splints and braces to maintain the best physiologic position between exercise periods, and discuss your findings with the physician.
- Assess amount and type of pain and report findings to physician.
- Reevaluate your technique to ensure you are performing the exercises correctly.
- Start exercises with less stress on joints. Do exercises for a shorter period of time and gradually increase time and range of joint mobility.

Ambulation

Nursing Process Data

ASSESSMENT Data Base

- Assess client's previous activity level.
- Check physician's orders for activity.
- Assess vital signs and physical ability to ambulate.
- Assess need for safety belt or assistive devices.
- Assess client for vertigo when moved into an upright sitting position.
- Determine if client feels pain from operative site.
- Observe client's balance.
- Assess any sensory deficits (visual, perceptual).

PLANNING Objectives

- To promote increased feelings of physical and mental well-being
- To develop increased tolerance for exercise
- To decrease hospitalization time
- To regain independence by regaining ability to walk
- To prevent paralytic ileus by increasing abdominal wall and gastrointestinal tract muscle tone
- To prevent thrombophlebitis by increasing circulation in the legs
- To promote healing by increasing circulation and muscle contraction

IMPLEMENTATION Procedures

- Minimizing Orthostatic Hypotension 384
- Ambulating With Two Assistants 384
- Ambulating With One Assistant 385
- Ambulating With a Walker 387
- Ambulating With a Cane 388

EVALUATION Expected Outcomes

- Feelings of physical and mental well-being increased.
- Balance and muscle tone improve.
- Client progresses from being dependant with ambulation to becoming independent in ambulation.
- Complications of immobility are prevented with ambulation.
- Correct use of assistive devices without supervision.

Critical Thinking Application 389

- Expected Outcomes 389
- Unexpected Outcomes 389
- Alternative Actions 389

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Minimizing Orthostatic Hypotension

Equipment

- Elastic stockings, if ordered
- Robe and slippers
- Stethoscope and sphygmomanometer

Procedure

1. Review client's chart before ambulation to check for a history of orthostatic hypotension. ► **Rationale:** This condition may occur in any client, but is more common in the elderly or with clients who have been immobilized.
2. Perform hand hygiene.
3. Check two forms of client ID, introduce yourself, and review procedure with client.
4. Place elastic stockings on client's legs if ordered. ► **Rationale:** Elastic stockings help to reduce blood stasis and promote venous return.
5. Move bed to LOW position. ► **Rationale:** This position enables client to have feet on the floor and is safer if client experiences vertigo.
6. *Slowly* raise head of bed to Fowler's position. ► **Rationale:** The more slowly the client's position is changed, the less the effect of postural hypotension.
7. Move client to edge of bed by placing one arm behind client's back and one arm under both thighs. Pivot client to a sitting position and assist to dangle legs over side of bed. ► **Rationale:** Dangling with feet flat on floor for several minutes with legs in a dependent position will reduce effects of postural hypotension.
8. Take client's blood pressure and pulse and observe for vertigo, fainting, pallor, etc.

9. *Slowly* assist client to stand. Instruct client to take a deep breath and exhale. If there is no evidence of orthostatic hypotensive symptoms, begin ambulation or transfer to a chair.

NOTE: If hypotension continues, client should be returned to flat position in bed.

Clinical Alert

If the client has been on prolonged bedrest or been immobilized, the risk of orthostatic hypotension is increased. Raising and lowering head of bed (HOB) several times to stimulate baroreceptors will help to prevent this condition.

Measuring Orthostatic Hypotension

Postural or orthostatic hypotension is often present after prolonged bedrest or immobilization. It is a sudden drop in blood pressure (25 mmHg systolic or 10 mmHg diastolic) when the client moves from a horizontal to a vertical (lying to sitting or standing) position. Symptoms include dizziness, lightheadedness, fainting, pallor, or nausea.

To measure orthostatic hypotension:

- With client in supine position for 5 minutes, measure pulse and blood pressure. ► **Rationale:** This amount of time allows for blood pressure to stabilize.
- Assist client to stand, wait 1 minute, and recheck pulse and blood pressure.
- Reassess blood pressure and pulse after 2 minutes. ► **Rationale:** This amount of time will allow for compensatory mechanisms to work.
- Notify physician if blood pressure and/or pulse remain abnormal after 15 minutes.

Ambulating With Two Assistants

Equipment

- Robe or second hospital gown (put on backwards so that client is not exposed)
- Shoes or slippers that fit well and have nonslip soles

Procedure

1. Perform hand hygiene.
2. Check two forms of client ID, introduce yourself, and explain the rationale for the procedure to the client.
3. Move client to side of bed and assist client to sit on the edge after placing bed in LOW position.
4. Assess the client for vertigo or faintness. Keep client in sitting position until he or she is able to stand without becoming dizzy. ► **Rationale:** Orthostatic hypotension can occur with prolonged bedrest (see skill *Minimizing Orthostatic Hypotension*).
5. Position one nurse on each side of the client and have each nurse grasp the client's upper arm with the hand that is closest to the client.
6. Have each nurse grasp the client's hand with the other hand and instruct the client to stand.
7. Encourage the client to maintain erect posture and look straight ahead, not down.
8. Ask the client to lift each foot to take a step. The client should not shuffle.
9. Walk the client only as far as he or she is capable of walking and returning without exhaustion.

▲ Move client to side of bed.

▲ Assist client to sit at edge of bed.

▲ Support is provided by two nurses when client's condition requires.

▲ Grasp client's arms firmly on both sides to provide support.

EVIDENCE-BASED PRACTICE

Early Mobilization Promotes Better Outcomes

Clients numbering 5,777 were included in 39 trials. Twenty-four trials evaluated bedrest after a variety of medical procedures. Seventeen trials favored early mobilization. Fifteen trials evaluated bedrest as a primary treatment, and all showed worse outcomes for clients on bedrest. The study provides evidence to support what clinicians have been doing for several decades—mobilizing clients as early as possible. There is evidence that prolonged bedrest is harmful for clients with low-back pain and myocardial infarction. There is a lack of evidence to determine the effects of bedrest for clients with multiple pregnancies, threatened abortion, and impaired fetal growth.

Source: *ACP Journal Club*, May/June 2000, vol. 132, no. 3. Review done on article by Allen, C., Glasziou, P., & Del Mar, C. (1999, October 9). Bed rest: A potentially harmful treatment needing more careful evaluation. *Lancet*, 354, 1229–1233.

EVIDENCE-BASED PRACTICE

Progressive Mobility Combating Deconditioning

Once a client's hemodynamic status allows forms of mobilization, it is essential to begin progressive mobilization. This decreases severe muscle wasting that occurs particularly in critically ill clients. Start with dangling, standing, and ambulation. Hemodynamic instability is due to prolonged periods in a stationery position.

Source: Rauen, C. A., Chulay, M., Bridges, E., Vollman, K. M., & Arbour, R. (2008). Seven evidence-based practice habits: Putting some sacred cows out to pasture. *Critical Care Nurse*, 28(2), 98–124.

Ambulating With One Assistant

Equipment

- Robe or second hospital gown (put on backward so that client is not exposed)
- Shoes or slippers that fit well and have nonslip soles
- Safety belt if indicated

Procedure

1. Check client's chart for ambulation problems, orthostatic hypotension, or any specific physician's orders.
2. Perform hand hygiene.
3. Check two forms of client ID, introduce yourself, and explain rationale for procedure to client.

▲ Use gait belt to assist client out of bed.

▲ Gait belt provides for stability when ambulating.

▲ Grasp belt firmly at client's back when ambulating.

4. Help client sit on side of bed after placing bed in LOW position.
5. Assess client for vertigo or faintness. ► **Rationale:** Keeping client in this position until he or she is able to stand without becoming dizzy will prevent falling.
6. Apply safety belt if client is unsteady. ► **Rationale:** Provides support if client is weak and prevents injury.
7. Bend forward facing the client, grasp belt, and gently rock back and forth about three times.
8. Instruct the client to assist with standing while pulling client upward with rocking motion, and on the third rocking motion, pull the client to a standing position. Have client take a deep breath and exhale while standing.
9. Stabilize client in a standing position.
10. Stand on weaker side, when client is moderately weak; for cerebrovascular accident (CVA) client, stand on unaffected side. ► **Rationale:** Flaccid muscles on affected side do not provide sufficient muscle strength for you to grasp and support client.
11. Encourage client to maintain good posture and to look straight ahead. ► **Rationale:** Tendency is for client to look down, which may increase vertigo.
12. Instruct client to lift each foot to take a step, not to shuffle.
13. Walk client as far as he or she is capable of walking without becoming exhausted. Remember client must walk back to room, so take this into consideration when walking. A wheelchair or walker can be pushed behind client so if he becomes tired he can sit down.

Clinical Alert

If client is collapsing, try to break the fall with your body and guide client to the floor. If client is unsteady or appears to be falling, support his or her body, especially the head and trunk, maintaining your body in good alignment with line of gravity within your base of support. This alignment prevents injury to yourself, while giving client adequate support. If necessary, guide client all the way to the floor.

▲ Grasp client under both arms if she begins to fall.

▲ Break client's fall using your body to prevent injury.

Ambulating With a Walker

Equipment

Robe or second hospital gown (put on backward so that client is not exposed)

Shoes or slippers that fit well and have nonslip soles

Walker with safety tips and rubber hand grips (nonrolling walker is used for clients beginning ambulation)

Procedure

1. Perform hand hygiene.
2. Check two forms of client ID, introduce yourself, and explain rationale for procedure to client.

▲ Place walker directly in front of client. Instruct client to hold on to hand grips.

3. Move client to edge of bed and seat client so feet touch floor.
4. Place walker directly in front of client at a comfortable distance. Instruct client to grasp hand grips on walker.
 - **Rationale:** To provide stability when getting up.
5. Ensure legs of walker are level to ground.
6. Instruct client to push self off bed. Client is cautioned to not step completely against front bar of walker.
 - **Rationale:** Client can lose balance.
7. Have client bend elbows slightly and move walker forward 6 to 8 in.; keep all four feet of walker on floor.
8. Instruct client to move weaker side first by supporting body weight on handles and advancing weaker leg into center of walker.
9. Instruct client to balance self and then move unaffected side by placing foot even with first foot.
10. Have client move walker forward and continue same pattern of ambulating.

NOTE: When moving to a chair, instruct client to back all the way to the chair until legs touch the front. Release hands from the walker and grasp the armrests of the chair. Instruct client to slowly lower herself or himself into the chair. Once in the chair, instruct to slide until back touches chair.

Clinical Alert

Adjust walker to client's height. Allow 20° to 30° flexion of the elbows when grasping hand grips of walker.

▲ Instruct client to bend elbows slightly and move walker forward.

▲ Instruct client to move weaker side first.

Ambulating With a Cane

Equipment

- Appropriate type of cane with rubber tips.
 - Straight-legged or standard cane
 - Tripod or three-pronged cane
 - Quad cane
- Sturdy shoes with nonskid soles
- Safety or gait belt (optional)

Procedure

1. Check physician's orders and client care plan.
 - ▶ **Rationale:** To ensure client is ready to use a cane and to ascertain that cane provides sufficient support for client.
2. Perform hand hygiene.
3. Check two forms of client ID, introduce yourself, and explain the purpose of using a cane for ambulation, and answer client questions.
4. Demonstrate use of cane if client is unfamiliar with its use.
5. Assist client to put on appropriate shoes and socks for walking.
6. Assist client to standing position with feet firmly on the floor.
7. Instruct client to hold cane on the stronger side of the body.
 - ▶ **Rationale:** This offers the most support.
8. Check that cane extends from greater trochanter to floor with 20° to 30° for elbow flexion.
 - ▶ **Rationale:** If cane is too long or too short, client may injure back.

▲ Specially marked cane indicates disability.

▲ Direct client to hold cane on stronger side of body.

9. Place cane about 12 in. in front of the foot and slightly to the outside.
 - ▶ **Rationale:** This position provides the best balance, because the client's center of gravity is within the base of support.
10. Determine that client can maintain balance and does not experience vertigo before taking the first step. Hold cane on unaffected side, keeping the cane close to the body.
 - ▶ **Rationale:** To distribute weight away from affected side and prevent the body from leaning forward.
11. Move cane and affected leg 4 in. (10 cm) in front of client.
12. Instruct client to shift his or her weight to affected leg and cane. Then move unaffected leg forward, ahead of cane.
13. Move cane forward, then bring affected leg forward until it is even with cane. Repeat these steps when walking with the cane.
14. Accompany client by walking beside him or her on the unaffected side, or use safety or gait belt if needed.
 - ▶ **Rationale:** If the client loses his or her balance, supporting client on unaffected side is most effective. Simply insert your hand and arm underneath the client's axilla and support his or her arm with your other hand.
15. Evaluate client's ability to use the cane, and instruct about its use as needed.
16. Reinforce the client's achievement to assist him or her to gain confidence in ambulating.
17. Continue to accompany client until the time for walking is completed.

▲ Instruct client to move affected leg forward first, even with cane.

18. Assist client to return to the room and to bed if indicated.
19. Position client for comfort.
20. Assess client's response to ambulation.
21. Perform hand hygiene.
22. Chart client's progress, and evaluate plan for increased periods of ambulation in terms of client's capability.

Managing Steps Using a Cane

Upstairs

- Take first step with strong leg.
- Move cane and affected leg to same step.
- Continue this procedure as client goes up stairs.

Downstairs

- Take first step by placing cane and unaffected leg on step.
- Lower affected leg to same step.
- Continue this procedure as client goes down stairs.

DOCUMENTATION for Ambulation

- Client's ability to balance
- Describe client's posture and gait during ambulation
- Time and distance of ambulation
- Strength and/or weakness of lower extremities
- Use of correct procedure for walker or cane
- Client's perceptions of ambulation

Legal Alert

Whenever the nurse is teaching clients how to use assistive devices, ensure that written instructions are also provided. Document what was taught, results of return demonstrations on use of equipment, and client's

understanding of use of equipment. The nurse and hospital can be held liable for negligence if the client falls and suffers an injury if the client does not follow specific instructions on use of assistive devices.

CRITICAL THINKING Application

Expected Outcomes

- Client is able to ambulate independently.
- Client is not experiencing complications of immobility.
- Client is able to prevent orthostatic hypotension by following protocol for moving out of bed.

- Client is able to ambulate using assistive devices without assistance.
- Client is able to ambulate safely with assistance.

Unexpected Outcomes

Client experiences vertigo or feels faint.

Alternative Actions

- If in the client's room, help the client return to the chair or bed.
- If in the hall, ease the client down the wall to the floor. Do not attempt to hold the client.
- Summon help if possible.
- Provide active and passive ROM before attempting ambulation.
- Begin ambulation protocol as soon as possible using assistive device.

Client is too weak to ambulate.

Unexpected Outcomes

Client is heavy or has poor balance.

Client feels unsafe to ambulate.

Critical Thinking Options

- Ask other nurses or staff to help you ambulate the client until able to walk on his or her own.
 - If necessary, enlist the aid of a stronger assistant whose presence may give the client additional psychologic as well as physical support.
 - Gradually increase ambulation as muscle tone improves and balance improves.
 - Request assistance for ambulation from physical therapist.
 - Obtain walker to assist client with ambulation. The walker will also provide reassurance to client.
-
- Ambulate more frequently for shorter periods and with more assistance to increase confidence.
 - Medicate at least 1 hour before ambulation to decrease pain.
 - With abdominal surgery, check with physician for an order for a binder to decrease fear of dehiscence and pain, if present.
 - Establish rapport with the client so you can discuss fears about ambulation.
 - Use assistive devices for client security.
-

Crutch Walking

Nursing Process Data

ASSESSMENT Data Base

- Assess physical ability to use crutches and strength of the client’s arm, back, and leg muscles.
- Observe client’s ability to balance self.
- Note any unilateral or unusual weakness or vertigo.
- Assess which gait is appropriate for client.
- Assess client’s understanding of crutch-walking technique.

PLANNING Objectives

- To improve client’s ability to ambulate when he or she has lower extremity injury
- To increase muscle strength, especially in the arms and legs
- To increase feeling of well-being when client can ambulate
- To promote joint mobility
- To resume activities of daily living after injury or surgery

IMPLEMENTATION Procedures

- Teaching Muscle-Strengthening Exercises 392
 - For Quadriceps-Setting Exercises 392
 - For Gluteal-Setting Exercises 392
 - For Pushups in Sitting Position 392
 - For Pushups in Prone Position 392
- Measuring Client for Crutches 392
- Teaching Crutch Walking: Four-Point Gait 393
- Teaching Crutch Walking: Three-Point Gait 393
- Teaching Crutch Walking: Two-Point Gait 394
- Teaching Swing-To Gait and Swing-Through Gait 394
- Teaching Upstairs and Downstairs Ambulation With Crutches 395
 - For Going Downstairs 395
 - For Going Upstairs 395
- Teaching Moving in and out of Chair With Crutches . . 396
 - For Moving Into Chair 396
 - For Moving Out of Chair 396

EVALUATION Expected Outcomes

- Client is able to ambulate without assistance.
- Client is able to use crutches to ambulate without fear or anxiety.
- Client is able to move in and out of chair with crutches.
- Crutches are measured appropriately to prevent numbness or tingling in fingers.
- Client is able to resume activities of daily living.

Critical Thinking Application 396

- Expected Outcomes 396
- Unexpected Outcomes 396
- Alternative Actions 396

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Teaching Muscle-Strengthening Exercises

Equipment

Books, boards, or other firm surface for each hand

Procedure

1. Check the client care plan for physician's orders.
2. Perform hand hygiene.
3. Check two forms of client ID, introduce yourself, and explain rationale for exercises to client.
4. Demonstrate the exercises that client will practice.

For Quadriceps-Setting Exercises

- a. Try to hyperextend the client's leg by pushing the popliteal area (the area behind knee) into the bed and lifting heel off the bed.
- b. Instruct client to contract muscle for a count of 5, then relax for a count of 5.
- c. Have client repeat exercise 2 to 3 times, gradually working up to 10 to 15 times an hour.

For Gluteal-Setting Exercises

- a. Tell client to pinch his or her buttocks together for a count of 5 and then to relax for a count of 5.
- b. Have client repeat exercise 10 to 15 times an hour.

For Pushups in Sitting Position

- a. Tell client to sit up in bed with arms at sides.
- b. Put books, boards, or something firm under the client's hands and have the client push down, raising hips off the bed. (This exercise may also be practiced while sitting in a chair.)
- c. Have client repeat exercise until he or she can do 10 to 15 pushups an hour.

For Pushups in Prone Position

- a. Tell client to lie prone in bed.
 - b. Ask client to place hands on the bed, close to the shoulders.
 - c. Tell client to extend arms and to push the upper part of the body into an upright position.
 - d. Have client repeat exercise until he or she can do 10 to 15 pushups an hour.
5. Monitor as the client performs the exercises and correct any problems that may occur.
 6. Assess the client for increasing strength as he or she continues to practice the exercises.
 7. Perform hand hygiene.

Measuring Client for Crutches

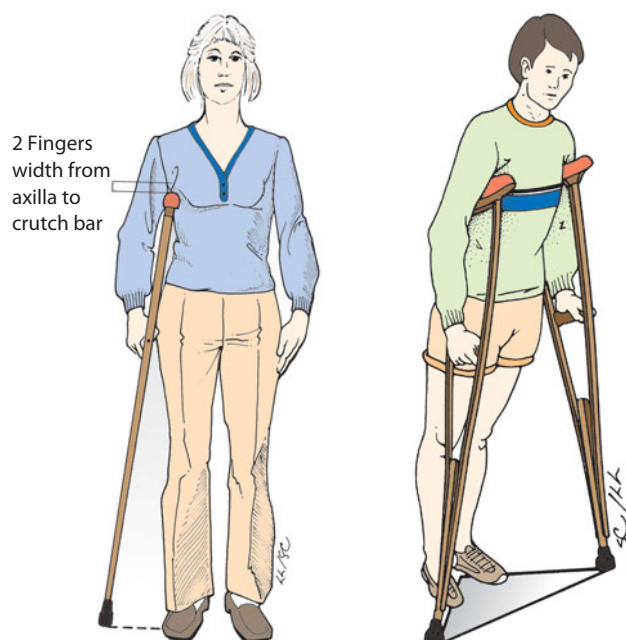

Equipment

Measuring tape
Hard-soled street shoes
Safety or gait belt

Procedure

1. Perform hand hygiene.
2. Check two forms of client ID, introduce yourself, and explain rationale for procedure to client.
3. Ask client to put on the shoes she or he will be wearing when using the crutches, if possible. Shoes should be low heel and non-skid.
4. Ask client to lie flat in bed with arms at sides.
5. Measure distance from client's axilla (armpit) to a point 15 to 20 cm (6–8 in.) out from heel.
6. Adjust hand bars on the crutches so that client's elbows are always slightly flexed.
7. Instruct client to stand with crutches under arms.
8. Measure the distance between client's axilla and arm pieces on the crutches. You should be able to put two of your fingers in the space between axilla and crutch bar.
► Rationale: Crutches that do not fit client correctly or crutches that are used incorrectly can damage the brachial plexus and cause paralysis of the arms.

NOTE: Use of gait belt can be beneficial when client is beginning to use crutches. **► Rationale:** The gait belt provides safety in preventing falls and promotes security for client.

▲ Measure from axilla to heel for crutch height, with crutch tip positioned 6 to 8 inches from foot.

▲ Teach tripod crutch stance for balance in crutch walking.

Teaching Crutch Walking: Four-Point Gait

Equipment

- Properly fitted crutches with rubber tips and axillary pads or Lofstrand or Platform crutch.
- Regular, hard-soled street shoes
- Safety belt, if needed

Procedure

1. Perform hand hygiene.
2. Check two forms of client ID, introduce yourself, and explain the rationale for the procedure to the client.
 - a. The gait is rather slow but very stable.
 - b. The gait can be performed when the client can move and bear weight on each leg.
3. Demonstrate the crutch-foot sequence to the client.
 - a. Move the right crutch.
 - b. Move the left foot.
 - c. Move the left crutch.
 - d. Move the right foot.
4. Help the client practice the gait. Be ready to help with balance if necessary. Use safety belt if necessary.

▲ Four-point gait.

5. Assess client's progress and correct mistakes as they occur.
6. Perform hand hygiene.

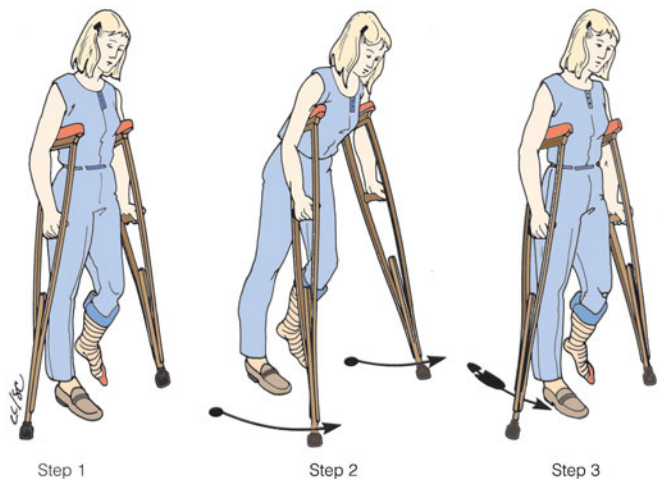

Teaching Crutch Walking: Three-Point Gait

Equipment

- Properly fitted crutches with rubber tips and arm pads
- Regular, hard-soled street shoes
- Safety belt, if needed

Procedure

1. Perform hand hygiene.
2. Check two forms of client ID, introduce yourself, and explain the rationale for the procedure to the client.
 - a. The gait can be performed when the client can bear little or no weight on one leg or when the client has only one leg.
 - b. This gait is fairly rapid and requires strong upper extremities and good balance.
3. Demonstrate the crutch-foot sequence to the client.
 - a. Two crutches support the weaker extremity.
 - b. Balance weight on the crutches.
 - c. Move both crutches and affected leg forward.
 - d. Move unaffected leg forward.
4. Assess the client's progress, and correct any mistakes as they occur.
5. Remain with client until crutch safety is ensured. Use safety belt if necessary.
6. Perform hand hygiene.

▲ Three-point gait.

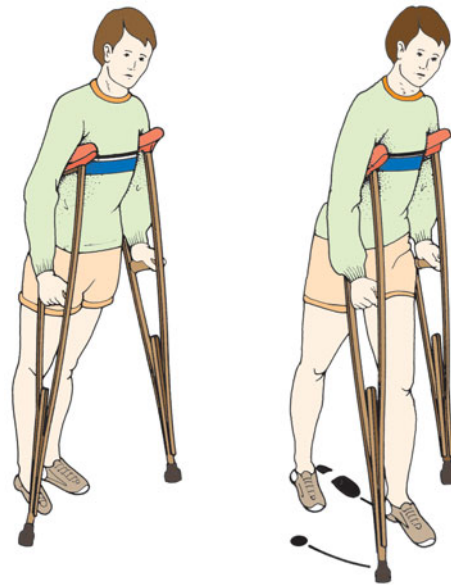

Teaching Crutch Walking: Two-Point Gait

Equipment

- Properly fitted crutches with rubber tips and arm pads
- Regular, hard-soled street shoes
- Safety belt, if needed

Procedure

1. Perform hand hygiene.
2. Check two forms of client ID, introduce yourself, and explain rationale for procedure to client.
 - a. Procedure is a rapid version of the four-point gait.
 - b. Gait requires more balance than the four-point gait.
3. Demonstrate the crutch-foot sequence to the client.
 - a. Advance the right foot and the left crutch simultaneously.
 - b. Advance the left foot and the right crutch simultaneously.
4. Help the client practice the gait. Use safety belt if necessary.
5. Assess the client's progress and correct any mistakes as they occur.
6. Perform hand hygiene.

Step 1

Step 2

▲ Two-point gait.

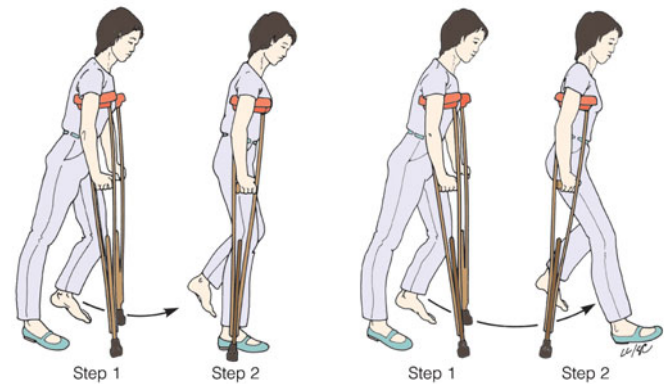

Teaching Swing-To Gait and Swing-Through Gait

Equipment

- Properly fitted crutches with rubber tips and arm pads
- Regular, hard-soled street shoes
- Safety belt, if needed

Procedure

1. Perform hand hygiene.
2. Check two forms of client ID, introduce yourself, and explain rationale for procedure to client.
 - a. These gaits are usually performed when the client's lower extremities are paralyzed.
 - b. The client may require braces.
3. Demonstrate the crutch-foot sequence to the client.
 - a. Move both crutches forward.
 - b. Swing-to gait: Lift and swing the body to the crutches.
 - c. Swing-through gait: Lift and swing the body past the crutches.
 - d. Bring crutches in front of the body and repeat.

▲ Swing to gait.

▲ Swing through gait.

4. Help the client practice the gaits. Use safety belt if necessary.
5. Assess the client's progress and correct any mistakes as they occur.
6. Perform hand hygiene.

Teaching Upstairs and Downstairs Ambulation With Crutches

Equipment

- Properly fitted crutches with rubber tips and arm pads
- Regular, hard-soled street shoes
- Safety belt, if needed

Procedure

1. Perform hand hygiene.
2. Check two forms of client ID, introduce yourself, and explain rationale for the procedure to the client.
3. Apply safety belt if client is unsteady or requires support.
4. Demonstrate procedure using a three-point gait.

For Going Downstairs

- a. Start with weight on the unaffected leg and crutches on the same level.
- b. Put crutches on the first step.
- c. Put weight on the crutch handles and transfer unaffected extremity to the step where crutches are placed.
- d. Repeat until client understands the procedure.

For Going Upstairs

- a. Start with the crutches and unaffected extremity on the same level.
- b. Put weight on the crutch handles and lift the unaffected extremity onto the first step of the stairs.
- c. Put weight on the unaffected extremity and lift other extremity and the crutches to the step.

▲ Crutch ambulation—up stairs and down stairs.

- d. Repeat until client understands the procedure.
5. Help the client practice.
6. Make sure that the client has adequate balance. Be ready to assist if necessary.
7. Assess the client's progress and correct any mistakes as they occur.
8. Perform hand hygiene.

▲ Use safety belt when client is first learning to manipulate stairs.

▲ Demonstrate going up or down stairs using a three-point gait.

Teaching Moving in and out of Chair With Crutches

Equipment

- Properly fitted crutches with rubber tips and arm pads
- Regular, hard-soled shoes
- Safety belt, if needed

Procedure

1. Perform hand hygiene.
2. Check two forms of client ID, introduce yourself, and explain procedure to client.
3. Apply safety belt if client is unsteady with crutches.
4. Instruct client to follow these steps.

For Moving Into Chair

- a. Stand in front of the chair, facing forward.
- b. Place both crutches in hand on affected side.
- c. Move backward slowly until back of lower legs touch center of chair.
- d. Hold on to chair arm on unaffected side.

- e. Lower self into chair by bending knees and hips, keeping back straight.
- f. Use crutches and unaffected leg as a support.

For Moving Out of Chair

- a. Move forward in chair by using unaffected side to slide body to edge of chair.
 - b. Hold on to chair arm on unaffected side.
 - c. Place both crutches in hand on affected side.
 - d. Lift self out of chair by grasping the chair arm and supporting self with crutches. Put weight on unaffected leg as you lift body out of chair.
 - e. Stand with back straight, bearing weight on unaffected leg and crutches.
 - f. Place crutches in front and slightly to side of body and begin crutch walking.
5. Perform hand hygiene.

DOCUMENTATION for Crutch Walking

- Time and distance of ambulation on crutches
- Balance
- Reason for safety belt, if used
- Problems noted with technique
- Remedial teaching
- Client's perceptions of ambulation with crutches
- Ability to move in and out of chair
- Fear of using crutches

CRITICAL THINKING Application

Expected Outcomes

- Client is able to ambulate without assistance.
- Client is able to use crutches to ambulate without fear or anxiety.

Unexpected Outcomes

Client states he or she is frightened of the crutches.

Client fears falling while dependent on crutches.

- Client is able to move in and out of chair with crutches.
- Crutches are measured appropriately to prevent numbness or tingling in fingers.

Alternative Actions

- Observe as the client practices the procedures to make sure that he or she is completing the steps correctly for each gait.
- Explain that it takes time to become proficient.
- Reassure the client that he or she will improve with continued practice.
- Assess the client's ability to use the crutches and evaluate level of confidence.
- Place safety or gait belt on client until he/she feels confident.
- Check with physician about obtaining an order for a walker until the client feels more confident.
- Slow down crutch protocol until client gains confidence at every level of mastery (e.g., four-point gait to two-point gait).
- Remain with client and give verbal reassurance and feedback for improvement.

Unexpected Outcomes

Shoulder girdle is too weak to bear client's weight for crutch support.

Slipping occurs with crutch walking.

Client complains of numbness and tingling in fingers when crutch walking.

Alternative Actions

- Increase exercise of shoulder (biceps and triceps setting) to gain strength.
 - Request physician to write an order for overhead frame with trapeze for shoulder exercise sets.
-
- Check crutch tips to ensure they cover all metal or wood.
 - Observe the client's stance or gait to determine if it is too broad.
 - Be sure that floor surface is dry and free of scatter rugs.
-
- Remeasure distance between axilla and crutch bars to determine if two finger breadths can be inserted.
 - Observe client's gait to determine if he or she is leaning on crutch inappropriately.
-

Chapter 13

UNIT 4

Adaptation for Home Care

Nursing Process Data

ASSESSMENT Data Base

- Assess family's knowledge of the principles of body mechanics.
- Assess home care provider's knowledge of how to use correct muscle groups for specific activities.
- Assess knowledge of how to improvise for a nonhospital bed.
- Assess knowledge and correct any misinformation about body alignment and ability to move client up in bed without assistance.

PLANNING Objectives

- To promote proper body mechanics while caring for clients
- To move clients without assistance, preventing back injury
- To provide knowledge of the musculoskeletal system, body alignment, and balance in order to prevent back injury when providing care for a client in the home
- To provide methods of improvising for a nonhospital bed
- To discuss four safety tips for home care clients requiring assistive devices

IMPLEMENTATION Procedures

- Positioning Nonhospital Bed for Client Care 399
- Moving a Helpless Client up in Bed Without Assistance 399
- Using Assistive Devices in Home 399
 - For Cane 399
 - For Crutches 399
 - For Walker 400
- Instructing Caregivers on Safety Devices 400

EVALUATION Expected Outcomes

- Correct body mechanics are used in caring for clients.
- Injuries are prevented to both nurse and client.
- Client care is facilitated by proper body mechanics.
- Client is able to move without assistance.
- Center of gravity is maintained when lifting objects.
- Nonhospital bed is easily adapted for home care.

- Critical Thinking Application** 400
- Expected Outcomes 400
 - Unexpected Outcomes 400
 - Alternative Actions 400

Pearson Nursing Student Resources

Find additional review materials at nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Positioning Nonhospital Bed for Client Care

Procedure

1. Position foam wedges to simulate change in position when head of bed does not move (high-Fowler's/90°; Fowler's/60°; semi-Fowler's/30°).
2. Use correct body mechanics to adjust height.
 - a. Flex body at knees and keep back straight if bed is only slightly low.
 - b. Kneel on pillow by bed or sit in chair alongside bed if bed is extremely low.
3. Lock each wheel or leg of bed in position by securing with bricks or blocks of wood.
4. Make footboard of lumber or item such as a TV tray; position legs of tray under mattress so that tray becomes footboard.

Correct Body Mechanics

- Place both feet flat on the floor and keep your back straight to prevent back injury.
- Hold objects close to the body to prevent muscle strain and possible back injury.
- Keep body in proper alignment by bending your knees and keeping back straight when lifting objects to prevent injury to back muscles.

Moving a Helpless Client up in Bed Without Assistance

Procedure

1. Lower head of bed and place pillow at head of bed.
2. Stand at side of client's bed.
 - a. Face far corner at foot of bed.
 - b. Place one foot behind the other, assume a broad stance, and flex knees.
3. Flex arms so forearms are level with bed. Place one arm under client's head and one under small of back.
4. Rock and shift weight from forward to rear foot; hips will move downward.
5. Guide the client as he or she slides diagonally across bed toward head.
6. Repeat for trunk and leg sections.
7. Move to other side of bed and repeat Steps 2 through 5.
8. Repeat until client is satisfactorily positioned in bed.

NOTE: Mechanical lift devices are made for home care clients. See Chapter 12.

Using Assistive Devices in Home

Equipment

Appropriate Device for:
 Assistance with walking
 Cane
 Walker
 Crutches
 Gait belt (optional)

Procedure

For Cane

1. Ensure client was measured appropriately for cane (refer to top of page 375).
2. Review steps in working with a cane. Demonstrate, if necessary.
3. Assist client to use gait belt if unsure of client's balance.
4. Assist client to walk stairs as needed.

5. Review safety issues with cane: observe tips of cane to ensure rubber covers top completely.
6. Instruct caregiver in proper method to walk with cane.

For Crutches

1. Ensure client was measured appropriately for crutches (refer to page 392).
2. Review steps in crutch walking according to type of gait: two point, four point, etc.
3. Demonstrate appropriate gait.
4. Instruct client to demonstrate gait; use gait belt constantly with crutches.
5. Instruct client to walk up and down stairs if needed and have client return demonstration.
6. Instruct client on how to sit down on chair using crutches.
7. Instruct client and caregiver to examine rubber tips and change if they become worn.

For Walker

1. Ensure client was measured appropriately for walker and appropriate type of walker was selected (with wheels, with seat, etc.).
2. Review steps in using walker.
3. Demonstrate moving walker and proper foot.
4. Discuss how to grasp handles on walker with both hands.
5. Instruct client and caregiver to examine rubber tips on walker and change if worn.

Instructing Caregiver on Safety Issues

Procedure

1. Inspect household for general safety issues. Instruct caregiver and client on change necessary to promote safety for clients using assistive devices.
2. Ensure adequate space to allow client to move throughout the house.
 - a. Remove small scatter rugs from pathway.
 - b. Keep electrical cords out of pathway.
 - c. Wipe up spills that can cause slips.
 - d. Position furniture to make space for assistive devices.
- e. Keep frequently used household items in easy access in lower shelves to prevent client from falling.
- f. Install nonslip bath mats and grab bars next to toilet and in shower. Install raised toilet seat and shower/tub seats.
- g. Encourage client to use fanny pack or apron to carry items about the house.
- h. Discuss issues related to house pets and safety.
3. Instruct caregiver to watch for warning signs of difficulty. Notify MD if any signs appear.

DOCUMENTATION for Home Care

Using appropriate home care forms, document the following:

- Environmental assessment and safety instruction
- Client's ability to use assistive devices safely
- Support needed for assisting client utilizing assistive devices
- Caregiver's ability to move client up in bed

CRITICAL THINKING Application

Expected Outcomes

- Client has safe environment in home for ambulation using assistive devices.
- Client provided appropriate instruction to make ambulation using assistive devices.

Unexpected Outcomes

Client not stable ambulating with crutches or cane.

Unable to lift client up in bed with single healthcare worker.

Client is not ambulating.

Alternative Actions

- Place safety belt on client and ambulate with walker.
- Increase both upper and lower muscle strength to increase ambulation with cane or crutches.
- If a second person is available, utilize him/her to assist in moving.
- Use sliding board if two healthcare workers are available.
- Rent a hydraulic lift or Hoyer lift to assist with moving up in bed or getting out of bed.
- Discuss with caregiver and client reasons why client is not ambulating.
- If client is afraid of falling, ensure that a gait belt is worn and the client uses a walker to start with and then moves to a cane, if possible.
- Use two individuals to assist with walking, if available.

GERONTOLOGIC Considerations

The Elderly Can Suffer Impaired Mobility and Disability Due to Decreased Physical Function or Accidents

- Nearly 23% of older people living in the community have some degree of disability.
- Persons 85 and older constitute 27% of those who have impaired mobility.
- Impaired mobility can lead to many subsequent problems, including depression, negative self-image, dependent behavior, and loss of independence.
- Effects of disability can influence the individual's body image, physical appearance, and bodily sensations.
- Posture becomes more flexed and center of gravity shifts.

Special Assessment Parameters Are Important for the Elderly

- Specific source of disability or impaired mobility
- Presence of accompanying disease state: arthritis, stroke, dementia, diabetes, heart failure, COPD
- Presence of pain
- Condition of skin
- Drug effects: sedation, incontinence, orthostatic hypotension
- Motivation for rehabilitation
- Nutritional status
- Best assistive aid for client
- Be aware of any vision problems your client may have, especially cataracts, glaucoma, or macular degeneration. Note poorly lighted areas in the home or dark areas in the corridors, throw rugs, uneven or uncarpeted areas adjoining carpeted areas, etc., which may cause the client to stumble or fall.
- Check your client's ability to be mobile—their gait, balance, and posture, and whether the client shuffles or is able to pick up his or her feet. Check if the client leans forward and is therefore off balance. Poor or unsteady mobility is often a direct cause of falling.
- Assess the client's degree of muscle strength on both sides of body and/or loss of flexibility because as age increases, strength declines, resulting in a fall. Check the degree of range of

motion to all joints before ambulating. Even a poor hand grip can be dangerous if the client is walking downstairs. If leg muscles are weak, it may be difficult to get off a bed or up from a chair and the client may lose his or her balance.

- Assess for certain medications the client is taking which may cause vertigo, poor balance, blurred vision, weakness, or even drowsiness. Review the medications for elderly clients, keeping in mind the fact that they may require only half the normal dose due to their age and inability to metabolize drugs. The use of alcohol may contribute to falls in the home environment, so if the client uses alcohol there should be client teaching that focuses on the potential danger.
- Chronic diseases such as osteoarthritis, Parkinson's, Alzheimer's, and diabetes with peripheral neuropathy can all contribute to falls. Clients who have these diseases may require special assessment and interventions to prevent falls.
- Most elderly clients are aware of the danger of falling and breaking a hip or a leg, so fear is usually present when they are moving or walking. Proper intervention and instructions with an assistive device (canes, walkers, wheelchairs, etc.) will help to allay these fears, which may become so overpowering that they cause immobilization and depression. Even fear itself, with its concomitant caution, may result in a fall; if the nurse can work with the client to discuss fears about falling and specific behaviors to prevent falling, it would be very therapeutic.

Develop Nursing Care Plan to Meet Elderly Client's Needs

- Focus on disability or impaired mobility.
- Establish supportive relationship.
- Teach activities of daily living. Determine activities that must be accomplished each day for individual to care for own needs and be as independent as possible.
- Use assistive devices until client is stable and able to ambulate independently.
- Increase activities as individual progresses and is able to resume activity.
- Give positive reinforcement for all effort expended.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- Range of motion is usually performed for the first time by or under the supervision of a licensed physical therapist or RN. If these members are not available, the nurse or

healthcare worker must understand the principles of the skill before performing it on the client. Range of motion is important for the client who is immobilized or on long-term bedrest, so if the skill is ordered more than once per day, it will probably be delegated to an LVN/LPN, CNA, or UAP. This staff member should be assigned to observe and be checked by personnel who understand the skill.

- Ambulation may be done by any healthcare worker and is often assigned to a CNA or UAP. However, the first time a

client is ambulated, an assessment is very important for safety reasons, and this should be performed by an RN or LVN/LPN. In some medical–surgical settings, a physical therapist may ambulate specific high-risk clients for the first time. A licensed nurse performing this task will minimize the possibility of orthostatic hypotension occurring, because assessment and vital signs are an important part of the skill.

- Crutch walking is a skill often performed initially with specialized personnel, such as the physical therapist. However, the nurse should understand the principles of crutch walking so that he or she may reinforce the correct steps of the procedure whether the client is in the hospital or in the home setting.

Communication Matrix

- Range-of-motion and muscle-strengthening exercises, ambulation, and crutch walking should all be included in the verbal report at change of shift to all personnel and charted in the client's record.
- Any problems that occur with the exercises or ambulation should also be noted and, if present, the task should be reassigned to licensed personnel. It is especially important to note occurrence of orthostatic hypotension and what actions were effective to minimize the effects on the client.

CRITICAL THINKING Strategies

Scenario 1

You are assigned to care for two clients during the day shift.

Client A: A 65-year-old obese client who had a hysterectomy yesterday. Her orders include ambulation and up-in-chair TID on the first postop day.

Client B: A 70-year-old female client who is to be discharged today after having an inguinal hernia repair yesterday.

1. What is your priority of care of these two clients?
2. What assessment will you focus on for both clients and which assessment will be your priority?
3. Briefly describe the discharge teaching that will be done for Client B.
4. When you approach Client B and tell her you would like to do her discharge teaching, she informs you, "Oh, at my age, I can be a couch potato so I don't need you to tell me anything." What is your best response?
5. Based on the information provided, what generalizations can you make about the general health and projected health of this client?
6. What is the primary danger to the health of this client? Describe how you will explain this to the client.
7. What plan (part of discharge teaching) can you devise to positively affect this situation?
8. You have elicited the help of a nursing assistant to help you ambulate Client A. As you are ambulating the client, she begins to fall. What steps should both you and the nursing assistant take to prevent client injury?

9. After your initial intervention, what other actions should be taken for this client?
10. What preliminary actions should have been taken to prevent this from happening?

Scenario 2

You are a student on an orthopedic unit and are assigned to assist the RN in the care of her clients for the day shift. You obtained the following information during report.

Client A: Client had a right-sided CVA 4 days ago and needs to be instructed on the use of a walker before being discharged to a long-term care facility this morning.

Client B: Client was instructed on the use of a cane yesterday, but no one has seen him practicing with the cane. He had a CVA several years ago and still has some instability when walking. He is 80 years old, wears a hearing aid, and is very independent.

Client C: Client is a 20-year-old who had an arthroscopy last night for injuries from football. He stayed overnight as a result of being nauseated and with low blood pressure. He is to be discharged this morning with crutches.

1. Which client should be assessed first?
2. Provide rationale for your choice.
3. Discuss your priority interventions for each of the clients.
4. Client A: Identify the major nursing action for this client before beginning instruction on the use of a walker.
5. Client B: What hunches do you have regarding why the client may not have been practicing with the cane?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. The movement of a bone away from the midline is termed:
 1. Flexion.
 2. Eversion.
 3. Adduction.
 4. Abduction.

2. Passive range-of-motion exercises (ROM) were ordered for the client. The nurse has just performed the exercises on the client who is on strict bedrest. The documentation for this skill includes
Select all that apply.
 1. Total time for exercises.
 2. Specific joints put through ROM.
 3. Specific joints that client was able to exercise independently.
 4. Movements that caused unusual pain.
3. During morning report the nurse states that the client assigned to you experienced orthostatic hypotension when getting out of bed. Your priority intervention before taking the client to the bathroom is to
 1. Move client to side of bed and assist him to transfer to a walker.
 2. Take vital signs before allowing client to stand up.
 3. Raise and lower head of the bed slowly several times before attempting to assist client out of bed.
 4. Obtain assistance from another health team member to assist client to ambulate.
4. Client teaching needs to be completed before the client uses a walker. The correct instructions include
 1. Place walker approximately 2 feet in front of client and instruct client to push self off bed, stand erect, and grasp hand grips on the walker.
 2. Move walker by pulling legs of walker slightly off floor as you move unaffected leg forward.
 3. Move weaker side of body first by supporting body weight on handles of walker and then advancing weaker leg.
 4. Grasp handles of walker and move weaker leg first by moving body toward center of walker.
5. Instructions provided to a client who is using a cane for the first time should include the following information
 1. “You will need to place the cane on the weaker side of your body.”
 2. “The cane is placed directly to the side of your weaker leg to help maintain balance.”
 3. “The cane and unaffected leg are moved together when walking.”
 4. “You need to move the cane forward, then bring the affected leg forward even with the cane.”
6. Instructions to the client who is learning to use the cane when walking steps should include
 1. “When going downstairs, the unaffected leg is placed on the step, followed by the cane.”
 2. “When going downstairs, the affected leg and cane are moved to the step before moving the unaffected leg to the same step.”
 3. “When going upstairs, the first step is placing the affected leg and cane on the step, then the unaffected leg.”
 4. “When going upstairs, the unaffected leg is placed on the step, followed by the cane and affected leg.”
7. Before the client uses crutches they must be measured to the appropriate length. Which of the following instructions will be given to the client?
 1. Place stocking feet flat on the floor and then measure height of crutches.
 2. With client lying in bed with shoes on, measure distance from axilla to a point 6 to 8 in. out from heel.
 3. Ensure axilla rests on bars of the crutches when measuring for length.
 4. Assist client to standing position with shoes on, keeping crutches tight to body, and measure distance from crutch bar to floor.
8. A client who can move and bear weight on each leg will be taught the _____ gait for crutch walking.
 1. Three-point.
 2. Four-point.
 3. Two-point.
 4. Swing-through.
9. Clients going upstairs with crutches will start with:
 1. Weight on the uninjured leg on the step, and placing crutches on upper step.
 2. Weight on the uninjured leg and crutches at same level.
 3. Crutches on upper step and then bringing injured leg to the step.
 4. Moving injured leg to first step with one crutch, then moving second crutch and uninjured leg to the next step.
10. The client states that when she uses the crutches, she slips. Which of the following critical thinking options should be implemented?
Select all that apply.
 1. Observe client using the crutches to see if she is leaning on them inappropriately.
 2. Reassure client that this will not occur as she becomes more proficient with the crutches.
 3. Observe client’s stance or gait to check if it is too broad, causing her to slip.
 4. Check crutch tips to ensure they cover all the metal or wood from the crutches.

Infection Control

LEARNING OBJECTIVES

1. Describe and draw the six steps in the chain of infection.
2. Explain what is meant by the body's natural defenses.
3. List and describe eight conditions that predispose clients to infection.
4. Describe what is meant by the term healthcare-associated (*nosocomial*) infection and discuss one intervention that will help to prevent it.
5. List the major organisms responsible for healthcare-associated infections.
6. State the main purpose of hand hygiene.
7. Demonstrate donning and removing a gown.
8. Define the terms *surgical asepsis* and *medical asepsis*.
9. Outline the steps in donning isolation clothing before entering an isolation room.
10. Outline the steps in removing isolation clothing before leaving the room.
11. State the isolation procedure for removing specimens and equipment from an isolation room.
12. Describe the modes of transmission of HIV.
13. List three precaution principles and explain their main purpose.
14. List blood and body fluid protection protocol.
15. Describe the difference between the first and second tier of precautions.
16. Compare and contrast infection control practices in the home and hospital.
17. Differentiate assessment modalities to determine potential for infection in home care and hospitalized clients.

TERMINOLOGY

- AIDS** acquired immunodeficiency syndrome—a serious condition characterized by a defect in natural immunity against disease. When the immune system is suppressed, the individual is vulnerable to a host of opportunistic infections.
- Antibody** protein substance developed by the body to fight disease organisms. Not effective against a virus that is inside the cells.
- Antimicrobial** an agent that prevents the development or pathogenic action of microbes.
- Antiseptics** agents that are applied to body tissues, such as skin or mucous membrane, to destroy or retard the growth of microorganisms.
- Asepsis** the absence of disease-producing microorganisms.
- Aseptic technique** a method to eliminate contamination, germs, or infection.
- Autoinfections** infections that arise from an individual's own body flora.
- AZT** an antiviral drug currently being used as an effective drug against HIV.
- Bacteriostatic** a substance that prevents the growth or multiplication of bacteria.
- Barrier nursing** any technique that reduces the risk of cross-contamination.
- Biohazard waste** any solid or liquid waste that may present a threat of infection.
- Carrier** a person or animal without signs of illness but who carries pathogens on or within his or her body that can be transferred to others.
- Cell-mediated immunity** reactions to antigens by cells rather than antibody molecules present in body fluids.
- Chemotaxis** attraction and repulsion of living protoplasm to a chemical stimulus.
- Cofactors** existing characteristics in the individual that may make them more susceptible to the AIDS virus.
- Colonization** organisms present in body tissue but not multiplying or invading the tissue.
- Contagious disease** a disease conveyed easily to others.
- Contamination** introduction of disease, germs, or infectious materials into or on normally sterile objects.
- Detergent** compounds (surfactants) that possess a cleaning action, often referred to as soaps. They are composed of a hydrophilic and a lipophilic substance.
- Disinfectants** chemical agents that are used to destroy or reduce microorganisms on inanimate surfaces and objects.
- Disinfection** a process that employs physical and chemical means to remove, control, or destroy most of the organisms that may be present on equipment or materials.
- Duration of the infectious challenge** sustained exposure to even a relatively small number of organisms that poses a significant risk to the client (e.g., intravenous catheters become colonized with microorganisms).
- Endogenous** organisms natural to an individual's own body.
- Enteric precautions** isolation practices designed to prevent transmission of pathogens through contact with fecal matter and vomitus.
- Exogenous** organisms external to an individual's own body.
- False negative** a negative test in someone who in fact has been infected by a microorganism but for some reason has not developed antibodies.
- False positive** a positive test for an antibody. Usually the result of an artifact of the laboratory test; the person has not in fact been exposed to the microorganism. All persons who test positive should have the test repeated.
- Granulation** formation of granules (roughened prominences). Each granulation represents an outgrowth of new capillaries and enriched blood supply.
- HAI Healthcare-Associated Infection** formerly Hospital-Acquired Infection or nosocomial; an infection not present and without evidence of incubation at the time of admission to a healthcare setting.
- HIV** human immunodeficiency virus is a blood-borne retrovirus that has a different life cycle from a normal virus.
- Host** an animal or person on which or within which microorganisms live.

Humoral immunity acquired immunity in which the circulating antibody is predominant.

Hygiene study of health and observance of rules pertinent to health.

Incubation period the time between infection from a microorganism and the onset of symptoms. Seems to range from 6 months to 7 years for AIDS. Not everyone who is exposed to the virus develops the disease.

Infection establishment of a disease process that involves invasion of the body tissue by microorganisms and the reaction of the tissues to their presence and to the toxins generated by them.

Isolation technique practices designed to prevent the transmission of communicable diseases.

Kaposi's sarcoma a type of cancer usually occurring on the surface of the skin or in the mouth. Kaposi's sarcoma may also spread to internal organs of the body and may be responsible for death.

Latex natural rubber used in many gloves and medical equipment. Latex proteins can enter the body and cause latex allergy.

MDR-TB multidrug-resistant tuberculosis is an in vitro resistant strain of TB to antituberculosis drugs.

Medical asepsis all practices that limit the number and growth of microorganisms and their transmission.

Microorganism minute living body, such as a bacterium, protozoan, or virus, not perceptible to the naked eye.

Nosocomial infection see HAI.

Opportunistic infections illness or diseases that would not be a threat to anyone whose immune system is functioning normally, but in a person with AIDS may be responsible for death.

Opsonin a substance in blood serum that acts on microorganisms and other cells and facilitates phagocytosis.

Outbreak a critical incident in which infections occur above an established level and are caused by the same infective agent.

Pathogen a microorganism that can cause infectious disease in the human body.

PEP postexposure prophylaxis; recommendations from the CDC on how to treat a healthcare worker's exposure to HIV.

Pneumocystis carinii pneumonia PCP is a parasitic infection of the lungs. This is one of the two rare diseases that affect 85% of AIDS clients. PCP has symptoms similar to other severe forms of pneumonia.

Primary immune response response that occurs when the B cell recognizes an antigen, becomes activated, and divides into more memory cells.

Protective isolation practices designed to protect a highly susceptible person from contagious diseases, reverse isolation.

Protocol description of steps taken in exact order—may be legally binding.

Resident (normal) flora organisms natural to an individual's own body. Organisms multiply in the environment, not merely survive there.

Retrovirus a virus with a life cycle in which the genetic information is in reverse of that in an ordinary virus: the RNA code is transcribed backward into DNA.

Sepsis condition resulting from the presence of pathogenic bacteria and their products.

Sterile free from any living microorganisms.

Subungual an area beneath a fingernail or toenail.

Surgical asepsis practices which will maintain area free from microorganisms, as by a surgical scrub or sterile technique.

Susceptible sites an area that is sensitive to or can be invaded by a bacterium or other infectious agent.

Virulence recognized pathogenic organisms designated because of their ability to invade and propagate in normal, intact, uncompromised individuals. Some organisms that are avirulent for normal individuals become pathogenic when defense mechanisms are impaired.

Virus minute, parasitic organism that depends on nutrients inside cells for its metabolic and reproductive needs. These organisms cause a variety of infectious diseases and stimulate host antibodies. Unlike a bacteria, viruses are unable to survive long on their own and are not affected by antibodies.

Waterless antiseptic agent an antiseptic agent that does not require use of exogenous water. Agent dries automatically after applying to hands and rubbing hands together.

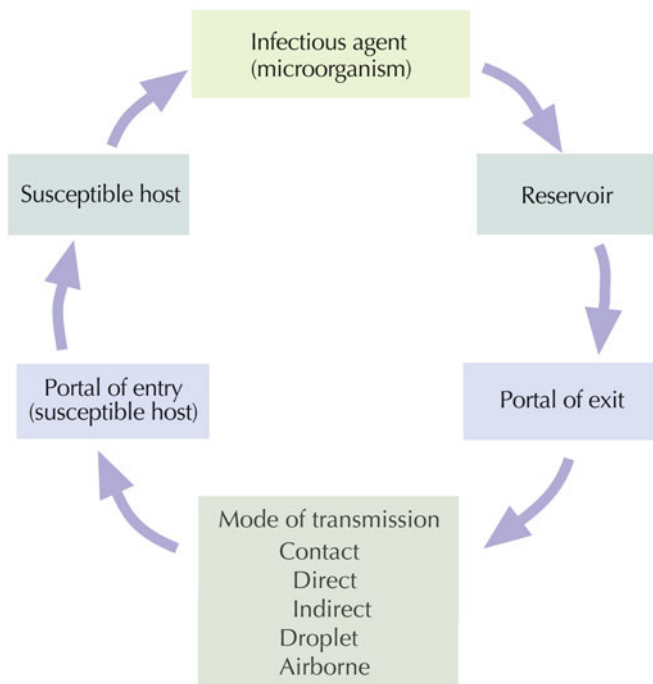

CHAIN OF INFECTION

For an infection to occur a chain of events must take place. If the chain is broken through the implementation of infection control measures, the infection is less likely to occur. The chain of infection involves six steps.

Infectious Agent (Microorganism) The first step in the chain involves the presence of an infectious agent, or microorganism. Whether the microorganism is capable of producing an infection depends on a number of circumstances: the virulence and number of organisms present, the susceptibility of the host, the existence of a portal of entry, and the affinity of the host to harbor the microorganism.

Reservoir A reservoir must provide a favorable environment for growth and multiplication of the microorganism. These reservoirs include the respiratory, gastrointestinal, reproductive and urinary tract, and blood.

Portal of Exit The third link in the chain must be a portal of exit, which allows the microorganism to move from the reservoir to the host. Without a portal of exit an infection cannot occur. The portal of exit is directly associated with the reservoir. For example, if the reservoir is the respiratory tract, the portal of exit is through sneezing, coughing, breathing, or talking. If the reservoir is blood, the portal of exit is through an open wound, needle puncture site, or nonintact skin surface.

▲ Six steps in the chain of infection.

Mode of Transmission The fourth step is transmission of microorganisms. There are five routes of transmission; the three primary routes are contact, droplet, and airborne. Two lesser routes are common vehicle (transmission by contaminated items such as food, water, devices, or equipment) and vector borne (transmission by vectors such as mosquitoes, fleas, or rats). This last mode of transmission is more significant in other parts of the world than in the United States.

Contact transmission, the most frequent source of nosocomial infection, is transmitted via two modes—direct and indirect contact. Direct contact involves a direct transmission, body-to-body, and the physical transfer of microorganisms from one infected person to another, for example, through sexual contact, kissing, or even touch. It also may occur when a healthcare worker touches a client, gives a client a bath, or performs other care activities. Indirect transmission involves contact with a contaminated intermediate object such as a needle, instrument, or dressing. This also occurs when contaminated hands are not washed, gloves are not changed between clients, and whenever there is a break in technique.

Droplet transmission is a form of contact transmission, but the mechanism of pathogen transfer is so different that it is considered a separate route of transmission. It occurs when droplets from the infected source person are projected a short distance to the host's nasal mucosa, mouth, or conjunctiva. These droplets are not suspended in the air, so it is not considered airborne transmission.

Airborne transmission occurs by dissemination of either small particle nuclei of evaporated droplets or dust particles containing the infectious agent. These agents can be dispersed widely by air currents, as with Legionnaire's disease, and may be inhaled by a susceptible host. These microorganisms include *Mycobacterium tuberculosis*, rubeola, and varicella viruses.

Portal of Entry The most effective barrier to transmission of microorganisms is an intact skin. For an infection to occur it must have a means of entering the body. A disruption in the integrity of the skin provides such a portal of entry for microorganisms. Microorganisms also enter the body the same way they leave the body. The respiratory system provides a viable portal of both exit and entry.

Susceptible Host For an infection to occur a susceptible host is needed—someone who is “at risk.” This includes clients who are immunosuppressed, fatigued, stressed, anemic, not immunized, poorly nourished, or those who have underlying diseases. Hospitalized clients with wounds, catheters, and IVs are at high risk for developing infections. Clients who require invasive procedures, blood specimen collections, and surgery are also in the high-risk category.

BARRIERS TO INFECTION

An individual's ability to resist infection is determined by the status of the body's defense mechanisms and by the person's general health. Factors that contribute to susceptibility to infection include altered nutritional status, stress, fatigue, disease, drugs, metabolic functions, and age. Clients with severe underlying diseases are most likely to develop nosocomial infections. The body is protected against infection by immunities, by the inflammatory process, and by anatomic barriers that include the skin and mucous membranes.

When the integrity of the skin or mucous membrane is broken, both resident and transient flora or bacteria have a direct route to the internal tissues of the body. To prevent the spread of infection, the body's internal defense mechanisms mobilize and begin clearing and repairing the damaged site. How quickly a wound heals depends on the degree of vascularization in the injured area, the location and cleanliness of the wound, and the degree of tissue damage.

The second way the body resists infections is through immunity, antitoxins, and vaccines. Natural immunity is inherited. Acquired immunity occurs after an individual has been exposed to a disease or infection or has been vaccinated.

The third way the body resists infection is through the inflammatory process. Inflammation involves use of metabolic energy, increased blood flow to the inflamed area, and, in many cases, drainage of inflammatory debris to the external environment.

When an area becomes inflamed, cells at the site activate the plasmin system, the clotting system, and the kinin system. The result of the activation of these systems is the release of histamine, which creates increased vascular permeability around the injured site, and the release of chemotoxic agents, which summon phagocytes into the vascular and tissue spaces. Phagocytes are white blood cells that combat and prevent infection by ingesting harmful microorganisms.

The Body's Natural Defenses

Any alteration in the body's natural defenses increases the probability that an infection will occur. Almost any organism can be the cause of a significant nosocomial infection, given the proper circumstances. Some of the variables that help

determine which organism emerges as the pathogen are the virulence and number of organisms, the exposure and attachment of the organism to a susceptible site, and the duration of the client's exposure to the infectious challenge. The following formula illustrates these variables.

$$\frac{\text{Dose} \times \text{Virulence}}{\text{Host Resistance}} = \text{Infection}$$

Using this formula, the client's risk factors can be evaluated. The inherent health and immunologic status of the client are also major factors in determining whether an infection occurs.

Alterations in the skin barrier include any physiologic break in the integrity of the skin. Intentional breaks are caused by the use of percutaneous catheters and needles and by surgical procedures. Unintentional causes of skin breakdown include the development of pressure ulcers and traumatic wounds.

CONDITIONS PREDISPOSING TO INFECTION

Certain conditions and invasive techniques predispose clients to infection because the integrity of the skin is broken or the illness itself establishes a climate favorable for the infectious process to occur. Among the most common are surgical wounds, changes in the antibacterial immune system, or alterations in the respiratory tract or genitourinary tract. Implants such as heart valves, prosthetic grafts, or vascular grafts can lead to nosocomial septicemias. The extensive use of IV therapy and central lines in clients has increased infections dramatically.

Surgical Site Infections

It has been documented that the longer a person is hospitalized before the surgical procedure, the greater the risk of postsurgical infection. Other factors that influence infection rates are duration of time in the operating room, time surgery is done (between midnight and 8:00 AM is period of greatest risk), whether the client has postsurgical drains in place, and if the surgery enters a colonized or infected part of the body.

It is useful for the nurse to be aware of conditions that increase the risk of postoperative infection. Risk reduction measures include preoperative showering with an antiseptic solution, the use of depilatory creams or the clipping of hair in lieu of shaving the surgical site, and keeping the incision site covered with a dry sterile dressing. A wet dressing, through osmosis and diffusion, pulls organisms down into the wound from the surface. This is particularly important during the first 45 hr before the wound becomes "watertight." Research shows that preoperative shaving results in disruption of normal flora on the surface of the skin.

Antibacterial Immune Mechanisms

There are three categories of abnormalities in antibacterial immune mechanisms: those affecting inflammatory responses, those affecting phagocytic functions, and those affecting opsonins (humoral immunity).

Anything that interferes with the migration of phagocytic cells to the area of contamination or with the physical contact

of phagocytes and bacteria enhances the development of an infection. Examples of such interferences include deficient blood supplies, the presence of ischemic or dead tissue, sutured material, foreign bodies, and hematomas. Vasopressor agents, radiation injury, uremia, severe nutritional deficiencies, and steroid therapy inhibit the synthesis of antibodies and other essential proteins.

Clients with severe thermal injuries and severe nutritional deficiencies have abnormalities involving the number of neutrophils collected at the site of an inflammatory response and defects of bactericidal chemotoxic capacity. Clients with Hodgkin's disease have a specific defect in cell-mediated immunity.

Genetic inability to synthesize complement components or specific antibodies can cause abnormalities in opsonins. Burn clients may have complement inactivated by a circulating substance released by the damaged tissue. Without complement, lysis of cells and destruction of bacteria cannot take place.

Respiratory Tract

Common alterations in the respiratory tract that facilitate the development of an infection include endotracheal intubation, tracheostomy, bronchotracheal suctioning, and stasis due to poor respiratory excursion for clients on bedrest.

The bronchi and trachea are so sensitive to foreign matter that they initiate the cough reflex whenever irritation occurs. Ciliated, mucus-coated epithelium lining the trachea and lungs aids in clearing the respiratory tract of bacteria and mucus by the beating motion of the cilia. Intubation bypasses the cough reflex and compromises the effectiveness of this action. Although the trachea is usually considered sterile, it does not remain sterile after 48 to 72 hr of intubation. Infections associated with endotracheal intubation include pneumonia, tracheitis, and purulent bronchitis.

Catheters placed directly in the trachea can force pathogenic microorganisms into the respiratory system. In addition, catheters may damage the mucous lining of the respiratory tract, further compromising the effectiveness of its clearing mechanisms.

Genitourinary Tract

Instrumentation, including catheterization of the bladder, and complicated obstetric delivery after prolonged confinement in bed are two procedures that introduce potentially pathogenic bacteria into the genitourinary tract. Acute urinary tract infection and pyelonephritis often occur after the use of a catheter or cystoscope.

The most common alteration is the placement of an indwelling urinary catheter. Research has demonstrated that significant bacteriuria develop in only 2% of the clients who have a single "straight" catheterization (in and out) to empty a distended bladder. Although bacteriuria may be considered benign and usually resolves after removal of the catheter, bacteriuria after catheterization may result in symptomatic cystitis and, occasionally, in acute pyelonephritis, chronic pyelonephritis, and persistent asymptomatic bacteriuria. Lack of adequate fluid intake, improper positioning of the catheter and bag, use of an open versus a closed drainage system, and inadequate emptying of the bladder all serve to increase the risk of infection in the catheterized client.

Invasive Devices

Most healthcare-associated (nosocomial) septicemias occur as a result of significant alterations in normal host defenses. These infections may be primary (caused by direct introduction of microorganisms into the bloodstream) or secondary (arising from an infection at another site such as the urinary tract). In fact, the most common site for a healthcare-associated infection (HAI) is the urinary tract.

The use of IV therapy and central line insertions greatly increases the risk of introducing harmful microorganisms. The incidence of septicemia in clients receiving IV therapy varies from 0 to 8%.

Septicemia may also be caused by the introduction of microorganisms from contaminated fluids, infected venipuncture sites, or foci of septic thrombophlebitis as a complication of using an indwelling IV catheter.

Venipuncture Sites

The wounds made by a percutaneous stick at the venipuncture site may become colonized or infected. This opening provides a reservoir for bacteria that could move along the catheter into the bloodstream.

Organisms that travel down the catheter ultimately reside in the thrombus, which is usually present on the catheter tip. Around the thrombus, bacteria are shielded from the immune response and antibiotics. When these microorganisms attain a critical level, they seed the bloodstream and cause bacteremia. Site infections can be reduced by several methods: selecting a catheter appropriate to the size of the vein; avoiding sites near joints; the performance of proper site preparation; maintaining a regimen for site care; and changing the site every 48 to 72 hr as well as maintaining a closed system of therapy. Discontinuing IVs started in emergency situations like codes or “field starts” in which proper site hygiene wasn’t carried out also reduces IV-related infections.

Total Parenteral Nutrition Therapy

Total parenteral nutrition therapy (TPN/TNA) is a means of achieving an anabolic state in clients who would otherwise be unable to maintain normal nitrogen balance. Problems with IV-related sepsis in TPN are the same as those seen in conventional IV therapy, only greatly magnified. The hypertonic solution used with these clients supports the growth of a wide variety of organisms, especially fungus, to a greater extent than conventional IV solutions. Clients on TPN are critically ill and malnourished. Peripheral inserted central catheter (PICC) lines are usually inserted for TPN infusions. These lines may not be changed for months. Infection control is of critical importance with TPN. Meticulous site care must be done at least every 3 days to preserve the site, and aseptic technique used when changing solution, tubing, dressings, and filters.

Implanted Prosthetic Devices

Commonly used implanted devices include artificial cardiac valves, synthetic vascular grafts, orthopedic prosthetic joints, neurosurgical shunts, and cerebrospinal fluid pressure monitoring devices. Most infections associated with prosthetic devices

require long-term IV antibiotic therapy. If the infection is not controlled, removal and replacement of the prosthesis is indicated.

HEALTHCARE-ASSOCIATED (NOSOCOMIAL) INFECTIONS (HAIs)

HAIs are infections that are acquired while the client is in the hospital—infections that were not present or incubating at the time of admission. The CDC estimates that as many as 2 million infections are acquired in hospitals every year, resulting in 90,000 deaths and an additional \$5 billion in healthcare expenses. As of 2006, only six states have adopted laws requiring hospitals to report the incidence of HAIs. Many of these infections are caused by pathogens transmitted from one client to another by healthcare workers. HAIs are usually caused by poor hand hygiene technique or no handwashing between clients. Hand hygiene is the single most important intervention to prevent these infections; various studies have shown that there is very poor compliance with handwashing techniques by healthcare workers. Other interventions important to the prevention of HAIs are the use of sterile technique when indicated, keeping the environment as free as possible of pathogens, and identifying and protecting at-risk clients. The CDC has studied rates of the four “hot spots”—infections of surgical sites, the bloodstream, and urinary tract, and ventilator-associated pneumonia in intensive care units.

The major organisms responsible for the majority of HAIs are *Clostridium difficile*, methicillin-resistant *Staphylococcus aureus* (MRSA), and vancomycin-resistant enterococcus (VRE). The most common organism, *C. difficile* is an anaerobic, gram-positive, spore-forming bacillus associated with infectious diarrhea (CDAD). Twenty to 40% of hospitalized clients become colonized within a few days of entering the hospital. Because it is often resistant to antimicrobial therapy, it is able to proliferate in the hospital setting. **Alert:** The alcohol-based gels do not kill *C. difficile*, so soap and water must be used.

MRSA

The second most common infection, affecting 40% of all critically ill or immunosuppressed clients, is pneumonia. The leading cause of this condition is gram-positive *Staphylococcus* that is methicillin resistant, labeled “healthcare-acquired” or “HA-MRSA.” This condition often occurs in clients who have invasive procedures such as intravenous or respiratory therapy treatments or surgical procedures. Healthcare personnel easily transmit MRSA to clients because it frequently colonizes skin. Vancomycin, the drug of choice to treat MRSA, is losing its effectiveness as a treatment.

A new and potentially lethal strain of MRSA has developed since the late 1990s (when MRSA was also increasing among hospital-acquired *S. aureus* infections) named the “community-acquired MRSA.” This strain is seen among healthy young people with no known exposure. Infections caused by CA-MRSA are easily transmitted through skin-to-skin contact or by contact with contaminated objects or surfaces. Although most clients can be treated successfully, they have the potential of

developing necrotizing fasciitis or pneumonia, sepsis, furunculosis, osteomyelitis, etc.

According to the CDC, there are at least three different strains of *Staphylococcus* that can cause CA-MRSA. This condition can occur without any exposure to HA-MRSA. It is a distinct and separate infection both genetically and epidemiologically from HA-MRSA. This type of MRSA can occur in totally healthy individuals and is not limited to any age group or related to any other diagnosis. This infection usually begins as a skin or soft tissue infection, such as a boil or rash, and can become invasive.

Treatment of CA-MRSA can range from incision and drainage, to hot soaks, to good wound care. Antibiotics are usually the treatment of choice, and it is important that the client continue to take them for the prescribed period (usually 7–10 days). Practicing excellent hand hygiene and proper disposal of contaminated dressings are important to not spreading the infection. Inform the client that if there is blood or body fluids on the hands, they should be washed for 15 seconds, rather than using antibacterial gel. (See Standard Precautions protocol.)

Two-Hour MRSA Test

The first rapid blood test that will detect MRSA and *Staphylococcus aureus* in 2 hr was approved by the U.S. Food and Drug Administration (FDA) in 2008. The manufacturer is BD Diagnostics. This company is developing more rapid assays to quickly identify VRC and *C. difficile*.

VRE

VRE is a gram-positive bacterium normally found in flora of the gastrointestinal tract. When this bacterium mutated and became resistant to common antimicrobial therapies, it became a major cause of HAIs in the hospital setting.

There is a new type of antibiotic available to fight resistant infections. An example of this drug (the first entirely new type of antibiotic in 35 years) is Zyvox. This drug and others of its genre are the drugs of choice for VRE and MRSA.

Innovative Infection Control Approaches

Founded in 1991, the Institute for Healthcare Improvement (IHI) offers healthcare facilities information on how to best control hospital infections. Thus far, 2,700 hospitals have joined together with the goal of saving 100,000 lives by eliminating hospital-acquired infections. Backed by solid evidence-based research, the institute makes recommendations addressing specific risk factors for different infections. There are six “bundles” focused on six separate interventions, three of which include a focus on preventing infections: central-line infections, surgical site infections, and ventilator-associated pneumonia. An example is the central line bundle, which specifies whole-body drapes, masks, and gowns during line insertion.

STANDARD PRECAUTIONS

In 1985, universal precautions were instituted as a result of the human immunodeficiency virus (HIV) epidemic in the United States. Blood and body fluid precautions were practiced on all clients regardless of their potential infectious state.

In 1987, body substance isolation (BSI) was proposed. The intent of this isolation system was to isolate all moist and potentially infectious body substances (blood, feces, urine, sputum, saliva, wound drainage, and other body fluids) from all clients, regardless of their infectious status, primarily through the use of gloves.

In the late fall of 1994, the CDC drafted new guidelines. The revised guidelines contain two tiers of precautions. The first tier, **Standard Precautions**, blends the major features of universal precautions (blood and body fluids precautions) and body substance isolation into a single set of precautions to be used for the care of all clients in hospitals, regardless of their diagnosis or presumed infection status. The new Standard Precautions apply to blood, all body fluids, secretions, and excretions, whether or not they contain visible blood; nonintact skin; and mucous membranes. These precautions are designed to reduce the risk of transmission of both recognized and unrecognized sources of infection in hospitals. As a result of the new category of Standard Precautions, clients with diseases or conditions that previously required category-specific or disease-specific precautions are now covered under this category and do not require additional precautions.

The second tier, **transmission-based precautions**, is designed only for the care of specified clients. (This term and isolation precautions are used interchangeably in much of the literature.) This tier reduces the disease-specific precautions into three sets of precautions based on routes of transmission. These categories are designed for clients documented or suspected to be infected or colonized with highly transmissible or epidemiologically important pathogens for which additional precaution must be used to interrupt transmission to others in the hospital. The three types of transmission-based precautions include airborne, droplet, and contact precautions. Airborne

▲ Many hospitals are adopting measures that support standard precautions. Shown is a Kiosk outside hospital doors that allows visitors to complete hand hygiene both entering and exiting the hospital.

precautions reduce the risk of airborne transmission of infectious agents, such as measles, varicella, and tuberculosis. Droplet precautions are used to prevent the transmission of diseases, such as meningitis, pneumonia, scarlet fever, diphtheria, rubella, and pertussis. Contact precautions are used for clients known or suspected to have serious illnesses easily transmitted by direct contact, such as herpes simplex, staphylococcal infections, hepatitis A, respiratory syncytial virus, and wound or skin infections.

Transmission-based precautions now include educational information to help family members and visitors. They should be taught/informed via fact sheets, pamphlets, and other material about preventing transmission of infections. It is also important to include rationale, risks to household members, and other routine infection prevention strategies, which are a part of respiratory precautions.

All three types of precautions may be used at one time when multiple routes of transmission are suspected in a client. These precautions are always used in conjunction with Standard

Precautions. Table 14-1 outlines recommendations for transmission-based precautions. Table 14-2 lists the diseases/conditions in which transmission-based precautions are required or advised.

Fundamental Principles Certain fundamental principles should be applied to all clients. *The first is hand hygiene.* Hand hygiene is the single most important means of preventing the spread of infection. (People carry between 10,000 and 10 million bacteria on each hand.) *A second fundamental principle involves the use of gloves.* Gloves are worn to provide a protective barrier, prevent gross contamination of the hands when touching body substances or blood, and reduce the risk of exposure to blood pathogens. Gloves also prevent the spread of microorganisms to other clients and to healthcare personnel.

The third fundamental principle is the proper placement of clients in the hospital to prevent the spread of microorganisms to others or to the client. Clients may not always be placed in private rooms when they are infected. They can be placed in a room where the second client has the same infectious process.

The fourth fundamental principle is the appropriate use of isolation equipment to prevent the spread of microorganisms to healthcare workers and other clients. The equipment required is based on the specific transmission route of the microorganism. Specific handling of client care items needs to be considered in preventing the spread of infection.

Hand Hygiene Wash hands with nonantimicrobial soap or use waterless antiseptic agent for routine hand hygiene and after removing gloves. An antimicrobial or antiseptic agent should be used for control of specific outbreaks of infection.

Gloves Clean, nonsterile gloves (or latex-free gloves if latex allergy is present) are worn when touching blood, body fluids, secretions, excretions, and contaminated items. Put gloves on just before touching mucous membranes and nonintact skin. Remove gloves immediately after use and wash hands before touching noncontaminated items and environmental surfaces or giving care to another client. Gloves should be discarded immediately and not reused.

Mask, Eye Protection, Face Shield Wear mask and eye protection during procedures in which splashes or sprays could come in contact with eyes and mucous membranes. Face shields protect the mucous membranes of the eyes, nose, and mouth from splashes of blood, body fluids, secretions, and excretions. Suctioning clients and assisting physicians in insertion of hemodynamic monitoring lines are examples of situations in which this type of protection is required.

Gown Nonsterile disposable gowns are used to protect the skin and clothing from contamination while providing client care. Gowns should be worn whenever there is a risk of contamination from blood, body fluids, secretions, or excretions. Soiled gowns should be removed immediately and hands washed to prevent the spread of microorganisms.

Linen Transport soiled linens in a manner that prevents skin and mucous membrane exposure, contamination of clothing,

Hand Hygiene, Hand Antisepsis, and Gloving: CDC Recommendations

- Hands must be washed with antiseptic soap and water or alcohol-based hand rub:
 1. Before and after client contact and between clients.
 2. After contact with a source of microorganisms.
 3. After removing gloves. Before donning gloves.
 4. After touching equipment or surfaces that may be contaminated.
 5. Before handling an invasive device (regardless of glove protocol).
 6. After contact with body fluids, excretions, nonintact skin, wound dressings.
 7. Before handling medication and/or preparing food.
 8. If moving from a contaminated body site to a clean body site during client care.
- Gloves should be used as an adjunct to, not a substitute for, hand hygiene:
 1. Remove gloves and wash hands after any hand contaminating activity.
 2. Change gloves between clients.
 3. Change gloves during care of a single client when moving from one procedure to another. (This is critical when moving from a contaminated to a clean body site.)
 4. Use disposable gloves only once.
 5. Do not touch any body surface that is moist without gloves. (Moisture can be considered potentially contaminated.)
 6. Have latex-free gloves available for personnel with an allergy or sensitivity to latex.
 7. Decontaminate hands before donning sterile gloves.

See CDC Web page for more information: <http://www.cdc.gov/hand/hygiene/training.html>

TABLE 14-1 HICPAC* Recommendations for Transmission-Based Precautions

	Contact	Droplet	Airborne
Purpose	Prevent transmission of known or suspected infected or colonized microorganisms by direct hand or skin-to-skin contact that occurs when providing direct client care.	Prevent transmission of large-particle droplets, larger than 5 microns (μm).	Prevent transmission of small-particle residue of 5 microns (μm) or smaller droplets.
Client Placement	<ul style="list-style-type: none"> • Private room • Can be placed in room of client with same microorganism 	<ul style="list-style-type: none"> • Private room • Can be placed in room of client with same diagnosis 	<ul style="list-style-type: none"> • Private room • Can be placed in room of client with same diagnosis • Monitor negative air pressure • Keep door closed • Keep client in room
Respiratory Protection	<ul style="list-style-type: none"> • Mask not necessary • Family, visitors respiratory hygiene/cough etiquette. <i>See page 417</i> 	<ul style="list-style-type: none"> • Use mask when working within 3 feet of client 	<ul style="list-style-type: none"> • Respiratory protective equipment • Do not enter room of clients with rubeola or varicella if susceptible to these infections
Gloves and Gown	<ul style="list-style-type: none"> • Wear gloves when entering room • Change gloves after contact with infective material, such as wound drainage or fecal material • Wash hands immediately after removing gloves • Wear gown when working with clients with diarrhea, ostomies, or wound drainage not contained in dressing • Wear gown if contact with client or environment will occur 	<ul style="list-style-type: none"> • Follow Standard Precautions 	<ul style="list-style-type: none"> • Follow Standard Precautions
Client Transport	<ul style="list-style-type: none"> • Transport only if essential • Ensure precautions are maintained to minimize risk of transmission 	<ul style="list-style-type: none"> • Transport only if essential • Place mask on client when outside room 	<ul style="list-style-type: none"> • Transport only if essential • Place mask on client when outside room
Client Care Items	<ul style="list-style-type: none"> • Client care items and environmental surfaces are cleaned daily • Dedicate equipment to single client use (i.e., stethoscope, thermometer) 		

*Hospital Infection Control Practices Advisory Committee.

and transfer of microorganisms to other clients and environments. This is usually accomplished through double-bagging linen before taking it to the laundry facility.

Occupational Health and Bloodborne Pathogens Take precautions to prevent injuries caused by needles, scalpels, or other sharp instruments or devices. Only use safety needles. Never recap used needles, purposely bend or break needles by hand, remove needles from disposable syringes, or otherwise handle needles directly. All such instruments should be placed in puncture-resistant containers for disposal. The use of needleless systems for IV management has dramatically decreased needle stick injuries.

Mouth pieces, resuscitation bags, or other ventilation devices should be used as an alternative to mouth-to-mouth resuscitation.

Client Placement Clients who are at risk for contaminating the environment or who are unable to maintain appropriate hygiene or environmental control should be placed in a private room. If this is not possible, other arrangements need to be made in consultation with the hospital's infection control department.

In addition to healthcare workers following Standard Precautions, the following guidelines should be considered when providing client care:

- Healthcare workers who have open lesions, upper respiratory infections, or weeping dermatitis should refrain from all direct client contact and from handling client care equipment.
- Because of the risk of transmission of HIV and hepatitis B virus (HBV) from mother to fetus, pregnant healthcare workers

TABLE 14-2 Disease Indications for Transmission-Based Precautions*

Contact (Direct and Indirect)	Modes of Transmission	
	Droplet	Airborne
<i>Clostridium difficile</i>	Diphtheria	Tuberculosis
Diphtheria	Influenza	Chickenpox
<i>Staphylococcus</i>	Pertussis	Herpes zoster
<i>E. coli</i>	<i>Streptococcal pharyngitis</i>	Measles
Hepatitis	Pneumonia	
Herpes simplex	Scarlet fever	
Impetigo	Rubella	
Scabies	Mumps

Cellulitis	Sepsis	
Respiratory conditions	Pneumonic plague	
Virus infection–wound/skin	Parvovirus B19	
Rotavirus infection		
Smallpox		
Ebola, Lassa, Marburg		
Rubella–chickenpox		

*Listed above are the diseases/conditions in which transmission-based precautions are required or advised as a part of the treatment protocol.

should be especially familiar with, and strictly adhere to, precautions to minimize risk of these viruses. Currently, pregnant healthcare workers are not known to be at greater risk of contracting HIV or HBV than other workers.

Health Care Worker Protection Act In 1997 the “Health Care Worker Protection Act” was passed to assist in the reduction of incidents in which healthcare workers are accidentally exposed to potentially contaminated, infected blood via a needle stick. This act makes the use of safe needle devices a requirement if the facility receives Medicare funding. The impetus for the bill was a direct result of statistics from the Centers for Disease Control and Prevention (CDC) indicating that more than 800,000 needle sticks and sharps injuries were being reported yearly. This is the most common cause of healthcare worker–related exposure to bloodborne pathogens. Needle stick injuries caused by hollow-bore needles accounted for 86% of all reported occupational HIV exposures. Nurses make up 24% of all the cases of HIV infection among healthcare workers known or thought to have been infected on the job. The use of protective needle devices is estimated to prevent up to 90% of needle sticks. For more

Principles of Hand Hygiene

Wash hands or use alcohol-based gel:

- At the beginning of the shift before providing client care.
- Before and after providing client care.
- Before and after preparing medications.
- After touching client surroundings (i.e., after handling soiled linen, equipment, or supplies).
- Between contact with different clients.
- After removing gloves.
- After you have sneezed or coughed.
- Before and after eating.
- After body fluid exposure/risk.
- Just before leaving the nursing unit.

▲ The single most important nursing action to decrease the incidence of hospital-based infection is washing your hands.

information, refer to the PEP protocol (PEP) described later in this chapter.

More than 20 pathogens can be transmitted through small amounts of blood. In addition to HIV and hepatitis B, syphilis, varicella-zoster, and hepatitis C can be transmitted via this route. Hepatitis B is the most common infectious disease transmitted through work-related exposure to blood. About 5,100 healthcare workers become infected with hepatitis B each year.

ACQUIRED IMMUNODEFICIENCY SYNDROME

Epidemiology and Modes of Transmission

The incidence of acquired immunodeficiency syndrome (AIDS) has grown exponentially since it was first recorded in 1981. The statistics are chilling. Internationally, an estimated 5 million people were infected with HIV in 2005 and, at the end of 2006, 1.1 million persons in the United States were living with HIV/AIDS. The CDC estimates that 56,300 new cases occurred in the United States in 2001. All areas of the world are expected to see increases in HIV (with the exception of the Caribbean), in spite of a massive educational prevention program.

Cumulatively, since AIDS was first identified, the death toll from AIDS in the United States has been 562,793. Data shows that in the number of AIDS cases reported, the highest is African Americans (51%), then Caucasians (29%) and Hispanics (18%).

Estimates for 2007, the most recent year for which data is available, are that the number of AIDS cases have remained stable and the number of deaths decreased.

Now the high-risk groups are male-to-male sexual transmission, accounting for 53% of AIDS cases, and 32% in high-risk heterosexuals. Estimates are that the percentage of AIDS cases will go up in women and in adolescents, who are rapidly becoming the newest high-risk group.

A new (2005) potent strain of HIV has been diagnosed in New York state. The man who received the diagnosis was resistant to three of four antiviral drugs and the HIV status progressed to full-blown AIDS in only 2 months. This situation, coupled with increased resistance to HIV drugs, is very alarming to health professionals.

Definitions

Acquired Immunodeficiency Syndrome AIDS is the most severe form of a continuum of illnesses associated with HIV infection. AIDS is defined by the CDC as an HIV infection in a person with a CD4+ T-lymphocyte count of less than 200 cells/microliter (μL) of blood or a CD4+ percentage of less than 14. Twenty-six clinical conditions are listed in the CDC AIDS surveillance case definition in category C. Once clients have a condition listed in category C, they remain in that surveillance category. Among those 26 conditions listed in the category are cytomegalovirus (CMV) retinitis; Kaposi's sarcoma; *Mycobacterium avium* complex (MAC) (which includes the *M. avium* and *M. intracellulare* organisms) or *M. kansasii*; *Mycobacterium tuberculosis*, any site; *Pneumocystis carinii*; and recurrent pneumonia.

Human Immunodeficiency Virus HIV is a bloodborne infective retrovirus that invades the CD4+ T-lymphocyte (immunity) cell, renders it useless, and then duplicates itself by means of that cell. With loss of the client's immune function, the disease becomes clinically manifested. Infection with HIV progresses to AIDS in at least 35% of those infected. Once a

client has been diagnosed with HIV, the usual approach to care includes evaluation of the immune system and classification by CDC grouping: (A) asymptomatic, (B) acute symptomatic, and (C) AIDS-indicator conditions. Identification and treatment of infectious and neoplastic complications, initiation of approved antiretroviral therapy, and consideration of experimental measures are also included in the evaluation.

HIV is transmitted through high-risk behaviors or other contact with the virus, including:

- Sexual contact with HIV-infected individuals
- Sharing needles with HIV-infected individuals
- Transfusions of blood or blood products from infected individuals (not common today, but new cases are still reported)
- Babies who become infected from the mother before or during birth, or through breast-feeding
- Contact with contaminated needles, blood, secretions, or excretions from an HIV-infected client

Healthcare Workers' Exposure to HIV

Prospective studies of healthcare workers have estimated that the average risk for HIV transmission after a percutaneous exposure to HIV-infected blood is approximately 0.3%, after a mucous membrane exposure is 0.1% and risk factors for transmission by skin exposure less than 0.1%. The CDC states that approximately 800,000 needle-stick injuries occur each year with potential risk of HIV exposure. The FDA has recently approved a point-of-care HIV test that provides a result in as few as 5 minutes. There are four versions of this test, which identifies the presence of HIV antibodies with 98% accuracy. Since these results are not 100%, a follow-up confirmation test must be done. If a positive Western Blot analysis is found, the healthcare worker would immediately be referred to postexposure prophylaxis (PEP). (See procedure "Obtaining a Gum Swab for HIV Antibodies," Chapter 20, p. 710.) Considerations that influence the use of PEP include the timing of the PEP—how soon after exposure PEP was begun—and the belief that the infection can be improved by the use of the antiretroviral drugs.

In 1997, the Public Health Service updated recommendations for management of healthcare worker exposure to HIV and recommendations for PEP. The decision to recommend HIV PEP takes into account the nature of the exposure, needle stick or mucous membrane contact, and the amount of blood or body fluid involved in the exposure. Other considerations include exposure to a virus known or suspected to be resistant to antiretroviral drugs. Pregnancy is also a consideration. Risk factor assessments are key determinants of PEP. Healthcare facilities should have the protocols available, and prompt reporting and postexposure care should be considered a healthcare emergency and treated as such. This includes access to clinicians who can provide postexposure care during all working hours and the antiretroviral agents for PEP immediately available. Healthcare workers must be educated to report occupational exposures immediately after they occur because PEP is most likely to be effective if implemented as soon after the exposure as possible.

Proper Handling of Biohazard Waste

Speaking for the Florida Department of Health and Rehabilitation Services, an epidemiologist stated that there was an 80% reduction in exposure to biohazard material in seven Florida hospitals after the enactment of the Florida Administrative Code. This code is an example of the principles that additional states are beginning to enact.

What Is Biohazard Waste?

Any solid or liquid waste that may present a threat of infection is considered “biohazard.” This could include laboratory waste, blood or blood products, body fluids, absorbent material saturated with blood or body fluids (either wet or dry), discarded sharps, and nonabsorbent disposable devices (such as drains, excretions, gloves, urine specimens, etc.).

Why Separate Biohazard From Other Medical Waste?

It is critical that the biohazard waste be separated at the point of origin or before it leaves the client’s room. This reduces the risk of exposure considerably. The principles of separation are:

- Use an impermeable red plastic bag labeled “biohazard”; close bag securely while inside the client’s room.
- Use a second red-labeled bag outside the room and place the inside bag in it so that the waste is “double-bagged.”
- Do not place red-labeled bag with other waste material, because it could contaminate all waste.
- Sharps should be separated from all other waste and placed in a leak- and puncture-proof container with a biohazard symbol on the outside.

- Fiberboard waste containers should NOT contain scalpels.
- Do not overfill sharps containers, because items could fall out.

Storage of Biohazard Material

Biohazard waste must be appropriately sealed. It may be stored for 30 days; time starts when material is placed in the sharps container or biohazard bag. All biohazard waste must be restricted, locked up, or placed in a separate storage area. Biohazard waste must be in a room with **no** carpeting. Sealed cement is necessary so that a spill can be cleaned up. Biohazard material must be labeled correctly so that there is a tracking method for each bag, container, etc. Labels should say “medical waste” and “biohazard” and be dated when the bag was first placed in the area.

Transporting Biohazard Waste

When transporting biohazard waste within the facility, containers must remain intact. Trash chutes must **not** be used. Outdoor containers should be secured against vandalism and marked or labeled.

A contingency plan for spilled material:

- Spilled or leaked biohazard material must be cleaned with industrial strength detergent and then disinfected.
- Onsite treatment and disposal of waste must be steamed, incinerated, or cleaned with an alternative method (chemical, dry heat, etc.).
- Each facility must post a “Spill Contingency Plan,” which includes which substance to be used to disinfect.

If each facility has an administrative code that includes a total plan, policies, and procedures for dealing with biohazard waste, as well as a training program for all employees in how to handle biohazard waste, the incidence of exposure could be dramatically decreased.

Source: Adapted from Department of Health and Human Services.

Recommendations for PEP include a basic 4-week regimen of two drugs (zidovudine and lamivudine, or Combivir, a combination of these two antiretroviral agents) for most HIV exposures. An expanded regimen that includes the addition of a protease inhibitor (indinavir or nelfinavir) is recommended for HIV exposures that pose an increased risk of transmission or when there is a known or suspected resistance to one or more of the antiretroviral agents recommended for PEP. There is now available a boosted protease inhibitor (Kaletra), which helps reduce the viral load in the body, thereby providing greater protection against retroviral activity.

OTHER INFECTIOUS DISEASES

Tuberculosis

Tuberculosis is an infectious disease caused by the tubercle bacillus *Mycobacterium tuberculosis*. The main reservoir for the organism is the human respiratory tract, and transmission

occurs between individuals through respiratory contact. The tubercle bacillus enters the respiratory tract on droplets transmitted through productive coughing from the infected individual. Symptoms may occur in 4 to 12 weeks after exposure or may go unnoticed for many years. Active pulmonary tuberculosis has a slow, insidious onset. The progression of the active disease and symptoms of cough, weight loss, and fever usually occur within the first 2 years after the infection. Latent infections, which are asymptomatic, are not infectious and may last a lifetime. Without treatment tuberculosis progresses to other body sites. Disseminated tuberculosis occurs in many of the body areas, not just the lungs. The incidence of tuberculosis cases in this country has increased greatly, due in large part to the AIDS epidemic. Immunosuppressed hosts are very vulnerable to the bacillus. In addition to immunosuppressed individuals, others considered at high risk for infection include alcoholics; IV drug abusers; individuals who share a closed environment with the infected individual; residents of institutions such as long-term care and correctional facilities; foreign-born individuals

from countries with a high prevalence of tuberculosis, such as Asia, Latin America, Africa, Mexico, and the former Soviet Union; low-income populations who are medically underserved; and clients who are noncompliant and do not complete the appropriate drug therapy. Healthcare workers who come in contact with any of the high-risk populations are at risk for infection.

A growing number of clients develop MDR-TB, multidrug-resistant tuberculosis. According to the CDC, MDR-TB now accounts for 1.2% of cases for which drug susceptibility data are available (2005). This type of tuberculosis is *in vitro* resistance of a strain of TBC to antituberculosis drugs. The disease can progress from diagnosis to death in as short a period as 4 to 16 weeks. The increasing incidence of MDR-TB can be attributed to delays in treatment, inadequate isolation and infection control practices, and lack of follow-through after hospital discharge. Clients develop resistance to the standard drug regimen (two first-line therapies, isoniazid and rifampin) as a result of noncompliance and/or inappropriate drug therapy. MDR-TB is also caused by person-to-person contact through sneezing or coughing or from a person with primary drug resistance.

Early recognition and treatment of tuberculosis must be initiated promptly and isolation measures instituted to prevent the spread of the disease. The CDC describes effective tuberculosis control requirements as early identification, isolation, and treatment of persons with active tuberculosis. The purified protein derivative (PPD) skin test is used to quickly identify the infection in the absence of clinical symptoms. Sputum specimens for acid-fast bacillus (AFB) TB culture, and sensitivity and chest x-rays are also ordered to rule out TB. A PPD skin test is read 48 to 72 hr after the injection. A positive skin test is indicated by an induration of 5 to 10 mm at the site of the injection. A two-step method is now being used, particularly with healthcare workers. This procedure involves the first PPD injection to be given and read within 48 to 72 hr. If the PPD is negative or doubtful, the PPD is repeated in 1 week. If the client has a positive reaction, he or she is started on a prophylaxis regimen. A client who is known to be HIV-positive with a 5 mm or larger induration at the site of the PPD injection should be considered positive for tuberculosis.

The CDC recommendation for tuberculosis isolation includes a directional air-flow, negative-pressure ventilation system in the room of tuberculosis clients. Negative-pressure ventilation pulls air away from hallways and exhausts it out of the room to areas away from air intake vents. Six air changes each hour are required to provide microbial dilution within the room. Ultraviolet irradiation lamps can be used to supplement ventilation systems when the risk of tuberculosis transmission is high.

Anyone entering the client's room should wear a mask that forms a tight-fitting seal against particulates 1 to 5 microns (μm). Two examples of tuberculosis masks are the high-efficiency particulate air (HEPA) mask used for suspected or confirmed multidrug-resistant (MDR) tuberculosis and the disposable submicron mask used for confirmed tuberculosis. Disposable particulate respirators are suggested by the CDC when adequate ventilation is not available in the room. All treatments and procedures should be performed in the client's room if at all possible. If the client must leave the room, a valveless particulate respirator must be used.

Viral Hepatitis

There are six forms of hepatitis. Each form differs in regard to incubation period, route of transmission, antigenic properties, and progression to chronicity. All forms of hepatitis produce an inflammatory response to the liver, which is characterized by liver cell necrosis, inflammation, and cell regeneration. The three major forms of hepatitis are hepatitis A virus (HAV), hepatitis B virus (HBV), and hepatitis C virus (HCV). Hepatitis D virus (HDV) is not as common and hepatitis E virus (HEV) is rare in the United States. Hepatitis G virus (HGV) is a recently isolated bloodborne infectious agent transmitted by needle sticks and blood transfusions.

Hepatitis A (HAV) is spread via the fecal-oral route and sexual transmission. Poor sanitation and hand hygiene is a major source of infection. Approximately 152,000 infections occur in the United States each year. Ninety-nine percent of those infected recover without any serious problems. HAVRIX vaccine is available to prevent HAV. Once exposed to the infection or as a preventative therapy, immune serum globulin is administered intramuscularly.

Hepatitis B (HBV) is spread through infected blood or body fluids and through two nonparenteral routes, sexual contact and perinatal transmission. Contaminated needles, syringes, and blood products are the most common mode of transmission, although about 30% of the cases are spread through sexual contact. An estimated 140,000 individuals are infected yearly in the United States. Two to 10% of adults become chronically infected with HBV after an infection. HBV is 100 times more infectious than HIV. HBV vaccine provides active immunity in more than 95% of recipients. The two common vaccines are Engerix-B and Recombivax HB. Hepatitis B immune globulin provides passive immunity to individuals who have had contact with HBV-contaminated material.

Hepatitis C (HCV) is transmitted primarily by contact with contaminated blood and blood products. Eighty-five percent of those infected with HCV will remain chronically infected. Chronic HCV infection is the main causal factor for nearly one-third of all liver transplants. There are three types of interferon used to treat HCV.

The CDC recommends the use of Standard Precautions with clients known to have hepatitis. The precautions should be maintained for 1 week after the onset of symptoms.

EMERGING VIRUSES (POSSIBLE PANDEMIC THREATS)

Severe Acute Respiratory Syndrome (SARS)

In 2003, there was a multi-country outbreak of a virus suspected to be a mutated form of the coronavirus (the common cold). The specific SARS pathogen is not known. There is speculation that this new virus has jumped from animal to human, setting up the possibility for a worldwide pandemic like the 1918 swine or Spanish flu that infected millions of people around the world and killed more than 20 million. Jumping species, from animal to human and being able to

transmit person-to-person, is the worst possible combination of events because it can cause havoc in a nonimmune population. Because of this potential for disaster, the World Health Organization (WHO) issued a global alert when this coronavirus rapidly spread to 26 countries. At this initial juncture, it was critical to employ stringent infection control protocols because both the exact pathogen, as well as the transmission mode, continued to elude scientists.

The primary symptoms of SARS are malaise, aching muscles, a persistent fever $>38^{\circ}\text{C}$ or 100.4°F , dry cough, shortness of breath or breathing difficulties, and an almost normal white blood count. People with these symptoms who have recently traveled to or been in the Far East are advised to see a doctor immediately. The unusual and discriminating characteristic of this illness is that while it appears to be a flulike illness, the symptoms persist and simply do not go away. Administering antiviral drugs (i.e., ribavirin, a drug also used to treat hepatitis C) does not appear to be effective. At this point, there is only supportive treatment, including oxygen and ventilatory assistance, when necessary.

In the initial stages, SARS was transmitted to healthcare personnel because they did not adhere to precise precautions while caring for SARS clients. Also, it was discovered that this particular virus can live for 24 hr or longer on various surfaces, making it even more dangerous.

According to Dr. Steven Garner, NY Methodist Hospital, the SARS virus, as of 2006, has mutated to a weaker virus and is no longer a threat. It could, however, reverse in the future. Even if this particular condition is eliminated, new viruses and bacteria will appear on the world stage and many of them could be mutated forms, not responsive to current antibiotics.

H1N1 (Swine) FLU

Swine influenza, the latest health threat to emerge, is a respiratory disease of pigs caused by type A influenza virus that regularly causes outbreaks of influenza in pigs. Usually, the death rate in pigs is low. This virus, type A H1N1, was first isolated from a pig in 1930. Over the years, variations of this virus have emerged. Now, there appear to be four main subtypes that have

been isolated in pigs, but the most recently isolated influenza virus is the H1N1.

While swine flu viruses do not normally infect humans, recently there have been cases that have occurred in persons with direct exposure to pigs. There are now documented cases of one person spreading the swine flu to others, so there is human-to-human transmission. This is thought to occur in the same way other types of flu are transmitted: coughing, sneezing, or touching. In October 2009, President Obama declared swine flu a national emergency, and since June 2009, it was declared an official global pandemic by WHO. However, as of 2010 WHO declared the pandemic over. The downgrade followed recommendations by global influenza experts who reviewed the status.

The symptoms of swine flu are essentially the same as those of seasonal flu: fever, fatigue, coughing, sore throat, body aches, headache, lack of appetite, and sometimes, vomiting and diarrhea. One of the most important teaching tasks of nurses is to teach clients how to protect themselves. People should wash their hands frequently or use antibacterial gel.

Whenever someone is near them and is coughing or sneezing, get out of range, at least 3 feet. Stay home from work or school if you feel symptoms developing. There are two types of flu vaccines: injection and nasal spray. The injection contains dead virus and is approved for healthy people, 6 months old and older. The nasal spray is made from live, attenuated virus, and is approved for healthy persons between 2 and 49 years of age.

There are four different antiviral drugs that are prescribed for the treatment of influenza: amantadine, rimantadine, oseltamivir, and zanamivir. The most recent H1N1 influenza viruses isolated in humans are resistant to amantadine and rimantadine. They currently have developed a swine flu vaccine and have millions of doses on hand. There are several antiviral medications available that prevent infected cells from releasing new viruses. They are known as neuraminidase inhibitors. These medications can prevent and reduce the severity of infection. They include Tamiflu, Relenza, and Peramivir, and the United States has stockpiled 50 million doses over the past few years.

Pandemic Influenza Preparedness and Response	
Precautions for Staff	Responses (to Infection)
Modify transmission-based infection control strategies to match organism.	Use airborne infection isolation rooms, including HEPA filter.
Use personal protective equipment: gloves, gown, goggles, face shields, etc.	Use single hospital rooms, or place clients with same organism (H1N1) together.
Modify administrative controls.	Limit number of persons entering area.
Use safe working practices (i.e., stringent hand hygiene).	Limit client transport.
	Use vigorous hand hygiene measures.
	Employ standard practices for used client care equipment.
	Educate clients on hand hygiene and cough etiquette.

The World Health Organization (WHO) maintains a global surveillance system that monitors presence of an influenza pandemic in progress. Pandemic status evolves and is not always accurately assessed or projected.

Avian Influenza

Avian (bird) influenza was a prior health threat to the world's population. Not since the outbreak of SARS in 2003 has the possibility of a worldwide pandemic caused such concern. Avian influenza is an infection caused by avian influenza viruses. These viruses are found in many varieties of wild birds and are carried in the bird's intestines and generally do not cause illness. However, if infection with the virus occurs, the influenza is very contagious among birds.

Infected birds shed influenza virus in their saliva, nasal secretions, and feces. Susceptible birds, including domesticated birds, become infected when they have contact with contaminated excretions or with surfaces that are contaminated with excretions or secretions. During an outbreak of avian influenza among poultry, there is a possible risk to people who have direct or close contact with infected birds, with surfaces that have been contaminated by secretions and excretions from infected birds, or who eat the meat of infected birds that has not been cooked well.

Avian flu viruses do not usually infect humans, but according to WHO, more than 100 confirmed cases of human infection with bird flu viruses have occurred since 1997. Outbreaks of avian influenza, H5N1, occurred among poultry in eight countries in Asia during late 2003 and early 2004. So far, spread of the H5N1 virus from person to person has not continued beyond one person. The concern is that all influenza viruses have the ability to mutate, and there is a 50/50 chance of the avian flu virus mutating. Scientists are concerned that the H5N1 virus one day could be able to infect humans and spread easily from one person to another.

Symptoms of avian influenza in humans have ranged from fever, cough, sore throat, and muscle aches to eye infections, pneumonia, and severe respiratory diseases. The symptoms of avian influenza may depend on which specific virus subtype and strain caused the infection. Because these viruses do not commonly infect humans, there is little or no immune protection against them in the human population. Right now, there is no commercially available vaccine to protect humans against the H5N1 virus. Research studies to test a vaccine that will protect humans against H5N1 virus began in April 2005, and a series of clinical trials is under way. However, if the virus mutates to human-to-human contact, it will take 6 months to produce a vaccine.

Since it is still unknown exactly how avian influenza may first transmit between humans, the CDC has made recommendations for precautions for healthcare workers involved in the care of clients with documented or suspected avian influenza.

Total infection control precautions are essential to prevent transmission for these potential pandemic threats. Isolation precautions should be instituted for clients with a history of travel within 10 days to a country with avian influenza activity and are hospitalized with a severe febrile respiratory illness, or are otherwise under evaluation for severe influenza. In addition, Standard Precautions, especially hand hygiene, should be followed. Use of gloves and gowns for all client contact is necessary. Goggles should be worn if within 3 feet of a client. Equipment such as stethoscopes and blood pressure cuffs should stay in the client's room. Airborne Precautions should

also be instituted. Clients should be placed in a HEPA-filtered, negative air pressure isolation room. Healthcare providers should use a respirator mask such as a custom-fitted N-95 face piece when entering the room.

The Secretary of Health and Human Services recommends that citizens begin storing some form of food supply (at least 2 weeks' worth) so that "social distancing," a basic tenet of public health, can be observed. She suggests that any community that fails to prepare will be in danger. Our transient and mobile global society makes it imperative that intervention and containment occur rapidly to prevent a worldwide pandemic when a new or mutated pathogen appears. The other imperative is that healthcare workers protect themselves using infection control protocols so that the spread of a new pathogen is contained in healthcare settings.

HOME CARE ADAPTATIONS

In the home setting, medical asepsis, or clean technique, is often used instead of sterile technique. The major reasons for this protocol change are the nature of the setting and the personnel providing care.

The greatest infection control problem in hospitals is healthcare-associated infections due to the large numbers of antibiotic-resistant organisms present in a hospital setting. When clients are in their own environment, however, they tend to develop fewer infections because they are subjected to fewer organisms. In the home setting, focus is on protecting home care staff and family, not other clients. While there may be transmission of organisms between individuals in the home, there are minimal data on the incidence of home care-acquired infections. Infection-preventing strategies in the home should focus on IV therapy and urinary tract, respiratory, and wound care.

Nevertheless, sterile technique and equipment, such as prepackaged catheter and irrigation kits, parenteral fluid equipment, and dressings, are often purchased for home care. When sterile technique is required, it is the responsibility of the nurse to provide the instruction and evaluate the family's ability to perform the skill accurately. Hospital techniques may need to be modified for the home setting, and ideal environmental working conditions may not be present. Unfortunately, the Division of Healthcare Quality Promotion of the CDC has not developed guidelines for infection control in home care settings at this time. Therefore, adaptations must be made, and the essential infection control measures must be maintained.

Just as in the hospital, effective hand hygiene is the *most* effective means of infection control in the home setting. There is one major difference between hospital and home. Equipment (soap, running water, and paper towels) that is readily available to the nurse in the hospital may not be available in the home. Even if running water is available, there may not be soap or clean towels. Nurses must bring their own handwashing supplies.

A decrease in the duration of hospital stays has dramatically increased the expanded scope of the home care nurse. Unfortunately, infection surveillance, prevention, and control efforts have not kept up. Many home care infection control

practices have been based on ritual and acute care practice, rather than scientific principles. Changes in infection control procedures in the home are currently occurring based on a scientific approach.

Home care assessment for potential infections relies on clinical signs and symptoms and tests, such as the urine dipstick, that can be performed in the home. Routine tests used in hospitals to diagnose infections of the urinary tract, respiratory tract, and wound or skin sites are not routinely done, as the current reimbursement system does not support cultures and laboratory tests. Only cultures that confirm and treat bloodstream infections for clients requiring home infusion therapy are obtained.

If the home care client is suspected of or diagnosed as having an infectious disease or the client is infected or colonized with VRE or MSRA, the nurse should use the same personal

protective equipment and protocol used in the hospital setting. The equipment includes gloves, disposable gown or apron, mask, cap, and goggles. Reusable equipment, such as stethoscopes and blood pressure cuffs, should stay in the home and not be used on other home care clients. If possible, these clients should be seen at the end of the day.

CULTURAL AWARENESS

Many cultures believe that certain substances protect one's health. For example, Italians, Greeks, and Native Americans believe that garlic or onions eaten raw or worn on the body will prevent a condition or illness such as infection. If a client wishes to include these items in his or her diet or wear them, the nursing staff should respect this practice, since it is an important cultural tradition for many groups.

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to use on client care plans when the components are related to clients requiring isolation protocol or sterile procedures.

NURSING DIAGNOSIS	RELATED FACTORS
Ineffective Community Coping	Deficits in social support, disease follow-up protocols, inadequate resources for disease prevention
Deficient Knowledge	Lack of access to healthcare facilities, lack of education, cognitive limitation
Ineffective Health Maintenance	Participation in high-risk activities, substance abuse, infectious states, religious or cultural beliefs detrimental to health
Infection, Risk for	Immunosuppressed hospitalized clients, HIV/AIDS clients, invasive procedures, lack of immunization Inadequate defenses (loss of skin integrity, leukopenia, low hemoglobin)
Latex Allergy Response	Allergies to certain foods, allergy to latex, lack of safety procedures for latex allergy
Noncompliance	Lack of motivation, education, or readiness; information misinterpretation; cultural or religious beliefs Medical condition (communicable disease, HIV-positive), hospitalization, terminal illness
Ineffective Protection	Poor compliance to protocols, lack of knowledge, lack of resources
Ineffective Family Therapeutic Regimen Management	Choices of daily living precludes maintaining treatment modalities (e.g., drug therapy, hand hygiene)

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. *Remember to wash your hands or use antibacterial gel before and after each and every client contact.*

IDENTIFY CLIENT Before every procedure, check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Chapter 14

UNIT 1

Basic Medical Asepsis

Nursing Process Data

ASSESSMENT Data Base

- Assess method of hand hygiene that is most appropriate for assigned task.
- Identify clients at risk for infection.
- Assess availability of equipment for frequent hand hygiene (soap and water or antiseptic cleansing agent).
- Evaluate health status of the nurse.
- Check agency policy for hand hygiene protocol.
- Assess need for use of nonsterile gloves.
- Assess nurses and clients for latex allergies.
- Assess need for latex-free equipment and/or environment.

PLANNING Objectives

- To deliver client care with pathogen-free hands
- To prevent pathogenic microorganisms from spreading client to client, environment, or healthcare personnel to client
- To protect clients from cross-contamination
- To protect healthcare workers

IMPLEMENTATION Procedures

- Hand Hygiene (Medical Asepsis) 421
 - *For Using Waterless Antiseptic Agents (foam or gels)* 422
- Cleaning Washable Articles 424
- Donning and Removing Clean Gloves 425
- Managing Latex Allergies 427

EVALUATION Expected Outcomes

- Decreased number of bacteria on hands from client to client.
- Delivered care with pathogen-free hands to clients.
- Prevented spread of microorganisms from healthcare workers or environment to clients.
- Prevented cross-contamination between clients.

- **Critical Thinking Application** 428
 - Expected Outcomes 428
 - Unexpected Outcomes 428
 - Alternative Actions 428

and Skill Checklists

Hand Hygiene (Medical Asepsis)

Equipment

- Nonantimicrobial soap* for routine handwashing
- Orangewood stick for cleaning nails
- Running warm water
- Paper towels
- Trash basket

Procedure

1. Stand in front of but away from sink. ► **Rationale:** Uniform should not touch sink to avoid contamination.
2. Ensure that paper towel is hanging down from dispenser.
3. Turn on water using foot pedal or faucet so that flow is adequate, but not splashing.
4. Adjust temperature to warm. ► **Rationale:** Cold does not facilitate sudsing and cleaning; hot is damaging to skin.

*According to 1997 HICPAC recommendations.

5. Wet hands under clean running water, keeping hands below elbow level. ► **Rationale:** Wet hands facilitate distribution of soap over entire skin surface.

▲ Use foot pedals when available to prevent contamination of hands.

Compliance Studies for Hand Hygiene

- A study of 2,800 opportunities for handwashing showed only a 48% compliance.
- Another study showed hands were washed only 8.5 to 9.5 seconds; a minimum of 15 seconds is necessary to prevent spread of infection.
- Compliance with handwashing technique is higher among nurses than physicians and other healthcare personnel; however, it is estimated to be only 30% to 50%.

Source: Centers for Disease Control and Prevention.

Clinical Alert

Nurses must wash hands for at least 15 seconds before and after each direct contact with a client or each use of client care items to prevent spread of infection (CDC).

EVIDENCE-BASED PRACTICE

Intervention Improves Handwashing Practice

After implementing an educational hand hygiene program, researchers found that before the program, 51% of all health-care workers complied with handwashing guidelines, and after the intervention, 83% did. For nurses, compliance went up from 56% to 89% after the intervention. The program included a handout that specified how important handwashing is and described the proper technique as well as the CDC's hand hygiene guidelines. Five posters were placed around the nurses' station.

Source: Creedon, S. A. (2006). Health care workers' hand decontamination practices: An Irish study. *Clinical Nursing Research*, 15(1), 6.

6. Place a small amount, 1 to 2 teaspoons (3–5 mL) of liquid soap on hands. Thoroughly distribute over hands. Soap should come from a dispenser, not bar soap. ► **Rationale:** This prevents spread of microorganisms.

Clinical Alert

CDC Alert: The CDC has stated that healthcare workers in contact with clients must remove all fake fingernails because they serve as a reservoir for microorganisms.

7. Rub vigorously, using a firm, circular motion, while keeping your fingers pointed down, lower than wrists. Start with each finger, then between fingers, then palm and back of hand. ► **Rationale:** This creates friction on all surfaces.
8. Wash your hands for at least 15 to 20 seconds. ► **Rationale:** Duration of washing is important to produce mechanical action and to allow antimicrobial products time to achieve desired effect.
9. Clean under your fingernails with an orangewood stick. (This should be done at least at start of day and if hands are heavily contaminated.) Move rings up and down fingers to clean if rings are left on.
10. Rinse your hands under running water, keeping fingers pointed downward. ► **Rationale:** This position prevents contamination of arms.
11. Resoap your hands, rewash, and rerinse if heavily contaminated.
12. Dry hands thoroughly with a paper towel, while keeping hands positioned with fingers pointing up. ► **Rationale:** Moist hands tend to gather more microorganisms from the environment.

▲ Wet hands thoroughly before applying soap to facilitate removal of pathogens.

▲ Use a generous amount of soap and friction during handwashing procedure.

▲ Keep fingers pointed down during handwashing to prevent contaminating arms.

▲ If foot pedal is not available, turn water off using paper towel.

▲ Waterless hand sanitizer kills 99.9% of the most common germs in 15 seconds.

13. Turn off water faucet with dry paper towel, if not using foot pedal. ► **Rationale:** To avoid recontaminating the hands.
14. Restart procedure at Step 5 if your hands touch the sink anytime between Steps 5 and 13.

For Using Waterless Antiseptic Agents (foam or gels)

1. Check dirt on hands and use waterless agent only if hands are clean. ► **Rationale:** Hands soiled with dirt or organic matter require soap or detergents that contain antiseptic and water to effectively clean.
2. Apply small amount of alcohol-based rub, foam, or gel (3–5 mL) on palm of hand.

How One Hospital Increased Doctors' Compliance in Hand Washing From 65% to 100%

Hospital management first tried self-reporting and nagging doctors to encourage them to wash their hands. This was useless. When they tried a hand hygiene safety posse who would give doctors a small reward (e.g., a \$10 Starbucks gift certificate) for washing their hands, this raised compliance to 80%. What radically worked to increase compliance was when they photographed cultured plates after doctors pressed their palms on the plates and used these disgusting gobs of bacteria (which showed up on the photographs) on every computer screen saver in the hospital. This raised compliance to close to 100%. Perhaps managing the system is preferable to managing the staff.

The CDC recommends rubbing hands for 15 to 20 seconds. If you need a timer, imagine singing "Happy Birthday" twice through to a friend.

EVIDENCE-BASED PRACTICE

Nail Polish and Microbial Threat

Studies show that chipped nail polish or polish worn more than 4 days is linked to higher microbial load than unpolished or freshly polished nails.

Source: Recommended practices for surgical hand antisepsis/hand scrubs. (2004). AORNJ, 79(2), 416.

3. Rub hands together vigorously, covering all surfaces, sides of hands, and fingers. ► **Rationale:** Failure to cover all surfaces can leave contaminated areas on the hands.
4. Rub hands until dry—waterless agent will dry quickly and automatically without using a towel.

Clinical Alert

OSHA requires that hands be washed with soap and water every third time the hands are cleansed.

5. **NOTE:** There are now available disposable germicidal wipes that are effective at killing 99.99% of harmful bacteria. These wipes are also effective at removing soil from hands because of natural friction when wiping. The wipes are made from cloth saturated with ethyl alcohol gel solution, free of fragrance and dye. These products are approved by the Environmental Protection Agency (EPA) for both hepatitis B and other viruses.

Clinical Alert

Antimicrobial soap or waterless agent should be used when there is identified resistant bacteria, colonization outbreaks, or hyperendemic infections with the exception of *C. difficile* and *norovirus*, which are not killed by an alcohol-based gel.

New Health Care Initiative From WHO

Led by WHO in 2009, an initiative to tackle healthcare-associated infection was launched. By focusing on hand hygiene, a major global effort to follow a detailed action plan to save lives has been introduced. This plan is based on global evidence that hand hygiene is integrally linked to transmission of infection by healthcare workers. Some international studies indicate that compliance is as low as 8% and even in developed countries, rates range from 5% to 15%. These rates can affect 10% to

40% of clients admitted to intensive care units. WHO has an improvement strategy that includes “My 5 Moments for Hand Hygiene,” which details when hand hygiene needs to be applied:

1. Before touching a client
2. Before clean/aseptic procedures
3. After body fluid exposure/risk
4. After touching a client
5. After touching client surroundings

▲ If hands are dirty, wash with soap and water; if clean, use alcohol—gel or foam—as hand hygiene agent.

HyGreen: New Trends

Completing hand hygiene, the staff member passes each hand under a wall-mounted sensor that notes the status of the worker's hands. The device sends a message to the badge the staff member wears. Then, a wireless monitor on the client's bed detects the status, and, if the caregiver's hands are not clean, a wireless message goes to the badge, which vibrates. This reminds the wearer to clean his/her hands before client contact.

The device records all hand hygiene events, allowing the hospital to document events and develop a comprehensive database. During a 5-month test of this device at a Florida medical center, infection rates dropped to zero.

▲ A new screening device from HyGreen could decrease the nearly 2 million in-hospital infections that occur each year.

EVIDENCE-BASED PRACTICE

The Hand Hygiene Resource Center states that 2 million people each year become ill as a result of hospital-acquired infections. Proper hand hygiene is critical to the prevention of these infections, which contribute to the death of nearly 90,000 hospital patients per year and \$4.5 billion in medical expenses.

Hand Hygiene Resource Center (www.handhygiene.org)

EVIDENCE-BASED PRACTICE

Bath Basin Contamination

Researchers sampled 92 bath basins at several acute care hospitals and found some form of bacteria in 98%. The conclusion was that bath basins can be reservoirs for bacteria that transmit hospital-acquired infections. Nurses should be aware of this link.

Source: American Association of Critical Care Nurses. (2009, October). www.aacnboldvoicesonline.org

Cleaning Washable Articles

Equipment

- Article to be washed
- Antiseptic solution (according to hospital policy)
- Running warm water
- Paper towels
- Trash basket
- Clean gloves

Procedure

1. Complete hand hygiene and don clean gloves.
2. Rinse under cold running water. ► **Rationale:** Cold water removes organic material. Hot water coagulates

protein of organic material (pus, blood) and it adheres to a surface.

3. Wash with warm, soapy water using friction or follow hospital protocol for cleaning equipment.
4. Rinse well with clear, hot water.
5. Dry thoroughly.
6. Return to proper place or prepare for sterilization or disinfection if indicated.
7. Remove gloves and complete hand hygiene.

NOTE: If norovirus is identified, use 1 part bleach to 50 parts water for contaminated surfaces. Put washable items in hot water with soap, and dry in hot dryer.

Donning and Removing Clean Gloves

Equipment

- Clean gloves
- Trash receptacle

▲ Wash your hands, or complete hand hygiene before donning gloves.

Procedure

1. Complete hand hygiene. ► **Rationale:** Donning gloves with unclean hands can transfer microorganisms outside gloves.
2. Remove glove from glove receptacle.
3. Hold glove at wrist edge and slip fingers into openings. Pull glove up to wrist.
4. Place gloved hand under wrist edge of second glove and slip fingers into opening.
5. Remove glove by pulling off, touching only outside of glove at cuff, so that glove turns inside out.
6. Place rolled-up glove in palm of second hand.
7. Remove second glove by slipping one finger under glove edge and pulling down and off so that glove turns inside out. Both gloves are removed as a unit.
8. Dispose of gloves in proper container, not at bedside.
9. Complete hand hygiene.

▲ Complete hand hygiene using anti-bacterial gel or by washing hands.

▲ Remove glove from dispenser.

▲ Hold glove at wrist edge and slip fingers into openings. Pull glove up to wrist.

▲ Place gloved hand under wrist edge of second glove and slip fingers into opening.

5 Remove glove by pulling off. Touch only outside of glove at cuff, so that glove turns inside out.

6 Continue pulling off first glove until it is inside out.

7 Fold rolled-up glove in palm of second hand.

8 Remove second glove by slipping fingers under glove edge.

9 Pull glove down and off so that glove turns inside out.

10 Dispose of gloves in proper container, not at bedside. Complete hand hygiene.

Clinical Alert

Ungloved hands should not touch anything that is moist coming from a body surface. The moisture coming from a body surface should be considered potentially contaminated during routine client care.

Source: Pittet, D., Dharan, S., Touveneau, S., Sauvan, V., & Perneger T. V. (1999). Bacterial contamination of the hands of hospital staff during routine patient care. *Archives of Internal Medicine*, 159, 821–826.

EVIDENCE-BASED PRACTICE

C. difficile on the Rise

A study done at 28 community hospitals in North Carolina showed that *C. difficile* infections are on the rise and have surpassed MRSA. The rate of HAI *C. difficile* was 0.28 cases per 1,000 client days and the rate for MRSA was 0.23 cases per 1,000 client days.

Source: Miller, B. (2010). Study presented at International Conference on Health Care Associated Infections.

Glove Selection

- Use sterile gloves for procedures involving contact with normally sterile areas of the body.
- Use examination gloves for procedures involving contact with mucous membranes, unless otherwise indicated, and for client care or procedures that do not require use of sterile gloves.
- Change gloves between clients.
- Do not wash, disinfect, or reuse surgical or examination gloves.
- Use general purpose utility gloves (rubber household gloves) for housekeeping tasks that involve potential blood contact and for instrument cleaning and decontamination procedures.

Managing Latex Allergies

Equipment

- Latex-free gloves
- Latex-free syringes
- Latex-free IV tubing and bags of solution
- Latex-free cart with supplies for client with latex allergy

▲ Provide a latex-free cart—supplies for staff and clients with latex allergies.

Procedure

1. Assess clients at high risk or suspected sensitivity to latex (high latex exposure, congenital defects, indwelling catheters, etc.).
2. Assess clients and staff with allergies to cherries, apricots, tomatoes, avocados, bananas, papaya, kiwi, or chestnuts.
 - **Rationale:** They may have cross-sensitivity to latex.
3. Recognize symptoms of latex allergy.
 - a. Contact dermatitis.
 - b. Type IV: facial swelling, itching, hives, rhinitis, eye symptoms.
 - c. Type I: potentially dangerous bronchospasms, generalized edema, difficulty breathing, cardiac arrest.
4. Replace latex-containing products (especially gloves) with nonlatex alternatives.
5. Obtain a latex-free cart when a client is identified as having a latex allergy.
 - a. Place cart inside client's room.
 - b. Check that cart is supplied with latex-free gloves, syringes, IV tubes, suction catheters, etc.
6. Ensure that anaphylaxis medication is available for both clients and staff if latex allergy is suspected.
 - **Rationale:** If there is a severe reaction, this medication may be lifesaving.

Ansell Healthcare Company has introduced a new latex-free glove made from synthetic polyisoprene. This glove is safe for use by latex-sensitive nurses, while having the characteristic of a natural rubber latex glove. The Yulex Corporation has introduced a new form of natural rubber latex made from the quayule bush that may prove to be a safer alternative for people with latex sensitivity.

Clinical Alert

Latex allergy or hypersensitivity can be life-threatening, so recognize the primary symptoms in both clients and staff.

DOCUMENTATION for Basic Medical Asepsis

- Infection control measures used
- Clean gloves used for procedure
- Latex allergy identified
- Use of latex-free gloves

CRITICAL THINKING Application

Expected Outcomes

- Decreased number of bacteria on hands from client to client.
- Delivered care with pathogen-free hands to clients.

Unexpected Outcomes

Infection occurs in client.

Latex allergy identified in healthcare worker or client.

- Prevented spread of microorganisms from healthcare workers or environment to clients.
- Prevented cross-contamination between clients.

Alternative Actions

- Assess mode of transmission of microorganism.
- Administer antibiotics specific to microorganism as ordered.
- Review handwashing technique.
- Attend in-service program on infection control procedures.
- Notify nurse manager of allergy.
- Institute latex safety procedures for staff and client (if identified).
- Educate staff about latex allergy.
- Replace latex-containing objects (particularly gloves) with nonlatex alternatives.
- Create a latex-free environment in which those who are allergic can work safely.

Standard Precautions (Tier 1)

Nursing Process Data

ASSESSMENT Data Base

- Assess for skin integrity.
- Assess for presence of drainage from lesions or body cavity.
- Assess for ability to deal with oral secretions.
- Assess for compliance to hygiene measures (i.e., covering mouth when coughing, ability to control body fluids).
- Assess ability to carry out activities of daily living (ADLs).
- Assess extent of barrier techniques needed (i.e., gloves, gown, mask, protective eyewear).
- Assess need for special equipment (i.e., hazardous waste bags, plastic bags for specimens).

PLANNING Objectives

- To prevent the spread of the microorganism to health professionals
- To reduce potential for the transmission of microorganisms
- To protect hospital personnel and others from contamination

- To provide appropriate equipment and techniques for preventive measures
- To prevent clients (especially compromised clients) from acquiring nosocomial infections.

IMPLEMENTATION Procedures

- Donning Protective Gear Utilizing Standard Precautions 430
- Exiting a Client's Room Utilizing Standard Precautions 431

EVALUATION Expected Outcomes

- Prevented spread of microorganisms between clients and/or healthcare workers.
- Reduced potential for transmission of microorganisms occurs.
- Protected hospital personnel and others from contamination.
- Provided appropriate equipment and techniques for preventive measures.
- Reduced incidence of nosocomial infections.

Critical Thinking Application 434

- Expected Outcomes 434
- Unexpected Outcomes 434
- Alternative Actions 434

Prepare for success with NCLEX®-style practice questions and Skill Checklists

STANDARD PRECAUTIONS For all patient care					
PROCEDURE					
Talking to patient					
Adjusting IV fluid rate or non-invasive equipment					
Examining patient without touching blood, body fluids, mucous membranes	X				
Examining patient including contact with blood, body fluids, mucous membranes	X	X			
Drawing blood	X	X			
Inserting venous access	X	X			
Suctioning	X	X	Use gown, mask, eyewear if bloody body fluid splattering is likely		
Inserting body or face catheters	X	X	Use gown, mask, eyewear if bloody body fluid splattering is likely		
Handling soiled waste, linen, other materials	X	X	Use gown, mask, eyewear only if waste or linen are externally contaminated and splattering is likely		
Intubation	X	X	X	X	X
Inserting arterial access	X	X	X	X	X
Endoscopy	X	X	X	X	X
Operative and other procedures which produce extensive splattering of blood or body fluids	X	X	X	X	X

Donning Protective Gear Utilizing Standard Precautions

Equipment

- Disposable gloves
- Gown
- Mask
- Protective eyewear

Procedure

1. Use alcohol-based antiseptic or wash hands using nonantimicrobial soap and dry.
2. Put on gown by placing one arm at a time through sleeves. Wrap gown around body so it covers clothing completely. ► **Rationale:** Gowns are worn when it is likely that personal clothing will come in contact with blood, body fluids, secretions, and excretions.
3. Bring waist ties from back to front of gown or tie in back, according to hospital policy. ► **Rationale:** This will ensure that entire clothing is covered by the gown, preventing accidental contamination.
4. Tie gown at neck or adhere Velcro strap to gown.
5. Don mask. ► **Rationale:** Masks are worn when there is an anticipated contact with respiratory droplet secretions (e.g., client with suspected or known tuberculosis), the client has a persistent cough and does not cover mouth, or when suction will be performed.
6. Don protective eyewear such as face shield. ► **Rationale:** Face shields will protect the nurse from splashing of blood or body fluids while caring for clients.
7. Don disposable gloves. ► **Rationale:** Gloves will prevent contamination of hands when there is contact with blood, body fluids, secretions, or excretions.

New Trends: Software to Improve Quality of Care

Meditech's Health Care Information System provides tools to help organizations increase client safety and assist them to meet The Joint Commission's goals.

Goal 7: Reduce the Risk of Healthcare Associated Infections

The infection control portion of Meditech's Laboratory Information System helps providers to

identify and track infections by automatically flagging infections by markers (site of infection, type of infection, and whether sensitive or resistant to certain antibiotics). The infection control group can receive alerts which will assist them in tracking healthcare-associated infections.

See The Joint Commission's goals in Chapter 7.

Source: <http://www.meditech.com/IndustryNews/homepage.htm>

▲ Face shield should be used when there is a risk of splashing from body fluids or blood.

▲ Place sharps container in area for easy access.

▲ Larger sharps containers are available for areas where usage is greater.

Standard Precaution Guidelines

The following Standard Precautions are recommended for use with clients to prevent transmission of infectious agents. Please follow these guidelines when caring for clients.

- Wash hands thoroughly or use alcohol-based antiseptic after removing gloves and before and after all client contact.
- Wear gloves when there is direct contact with blood, body fluids, secretions, excretions, and contaminated items. This includes a neonate before first bath. Wash as soon as possible if unanticipated contact with these body substances occurs.
- Protect clothing with gowns or plastic aprons if there is a possibility of being splashed or in direct contact with contaminated material.
- Wear masks, goggles, or face shield to avoid being splashed; includes during suctioning, irrigations, and deliveries.
- Do not break or recap needles; discard them intact into puncture-resistant containers.
- Place all contaminated articles and trash in leakproof bags.
- Clean spills quickly with a 1:10 solution of bleach, or according to facility policy, or EPA-approved germicide if spill occurs in an HIV/AIDS client's room.
- Place clients at risk for contaminating the environment in a private room with separate bathroom facilities, or with another client with same infectious organism.
- Transport infected clients using appropriate barriers, i.e., mask and gown.

Exiting a Client's Room Utilizing Standard Precautions

Equipment

- Linen hamper
- Garbage bag

Procedure

1. Untie string of gown at waist. ► **Rationale:** Any surface below waist level is considered contaminated; therefore,

▲ Place rolled-up glove in palm of second hand. Remove second glove by slipping one or two fingers under edge and pulling down and off. Remove second glove by slipping finger under glove edge. Both gloves are removed as a unit.

the strings at the waist are untied before removing gloves.

2. Remove first glove by turning it inside out, place rolled-up glove in second hand, remove second glove by slipping one finger under glove edge and pulling glove off. Dispose of them in garbage bag.
3. Untie gown at neck. ► **Rationale:** The back of the neck is considered clean and the tie should not be touched with contaminated gloves.
4. Take off gown by pulling down from shoulders, turn gown inside out, and pull arms out of gown. ► **Rationale:** The inside of the gown is not considered contaminated and therefore, if it accidentally touches your uniform, it will not be contaminated.
5. Dispose of gown in linen hamper. If disposable, place in garbage bag.
6. Remove protective eyewear.

1 Remove gown by first untying string at waist (or in back, as shown in photo).

2 Remove first glove by pulling it off so glove turns inside out. Place rolled-up glove in palm of second hand and remove second glove.

3 Untie gown at neck and take off gown by pulling down from shoulders.

4 Turn gown inside out and pull arms out as you pull gown off.

5 Dispose of gown in linen hamper; if disposable, place in garbage bag.

6 Remove protective eyewear, if worn, and mask.

7 Wash hands in room or use antiseptic gel. After exiting room, repeat hand hygiene.

8 Dispose of all soiled equipment or contaminated material in appropriate receptacle.

Clinical Alert

Disposal Precautions

Secretion: Client should be instructed to expectorate into tissue held close to mouth. Suction catheters and gloves should be disposed of in impervious, sealed bags.

Excretion: Excrement should be disposed of by flushing into sewage system. Strict attention should be paid to careful hand hygiene; disease can be spread by oral–fecal route.

Blood: Needles and syringes should be disposable. Used needles should not be recapped. They should be placed in a puncture-resistant container that is prominently labeled “isolation.” Specimens should be labeled “blood precaution.”

Clinical Alert

HIV–HBV

Sample protocol for accidental contact with blood or body fluids.

1. Any percutaneous or mucocutaneous exposure should receive immediate first aid.
 - a. Percutaneous exposure—a break in the skin caused by contaminated needle or sharp instrument, broken glass container holding blood or body fluids, or human bite.
 - b. Mucocutaneous exposure—body fluid contact to open wounds, nonintact skin (eczema), or body fluid splash to mucous membranes (mouth, eyes).
2. Apply immediate first aid to site.
 - a. Needle stick or puncture wound: Scrub area vigorously with soap and water for 5 minutes.
 - b. Oral mucous membrane exposure: Rinse area several times with water.
 - c. Ocular exposure: Irrigate immediately with water or normal saline solution.
3. Report unusual occurrence to the charge nurse or supervisor. (See explanation of form and sample in Chapter 3.)
4. Complete an unusual occurrence form and follow reporting requirements mandated by OSHA.
5. Follow facility protocol for emergency care. If risk assessment indicates, follow PEP protocol.
6. Document circumstances of exposure, postexposure management, counseling, and follow-up procedures in healthcare worker’s confidential medical file.
7. The CDC has now approved rapid result tests for HIV. Most people exposed to HIV develop antibodies within 2 to 8 weeks, but within 20 minutes will know the results from one of these new diagnostic tests. See Chapter 20 on specimen collection.
 - d. Human bite: Cleanse wound with povidone–iodine (Betadine) and sterile water.

NOTE: Use of antiseptics is not contraindicated; however, they have not been proven effective in postexposure care.

7. Remove mask and place in garbage bag.
8. Wash hands or use alcohol-based antiseptic in room.
9. Exit room and complete hand hygiene at nearest sink.
 - ▶ **Rationale:** To prevent spread of microorganisms.
10. Dispose of all double-bagged equipment by taking to “soiled” utility room. Send specimens to laboratory and deposit linen in appropriate linen hamper.
11. Complete hand hygiene.

TABLE 14-3 Basic and Expanded HIV Postexposure Prophylaxis Regimens

Regimen Category	Application	Drug Regimen
Basic	Occupational HIV exposures for which there is a recognized transmission risk	4 weeks (28 days) of both zidovudine 600 mg every day in 2 or 3 divided doses and lamivudine 150 mg twice a day. Now available combined as Combivir, single tablet given 2 × daily.
Expanded	Occupational HIV exposures that pose an increased risk for transmission (e.g., larger volume of blood and/or higher virus titer in blood)	Basic regimen plus either indinavir 800 mg every 8 hr on an empty stomach or nelfinavir 750 mg 3 × daily with meals or snacks.

Recommendations for the Selection of Drugs for PEP

The selection of a drug regimen for HIV PEP must strive to balance the risk for infection against the potential toxicity of the agent(s) used. Because PEP is potentially toxic, its use is not justified for exposures that pose a negligible risk for transmission. Also, there is insufficient evidence to recommend a highly active regimen for all HIV exposures. Therefore, two regimens for PEP are provided: a “basic” two-drug regimen that should be appropriate for most HIV exposures and an “expanded” three-drug regimen that should be used for exposures that pose an increased risk for transmission or where resistance to one or more antiretroviral agents is known or suspected. When possible, the regimens should be implemented in consultation with persons having expertise in antiretroviral treatment and HIV transmission.

Source: Centers for Disease Control and Prevention. (2001). Appendix C: Basic and expanded HIV postexposure prophylaxis regimens. *Morbidity and Mortality Weekly Report (MMWR)*. Available at: <http://cdc.gov/mmwr/preview/mmwrhtml/rr5011a4.htm>.

*Indinavir should be taken on an empty stomach (i.e., without food or with a light meal) and with increased fluid consumption (i.e., drinking six 8-oz glasses of water throughout the day); nelfinavir should be taken with meals.

DOCUMENTATION for Standard Precautions

- Standard Precautions maintained
- Client's response to care and protocol used
- Specimens sent to laboratory if appropriate
- Disposal precautions utilized if appropriate

CRITICAL THINKING Application

Expected Outcomes

- Prevented spread of microorganisms between clients and/or healthcare workers.
- Reduced potential for transmission of microorganisms occurs.
- Protected hospital personnel and others from contamination.
- Provided appropriate equipment and techniques for preventive measures.
- Reduced incidence of nosocomial infections.

Unexpected Outcomes

Contaminated blood or body fluid comes in contact with your skin or mucous membranes.

Alternative Actions

- Report incident, and complete unusual occurrence report. (Very important for follow-up legal and medical implications.)
- Follow hospital guidelines (they may differ per facility) for postexposure prophylaxis (PEP).
- HIV exposure should be immediately reported, as most hospitals offer AZT preventive therapy. This therapy should be administered within 1 hr, not more than 24 hr after exposure.
- Obtain AIDS antibody test in ensuing months.
- Continue to monitor own health status and carry out specific activities to build immune system.
- Do not smoke or drink excessively.
- Eat well-balanced meals with reduced fat intake.
- Take vitamin supplements designed to boost immune system (vitamin C, beta-carotene, vitamin A, coenzyme Q10, zinc). Check with nutritionist or holistic physician for complete protocol.
- Exercise frequently.
- Obtain adequate sleep and rest.
- Learn and practice stress reduction activities (stress is known to lessen effectiveness of immune system).

Working with AIDS clients becomes extremely stressful, and the nurse experiences burn-out.

- Request consultation therapy to handle feelings and learn new methods of coping with stress.
- Leave this type of work temporarily.
- Change other aspects of your life to reduce stress.
- Follow above-mentioned regimen to enhance immune system.

Isolation

Nursing Process Data

ASSESSMENT Data Base

- Identify appropriate times for hand hygiene.
- Identify type of protective clothing required for barrier nursing.
- Identify epidemiology of the disease to determine how to prevent infection from spreading.
- Identify equipment needed to prevent spread of organisms.
- Assess method of terminal cleaning and disposing of equipment.

PLANNING Objectives

- To prevent the spread of endogenous and exogenous flora to other clients
- To reduce potential for transferring organisms from the hospital environment to the client
- To protect hospital personnel from becoming infected
- To prevent immunosuppressed clients from acquiring nosocomial infections

IMPLEMENTATION Procedures

- Preparing for Isolation 436
- Donning and Removing Isolation Attire 437
 - For Donning Attire 437
 - For Removing Attire 439
- Using a Mask 439
- Assessing Vital Signs 440
- Removing Items From Isolation Room 440
- Removing a Specimen From Isolation Room 441
- Transporting Isolation Client Outside the Room 441
- Removing Soiled Large Equipment From Isolation Room 442

EVALUATION Expected Outcomes

- Prevented client-to-client spread of endogenous and exogenous flora.
- Protected hospital personnel from becoming infected.
- Prevented immunosuppressed clients from acquiring nosocomial infections.
- Reduced transference of organisms from hospital environment to clients.

Critical Thinking Application 443

- Expected Outcomes 443
- Unexpected Outcomes 443
- Alternative Actions 443

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Preparing for Isolation

Equipment

Specific equipment depends on isolation precaution system used

▲ Place isolation cart outside client's door when cart is required.

Soap* and running water

Isolation cart containing masks, gowns, gloves, plastic bags, isolation tape

Linen hamper and trash can, when needed

Paper towels

Door card indicating precautions

Procedure

1. Check physician's order for isolation.
2. Obtain isolation cart from central supply, if needed.
3. Check that all necessary equipment to carry out the isolation order is available.
4. Place isolation card on the client's door.
5. Ensure that linen hamper and trash cans are available, if needed.
6. Explain purpose of isolation to client and family.
7. Instruct family in procedures required.
8. Wash hands with antimicrobial soap* or use alcohol-based gel before and after entering isolation room.

*Type of antimicrobial soap or agent depends on infectious agent and client condition.

EVIDENCE-BASED PRACTICE

An isolation client with an infection that can be transmitted via airborne route should be admitted to a room that has a directional air-flow negative pressure ventilation system, with a connected anteroom. The door should be kept closed at all times, and the air should undergo 12 air exchanges per hour for rooms developed after 2001. Air should be filtered through a HEPA filter or directly discharged to the outside.

▲ Entrance to Negative Pressure isolation room and the adjoining Anteroom.

▲ View from anteroom to client's isolation room with directional air-flow negative pressure ventilation system.

▲ Anteroom connected to isolation room. Staff should use this access to client's room and keep door closed at all times.

Source: Centers for Disease Control and Prevention. (2003, June). Guidelines for Environmental Infection Control in Health Care Facilities. *MMWR Morbidity and Mortality Weekly Report*, 52, 1–4.

EVIDENCE-BASED PRACTICE

Conditions Caused by HAIs

Statistics from the CDC indicate that HAIs (ranging from pneumonia to MRSA) cost hospitals up to \$45 billion each year and kill an estimated 100,000 people a year.

Source: TeleTracking Technologies: Fighting hospital-acquired infections with patient flow software. <http://onemedplace.com/blog/archives/5868>.

Donning and Removing Isolation Attire

Equipment

- Gown
- Clean gloves

Procedure

For Donning Attire:

1. Complete hand hygiene.
2. Take gown from isolation cart or cupboard. Put on a new gown each time you enter an isolation room.
3. Hold gown so that opening is in back when you are wearing the gown.
4. Put gown on by placing one arm at a time through sleeves. Pull gown up and over your shoulders.
5. Wrap gown around your back, tying strings at your neck.
6. Wrap gown around your waist, making sure your back is completely covered. Tie strings around your waist.
7. Don eye shield and/or mask, if indicated. ► **Rationale:** Mask is required if there is a risk of splashing fluids.
8. Don clean gloves and pull gloves over gown wristlets. ► **Rationale:** Prevents contamination of exposed skin.

For Removing Attire:

1. Untie gown waist strings.
2. Remove gloves and dispose of them in garbage bag.
3. Next, untie neck strings, bringing them around your shoulders so that gown is partially off your shoulders.
4. Using your dominant hand and grasping clean part of wristlet, pull sleeve wristlet over your nondominant

- hand. Use your nondominant hand to pull sleeve wristlet over your dominant hand.
5. Grasp outside of gown through the sleeves at shoulders. Pull gown down over your arms.
6. Hold both gown shoulders in one hand. Carefully draw your other hand out of gown, turning arm of gown inside out. Repeat this procedure with your other arm.
7. Hold gown away from your body. Fold gown up inside out.
8. Discard gown in appropriate place.
9. Remove eye shield and/or mask and place in receptacle.
10. Complete hand hygiene. ► **Rationale:** This prevents cross-infection to other clients.

Deadly New Superbug Appears in 2010

A deadly superbug has been detected, surfacing for the first time in India in 2009. Named the New Delhi metallo-beta-lactamase 1, or NDM-1, this bug is an enzyme that can live inside different bacteria. The two types of bacteria that have been host to NDM-1, are *e-coli* (from a human intestine) and *Kebsiella*, found in the lungs. The NDM-1 gene alters these bacteria making them resistant to almost all known antibiotics. The young and elderly are the most susceptible to this superbug, which has caused numerous deaths internationally.

Source: Kumarasamy KK, Toleman MA, Walsh TR, et al. (August 2010). Emergence of a new antibiotic resistance mechanism in India, Pakistan, and the UK. *Lancet Infect Dis* 10 (9): 597–602.

Donning Isolation Gear

▲ Isolation gown is put on before mask, eye shield, or gloves.

▲ Cover wristlets completely to prevent contamination of exposed skin.

Removing Isolation Gear

1 Remove gloves before gown, mask or eye shield.

3 Pull gown off shoulders, then down over arms.

5 Dispose of equipment in appropriate containers that should be in client's room.

2 Dispose of gloves in appropriate receptacle.

4 Hold gown away from body when rolling inside out.

Pediatric Considerations

Isolation precautions can increase an already stressful situation for a hospitalized child. Younger children have limited cognitive abilities to understand the implications of isolation. Particularly frightening for them is the presence of people in gowns and masks. To help decrease their fears, preparation is important. Letting the children see and play with the equipment lessens some of the anxiety. Healthcare workers should introduce themselves to the child before donning a mask. Frequent visits to the child can also lessen the fear and loneliness associated with isolation.

Clinical Alert

Some isolation gowns do not tie at the neck; they slip over the head. When removing these gowns, pull shoulders forward to loosen the Velcro at the neck area. Remove gown in the same manner as you would if tied at the neck.

Using a Mask

Equipment

Clean mask

Procedure

1. Obtain mask from box.
2. Position mask to cover your nose and mouth.
3. Bend nose bar so that it conforms over bridge of your nose.
4. If you are using a mask with string ties, tie top strings on top of your head to prevent slipping. If you are using a cone-shaped mask, tie top strings over your ears.
5. Tie bottom strings around your neck to secure mask over your mouth. There should be no gaps between the mask and your face.
6. *Important:* Change mask every 30 minutes or sooner if it becomes damp. ► *Rationale:* Effectiveness is greatly reduced after 30 minutes or if mask is moist.
7. Complete hand hygiene before removing mask.
8. To remove mask, untie lower strings first, or slip elastic band off without touching mask. ► *Rationale:* Only strings are considered clean.
9. Discard mask in a trash container.
10. Complete hand hygiene.

▲ Sample masks used for isolation protocol.

Clinical Alert

Protective eyewear such as goggles and face shield are worn when there is a risk of splashes or sprays from blood, secretions, excretions, or body fluids. Eyewear is removed before taking off mask.

Clinical Alert

Respiratory N95 or HEPA respirators (high-efficiency particulate air) masks are recommended for infectious diseases transmitted by airborne mode; for example, influenza or suspected or confirmed multidrug-resistant tuberculosis.

- Masks are fitted to worker. Mask should have a good sealing surface with no leakage around the edge, providing a tight seal over the nose and mouth.
- Wear mask until it becomes difficult to breathe. This indicates mask is clogged.
- When not in use, store mask in zip-lock bag in safe area.
- Masks are expensive and can be used repeatedly until it is difficult to breathe through them.

▲ Particulate filter respirator mask must be airtight.

Filligent Limited Biomask

A new flu-killing mask called the Biomask is available in 2010. Made of interwoven cellulose fibers that bind to bacteria and viruses, this mask destroys the cell walls and kills 99.9% of the flu virus. This mask kills germs on contact and can be worn multiple times per day, unlike conventional masks.

▲ Filligent Limited Biomask.

EVIDENCE-BASED PRACTICE

Using a Mask

A study was done at McMaster University in Canada comparing a surgical mask with the N95 mask for clients with laboratory confirmed influenza. It showed that within a prespecified margin, the surgical mask appeared to be no worse than N95 masks in preventing influenza transmission.

Assessing Vital Signs

Equipment

Thermometer
 Stethoscope
 Blood pressure cuff and sphygmomanometer
 Thermometer stand
 Watch with sweep second hand
 Isolation clothing

Procedure

1. Complete hand hygiene and use two forms of client ID.
2. Don isolation clothing as required by type of isolation.
3. Proceed to take vital signs as you would for any client.
4. Place equipment in appropriate area if it is to be left in room. Follow appropriate protocol to remove equipment from isolation room.
5. Remove isolation clothing according to protocol.
6. Complete hand hygiene.
7. Wipe watch if accidentally contaminated. Use appropriate solution.

Removing Items From Isolation Room

Equipment

Large red isolation bags
 Specimen container
 Plastic bag with biohazard label
 Laundry bag

Red plastic container for sharps
 Cleaning articles

Procedure

1. Place laboratory specimen in biohazard plastic bag.
2. Dispose of all sharps in appropriate red plastic container in room.
3. Place all linen in linen bag.

▲ Close bag securely and label contents, if necessary.

▲ Set up new biohazard bag for continued use in client's room.

▲ Place red biohazard bag in specified area for disposal.

- Place reusable equipment such as procedure trays in plastic bags. ► **Rationale:** Appropriate separation of equipment from isolation room alerts central supply staff that it is contaminated and special handling needs to be carried out.
- Dispose of all garbage in plastic bags.
- Place all material to be removed from isolation room in anteroom (if available). ► **Rationale:** All material removed from an isolation room is potentially contaminated. This will prevent spread of microorganisms.

Clinical Alert

Linen and burnable trash are disposed of in the same manner. Ensure that when placing bags in containers in “dirty” utility room you place in correct container according to bag contents.

- Replace all bags, such as linen bag and garbage bag, in appropriate container in room.
- Clean client’s room as necessary, using germicidal solution, according to facility protocol.
- Prepare to leave the client’s room.

Removing a Specimen From Isolation Room

Equipment

- Specimen container
- Clean biohazard bag

Procedure

- Follow dress protocol for entering isolation room, or, if you are already in the isolation room, continue with Step 2.
- Mark a specimen container with the client’s name, type of specimen, and the word “isolation” before entering an isolation room.
- Collect specimen, and place container in a clean plastic biohazard bag outside the room. ► **Rationale:** Use clear bags so that laboratory personnel can see the specimen easily.
- Complete hand hygiene.
- Send specimen to laboratory with appropriate laboratory request form.

▲ Biohazard bag for transportation of specimens from isolation room.

Transporting Isolation Client Outside the Room

Equipment

- Transport vehicle
- Bath blanket
- Mask for client if needed

Procedure

- Explain procedure to client.
- If client is being transported from a respiratory isolation room, instruct him or her to wear a mask for the entire time out of isolation. ► **Rationale:** This prevents the spread of airborne microbes.
- Cover the transport vehicle with a bath blanket if there is a chance of soiling when transporting a client who has a draining wound or diarrhea.
- Help client into transport vehicle. Cover client with a bath blanket.

▲ Place surgical mask on client if he needs to be transported outside room.

5. Tell receiving department what type of isolation client needs and what precautions hospital personnel should follow.
6. Remove bath blanket and handle as contaminated linen when client returns to room.
7. Instruct all hospital personnel to complete hand hygiene before they leave the area.
8. Wipe down transportation vehicle with an antimicrobial solution if soiled.

Removing Soiled Large Equipment From Isolation Room

Equipment

Antimicrobial agent and articles needed to wash equipment
Plastic bag

Procedure

1. Don isolation garb as recommended.
2. Wash equipment with an antimicrobial agent. ▶
Rationale: Washing is preferred to spraying in order to ensure all surfaces are cleaned.
3. Cover equipment with a plastic bag.
4. Remove garb, and complete hand hygiene outside the room. Take equipment to the decontamination area of central supply room (CSR).

Protocol for Leaving Isolation Room

1. Untie gown at waist.
2. Take off gloves.
3. Untie gown at neck.
4. Pull gown off and place in laundry hamper.
5. Take off goggles or face shield.
6. Take off mask.
7. Complete hand hygiene.

▲ Wash isolation equipment with antimicrobial agent.

Guidelines for Disposing of Contaminated Equipment

- **Disposable glass:** Place in isolation bag separate from burnable trash and direct to appropriate hospital area for disposal.
- **Glass equipment:** Bag separately from metal equipment and return to CSR.
- **Metal equipment:** Bag all equipment together, label, and return to CSR.
- **Rubber and plastic items:** Bag items separately and return to CSR for gas sterilization.
- **Dishes:** Require no special precautions unless contaminated with infected material; then bag, label, and return to kitchen.
- **Plastic or paper dishes:** Dispose of these items in burnable trash.
- **Soiled linens:** Place in laundry bag and send to separate area of laundry room for special care. If possible, place linens in hot-water-soluble bag. This method is safer for handling, as bag may be placed directly into washing machine. (Double-bagging is usually required because these bags are easily punctured or torn. They also dissolve when wet.)
- **Food and liquids:** Dispose of these items by putting them in the toilet—flush thoroughly.
- **Needles and syringes:** Do not recap needles; place in puncture-resistant container.
- **Sphygmomanometer and stethoscope:** Require no special precautions unless they are contaminated. If contaminated, disinfect using the appropriate cleaning protocol based on the infective agent.
- **Thermometers:** Dispose of electronic probe cover with burnable trash. If probe or machine is contaminated, clean with appropriate disinfectant for infective agent. If reusable thermometers are used, disinfect with appropriate solution.

DOCUMENTATION for Isolation

- Type of isolation protocol being practiced
- Specimens sent to laboratory
- Client's reactions to sensory deprivation
- Vital signs if appropriate

Legal Considerations

Every year while in hospitals, 90,000 Americans acquire infections that kill them. In addition, hospital-acquired infections cost an estimated \$20 billion each year, according to the CDC.

Source: AARP, March 2009

It may be that while there is no case law relating specifically to noncompliance with infection control practices, current case law could be used to establish whether or not a healthcare professional who had failed to implement acceptable standard infection control practices had acted negligently, and as a result, caused a patient to develop a healthcare-associated infection.

Source: Portsmouth, R. (2007). Infection control and the law. *British Journal of Infection Prevention*, 8(2), 14–19.

CRITICAL THINKING Application

Expected Outcomes

- Prevented client-to-client spread of endogenous and exogenous flora.
- Protected hospital personnel from becoming infected.
- Prevented immunosuppressed clients from acquiring healthcare-associated infections.
- Reduced transference of organisms from hospital environment to clients.

Unexpected Outcomes

Outbreak of disease occurs in isolation environment.

Alternative Actions

- Identify cause of outbreak, and contact the infection control practitioner for consultation.
- Examine handwashing and infection control practices among staff.
- Attend in-service education program on isolation techniques to increase your awareness of appropriate procedures.

Chapter 14

UNIT 4

Home Care Adaptation

Nursing Process Data

ASSESSMENT Data Base

- Assess need for hand hygiene.
- Identify clients at risk for infection.
- Assess need for cleaning equipment and decontaminating equipment.
- Identify type of waste material requiring special disposal.
- Assess equipment needed to deliver care in the home.
- Assess need for teaching preventive measures in the home of HIV or AIDS clients.

PLANNING Objectives

- To deliver client care with pathogen-free hands
- To clean equipment properly to prevent cross-contamination
- To protect client from cross-contamination
- To protect the nurse
- To properly dispose of contaminated waste material
- To protect client's significant others from contamination of infected material

IMPLEMENTATION Procedures

- Preparing for Client Care 445
- Assessing Client for Potential Infection 446
- Disposing of Waste Material in the Home Setting 446
- Caring for an AIDS or HIV Client in the Home Setting 447
- Cleansing Equipment in the Home Setting 447
- Teaching Preventive Measures in the Home Setting 448
- Teaching Safer Practices to IV Drug Users 449

EVALUATION Expected Outcomes

- Cross-contamination is prevented.
- Nurse is protected from infection.
- Equipment is cleaned appropriately.
- Waste is disposed of in proper manner.

- **Critical Thinking Application** 449
 - Expected Outcomes 449
 - Unexpected Outcomes 449
 - Alternative Actions 449

Pearson Nursing Student Resources

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Preparing for Client Care

Equipment

Community health nursing bag
 Liquid soap
 Antibacterial gel for hand hygiene
 Disposable gloves
 Disposable apron or gown
 Goggles
 Masks, air-purifying mask
 Thermometers (oral and rectal)
 Thermometer sheaths
 Nex Temp (disposable thermometer)
 Vaseline or lubricant
 Cotton balls
 Alcohol, one small bottle
 Antimicrobial wipes
 Cotton-tipped applicators
 Tongue depressors
 Sterile 4 × 4s
 Band-Aids
 Bandage scissors
 Nonallergic tape
 Plastic bags with ties
 Keto-Diastix and Chemstrips
 Sphygmomanometer
 Stethoscope
 Paper cups
 Bleach, one small bottle

Procedure

1. Arrange equipment in bag before making home visit so that hand hygiene equipment is accessible. Bring only the supplies needed. ► **Rationale:** This procedure decreases the possibility of cross-contamination.
2. Place bag on flat, dry surface to establish a clean work area during visit. Use of disposable barrier under bag is recommended. ► **Rationale:** To prevent potential spread of infection between clients' homes. The risk can be high for transmitting undiagnosed infections between home clients.
3. Perform hand hygiene.
 - a. Use liquid soap and paper towels from bag and client's water supply. Wash hands with clean running water and apply soap. Rub hands together to make a lather and scrub all surfaces. Rub hands for 10 to 15 seconds. Rinse hands well under running water. Dry hands using paper towel from nurse's bag. Turn off faucet using paper towel.
 - b. Use antimicrobial gel as alternative for handwashing when soap and water are not available. Squeeze small amount of germicide onto palm of hand and rub all surfaces of hands, fingers, and nails. Rub until hands and fingers are dry. Germicide evaporates into air, making towels unnecessary.
4. Don disposable gloves when appropriate for infection control, especially when handling blood and body fluids.
5. Take other equipment that will be needed during the visit out of the bag and place on clean work surface.
6. Keep bag closed when not in use to promote cleanliness, safety, and security. Care should be taken not to reenter bag wearing soiled gloves. Washing hands between reentering bag is not necessary unless soiled.
7. Wear disposable apron or gown, goggles, or masks if necessary. ► **Rationale:** This protects the caregiver from blood or body fluid exposure.
8. Cleanse thoroughly any equipment that left clean area and is to be returned to the bag on completing care.
 - a. Rinse equipment (such as bandage scissors, forceps) under *cold* water, wash with soap and water. Use client's personal equipment or disposable equipment whenever possible.
 - b. Return stethoscope and blood pressure cuff to nursing bag. ► **Rationale:** Clean items can be returned to nursing bag if no visible soiling.
9. Ensure nursing bag is monitored regularly for safety.
 - a. Keep bag out of reach of children.
 - b. Keep bag in trunk of car or keep in your home overnight. ► **Rationale:** Unattended bags in cars are more often stolen.
 - c. Clean bag monthly and PRN.

Clinical Alert

If item is soiled and cannot be returned to the bag, place in separate container for transport to agency. Clean item when it is returned to agency. Most items for home care are disposable.

Assessing Client for Potential Infection

Equipment

- Disposable gloves
- Disposable impenetrable plastic bag
- Disposable gown (if drainage present)
- Mask, cap, goggles (if potential respiratory infection)
- Blood pressure cuff
- Stethoscope
- Thermometer
- Urine container and dipstick
- Blood specimen tubes and Vacutainer with needle
- Alcohol swabs
- Soap and water and/or germicidal gel

Procedure

1. Wash hands or complete hand hygiene.
2. Don disposable gloves when appropriate for infection control.
3. Take equipment out of bag and place on clean work surface.
4. Don disposable equipment as necessary for infection control.
5. Obtain vital signs; check for elevated temperature and pulse rate.
6. Complete physical assessment; carefully evaluate heart and lung sounds.
7. Observe urine output; color, odor, amount. If catheter in place; observe for purulent drainage around catheter site and consistency of urine in drainage bag. Check for tenderness at insertion site, pain, and swelling. Obtain sample and complete dipstick test if urinary tract infection is suspected.
8. Observe color and consistency of sputum.
9. Observe IV catheter insertion site for erythema, tenderness, pain at site, and patency of IV.
10. Observe for inflammation, erythema, warmth of affected soft tissue sites.
11. Evaluate pain; location and severity. Use pain scale.
12. Clean equipment such as stethoscope and blood pressure cuff. Place back into bag.
13. Dispose of any supplies used by placing in appropriate disposal bag (impenetrable plastic) if infection is suspected.
14. Complete hand hygiene and dispose of gloves in plastic bag.
15. Document findings; if symptoms are indicative of potential infection, call physician.

Disposing of Waste Material in the Home Setting

Equipment

- Plastic bags, heavy duty
- Disposable gloves
- Receptacle, rigid and puncture-proof
- Bleach
- Germicide

Procedure

1. Dispose of wastes contaminated with blood or body fluids.
 - a. Place waste products in impenetrable, heavy-duty plastic bag.
 - b. Remove plastic gloves by rolling inside out (so contaminated side is on inside) and drop into plastic bag.
 - c. Seal plastic bag with tie.
 - d. Discard in client's trash.
 - e. Perform hand hygiene with soap and water or germicide.
2. Dispose of body wastes, such as urine, feces, respiratory secretions, vomitus, and blood, by flushing them down the toilet. (This is true whether the toilet empties into a septic tank or a sewage system.)
3. Dispose of needles and sharp objects.
 - a. Do *not* remove needle from syringe or bend, break, clip, or recap after use.
 - b. Drop entire disposable safety syringe intact into rigid, puncture-proof receptacle provided by agency.
 - c. Complete hand hygiene.
4. Discard other trash.
 - a. Place in plastic bag.
 - b. Discard in client's trash.

NOTE: Clothes and bedding do not need to be destroyed. They are laundered separately in hot water with a 10% bleach solution added to the detergent in the washer.

Clinical Alert

All items contaminated with blood, exudates, or other body fluids should be considered to present a risk of transmission of HIV or hepatitis B. These items should be disposed of by incineration if possible. Use mechanisms for disposal of waste into normal trash only when incineration is not available.

Clinical Alert

Do not use glass bottles or plastic bottles that can be returned to store.

Bleach bottle with screw lid can be left in home for use as a sharp container. Tape closed before disposing of bottle. Small biohazard containers can be obtained from drug stores.

Caring for an AIDS or HIV Client in the Home Setting

Equipment

Gloves
 Disposable mask, gown, or apron
 Protective eyewear
 Specimen container if needed
 Plastic bag for transport of specimen
 Chlorine bleach solution (Clorox)

Procedure

1. Perform hand hygiene before and after client care and after disposing of soiled materials.
2. Don disposable gloves for any procedure.
 - a. Don double gloves if tearing is likely during the procedure.
 - b. If staff member has any type of open wound or weeping dermatitis, she or he should not administer care (even with gloves) until condition is resolved.
3. Don disposable gown or apron to protect clothing from soilage.
4. Put on mask and protective eyewear if splattering is anticipated during the procedure (e.g., suctioning, wound irrigations).
5. Collect specimens in appropriate containers. Place in plastic sealable biohazard bags.
6. Use extraordinary care to avoid puncture wounds with needles and other sharp objects.
 - a. If puncture occurs, bleed wound and wash with soap and water.
 - b. Notify supervisor immediately and fill out unusual occurrence report.
7. Transport all specimens in an impermeable container, keeping the container separate from nurse's bag and supplies.
8. Clean spills of blood and body fluids with 10% bleach solution (one part liquid chlorine bleach to nine parts water). Make solution fresh each visit.
9. Wash eating utensils (dishes and silverware) in hot soapy water. Water should be hot enough to need gloves to tolerate the temperature. No other special precautions are required. It is best to use a dishwasher, if available. It is not necessary to wash client's dishes separately.
10. Store linens and laundry soiled with body fluids in a plastic bag and then wash separately with very hot water. Use a detergent and a 10% bleach solution. (Nonchlorine bleaches such as Clorox II are acceptable for colored clothing.)
11. Dispose of gown or apron in plastic bag after completing care.
12. Take off gloves by peeling them down and turning them inside out so that contaminated side is on the inside. Place in plastic bag.
13. Perform hand hygiene.
14. Take off mask and goggles.
15. Perform hand hygiene.

Cleansing Equipment in the Home Setting

Equipment

Article to be cleansed
 Soap
 Running water
 Paper towels
 Plastic bags
 Disposable gloves

Procedure

1. Don gloves when working with equipment contaminated with any body fluid or blood.
2. First rinse article with cold running water. ► **Rationale:** Cold water releases organic material from the equipment and warm water may make it adhere to the surface.
 3. Second wash with hot, soapy water using friction.
 4. Rinse well with clear water.
 5. Dry thoroughly.
 6. Disinfect equipment or article as indicated: one part chlorine bleach (Clorox) to nine parts water.
 7. Dry thoroughly.
 8. Remove disposable gloves.
 9. Dispose of gloves (inside out) into plastic bag.
 10. Perform hand hygiene.

Clinical Alert

If durable medical equipment cannot be sterilized by ethyl oxide or autoclaved, it should be cleaned with 10% chlorine bleach solution after washing with hot soapy water.

Urinary drainage bags can be disinfected in the home. Use soap and water and clean and dry well. Antiseptic solution can be placed in the bag for a few minutes, then bag is rinsed well and dried before attaching to urinary catheter.

Teaching Preventive Measures in the Home Setting

Procedure

1. Discuss the inadvisability of allowing any person who is ill or who has depressed immune function to come in contact with the client.
2. Teach the client these appropriate hygiene principles:
 - a. Wash hands after use of toilet or contact with any body fluids.
 - b. Do not share thermometers, razors, razor blades, toothbrushes, douche, or enema equipment.
 - c. Do not cough without covering mouth.
 - d. Be careful to dispose of nasal secretions in tissue, then in plastic bags.
3. Teach these guidelines for sharing kitchens and bathrooms:
 - a. Good household cleaning practices prevent spread of infection.
 - b. Don't share eating and drinking utensils. After use, they must be cleaned with hot water (hot enough to necessitate use of gloves) and soap. Use of a dishwasher and soap is appropriate.
 - c. Kitchen and bathroom surfaces should be cleaned every day with scouring powder or with chlorine bleach solution (10%, one part bleach to nine parts water). Use disposable bathroom cups. Use covered individual toothbrush holders.
 - d. Clean refrigerators regularly with soap and water; remove old food to prevent mold.
 - e. Mop floors in bathroom and kitchen weekly. Pour dirty water down the toilet and disinfect with bleach solution.
 - f. Clean toilet, tub, and shower weekly or as often as necessary with 10% bleach solution. If urine or diarrhea spills on toilet or floor, wipe immediately with the 10% bleach solution.
 - g. Sponges used to clean floors or body fluid spills should be soaked for 5 minutes in a 10% bleach solution.
4. Teach the following principles of food preparation:
 - a. Discuss the fact that people infected with HIV may prepare food for others. They should follow usual practices for safe food preparation and be especially diligent about handwashing.
 - b. Wash hands thoroughly before any food preparation.
 - c. Do not lick fingers or taste from the mixing spoon while cooking.
 - d. Avoid unpasteurized milk (danger of contact with *Salmonella*); do not eat old or moldy food (danger of food poisoning); and carefully wash and thoroughly cook chicken.
 - e. Wash all fresh (raw) fruits and vegetables before eating.
5. Teach how to care for linens and laundry.
 - a. When clothing or linen is soiled with blood or body fluids, it should be stored separately in a plastic bag. Wash separately with very hot water, detergent, and bleach. Use Clorox II for colored clothing.
 - b. Wear disposable gloves when touching soiled clothes or linen.
 - c. Do not share used towels or washcloths, and wash separately. (Towels and washcloths are, however, safe to use after washing.)
 - d. Change towels and washcloths daily.
6. Inform client and family of measures for disposing of trash.
 - a. Flush body wastes down the toilet.
 - b. Discard dressings, diapers, Chux, or any materials soiled with secretions in a plastic bag. Discard into the regular trash.
 - c. Sharp items (e.g., razors, needles) should be placed in a rigid, puncture-proof container with a solution of 10% bleach. Incinerate when container is full. Pharmacies collect the used containers in some areas.
7. Discuss procedures for caring for pets.
 - a. Clean bird cages wearing gloves. Birds can spread psittacosis (*Chlamydia psittaci*) or *Cryptococcus*.
 - b. Clean cat litter boxes wearing gloves to prevent spread of toxoplasmosis.
 - c. Tropical fish tanks should not be cleaned by the person with AIDS to prevent spread of *Mycobacterium*.
8. Teach general principles of preventing cross-infection.
 - a. Wear gloves when handling body fluids, linens, or other objects contaminated with body fluids.
 - b. Disposable gowns or aprons protect clothing from becoming soiled.
 - c. Caregivers should not provide care when ill themselves. If this is not possible they should wear a mask when in close contact with the person with AIDS. AIDS clients are very susceptible to infections.
 - d. Maintain adequate ventilation in the living quarters.
9. Discuss steps to prevent spread of contagious disease; cold, flu, strep throat.
 - a. Clean hands thoroughly before eating or touching food, after using the bathroom, taking out trash, playing with a pet, or being in contact with someone who is ill.
 - b. Use tissues when sneezing or coughing, cover mouth and nose, and discard tissue immediately. If tissue is not available, cover mouth and nose with bend in your elbow or your hands. Clean hands immediately.
 - c. Avoid contact with others if you are ill.
 - d. Maintain up-to-date vaccinations.
10. Medical supplies should be kept in a clean, dry location. If refrigeration is required, place medication in sealed plastic storage bag.

Teaching Safer Practices to IV Drug Users

Procedure

1. Inform persons of risk behaviors and factors associated with IV drug use.
 - a. Direct transmission occurs with shared needles and syringes; permits blood-to-blood contact, the most direct method of transmitting the AIDS virus and hepatitis B.
 - b. Transmission to sexual partners; permits contact of body fluids.
 - c. Transmission to fetus during pregnancy.
 - d. Suppression of the immune system caused by alcohol or drug use.
 - e. Impaired judgment while under the influence of drugs.
2. Teach IV drug users how to reduce the risk.
 - a. Do not share needles or syringes with others.
 - b. Clean needles and other equipment vigorously. Wash twice with full-strength bleach or alcohol; rinse twice with water.
 - c. Boil needles and other equipment for 15 minutes.
 - d. Do not borrow or use needles or equipment from others, even if they appear healthy or say that they do not have AIDS.
3. Teach basic health maintenance measures.
 - a. Decrease use of all immunosuppressive drugs (marijuana, speed, cocaine, alcohol).
 - b. Maintain an adequate, nutritionally sound diet.
 - c. Reduce stress on self through stress-reduction practices or removing self from a stressful situation (living with others who routinely use drugs).
 - d. Obtain regular medical and dental care.
 - e. Follow lifestyle that provides adequate rest and exercise.
 - f. Obtain counseling to assist in living life without dependence on drugs.

DOCUMENTATION for Home Care Adaptations

- Document findings on appropriate home care forms
- Therapies provided and client response
- Follow treatment plan and document goal achievement
- Client status, physical findings, ability to care for self
- Clinically significant observations stated objectively related to potential infection
- Clinically significant observations related to environmental findings related to potential infections

CRITICAL THINKING Application

Expected Outcomes

- Clients do not acquire infections during home care visits.
- Early detection of potential infections is identified through appropriate assessment techniques.
- Infections are treated appropriately and not transmitted to other home care clients or the nurse because effective preventative measures are utilized.

Unexpected Outcomes

There are potential infection sources in the home environment.

Critical Thinking Options

- Explain the necessity of keeping the environment free of potential organisms, by keeping it clean and uncluttered.
- Instruct the client and family members on proper hand hygiene technique.
- Explain and develop a plan for family members to discard soiled dressings, diapers, etc., to prevent potentially infecting other household members.

GERONTOLOGIC Considerations

- Social isolation resulting from infection control requirements is more intense with the elderly. They need frequent contact with healthcare workers. Sometimes being ill is the only attention they receive.
- Elderly clients can become confused in the hospital, and when placed in isolation, there is an even greater risk. Frequent monitoring for safety issues is necessary.
- Frequent explanations of why isolation is necessary are important for the elderly. They may have a lapse of memory and forget earlier discussion about isolation.
- Ensure that call lights are easily accessible and the client understands how to call for assistance. They may have impaired hearing and sight, which can interfere with communications.

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- LVN/LPNs and CNAs may be assigned to clients requiring infection control precautions and barriers. Ensure that all healthcare workers have been properly educated in infection control procedures before assigning them to clients requiring these measures.
- It is the RN's responsibility to make assignments that take into account the type of isolation precautions and potential cross-contamination of other clients in the care of the healthcare worker. For example, the same healthcare worker should not take care of a client in contact isolation and an immunosuppressed client.

Communication Matrix

- Ensure that appropriate designations are posted on the door of the room indicating the type of isolation precautions necessary for the client.

- Indicate the type of isolation precautions on the client's chart.
- During shift report and team report, review the type of isolation precautions being maintained for the client.
- Inform and instruct all visitors on the isolation precautions.
- Monitor that all hospital staff practice good hand hygiene technique. Review appropriate technique with those who do not practice these techniques.
- Review isolation precautions, particularly standard precautions, with all new personnel and on a regular basis with all personnel to ensure compliance with hospital policy.
- Monitor healthcare workers for appropriate use of gloves, masks, and gowns when caring for clients in isolation. Instruct healthcare workers in proper use of these items when providing client care.

CRITICAL THINKING Strategies

Scenario 1

You are assigned to care for two clients. One client has just returned from surgery for an abdominal resection. The second client is hospitalized with an acute case of tuberculosis.

1. Is this assignment appropriate, considering the two diagnoses? Provide a rationale for the answer.
2. What special precautions will you take when providing care for these two clients?
3. CDC guidelines are specific for clients with tuberculosis. Identify the differences in providing care for this client versus other clients requiring barrier nursing.

4. Describe the procedure for leaving the tuberculosis client's room. Provide a rationale for the prioritized steps.

Scenario 2

You are assigned to take two clients' vital signs, complete a focus assessment, provide hygienic care, monitor IVs, and complete a dressing change for a client with an abdominal resection.

1. What task will have priority with this assignment?
2. Develop a time management plan and provide a rationale for the time frames and activities.

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. When assessing the following client care situations, which one would require the nurse to wear goggles?
 1. Changing a dressing.
 2. Administering an IM injection.
 3. Catheterizing the urinary bladder.
 4. Emptying a Foley drainage collection bag.
2. A client is hospitalized with complications of AIDS. The best way to clean up a hazardous waste spill is to use
 1. Waterless antiseptic.
 2. 1:10 bleach solution.
 3. Soap and water.
 4. Alcohol solution.
3. Isolation is used for hospitalized children who
 1. Have chicken pox (varicella).
 2. Are immunocompromised.
 3. Are coughing or vomiting.
 4. Have tuberculosis.
4. When working with infants, the most important action for breaking the chain of infection is
 1. Using sterile technique.
 2. Isolation of ill people near the infant.
 3. Treatment with antibiotics.
 4. Proper hand hygiene.
5. When caring for a person with AIDS in the home, the best way to dispose of contaminated needles and syringes is to
 1. Break the needle from the syringe and dispose.
 2. Place them in a puncture-resistant container in the home.
 3. Recap them and bring them to an appropriate disposal area.
 4. Soak them in bleach and then dispose of them in the trash.
6. A nurse is giving an emaciated client an injection. While withdrawing the needle from the site, the needle slips and pierces the nurse's finger. The action most appropriate is to
 1. Recap the needle and save it for laboratory analysis.
 2. Break the needle and discard it in a puncture-proof container.
 3. Obtain an order for the client to receive gamma globulin.
 4. Wash the finger with an antiseptic and water solution.
7. The nurse observes a nursing assistant putting on gloves to deliver a lunch tray to a client with AIDS. The therapeutic intervention would be to
 1. Commend the nursing assistant for the action.
 2. Explain to the nursing assistant that gloves do not need to be worn if there is no client contact.
 3. Ask the nursing assistant to wear a gown, also.
 4. Make sure the nursing assistant does not touch the client.
8. The most frequent mode of transmission of HAI (nosocomial) infections such as vancomycin-resistant enterococcus (VRE) in healthcare facilities is
 1. Soiled linens.
 2. Hands of healthcare workers.
 3. Medical equipment.
 4. Food trays.
9. When leaving an isolation room, prioritize the steps to maintain proper protocol.
 1. Hand hygiene.
 2. Taking off your mask.
 3. Removing your gloves.
 4. Untying waist strings of the gown.
10. To prevent the spread of infection between clients, the home care nurse should:
 1. Use only disposable supplies and equipment in the home and dispose of them in the home before leaving.
 2. Take out necessary supplies from the bag and bring them into the house, leaving the bag in the car.
 3. Take needed supplies from the bag and place on clean work area, then close bag immediately.
 4. Wear clean gloves throughout the visit, and place them in the garbage as you leave the house.

Disaster Preparedness— Bioterrorism

LEARNING OBJECTIVES

1. Discuss the concept of preparedness for a terrorism attack.
2. List the effects on infrastructure that may result from a mass casualty incident.
3. Compare and contrast external and internal communication systems.
4. State the chain of command and reporting requirements when a mass casualty incident occurs.
5. Differentiate between a chemical and a biological attack.
6. Discuss diversity considerations when healthcare workers are responding to a terrorist event.
7. List at least two ethical issues you might encounter during a mass casualty event.
8. List components of a home safety plan.
9. Discuss earthquake safety principles.
10. Identify two diarrhea-related diseases.
11. List signs and symptoms of various biological agents and describe how to distinguish between them.
12. Discuss the clinical features of smallpox.
13. Identify the high-risk groups for smallpox vaccination.
14. Demonstrate the procedure for smallpox vaccination (include reconstituting *vaccinia* vaccine).
15. Describe the steps of collecting and transporting a potentially contaminated clinical specimen.
16. Describe the major agents of a chemical attack.
17. List the primary interventions necessary to care for the psychological needs of disaster victims.
18. Describe how to measure external radiation levels.
19. Review the equipment included in Standard Precautions.
20. List the steps of decontamination via triage.
21. Explain the protective equipment necessary for biological exposure (individualize for anthrax, plague, botulism, and smallpox).
22. Differentiate decontaminating victims after a biological and chemical attack.
23. Demonstrate decontamination procedures for victims of a radiological attack.
24. Discuss establishing public health parameters for triage.
25. Explain the term triage and list the steps of triage.
26. Demonstrate the steps of treating life-threatening conditions.
27. Discuss post-traumatic stress disorder.

TERMINOLOGY

Aerosol very fine liquid or solid particles suspended in air—small particles in a gaseous medium.

Airborne microorganisms spread by droplets dispersed in the air; a deliberate release of pathogens; could be carried out by using an aerosol delivery system.

Antimicrobial an agent that prevents the development or pathogenic action of microbes.

Antidote a substance that neutralizes a poison or the effects of a poison.

Bioterrorism the planned, deliberate use of a chemical or biological agent (bacteria, virus, fungi, or toxin) with the intent to harm or kill people. Bioterrorism is a general term used to encompass all forms of terrorism.

Centers for Disease Control and Prevention (CDC) a U.S. government agency with the stated purpose of preventing the transmission of communicable diseases. This agency is responsible for identifying and disseminating standards and guidelines for isolation precautions.

Chemical terrorism use of a chemical agent (nerve, blood, blister, volatile) with intent to harm or kill people.

Communicable disease a disease that can be transmitted person-to-person.

Community disaster plan a document that specifies who is in charge, lines of communication, and agencies and resources that will be involved.

Contamination introduction of disease, germs, or infectious materials into or onto normally sterile objects.

Decontamination process of removing contamination from people, equipment, or environment—usually done through a physical (i.e., shower) or chemical process.

Disaster an event of such magnitude that essential services are disrupted and current resources are overwhelmed.

Emergency any event or situation that occurs as an unexpected and sudden incident, demanding immediate action.

EMTALA Emergency Medical Treatment and Labor Act—a federal law to stop hospital EDs from refusing to treat poor or uninsured clients or from transferring clients to other facilities before their medical conditions have stabilized.

Equivalent dose a measure of the effect that radiation has on humans—takes into account the type and absorbed dose of radiation.

Exposure inhalation or contamination by a substance that contains a biological, chemical, or radioactive agent.

Federal Bureau of Investigative (FBI) investigative agency of United States Department of Justice; it has authority and responsibility to investigate specific crimes, such as a bioterrorism event.

Federal Emergency Management Agency (FEMA) primary or lead federal agency that responds to a disaster, such as a terrorism incident.

First responder first trained personnel to arrive at an emergency.

Gray a measurement of the absorbed dose of radiation; used more often than RAD—(1 Gy = 100 RADS).

Hazardous material any substance that is potentially toxic to a biological system.

HAZMAT model hazardous materials; this model is used for situations involving certain toxic or chemical exposures.

Homeland Security the Department of Homeland Security (DHS) coordinates all activities related to a terrorist attack.

Immunization process of rendering a person immune, usually done through vaccination.

Incident Command System (ICS) local and national command structure that organizes emergency responses.

Incubation period time between infection from a microorganism and onset of symptoms.

Infection establishment of a disease process that involves invasion of body tissue by microorganisms, reaction of tissues to their presence, and to toxins generated by them.

Inhalation exposure to a substance through the respiratory tract.

Isolation practices or actions designed to prevent transmission of communicable diseases.

Ionizing radiation radiation that has the energy to cause atoms to lose electrons and become ions—alpha, beta, gamma, and x-rays are examples.

Isotopes elements that have neutrons (they have neither a positive nor negative charge). Not all isotopes are radioactive; those that are, are called radionuclides. Cobalt-69 is an example of a radioactive isotope.

Mass casualty incident (MCI) an incident or emergency event associated with many casualties (airplane crash, terrorism, chemical spill) that has a negative impact on emergency resources.

Microorganism a minute living body, such as a bacterium, protozoan, or virus, not perceptible to the naked eye.

NBC military acronym for nuclear, biological, and chemical weapons.

Nerve agent chemical agent that acts on the body by disrupting normal function of the nervous system.

Occupational Safety and Health Administration (OSHA) section of the Department of Labor that develops and implements

regulations requiring employers to have safety policies and to provide training and personal protective equipment to employees who may be exposed to toxic substances.

Outbreak critical incident in which infections occur above an established level and are caused by the same infective agent.

Pandemic denotes a disease that affects the population of a large region, country, or continent.

Pathogen microorganism that can cause disease; may be bacteria, fungi, parasites, or viruses.

Percutaneous agent substance that can be absorbed through the skin.

Personal protective equipment (PPE) equipment for protection of emergency personnel; includes gloves, masks, gowns, eye shields, biohazard bags, and in some cases, head and shoe covers.

Poison any substance that enters the body by absorption, ingestion, inhalation, or infection and interferes with normal physiological functions.

RAD radiation absorbed dose—the unit of measure for radiation exposure.

Radiation energy in the form of waves or particles that is emitted from radioactive material or equipment.

Radioactive contamination radioactive material distributed over some area, equipment, or person; must be decontaminated.

Radiation dose quantity of radiation energy deposited in a material by the radiation to which victim is exposed.

REM roentgen equivalent man—the unit of dose or measure—takes into account type of radiation producing the exposure.

Sodium hypochlorite 0.5% diluted bleach is the active ingredient used for decontamination.

START acronym that stands for “simple treatment and rapid triage,” an initial triage system used for triaging large numbers of victims.

Standard (Universal) Precautions a system of disease control; assumes that direct contact with body fluids is infectious and recommends a series of procedures to protect the staff.

Terrorism the use of force or violence against people or property in violation of the criminal laws of the United States for purposes of intimidation, coercion, or ransom (FBI).

Threat assessment an assessment of a community’s vulnerability and risk potential.

Toxin poisonous substance produced by a living organism.

Trauma multisystem condition or injury that is potentially life-threatening to the individual.

Vaccine preparation of a killed or weakened microorganism used to induce immunity against disease.

Vesicles blisters on the skin.

Virulence the power of a microorganism to cause disease in a given host.

Virus an infectious microorganism that normally lives within other living cells and cannot reproduce outside the cell.

Weapons of mass destruction (WMD) nuclear, biological, chemical, incendiary, or conventional explosive agents that pose a threat to health, safety, food supply, property, or the environment.

INTRODUCTION

America's world changed on September 11, 2001. From this time, our greatest challenge became to adopt the awareness that we are no longer invulnerable; that biological, chemical, and nuclear terrorism is a future reality; and that we must change our perspective of how to function in the world. Senator Bill Frist stated it clearly: "The United States faces a grave and growing threat from bioterrorism."

Years ago, this chapter would never have been written. Today, a page in history has been turned, and the medical community—indeed, the world—must face terrorism and the probability of disasters caused by terrorism. We cannot predict—we can prepare. In order to steer a course toward a viable future, we must be prepared to cope with such a disaster.

Preparedness for a terrorist-caused disaster is critical for containment and protection of the population. There must be coordinated emergency preparedness plans in place in order that a prompt and effective response to a biological, chemical, or radiation attack is initiated.

Meeting this new challenge will require preparedness in all communities, cities, and states in the United States of America. Nurses are an important part of this response.

NATURAL DISASTERS

Although disasters may be natural or man-made, there are numerous definitions of a disaster. For our purposes, natural disasters will be examined regarding how they affect health and health services. From this standpoint, the type and timing of a disaster event will create the types of injuries and illnesses that occur. Disasters that have a prior warning, such as hurricanes or floods, generally have fewer injuries and deaths than those that occur with little or no warning, such as tsunamis or earthquakes. These disasters tend to have more casualties because the individuals have little time to prepare or to evacuate before the disaster strikes. Of course, there may be a combination of disasters like that which occurred in New Orleans; it started with a hurricane and ended with a severe flood.

Natural disasters have the potential to significantly affect the public health of the people, since access to medical care can be severely limited and resources such as food, water, and medicines become unavailable or depleted.

Natural Disasters

- Earthquakes
- Hurricanes
- Floods
- Tornadoes
- Tsunamis
- Volcano eruptions
- Wildfires
- Landslides and mudslides
- Extreme heat and snow/cold

Disaster Defined

Disaster is defined as an event of such magnitude that essential services are disrupted and current resources are overwhelmed. Disasters may be natural (as listed) or caused by human actions such as civil disturbance, a hazardous material incident, or act of terrorism.

Whatever the cause, disasters have several characteristics in common: They are unexpected and there has been little or no warning; lives, public health, and the environment are endangered; and emergency services and personnel must be called to action if not available during the initial stages of the disaster. The terrorist attack that occurred in Washington, D.C., and New York on September 11, 2001, and the Katrina disaster in 2005 were just such events, events that carried an unforeseen and immediate threat to public health and required the intervention of others to provide outside resources.

PUBLIC POLICY

Mass Casualty Characteristics

- Mass casualty incidents are community-wide incidents—not confined to individual hospitals.
- Event occurs in local community.
- Local government provides "first responders."
- State and federal government will be involved if incident is large enough.
- Hospitals are last link in community response to mass casualty incident.
- Hospitals will receive most seriously injured and ill casualties.

Hospitals are the most comprehensive community health resource. As the last link in the community chain of readiness, the hospital is the organization that will have to, by default, make up for the inadequacies in community preparedness.

Hospitals must follow federal legislation known as EMTALA (the Emergency Medical Treatment and Labor Act), which governs what a hospital must do when clients present themselves. If the emergency department is closed because of client overload or to protect the health of current clients, by federal law the hospital is not allowed to turn away clients. EMTALA ensures that all individuals who appear at an emergency department must be screened, evaluated, and stabilized before being transferred. If the State Survey Agency determines that a violation has occurred, it begins the process to terminate the hospital's Medicare provider agreement. Triage is not equivalent to medical screening, so a hospital could easily be overwhelmed in a disaster, even when victims are processed in the field via triage.

Also, this legislation is still in place even if the community designates some hospitals to receive victims of a disaster and others to remain open to clients not exposed to the contaminant. Authorities are suggesting that an open dialogue with the federal government (officials of the Department of Health and Human Services [HHS]) to revise provisions of EMTALA is necessary, now that the potential for mass casualty disaster is present.

Lessons From Natural Disasters

The implications of natural disasters for nurses and other healthcare providers are profound. For example, throughout a storm-devastated area, nurses were called upon to provide hospital care under extreme conditions caused by the lack of electricity, food, water, and medical supplies, as well as the inability to evacuate patients. Other nurses who assisted at evacuation centers were overwhelmed by the surge of sick and injured.

Potential Threats From Natural Disasters

Certain natural disasters, such as earthquakes and tornadoes, are very unpredictable; others, like Hurricane Katrina in 2005, are carefully tracked. As a major storm approaches, the national weather agencies estimate the potential for major damage and disruption (i.e., wind velocity, snow depth, temperature, tidal surges), which are widely publicized by the media. The lesson is to hope for the best, but prepare for the worst. Soon after Katrina, another hurricane threatened the region. When residents of several Texas cities followed evacuation orders, they experienced traffic delays, gasoline and water shortages, and other obstacles during their disorderly evacuation.

Do Not Assume Government Agencies Will Provide Immediate Relief

The government agencies involved with disaster relief include local police, National Guard, Federal Emergency Management Agency (FEMA), federal troops, the U.S. Coast Guard, and many nongovernmental organizations, such as the Red Cross. The coordination among all these organizations has often failed in a morass of bureaucracy and red tape. Several dire predictions have been made

concerning the potential threat to an area from a disaster, with effective response plans either not in place or that have not been tested.

Learn to Cope Without Electricity and Water

Storms involving strong wind, snow, or ice usually disrupt electrical power. So do earthquakes, wildfires, and floods. A severe hurricane's winds can topple trees into power lines and blow down cell phone towers. A storm surge and flood can disable emergency generators and disrupt water and sewer service. Normal communications are crippled as cell phones and cordless phones do not operate, nor do television, air conditioning, refrigeration, hospital equipment, or services that depend upon electricity. The ability to communicate with the "outside world" may be extremely limited, leaving hospitals and evacuation centers unable to adequately communicate their emergency needs or to learn when and in what form they could expect assistance.

Disruption of the water service could result in extreme hardship to many thousands of stranded survivors. Many may have to endure several days without adequate water, ice, or food until they are either rescued or make their way to an emergency center. The implication of the loss of utilities for the individual nurse is that you must keep an emergency supply of water at home, in your automobile, and at work (in case you are stranded at work or in transit) adequate for 3 days. Refer to "Creating a Safety Plan for Disasters," page 470, for a checklist of emergency supplies.

Another lesson learned from natural disasters is that healthcare professionals who may be called upon to assist with disaster relief should be up-to-date with tetanus, hepatitis A, and other preventative injections.

Bioterrorism Response Act

The Public Health Security and Bioterrorism Response Act of 2002, signed into law in June 2002, authorized \$4.3 billion to combat terrorism. As of January 2005, the U.S. Department of Homeland Security has provided \$2.2 billion in counterterrorism grants to the states. The federal government has focused on three components: detection, treatment, and containment.

One aspect of the law is to allocate funds for the training of healthcare workers, including nurses. The American Nurses Association (ANA), together with HHS, has established the National Nurses Response Team (NNRT). This team, made up of a large number of nurses, is poised to respond to any major disaster, such as an anthrax or smallpox attack.

These nurses, as well as other healthcare professionals, will be "federalized," thus receiving umbrella coverage for licensure, liability, and expenses. Deployments will be limited to 2 weeks. In the law-signing ceremony, President Bush pointed out that biological attacks could occur covertly, and healthcare professionals may well be the first to recognize such an attack. He went on to say, "The speed with which they detect and

respond to a threat to public health will make the difference between containment and catastrophe."

To encourage hospitals to be ready to combat bioterrorism, the federal Health Resources and Services Administration is giving millions in grants. The major expenditure is \$800,000 to each of 10 hospitals designated as disaster resource centers who will coordinate emergency training and preparedness. These centers will be required to implement procedures that can deal with a "worst case scenario" or a disaster affecting hundreds of thousands of casualties.

The Department of Homeland Security, created in September 2001, coordinates multiple agencies and programs into a single integrated agency focused on protecting the American people and our homeland. This organization directs a comprehensive national strategy to connect agencies at all levels. There are 15 major agencies, including Federal Emergency Management Agency (FEMA), Transportation Security Administration, Customs and Border Protection, U.S. Coast Guard, and the Secret Service.

The Disaster Medical Assistance Team (DMAT) is a regional group under the control of Homeland Security. These groups

are trained to activate as a unit that can deploy for any type of disaster; they are trained to provide care for any type of casualty. The three major responsibilities of DMAT are triage, staging, and providing medical care.

Nurses are an essential part of the disaster team and must be prepared to function in the event of either a man-made or natural disaster. To accomplish this effectively, nurses must have a personal and family disaster plan, for it is difficult to care for others if one's own family is not safe.

DISASTER IMPACT ON THE INFRASTRUCTURE

When a disaster occurs, the impact on the infrastructure may be severe. Services and delivery systems, transportation, utilities, fuel, food, water supplies, and communication systems may be affected. Disaster experts point out that when one of the support systems breaks down, it has a domino effect and all elements of the infrastructure could be affected. According to Community Emergency Response Team (CERT) information, some of the ways in which the infrastructure can be affected after a disaster are shown below.

Service	Effect
Transportation	Inability to get emergency service personnel into the affected area Inability to transport victims away from the area
Electrical	Increased risk of fire and electrical shock Possible disruption to transportation system if downed lines are across roads
Telephone	Lost contact between victims, service providers, and family members System overload due to calls from/to friends or relatives
Water	Disruption of service to homes, businesses, and medical providers Inadequate water supply for firefighting Increased risk to public health if there is extensive damage to the water supply or if it becomes contaminated
Fuel supplies	Increased risk of fire or explosion from ruptured fuel lines Risk of asphyxiation from natural gas leaks in confined areas

The Community Emergency Response Team (CERT) concept was originally developed and implemented by the City of Los Angeles Fire Department after the 1987 Whittier Narrows earthquake. They realized that citizens would likely be on their own at least during the early stages of a catastrophic disaster, and thus there was a need for a Disaster Preparedness program. So far, thousands of people and hundreds of teams have been trained.

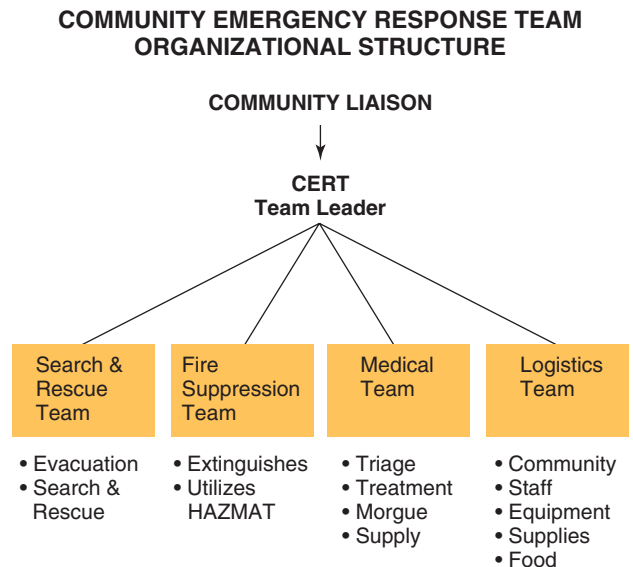

Disaster Mitigation

When examining how to mitigate the effects of a disaster, safety precautions and preparation must be considered first, that is, personal safety, home preparation, and community preparation. Individual safety and home preparation need to be dealt with on a personal level. Focusing on both natural disasters, such as earthquakes and floods, and man-made disasters, each family or community should develop a Preparedness Plan. In addition, each healthcare facility must have its own Preparedness Plan, developed enough to implement under the chaotic circumstances of a disaster.

The purpose of this chapter is to focus on natural and man-made disasters, such as a terrorism event, and how the medical community, specifically nurses, could develop their own Preparedness Plan to cope with a mass casualty disaster.

Community Response Plan

Apart from personal safety and home preparation before a disaster, a planned community response is a critical element. A CERT that is trained and prepared to intervene will do more to mitigate disaster outcomes than any other planned approach. A CERT organizational structure would look like this:

Strategic Plan for Responding to Biological or Chemical Terrorism

The CDC has formulated a Strategic Planning Workgroup to combat the deliberate dissemination of biological or chemical agents. The plan encompasses detection and surveillance, laboratory analysis, emergency response, and communication systems. Success of the plan hinges on the relationship between medical and public health professionals working together for emergency management.

Five Focus Areas in the CDC's Strategic Plan

- *Preparedness and Prevention:* Emergency coordinated preparedness teams are to be developed in all cities and states in order to respond effectively. The CDC will assist in developing tools and strategies to prevent and mitigate illness and injury.
- *Detection and Surveillance:* Early detection is critical for prompt responding. The CDC will develop disease surveillance systems, as well as mechanisms for detecting, evaluating, and reporting suspicious events. This will be done in partnership with front-line medical–hospital emergency professionals. Reporting of unexplained injuries and illnesses will be part of routine surveillance systems.
- *Diagnosis and Characterization of Biological–Chemical Agents:* The CDC and its partners will create a multilevel laboratory response network to analyze biological agents. Diagnostic technology will be disseminated to state laboratories for diagnostic confirmation and reference support for terrorism response teams.
- *Response:* The CDC will develop a comprehensive public health response to a terrorist event that will encompass

investigation, medical treatment, prophylaxis for infected persons, and disease prevention and decontamination measures.

- *Communication Systems:* The ability of the United States to be prepared and intervene effectively when a terrorist event has been identified is dependent on well-trained healthcare and public health professionals having access to emergency information via state-of-the-art communication systems. Effective communication with the public is also essential. Through this sophisticated communication network, the CDC will disperse information regarding disease outbreaks, dissemination of diagnostic results, and emergency health information.

In 2004, the Homeland Security Council, in partnership with the Department of Homeland Security and federal, state, and local agencies, developed a series of planning scenarios for various types of disasters. They included a general description, timeline dynamics, secondary events, key implications, interventions, and recovery. These scenarios were designed to provide the foundation structure for the development of national preparedness standards from which capabilities can be measured. Please check the Homeland Security Web site for more information about disaster planning for your facility.

Home Emergency/Disaster Kit*

Prescription medications (to last a minimum of 1 month)
 First aid kit and handbook; gloves for work and protection
 Bottled water (1 gallon/person/day; minimum 15 days)
 Nonperishable foods that do not have to be prepared;
 comfort snack foods high in protein and calories; can
 opener
 Extra pet food
 Battery or hand-cranked radio, extra batteries
 Emergency lighting (flashlights, oil lamps)
 Cellular phone or CB radio
 Emergency cash in small bills
 Emergency phone numbers
 Tools and supplies: whistle (to alert rescuers to your
 location); wrench (to turn off water and gas); duct
 tape (for broken windows, etc.); buckets and heavy
 plastic bags for waste
 Blankets, sleeping bags, warm clothing, rain gear
 Comfort items (games, books, teddy bears, etc.)
 Special items for adults (contact lens equipment, glasses)
 and children (formula, diapers, powdered milk)
 Place items in waterproof containers that are easily
 accessible
 Replace perishable items (water, food, medications,
 batteries) yearly

The Joint Commission Standards

The Joint Commission has focused on security management and has developed a plan that describes how the organization will establish and maintain a security program to protect those involved. The plan provides for designation of personnel who will report and investigate security incidents, provide identification for participants, and control access and egress to sensitive areas. As of 2005, this plan has been modified to include communication and coordination between healthcare organizations. Now, to meet The Joint Commission standards, hospital emergency departments are expected to include four specific phases of disaster management: mitigation, preparedness, response, and recovery. They are also expected to participate in at least one annual drill.

The Joint Commission, together with Homeland Security, has insisted that hospitals strengthen their disaster plans. Hospitals that are renovating or expanding must include new features like decontamination showers, personal protective equipment, hurricane-resistant glass windows, and better power generators. Hospitals must also develop a plan to recover from a disaster and return to predisaster status.

Hospitals Must Be Disaster Ready

A major step in creating a disaster plan is to evaluate the individual hospital's vulnerability in different situations. For example, a hospital on the San Andreas fault in northern California would be vulnerable in different ways than a hospital on the Florida coast. These aspects should be taken into account when a disaster plan is formulated. The plan should also be open, up-to-date, and frequently examined. One consultant on

*The Department of Homeland Security (DHS) has developed the READY.gov Web site. You can find an emergency planning and preparation guide on this site.

TABLE 15-1 Disaster Preparation

	Focus of Concern-Safety	Preparation and Coping
Power	<p>Electricity—Millions may lose power for days</p> <p>Gas—Natural gas, the main source of heat for many, will be lost when gas lines rupture</p> <p>Gas may leak into homes, especially from fallen water heaters</p> <p>Oil—Damaged oil refineries or oil lines could catch on fire—no oil available</p>	<p>Have flashlights and batteries or oil lamps on hand</p> <p>Turn off gas if you smell it</p> <p>Carefully anchor a gas-powered water heater</p> <p>Have wood available to burn for heat if you are in a cold climate</p>
Structures	<p>Homes—could become uninhabitable, especially after an earthquake</p> <p>Inspect any damage before living in structure</p> <p>Schools—Many do not yet meet current standards for seismic retrofitting</p>	<p>Bolt down home to foundation or refit to meet seismic requirements</p> <p>Have buildings inspected and subsequently reinforced</p> <p>Attach large pieces of furniture to the wall</p> <p>Plan safe areas in the home (basement) for tornadoes, high winds, or hurricanes</p> <p>Protect window glass with wood shutters, etc.</p> <p>Keep an ax close in case you have to break out of structure</p>
Communication	<p>Land lines—Most may survive, but if there is an earthquake or flood, they will be interrupted</p> <p>Power grid—If down, no calls will go through</p> <p>Wireless—Mobile phone towers could topple, leaving dead zones</p>	<p>Have at least one phone that does not require electricity</p> <p>Keep extra charged battery for cell phone</p> <p>Have wind-up radio or extra battery-powered radio to receive information after disaster</p>
Water	<p>If water comes into the home by pipeline, these could be interrupted or destroyed for weeks or months</p> <p>Wells could be destroyed by a disaster</p>	<p>Keep 1 gallon pure water/person/day for a minimum of 15 days</p> <p>Have a portable water purifier on hand to make potable water from pools, ponds, creeks, etc.</p>

disaster planning says if the plan cannot be reduced to a one-page flowchart, it is probably too complicated.

DISASTER MANAGEMENT

Everyday communication systems are likely to be overwhelmed in a disaster. Preparing for this eventuality by establishing backup and redundant communication systems is essential.

First responders will be local. They will work in conjunction with the state and federal organizations, and therefore, there must be an integrated system of in-hospital and out-of-hospital team members with state and federal agencies.

Local systems, both in and out of the hospital, will comprise the critical human infrastructure for responding to weapons of mass destruction (WMD) incidents. Communication coordination will be an essential component in this infrastructure system. One measure is to include a 24-hr wireless radio dedicated communication system to communicate with other healthcare facilities if telephone lines and the Internet do not function.

Communication among the triage team (out-of-hospital) establishing victim care priorities, the hospital or treatment staff (in-hospital), and state and federal agencies' forensic investigation needs must also be established as a cooperative

effort. Training through drills and scenarios would provide practice so that these vital communication functions would be implemented instantly if there were to be a WMD incident.

Following from the local communication structure, where there should be one single community-identified person or small group in command acting as liaison agent, the state and federal response teams will be integrated into the communication system. An example of a local system used nationally might be the Incident Command System (ICS), commonly used among EMS personnel. It is a logical management command and control structure that should be part of hospital planning. Specific roles and positions carry specific duties and responsibilities. Each position has a prioritized list of tasks that are checked off as they are completed. When an emergency occurs, the "incident commanders" take command. They can, in turn, appoint liaison or safety officers or any other position to communicate back to any local or regional ICS, according to the needs created by the emergency. This system organizes emergency responses in five categories: command, planning, operations, logistics, and administration.

A new program introduced by the CDC expands on the ICS. This program, National Incident Management System (NIMS) or NIMS, includes guidelines that all community

organizations, including healthcare facilities, are required to follow if they receive grant funds for disaster preparation. All employees who will be involved in disaster response must show evidence of having learned about the NIMS guidelines.

Hospital Evacuation Plans

Evacuation plans must be in place with a designated authority who will order the implementation. There are several types of evacuation:

- *Shelter in Place:* Staying where everyone is may be the safest plan, especially if there is a known contaminant released in the area or it is too dangerous to leave due to a storm, hurricane, etc.
- *Moving Either Up or Down Levels:* Moving all people (clients, staff and visitors) to another, safer level. Examples

are moving up to avoid flood waters or down to the basement to take shelter from an airborne attack.

- *Total Evacuation:* Removing all people from a building and relocating them to a safe area.

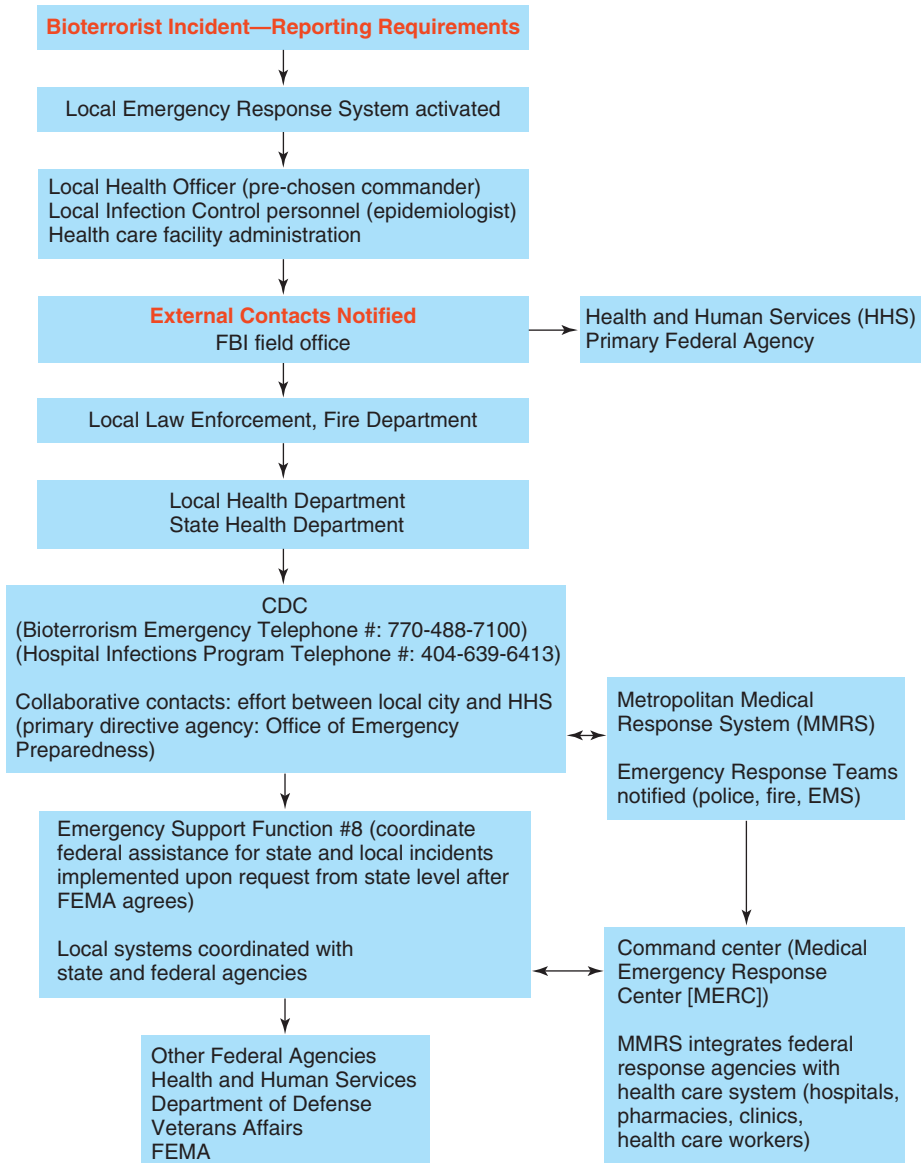

Once the evacuation plan is in place, the staff must be drilled on a regular basis so that the plan may be carried out in safety.

The hospital should also have a plan to accommodate special populations if they must evacuate the hospital. For example, if they must evacuate babies, they should have on hand special aprons that hold several babies in pockets.

Internal (or In-Hospital) Communication

Hospitals will have to expand their sphere of influence to include community-level teams. They must have an ongoing, open channel of communication with emergency response

MASS CASUALTY COMMUNITY-WIDE COMMUNICATION NETWORK

teams who will have been notified first of a mass casualty incident. A community-wide network, all using the same channel of communication, is necessary.

Family and friends, calling to learn about their loved ones after the arrival of casualties, will rapidly overload the system and isolate the hospital. To cope with this eventuality, a single communication site for obtaining victim and locator information should be established. The Red Cross or comparable organization could serve as this third-party, off-site source of information.

A clear and open information system, using both telecommunications and a position-to-position cascade in the event of the primary system being overloaded, is necessary. This cascade should be designated by position (e.g., emergency room supervisor), not person, due to turnover, multiple shifts, and personnel reassignment during a disaster. One hospital instituted a text message alert system by pager that could be sent to many personnel at one time. In addition to a communication system being established, adequate equipment, such as cell phones, walkie-talkies, even runners, must be available because current phone land lines may be totally overwhelmed.

TRIAGE SYSTEMS

Triage is from a French word (*trier*) meaning to sort. It is a medical process of prioritizing treatment urgency. One example of a triage system is START, an acronym for “simple triage and rapid treatment.” This is a standardized system that provides a framework for triage decisions, especially useful for triaging large numbers of victims at an emergency incident. START was developed in the 1980s in California as a way of preparing for a disaster.

Emergency department personnel use the triage system to quickly assess large numbers of people with multiple problems. Rapid identification in the hospital is important to determine which clients require immediate treatment and which can safely wait.

The three-level triage system has been used for years to differentiate the levels of emergency cases waiting to be seen. Now, the five-level system appears to be preferred because it decreases the ambiguity of the middle level of emergency care (where the majority of casualties would fall).

There are several methods of categorizing casualties according to the three-level system. One option is as follows:

1. **Emergent** triage refers to a life-threatening or potentially life-threatening condition that requires immediate treatment. These conditions could include multisystem failure, cardiopulmonary arrest, bleeding, airway loss, multiple trauma, severe shock, cervical spine injury, and so on.
2. **Immediate** or Urgent triage is not life-threatening or acute, but refers to clients who need treatment as soon as possible (within 2 hr). These clients have stable vital signs and there is no immediate crisis. This category would include fever, minor burns, lacerations, significant pain, and fractures.
3. The third category is **Nonemergent** or Nonurgent, including clients who have a condition that would not be affected by a delay in treatment. These are clients with chronic or minor injuries, strains, rash, back pain, and so on.

A second way of implementing the three-level strategy of triage is as follows:

1. **Immediate (I)**—the victim has a life-threatening injury (airway, bleeding, or shock) that demands immediate attention (the same as Emergent).
2. **Delayed (D)**—an injury that does not jeopardize the victim’s life if definitive treatment is delayed.
3. **Dead (DEAD)**—no respiration after two attempts to open airway. (CPR is not performed in a disaster environment because it demands extensive resources, including personnel time.)

The above strategy will probably be the one used (if a three-level system is adopted) if there is a mass casualty disaster, because **the goal of triage is to do the greatest good for the greatest number**. Triage must occur as quickly as possible after victims are located.

Field Triage

An example of a five-level system of triage is the Emergency Severity Index (ESI), developed by two physicians in the late 1990s who found that a five-level triage system was more reliable than the three-level. The assessment begins with whether the client has a life-threatening condition or if the problem is potentially fatal. Included in this assessment is vital signs and, for the lower acuity casualty, the number of resources required. A level from 1 (most acute) to 5 (least acute) is assigned. Some U.S. hospitals have switched from a three- to a five-level system and have developed their own criteria. A five-level system improves client flow and allows nonacute clients to be screened, but not take space in an ED bed. Because of this, hospitals feel that this system is more effective and reliable than the former three-level system for handling disaster casualties.

Emergency Severity Index			
Level	1	Most Acute	Life-threatening—potentially fatal
			Includes vital sign assessment
Level	3	Lower Acuity	Resources required from this level to 5
			4
Level	5	Least Acute	Not life-threatening—minimal resources

During a disaster, instead of a finite number of victims coming to emergency departments that are able to utilize all of the hospital’s resources, victims arrive in huge numbers and overwhelm the emergency department. In this case, there are actually so many injured, triage must occur in the field, thus the term *field triage*.

Field triage would be used in case of a major disaster—either natural (earthquake, tornado, hurricane), or one caused by man, including events such as a chemical spill, plane crash, explosion, fire, or a terrorist event. The numbers of injured would exceed the resources of any emergency

medical personnel at the scene. Thus decisions will be triage driven, not treatment driven. These victims would be classified according to a color-coding tag system.

Colored Tags	Classification
Red	= Emergent
Yellow	= Immediate
Green	= Urgent
Blue	= Psychological Support or First-Aid level
Black	= Dead or Imminently Terminal

Catastrophic Triage

When events are cascading out of control or disaster has wiped out primary treatment resources, the choice of triage system will be limited. Basically, there are two options. One option is to follow first and second steps and the other is severely limited to those who have the potential to survive—they will be Red Tagged. Thus triage categories change during a disaster. The primary assessment is one of acuity, but the victim must have the ability to survive. Making these decisions will be terribly difficult, but this system seems to be the only realistic method of categorizing thousands of victims from a deadly disaster.

First Step The most direct and expedient method of field triage would be to evaluate victims according to these categories:

I	=	Immediate
D	=	Delayed
Dead	=	Dead

Everyone must be tagged.

Second Step Treat victims immediately.

Check airway and breathing rate	▶	Initiate airway management
Check circulation	▶	Initiate bleeding control
Check mental status	▶	Treat for shock

Document Results

Necessary for effective deployment of resources
 Information on location of victims
 Quick record of number of casualties by degree of severity

Triage Victim Flow

From triage, victims are taken to a designated medical treatment area (Immediate Care, Delayed Care, or Morgue), and from there, transported out of the disaster area (see flowchart below). There are various methods of implementing triage that include minimal to massive numbers of victims. Whichever triage method or strategy is chosen, the community or identified team must be aware of the specific categories.

TRIAGE VICTIM FLOW CHART*

Incident Location	Triage	Medical Treatment	Transportation
		Delayed Care Area	Air Transportation
Search and Rescue	Triage Team	Immediate Care Area	Transportation Manager
		Morgue	Ground Transportation

*CERT Training: Participant Handbook.

Decontamination

Every facility should have a protocol and site for decontamination, both outside and inside. Rooms with negative pressure are especially important for toxic areas and soiled infectious areas. For example, if there is a pandemic flu, that client should be isolated and the air in that room exhausted to the outside to prevent it from contaminating the rest of the facility.

Triage and Decontamination

While triage is an essential component of disaster management, decontamination prioritization is also critical. This is a process to determine the need for and order of victim decontamination. Both processes may be implemented simultaneously. The same triage rule of thumb applies; namely, **providing the greatest benefit for the greatest number**.

If there are mass casualty victims inside a “hot zone,” the Incident Commander may assign personnel to manage both medical triage and decontamination. The first step may be to group victims into ambulatory and nonambulatory categories. Prioritization of these victims may be done using the medical triage system, START.

The highest priority for Ambulatory decontamination (classified as Immediate) casualties includes:

- Victims closest to the point of release
- Those who report exposure to aerosol
- Victims with evidence of liquid deposits on skin or clothing
- Those who are clinically symptomatic (i.e., shortness of breath) but were not as close to point of release
- Victims evidencing conventional injuries, such as open wounds

Nonambulatory casualties includes:

- Victims who are unconscious or unresponsive and will remain in place while further prioritization for decontamination occurs
- Those triaged as *Delayed* (casualties who may have serious injuries, but can wait without compromising the outcome)

Triage Categories for Use During a Disaster

Field Triage

Red	=	Emergent (hyperacute—1st priority)
Yellow	=	Immediate (serious—2nd priority)
Green	=	Urgent (injured—3rd priority)
Blue	=	First aid
Black	=	Dead or dying

Catastrophic Triage (First Option)

I	=	Immediate (life-threatening)
D	=	Delayed (may delay treatment without death)
Dead	=	Dead

Catastrophic Triage (Second Option)

Red Tag	=	Potential to survive
No other victims tagged.		

START Categories

Color Tag		Decontamination Priority
Red Tag	= Immediate	1. Serious signs/symptoms Known agent contamination
Yellow Tag	= Delayed	2. Moderate-to-minimal signs/ symptoms Known agent or aerosol contamination Close to point of release
Green Tag	= Minor	3. Minimal signs/symptoms No known exposure to agent
Black Tag	= Deceased/ Expectant	4. Very serious signs/symptoms Grossly contaminated Unresponsive

Highest priority for overall decontamination includes casualties:

- Who are medically triaged as *Immediate*
- In need of lifesaving medical procedures that can be performed on the spot
- Who have been exposed to nerve agents—decontamination as soon as possible may be lifesaving

Post-Triage Organization

After evaluation and prioritizing victims into treatment groups and providing immediate lifesaving measures, clients will be transported to three locations: Immediate Treatment, Delayed Treatment, and the Morgue.

Treatment area personnel will then:

1. Perform additional *triage* as needed.
2. Complete *physical assessment* (head-to-toe) to determine extent of injuries.
3. Render *first aid* if needed.

After this post-triage assessment, personnel will provide immediate treatment for burns, open wounds, fractures, sprains, hypothermia, frostbite, and so on. After triage and post-triage assessment, it is essential to document the number of victims in each category (immediate, delayed), as well as the dead victims. See Unit 3 for skills in Post-Triage.

The number of victims may exceed local capacity for treatment. Survivors will assist others, but it cannot be assumed they will know how to give lifesaving aid or post-disaster survival techniques. Therefore, outside resources will be requested. For example, the U.S. government has an action plan in place.

This federal response plan includes a stockpile of specialized medical supplies assembled in eight guarded secret warehouses nationwide. More than 100 air cargo containers (each one fills a Boeing 747) are ready to be sent to any city in the United States within 12 hr. State and local officials will be able to track the cargo sent by ground transport to a final, local destination.

When the CDC, in consult with local officials, agrees that an attack has occurred and the local system is insufficient to cope, a container of supplies will be dispersed, as well as physicians and health personnel, if needed.

WEAPONS OF MASS DESTRUCTION

Biological Agents

Biological terrorism is the use of specific agents to cause harm or kill people, and includes the use of organisms such as bacteria, viruses, and toxins. The use of biological agents as weapons poses a difficult problem for public health officials because these agents present with an insidious onset and mimic natural epidemics of influenza. Symptoms may take days to develop before victims seek medical care.

These agents are classified as a threat to national security because they possess unique characteristics:

- Agents that are easily disseminated or transmitted person to person and could be dispersed over a wide geographical area
- Agents that cause high mortality with the potential for major public health impact
- Agents that require specific actions in order that public health preparedness is secured

Biological weapons have a history that goes back as far as the sixth century. Recent history reveals the fact that many nations have biowarfare capability with agents such as anthrax, plague, and smallpox. In spite of the fact that the Geneva convention prohibited use of biological and chemical warfare, and in 1972 many nations agreed to stop research, the United States remains vulnerable to a biowarfare attack.

A biological agent cannot be detected directly. The way it will be identified is when victims arrive at clinics and hospitals and, either through the awareness and perception of professionals who correlate the unusual influx of victims with similar symptoms, or through a retrospective of “putting the pieces together,” the biological cause will be identified.

To accomplish the goal of identifying a biological attack, several steps need to be taken.

TABLE 15-2 Bioterrorism Agents

Disease	Signs & Symptoms	Incubation Period	Person-to-Person Transmission
Anthrax (Inhalational) Organism— <i>Bacillus anthracis</i>	Nonspecific flulike, with fever, malaise, fatigue, cough Delayed symptoms—severe respiratory distress	1–7 days (usually 48 hr) Can be 6 weeks	No
Botulism (Inhalational) Organism— <i>Clostridium botulinum</i> toxin	Increasing muscle weakness, drooping eyelids, blurred vision, difficulty speaking and swallowing; progresses down body to paralysis	12–36 hr after exposure	No
Pneumonic Plague Organism— <i>Yersinia pestis</i>	Sudden onset of high fever, chills, chest pain, headache, and cough with bloody sputum. Possibly vomiting and diarrhea. Advanced: skin lesions, respiratory failure.	2–3 days (1–6 days after exposure)	Yes, through droplet, aerosol
Smallpox Organism— <i>Variola virus</i>	Sudden onset of high fever, headache, and backache. Then, painful rash of small, red spots starts on face and spreads over entire skin surface. Progresses from macules to papules.	7–17 days after exposure (average is 12 days)	Yes, airborne, droplet or direct contact with skin lesions (until scabs fall off—3–4 weeks)
Typhoid Tularemia Organism— <i>Francisella tularensis</i>	Sudden onset of high fever, weakness, weight loss, chest pain, and cough	3–5 days after exposure	No
Viral Hemorrhagic Fevers (Filoviruses, such as Ebola and Marburg, and arenaviruses, such as Lassa and Junin)	Sudden onset of fever, muscle aches, and profound weakness, followed by circulatory compromise	2–21 days after exposure	Yes, risk higher during late stages of disease

1. Set up bioterrorism education programs and training for healthcare professionals who must be able to recognize signs and symptoms of a biological attack.
2. Prepare and distribute educational materials that will inform and remind healthcare professionals of the signs and symptoms of various biological weapons.
3. Establish communication systems to ensure that accurate information is delivered.
4. Recognize the signs and symptoms of major high-priority agents. For example:
 - *Variola major* (smallpox)
 - *Bacillus anthracis* (anthrax)
 - *Francisella tularensis* (tularemia)
 - *Yersinia pestis* (plague)
 - *Clostridium botulinum* toxin (botulism)

Chemical Agents

Chemical terrorism is the deployment of chemical weapons with the intention of causing havoc, harm, and death to the recipients. The release of these weapons will quickly cause death, especially if released in an enclosed space. The U.S. Army Medical Research Institute of Chemical Defense has classified these

agents as potential weapons. These chemical weapons can be pulmonary agents (phosgene, chlorine), cyanide agents (hydrogen cyanide), vesicant agents (mustard, oxime), nerve agents (tabun, sarin, VX), or incapacitating agents (agent 15, BZ). These weapons will inflict painful external and internal injuries, psychological devastation, and death. An act of chemical terrorism is likely to be overt because the effects of these agents on people are immediate and obvious; the agents are absorbed through the skin, mucous membranes, or pulmonary system.

Perhaps the most dangerous of these agents are nerve gases (sarin, tabun, VX), which are extremely toxic and easy to disseminate in the air. These nerve agents are designed to kill people by binding up a compound known as acetylcholinesterase, which is the body's "off" switch. When acetylcholinesterase is significantly decreased or absent in the body, the glands and voluntary muscles continue to be stimulated, eventually wear out, and the body can no longer sustain healthy function.

Decontamination of some chemical agents is time- and labor-intensive and requires tremendous resources. However, if chemical agents are widely dispersed, every one of thousands of persons affected cannot be individually decontaminated. Also, decontamination may not be required for certain chemical incidents. The triage team may remove victims to an uncontaminated area and/or send victims home to shower.

TABLE 15-2 Bioterrorism Agents (Continued)

Treatment	Death Rate if Untreated	Death Rate if Treated	Isolation Precautions/Standard Precautions
Antibiotics, including ciprofloxacin 500 mg PO q12 hr. Doxycycline 100 mg PO q12 hr; also, combined IV and PO.	High	Improved chances for survival. Once symptoms appear, treatment is less effective.	Standard Precautions
Antitoxin—requires skin testing. Supportive care and ventilate until victim can breathe on his own.	High	Low, if breathing can be supported for duration of illness (weeks to months, in some cases)	Standard Precautions
Antibiotics, including ciprofloxacin 400 mg IV q12 hr. Doxycycline 200 mg PO, then 100 mg PO q12 hr.	Almost always fatal	Treatment is highly effective if taken within 24 hr of first symptoms	Bubonic form: Standard Precautions. Pneumonic form: Standard Precautions plus Droplet Precautions until 48–72 hr after antibiotic treatment
Vaccination is effective if given within 3–4 days of exposure; passive immunization with VIG if 3 days post-exposure.	3–30%.	If vaccinated, less than 1%.	Strict Isolation Precautions: Airborne (includes N95 mask) and Contact, in addition to Standard Precautions
Antibiotics, including doxycycline and ciprofloxacin	33%	1–3% if treated within 24 hr of exposure.	Standard Precautions
Little is known. Antiviral agents, such as ribavirin, may be useful.	15–90%	Unknown. Including negative-pressure room with anteroom.	Strict Isolation Precautions

Radiation

The threat of terrorists using nuclear or radioactive materials in the United States is considered to be real. While we cannot predict which form this terrorist event might take, we can prepare to cope with the situation should it arise.

Radiation presents unique characteristics, in that exposure may occur without individuals coming in direct contact with the source of radiation. With other bioterrorism agents, the victim must be in contact with the material, either through inhalation, ingestion, or through the skin.

Radioactive substances emit radiation in the form of rays (waves) or extremely small particles. *Waveforms* are x-ray and gamma rays; *particle forms* are alpha, beta, and neutron. Ionizing radiation is radiation that has enough energy to cause atoms to lose electrons and become ions. Charged particles are emitted from ionizing radiation. These particles (alpha and beta) are the most likely to be dispersed after a terrorist attack. They may adhere to airborne dust particles or attach to clothing, and could be inhaled, causing internal contamination. Beta rays are found in “fallout” and alpha particles are emitted from plutonium. Gamma rays, also an example of ionizing radiation, are emitted in a nuclear blast and have high penetration potential, causing severe damage to the individual, but do not

require decontamination. In the event of a nuclear attack, both rays and particle forms are likely to be dispersed.

A cell that has been exposed to any type of radiation is damaged and may die. If a terrorist event causes radiation to be released, it could result in either external or internal hazards that could be major or insignificant.

Internal–External Exposure Exposure to radiation from a source outside the body is external exposure; exposure from inside the body is internal. Internal exposure occurs when radioactive material is assimilated into body tissues. This occurs from inhalation, ingestion, or insertion, such as a radioactive implant of iodine-131. A critical point of discrimination is whether the victim was exposed to or contaminated by radiation. If exposed, the victim is *not* a hazard to others. The radiation is absorbed by or passes through the body, but does not result in radioactive contamination.

Radioactive contamination as radioactive particulate material is a major cause for concern. The source of contamination, resulting from spillage, leakage, deliberate dispersal, or attached to dust particles in the air, can be passed on to healthcare workers. If this were to occur, it could become an internal exposure hazard as it is incorporated into the body, as well as an external exposure.

Measuring Radiation The term *RAD* (radiation absorbed dose) is a unit of measure for radiation exposure; 1 RAD results in absorption of 100 ergs of energy/gram of tissue exposed. The international system now measures the unit of exposure by Gray (Gy); thus the amount of absorbed radiation is more commonly measured by the Gray, rather than RAD (1 Gy equals 100 RADs).

Radiation dose is a specific calculated measurement of the amount of energy deposited in the body. The unit of dose is called REM, which takes into account the type of radiation. It is not necessary for the reader to understand the technical specifics of exposure and dose. It is important to know how to measure external radiation levels and to understand the dangers of exposure.

A survey instrument measures radiation levels. The readout is in units of R (which can be either RAD or REM), which is exposure or dose. An instrument reading of 50R/hr tells the healthcare worker that if he stays in the exposed area for 1 hr, he will receive a 50-RAD exposure. Some instruments measure dose over time, called radiation dosimeters; these instruments should be worn by personnel working in a contaminated area. A radiation detection device (film badge) should be worn by personnel who come in contact with the exposed area or victims. Both survey instruments and dosimeters have limitations. In the case of survey instruments, they need to be recalculated at regular intervals and, because they use batteries, should be checked and replaced periodically. Dosimeters also must be zeroed and checked at regular intervals.

Health Effects of Radiation A victim contaminated by radiation is at risk—how much risk is dependent on how much radiation is absorbed. Victims who absorb less than 0.75 Gy will not experience symptoms of exposure. Those who absorb 8 Gy could die. Between 0.75 and 8 Gy, the victim could develop acute radiation syndrome (ARS). See box on page 487.

Low exposures do not cause major damage, such as bone marrow damage or birth defects. High exposure may kill cells and significantly increases the incidence of cancer. Regardless of the type of exposure, triage must focus on life-threatening injury before radiological injury.

Background Radiation We are all exposed to a certain amount of radiation from our daily environment. This is known as background radiation and is derived from natural sources such as radiation from outer space; industrial, academic, or military uses of radiation; and radiation used in medicine. All these sources combine to give us a background radiation dose of 0.360 REM per person per year.

American Nurses Association Response to Disaster Planning

- RN should notify employer in writing of any disaster or emergency preparedness education
- RN should request written approval for participation on an emergency response team
- RN should provide employer with ongoing documentation of all continuing education related to disaster preparedness
- RNs who are preapproved members of emergency preparedness team should give written notice to employer of deployment to emergency team

ETHICAL CONSIDERATIONS

When we consider the profession of nursing, a central theme must be the ethical considerations of the practice of nursing. Under the chaotic and challenging conditions of a terrorist event, ethics may seem unimportant; while they may not be addressed overtly during a disaster, ethical considerations form the bedrock of nursing interventions.

In the midst of a crisis, when resources are limited or unavailable, and the emergency medical and nursing staff do not have the capability of handling the disaster, decision making, nursing judgments, indeed, even functioning ability will rest on one's code of ethics. To review the Nurses Code of Ethics, see chapter 1, page 2.

DIVERSITY CONSIDERATIONS

If a mass casualty terrorist event were to occur in the United States, many citizens could potentially be harmed. Because approximately 30% of our population is nonwhite, it is important for nurses to be aware of the impact of culture, beliefs, and values on responses to a disaster. Cultural competence in disaster nursing should be addressed because nurses may be called upon to perform in areas where they are not familiar with the diverse client population. They may not speak the language of the ethnic groups and may not be familiar with the cultural components. They can, however, convey concern, empathy, and the willingness to communicate with the victims who are suffering the effects of a disaster. Nurses who travel to a disaster area should learn from and model local helpers so that their actions are culturally sensitive. Simply being aware of diversity within populations will assist the emergency team to recognize different responses to a mass casualty incident and to relate in a sensitive, appropriate manner.

During the initial assessment after a disaster, the nurse should be aware of the following cultural components:

- Language—(non-English-speaking) communication
- Cultural background and beliefs
- Values, patterns relating to health practices
- Religious practices—limitations
- Nutritional parameters
- Assessment variances for people of color

A possible terrorism event involving radiation dispersal could be:

- An attack on a nuclear facility or detonated nuclear weapon
- A radiation dispersal device: “dirty bomb” (embedding radioactive material in a conventional explosive)
- Radioactive material dispersal

SUMMARY

In November 2001, 800 public health and military professionals participated at a joint conference. They identified the chief challenge in formulating a strategic plan for preparedness response as “lack of training among front-line responders—physicians and nurses—and inadequate planning at the local, state, and federal levels.” Combining these deficit areas—lack of planning, identified skills, and training—helps us to design a framework for nurses to acquire the knowledge necessary for strategic planning and preparedness. Nurses are a vital part, along with physicians and other healthcare professionals, of preparedness programs throughout the country. Nurses must identify their own skill level and the skills necessary to participate as members of the medical response team.

The term “*skill*” may be applied to performance. A complex series of actions to accomplish a task may be called skilled performance. A skill can be learned, but it takes experience in performing step-by-step actions before a well-defined response pattern is accomplished. In addition, the change from hesitant

responses in the middle of performing a skill to a competent, automatic response takes place only with practice. Thus the skills necessary to participate in a medical response system when there has been a disaster caused by a WMD must be identified, practiced, and mastered.

This chapter identifies certain skills, drawn from performance-based learning objectives, that nurses must acquire to become high-level task performers on a disaster response team.

Note to Readers

The skills in this chapter have been formulated according to the latest information and protocols available at the time of publication. Because events change, please check periodically with the appropriate government sources (i.e., CDC, DHS, NIOSHA, AHA, APIC, The Joint Commission, FEMA, etc.) for the latest information and updates on procedures and protocols.

TABLE 15-3 Terrorism Response Drill: What Did They Learn?

Problems	Solutions
<p>Communication</p> <p>Implemented Hospital Emergency Incident Command System (HEICS) but failed to identify a “point person”; communication between the ED and command center was inadequate.</p>	<p>Appoint individual to be “point” who will maintain communication between command center and ED. Secure two-way radios for hospital staff.</p>
<p>Patient Management</p> <p>Tracking victims from arrival in ED to admission or discharge difficult.</p> <p>Comparing identification number for incoming patients from the field to hospital also inadequate.</p>	<p>Implement a patient tracking form and use ID bands to track unidentified patients.</p>
<p>Pediatric Patients</p> <p>Difficult to track young children with no ID and no parents available.</p>	<p>Use ID bands and instant photos to identify children and match with parents.</p> <p>Request extra social workers.</p>
<p>Clinical Protocols</p> <p>Staff did not suspect which infectious disease was used in bioterrorism attack and did not have a treatment protocol identified.</p>	<p>Create an up-to-date clinical protocol of all potential bioterrorism agents and their treatment and distribute to all staff in the ED and hospital.</p>
<p>Supplies</p> <p>Lack of food and water for the emergency staff. Also deficient supplies of garbage cans, linens, IV equipment, and disaster packets.</p>	<p>Have necessary supplies on hand and develop standardized procedures for obtaining extra supplies during disaster.</p>
<p>Facilities Management</p> <p>Lack of adequate security to secure the ED; not enough space in the morgue.</p>	<p>Plan to call in extra security immediately after disaster is recognized; assign extra space for dead victims.</p> <p>Request government to suspend the EMTALA law to reroute “worried well” patients not in immediate need of treatment.</p>

NURSING DIAGNOSES

The following nursing diagnoses appropriate to use on client care plans when the components relate to a client who requires treatment related to a disaster.

NURSING DIAGNOSIS	RELATED FACTORS
Ineffective Community Coping	Disaster-overwhelmed community resources Lack of access to healthcare facilities Infrastructure (services) not functioning at 100% Deficits in social support
Deficient Knowledge	Lack of information about bioterrorism agent, triage, decontamination methods, treatment
Ineffective Protection	First responders' and healthcare personnel protection not appropriate for identified bioterrorism agent
Ineffective Role Performance	First responders and healthcare personnel unclear or unable to function in designated roles
Ineffective Therapeutic Regimen Management	First responders and healthcare personnel unclear about or unable to function in designated roles Communication network inadequate for crisis

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. *Remember to wash your hands or use antibacterial gel before and after each and every client contact.*

Natural Disasters

Nursing Process Data

ASSESSMENT Data Base

- Identify need for information on creating a safety plan for disasters.
- Determine components of a safety plan, including a disaster supply kit.
- Assess need for teaching earthquake safety.
- Identify epidemiologic features of diarrhea-related diseases.
- Assess knowledge of preventive techniques for diarrhea-related diseases.

PLANNING Objectives

- To assist client to create a safety plan for disasters
- To include components of a disaster supply kit
- To identify major challenges (medical/health and infrastructure) after a natural disaster
- To teach earthquake safety to appropriate clients
- To prevent diarrhea-related diseases

IMPLEMENTATION Procedures

- Creating a Safety Plan for Disasters 470
- Teaching Clients Earthquake Safety 470
- Preventing Diarrhea-Related Diseases After a Natural Disaster 471

EVALUATION Expected Outcomes

- Clients are taught how to create a safety plan for disasters.
- Clients learn how to prepare for an emergency.
- Clients know what to include in a disaster kit.
- Earthquake safety principles are taught to nurses and clients.
- Diarrhea-related diseases are identified early with subsequent interventions.

Critical Thinking Application 472

- Expected Outcomes 472
- Unexpected Outcomes 472
- Alternative Actions 472

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Creating a Safety Plan for Disasters

Procedure

1. Hold a meeting with family members to make a plan if a disaster occurs.
2. Pick two places to meet, one outside the house and the other outside the neighborhood.
3. Choose someone in another state whom all members of the family can check in with during a disaster.
4. Formulate an evacuation plan so everyone will know how to leave the area.
5. Prepare your home for an emergency.
 - a. Teach family how to turn off all utilities (especially gas).
 - b. Post emergency numbers near the phone.
 - c. Put smoke detectors in every room and have fire extinguishers accessible.
 - d. Fix potential hazards in the home (anchoring water heater, heavy bookcases, etc.).
- e. Learn first aid and take a CPR course and have supplies available.
- f. Have emergency supplies available and a disaster kit.
6. Include the basics in a disaster supply kit.

Critical/Survival Issues

Lack of safe shelters
 No safe food or water
 No access to needed medicines (insulin, heart drugs)
 No access to medical care for injuries or diseases
 Chaos in the streets
 Lack of normal resources

Disaster Supply KIT

- Water—1 gallon/person/day for a minimum of 1 to 2 weeks
 - Food—selection of ready-to-eat foods, high in protein, for 1 to 2 weeks
 - First aid kit with bandages, gloves, soap, H₂O₂, OTC medications for pain, stomach ills, etc.
 - Prescription drugs (with copies of prescriptions) that are essential for health (insulin, heart meds [1 month supply], etc.)
 - Supplies—radio (battery-operated) with extra batteries, flashlights or oil-burning lamps, wood for heat in a fireplace, personal maintenance items (contact lens supplies, feminine products, denture needs, extra glasses, etc.)
 - Clothing and bedding supplies—warm clothing for winter, blankets, sleeping bags, rain protection gear, etc.
 - Family documents—personal identification, all records that are essential (passport, wills, trusts, insurance records)
 - Credit card and cash
- Check and replenish supplies and kits once a year, practice evacuation procedures, and check your disaster plan.

Teaching Clients Earthquake Safety

Procedure

1. Make a plan for you and your family if an earthquake should occur. Create a disaster-preparedness plan. (See above.)
2. Create a disaster kit, both for the home and car. (See above.)
3. Identify potential hazards in the home and have them fixed. ► **Rationale:** A toppled water heater could cause a fire, and loose, large furniture could be a hazard.
4. Teach how to protect self during severe shaking.
 - a. Indoors: drop to floor, take cover and hold on; find a space beside a couch or table. ► **Rationale:** Earthquake specialists advise taking cover beside the item, not under it (such as a car) because when items fall they create a “triangle safe space” beside the large object.
 - b. Avoid exterior walls, windows, hanging objects, and cabinets filled with items.
 - c. Outdoors: move to a clear area; avoid buildings, power lines, trees.
 - d. Driving: Pull over and stop; set brake. Wait beside the car (not under it) until shaking stops.
5. After the quake, check for injuries and damage (fire, gas leaks, damaged electrical wiring, downed utility lines, chemical spills, damaged structures).
6. Follow disaster plan after earthquake: listen to communication for safety advisories; pay attention to safety precautions; check food and water supplies.

Preventing Diarrhea-Related Diseases After a Natural Disaster

Procedure

1. Recognize early clinical features.
 - a. Early symptoms: abrupt, painless watery stool, vomiting; diarrhea may be mild or fulminating.
 - b. Delayed symptoms: water and electrolyte depletion leading to thirst, oliguria, and, if untreated, circulatory collapse.
2. Identify cholera as the diagnosis.
 - a. Know incubation is 1 to 3 days.
 - b. Mode of dissemination—ingestion of contaminated water is most common.
3. Teach preventive techniques.
 - a. Purify all drinking water; boil, chlorinate, or use water purification tablets.
 - b. Wash all vegetables, fruit, and fish in clean water and cook thoroughly.
 - c. Properly dispose of human excrement.

Major Challenges Following a Natural Disaster

Medical/Health

Contaminated food and water (sewage)
 Sanitation—decomposing bodies
 Interruption of existing/traditional medical/health care
 Ease of disease transmission
 Infections such as malaria and cholera and secondary infections (pneumonia)
 Insect infestation
 Skin infections from open wounds and dirty water
 Diseases from animal carcasses and spilled chemicals in homes and companies
 Contamination from gas/oil in water

Possible epidemics—malaria, cholera, typhoid; and hepatitis A

Mental health concerns—posttraumatic stress disorder

Infrastructure

Destroyed infrastructure contributing to the above issues
 Structural damage to homes, hospitals, and other structures
 Downed power lines/no electricity
 No public transportation
 No communication on land lines/cell towers down

TABLE 15-4 Monitoring Survivors of Natural Disasters for Signs of Illness*

Potential Illness	Causative Conditions	Occurrence of Symptoms	Manifested Symptoms	Mode of Transmission
West Nile Virus	Standing water (3 to 4 weeks for mosquito production)	3 to 14 days after mosquito bite	Meningitis, encephalitis, fever, headache, rash, fatigue, muscle aches	Not spread person to person
Leptospirosis	Exposure to infected animals (dogs, rodents, etc.) or water contaminated with urine of infected animals	2 days to 4 weeks	Symptom range: none to high fever, severe headache, jaundice, muscle aches	Not spread person to person
<i>Vibrio vulnificus</i>	Bacteria living in brackish water	Short time after exposure to rapid progression	Pain, redness, swelling, infected wounds, shock	Not spread person to person; susceptible are those with weakened immune systems
Norovirus	Cramped spaces of shelters	Acute onset after exposure	Vomiting, diarrhea, fever, headache, cramps (lasts 3 to 4 days)	Acutely contagious, spread person to person
Tuberculosis	Cramped spaces of evacuation centers	4 to 12 weeks after exposure	Cough lasting more than 3 weeks, chest pain, fatigue, weight loss, fever, night sweats, chills	Spread through droplet of infected person

*NOTE: These are the most commonly detected conditions/illnesses following a disaster where thousands of survivors are gathered.

DOCUMENTATION for Natural Disasters

- Safety plan presented to clients
- A basic disaster supply kit is discussed and presented to clients
- Principles of earthquake safety taught to clients
- Clinical features and preventive techniques of diarrhea-related diseases

CRITICAL THINKING Application

Expected Outcomes

- Clients are taught how to create a safety plan for disasters.
- Clients learn how to prepare for an emergency.
- Clients know what to include in a disaster kit.
- Earthquake safety principles are taught to nurses and clients.
- Diarrhea-related diseases are identified early with subsequent interventions.

Unexpected Outcomes

Clients and staff do not acknowledge need for a safety plan.

Clients and staff do not have a disaster supply kit.

Staff and clients are not aware of the major challenges after a natural disaster.

People do not understand the need to learn about earthquake safety.

Diarrhea-related diseases occur after a natural disaster (similar to Katrina).

Alternative Actions

Hold meetings and bring in consultants to present rationale and need for a safety plan for both man-made and natural disasters.

Discuss need for a supply kit and the components so that clients and staff will follow through and implement the plan.

Hold meetings to discuss the major challenges so that all are prepared.

Hold discussion groups about the components of earthquake safety for both clients and hospital staff.

Include the signs and symptoms of these diseases in the preparedness plan so staff will be able to recognize them.

Institute preventive measures to combat these diseases immediately after a disaster.

Hold meetings to discuss preventive techniques and have the necessary items available (e.g., water purification tablets).

Bioterrorism Agents, Antidotes, and Vaccinations

Nursing Process Data

ASSESSMENT Data Base

- Identify epidemiologic features.
 - Rapidly increasing incidence of specific signs and symptoms.
 - Unusual number of clients seeking care, especially with flulike symptoms, fever, respiratory complaints.
 - An endemic disease that rapidly emerges.
 - Clusters of clients from one area.
 - Large numbers of fatalities.
- Identify mode of dissemination and incubation period.
- Assess the appropriate therapy/antidotes necessary to treat victims of a bioterrorist attack.
- Determine clients who could be in a high-risk group for smallpox vaccination.
- Assess need for smallpox vaccination.
- Observe post-vaccination reactions and compare with adverse reactions.
- Assess client's understanding of post-vaccination evaluation.
- Assess need for collecting a clinical specimen to identify a specific bioterrorism agent.
- Identify acute radiation syndrome.
- Assess radiation dose exposure of client.

PLANNING Objectives

- To recognize a possible terrorist attack
- To provide clinical knowledge to recognize features of a biological–chemical–nuclear attack
- To enhance ability to detect a biological attack by distinguishing signs and symptoms of various agents
- To participate in an effective medical response to a terrorist attack
- To provide focused educational content for healthcare professionals as knowledge base
- To possess the skills to initiate an effective response to a terrorist event
- To identify the steps of reconstituting smallpox vaccine
- To be able to recognize post-vaccination reactions (expected and adverse) and instruct clients in these reactions
- To identify need for *vaccinia* immune globulin (VIG)
- To know how to collect and transport a clinical specimen
- To be able to respond to a nuclear disaster

IMPLEMENTATION Procedures

- Identifying Agents of Biological Terrorism 474
- Prioritizing High-Risk Groups for Smallpox Vaccination . . 478
- Reconstituting *Vaccinia* Vaccine for Smallpox 479
- Administering Reconstituted Smallpox Vaccine 480
- Understanding Post-Vaccination Reactions 482
- Instructing Client in Post-Vaccination Evaluation 482
- Identifying Indications for *Vaccinia* Immune Globulin (VIG) Administration 483
- Collecting and Transporting Specimens 484
- Identifying Chemical Agent Exposure 484
- Triage for Chemical Agent Exposure 485
- Managing Care After Chemical Agent Exposure 486
- Identifying Acute Radiation Syndrome 486
- Dealing With a Nuclear Disaster 487

EVALUATION Expected Outcomes

- Epidemiologic features of disease are identified.
- Preparedness plans for hospitals are in place and staff are aware of the components.
- If smallpox vaccinations are imposed, staff are knowledgeable about the procedure.
- Smallpox vaccinations are given with no untoward effects.
- Radiation dose remains at safe levels.
- Healthcare workers learn how to respond safely to a nuclear event.
- Victims of a man-made disaster (chemical, biologic, or nuclear) are treated according to protocols.

Critical Thinking Application 488

- Expected Outcomes 488
- Unexpected Outcomes 488
- Alternative Actions 488

Identifying Agents of Biological Terrorism

ANTHRAX

Definition: An acute infectious disease caused by *Bacillus anthracis*, a spore-forming gram-positive bacillus. Human anthrax occurs in three forms: inhalation (the form most dangerous), cutaneous, or gastrointestinal.

Procedure

1. Recognize clinical features. The first line of defense for an outbreak of anthrax is rapid identification.
 - a. Inhalation or pulmonary form.
 1. Early signs and symptoms: developing within days, nonspecific flulike illness with malaise, dry cough, mild fever, and headache.
 2. Delayed signs and symptoms: severe respiratory distress, hemodynamic collapse—victim may die, even with antibiotic treatment.
 - b. Cutaneous form.
 1. Early signs and symptoms: local skin involvement with intense itching; painless, papular lesions (commonly seen on head, forearms, or hands).
 2. Delayed signs and symptoms: papular lesion turned vesicular, developing into black eschar with edema.
 - c. Gastrointestinal form (from contaminated meat).
 1. Early signs and symptoms: abdominal pain, nausea and vomiting, severe diarrhea.
 2. Delayed signs and symptoms: gastrointestinal bleeding and fever; usually fatal after progression to toxemia and sepsis.
2. Know mode of dissemination and incubation period.
 - a. Inhalation of spores: aerosol—no person-to-person transmission. Incubation: 2–60 days (usually 48 hr).
 - b. Cutaneous: direct contact with skin lesions.
 - c. Gastrointestinal ingestion of contaminated food: no person-to-person transmission; incubation: 1–7 days.
3. Manage decontamination.
 - a. Remove contaminated clothing.
 - b. Instruct clients to shower thoroughly with soap and water.
 - c. Instruct personnel to use Standard Precautions.*
 - d. Decontaminate environment with 0.5% diluted bleach (1 part to 9 parts water), or EPA-approved germicidal agent.
4. Institute isolation precautions.
 - a. Inhalation—Standard Precautions,* wash victim thoroughly (use 0.5% diluted bleach for visible contamination); store clothing in sealed plastic bag with biohazard label.

▲ Be familiar with disaster and preparedness plan in the hospital. Perform mock disaster scenarios to maintain skill level and knowledge of procedures if disaster occurs.

- b. Cutaneous—contact precautions (gown and gloves).
- c. Gastrointestinal—Standard Precautions.*
5. Assign client placement.
 - a. Private room placement *not* necessary.
 - b. Airborne transmission does *not* occur.
 - c. Skin lesions may be transmitted by direct skin contact only.

Understand the Danger of Biologically Toxic Agents

1. Biological incidents will be the most difficult of all attacks for the community to recognize and effectively coordinate a response.
2. Most viruses are useful as bioterror agents—they cause unique signs and symptoms that require intervention and isolation of the victims to prevent spread.
3. Specific incapacitating viral or bacterial agents slowly produce signs and symptoms.
 - a. Signs and symptoms are nonspecific and difficult to recognize; onset of incident may remain unknown for days before symptoms appear.
 - b. It may be necessary to identify “clusters” of illness—many victims in one location become sick within a short period of time.
4. If agents are detected early, most can be treated with antibiotics or antivirals.
5. The most common form of agents that could be used in a bioterror attack are bacteria.

*Standard Precautions: See Chapter 14, pg. 410.

6. Implement therapy for anthrax infection.
 - a. Ciprofloxacin 400 mg IV q8–12 hr; 500 mg PO q12 hr; doxycycline 200 mg IV (1 dose); 100 mg IV q8–12 hr; or 100 mg PO q12 hr, or amoxicillin may also be ordered.
 - b. Continue treatment for 60 days.
 - c. Mass casualty—oral therapy with standard doses.

Plague

Definition: Acute, severe bacterial infection, caused by gram-negative bacillus. Seen in bubonic or pneumonic form; caused by bacillus *Yersinia pestis*. A bioterrorism outbreak could be airborne, causing pneumonic plague.

Procedure

1. Recognize clinical features.
 - a. Bubonic form.
 1. Swollen, tender lymph nodes (femoral or inguinal commonly most involved).
 2. High temp 103.1–105.8°F (39.5 to 41°C), chills.
 3. Pulse rapid, hypotension.
 4. Extreme exhaustion.
 - b. Pneumonic form.
 1. High fever, chills, tachycardia, headache.
 2. Cough with foamy hemoptysis.
 3. Tachypnea and dyspnea.
2. Know mode of dissemination and incubation period.
 - a. Transmitted from rodents to humans by infected fleas; incubation 2–8 days.
 - b. Human-to-human transmission occurs by inhaling droplets through cough; incubation 1–6 days.
 - c. Bioterrorism-related through dispersion of aerosol; incubation: 1–3 days.
3. Manage decontamination—procedure should be done in a room designed for this purpose or at a special site outside the hospital.
 - a. Instruct clients to remove clothing and store in closed plastic biohazard bags.
 - b. Instruct clients to shower thoroughly with soap and water—include all crevices.
 - c. Home decontamination: employ Standard Precautions (gloves, gown, face shield, when necessary).
 - d. Use 0.5% diluted bleach or EPA-approved germicidal agent.
4. Institute isolation precautions.
 - a. Bubonic form—routine aseptic (Standard) Precautions.
 - b. Pneumonic form—add droplet precautions to Standard Precautions (eye protection and surgical mask when within 3 feet of client) until 72 hr of antimicrobial therapy.
5. Assign client placement.
 - a. Bubonic form—private isolation room or cohort with clients with similar symptoms.

A Holistic Approach to Coping With Plague

Athens, 200 B.C.: Hippocrates uses precious oils to protect and treat his patients. It is known that essential oils, volatile molecules, float in the air and enter the olfactory system where the limbic system is stimulated to release chemical messages that activate a physical response. Oils have the ability to oxygenate, transport nutrients, and heal. One particular oil blend, “Thieves,” was created from research looking back to the fifteenth century when four thieves used clove, rosemary, lemon, cinnamon, and eucalyptus to protect themselves while robbing plague victims in England. The thieves did not die from plague, while hundreds of thousands did. These oils may be used today to protect oneself from certain diseases.

Source: Young, D., & Gary, N. D. (2002). *An introduction to young living essential oils* (10th ed.). Payson, UT: Young Living.

- b. Maintain at least 3 feet between clients when cohorting is not possible.
 - c. Do not place client with immunosuppressed client.
6. Implement therapy.
 - a. Doxycycline 100 mg 2× daily.
 - b. Ciprofloxacin 500 mg 2× daily.

Botulism

Definition: A muscle-paralyzing disease caused by an anaerobic gram-positive bacillus that produces a potent neurotoxin. Food-borne botulism is the most common form; inhalational botulism is most likely to occur through a bioterrorist release of aerosol.

Procedure

1. Recognize clinical features.
 - a. Food-borne botulism.
 1. Gastrointestinal symptoms: nausea, vomiting, diarrhea.
 2. Leads to symptoms of inhalational botulism.
 - b. Inhalational botulism.
 1. No fever—client is responsive.
 2. Symmetric cranial nerve paralysis: drooping eyelids, blurred vision, diplopia, difficulty swallowing, dry mouth.
 3. Symptoms progress to paralysis of arms, respiratory muscles, and legs.
 4. Symptoms may be confused with Guillain-Barré syndrome or myasthenia gravis.
2. Know mode of dissemination and incubation period.
 - a. Food-borne botulism: generally transmitted through toxin-contaminated food; incubation is 12–36 hr after ingestion.
 - b. Inhalational botulism: transmitted through aerosolization of the toxin. Incubation is 24–72 hr postexposure.

3. Manage decontamination.
 - a. Client does not require decontamination.
 - b. Contaminated clothing washed with commercial soap.
4. Institute isolation precautions.
 - a. No evidence of person-to-person transmission.
 - b. Standard Precautions for clients.
5. Assign client placement: client room selection and care according to facility policy. Client-to-client transmission does not occur.
6. Implement therapy.
 - a. Early recognition of botulism important for administration of antitoxin that may stop or reduce paralysis.
 - b. Administer trivalent botulinum antitoxin (per CDC orders); requires skin testing due to 95% hypersensitivity reactions.
 - c. Monitor client for respiratory failure and provide supportive care.
4. Institute isolation precautions.
 - a. This disease is not transmitted person to person, so isolation measures are not required.
 - b. Standard Precautions recommended.
5. Assign client placement: cohort clients and do not place with immunosuppressed clients.
6. Implement therapy: ciprofloxacin 250 mg PO q12 hr × 14 days, streptomycin 15 mg/kg BID IM × 10–14 days, or gentamicin 1.5 mg/kg q8 hr IV × 10–14 days.

Viral Hemorrhagic Fever (VHF)

Definition: An infection caused by agents such as Ebola, Marburg, Lassa, Argentine, yellow, and dengue fevers. These viruses could be life-threatening (moderately high lethality) and could be delivered by aerosol in a biological attack.

Procedure

1. Recognize clinical features.
 - a. Each illness has unique clinical manifestations; however, some features are similar.
 - b. Characterized by abrupt onset of fever, myalgia, headache, prostration.
 - c. Other signs and symptoms are nausea and vomiting, diarrhea, pain in abdomen and chest, cough, and pharyngitis.
 - d. A maculopapular rash, prominent on the trunk, develops in most clients 5 days after onset of illness.
 - e. Bleeding manifestations may occur as the disease progresses. Even though it is rare for this life-threatening condition to occur, bleeding (intracranial hemorrhage) could result, hence the term hemorrhagic fever.
2. Know mode of dissemination and incubation period.
 - a. Viruses are zoonotic (animal-borne), but can be spread person-to-person.
 - b. All viruses (except dengue fever) could be spread by aerosol in a biological attack.
 - c. Incubation period: usually 5–10 days, with a range of 2–21 days.
3. Manage decontamination: the virus is transmitted person-to-person; decontamination with overt attack: victim undresses, showers with soap or 0.5% diluted bleach.

Typhoidal Tularemia

Definition: A disease caused by *Francisella tularensis* bacterium. It is extremely infectious and can be transmitted via aerosol or contaminated water or food.

Procedure

1. Recognize clinical features.
 - a. Early symptoms: headache, cough, fever, and chills, malaise.
 - b. Delayed symptoms: pharyngeal ulcers, pleuritic chest pain, pneumonia, pericarditis—may progress to respiratory failure.
2. Know mode of dissemination and incubation period.
 - a. Bioterrorism mode is aerosol.
 - b. This disease may not be recognized unless a bioterrorism attack is suspected.
 - c. Incubation period: 2–12 days (average 3–5 days) after exposure.
3. Manage decontamination: general decontamination measures for clothing of infected person—shower with soap or use 0.5% diluted bleach. Because there is no person-to-person transmission, no other measures are necessary.

EVIDENCE-BASED PRACTICE

Lessons Learned From a Full-Scale Bioterrorism Exercise

In May 2000, three hospitals in metropolitan Denver and officials from local, state, and federal agencies participated in a simulated bioterrorism attack exercise involving the simulated release of *Yersinia pestis* aerosol that infected 2,000 people. During the attack, decision making became inefficient and many problems were identified. The single most important lesson learned from this experience was that three aspects must receive equal effort: controlling the spread of disease, triage, and treatment of ill persons.

In April 2005, there was a federal terrorism response exercise developed by the U.S. Department of Homeland Security. The drill involved 84 acute-care hospitals in New Jersey and Connecticut, nearly 10,000 simulated deaths, and more than 22,000 volunteers. (See results, pg. 000.)

4. Institute isolation procedures.
 - a. Communicable person-to-person; risk is highest after infection has progressed. Isolation precautions (including airborne and contact), including respirators, face shields, gowns, gloves, shoe and head covers.
 - b. Negative-pressure ventilated rooms with an anteroom.
5. Assign client placement.
 - a. Clients should be under strict isolation precautions, including a negative-pressure room with anteroom.
 - b. Only clients with the same form of hemorrhagic infection should be cohorted.
6. Implement therapy.
 - a. Primarily supportive.
 - b. Ribavirin, 30 mg/kg IV \times 1 dose; 15 mg/kg IV q6 hr \times 4 days.

Q Fever

Definition: A rickettsial organism (*Coxiella burnetii*) naturally found in sheep, cattle, and goats. Bioterrorism mode of dissemination will be aerosol or food supply sabotage.

Procedure

1. Recognize clinical features.
 - a. Early signs and symptoms: headache, fever, chills, malaise, diaphoresis, anorexia; insidious onset with nonspecific flulike symptoms.
 - b. Delayed signs and symptoms: double vision, sore throat, cough, chest pain, nuchal rigidity, encephalitis, hallucinations, weight loss.
 - c. Differential diagnosis: atypical pneumonias.
2. Know mode of dissemination and incubation period.
 - a. Aerosol or food supply.
 - b. Incubation period: 10–40 days (average 10–14 days).
3. Manage decontamination.
 - a. Have victim undress and shower thoroughly with soap. May use 0.5% diluted bleach.
 - b. Clean environment with 0.5% diluted bleach.
4. Institute isolation precautions: none required. Rarely transmitted person to person. Use Standard Precautions.
5. Assign client placement: transmissibility rare, so clients can be cohorted.
6. Implement therapy.
 - a. Tetracycline 500 mg PO q6 hr \times 5–7 days; doxycycline 100 mg PO q12 hr \times 5–7 days.
 - b. Continue treatment for 2 days post-febrile condition.

Ricin Toxin

Definition: Produced from the castor bean plant and secreted in castor seeds; *Ricinus communis* is a cytotoxin that blocks protein synthesis, killing the cell.

Procedure

1. Recognize clinical features.
 - a. Signs and symptoms depend on route of exposure. Diagnosis is difficult. ELISA test of blood will identify ricin.
 1. Ingestion: nausea, vomiting, diarrhea, and severe abdominal cramps occur before vascular collapse (GI bleeding), leading to death on third day.
 2. Aerosol—inhalation: cough, fever, hypothermia, and hypotension (usually nonspecific symptoms); cardiovascular collapse leads to death in 36–48 hr.
 - b. This biotoxin has been used by assassins; causes death within minutes when placed on the skin. In 2003, ricin was found in a terrorist cell in England—potential use unknown.
2. Know mode of dissemination and incubation period.
 - a. Ricin will be delivered via the castor bean through a chemical process (ingested) or through inhalation method.
 - b. Incubation period is within hours to days (ingestion: 3 days; inhalation 3–4 days).
3. Manage decontamination.
 - a. Ingested biotoxin does not require decontamination.
 - b. Aerosol exposure—victim should shower with soap or use 0.5% diluted bleach.
4. Institute isolation precautions. This toxin is not transmitted to others, but Standard Precautions should be implemented.
5. Assign client placement. There is no communicability person to person or transport through the skin, so placement is planned to protect client's immune system.
6. Implement therapy. There is no approved antitoxin treatment or prophylaxis (vaccination) at this time.
 - a. Therapy is supportive; give oxygen and hydration.
 - b. If there is ingestion, GI decontamination would be implemented.

Smallpox

Definition: An acute viral disease caused by the *variola virus*. It was eradicated worldwide in 1977, and in the early 1980s, routine vaccinations were discontinued. Because there is a large nonimmune population, authorities fear it could be a bioterrorism weapon, transmitted via the airborne route as aerosol or by infected human vectors.

Procedure

1. Recognize clinical features.
 - a. Initially, symptoms resemble an acute viral illness like influenza with high fever, myalgia, headache, and backache.
 - b. Rash appears (when smallpox becomes most contagious), progressing from macules to papules (in 1 week) to vesicles, and scabs over in 1–2 weeks.
 - c. Distinguishing rash from varicella (chicken pox): smallpox has a synchronous onset on face and extremities, rather than arising in “bunches,” starting on the trunk.

Dangers of Smallpox Vaccination: The Debate Continues

Smallpox vaccination results in 2–4 deaths per million—as many as 1,000 deaths could occur if everyone in the United States were to be vaccinated. In 2003, there were 300 million doses of vaccine available, enough to vaccinate everyone in the United States. Live virus is dangerous, especially to those who have a compromised immune system, those with cardiovascular conditions, and those with skin diseases, such as eczema and psoriasis. Those who were already vaccinated 30 years ago have been tested and some have been found to have what appears to be a significant level of immunity, but is it enough? Others who received vaccinations in the 1970s and earlier are believed to have no useful immunity. There is still a debate: Should the vaccinations be voluntary? Should only first responders and emergency personnel receive vaccinations? Should only those who were never vaccinated receive vaccinations?

2. Know mode of dissemination and incubation period.
 - a. Smallpox is transmitted by large and small respiratory droplets; thus both respiratory and oral secretions spread the disease, as well as lesion drainage and contaminated objects such as bed linens.
 - b. Clients are considered more infectious if they are coughing or have a hemorrhagic form of the disease.
 - c. Vaccination effective if given within 3–4 days.
 - d. Incubation: 7–17 days; average is 12 days.
3. Manage decontamination.
 - a. Decontamination of clients is not indicated with smallpox.
 - b. Careful management using contact precautions of potentially contaminated equipment and environmental surfaces—clean, disinfect, and sterilize when possible.
 - c. Dedicated or disposable equipment for each client should be used.
4. Institute strict isolation precautions *immediately*.
 - a. Airborne and contact precautions in addition to Standard Precautions; includes gloves, gown, eye shields, shoe covers, and correctly fitted masks (very important).
- b. Airborne precautions: Microorganisms transmitted by airborne droplet nuclei (particles 5 µm or smaller).
 1. Respiratory protection when entering client's room (particulate respirators, N95); must meet National Institute for Occupational Safety and Health (NIOSH) standards for particulate respirators.
 2. Isolate in room under negative pressure with high-efficiency particle air filtration.
- c. Contact precautions: Clients known to be infected or colonized with organisms that can be transmitted by direct contact or indirect contact with contaminated surfaces.
 1. Wash hands using antimicrobial agent when entering and leaving room.
 2. Don gloves when entering room.
 3. Wear gown for all client contact or contact with client's environment.
 4. Wear gown when entering room and remove before leaving isolation area.
5. Assign client placement.
 - a. Rooms must meet ventilation and engineering requirements for airborne precautions.
 1. Monitored negative air pressure with 6–12 air exchanges/hr.
 2. Appropriate discharge of air to outdoors or high-efficiency filtration of air.
 - b. Door to room must remain closed; private room is preferred. Clients with same diagnosis may be cohorted.
 - c. Limit transport of clients; use appropriate mask if unavoidable.
6. Implement therapy.
 - a. Post-exposure immunization (*vaccinia virus*) is available.
 1. Vaccination alone if given within 3–4 days of exposure.
 2. Passive immunization (VIG) if greater than 3 days post-exposure.
 3. VIG given at 0.6 mL/kg IM. See administration skill, pg. 480. Check with CDC for up-to-date recommendations.
 - b. Prophylactic care with precautions.

Prioritizing High-Risk Groups for Smallpox Vaccination

Procedure

1. Identify healthcare workers. ► **Rationale:** All persons potentially exposed to the virus must be evaluated for possible vaccination.
 - a. Personnel involved in evaluation, care, or transportation of confirmed, probable, or suspected smallpox clients.
 - b. Laboratory personnel involved in collection or processing of clinical specimens.
 - c. Other persons with increased likelihood of contact with infectious materials from a smallpox client (laundry or medical waste handlers).

- d. Other persons or staff who have a reasonable probability of contact with smallpox clients or infectious materials (e.g., selected law enforcement, emergency response, or military personnel).
 - e. Because of potential for greater spread of smallpox in a hospital setting due to aerosolization of the virus from a severely ill client, all individuals in the hospital may be vaccinated.
2. Identify clients exposed to the smallpox virus. ► **Rationale:** The sooner clients are identified, the earlier they can receive smallpox vaccination, which must be given within 4 days to be effective.
 - a. Persons who were exposed to initial release of the virus.
 - b. Persons who had face-to-face, household, or close-proximity contact
 3. Determine contraindications for vaccination of noncontacts. ► **Rationale:** Persons with certain medical conditions are known to have a higher risk of developing severe complications after vaccination with *Vaccinia* vaccine.
 - a. Persons with diseases or conditions that cause immunodeficiency, such as HIV, AIDS, leukemia,

lymphoma, persons with cardiac conditions, therapy with alkylating agents, antimetabolites, radiation, or large doses of corticosteroids.

- b. Persons with serious, life-threatening allergies to the antibiotics polymyxin B, streptomycin, tetracycline, or neomycin. ► **Rationale:** Dryvax contains trace amounts of these antibiotics.
- c. Persons who have ever been diagnosed with eczema, even if the condition is mild or not presently active.
- d. Women who are pregnant.
- e. Persons with other acute or chronic skin conditions such as atopic dermatitis, burns, impetigo, or varicella zoster (shingles). These persons should not be vaccinated until the condition resolves.

Clinical Alert

A household member who has eczema or a history of eczema who has been exposed to a recently vaccinated household member is at higher risk for developing a post-vaccine complication from the vaccination site of the vaccinated person.

Reconstituting *Vaccinia* Vaccine for Smallpox

Equipment

- Vial of vaccine (Dryvax)
- Prefilled syringe of diluent
- Clean or latex-free gloves
- Biohazard bag and label

Procedure

1. Remove vaccine vial from refrigerated storage and allow vial to come to room temperature. ► **Rationale:** Vaccine must be at room temperature to be reconstituted.
2. Wash hands and don gloves. ► **Rationale:** Personnel must be protected from touching vaccine.
3. Lift tab of aluminum seal of vaccine vial. DO NOT BREAK OFF OR TEAR DOWN TAB.
4. Place vaccine vial upright on a hard, flat surface.
5. Remove cap from prefilled syringe of diluent. ► **Rationale:** Diluent is required for reconstitution before administration.
6. Inject 0.25 mL of diluent into vaccine vial. ► **Rationale:** This amount of diluent reconstitutes vaccine.
7. Withdraw needle and syringe and discard in appropriate biohazard sharps container. ► **Rationale:** This needle and syringe are now contaminated with the vaccine.
8. Allow vaccine vial to stand undisturbed for 3–5 minutes. Then, if necessary, swirl vial gently. ► **Rationale:** Complete reconstitution of vaccine must take place.
9. In the space provided on vaccine vial label, record date and time diluent was added. The vaccine is now ready for use. ► **Rationale:** Use reconstituted vaccine for time period recommended by manufacturer if stored at 35.6–46.4°F (2–8°C) when not in actual use.
10. Dispose of diluent syringe, needle used for diluent reconstitution of vaccine, and any gauze or cotton that came in contact with vaccine as follows: in a biohazard bag labeled to burn, boil, or autoclave before final disposal. ► **Rationale:** Staff could be inadvertently inoculated by touching these items.

▲ Prefilled syringe of diluent. This will be injected into vaccine vial to reconstitute.

▲ After injecting diluent into vaccine vial, discard syringe into biohazard container.

Administering Reconstituted Smallpox Vaccine

Equipment

- Clean or latex-free gloves
- Vaccine vial
- Sterile container
- Swab if necessary
- Sterile bifurcated (two-pronged) needle
- Sterile gauze
- 4 × 4 gauze bandage
- Tape

Preparation

1. Identify client(s) to be vaccinated according to public health protocol.
2. Issue information client must receive before smallpox vaccination.
 - a. Preapproved vaccine information entitled “What You Need to Know about Smallpox Vaccinations.”
 - b. An 11-minute CDC video describing the process and results of a vaccination.
 - c. The understanding that vaccination is voluntary.
 - d. Personal information packet and signed permission form.
3. Obtain reconstituted *Vaccinia* vaccine vial from pharmacy. (Public Health Centers are issued vials that hold 100 doses that are administered at scheduled times.)
4. Inspect vaccine for particulate matter or discoloration; if present, do not use.
5. Gather equipment.
6. Perform hand hygiene.

NOTE: Vaccinators must attend classes, read appropriate material, and watch a CDC video before administering vaccination.

Procedure

1. Don clean or latex-free gloves.
2. Remove rubber stopper from vaccine vial and place in sterile container. ► **Rationale:** Stopper should remain sterile as it will be used to recap the vial containing vaccine.
3. Choose site of vaccination—one that is easily accessible for vaccination and evaluation of vaccine “take” on post-vaccination day 7. The outer aspect of the upper right arm over the insertion of the deltoid muscle is the standard (and CDC recommended) vaccination site. ► **Rationale:** This prevents confusion with vaccination site from a previous vaccination.
4. Ask client if he/she has applied lotion or anything on upper arm. If so, wash with soap and water.
5. Clean vaccination site only if grossly contaminated. Let dry thoroughly. Under no circumstances apply alcohol to the skin (per CDC 2002). ► **Rationale:** Alcohol will inactivate vaccine deposited on skin.
6. Dip point of a sterile bifurcated needle into vial of reconstituted vaccine and withdraw needle perpendicular to the floor.

NOTE: Needles are designed to hold designated dose of vaccine (2.5 µL) between needle prongs to allow delivery to skin surface.

7. Hold skin of upper arm taut and place wrist firmly on the arm.
8. Hold needle at a 90° angle (perpendicular) to skin and apply up-and-down (perpendicular) strokes rapidly within a 5-mm diameter area.
 - a. First-time smallpox vaccination recipients: Deliver 3 strokes with a bifurcated needle. Observe for blood appearing within 15–30 seconds. If blood does not appear, deliver 3 additional punctures with the same needle *without* reinserting needle into the vaccine vial. ► **Rationale:** New guidelines from the Advisory Committee on Immunization Practices (APIC) were

▲ It is important that client understand that smallpox vaccination is voluntary.

▲ Obtain reconstituted vaccine vial (which was stored at 2° to 8°C) from pharmacy.

▲ Sterile bifurcated (two-pronged) needle is provided individually wrapped.

4 Dip point of bifurcated needle into vial of reconstituted vaccine.

5 Hold needle at 90° angle and apply rapid strokes within a 5-mm diameter.

6 Wait for a trace of blood at site to indicate successful vaccine delivery.

7 Dispose of bifurcated needle in puncture-resistant medical waste sharps container.

8 Cover vaccination site with semipermeable dressing.

announced February 2003 to change the number of strokes from 15 to 3 for first-time recipients to conform to the FDA-approved package insert from Wyeth, the manufacturer of the Dryvax vaccine.

b. Revaccination recipients: Deliver 15 up-and-down strokes with a bifurcated needle.

9. Examine for a trace of blood at vaccination site, which usually takes 15 to 30 seconds to appear. ► **Rationale:** This indicates successful vaccine delivery.

10. Cover vaccination site with gauze bandage and tape or semipermeable dressing. ► **Rationale:** This prevents contact transmission of virus to unvaccinated persons (people with contraindications to vaccination) or inadvertent inoculation of another body site.

a. Keep vaccination covered until scab separates.

b. Change dressing if exudate builds up. The CDC recommends changing dressing daily, or every 3 days.

NOTE: The CDC recommends using a semipermeable dressing (Tegaderm) when at a work site, in public, or for showering. When site is totally blocked from air, skin at site might soften and wear away.

Clinical Alert

Do not redip needle into vaccine vial if needle has touched skin. This contaminates the vial.

Clinical Alert

When administering smallpox vaccination, strokes should be made rapidly and be sufficiently vigorous to elicit a trace of blood at vaccination site. If trace of blood does not appear, strokes have not been sufficiently vigorous and procedure should be repeated.

11. Dispose of bifurcated needle in a puncture-resistant medical waste sharps container. ► **Rationale:** Bifurcated needle is for single usage only.

12. Instruct client to keep site dry and not to rub or scratch vaccination site.

NOTE: Vaccinia virus may be recovered from vaccination site, beginning at the time of development of a papule (2–5 days post-vaccination) until scab separates from skin (14–21 days post-vaccination) and underlying skin has healed.

13. Recap vial with sterile rubber stopper and store capped vial at 35.6–46.4°F (2–8°C.) Note number of doses left in vial. ► **Rationale:** This temperature will allow vaccine to be saved for subsequent use.

14. Remove gloves, discard in appropriate hazardous waste receptacle, and perform hand hygiene.

Understanding Post-Vaccination Reactions

Procedure

1. Identify persons who should be revaccinated.
 - ▶ **Rationale:** If the vaccination did not take, the individual will remain vulnerable to the smallpox virus.
 - a. They will have delayed type of skin sensitivity consisting of *erythema only* within 24–48 hr.
 - b. This represents a response to inert protein in a previously sensitized person and can occur in a highly immunized person or in individuals with little or no immunity; it is indistinguishable from the immediate or immune reaction.
2. Confirm successful vaccination and enter results in client's record. ▶ **Rationale:** So that the client will not have to be revaccinated.
 - a. Presence of a pustular lesion in previously unvaccinated persons.
 - b. Pustular lesion or an area of definite induration or congestion surrounding a central lesion 7 days after revaccination in a previously vaccinated person.
3. Recognize adverse reactions. ▶ **Rationale:** Identifying an adverse reaction is important so that VIG may be administered.
 - a. The overall risk of serious complications after vaccination with *vaccinia* vaccine appears to be low.
 - b. Complications occur more frequently in persons receiving their first dose of vaccine, and among young children.
 - c. The *most frequent* complications of vaccination are inadvertent inoculation, generalized vaccinia, eczema vaccination, progressive vaccinia, and post-vaccination encephalitis.
 - d. Unexpected cardiovascular complications resulted in reevaluation of the vaccination program in 2003.
4. Document results on vaccination record in client's chart.
 - c. Vaccinees who do not exhibit a “major” reaction at vaccination site on day 7 should be revaccinated.

▲ Example of semi-permeable dressing covering site at eighth day post-vaccination.

▲ Example of pustular lesion 8 days following revaccination in a previously vaccinated person.

Instructing Client in Post-Vaccination Evaluation

Procedure

1. Tell client that successful vaccination is normally associated with tenderness, redness, swelling, and a lesion at the vaccination site.
2. Instruct client that vaccination may also be associated with fever for a few days, malaise, and enlarged, tender lymph nodes in the axilla of the vaccinated arm.
3. Check for inoculation site becoming reddened and pruritic 3–4 days after vaccination and every 3 days following; place results in the record. ▶ **Rationale:** This is a primary reaction after vaccination.
 - a. A vesicle surrounded by a red areola enlarges, becomes umbilicated, and then pustular by the 7th to 11th day after vaccination.
 - b. The pustule begins to dry, redness subsides, and lesion becomes crusted between 2nd and 3rd week.

NOTE: These symptoms are more common in older children and clients receiving their first dose of vaccine (15%–20%) than in persons being revaccinated (0%–10%).

4. Inform client that by the end of the 3rd week, scab falls off, leaving a permanent scar that at first is pink in color, but eventually becomes flesh-colored.
5. Instruct person who has been previously vaccinated (a partially immune person) that an attenuated primary vaccine site reaction will occur with the following characteristics.
 - a. Absence of fever or constitutional symptoms.
 - b. Papule by 3rd day that becomes vesicular by 5th to 7th day and dries shortly thereafter.
 - c. A relatively small vesicle and areola.
 - d. Scar, if present, is usually insignificant and disappears within 1–2 years.

Clinical Alert

Instruct client to wash hands thoroughly after touching vaccination site to prevent inadvertent inoculation at another site.

EVIDENCE-BASED PRACTICE

Complications From Inadvertent Inoculation

Inadvertent smallpox inoculation at other sites accounts for about 50% of all complications after primary and revaccination. This complication of vaccinia vaccination occurs at a rate of about 1 in 2,000 primary vaccinations and usually results from autoinoculation when virus is transferred by hand from the site of vaccination to other areas. The most common sites involved are the face, eyelid, nose, mouth, genitalia, and rectum. Most lesions will heal without specific therapy.

Source: Vaccination guidelines for state and local health agencies (2002). Centers for Disease Control, U.S. Department of Health and Human Services.

Identifying Indications for *Vaccinia* Immune Globulin (VIG) Administration

Procedure

1. Identify post-vaccination complications for which VIG may be indicated. ► **Rationale:** VIG is indicated for some complications, but not others.
 - a. Eczema vaccinatum.
 - b. Progressive *vaccinia* (*vaccinia* necrosum).
 - c. Severe generalized *vaccinia* if client has a toxic condition or serious underlying illness.
 - d. Inadvertent inoculation of eye or eyelid without vaccinia keratitis.
2. Check physician's orders for VIG treatment of complications due to *vaccinia* vaccination.
 3. Administer VIG intramuscularly (IM) as early as possible after onset of symptoms.
 4. Give VIG in divided doses over a 24–36-hr period. Doses may be repeated at 2–3-day intervals until no new lesions appear. ► **Rationale:** Because the therapeutic dose of VIG may be large (e.g., 0.6 mL/kg body weight), it is given in divided doses.
 5. Instruct staff that VIG is not indicated for treatment of post-vaccination encephalitis and is contraindicated for vaccinia keratitis.

Possible Adverse Reactions to Smallpox Vaccination

- **Inadvertent Inoculation at Another Site:** Virus is transferred by hand from vaccination site to another body area. Most lesions heal without therapy.
- **Generalized Vaccinia:** Bloodborne dissemination of *Vaccinia* virus resulting in vesicular rash of varying extent (occurs 1 in 5,000 vaccinations). Usually self-limiting.
- **Eczema Vaccinatum:** Skin lesions that cover area affected by eczema or a chronic skin condition. Illness (fever, lymphadenopathy) is usually mild, but can be fatal (occurs 1 in 26,000 primary vaccinations).
- **Progressive Vaccinia:** Severe and potentially fatal; occurs in persons with immune deficiencies. Characterized by failure of lesion to heal with progressive necrosis. VIG is used to treat this condition.
- **Post-Vaccination Encephalitis:** All symptoms of encephalitis occur between 8 and 15 days post-vaccination. Incidence is 1 in 300,000 vaccinations, and there is no cure.
- **Cardiac complications:** Heart inflammation (myocarditis, pericarditis), angina, and a few heart attacks have occurred. Incidence is 1 in 20,000 individuals vaccinated for the first time. Experts are evaluating the connection.

Collecting and Transporting Specimens

Equipment

- Disposable gown
- 1 N95 mask
- Eye shield
- Shoe covers
- 2 pair gloves
- 2 zip-closure plastic bags
- 2 biohazard bags
- Label for specimen and chain of custody form

Procedure

1. Acquire and follow specific recommendations for diagnostic sampling of the specific agent.
 - a. Perform all sampling according to Standard Precautions.
 - ▶ **Rationale:** For protection of healthcare workers.
 - b. Check that laboratory has capacity and equipment to handle specific sample. There are four laboratory levels.

NOTE: Proposed laboratory levels (A through D): local clinical labs for minimal identification of an agent; county or state labs; state and other large labs with advanced capacity for testing; and level D, CDC, or select Department of Defense labs with Bio Safety Level (BSL) testing capacity.

2. Wear protective gear when entering environment where potential for exposure exists. ▶ **Rationale:** It is important to safeguard health and safety of persons collecting specimen.
 - a. Disposable gown.
 - b. Properly fitted N95 mask.

NOTE: Mask will not protect males with beards.

▲ Biohazard specimen bag.

- c. Gloves.
- d. Eye shield.
- e. Shoe covers if indicated.
3. Choose gown with sleeve cuffs that can be covered by stretching gloves up and over cuff. ▶ **Rationale:** No skin should be exposed.
4. Collect specimen and place in appropriate container (zip-closure plastic bag, sealed).
5. Remove original gloves handling specimen, and place in biohazard container. ▶ **Rationale:** These gloves may have been contaminated.
6. Don new pair of gloves.
7. Place specimen bag in second zip-closure bag and seal, or if specimen is large, in trash bag.
8. Remove protective gear and place in biohazard bag. ▶ **Rationale:** Protective equipment may be contaminated.
9. Label specimen on outside of bag with appropriate label: date, person collecting specimen, location, and contact person.
10. Wash hands or complete hand hygiene.
11. Document specimen collection in duplicate, fill out worksheet, “Possible Biological Agent Exposure Contact.” ▶ **Rationale:** This will warn staff who transport specimen to protect themselves.
12. Give to person designated for this location.
13. Collect an acute phase serum sample, as well as a later convalescent serum sample. ▶ **Rationale:** The two samples will be compared as follow-up study.
14. Transport specimens by coordinating with local, state health departments, and the FBI.
 - a. Include a chain of custody form with specimen information from moment of collection, completed each time specimen is transferred to another party.
 - b. Plan ahead for care of specimens by having appropriate packaging materials and transport media available.

Clinical Alert

Be careful not to contaminate outside of either of the two disposal bags during handling.

Identifying Chemical Agent Exposure

Procedure

NOTE: Chemical agents may be solid, liquid, or gas; there are numerous ways of disseminating the agent.

1. **Pulmonary agents:** such as chlorine, chloropicrin, or phosgene, when inhaled produce pulmonary edema with little damage to other pulmonary tissues (with resulting hypoxemia) and hypovolemia.
 - a. Immediate symptoms are irritation of eyes, nose, and upper airways—often not distinctive enough to be recognized as chemical agent exposure.
 - b. Two to 24 hr later, victim develops chest tightness, shortness of breath with exertion (later, at rest).

- c. Cough produces clear, frothy sputum, fluid that leaked into lungs.
 - d. If symptoms begin soon after exposure, death may occur within hours.
2. **Cyanide agents:** may be gases or solids, such as hydrogen cyanide or cyanogens chloride; with high concentrations, death occurs in 6–8 minutes.
- a. Initial symptoms are burning irritation of eyes, nose, and airways, and smell of bitter almonds.
 - b. Victim's skin may be acyanotic, cherry-red (oxygenated venous blood), or normal.
 - c. Large amount of gas inhaled: hyperventilation, convulsions, cessation of breathing (3–5 minutes), and no heartbeat (6–10 minutes).
3. **Vesicant agents:** cause vesicles or blisters. Common agents are sulfur mustard and lewisite. More lethal than pulmonary agents and cyanide.
- a. Mustard—initial symptoms not observable. Effects begin hours after exposure: erythema, burning and itching with blisters; burning of eyes; airway pain, sore throat, nonproductive cough.

Clinical Alert

Suspect a chemical agent exposure if healthcare facility is presented with several nontrauma clients with similar symptoms.

- b. Lewisite—oily liquid that results in topical damage. Vapor causes immediate pain, burning, and irritation of eyes, skin, and upper airways.

NOTE: This is distinguishing feature of lewisite versus mustard when initial symptoms are not observable.

Cellular damage occurs that can result in hypovolemic shock.

4. **Nerve agents:** liquids or vapors that are the most toxic of all chemical agents. Common agents are Sarin, tabun, Soman, GF₃, and VX.
- a. Nerve agents block the enzyme acetylcholinesterase, so activity in organs, glands, muscles, smooth muscles, and central nervous system cannot turn off; body systems wear out.
 - b. Effects of nerve agent depends on route (vapor or droplet) of exposure and amount; it is felt within seconds.
 - 1. Felt first on face: eyes, nose, mouth, and lower airways—watery eyes, runny nose, increased salivation, and constriction of airways, shortness of breath.
 - 2. Large concentration of vapor: loss of consciousness, convulsions, no breathing.

Clinical Alert

The most common sign of nerve vapor exposure is constricted pupils (miosis) with reddened, watery eyes.

Triaging for Chemical Agent Exposure

Procedure

1. **Pulmonary agents.**
 - a. Victim complaining of dyspnea within 6 hr of exposure requires immediate intervention—bedrest (no exertion) and oxygen.
 - b. Continued care.
 1. Continue airway support with oxygen.
 2. Monitor for hypovolemia and correct acidosis.
 3. If symptoms are not present within 12 hr, and x-ray, physical exam, and ABGs normal, client may be discharged.
2. **Cyanide agents.**
 - a. Antidotes should be administered within minutes of inhalation if client has seizures or respiratory symptoms.
 - b. Mild symptoms: give supportive care and monitor.
3. **Vesicant agents.**
 - a. Almost all victims will have delayed treatment for skin, eyes, and airway injuries.
 - b. Clients with severe airway injury (dyspnea) require intensive pulmonary care.

4. Nerve agents.

- a. Victims exposed to liquid nerve agent who show signs of nerve exposure must be decontaminated immediately. ► **Rationale:** Rapid decontamination will decrease reaction, but not prevent it.
- b. Administer antidotes immediately according to symptoms—multiorgan involvement, respiratory difficulty, convulsions.
- c. Victims suspected of exposure, but who present with no symptoms, may have delayed treatment.

Triage in the Hot Zone After a Chemical Agent Terrorist Attack

- First responders will probably not be able to identify the exact agent.
- Early intervention is critical for nerve agents and cyanide.
- Pulmonary agent exposure will be treated later.
- Intervention in the hot zone generally has to do with airway, breathing, and circulation (ABCs); add antidotes for nerve agents.

Managing Care After Chemical Agent Exposure

Procedure

1. **Pulmonary agents:** Client with pulmonary edema must be on immediate bedrest with no exertion and receive oxygen.
2. **Cyanide agents:** Administer antidotes.
 - a. Client inhales amyl nitrite, or is given sodium nitrite IV (10 mL; 300 mg); frees bound cyanide from hemoglobin to allow O₂ transport.
 - b. Sulfur thiosulfate IV (50 mL; 12.5 gm); sulfur converts cyanide to form a nontoxic substance.
 - c. Give antidotes sequentially and slowly, titrated to monitor effects; ventilate with oxygen and correct acidosis.
3. **Vesicant agents.**
 - a. Mustard: Immediate decontamination (within 1 minute) will minimize damage; longer will be too late. Irrigate affected skin areas and eyes frequently and apply antibiotics to skin 3 to 4 times/day.
 - b. Lewisite: Similar to mustard. Immediate decontamination is important. An antidote for systemic lewisite is British anti-Lewisite (BAL), a drug given IV for heavy metal poisoning.
4. **Nerve agents.**
 - a. Personal protection equipment is necessary when decontaminating victims. Decontamination must take place first, before management begins.

b. Antidotes:

1. *Atropine* 2–6 mg (average dose 2–4 mg) IM; 2 mg more may be administered in 5–10 minutes if no improvement. A high initial dose is necessary to block excess neurotransmitter, especially if victim is unconscious.
2. *Protopam*, an oxime, 600 mg given slowly IV to counteract nerve agent by removing agent from the enzyme.
3. *Valium* might be used for prolonged convulsions.
- c. The military has a device (Mark I Auto-Injection Kit) that holds two spring-powered injectors containing two antidotes, atropine and Protopam, that can be used effectively and quickly to administer antidotes.

Chempacks, which include chemical weapon antidotes, are being shipped to all states from federal stockpiles. Each pack will treat 1,000 clients and will be available to medical facilities within 12 hr of an emergency.

Source: Office of Terrorism Preparedness and Emergency Response, CDC, 2006.

Identifying Acute Radiation Syndrome

Procedure

1. Assess for an acute illness characterized by manifestations of cellular deficiencies. ► **Rationale:** Early recognition of the body's reaction to ionizing radiation is important.
 - a. Prodromal period: loss of appetite, nausea, vomiting, fatigue, and diarrhea.
 - b. Latent period: symptoms disappear for a period of time.

▲ Wear film badge when likely to be exposed to radioactive material.

- c. Overt illness follows the latent period—infection, electrolyte imbalance, diarrhea, bleeding.
- d. The final phase is a period of recovery or death.
2. Determine the radiation dose, if possible.
3. Attempt to identify dose exposure of client.

► **Rationale:** Treatment is according to dose exposure.

 - a. Dose less than 2 Gy (200 RADS) is usually not severe; nausea and vomiting seldom experienced at 0.75–1 Gy (75–100 RADS) of penetrating gamma rays.
 1. Hospitalization unnecessary at less than 2 Gy, thus outpatient care indicated.
 2. Closely monitor and administer frequent CBC with differential blood tests.
 - b. Dose greater than 2 Gy (200 RADS).
 1. Signs and symptoms become increasingly severe with increased dose.
 2. See box on page 487 for description of four syndromes.

Clinical Alert

The higher the radiation dose, the greater the severity of early effects and possibility of late effects.

- c. Give supportive care—treat gastric distress with H₂ receptor antagonists (Tagamet, Pepcid, etc.).
 - d. Prevent and treat infections—monitor viral prophylaxis.
 - e. Consult with hematologist and radiation experts.
 - f. Observe for erythema, hair loss, skin injury, mucositis, weight loss, and fever.
4. Identify if radiation dose includes radioactive iodine.
 - ▶ **Rationale:** Uptake of this isotope could destroy thyroid tissue.
 5. Administer potassium iodide before exposure, if possible, or as soon as available (within 4 hr). ▶ **Rationale:** Blocks uptake of specific damaging isotope which protects thyroid tissue.

Dealing With a Nuclear Disaster

Procedure

1. Move away from blast area as soon as possible.
 - ▶ **Rationale:** Downwind contamination and dispersed radioactive material will contaminate.
2. Travel in a direction that keeps wind to left or right.
 - ▶ **Rationale:** If wind is blowing from blast toward you, this will give you the least exposure.
3. Cover your face with cloth or mask. ▶ **Rationale:** This will help you avoid inhaling radioactive dust.
4. Remove your outer clothing and shower as soon as you are in a safe area. ▶ **Rationale:** Fallout dust is dangerous because it emits radiation energy that can go through clothing.
5. Find a shelter with enough mass (thickness) to shield you from penetrating radioactive dust. ▶ **Rationale:** The denser the shelter mass or walls, the more effective at blocking (thickness required to stop 99% of radiation is 5 inches of steel, 16 inches of brick or concrete blocks filled with sand or mortar, 2 feet of packed earth, or 3 feet of water).

Acute Radiation Syndromes

- **Hematopoietic syndrome:** Characterized by deficiencies of red blood cells, lymphocytes, and platelets, with immunodeficiency; increased infectious complications, including bleeding, anemia, and impaired wound healing.
- **Gastrointestinal syndrome:** Characterized by loss of cells lining intestinal crypts and loss of mucosal barrier with alterations in intestinal motility; fluid and electrolyte loss with vomiting and diarrhea; loss of normal intestinal bacteria, sepsis, and damage to the intestinal microcirculation, along with the hematopoietic syndrome.
- **Cerebrovascular–central nervous system syndrome:** Primarily associated with effects on the vasculature and resultant fluid shifts. Signs and symptoms include vomiting and diarrhea within minutes of exposure; confusion, disorientation, cerebral edema, hypotension, and hyperpyrexia. Fatal in short time.
- **Skin syndrome:** Can occur with other syndromes; characterized by loss of epidermis (and possibly dermis) with “radiation burns.”

DOCUMENTATION for Bioterrorism Agents, Antidotes, and Vaccinations

Agents of Bioterrorism Identified

- Clinical features of agent (anthrax, plague, botulism, typhoid, VHF, Q fever, smallpox, ricin)
- Incubation period
- Decontamination, if necessary
- Client placement and isolation precautions implemented
- Therapy–treatment implemented

Clients to Whom *Vaccinia* Smallpox Vaccine Administered

- Post-vaccination reactions noted
- Adverse reactions of smallpox vaccination assessed

- Client to whom *vaccinia* immune globulin (VIG) administered
- Specimens collected and destination of transport (Lab)

Chemical Agents Identified (Pulmonary, Cyanide, Vesicant, Nerve)

- Triaging, if necessary, for chemical exposure
- Treatment administered to chemically exposed client

Acute Radiation Syndrome Identified

CRITICAL THINKING Application

Expected Outcomes

- Epidemiologic features of disease are identified.
- Preparedness plans for hospitals are in place and staff are aware of the components.
- If smallpox vaccinations are imposed, staff are knowledgeable about the procedure.

Unexpected Outcomes

Epidemiologic features of disease cannot be identified.

An effective community response to a terrorist attack is unlikely (hospital does not have a Preparedness Plan in place).

The U.S. government orders your hospital staff to vaccinate a targeted population for smallpox.

Client receives smallpox vaccination and inadvertently inoculates another site (face, eyelid, nose, etc.).

- Smallpox vaccinations are given with no untoward effects.
- Radiation dose remains at safe levels.
- Healthcare workers learn how to respond safely to a nuclear event.
- Victims of a man-made disaster (chemical, biologic, or nuclear) are treated according to protocols.

Alternative Actions

- Examine clusters or unusual numbers of clients with similar signs and symptoms by communicating with other hospitals in the community.
- Gather specimens and send them to the appropriate laboratory.
- Institute Standard Precautions plus airborne and contact precautions until specific agent is identified.
- Form a hospital committee to prepare a Preparedness Plan.
- Collect educational materials to fill in areas of content the response team requires to function effectively in the event of a disaster.
- Set up practice sessions with post-evaluation to increase response effectiveness.
- Establish a communication network so it is already in place in the event of a terrorist attack; assign roles and a command center spokesman.
- Collect the necessary material to identify high-risk clients and have the knowledge base to perform the skill of administering smallpox vaccinations.
- Practice administering smallpox vaccinations without using the actual vaccine until staff is proficient in the skill.
- Request orders to administer VIG IM for complications, if client is appropriate.
- Assess that no new lesions appear after VIG doses given over 24–36 hr.

Personal Protective Equipment and Decontamination

Nursing Process Data

ASSESSMENT Data Base

- Identify clients who present risk to healthcare professionals.
- Assess need for special equipment (biohazard bags, specimen bags, etc.).
- Determine type of protection equipment required according to an identified biohazard (biological, chemical, or radiological).
- Assess need for decontaminating victims before triage.
- Assess strategy for decontamination at site of incident.
- Assess need for mass casualty decontamination.

PLANNING Objectives

- To select and utilize appropriate personal protection equipment
- To demonstrate Standard Precaution techniques
- To demonstrate behaviors that help to ensure personal safety
- To understand containment principles to avoid spreading contamination
- To prevent further spread of biological–chemical–radiological agents with appropriate decontamination procedures
- To understand principles of decontaminating via triage
- To prevent spread of bioterrorism agents by following guidelines of mass casualty decontamination

IMPLEMENTATION Procedures

- Implementing Hospital Infection Control Protocol 490
- Decontaminating via Triage 492
- Choosing Protective Equipment for Biological Exposure 493
- Choosing Protective Equipment for Chemical Exposure 494
- Choosing Protective Equipment for Radiological Attack 495
- Decontaminating Victims After a Biological Terrorist Event 496
- Decontaminating Victims After a Chemical Terrorist Event 496
- Decontaminating Victims After a Radiation Exposure 497
- Controlling Radiation Contamination 498

EVALUATION Expected Outcomes

- Infection control protocols are followed.
- Staff is familiar with protective equipment and the protocols to use it.
- Staff knows decontamination procedures and implements them safely.
- Decontamination procedures for mass casualty disasters are implemented.
- Radiation exposure is controlled.

Critical Thinking Application 499

- Expected Outcomes 499
- Unexpected Outcomes 499
- Alternative Actions 499

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Implementing Hospital Infection Control Protocol

Equipment

- Handwashing material
- Gloves
- Masks (HEPA or N95 for respiratory problems, pneumonia, plague, smallpox, etc.)
- Eye shields or face shields
- Gowns
- Disinfecting material

Procedure

1. Utilize Standard Precautions for all clients admitted to or arriving at the hospital. For specific protocols and skills, see Chapter 14, Infection Control. ► **Rationale:** Agents of bioterrorism are generally not transmitted person to person.
2. Follow routine client placement for normal number of admissions.
 - a. Isolate suspicious cases.
 - b. Group similar cases.
3. Utilize alternative placement for large numbers of clients.
 - a. Co-group clients with similar syndromes in a designated area.
 - b. Establish designated unit, floor, or area in advance.
 - c. Place clients based on patterns of airflow and ventilation with respirator problems, smallpox, or plague. ► **Rationale:** Transmission is through droplets (touching).
 - d. Place clients after consultation with engineering staff. ► **Rationale:** Adequate plumbing and waste disposal must be available.
4. Control entry to client designated areas. ► **Rationale:** Minimizes possibility of transmission to other clients and staff.
5. Transport bioterrorism clients as little as possible—limit to essential movement. ► **Rationale:** This practice will reduce opportunity for microorganism transmission within facility.
6. Clean, disinfect, and sterilize equipment according to principles of Standard Precautions.

▲ Clients who are placed in isolation require a room with a directional airflow, negative-pressure ventilation system with minimum of 6 to 12 air exchanges per hour. An anteroom entry is preferred to maintain isolation protocol.

▲ Clean all reusable large equipment thoroughly with antimicrobial or antiseptic agent as required by hospital policy.

- a. Use procedures facility has in place for routine cleaning and disinfection.
- b. Have available approved germicidal cleaning solutions.
- c. Contaminated waste should be sorted and disposed of in accordance with biohazard waste regulations. See Handling Biohazard Waste in Chapter 14, page 415.
- d. For clients with bioterrorism-related infections, use Standard Precautions for cleaning unless infecting organism indicates special cleaning.

Glove Protection From Toxic Chemicals

- OSHA's new PPE standard requires companies to perform a hazard assessment to determine the need for protective clothing.
- Wide variations in chemical resistance of gloves and protective clothing make equipment selection difficult.
- Many factors affect the performance of gloves during actual use. Toxic chemicals such as pesticides, aromatic amines, and isocyanates can permeate gloves and protective clothing. In addition, flexing, stretching, pressure, and abrasion are physical factors that can cause premature breakthrough.
- A new generation of products produce a color change when permeation occurs, thus providing a method for field validation of the efficacy of protective clothing.
- PERMEA-TEC™ sensors are an example—they are attached to hands before gloving. The detector is placed on thumb, middle finger, and palm, as these areas represent the highest area of contact and abrasion.
- Sensors should be checked hourly to determine when breakthrough occurs, indicating gloves must be changed.

Standard Precautions

Hand hygiene Use antimicrobial soap or waterless antiseptic agent to clean hands.

Donning gloves Wear clean nonsterile gloves to protect healthcare personnel from touching blood, body fluids, secretions, excretions, and contaminated items.

Donning a gown A clean, nonsterile gown will protect skin and prevent soiling of clothes.

Wearing a mask Wear a mask to protect mucous membranes of nose and mouth for workers and victims.

Wearing special masks: HEPA or particulate filter respiratory mask When bioterrorism agent is suspected and is transmitted via aerosol or airborne, special masks are indicated. Individually fit each mask.

Wearing eye or face shield Shield will protect mucous membranes of eyes from splash or spray of victim's body fluids.

Decontaminating via Triage

Equipment

Personal protection equipment including clothing
 Water source
 Soap
 0.5% sodium hypochlorite (HTH chlorine or diluted bleach) cleaning solution
 Towels
 Waste container for contaminated clothes
 Masking tape, 2 in wide
 Body bags
 Film badge or chemical agent detector

Procedure

1. Decontaminate at scene of incident (hot zone).
 - ▶ **Rationale:** Prevents hospital system from absorbing contaminated victims and protects healthcare providers and uncontaminated casualties.
 2. Familiarize emergency personnel with stages of decontamination. ▶ **Rationale:** Effective decontamination is essential for victim and staff protection.
 - a. Gross decontamination.
 1. Decontaminate those who require assistance.
 2. Remove and dispose of exposed victim's clothing.
 - ▶ **Rationale:** This will remove 70%–80% of contaminant.
 3. Perform a thorough head-to-toe tepid water rinse.
 - ▶ **Rationale:** Cold water can cause hypothermia and hot water can result in vasodilation, speeding distribution of the contaminants.
 - b. Secondary decontamination.
 1. Perform a full-body rinse with clean tepid water.
 - ▶ **Rationale:** Water is an effective decontaminant because of rapidity of application.
 2. Wash rapidly from head to toe with cleaning solution (HTH chlorine is effective) and rinse with water.
 - ▶ **Rationale:** HTH chlorine can decontaminate both chemical and biological contaminants.
- NOTE:** Undiluted household bleach is 5.0% sodium hypochlorite.
- c. Definitive decontamination.
 1. Perform thorough head-to-toe wash and rinse.
 2. Dry victim and don clean clothes.

Salvageable Victims

First Priority: Decontaminate exposed victims with no symptoms.

Second Priority: Decontaminate exposed victims with minor injuries who require minimal resources.

Third Priority: Decontaminate exposed victims needing maximum medical care.

Last to decontaminate are deceased victims.

3. Initial decontamination may be accomplished by the fire department with hoses spraying water at reduced pressure. ▶ **Rationale:** This will remove a high percentage of contaminant at an early stage.
4. Decontaminate salvageable clients first. ▶ **Rationale:** The goal is to decontaminate victims who have been exposed, yet are salvageable. Clients who are dead or unsalvageable have lowest priority for decontamination.
5. Reduce extent of contamination in facility by decontaminating clients before receiving in healthcare facility. ▶ **Rationale:** Necessary to ensure safety of clients and staff.
 - a. Establish decontamination site outside facility using a decontamination tent before needing it.
 - ▶ **Rationale:** To protect clients and staff inside facility.
 - b. Set up procedures for decontamination, depending on infectious agent.
6. Implement procedure for decontaminating client.
 - a. Don appropriate personal protective gear before assisting clients to decontaminate.
 - b. Remove contaminated clothing and place in appropriate double biohazard bags.
 - c. Instruct or assist client to shower with soap and water. ▶ **Rationale:** Bathing clients in bleach may be potentially harmful. For specific infections, diluted bleach 0.5% is indicated.
 - d. Use clean water, normal saline, or ophthalmic solution for rinsing eyes.

Guidelines for Setting Up Site for Decontamination

- Establish upwind from contamination area.
- Set up site on a downhill slope, if possible, or on flat ground (so that runoff can be captured).
- Have water source available and, if possible, decontamination solution.
- Have decontamination equipment available, if possible.
- Supply personal protection equipment for healthcare personnel.
- Notify healthcare facilities nearby to be available, if possible.
- Maintain security and privacy for site.
- Institute post-decontamination monitoring and checks.

Choosing Protective Equipment for Biological Exposure

Equipment

Listed below in procedure

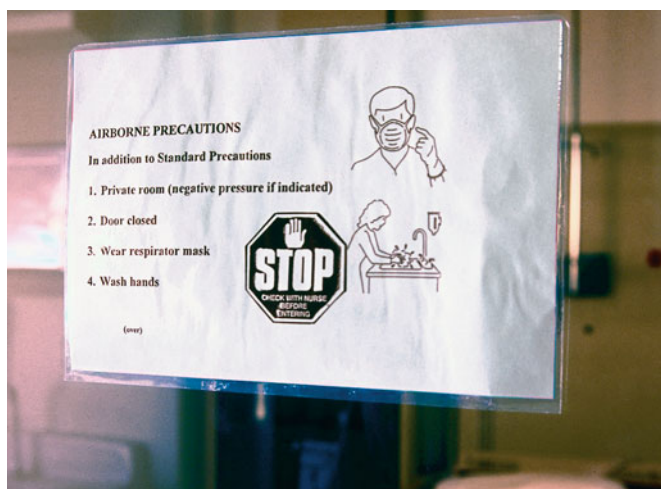

Procedure

1. Plan for protection from biological hazards.
 - a. First responders to a biological hazard may be exposed to bacteria, viruses, or toxins via inhalation (through respiratory tract) or ingestion (contact with mucous membranes of eyes, nasal tissues, or open cuts).
 - b. Biological weapons are particles and will not penetrate proper protective equipment.
 - c. Respirators—type selected according to hazard identified and its airborne concentration.
 1. High level of protection: Self-contained breathing apparatus (SCBA) with full facepiece. Provides highest level of protection against airborne hazards when used correctly. ► **Rationale:** Reduces exposure to hazard by a factor of 10,000.
 2. Minimal level of protection: Half-mask or full facepiece air-purifying respirator with particulate filters like N95 (used for TB) or P100 (used for hantavirus).
 - d. Protective clothing includes gloves and shoe covers—necessary for full protection. ► **Rationale:** Prevents skin exposure and/or contamination of other clothing.
 1. Level A Protective Suit used when a suspected biological incident occurs and type, dissemination method, and concentration are unknown.
 2. Level B Protective Suit used when biological aerosol is no longer present.
 3. Full facepiece respirator (P100 or HEPA filters) used if agent was *not* aerosoled or dissemination was by letter or package that could be bagged.
 - e. If possible, have biological detection equipment in place—SMART tickets are a handheld point detection system developed by the Navy Medical Institute. Instrument captures antigen and changes color according to eight different biological agents detected.
2. Identify *anthrax* precautions.
 - a. Implement and maintain Standard Precautions (gowns, gloves, and mask). Use Contact Precautions for cutaneous anthrax.
 - b. Isolation or decontamination is not implemented. ► **Rationale:** Anthrax is not transmitted by person-to-person contact.
 - c. If client has been exposed and clothing may be contaminated, decontamination is advised.
3. Identify *plague* precautions.
 - a. In a bioterrorism attack, bacterium (*Yersinia pestis*) may be spread by inhalation of droplets, aerosols, or disseminated via infected fleas or other biting insects. ► **Rationale:** Droplet precautions are used until client has been treated for 2–3 days (gown, gloves, and mask).
 - b. Strict isolation until client has been treated for 2–3 days. ► **Rationale:** So that airborne contaminants do not spread throughout the hospital or community.
 - c. Decontamination precautions: soap/shower; 0.5% diluted bleach for visible contamination.
 - d. Disinfect environment: 0.5% diluted bleach or EPA-approved detergent.
4. Identify *botulism* precautions.
 - a. A bioterror attack could disseminate an aerosol of the bacterium or purified neurotoxins. Therefore, use Standard Precautions. ► **Rationale:** If toxin is used, there is no danger of person-to-person transmission.
 - b. Decontamination procedures: toxin may be removed from skin by soap and water.
 - c. Place contaminated clothes in sealed plastic bag for biohazard disposal.
 - d. Other precautions:
 1. Environment: diluted bleach 0.5%, 15–20 seconds, or EPA-approved germicidal detergent.
 2. Boil water for 15 minutes.
 3. Cook food at 176°F for 30 minutes.
5. Identify *smallpox (variola)* virus.
 - a. Spread through airborne or direct contact with skin lesions or secretions. Use Standard Precautions with airborne (respiratory isolation; N95 or P100 mask) and contact precautions (gown and gloves). ► **Rationale:** Virus is spread through droplet or contact; therefore, isolation decontamination precautions are used.
 - b. Isolate and quarantine victim immediately and place in negative pressure room with HEPA filtration or direct exhaust to the outside.
 - c. All direct contacts are quarantined for at least 17 days. ► **Rationale:** Incubation period is 7–17 days.
 - d. Cleanse with soap/shower; use 0.5% diluted bleach for gross or visible contamination.
 - e. Place mask on victim, if not in isolation. ► **Rationale:** Virus is spread through airborne method so mask will protect others.

▲ For minimal protection, use particulate filter N95 or HEPA filter respirator when you may be exposed to an unknown biological hazard.

- f. Healthcare workers maintain standard/airborne/contact precautions for minimum 17 days (until all scabs separate). ► **Rationale:** When scabs separate, client is no longer contagious.
 - g. All bedding and clothing must be autoclaved or laundered in hot water and bleach.
6. Identify *brucellosis* precautions.
- a. Bioterrorism mode of dissemination could be aerosol or food supply sabotage. Standard Precautions indicated. If lesions are draining, use contact precautions.

▲ Institute airborne precautions when certain bioterrorism agents such as plague and smallpox are suspected.

- b. Decontamination—victim should undress and use soap/shower.
 - c. Environment: 0.5% bleach.
7. Identify *typhoidal tularemia* precautions.
- a. Bioterrorism mode of dissemination would probably be aerosol with nontransmission. Use Standard Precautions.
 - b. Isolation/decontamination precautions. Victim should undress, use soap, and shower. For visible contamination, use 0.5% bleach.
 - c. Environment: 0.5% bleach.
8. *Viral encephalitides* precautions.
- a. Bioterrorism mode of dissemination is aerosol. Use Standard Precautions.
 - b. Isolation/decontamination precautions. Victim should undress, use shower with soap and large quantity of water.
 - c. Mosquito control × 72 hr.
 - d. Environment: 0.5% bleach.

The U.S. Government is now launching an early warning system that detects bioterrorism agents released into the air. Adapting 3,000 existing monitors that now are used for air pollution, this system could detect biological agents, such as smallpox or anthrax. Results of early warnings could be confirmed at a network of laboratories within 24 hr using DNA analysis.

Choosing Protective Equipment for Chemical Exposure

Equipment

Listed below in procedure.

Procedure

1. Identify victims who were exposed to chemical substance. ► **Rationale:** Early identification is essential to save lives, especially from nerve agents or cyanide.
2. Cover all skin surfaces with protective clothing impervious to chemicals. ► **Rationale:** Necessary for protection until exact chemical agent is identified.
 - a. Use Mission-Oriented Protective Posture (MOPP) suit, if available (chemical protection suit).
 - b. Use fire department chemical suits as alternative.
3. Don masks with filtered respirator. (HEPA filter respirator—P100 with full facepiece—and fit-tested N95 meet CDC performance criteria for chemical exposure.) ► **Rationale:** Chemicals can be inhaled.
4. Wear boots or boot covers. ► **Rationale:** Feet should be covered to prevent tracking contaminant.
5. Initiate decontamination procedures with trained personnel.

▲ For chemical or certain biological exposure, masks with HEPA filtered respirator or N95 should be used.

- a. Decontaminate at site, if possible.
 - b. Otherwise, decontaminate outside of facility.
6. Use chemical detection devices, if available.
- **Rationale:** Devices would validate presence or absence of agent.
 - a. M8 Paper: Sheet of chemically treated paper—if colored spots appear within 20 seconds, chemical agent is present.
 - b. M9 Tape: Affix adhesive-backed paper to equipment or protective clothing—color changes when exposed to chemical agent.
 - c. M2S6A1 Chemical Agent Detector Kit: Can detect nerve, blister, or blood agent vapors; a glass ampule contains substance that, when placed on test spot, changes color.
 - d. Chemical Agent Monitors (CAMs): Contain a microprocessor chip that identifies presence of certain nerve and blister agents.

Choosing Protective Equipment for Radiological Attack

Equipment

Listed below in procedure.

Procedure

1. Identify victims contaminated by radiation. ► **Rationale:** If victim is contaminated, clothes, skin, etc., can transmit contamination to others.
 - a. If victim was exposed to ionizing radiation (most common are alpha, beta particles, and gamma rays), contamination occurred.
 - b. The higher the dose of radiation, the greater the severity of contamination.
2. Don protective clothing: basic gear will stop alpha and some beta particles, not gamma rays.
 - **Rationale:** Necessary to protect responders from exposure and to prevent cross-contamination, exposing other clients.
 - a. Scrub suit.
 - b. Gown and cap.
 - c. Mask.
 - d. Eye shield.
 - e. Double gloves—one pair under cuff of gown and taped to close all entry; second pair can be removed and/or replaced.
 - f. Masking tape, 2 ins. wide.
 - g. Shoe cover with all seams taped.
 - h. Radiation detection device: able to detect energy emitted from a radiation source. Several detectors available: Geiger counters, dosimeters, etc.
 - i. Film badge.
3. Transport victim to facility.
 - a. If victim is not decontaminated at site, set up portable decontamination unit before entering facility.
 - b. Double-bag all victim's clothing in sealed biohazard plastic bags marked "Radioactive."
4. Institute decontamination procedures.
 - a. Open wounds or nonintact skin: irrigate with sterile water or normal saline (NS); cover with dry, sterile dressing.
 - b. Eyes: irrigate with sterile water of NS according to skill, "Irrigating the Eyes," Chapter 18.
 - c. Intact skin: wash skin with soap and warm water. Bleach, 0.5%, may also be used.
 - d. Radiation burns: treat as other burns are treated.
5. Recheck radiation levels at each stage of treatment until reduced to background levels.
6. Dispose of used protective gear appropriately. ► **Rationale:** This gear is radiologically contaminated waste, and to prevent cross-contamination, it must be treated as such.

▲ When exposed to radiological material, double gloves that cover all skin exposure should be worn.

New Trends: Tiny Radiation Detector Saves Lives

Because the greatest threat to our national security is the use of a nuclear device, this matchbook-size detector that you can keep on your key chain could save your life. This device, called a NukAlert, measures levels of radiation (like a Geiger counter) and lets you know the areas that are safe or dangerous by emitting a chirp sound. The more chirps, the greater the danger. This device is reasonably priced—you may contact KI4U in Texas for more information.

Decontaminating Victims After a Biological Terrorist Event

Equipment

- Protective clothing for healthcare worker
- Biohazard bags
- Soap and water; diluted sodium hypochlorite (bleach)

Procedure

1. Don protective clothing and adhere strictly to Standard Precautions for emergency personnel. ► **Rationale:** This will prevent secondary contamination of personnel.
2. Identify dermal exposure, if possible. ► **Rationale:** Biological agents are difficult to detect.
3. Remove victim's clothing as soon as possible and place in biohazard bags. ► **Rationale:** If victim was exposed, clothing is contaminated.
4. Cleanse exposed areas using soap and tepid water (large amounts) or diluted sodium hypochlorite (0.5%).
5. Send victims home, if possible, to continue decontamination procedure by washing thoroughly with soap and water.
 - a. Instruct victims to monitor for signs and symptoms of agent.
 - b. Inform victim of result of lab analysis as soon as possible.

▲ Dispose of all contaminated clothing in appropriate biohazard bags.

Decontaminating Victims After a Chemical Terrorist Event

Equipment

- Protective equipment for healthcare workers
- Biohazard bags
- Soap and water; diluted sodium hypochlorite (bleach)
- Saline or isotonic bicarbonate
- Chemical agent monitor or M8 paper

Procedure

1. Know general principles to guide actions after a chemical agent incident.*
 - a. Expect a 5:1 ratio of unaffected:affected casualties.
 - b. Decontaminate immediately (ASAP).
 - c. Disrobing is decontamination, head to toe; the more removal, the better.
 - d. Large-volume water flush is best decontamination method.
 - e. After exposure, first-responders must decontaminate immediately to avoid serious effects.
2. Practice triage guidelines for Mass Casualty Decontamination.* ► **Rationale:** Chemical exposure can be deadly, so early decontamination is critical. Decontaminate according to:
 - a. Casualties closest to point of release.
 - b. Casualties reporting exposure to vapor or aerosol.
 - c. Casualties with liquid deposits on clothing or skin.

▲ Place contaminated clothing in bins or biohazard bag labeled "RADIOACTIVE" if that is source of contamination.

- d. Casualties with serious medical conditions.
- e. Casualties with conventional injuries.
3. Decontaminate victims as early as possible. ► **Rationale:** Requirements differ according to type of chemical agent used: sarin dissipates quickly in the air; VX remains lethal for hours.
 - a. Nerve agents may be absorbed on all body surfaces—must be removed quickly to be effective.
 - b. Vesicant (blister) agents are not always identified due to latent effects.
4. Treat eyes and mucous membranes with special protocol.
 - a. Flush with copious amounts of water. ► **Rationale:** Eyes and mucous membranes are too sensitive to use other skin decontaminant solutions.
 - b. If available, isotonic bicarbonate (1.26%) or saline (0.9%) may be used as a flushing agent.
5. Monitor victim for remains of agent or contaminant using chemical agent monitor (CAM) or M8 paper for chemical agents. ► **Rationale:** To validate removal of contaminant.

NOTE: Skin decontamination kits (M258A1) designed for chemical decontamination are available. They hold wipes that contain a solution that neutralizes most nerve and blister agents.

*Source: Guidelines for Mass Decontamination During a Terrorist Chemical Agent Incident. U.S. Army Soldier and Biological Chemical Command, January 2000. Available at <http://orise.oran.gov/reacts/resources/guide/management.htm>

Decontaminating Victims After Radiation Exposure

Equipment

Personal protection equipment including self-contained breathing equipment and flash suits, if indicated
 Surgical attire or disposable garments, shoe covers, eye shield, gloves, and masks with respirators
 Water source and container to catch runoff
 Bins for contaminated clothing
 Biohazard bags
 Vacuum cleaner with HEPA filter
 Radiation dose meter

Procedure

1. Determine cause of incident to identify radiation exposure or contamination. ► **Rationale:** Exposure does not necessarily indicate need for decontamination.
 - a. First responders may be told by those requesting assistance that there has been a radiation-exposure event.
 - b. First responders may recognize radiation exposure from observation at incident site.
2. Understand difference between exposure and contamination.
 - a. Exposed victim: presents no hazard, requires no special handling, and presents no radiological threat to personnel. ► **Rationale:** This is no different from client who has had diagnostic x-rays.
 - b. Externally contaminated victim: may mean individual has come in contact with unconfined radioactive material. ► **Rationale:** Any person or object contaminated by radioactivity must be considered contaminated. Steps should be taken to minimize contamination.
 - c. Internal contamination: occurs by inhalation or ingestion (airborne radioactive particles) or through an open wound. *Usually* this form of contamination is not a hazard to others.
3. Use appropriate personnel protection equipment (PPE). ► **Rationale:** This will protect personnel who may come in contact with contaminated victim.
 - a. If radiation incident is suspected, self-contained breathing apparatus (SCBA) and flash suits are indicated. ► **Rationale:** This will reduce potential exposure of healthcare providers. Inhalation of radioactive particles is cross-contamination hazard.
 - b. If SCBA suits not available:
 1. Use surgical attire or disposable garments (such as those made of Tyvek).
 2. Use eye protection and double gloves.
 3. Use masks with respirators. ► **Rationale:** These will protect healthcare workers from inhaling radioactive particles leading to internal contamination.
 - c. It is important to recognize that external radiation (such as penetration by gamma rays) is *not* dangerous to emergency personnel—the only exception to this rule is a rare neutron radiation exposure. ► **Rationale:** Gamma ray radiation is absorbed by or passes through the body, but does not leave radioactive contamination.
 - d. If monitoring for radiation is not available, consider all clients contaminated.
 - e. Personnel should minimize time in radiation zone. ► **Rationale:** Radiation exposure depends on time, distance, and shielding.

4. Triage client's medical condition first, regardless of radiation exposure. ► **Rationale:** First priority is delivery of emergency medical services, including transport.
 - a. Administer emergency medical treatment to radiation-exposed clients.
 - b. Decontaminate clients who have been contaminated on the scene before transport.
5. Complete decontamination of victims. ► **Rationale:** Until decontamination is complete, victims are an exposure risk to selves, staff, and others.
 - a. Remove client's clothing and have client do a total body wash, scrubbing skin with soap and soft brush. ► **Rationale:** Removal of victim's clothing will reduce 80% of the contamination.
 - b. Place contaminated clothing in bins or biohazard bag labeled "Radioactive."
- c. Capture runoff of water; contain and label "Radioactive."
- d. Wash area down between washing victims. ► **Rationale:** This will prevent transfer of contaminated material.
- e. Capture material with vacuum cleaner with HEPA filter, if appropriate. ► **Rationale:** This prevents release of radioactive material into the air.
- f. Monitor client with radiation meter to measure radiation.
6. Implement isolation techniques for contaminated victims. ► **Rationale:** To confine contamination and protect personnel.
7. Determine source of radiation, type of radioactive material, length of time of exposure, if possible. ► **Rationale:** This is valuable data for long-term interventions, but does not alter immediate handling and transport of victim.

Controlling Radiation Contamination

Equipment

Soap and water
 Disposable client equipment
 Biohazard bags
 Wide tape
 White tape
 Heavy, wide paper
 Plastic-lined containers
 Radiation meter

Procedure

1. Decontaminate all victims; remove all clothing and complete a full body wash. ► **Rationale:** This will reduce most of the contamination.
2. Institute isolation techniques. ► **Rationale:** This will confine contamination and protect others.
3. Decontaminate equipment touched by client.
 - a. Gurney used to transfer client.
 - b. Equipment used in client care (BP cuff, stethoscope, etc.)
 - c. Ambulance.
4. Decontaminate care providers who touched or moved client. ► **Rationale:** Protective clothing may be contaminated.
5. Examine surrounding area (walls, floor that client may have touched).
6. Control entry and exit of victims. ► **Rationale:** Radioactive particles adhere to dust, may become airborne, and can contaminate other clients and personnel.
 - a. Mark entry area with white tape to differentiate areas.
 - b. Restrict access to controlled area.
 - c. Monitor everyone leaving controlled area—have persons cleared by radiation safety officer.
7. Cover floor areas with rolls of heavy, wide paper and tape securely to floor. ► **Rationale:** To prevent tracking of contaminants.
8. Control waste by using large plastic-lined containers for contaminated articles.
9. Monitor radiation by using meter.

DOCUMENTATION for Personal Protective Equipment and Decontamination

- Specific infection control protocols implemented (i.e., Standard or Airborne Precautions)
- Personal protection gear and equipment used
- Decontamination site established
- Decontamination procedure used for biological or chemical event
- Radiation exposure decontamination procedure

CRITICAL THINKING Application

Expected Outcomes

- Infection control protocols are followed. Staff is familiar with protective equipment and the protocols to use it.
- Staff knows decontamination procedures and implements them safely.

Unexpected Outcomes

Mass casualty disaster occurs with hundreds of victims affected in one area.

Type of personal protection equipment is unknown for agent exposure.

Clients are admitted with potential radiation exposure.

- Decontamination procedures for mass casualty disasters are implemented.
- Radiation exposure is controlled.

Alternative Actions

- Don protective gear before approaching WMD site.
- Identify weapon or agent used to create disaster, if possible.
- Institute field triage (triage first done at site before victims sent to community healthcare facilities).
- Decontaminate victims at site before transporting to treatment facility.
- It is critical that response team be fully protected; thus choose highest level of equipment; that is, assume you need:
 1. airborne protection with respirators—self-contained breathing apparatus (SCBA) with full face piece.
 2. full Level A protective suit.
 3. shoe covers and double gloves.
 4. biological detection device, if available.
- Determine if radiation is exposure or contamination; if the latter, use protective gear and radiation dose meter.
- Decontaminate clients by removing all clothing and giving a full body wash—institute isolation techniques.
- Decontaminate all equipment, surfaces, and personnel that came in contact with client.
- Administer treatment according to dose exposure: supportive care, frequent blood tests (CBC and differential), and prevent infection.

Chapter 15

UNIT 4

Triage, Treatment, and a Communication Matrix

Nursing Process Data

ASSESSMENT Data Base

- Assess the need to establish triage treatment areas.
- Validate that public health parameters are established.
- Observe that the steps of triage are followed.
- Assess that victim is not in immediate danger or, conversely, requires immediate intervention.
- Assess vital signs of victims.
- Assess the treatment steps necessary to treat life-threatening conditions.
- Observe for signs of respiratory distress.
- Assess need for establishing an airway.
- Observe for amount and source of bleeding and need for intervention.
- Recognize shock state and need for intervention.
- Assess victims post-triage and observe for any signs or symptoms that indicate major injury.
- Identify victims having a severe psychological reaction to bioterrorism event.
- Assess possibility of post-traumatic stress syndrome developing.
- Assess that lines of communication are established and activated.
- Assess that Federal Response Plan is activated.
- Assess that external, internal, and collaborative communication networks are in place.

PLANNING Objectives

- To establish a triage site taking into account public health parameters
- To establish triage treatment areas appropriate to number and injuries of victims
- To follow steps of triage
- To observe for any signs/symptoms that indicate major injury
- To treat life-threatening conditions
- To care for clients with major psychological reactions to bioterrorism event
- To prevent post-terrorism trauma
- To develop a communication network including external, internal, and collaborative communication

IMPLEMENTATION Procedures

- Establishing Triage Treatment Areas 501
- Establishing Public Health Parameters 501
- Developing a Communication Network 501
- Establishing Viable Communication 502
- Carrying Out Steps of Triage 503
- Treating Life-Threatening Conditions 503
- Assessing Victims Post-Triage 504
- Caring for Those Who Died 505
- Caring for Clients With Psychological Reactions 505
- Identifying Post-Traumatic Stress Disorder (PTSD) .. 506

EVALUATION Expected Outcomes

- Triage treatment areas are established within public health parameters.
- Staff follows appropriate steps of triage protocol.
- Life-threatening conditions are identified and treated.
- Post-triage assessment is completed.
- Post-traumatic stress disorder (PTSD) is identified and clients are referred appropriately.

- **Critical Thinking Application** 507
- Expected Outcomes 507
- Unexpected Outcomes 507
- Alternative Actions 507

nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Establishing Triage Treatment Areas

Procedure

1. Assign roles to personnel in treatment areas.
2. Select a site as soon as possible—advance planning is essential.
 - a. Select safe area, free of hazards and debris.
 - b. Position site upwind of hazard zone.
 - c. Determine whether site is accessible to transportation vehicles (ambulances, trucks, helicopters).
 - d. Be sure site is able to expand.
3. Protect treatment area and delineate area using tarps, etc. If possible, do not contaminate a crime scene.
4. Set up signs to identify subdivisions of area.
 - a. I = Immediate care.
 - b. D = Delayed care.
 - c. Dead = Dead for morgue.
5. Establish I and D areas close together. ► **Rationale:** Facilitates verbal communication between workers who can also share medical supplies and transfer victims quickly when status changes.
6. Position victims in head-to-toe configuration, with 2–3 feet between victims. ► **Rationale:** This system will effectively use space and personnel.
7. Establish morgue site secure and away (and not visible) from medical treatment areas.

Clinical Alert

Survey entire scene, including area above you, for threats to your safety before beginning triage or team work.

Establishing Public Health Parameters

Equipment

Soap and water; antibacterial gel
 Gloves
 Mask and goggles
 Biohazard waste disposal containers
 Plastic bags
 Water purification equipment
 Search and rescue equipment

Procedure

1. Assign personnel to monitor public health concerns where disaster victims are sheltered. ► **Rationale:** To avoid or minimize spread of disease.
2. Have available search and rescue safety equipment.
 - a. Helmet or hardhat.
 - b. Goggles.
 - c. Sturdy work gloves and shoes.
 - d. Clothing appropriate for weather conditions.
 - e. Dust mask or appropriate filtered mask (see Protection section).
 - f. Rescue whistle.
3. Maintain proper hygiene by washing hands and using gloves.
 - a. Wash hands with soap and water if dirty or antibacterial gel between victims.
 - b. Wear gloves at all times.
 - c. Change gloves between victims if possible. If not, clean them between victims in a bleach and water solution (1 part bleach to 9 parts water).
4. Wear a mask and goggles.
5. Avoid direct contact with body fluids.
6. Maintain sanitation.
 - a. Mark and have available specific biohazard waste disposal containers where bacterial sources (gloves, dressings, etc.) are discarded.
 - b. Place waste products in plastic bags and bury them in designated area.
 - c. Bury human waste.
7. Purify water for drinking, cooking, medical use, if potable water is not available.
 - a. Boil water at rolling boil for 10 minutes.
 - b. Use water purification tablets.
 - c. Use unscented liquid bleach (16 drops per gallon of water or 1 teaspoon per 5 gallons; mix and let stand for 30 minutes).

Developing a Communication Network

Procedure

1. Understand lines of communication. ► **Rationale:** When lines of communication are compromised, effective triage and intervention cannot take place.
 - a. Mass casualty incident occurs.
 - b. Local public health official notifies FBI—lead agency for crisis plan.
 - c. FBI notifies DHS, HHS, CDC, and FEMA.
 - d. State health agency requests CDC to deploy response teams if needed.

2. Understand the network of communication that will be activated in response to a suspected or actual bioterrorism event.
 - a. Emergency response team:
 - Local and state public health officials.
 - Infection control personnel in notified facilities.
 - FBI field offices (Department of Homeland Security).
 - CDC.
 - Local emergency medical services (EMS).
 - Local police and fire departments.
 - b. In turn, the Federal Response Plan will be activated.
3. Activate Federal Response Plan. ► **Rationale:** When the local area cannot cope with the disaster, federal assistance is available.
 - a. Department of Health and Human Services (HHS) is primary agency.
 - b. Office of Emergency Preparedness is action agency.
 - c. Emergency Support Function N8 coordinates federal assistance to supplement state and local resources (directed by HHS).
 - d. Implemented when state requests assistance and FEMA agrees.

EVIDENCE-BASED PRACTICE

Who Can You Count On?

Research has repeatedly shown that disasters result in increased pro-social behavior, where cooperation and consensus are present during the emergency response phase, and self-interested activity is set aside.

Source: Tierney, K., Lindell, M., & Perry, R. (2001). *Facing the unexpected: Disaster preparedness and response in the United States*. Washington, DC: Joseph Henry Press.

Establishing Viable Communication

Procedure

1. Set up **external communication** system designated spokesperson.
 - a. A viable system will minimize disruption.
 - b. All communication goes through designated spokesperson—no staff will communicate with the public, press, or outside persons.
2. Report to appointed community-wide regional spokesperson or small group designated as being in command throughout the incident. Spokesperson will be in charge of coordination of all media relations.

► **Rationale:** One person or small group in charge will minimize confusion.
3. Set up a single community site for family and friends to obtain victim-locator information. ► **Rationale:** More than one site will lead to mass confusion.
 - a. Provide clear, consistent, and verifiable information to clients and general public.
 - b. Plan in advance methods and channels of communication to be used to inform the public.
4. Establish **internal communication**.
 - a. Determine position (not person) that will be in charge (i.e., emergency department supervisor, called “incident commander”). ► **Rationale:** Position, rather than person, will negate confusion when there is staff turnover, multiple shifts, or reassignment of staff.
 - b. Communicate only through established lines of communication with designated commander or liaisons.
5. Establish a **collaborative communication system**.
 - a. Establish ongoing, open channels of communication with emergency response teams. ► **Rationale:** Response teams may have first awareness of the disaster and will need to communicate with the hospital.
 - b. Appoint person (reporting to spokesperson) to collaborate with response team and link to community representative.
 - c. Develop a community-wide communications network. ► **Rationale:** If different organizations cannot communicate with each other, precious time will be lost.
 - d. Test the communications network so overload does not occur in the event of a mass casualty incident.
6. Develop clear communication systems that have access to telecommunications as well as a person-to-person communication system. ► **Rationale:** This position-to-position or person-to-person system is necessary if telecommunications are overwhelmed or unavailable.
 - a. Use pagers, walkie-talkies, and the Internet via e-mail as substitutes for communication network during a disaster.
 - b. Develop horizontal and vertical relationships between organizations, governmental and private, that will have to work together in a mass casualty event.

NOTE: Local areas are beginning to establish their own interconnected networks to facilitate communication. For example, all of New York City’s hospitals are connected via the Internet, so if victims begin to funnel into several facilities, their symptoms can be quickly correlated to establish a diagnosis.

Clinical Alert

The goal of disaster medical interventions is to do the greatest good for the greatest number of victims.

Carrying Out Steps of Triage

Procedure

1. Evaluate the disaster area: stop, look, listen, check safety, and designated treatment areas.
2. Don protective gear (based on type of disaster) for your safety.
3. Quickly assess conditions for triage before beginning.
4. Conduct voice triage—tell victims to move, if they are able, to designated areas of triage.
 - a. Immediate triage for life-threatening conditions.
 - b. Delayed triage for those who can wait to be treated.
5. Treat immediate victims (airway, bleeding, and shock).
6. Tag all victims, even those who are dead.
7. Document results.

Treating Life-Threatening Conditions

Equipment

Protective gear
 Dressings/bandages
 Tourniquets
 Stethoscope
 Tongue blades
 Automated external defibrillator (AED), if available

Procedure

1. Implement Simple Triage and Rapid Treatment (START).
 - **Rationale:** This is the first step for treating multiple casualties in a disaster.
2. **Check breathing immediately.**
 - a. Open airway. ► **Rationale:** If airway is obstructed, victim cannot get oxygen.
 - b. Move fast—time is critical. ► **Rationale:** Heart function will be affected within minutes, and brain damage is possible after 4 minutes.
 - c. Check if tongue is obstructing airway. ► **Rationale:** This is the most common airway obstruction (especially when victim is positioned on back).
3. Use head-tilt/chin-lift method if victim is not breathing and airway is not obstructed.
 - a. Touch victim and shout, “CAN YOU HEAR ME?”
 - **Rationale:** To ensure victim has not fainted.
 - b. If victim does not respond, place one hand on forehead, two fingers of other hand under chin, and tilt jaw upward and head back slightly. ► **Rationale:** This position opens airway.
 - c. Look for chest to rise, listen for air exchange, and feel for abdominal movement. ► **Rationale:** Reliable indicator of open airway is feeling or hearing air movement.
 - d. If no response (victim does not start breathing), repeat procedure. (If AED is available, may apply to victim.)
 - e. If victim does not respond after second attempt, move on to next victim. ► **Rationale:** Goal of disaster intervention is to do the greatest good for the greatest number of victims.
4. **Control bleeding.** ► **Rationale:** If bleeding is not controlled within a short period of time, victim will go into shock. Loss of 1 liter of blood—out of a total of 5 in the human body—will present risk of death.
 - f. If the victim begins breathing, maintain airway (hopefully with a volunteer holding airway open) or place soft object under victim’s shoulders to elevate them, keeping airway open.
5. Identify type of bleeding.
 - a. Arterial bleeding (spurting blood)
 - b. Venous bleeding (flowing blood)
 - c. Capillary bleeding (oozing blood)
6. Choose appropriate method to control bleeding.
 - a. Direct local pressure—place direct pressure over wound (using clean or sterile pad) and press firmly.
 - **Rationale:** 95% of bleeding can be controlled by direct pressure with elevation.
 - b. Maintain compression by wrapping wound firmly with pressure bandage.
 - c. Elevate wound above level of heart.
 - d. Use pressure point to slow blood flow to wound, brachial point for arm, femoral point for leg.
 - **Rationale:** Using pressure on a pulse point on a major artery will slow blood flow.
7. Use tourniquet if bleeding cannot be controlled by other methods (consider this a last resort). ► **Rationale:** Tourniquets can pose serious risks to affected limbs.
 - a. Incorrect material or application can cause more damage and bleeding; if too tight, nerves, blood vessels, or muscles may be damaged.
 - b. If tourniquet is left in place too long, limb may be lost.
 - c. If tourniquet is applied, leave in plain sight and affix label to victim’s forehead, stating time tourniquet was applied.
 - d. Notify physician to remove tourniquet.
8. **Recognize and treat shock.** ► **Rationale:** If the victim remains in shock, it will lead to death of cells, tissue, and organs.
 - a. Body will initially compensate for blood loss, so signs of shock may not be observable.
 - b. Continually evaluate victim’s condition.

Steps of Trauma Assessment Applied to Triage

1. Perform a rapid systematic assessment. ► **Rationale:** Trauma is a multisystem condition so all systems must be assessed.
2. Complete a primary trauma assessment. ► **Rationale:** To identify victim's primary and critical problem.
 - a. Airway
 - b. Breathing capability
 - c. Shock—circulation and bleeding
 - d. Neurologic—level of consciousness, mental status
 - e. Exposure to contaminate
 - f. Disability
 - g. Evacuation necessity
3. Complete a secondary assessment (post-triage) that includes a focus assessment.

Clinical Alert

Experts agree that 49% of disaster victims could be saved by providing simple medical care for life-threatening conditions: airway obstruction, bleeding, and shock.

9. Observe for signs/symptoms of shock:
 - a. Rapid, shallow breathing
 - b. Cold, pale skin (capillary refill)
 - c. Failure to respond to simple commands
10. Administer treatment for shock:
 - a. Position victim supine with feet elevated 6–10 in.
 - b. Maintain open airway.
 - c. Maintain body temperature (cover ground and victim).
 - d. Avoid rough or excessive handling, and do not allow victim to eat or drink.

Assessing Victims Post-Triage

Procedure

1. Perform head-to-toe assessment, always in the same order. ► **Rationale:** Performing assessment in same way every time will enable you to complete it more quickly and accurately.
 - a. Head
 - b. Neck
 - c. Shoulders
 - d. Chest
 - e. Arms
 - f. Abdomen
 - g. Pelvis
 - h. Legs
 - i. Back
2. Complete assessment before beginning any treatment. ► **Rationale:** In order to prioritize treatment interventions, a complete assessment must be done.
3. Observe for any sign/symptom that indicates major injury.
 - a. Assess how person received injury (mechanism of injury)
 - b. Airway obstruction
 - c. Signs of shock
 - d. Labored or difficult breathing
 - e. Excessive bleeding
 - f. Swelling/bruising
 - g. Severe pain
4. Provide immediate treatment. During treatment, reclassify victim, if necessary.

Cultural Awareness

During a disaster, it remains a priority for staff to address ethnic, religious, and cultural customs of diet, death, and burial.

5. Assess that victim is not in immediate danger. If available staff, continue to assess for signs of head, neck, and spinal injury.
 - a. Change in level of consciousness (unconscious, confused)
 - b. Unable to move body part
 - c. Severe pain in head, neck, back
 - d. Tingling or numbness in extremities

Phases of Death Due to Trauma

- Phase 1 Death within minutes due to overwhelming and irreversible damage to vital organs.
- Phase 2 Death within several hours due to excessive bleeding.
- Phase 3 Death within several days or weeks due to infection or multiple system failure (not from injury per se).

Experts agree that more than 40% of disaster victims in Phases 2 and 3 of death could be saved by providing basic medical care.

- e. Difficulty breathing or seeing
 - f. Heavy bleeding/blood in eyes or nose
 - g. Seizures
 - h. Nausea, vomiting
 - i. Possible closed compression injury (e.g., victim found under collapsed structure)
6. Immobilize head, neck, or spine by keeping spine in straight line, putting cervical collar on neck, or placing victim on board—if equipment is available.
 7. Document who person is and relevant medical information.
 - a. Available identifying data
 - b. Description, clothing
 - c. Injuries
 - d. Treatment
 - e. Transfer location

Caring for Those Who Died

Procedure

1. Tag victims pronounced DOA (dead on arrival).
 - a. Add special tag “not to remove personal effects.”
 - b. Incorporate special instructions for people performing autopsies, preparing bodies for burial or transportation.
2. Place bodies in cordoned-off area for field triage.
 - ▶ **Rationale:** Decontamination may have to be completed before transport.
3. Notify those performing post-mortem care of victim’s diagnosis. ▶ **Rationale:** For protection of staff handling post-mortem care.
 - a. Autopsies performed carefully using all personal protective equipment and Standard Precautions, including use of masks and eye protection.
 - b. Incorporate any special instructions about biological–chemical–radiological agent present.
4. Complete a record for all bodies including identification, name of person declaring death, diagnosis, if known, name of agency removing body, etc.

Caring for Clients With Psychological Reactions

Procedure

1. Expect major psychological reactions of fear, panic, anger, horror, paranoia, unrealistic concerns about infection, fear of contagion, social isolation, demoralization, etc., after a bioterrorism event.
2. Plan prior to such an event for professional and educated volunteers to be on site.
3. Minimize fear and panic in staff.
 - a. Provide educational materials that include risks to healthcare workers, accurate information of bioterrorism facts, plans for protecting workers, and how to use personal protection equipment.
 - b. Encourage team participation in disaster drills.
 - ▶ **Rationale:** Experience in handling a disaster will build confidence and allay anxiety.
4. Cope with psychological reactions of fear and anxiety.
 - a. Minimize panic by clearly explaining care given with explanations.
 - b. Offer rapid evaluation and treatment and avoid isolation, if possible. ▶ **Rationale:** Waiting for evaluation and treatment (as well as isolation) will cause anxiety.
5. Treat major anxiety reactions in unexposed persons with factual information, reassurance, and medication, if indicated. ▶ **Rationale:** Anxiety is communicable; prompt intervention will allay group anxiety. (“Worried well” persons could overwhelm hospitals if they leave disaster area and go to closest healthcare facility.)
6. Prevent post-terrorism trauma. ▶ **Rationale:** Early intervention may reduce stress disorder.
 - a. Gather victims into a group with a skilled therapist soon after event (within 24 hr) to prevent a major post-trauma reaction.
 1. Early opportunity for catharsis will help prevent suppression of traumatic event emotions.
 2. Group victims according to age and experience.
 - b. Follow initial group meeting with subsequent meeting within 1 week to discuss feelings about event.
 - ▶ **Rationale:** Research has found that group meetings after traumatic event have eliminated 80% of post-traumatic stress disorder.

EVIDENCE-BASED PRACTICE

Studies on mass casualty incidents have reported enormous stress and pressure faced by health workers. Effective response to the crises requires considerable support services for themselves.

Source: Caro, D. (1999). Towards integrated crisis support of regional emergency networks. *Health Care Management Review*, 24(4), 7–19.

Clinical Alert

If a disaster occurs, be alert to signs of disaster trauma in yourself and/or coworkers and take steps to alleviate stress before it becomes incapacitating.

Identifying Post-Traumatic Stress Disorder (PTSD)

Procedure

1. Recognize possibility of existing condition.
 - a. Traumatic event occurs and is reexperienced as flashbacks, dreams, or memory state.
 - b. Abreaction occurs: vivid recall of painful experience with original emotions.
 - c. Individual cannot adjust to event.
2. Assess signs and symptoms of anxiety and depression.
 - ▶ **Rationale:** Early recognition will assist in therapeutic intervention.
 - a. Emotional instability, withdrawal, and isolation.
 - b. Nightmares, difficulty sleeping.
 - c. Feelings of detachment or guilt.
3. Assess aggressive or acting-out behavior; may be explosive or impulsive behavior.
4. Assist client to go through recovery process.
 - ▶ **Rationale:** Client may have to be assisted through recovery steps to reach adjustment.
 - a. Recovery—reassure client that he is safe after experience of the traumatic event.
 - b. Avoidance—client will avoid thinking about traumatic event; support client.
 - c. Reconsideration—client deals with event by confronting it, talking about it, and working through feelings.
 - d. Adjustment—client rehabilitates and adjusts to environment after event; client functions well and is able to view future positively.

Post-Traumatic Stress Syndrome (PTSD) After a Natural Disaster

After the Katrina disaster, one third of the people hardest hit could develop PTSD. Disaster-related mental problems such as anxiety, substance abuse, and depression could also occur.

The major contributors to the risk of psychological trauma and later PTSD are:

- Severity of person's exposure to the tragedy
- Threat to life
- Severity of property damage or loss
- Degree of injuries to self or family members
- Degree of panic during disaster
- Separation from family members
- Amount of financial loss
- Predisaster history of mental illness or those already under stress
- Lack of resources (social, family, or financial) after disaster
- Statistics reveal that females over males, ethnic minorities, and adults age 40 to 60 are more challenged by a disaster

Nurses doing psychological triage after a disaster need to evaluate the individuals based on risk assessment. They need to identify potential danger to self or others and intervene accordingly.

EVIDENCE-BASED PRACTICE

Post-Traumatic Stress Syndrome (PTSD) After a Natural Disaster

In 1992, after Hurricane Andrew, one study found that 36% of South Florida subjects exposed to the disaster met the criteria for new onset of PTSD 6 months after the storm, and 30% suffered major depression.

Source: David, D., Mellman, T. A., Mendoza, L. M., Kulick-Bell, R., Ironson, G., & Schneiderman, N. (1996). Psychiatric morbidity following Hurricane Andrew. *J Trauma Stress* 9(3), 607–612.

DOCUMENTATION for Triage, Treatment, and Communication Matrix

- Triage treatment areas established—note site and subdivisions
- Triage format for assessing victims
- Public health parameters followed
- Protection equipment used for site selection and maintenance
 - Sanitation procedures
 - Purified water procedure
 - Search and rescue procedures
- Protection gear and equipment used for triaging victims
- Procedures implemented for individual life-threatening conditions
- Post-triage assessment of victim
- Assessment of psychological reactions
- Interventions for identifying post-traumatic stress disorder
- Communication network established:
 - Internal communication lines
 - External communication lines
 - Collaborative communication lines

CRITICAL THINKING Application

Expected Outcomes

- Triage treatment areas are established within public health parameters.
- Staff follows appropriate steps of triage protocol.
- Life-threatening conditions are identified and treated.

Unexpected Outcomes

Triage site does not conform to public health requirements.

Multiple casualties exhibit life-threatening conditions.

Large group of victims are experiencing major psychological reactions of fear, panic, and horror.

- Post-triage assessment is completed.
- Post-traumatic stress disorder (PTSD) is identified and clients are referred appropriately.

Alternative Actions

- Assign additional personnel to monitor for public health concerns (in addition to triage and treatment).
- Collect waste in disposable containers for human waste or place in plastic bags and bury.
- Boil water or use water-purifying tablets if potable water is not available.
- Use diluted bleach (0.5%) to decontaminate surfaces.
- Implement triage principles—simple triage and rapid treatment (START)—check breathing, control bleeding, and treat shock.
- Assess and treat victims post-triage and post-initial interventions, then refer to community facility.
- Assign personnel and/or volunteers to separate and group victims according to age and degree of reaction.
- Assign skilled therapist to work with group at least 15–30 minutes, allowing them to talk about their fears and feelings.
- Refer victims to post-trauma group to prevent post-traumatic stress disorder.

GERONTOLOGIC Considerations

Under the circumstances of a bioterrorism event, all victims will be triaged and treated according to the system established. The elderly will be included in general triage decisions according to their injuries, not age.

For natural disasters, elderly victims will be treated according to the triage system used. The first responders will, however, have to take into account certain principles when dealing with elderly casualties.

- Number of elderly residents in nursing homes expected to double by 2030 to 3.2 million
- Elderly are more vulnerable to disaster conditions—aging immune system, mobility, and physical limitations

- Special concerns for elderly in disaster situations due to:
 - Mobility impairment
 - Chronic health issues
 - Slowed response time
 - Need for multiple meds
 - Sensory changes
 - Memory changes
 - Communication barriers

MANAGEMENT Guidelines

Delegation

- Pre-emergency/disaster planning and coordination will have (should have) occurred before the terrorist event.
- Personnel roles and lines of authority will have been previously delineated so healthcare workers will refer to the Preparedness Plan posted in each facility and report to the designated superior or Incident Command Center.
- Each member of the responder team should have an identified role, have practiced actions necessary to perform

in this role, studied the educational materials, and demonstrated knowledge necessary to perform in this designated role.

- Role responsibilities must be decided before a disaster occurs. For example, in one disaster scenario, the nursing supervisor is responsible for setting up the command center, the administrator will be in contact with outside resource organizations, and the director of nursing will do the administrator's functions.

- Because emergency response teams must work together as a team, be flexible and adapt to the requirements of a changing situation, team response must have practice sessions.
- Duties of command center designated person:
Find adequate nursing personnel and assign roles and responsibilities
Assign responsible person to switchboard
Limit all routine nonemergency admissions
Refer all public information calls and media to designated place
- Reporting of the incident takes place (see Reporting Requirements on page 000).
- The community liaison notifies Community Emergency Response Team (CERT) team leader (out-of-hospital staff), who notifies medical–nursing group (in-hospital staff).
- Federal agencies notified.
- A community-wide network is established—all using the same channels of communication.
- Position-to-position (not person) cascade of communication (community liaison ► command center person ► team leader) is established.
- A single off-site communication center for family and friends of victims must be established to avoid overloading system.

Communication Matrix

Once a disaster has been declared, the information flow is delineated in the Preparedness Plan.

CRITICAL THINKING Strategies

Scenario 1

Your hospital has not developed a total Preparedness Plan, including specific recommendations and strategies.

1. What are the implications of this situation under disaster conditions? Include a list of several consequences.
2. What strategies would you suggest to increase hospital administration awareness?
3. Describe the steps you would suggest to alter this situation so that a viable Preparedness Plan is in place.

Scenario 2

A Russian organized crime syndicate has stolen radioactive isotopes from an unprotected nuclear research facility and sold the material to an al-Qaeda group. This terrorist group smuggled the material into the United States via Canada. At a professional football game, this group detonates the weapon, creating a small explosion that rapidly spreads radiological material. The firefighters and police who rushed to the site had no radiation detectors, so they were exposed to radiological fallout. HAZMAT teams were sent to the area, detected radiation, and set up decontamination equipment.

You are part of the Preparedness Plan team for the local hospital in charge of the command center. Upon being notified of the disaster:

1. What additional information does your team need to make decisions about coping with this disaster?
2. What are the priority actions you would take?
3. What further assessment of contamination is necessary?
4. Describe the special protective equipment your team would require.

Scenario 3

You are tasked with developing a disaster kit for people to carry in their cars in case of a disaster that occurs when they are away from home.

1. What items would you suggest be included in a car disaster kit?
2. Add a rationale for including each item.

NCLEX[®] Review Questions

Unless otherwise specified, choose only one (1) answer.

1. During an earthquake, the best rationale for finding a space *beside* a large piece of furniture or a car (rather than *under* it) is
 1. To protect your head if the car or furniture caves in.
 2. That research has shown this will be a triangle of safe space.
 3. A large piece of furniture may not completely cover you.
 4. That it is easier and quicker to get beside the item rather than under it.
2. The best definition of a disaster is an event that
 1. Is unexpected and occurs with little warning.
 2. Is of great magnitude which disrupts and overwhelms current resources.
 3. Places the public and environment in danger.
 4. Carries an immediate threat to public health.

3. If a weapon of mass destruction strike occurs in the United States, the most difficult type or agent to identify would be
 1. A nuclear attack.
 2. Smallpox.
 3. Sarin gas.
 4. A biological agent.
 4. The most Grays (units of exposure to radiation) that a person can absorb before experiencing symptoms of radiation poisoning are
 1. Over 8 Gy.
 2. Between 0.75 and 8 Gy.
 3. Less than 0.75 Gy.
 4. Over 10 Gy.
 5. Which of the following biological agents might be used by terrorists to cause a mass casualty incident?
Select all that apply.
 1. Anthrax.
 2. Botulism.
 3. Radiation.
 4. Smallpox.
 5. Typhoid.
 6. Sarin gas.
 6. In triage, the rationale for choosing a 5-level system over the more common 3-level is that
 1. The 5-level system decreases ambiguity of the middle level of emergency cases.
 2. More rapid identification of the client condition can be made.
 3. There is more variety in categorizing client conditions.
 4. This method is more appropriate for categorizing large numbers of victims.
 7. You are assigned to establish a site for decontaminating victims. Place the steps of setting up the site in order.
 1. Set up the site on a downhill slope.
 2. Establish the site upwind from the contamination area.
 3. Supply personnel protection equipment for all health personnel.
 4. Find a source for water.
 8. An indication that *vaccinia* immune globulin (VIG) should be administered is
 1. Encephalitis.
 2. Cardiac complications.
 3. The client is pregnant.
 4. Eczema vaccinatum.
 9. Which of the following weapons of mass destruction would fall into the category of chemical agent?
 1. Q fever.
 2. Cyanide.
 3. Ricin.
 4. Smallpox.
 10. When administering a smallpox vaccination, the nurse will evaluate the success of the procedure by observing
 1. A lump where the vaccine was administered.
 2. No blood at the site.
 3. A trace of blood at the site.
 4. A needle mark where the needle entered the skin.
-

Pain Management

LEARNING OBJECTIVES

1. Discuss what is meant by the experience of pain.
2. Explain how natural endorphins work for pain control.
3. Describe the body's physiologic response to pain.
4. Identify the most important information elicited from the client regarding pain.
5. Discuss what it means for the nurse to be the client's advocate in relation to pain control.
6. Discuss the main components of The Joint Commission's Standards for Pain Management.
7. Compare assessing pain by quality and intensity.
8. Outline the main points of one nonpharmacological method of relieving pain.
9. Select a comfort measure for a client in acute pain and for a client in chronic pain.
10. Describe two different pain scales.
11. Describe the behavioral responses to mild versus severe pain.
12. Discuss two advantages of epidural narcotic analgesia.
13. Describe the potential side effects of narcotic medications via IV or epidural route.
14. List three criteria for client selection for patient-controlled analgesia (PCA).
15. Explain the steps involved in loading, priming, and changing a PCA syringe.
16. Describe the steps of teaching PCA to a client.
17. Discuss two components of pain management.

CHAPTER OUTLINE

Theoretical Concepts

Coping With Pain	512
Noninvasive Pain Relief	516
Techniques for Pain Control	517
UNIT 1 Pain Assessment	520
UNIT 2 Nonpharmacological Pain Relief	523
UNIT 3 Pharmacological Pain Management	527

Gerontologic Considerations	542
Management Guidelines	543
<i>Delegation</i>	543
<i>Communication Matrix</i>	543
Critical Thinking Strategies	543
<i>Scenarios</i>	543
NCLEX® Review Questions	544

UNIT 1 Pain Assessment	520
Nursing Process Data	520
Procedures	520
Assessing Pain	521
Assessing Pain in a Cognitively Impaired or Nonverbal Client	522
Assessing Pain in Young Children	522
UNIT 2 Nonpharmacological Pain Relief	523
Nursing Process Data	523
Procedures	523
Alleviating Pain Through Touch (Massage)	524
Using Relaxation Techniques	524

UNIT 3 Pharmacological Pain Management	527
Nursing Process Data	527
Procedures	527
Administering Pain Medications	528
Improving Client Satisfaction With Pain Control	528
Administering Epidural Narcotic Analgesia	530
Managing Pain With Patient-Controlled Analgesia (PCA)	533
Qualifying the Client for PCA	533
Preparing for PCA IV Administration	534
Administering IV PCA to a Client	534
Loading PCA—Alaris Model	534

Priming PCA	535	Giving Bolus Dose	538
Changing Syringe on PCA	535	Stopping Bolus, Loading, or PCA Dose	538
Changing Program/Mode	536	Ongoing Assessment of the PCA Client	539
Checking PCA at Shift Evaluation	536	Teaching PCA to a Client	539

TERMINOLOGY

- Acupressure** Chinese method of treatment that involves compression of certain areas of the body by following a system of meridians or energy flow.
- Adaptive reaction** a response by which the person attempts to improve or alter his or her condition in relation to the environment.
- Alleviate** to make more bearable; reduce (pain, grief, or suffering).
- Angina** a sense of suffocation with symptoms of severe, steady pain and feeling of pressure in region of the heart.
- Arrhythmia** irregular rhythm.
- Arthritis** inflammation of a joint, usually accompanied by pain and, frequently, deformity.
- ATC** around-the-clock medication for persistent pain.
- Autogenic training** a method of deep muscle relaxation that enables one to reduce the stress response, regain homeostasis, and prepare to handle additional stress.
- Autonomic nervous system** the part of the nervous system that regulates the functioning of internal organs and glands; it controls such functions as digestion, respiration, and cardiovascular activity.
- Behavior** the manner in which one acts.
- Biofeedback** a training technique that uses monitoring instruments to assist people to control stress-related disorders through self-regulation of internal functions.
- Booster dose** an additional dose given to a client on a PRN basis. Ordered by physician, administered by RN.
- Brady** prefix indicating slow.
- Bradycardia** slowed heart action, below 60 beats/min.
- Capnography (side-stream)** a module attached to PCA to detect client hypoventilation and/or a change in respiratory status.
- Cardiovascular** pertaining to the heart and blood vessels.
- Cerebral cortex** the extensive outer layer of gray tissue of the cerebral hemispheres (brain), responsible for higher nervous functions.
- Coping mechanisms** means by which an individual adjusts or adapts to a threat or a challenge; actions that assist in maintaining homeostasis.
- Diaphoresis** profuse sweating.
- Dynamics of homeostasis** danger or its symbols, whether internal or external, resulting in the activation of the sympathetic nervous system and the adrenal medulla. The organism prepares for fight or flight.
- Emotional** affected by strong feelings, as of joy and sorrow.
- Endorphins** a naturally occurring body chemical similar to morphine but many times stronger.
- Fight or flight** one's immediate response to stress that is, although archaic and often inappropriate, part of our central nervous system biologic heritage.
- Four (4)-hour limit (mL)** the maximum amount of drug that can be administered to client during a 4-hour period.
- Gastrointestinal** pertaining to the stomach and the intestine.
- General adaptation syndrome** a general theory of stress response formulated by Dr. Hans Selye; describes the action of stress response in three stages: the alarm reaction, the stage of resistance, and the stage of exhaustion.
- Health** the state of physical, psychologic, and sociologic well-being.
- Hypertension** a condition in which the client has a higher blood pressure than judged to be normal.
- Illness** a state characterized by the malfunction of the biopsychosocial organism.
- Insomnia** inability to sleep.
- Ischemic** local and temporary anemia due to obstruction of the circulation to a part.
- ISMPP** Institute for Safe Medication Practices is a nonprofit organization that focuses on preventing medication errors by providing medication safety information to healthcare practitioners.
- Loading dose (optional)** initial dose given to client as ordered by physician.
- Lockout interval** period during which the PCA cannot be activated and no analgesic can be delivered by client. (A booster dose can be given during lockout interval if ordered.)
- Meditation** the act of reflecting on or pondering; contemplation.
- Musculoskeletal** pertaining to the muscles and the skeleton.
- Nausea** inclination to vomit, usually preceding emesis.
- Opioid (narcotic) addiction** pattern of compulsive drug use characterized by continued craving for the narcotic—creates both a psychological and physiological dependence.
- Pain** a sensation in which a person experiences discomfort, distress, or suffering. There are three main types of pain: acute, chronic, and malignant.

Parasympathetic nervous system a division of the autonomic nervous system that regulates acetylcholine and conserves energy expenditure; it slows down the system.

PCA—Patient-controlled analgesia a method of delivering pain medication via IV pump. Within physician-ordered parameters, the client can control the medication amount necessary to manage his or her pain level.

Physiologic concerning body function.

Psychogenic of mental origin.

Referred pain pain felt in a part removed from its point of origin.

Regression a turning back or return to a former state.

Relaxation a lessening of tension or activity in a part.

Resistance opposition to or the ability to oppose.

Stamina constitutional energy; strength; endurance.

Stress a nonspecific response of the body to any internal or external event or change that impinges on a person's system and creates a demand.

Stressor a specific demand that gives rise to a coping response.

Sympathetic nervous system a division of the autonomic nervous system that controls energy expenditure and mobilizes for action when confronted with a threat.

Tachy prefix meaning fast.

Tachycardia abnormal rapidity of heart action; above 100 beats/min.

TENS—Transcutaneous electrical nerve stimulation a noninvasive method to relieve pain that involves stimulation to the skin via a mild electric current.

The Joint Commission sets standards of care and accredits healthcare facilities (formerly JCAHO).

Traction determining the concentration of a solution.

Tolerance a larger and larger dose of an opioid is required to have the same effect.

Touch a tactile sense.

Visceral pertaining to internal organs.

Wellness a state of physical, psychological, and sociologic well-being of a whole person.

COPING WITH PAIN

Pain is now considered the fifth vital sign and, according to The Joint Commission's Standards for Pain Management, is essential to regularly assess and manage in order to maintain the client's homeostasis and quality of life.

The experience of pain is direct and personal. In this culture we tend to view pain as a negative condition and often go to any lengths to avoid the sensation. The positive aspect of pain is that it is an early warning system; its presence triggers an awareness that something is wrong in the body. Without the sensation of pain we could not survive, because pain provides the cues that allow us to modify our reactions and direct our behavior. One perspective of pain is that it is a message to our conscious self to check out any pain sensation before it gets worse, for that is the nature of pain. Without intervention the condition may well get worse.

Margo McCaffery, a nurse-researcher who writes about caring for the client in pain, defines pain as "whatever the patient experiencing pain says it is, existing whenever he says it does." The nurse is totally dependent on the client to describe the sensation of pain, identify the location, and tell about what kind of pain is being experienced.

The most important information in pain assessment, then, is the client's report. The pain experience is totally subjective. The onset of acute pain stimulates the sympathetic nervous system "fight or flight" response that results in certain signs or symptoms. While observation of these symptoms provides objective data, it cannot be considered conclusive evidence to the identification of pain—that must come from the client.

The sensation of physical pain arouses some specific responses in the client. The sympathetic nervous system response is usually stimulated by superficial pain, and the parasympathetic nervous system response is usually stimulated by deeper pain and results in the slowing down of all the systems to conserve energy.

Theories of Pain

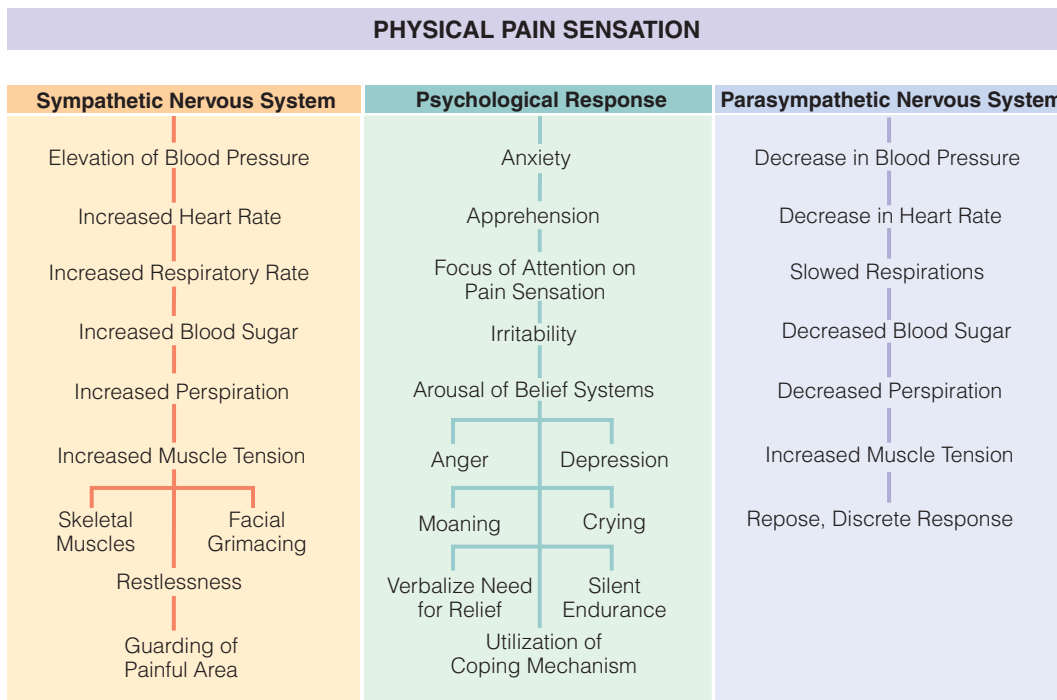

The neurophysiologic basis of pain can be explained by several theories, none of which is mutually exclusive nor totally comprehensive.

Specificity Theory This theory suggests that certain pain receptors are stimulated by a specific type of sensory stimuli that sends impulses to the brain. This theory dealt with the physiologic basis for pain but did not take into account the psychologic components of pain, nor the degree of pain tolerance.

Pattern Theory This theory attempts to include factors that were not adequately explained by the specificity theory. This theory suggests that pain originates in the dorsal horn of the

Types of Pain

Acute pain	Pain that occurs only in a defined period of time (6 months or less) and is caused by specific stimuli that damage the tissue. Usually of recent onset and varies in intensity.
Chronic pain	Prolonged, persistent nonmalignant pain that occurs over a 6-month period or longer. Pain varies in intensity and may serve no useful function.
Malignant pain	Recurrent, acute episodes of pain, which may also include chronic pain. This pain may vary in intensity and have rapid or slow onset. It may last longer than 6 months and be intractable.
Intractable pain	Severe and constant, usually resistant to relief measures.

spinal cord. A certain pattern of nerve impulses is produced and results in intense receptor stimulation that is coded in the central nervous system (CNS) and signifies pain. Like the specificity theory, the pattern theory does not explain the psychological factors of pain.

Gate Control Theory One of the most popular and credible concepts is the gate control theory. The first premise of the gate control theory is that the actual existence and intensity of the pain experience depends on the particular transmission of neurologic impulses. Second, gate mechanisms along the nervous system control the transmission of pain. Finally, if the gate is open, the impulses that result in the sensation of pain are able to reach the conscious level. If the gate is closed, the impulses do not reach the level of consciousness and the sensation of pain is not experienced.

Three primary types of neurologic involvement affect whether the gate is open or closed. The first type involves activity in the large and small nerve fibers that affect the sensation of pain. Pain impulses travel along small-diameter fibers. The large-diameter nerve fibers close the gate to the impulses that travel along the small fibers. The technique of using cutaneous stimulation on the skin, which has many large-diameter fibers, may help to close the gate to the transmission of painful impulses, thereby relieving the sensation of pain. Interventions that apply this theory to practice include massage, hot and cold applications, touch, acupuncture, and transcutaneous electric nerve stimulation. These interventions are described in detail later in this chapter.

The second form of neurologic involvement is the impulses from the brainstem that affect the sensation of pain. The reticular formation monitors in the brainstem regulate sensory input. If the person receives adequate or excessive amounts of sensory stimulation, the brainstem transmits impulses that close the

gate and inhibit pain impulses from being transmitted. If, on the other hand, the client experiences a lack of sensory input, the brainstem does not inhibit the pain impulses, the gate is open, and the pain impulses are transmitted. Interventions that apply to this part of the gate control theory are those

Wong-Baker FACES Rating Scale

For a child under age 3 or a client who doesn't speak English, use the Wong-Baker FACES Pain Rating Scale

▲ Ask the client to choose the face that best describes how he or she feels pain. Try to be specific about which pain (injection or incision), where it hurts, and what time (now, earlier, after lunch, etc.).

Source: Wong-Baker FACES Pain Rating Scale (from Wong, D. L., et al. (1999). *Nursing care of infants and children* (6th ed). St. Louis: Mosby.

related in some way to sensory input, such as techniques of distraction, guided imagery, and visualization.

The third type of neurologic involvement is the neurologic activities or impulses in the cerebral cortex and thalamus. A person's thoughts, emotions, and memories may activate certain impulses in the cortex that trigger pain impulses, which are transmitted to the conscious level. Past experiences relating to pain affect how the client responds to current pain. For this reason, it is important to explore the client's previous experiences and teach the client what to expect from the present situation. Interventions that apply to this part of the gate control theory include using and teaching various relaxation techniques, teaching the client about what expectations to have about pain as related to a specific illness, allowing the client to feel he or she has some control over the taking of medication for pain relief, and giving medications properly (i.e., preventively, before the pain is so severe that the client fears he or she will receive no relief).

Endorphins, Natural Opiates

A relatively recent theory of pain relief was developed when Avron Goldstein, looking for morphine and heroin receptors, discovered receptors in the brain that fit only morphine or morphine-like molecules. He asked himself why these receptors were located in the brain, when opiates are not naturally found in this area. The answer, learned through diligent research, is that the brain produces natural brain opiates. These substances are hormones, chemicals produced by different parts of the body to regulate certain biologic processes. At present, five of these natural opiates have been found. Three are called endorphins, one dynorphin, and one enkephalin. Endorphins fit into special cells, called receptors, and thereby activate their regulating powers. In addition to endorphin "keys" and receptor "locks," researchers have found antilocks, called antagonists, that keep endorphins from working. Endorphin receptors and antilocks have been found throughout the body—in the stomach, intestines, pancreas, spinal cord, and bloodstream, as well as the brain.

A beta-endorphin is 50 times stronger than morphine, and a dynorphin is 190 times stronger than morphine. In one test,

14 men and women suffering from extreme pain from cancer were given tiny injections of an endorphin. All felt relief within minutes and the relief lasted for 1 to 3 days.

Endorphins are now being produced synthetically, but they are very expensive and at this time are used only for research. Researchers must discover how the body makes and releases endorphins before a method is developed to encourage the body to produce more of its own endorphins to control pain.

Pain Pathways

The pathway to pain is a complicated, fascinating expression of how our amazing bodies work. First there is the source of pain, a direct causative factor. Stimulation of a pain receptor may be mechanical, chemical, thermal, electric, or ischemic. The sensation travels along the sensory pathways and ascends the spinal cord to the thalamus. The autonomic nervous system is activated, and sensations travel to the sensory area of the cerebral cortex. Pain reception occurs in the thalamus, where awareness and integration take place, and pain interpretation occurs in the cerebral cortex. Once awareness of pain takes place and it has been interpreted by the cerebral cortex, the person becomes aware and the response patterns are activated.

The Pain Experience

The pain experience is a mixture of physical sensations, physiologic changes, and psychosocial (including psychological, sociocultural, and environmental) factors. The client's interpretation of the physical sensation is influenced by the client's culture, previous experiences with and without pain, beliefs about self, interpretation of the future, present environment, and the persons in that environment. The intensity of pain is influenced by what the sensation means to the client, the client's level of anxiety, degree of fatigue, and the number of stressors in the client's environment.

There are several methods of assessing the degree or level of pain a client may be experiencing. Note the examples of pain scales you may use to assess your client's pain. After explaining the scale you are using, ask your client what level of pain he or she is experiencing at the moment. You may use a numeric scale of 1 to 10, an intensity scale with 3 or more categories to

▲ Nurse's badge with Wong-Baker FACES Pain Rating Scale reminds both nurse and client to pay attention to pain level.

rate client pain, a pain distress scale, or the Wong-Baker FACES scale. Note the photo in which the nurse is wearing a FACES scale badge. The FACES pain scale is very important for pediatric clients, since children may have difficulty verbalizing the degree of pain they are experiencing. The different faces help them relate to pain by how sad the face appears, thus identifying for the nurse the level of pain they are feeling. Whichever scale is chosen, maintain its use throughout the course of pain control.

The Joint Commission Standards for Pain Management

In 2000, The Joint Commission described the appropriate standards for pain management for all healthcare facilities. The standards below were adapted from the comprehensive accreditation manual for hospitals.

- Recognize that clients have the right to appropriate assessment and management of pain. Pain assessment is to be considered

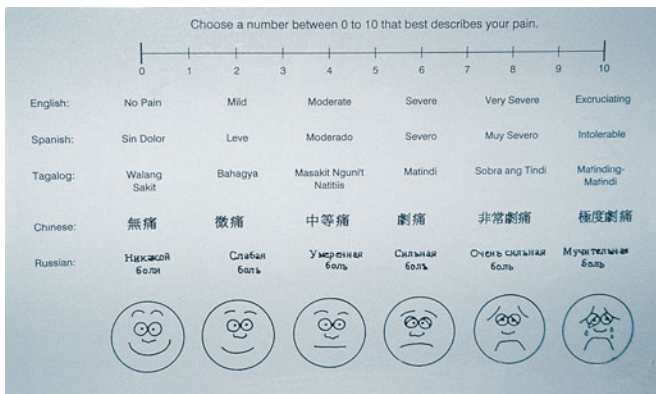

How to Measure Pain

Location	Ask the client to locate pain on or within the body—exactly where is the pain felt?
Intensity	Determine strength, power, or force of the pain the client is experiencing. Use numeric or verbal scales or the faces pictures.
Quality	Determine the features or characteristics that distinguish this pain, such as searing, dull, throbbing, sharp, burning, etc.
Pattern	Ask client how pain changes and timing of the pain, such as is it continuous, steady, intermittent, transient?

▲ Pain assessment form.

- a priority; in fact, it is now considered by many facilities and several states to be the fifth vital sign. This will enable the client's pain level to be assessed as frequently as vital signs.
- The facility must provide appropriate pain assessment tools (see pain scales and faces), and *pain levels should be recorded so that regular reassessment and follow-up can be done.*
- *Policies will be in place so that clients will be treated for pain, and adequate doses of opioids to relieve pain without unacceptable side effects will be given. Clients will be involved in their own pain management.*
- *If a facility, such as a long-term home care facility, cannot treat the client adequately for pain, the client should be referred to an appropriate facility.*
- *Facilities should collect data to monitor the effectiveness of pain management.*
- *Facility staff should receive education so they are competent in pain assessment and management.*
- *Clients and their families should be informed about pain management and client's needs for symptom control, and these should be included in discharge planning.*

Again, in 2001, The Joint Commission released revised standards for the assessment and management of pain. They stated that all healthcare facilities are expected to comply with these standards and that accreditation will be granted only on this basis. Margo McCaffery, an expert on pain management, believes that these revised standards may do more to

▲ A multilanguage pain chart facilitates an accurate description of pain.

improve pain management than any other development in managing pain.

NONINVASIVE PAIN RELIEF

When a method to relieve pain is noninvasive, it is safer and results in fewer potential side effects for the client. Such measures are becoming the pain control choice of the future.

Current practice for controlling pain is to use both drugs and nondrug options because both, separately or combined, meet the objectives of relieving pain and making the client more comfortable.

Recommendations for Pain Management

The University of Iowa has developed guidelines for acute pain management, including a set of major recommendations. The main topics covered are:

- Complete a baseline pain assessment, including pain level.
- Educate client and family about pain management.
- Monitor the acute pain the client is experiencing, including intensity, duration, and effect of pain.
- Follow guidelines of pharmacological management.
- Implement nonpharmacological management.
- Assess the effectiveness of pain management.

Nondrug options may include the use of specific cognitive-behavioral techniques—deep breathing, visualization, imagery; physical agents—electric stimulators, massage-vibration, and biofeedback systems; and various adjunct therapies—cold therapy, heat therapy, or counterirritants.

The nonpharmacological approach (Table 16-1) is appropriate for clients who are receptive to alternative methods; who have a high level of anxiety around the issue of pain; who would benefit from reducing dependence on drug therapy; who anticipate long-term or have chronic pain; or who receive inadequate pain relief from pharmacological interventions.

Characteristics of Pain

Location

- Area of the body
- Diffuse or localized
- Radiates and area involved

Quality

- Stabbing, knife-like
- Throbbing
- Cramping
- Vise-like, suffocating
- Searing, burning
- Superficial, deep

Intensity

- Rate on scale: 0–10 (0 = no pain, 10 = most pain ever experienced)

Factors Associated With Pain

- Nausea
- Vomiting
- Bradycardia, tachycardia
- Hypotension, hypertension
- Profuse perspiration
- Apprehension or anxiety

Precipitating Factors

- Motion affecting incision area (e.g., coughing, turning, deep breathing)
- Fear and emotional distress
- Inflammation or infection
- Trauma
- Disease state

Aggravating Factors

- Position changes
- Environmental stressors
- Fatigue
- Inadequate pain relief measures

Alleviating Factors

- Position change
- Medications
- Biofeedback
- Visualization
- Relaxation techniques
- TENS
- Massage

The Nurse's Role

Pain reduction methods include a wide range of techniques and medications. Rarely is pain relief successfully achieved with only one method. Even massive doses of narcotics do not always control pain effectively—especially when it has been allowed to escalate.

One of the most important influences on pain relief is the relationship that exists between nurse and client. With most methods (the exception is PCA), the nurse has the power to relieve pain or to withhold pain relief. This knowledge creates anticipatory anxiety for the client. The client may request less medication when the nurse is supportive, caring, and assists with pain management.

The single most critical factor in achieving pain relief is for the nurse to be the client's advocate. The comfort of the client is the nurse's primary concern.

Nursing interventions that provide effective pain relief, in addition to pain medication, are those that encourage behaviors that assist the client not to focus on pain. For example, when the client is talking about something of great interest or pleasure, he or she is not thinking about pain. Teaching the client techniques, such as deep, slow breathing and relaxation, lessens pain, whereas muscle tension and anxiety increase it. If the nurse teaches pain relief techniques before surgery, the client can more easily implement them when the pain is intense. The nurse may also encourage the client to use techniques that he or she has already found effective, no matter how "unscientific" they may be. Whatever method or technique the nurse uses to assist the client with relieving pain, the single most critical intervention is a caring and supportive attitude.

To provide pain management effectively to clients from other cultures, the nurse must understand a client's culture and how it affects the client's response to pain. To accomplish this, the nurse must take into account a client's religious beliefs and the external influence these may have on the client's pain experience.

TECHNIQUES FOR PAIN CONTROL

IV Patient-Controlled Analgesia (PCA)

One of the most successful methods of pain relief, introduced in the 1970s, was patient-controlled analgesia (PCA). The primary purpose of PCA is to allow the client to self-administer an analgesic dose of medication predetermined by the physician. PCA enables the client to assess and control his or her own pain level. This method of pain control has been found to be very efficacious because the client feels in more control of his or her life situation, there is no significant difference in the amount of analgesic medication used (if anything, it is usually less), there is better pain control than IM injections, and this method of pain control is less time-consuming for the nurse.

Epidural Pain Control

An effective technique for controlling pain is the use of an epidural catheter inserted into the epidural space. The advantage of epidural pain control is that the narcotic moves directly from the epidural space into the spinal fluid and binds with

▲ Continuous IV narcotic drip for pain control.

opiate receptors in the spinal cord, blocking reception of pain. Administered by this method, the required drug dose is considerably lower because it is not metabolized in the liver.

Direct IV Pain Control

In addition to the new methods of pain control, a client may receive a continuous infusion via direct IV. The dosage may be titrated to achieve pain relief with the lowest dose (10 mg or

Pain—the Fifth Vital Sign

Many states have passed into law the requirement that pain be considered the fifth vital sign. It must be assessed and documented at the time other vital signs are taken. The Veterans Administration, as well as other states and facilities, has incorporated pain on their vital signs graphic record.

▲ A method for managing breakthrough pain is oral transmucosal, delivering medication via a lozenge on a stick.

1/6 g of morphine sulfate). The dose is individualized according to the client's needs, tolerance, and response. When pain relief is not achieved, increments of at least 25% of the previous dose should be implemented. When morphine is administered IV, a dark bag should be placed over the narcotic bag because the medication is light-sensitive.

Breakthrough Pain Control

There are two major types of pain—continuous and breakthrough. Many clients with cancer experience long periods of persistent pain and may also experience severe flare-ups that occur even when the client is on around-the-clock (ATC) medication. Studies suggest that nearly 70% of cancer clients experience breakthrough pain. These episodes typically last about 30 minutes, but tend to totally decimate the client.

Generally, breakthrough pain occurs as two types:

- Incident pain—caused by movement or activity (for example, sitting up, walking, or coughing).
- Spontaneous pain—does not seem to be linked to any specific source, but occurs with no warning or relation to activity or movement.

Breakthrough pain can be managed by different protocols, some of which are listed below.

- Increasing the dose of ATC so that breakthrough pain is eliminated—this method is not always advisable because sedation and other side effects of the drug may occur.
- Changing the ATC so that relatively constant analgesia occurs (use long-acting oral opioids or fentanyl patches).

- Prescribing a supplemental dose of a short-acting morphine-like drug so that it is taken 30 minutes before incident pain when this type of pain is predictable.
- When spontaneous pain occurs, instruct the client to take the dose as soon as possible after onset. At this point in pain control, this is the best plan, even though there may be a “pain gap.” New drugs, currently being researched in clinical trials, may solve this problem.
- A new delivery method, oral transmucosal, delivers fentanyl citrate via a sucker. An example of this drug is Actiq, 1,600 mcg/sucker. This has the advantage of being quickly absorbed through the mucous membrane of the mouth and working rapidly to control breakthrough pain. This medication should be taken only by clients already taking prescription opioid (narcotic) drugs on a regular schedule.

Analgesic Patches

Two types of patches are now available to assist in pain management. One, the size of a credit card, uses a slight electric current to deliver medication through the skin of the arm or chest. In a survey of postsurgical clients, 77% rated this method good to excellent (*Journal of American Medical Association*, March 17, 2000). The second type of patch is transdermal, may be placed at the point of chronic pain (for example, a ruptured disc in the back), and delivers fentanyl (Duragesic).

The Institute for Safe Medication Practices (ISMP) suggests that serious adverse reactions can occur when new transdermal patches (for example, opioids for pain relief) are applied without the removal of existing patches. To avoid a potential overdose, the site and time should be clearly charted on the medication record when the patches are applied and removed.

CULTURAL AWARENESS

Healthcare personnel working in a variety of settings maintain that pain is a culturally influenced phenomenon. How pain is experienced and expressed varies by cultural group. For example, some cultures (such as the Italians and Jewish people) encourage open expression of feelings like pain, while others (the stoic English, Irish, and Chinese) believe that pain is something to be ignored or endured in silence. This was demonstrated by Zborowski's study done as early as the 1950s. While these general conclusions may lead to stereotyping, it is important to consider the impact of the individual's culture in the assessment of pain level.

Source: Spector, R. (2001). *Cultural diversity in health and illness* (5th ed.). Upper Saddle River, NJ: Prentice Hall Health

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to include on client care plans when the components are related to alleviating pain in a client.

NURSING DIAGNOSIS	RELATED FACTORS
Anxiety	Anticipation of discomfort, fear, helplessness, inability to relax
Compromised Family Coping	Family members have difficulty dealing with client's pain, functions as proxy for pain relief (see Table 16-3 for proxy explanation)
Ineffective Coping	Poor adjustment to pain/illness, fear
Fear	Long-term disability, terminal disease, hospitalization, invasive procedures, lack of knowledge, surgery and its outcome
Acute or Chronic Pain	Trauma, immobility, surgery, chronic illness

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. *Remember to wash your hands or use antibacterial gel before and after each and every client contact.*

IDENTIFY CLIENT Before every procedure, check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Chapter 16

UNIT 1

Pain Assessment

Nursing Process Data

ASSESSMENT Data Base

- See skill Assessing Pain, page 521

PLANNING Objectives

- To determine presence of pain in terms of type, location, quality, intensity, and level of discomfort
- To identify associated symptoms
- To identify a database that will assist in formulating a plan for pain management
- To increase client's satisfaction with pain management

IMPLEMENTATION Procedures

- Assessing Pain 521
- Assessing Pain in a Cognitively Impaired or Nonverbal Client 522
- Assessing Pain in Young Children 522

EVALUATION Expected Outcomes

- Pain level of client is identified and a plan for decreasing pain is formulated.
- Client is able to experience decreased pain level after interventions.
- Client's anxiety level is decreased in relation to pain.

Critical Thinking Application 522

- Expected Outcomes 522
- Unexpected Outcomes 522
- Alternative Actions 522

Prepare for success with NCLEX®-style practice questions and Skill Checklists

Assessing Pain

Procedure

1. Assess type of pain, and ask client to describe pain using his or her own words.
 - a. Acute pain: short duration of a few seconds/minutes to 6 months.
 - b. Chronic pain: prolonged, persistent pain, 6 months to years.
 - c. Intractable pain: severe and constant, resistant to relief measures.
 - d. Malignant pain: recurrent, acute episodes, which may include chronic pain and may last longer than 6 months.
2. Assess location.
 - a. Ask client to point to area of the body or verbalize location of pain.
 - b. Ask if pain is superficial or deep.
 - c. Ask if pain is diffuse or localized.
 - d. Ask if pain radiates and where it goes.
3. Assess quality.
 - a. Stabbing, knife-like.
 - b. Throbbing.
 - c. Cramping.
 - d. Vise-like, suffocating.
 - e. Searing or burning.
4. Assess intensity.
 - a. Ask client to indicate intensity of pain using a pain scale; for example, a scale of 0–10. Use the same pain scale comparing intensity before and after interventions.
 - b. Ask client what measures have reduced the level of pain on the scale.
5. Assess onset of pain and aggravating factors.
 - a. What triggers the pain?
 - b. How does movement affect pain?
 - c. Does coughing affect pain?
 - d. What is impact of emotion on pain?
 - e. How does position or fatigue affect pain level?
6. Assess associated factors.
 - a. Nausea and vomiting.
 - b. Hypotension/hypertension.
 - c. Profuse perspiration.
 - d. Apprehension or anxiety.
 - e. Respiratory and heart rate.
7. Assess alleviating factors.
 - a. Position.
 - b. Elevation of extremity.
 - c. Techniques used at home for pain relief.
 - d. What pain medications does client use?
8. Assess client's behavioral responses to pain.
 - a. No pain—relaxed, calm, and alert. (0)
 - b. Mild pain—stressed, tense, occasional grimace or frown. (1–3)
 - c. Moderate pain—stoicism, squirming, grimacing, more reassurance to comfort. (4–6)
 - d. Severe pain—moaning, restless, muscle twitching, difficult to comfort. (7–9)
 - e. Worst pain—crying, constant moaning, withdrawn, unable to comfort. (10)
9. What is the client's level of sedation and is it safe to administer the next pain medication?
 - a. Is the client awake and responsive? (1)
 - b. Is the client frequently drowsy? (2)
 - c. Is the client continually falling asleep, even in mid-sentence? (3)
 - d. Is the client difficult to arouse? (4)
 - e. Is the client somnolent—unable to arouse? (5)
10. By checking the level of sedation above, determine the level of response by number.
 - a. Level 1 and 2—generally safe to administer the next pain medication.
 - b. At level 3, it may be dangerous to administer the next pain medication.
 - c. At levels 4 and 5, it would be dangerous to administer the next pain medication. Notify physician.

▲ Assist client to describe pain in detail so that your assessment is complete.

Clinical Alert

Assess the sedation level of the client before administering a pain medication, even if it is within the time limit allowed by physician's orders (e.g., every 2 hr) or risk CNS depression. See Assessment Scale (9. and 10.) above.

11. When to reassess for follow-up pain medication administration.
 - a. Post-op client—every 2 hr or until pain is controlled.
 - b. Client experiencing pain—every 4 hr.
12. After pain medication is given, the appropriate follow-up time for reassessment is as follows:
 - a. Injection—5–30 minutes.
 - b. Oral medication—60–90 minutes.
 - c. Sustained-release analgesic or transdermal patch—4 hr.

Assessing Pain in a Cognitively Impaired or Nonverbal Client

Procedure

1. Assess client's level of understanding (i.e., Alzheimer's client may still be able to answer questions about pain he or she is experiencing).
2. Assess nonverbal cues if a verbal response is not elicited.
 - a. Facial expressions.
 - b. General behavior.
 - c. Unusual movements, twisting or turning, restlessness, pacing, immobility.
 - d. Vocal sounds—moaning, crying, gasping, groaning.
 - e. Muscle contractions especially around the eyes.
3. Evaluate changes after pain relief intervention to determine whether further assessment is indicated.

Assessing Pain in Young Children

Procedure

1. Assess unidimensional indicators.
 - a. Increase in heart rate.
 - b. Elevation in blood pressure.
 - c. Sweating.
 - d. Changes in skin color.
2. Assess multidimensional indicators.
 - a. High-pitched cry.
 - b. Baby or child is inconsolable.
 - c. Awake continuously—not able to sleep.
 - d. Fussy.
 - e. Grunting sounds.
3. Assess behavioral responses.
 - a. Facial movement.
 - b. Bulging of area between eyebrows.
 - c. Tightly closed eyes.
 - d. Rigid mouth and tongue.

DOCUMENTATION for Assessing Pain Level

- Describe client's pain, including all of the assessment parameters.
- Describe pain level, including behavioral and verbal manifestations used to determine level for the cognitively impaired or nonverbal client.
- Describe behavioral cues used to assess pain level in a young child.

CRITICAL THINKING Application

Expected Outcomes

- Pain level is assessed adequately.
- Pain level in a cognitively impaired or nonverbal client is adequately assessed.
- Pain in a young child is assessed correctly.

Unexpected Outcomes

Pain level is incorrectly or inadequately assessed.

Client reports new level of pain or pain not relieved by previously effective strategies.

Pain level in a cognitively impaired or nonverbal client is not assessed correctly as facial expressions and behavior indicates.

Pain level in a child is not assessed adequately.

Alternative Actions

- Begin again to assess pain level after all of the steps of assessment.
- Pay close attention to client's report of pain level.
- Do not attribute this report to preexisting cause, but let this report trigger a diagnostic evaluation.
- Reassess according to the steps of assessment.
- Request a consult from a pain expert. Try an alternative method of pain control.
- Reassess pain level, paying close attention to behavioral expressions.
- Request a consult with the physician to change pain medication.

Nonpharmacological Pain Relief

Nursing Process Data

ASSESSMENT Data Base

- Assess type of pain.
 - Acute pain: short duration of a few seconds to 6 months
 - Chronic pain: longer duration of 6 months to years
 - Malignant pain: severe and constant and resistant to relief measures
- Choose a pain-intensity scale and identify the level or degree of pain the client is experiencing.
- Assess nonverbal indications of pain.
- Assess client's behavioral responses to pain.
 - Depression, withdrawal, or crying
 - Stoicism or expressive
- Assess location, quality, intensity, onset, duration, pattern, aggravating factors, associated factors, and relief or alleviating factors. (See *Physical Pain Sensation* chart, page 513.)

PLANNING Objectives

- To relieve pain or prevent pain from escalating by relaxing muscles; muscle tension increases the pain
- To decrease client's anxiety that present and future pain relief will not be achieved
- To bring pain relief to a level acceptable to the client
- To educate clients to communicate their pain level
- To improve client satisfaction with pain management

IMPLEMENTATION Procedures

- Alleviating Pain Through Touch (Massage) 524
- Using Relaxation Techniques 524

EVALUATION Expected Outcomes

- Pain is controlled through nonpharmacological methods such as massage, relaxation techniques, or TENS.
- Client is satisfied with level of pain control.
- Client receives adequate pain medication; pain level does not interfere with client's activity.
- Client's anxiety level is lowered in relation to pain.

Critical Thinking Application 526

- Expected Outcomes 526
- Unexpected Outcomes 526
- Alternative Actions 526

EVIDENCE-BASED PRACTICE

Herbal Remedies Used for Pain Control

This review of the literature summarizes existing studies of herbal remedies used to relieve pain for the period of 1966–2005. The most common natural products were echinacea, ginseng, ginkgo biloba, and garlic. Pain relief was the most frequently cited reason for seeking alternative medicine. The results indicated few well-controlled studies and also documented limited efficacy of herbal therapies.

Source: Wirth, J. H., Hudgins, J. C., & Paice, J. (2005). Use of herbal therapies to relieve pain: A review of efficacy and adverse effects. *Pain Management Nursing*, Vol. 6, No. 4, Dec 05, pp. 145–167.

Nonpharmaceutical Treatment for Chronic Pain

Norman Shealy, MD, PhD, is director of the Shealy Pain Institute and has treated more than 30,000 clients for chronic, disabling pain. Many clients' pain was the result of back surgery failures; others suffered from migraines, arthritis, compression fractures, nerve or cord injury, and cancer. The focus of treatment in this clinic was alternative—acupuncture, TENS, biofeedback, autogenic training, and ancillary techniques such as massage, exercise, and nutrition. Dr. Shealy has a success rate of 85%, and 70% for clients with long-term chronic pain.

Alleviating Pain Through Touch (Massage)

Equipment

- Body lotion
- Massage oil
- Towel or drape

Procedure

1. Establish a quiet, private environment.
2. Determine whether client achieves more relief from pain with massage over painful area, near painful area, or from foot rub, back rub, or hand rub.
3. Warm your hands by rubbing them together or rinsing in warm water.
4. Warm lotion to be used by holding closed bottle under warm running water.
5. Massage area of client's choice with slow and steady motion.
6. Use deep pressure or light stroking motion, whichever is more comfortable for the client. ► **Rationale:** Relaxed muscles result in a decreased pain level.

Using Relaxation Techniques

Equipment

- A printed relaxation technique (the nurse can read slowly until client learns technique)
- CD and disc or cassette recorder and tape

Procedure

1. Help client assume a comfortable position.
 - a. If lying, place support under knees, lower legs, and under head. Be sure body is in good alignment.
 - b. If sitting, sit comfortably positioned with both feet on the floor, hands on knees, back straight, and head balanced comfortably straight.
2. Instruct client to inhale deeply, hold breath for a moment, then exhale deeply. Repeat several times.
3. Give the following instructions to client, using a slow, soothing voice.
 - a. Continue to breathe in and out slowly. Concentrate on my voice and follow my words.
 - b. Find a point of tension in your body.
 - c. As you identify the tension, tense the area up even more.
 - d. Then relax the area, letting all the tension drain out.
4. Continue with these instructions until the client has had time to relax all points of tension.
5. To end the process, instruct the client to open eyes slowly and say, "I feel relaxed and awake."

NOTE: For more relaxation skills, see "Teaching Controlled Breathing," "Teaching Body Relaxation," and "Using Meditation," Chapter 17, pages 565–566.

TABLE 16-1 Nonpharmacological Approaches to Pain

Physical Methods	Advantages
TENS—stimulating skin with mild electric current—provides pain relief by blocking pain impulses to the brain	Noninvasive method Higher level of activity Studies show more effective for postoperative pain Gives staff confidence they can assist client with pain Choice for chronic pain
Acupuncture—ancient Chinese form of treating diseases and pain through insertion and manipulation of needles at specific points on the body	Insertion of thin needles is not painful to the client Pain relieving capacity extends beyond actual procedure Method may provide relief when no other method works
Biofeedback—electric monitoring device that feeds back effect of behavior so client can control internal processes (e.g., heartbeat)	Noninvasive method Completely controlled by client Promotes stress reduction as well as pain relief After mastery, instruments are not needed to achieve result
Vibration or massage—hands-on manipulation of muscles or electrical form of massage (vibration)	Noninvasive method—electrically alleviates pain by numbness or paresthesia or through touch Increases circulation and endorphins to area Relaxes muscles and reduces tension on nerves and promotes relaxation Useful only for light to moderate pain
Cold therapy—cold wraps, gel packs, cold therapy, ice massage; do not use on irradiated tissue or when clients have peripheral vascular disease	Relieves pain faster than heat therapy Numbs nerves and decreases inflammation and spasms Effective for nerve, abdominal, and lower back pain Alters pain threshold Decreases tissue injury response
Heat therapy—hot wraps, dry heat, moist heat; do not use on irradiated tissue or tumors	Noninvasive method Decreases pain by reducing inflammation Promotes relaxation of muscles Increases vasodilation and blood flow to area Facilitates clearance of tissue toxins and fluids
Counterirritants—mentholated ointments or lotions (Ben-Gay or Icy Hot)	May contain salicylates (reduces inflammation) but dangerous if client has potential bleeding problems May be irritating to the skin—potential skin breakdown
Acupressure application—based on the ancient Chinese method of acupuncture, this method involves using specific points located on meridians at various places on the body	Noninvasive method Redirection of energy flow through pressure on meridian points Reduces pain and increases endorphins
Chiropractic adjustment	Manipulation of muscles and realignment of spinal column Nerve function is restored Structural integrity and balance are restored
Cognitive—Behavioral Methods	Advantages
Relaxation—body relaxation of muscles used with imagery, therapist instruction	Relaxes tense muscles and reduces stress Effective in reducing pain Easy to learn and implement techniques for self-mastery Reduces fear and anxiety connected to pain
Imagery—visualization technique of forming sensory images, or seeing in the “mind’s eye” an image that distracts from the sensation of pain	Effective in reducing pain Client can control use and timing of technique Reduces high-level anxiety connected to pain
Deep breathing—techniques using breath to control pain	Effective in reinforcing body relaxation and visualization Reduces pain through breath control; increases oxygen utilization
Hypnosis—creating a state of altered consciousness so that client is susceptible to instruction	Effective with a client who is suggestible and who experiences tension and anxiety accompanying pain

NOTE: Other alternative techniques are presented in Chapter 17.

DOCUMENTATION for Nonpharmacological Pain Relief

- Describe the client's pain, including onset, pattern, location, quality, intensity, precipitating factors, associated factors, and aggravating factors
 - Describe alleviating factors, including what the client does to relieve pain as well as nursing assistance
 - Describe behavioral changes due to pain relief or the absence of objective changes in response to nursing interventions
 - If there is a poor response to therapy, state what other measures will be attempted, and chart results
 - Continue to document attempts to relieve pain until relief occurs and the client is satisfied
-

CRITICAL THINKING Application

Expected Outcomes

- Pain is controlled through nonpharmacological methods such as massage, relaxation techniques, or TENS.
 - Client is satisfied with level of pain control.
 - Client receives adequate pain medication; pain level does not interfere with ambulation, getting out of bed, etc.
 - Client's anxiety level is lowered in relation to pain.
-

Unexpected Outcomes

Client achieves no relief from massage.

Client cannot focus on relaxation technique.

Alternative Actions

- Try combining method with use of medications (i.e., while waiting for the medication to take effect).
 - Client has to trust the technique before it can be effective. Have client talk to another person who has found technique helpful.
 - Start with very simple breathing techniques and progress slowly to relaxation and visualization (see Chapter 17 for specifics).
-

Pharmacological Pain Management

Nursing Process Data

ASSESSMENT Data Base

- Assess client's type, description, rating (use a pain-intensity scale), and level of pain.
- Assess vital signs for baseline comparison.
- Assess allergy to ordered pain medication.
- Assess patency of IV lines or epidural catheter.
- Assess sedation level of client on epidural analgesia.
- Assess insertion site for drainage, inflammation, etc.
- Assess potential use of PCA as method of pain control.
- Assess PCA risks.
- Assess reliability of candidate—ability to self-administer PCA.
- Assess client throughout PCA therapy (every 2 hr during first 24 hr, then every 4 hr).

PLANNING Objectives

- To implement strategies to decrease pain
- To prevent pain from retarding recovery
- To prevent pain from causing nausea and vomiting, a decrease in fluid intake which results in fluid and electrolyte imbalance
- To prevent pain from causing undue fatigue
- To prevent pain from inhibiting moving, ambulating, turning, and coughing; pain increases the possibilities of secondary problems from inactivity (e.g., pneumonia, emboli)
- To provide a consistent level of pain control without unacceptable side effects
- To enable the client to feel in control of his or her pain management
- To decrease the client's anxiety around the pain control issue
- To allow the client, according to needs for pain control, to self-administer pain medication via PCA

IMPLEMENTATION Procedures

- Administering Pain Medications 528
- Improving Client Satisfaction With Pain Control 528
- Administering Epidural Narcotic Analgesia 530

Managing Pain With Patient-Controlled Anesthesia (PCA)

- Qualifying the Client for PCA 533
- Preparing for PCA IV Administration 534
- Administering IV PCA to a Client 534
- Loading PCA—Alaris Model 534
- Priming PCA 535
- Changing Syringe on PCA 535
- Changing Program/Mode 536
- Checking PCA at Shift Evaluation 536
- Giving Bolus Dose 538
- Stopping Bolus, Loading, or PCA Dose 538
- Ongoing Assessment of the PCA Client 539
- Teaching PCA to a Client 539

EVALUATION Expected Outcomes

- Client feels competent to self-administer pain medication via PCA.
- PCA infuser works efficiently to administer medication.
- IV site or epidural site remains free of complications.
- Pain is controlled to client's satisfaction.
- Client's anxiety level remains low or manageable around issue of pain control.
- Family and friends (proxy) are educated not to interfere with pain relief protocols.

Critical Thinking Application 541

- Expected Outcomes 541
- Unexpected Outcomes 541
- Alternative Actions 541

Prepare for success with NCLEX®-style practice questions
 and Skill Checklists

Administering Pain Medications

Equipment

- Pain-Assessment Scale
- Ordered pain medication

Procedure

1. Assess pain according to the parameters of pain assessment and select a pain tool based on client's preference.
 - a. Verbal description scale.
 - b. Numeric rating scale.
 - c. FACES pain scale.

2. Check chart for any allergy to pain drug and physician's orders for changes in pain medication.
3. Administer ordered pain medication or request change in dosing schedule of infusion, PCA, etc.
4. Ensure analgesic is individualized to client, taking into account type of pain, intensity, and potential for toxicity (age, renal impairment, peptic ulcer, etc.).
5. Record results and set schedule for follow-up reassessment.

See chart on *Narcotic Analgesics*, page 529.

TABLE 16-2 Pain Management

Effective Pain Management	Barriers to Effective Pain Control
Listens to and believes clients when they describe the level of pain they are experiencing. This is the single most important pain assessment tool.	Insensitive response or not believing the client's subjective experience of pain.
Intervenes or administers the pain medication when it is needed.	Nurse wants reassurance the pain really necessitates medication—does not just respond to the client's request.
Does not allow the pain to escalate but anticipates when pain medication is needed.	Believes drug tolerance will make the medication less effective, so the less medication given, the better.
Works with the client to control the pain and requests different medications or dosages from the physician when needed.	Believes the physician knows best about the amount of pain medication for the client.
Is not concerned about addiction when administering pain medication. (The incidence of opioid addiction in hospitalized clients is less than 1%.)	Concerned about drug dependence or addiction—believes it is more important than effective pain management.
Understands the various actions of drugs and their role in pain control.	Inadequate knowledge about pain medications, so dosage, duration of action, or synergistic drug interactions are miscalculated.

Improving Client Satisfaction With Pain Control*

Procedure

1. Identify client receiving pain medication using two forms of client ID.
2. Inform client you will be asking questions to determine his/her level of satisfaction with pain medication protocol.
3. Ask, on a scale of 1 to 5 with 1 being very satisfied, "Can you tell me how satisfied are you with our pain control program?"
4. Ask, on the same scale, 1 to 5, "How do you rate nurse intervention for your pain control?"
5. Determine how often in hours during a 24-hr period they experience pain.
6. Ask, "During which shift of the three 8-hr shifts do you experience the most pain?"
7. Ask, "How long does it take you to receive pain relief when you have requested it?"

*These are only guideline questions. Your hospital may wish to develop its own short questionnaire to increase client satisfaction with pain control and meet The Joint Commission Pain Standards.

EVIDENCE-BASED PRACTICE

Preoperative Preparation for Pain Management

Researchers studied 38 post-op clients who underwent knee replacement surgery. A control group viewed a 10-minute video that described how to manage their pain; the intervention group watched a 15-minute video that described how to manage their pain as well as how to specifically describe it. Subjects in the intervention group reported greater pain relief and less pain interference.

Source: McDonald, D. D., Thomas, G. J., Livingston, K. E., & Severson, J. S. (2005). Assisting older adults to communicate their postoperative pain. *Clinical Nursing Research*, 14(2), 109–126.

Medications Used for Pain and Postoperative Care

Narcotic Analgesics Used for Pain Relief

- A. Pharmacological action—reduces pain and restlessness.
- B. General side effects.
 1. Drowsiness
 2. Urinary retention
 3. Sedation
 4. Respiratory depression
 5. Nausea and vomiting
 6. Constipation
 7. Pruritus
- C. Given at 3- to 4-hr intervals for first 24–48 hr for consistent action and pain relief.
- D. Types of analgesics.
 1. Opioids (narcotics)
 - a. Morphine sulfate—potent analgesic.
 - (1) Specific side effects: miosis (pinpoint pupils) and bradycardia
 - (2) Usual dosage: 10 mg IM/PO every 4–6 hr PRN
 - b. Hydromorphone (Dilaudid)—potent analgesic.
 - (1) Specific side effects: hypotension, constipation, euphoria
 - (2) Usual dosage: 1.5–2 mg PO, IM, or IV every 4–6 hr
 - c. Oxymorphone (Numorphan)—potent analgesic.
 - (1) Specific side effects: urinary retention, ileus, euphoria
 - (2) Usual dosage: 1–1.5 mg subcutaneously or IM every 4–6 hr; 0.5 mg IV every 4–6 hr.
 2. Synthetic opiate-like drugs.
 - a. Demerol (meperidine)—potent analgesic (rarely used as of 2000)
 - (1) Specific side effects miosis or mydriasis (dilatation of pupils), hypotension, and tachycardia
 - (2) Usual dosage: 25–100 mg every 3–4 hr IM.
 - (3) Used less frequently today.
 - b. Talwin (pentazocine)—potent analgesic.
 - (1) Specific side effects: gastrointestinal disturbances, vertigo, headache, and euphoria
 - (2) Usual dosage: 50 mg oral tablets every 3–4 hr; 30 mg IM every 3–4 hr PRN

- d. Hydrocodone (Vicodin)—potent analgesic.
 - (1) Specific side effects: dizziness, drowsiness, sedation, nausea, and vomiting
 - (2) Usual dosage: 10 mg orally every 3–4 hr
- e. Codeine sulfate—mild analgesic.
 - (1) Specific side effect: constipation
 - (2) Usual dosage: 30–60 mg every 3–4 hr IM. (May be combined with Tylenol 300 mg.)
- f. Oxycodone HCl; also Percocet (with acetaminophen) and Percodan (with aspirin).
 - (1) Potent opioid analgesic that is very addictive, especially with high dosage and long-term use
 - (2) Usual dosage is 20–30 mg PO every 3–5 hr
 - (3) This drug is very popular “on the street” and is dangerous because of its addictive quality.

Pain Management Options

Medications Approved for Pain Relief

DepoDur (morphine) an MS extended-release liposome injection to treat pain after major surgery. Lasts up to 48 hr; 5–15 mg given by lumbar epidural injection.

Hydromorphone (Palladone) opioid drug available as extended-release tablets. Used for clients already taking opioid medications; 12–32 mg.

Current Standards of Pain Care

Continuous IV infusion of pain medication PCA—combination of continuous infusion with client-controlled bolus dosing for breakthrough pain

Epidural analgesia (continuous infusion or PCA analgesia)

Adjunctive medications, i.e., anti-inflammatory, antiemetics to enhance effects of opioids

Transition to long-acting oral meds before discontinuing IV analgesics

Transdermal pain patches for chronic moderate-to-severe pain

Administering Epidural Narcotic Analgesia

NOTE: Many hospitals require specific certification before the RN can administer narcotics via an indwelling epidural catheter. A student nurse should not administer solutions via epidural catheter. Verify the regulations and role parameters for each healthcare worker. All nurses should, however, be aware of the safety precautions.

Equipment

Labels for safety precautions:

At head of bed: "Epidural Protocol Client"

At end of catheter: "Epidural Catheter"

3-mL syringe and ampule of naloxone hydrochloride (Narcan: 0.4 mg) as ordered at bedside

Ambu bag at bedside

Respiratory record, apnea monitor, or pulse oximeter

Sterile gloves

Tape

For Bolus Injection

Prescribed medication solutions prepared by pharmacy in prefilled syringe or bag

Antimicrobial swabs (alcohol should NEVER be used)

Sterile 2 × 2 gauze

For Continuous Infusion

Infusion pump

IV Epidural infusion tubing

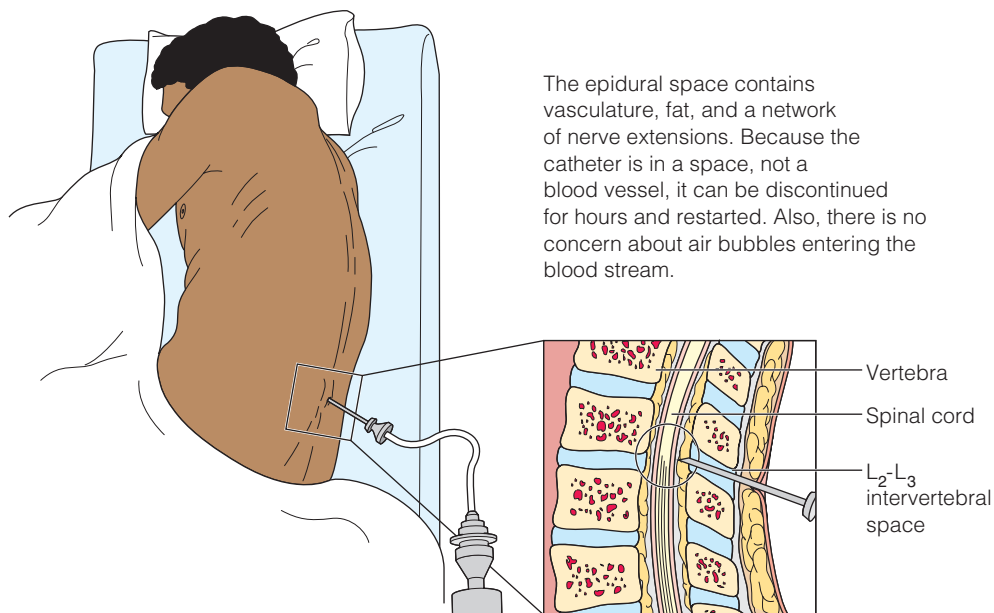

Prediluted preservative-free narcotic container/syringe or bag

▲ When a client is receiving epidural analgesia, there should be a sign over the bed stating "Epidural Protocol Client."

Preparation

1. Check physician's orders for epidural narcotic indicating minimum and maximum dosage.
 - a. Preservative-free narcotic, preordered from pharmacy; preservative-free saline and amount ordered.
 - b. Interval between doses.
 - c. Infusion rate and concentration, if appropriate.
2. Check that safety sign is over bed: "Epidural Protocol Client." ► **Rationale:** Identifies client to all staff as having epidural tubing.

The epidural space contains vasculature, fat, and a network of nerve extensions. Because the catheter is in a space, not a blood vessel, it can be discontinued for hours and restarted. Also, there is no concern about air bubbles entering the blood stream.

▲ Placement of indwelling catheter in the epidural space.

3. Check that catheter is labeled “Epidural catheter.”
 ▶ **Rationale:** Identifies catheter and avoids confusing epidural catheter with IV tubing.

4. Check that a Narcan ampule and 3-mL syringe are at bedside. ▶ **Rationale:** Respiratory depression can be treated with IV Narcan, a narcotic antagonist.

5. Check that there is IV access for administration of Narcan. ▶ **Rationale:** It may be necessary to quickly administer a narcotic antagonist if respiratory depression occurs.

NOTE: IV should be accessed with needleless syringe.

6. Check that Ambu bag is available on unit.
 ▶ **Rationale:** Necessary for complication of respiratory depression.

7. Check if an apnea monitor or pulse oximeter is ordered. ▶ **Rationale:** It is important that clients be monitored closely (at least for the first 12 hr) because of dangerous side effects, especially respiratory depression.

8. Assemble equipment.

9. Perform hand hygiene, and maintain strict aseptic technique. ▶ **Rationale:** Maintaining sterility of insertion site, administered solutions, and infusion lines decreases potential for complications.

10. Check two forms of client identification.

11. Position client on side in knee-chest position or leaning over bedside table.

3. Verify narcotic with a second nurse before administering. ▶ **Rationale:** It is important to take every precaution to prevent inadvertent administration of a drug that could cause spinal cord damage.

4. Check epidural pump function and report any problems.

5. Continue assessment of client’s pain level and volume of medication delivered every 8 hr (per policy).

6. Monitor insertion site.

7. Disinfect catheter injection port (Luer-Lok port or the injection cap) with nonalcohol antimicrobial wipe.

▶ **Rationale:** Alcohol must *never* be used because it is extremely toxic to the spinal cord.

8. Dry injection cap or port with sterile 2 × 2 gauze.

9. Insert cannula into injection cap or port, and attempt to aspirate for 30 seconds. ▶ **Rationale:** See Clinical Alert above.

Narcotic Administration

Narcotics Commonly Administered Via Epidural Continuous Infusion

- Preservative-free Morphine sulfate (Duramorph): 0.2–1.0 mg/hr
- Hydromorphone hydrochloride (Dilaudid): 0.05–0.3 mg/hr
- Fentanyl (50–150 µg/hr)

Procedure

For Bolus Injection

1. Put on sterile gloves and maintain sterile technique.
2. Check again that preprepared narcotic is preservative-free, nonbacteriostatic opioid, as ordered. ▶ **Rationale:** Preservatives are toxic to neural tissues.

Clinical Alert

If client is elderly, the dose should be adjusted downward (25% to 50%) initially, then titrated according to client response.

Clinical Alert

Place IV line as far as possible from an epidural catheter and label epidural catheter to avoid mistaking it for IV catheter—this could be a *fatal* mistake. Some catheters are specifically labeled. For example, the DuPen permanent epidural catheter has a yellow band near the Luer-Lok tip that has a sign “Epidural catheter—not an IV access.”

EVIDENCE-BASED PRACTICE

Pain Relief for the Elderly

Researchers analyzed the records of 709 elderly clients who were hospitalized for hip fracture. While around-the-clock PRN medication was recommended, only one-third of 87% of the nurses believed this method should be used. Also, in spite of this study finding that 75% of the nurses were aware that meperidine use should be avoided in the elderly (because it may cause seizures) and other drugs are more appropriate, 57% of the clients received at least one dose.

Source: Titler, M. G., Herr, K., Schilling, M. L., Marsh, J. L., Xie, X. J., Arderly, G., Everett, L. Q. (2003). Acute pain treatment for older adults hospitalized with hip fracture: Current nursing practices and perceived barriers. *Applied Nursing Research*, 16(4), 211–227.

Clinical Alert

If more than 1 mL of fluid or blood is returned during aspiration of the catheter, the procedure *must be terminated* (because the catheter may have migrated) and physician notified.

What's a Smart Pump?

Infusion pumps have revolutionized the way nurses administer IV therapy. Now they have become “smarter.” The pump’s “brain” includes software that contains a drug library and alerts you if a medication is outside the recommended parameters, such as dose, dosing unit, rate, or concentration. Smart pumps also log data about all these alerts. As required by The Joint Commission, smart pumps include safety features that will prevent unintentional overdoses of a medication or fluid. The smart pumps available include Alaris System with Guardrails Safety Software (Cardinal Health), Colleague CX with Guardian feature (Baxter), Outlook 100-400 Safety Infusion Systems with Dose Guard (B. Braun Medical), PlumA+ and Life Care infusion system with Hospira MedNet Software (Hospira).

Smart Pump Protocol

- Turn on the smart pump and designate the specific client care area you’re going to use it in. (The pump will automatically configure itself to give you the infusion parameters for that area, e.g., Pediatrics.)
- Program the pump by choosing the intended drug and concentration from the pump’s list.
- Enter the ordered dose and infusion rate. (The pump checks this information against the drug library.)
- If what you’ve programmed is outside the allowed parameters, the pump will alert you. The pump will sound a “soft” alarm, which you can override to allow the infusion to begin, or a “hard” alarm. This will require you to reprogram the pump to be within the facility’s specified limits.
- The pump logs and tracks all alerts to provide the hospital with data to shape current practice guidelines.

Integrating a Smart Pump With Bar Coding

When a hospital integrates a smart pump with a bar-code medication administration system (BCMA), it will address all five “rights” of medication administration.

The FDA mandated that, by 2006, drug manufacturers must label most prescription drugs and certain OTCs with a machine-readable bar code.

General Steps of Using a Bar Code

- Check the client’s electronic medication record (which tells you which IV meds were ordered and time of administration).
- Enter client’s room with scanning device and scan bar codes on the medication, the client’s ID, and your own ID badge.
- The bar-code label on the drug is then programmed into the pump. Software ensures medication in bar-coded drug vial is consistent with hospital guidelines. When all scanned information is received, the pump will allow you to begin the infusion.
- The pump will automatically communicate with a computer in the pharmacy so that an up-to-date status of your client is available.

▲ Alaris Smart Pump with attached modules.

- Inject medication slowly.
- Remove cannula from injection cap or port.
- Dispose of syringe in appropriate container.
- Check that a sterile, occlusive dressing is over insertion site. Dressing is changed every 72 hr (certified RN or MD to change dressing) or when wet.
- Tape all injection ports on epidural line if there is no continuous infusion. ► **Rationale:** This will prevent injecting a solution meant for the IV line into the epidural line.
- Closely monitor respirations every 1 hr for 24 hr or use apnea monitor or pulse oximeter. ► **Rationale:** Due to risk of respiratory depression, close monitoring after administration of an epidural narcotic is essential.
- Monitor vital signs: BP and pulse every 30 minutes for 1 hr after initial epidural dose, then every 8 hr.

▲ Intrapleural catheter may be used for pain medication instillation.

17. Monitor for possible side effects of narcotic administration: respiratory depression, urinary retention, nausea and vomiting, and pruritus.
18. Document dose and client status.

For Continuous Infusion

1. Check physician's orders for epidural narcotic.
2. Check that safety signs are near bed and label is on catheter.
3. Complete hand hygiene and don gloves.
4. Attach container of narcotic to infusion pump tubing.
5. Prime tubing (see Chapter 28 for step-by-step instruction).
6. Attach proximal end of tubing to pump and distal end to epidural catheter.
7. Tape all connections securely.
8. Set infusion pump to ordered calibration.
9. Observe for side effects of narcotic or client response and pain level.
10. Dispose of gloves and complete hand hygiene.
11. Chart pump reading every hour for 12–24 hr or as dictated by institutional policy.
12. Record narcotic on appropriate sign-out sheet.

Clinical Alert

Low-molecular-weight heparin (LMWH) should NOT be used concurrently with epidural or spinal analgesia.

Managing Pain With Patient-Controlled Analgesia (PCA)

Qualifying the Client for PCA

Procedure

1. Determine whether physician wishes to use PCA for pain control.

NOTE: The greatest use of PCA is in the management of pain after surgery. There are 73 million surgical procedures performed annually in U.S. hospitals, with 86% of postoperative clients reporting pain in the moderate-to-severe level.

2. Determine whether client is a candidate for PCA.
 - a. Check criteria for client selection.
 - b. After explaining PCA, determine whether client wishes to use this method of pain control.
3. Determine which type—electronic or mechanical—PCA unit is appropriate.
 - a. A mechanical device is fed by gravity rather than electricity; it is simple, inexpensive, disposable, and does not interfere with the client's mobility.
 - b. A pump or electronic device has a computer for dosage monitoring, is more flexible, and can be reset as necessary.

4. Assess any allergy to prescribed pain medication.
5. Perform basic physical assessment before initiating PCA.
 - a. Establish baseline vital sign chart.
 - b. Specifically assess client's respiratory system for ongoing evaluation during PCA therapy.

Clinical Alert

Determine whether client is allergic to pain medication prescribed—usually morphine, hydromorphone, Dilaudid, or fentanyl.

Criteria for Client Selection for PCA

- Clients requiring parenteral analgesic treatment.
- Clients requiring postoperative pain relief.
- Trauma clients who have clear sensorium.
- Clients suffering from chronic pain (terminal cancer).
- Clients who are mentally alert and able to understand and comply with procedure instructions.
- Clients without a handicap that impairs ability to use PCA.
- Clients with no prior addiction to drugs or alcohol.
- Eighteen years of age is the usual minimum age for PCA use, but it has been used in children as young as 7 years of age.

Preparing for PCA IV Administration

Equipment

NOTE: This skill applies to the ALARIS Medley System. Specific steps of administering PCA vary with different manufacturers' equipment (ALARIS is used only as an example for teaching).

- Specific physician's orders for PCA
- Gloves
- PCA central unit, infuser pump, and PCA module
- PCA administration tubing
- IV start kit, tubing, catheter, and ordered fluid
- Extension set with Luer-Lok adapter
- Analgesic medication cartridge and injector (vial injector)
- PCA administration record
- PCA booklet for client

Procedure

1. Check that physician's orders, including medication orders for PCA, are complete.

NOTE: Morphine is available in 30-mL vial injectors (concentration of 1 mg/mL or 5 mg/mL; hydromorphone concentration 0.2 mg/mL; fentanyl concentration 50 mcg/mL).

2. Check PCA medication recommendations for dose and lockouts.
 - a. Morphine: 1 mg, lockout is 8 minutes.
 - b. Hydromorphone: 0.2 mg, lockout is 8 minutes.
 - c. Fentanyl: 10 mcg, lockout is 6 minutes.
3. Check two forms of client ID.
4. Assemble IV administration set (refer to Chapter 28, Preparing the Infusion System).
 - a. Perform hand hygiene and don gloves.
 - b. Start IV line. ► **Rationale:** This establishes venous access for PCA.
5. Assemble PCA module following manufacturer's instructions.

Administering IV PCA to a Client

Equipment

Follow machine steps to know how to set various parameters, i.e., loading dose, lockout intervals, etc.

Procedure

1. Administer loading dose if ordered. ► **Rationale:** This initiates pain relief to client.
2. Set lockout interval on pump.
3. Set volume to be delivered using dose-volume control.
4. Press and release loading-dose switch.
5. Now set parameters for dosage control following physician's orders.
6. Calculate volume of medication needed to deliver ordered dose (example: 30 mg morphine per 30-mL vial).

7. Set dose volume which is the amount of fluid and medication.
8. Set rate as ordered if client is receiving continuous infusion (basal rate). **NOTE:** Basal rate is no longer being used in many hospitals.
9. Set lockout interval—minimum time between doses. ► **Rationale:** Prevents drug overdose.
10. Set 4-hr limit by pushing control switch. ► **Rationale:** Limits volume to be given in any 4-hr period.
11. Check dose given to client every 1–2 hr by pressing total dose switch. ► **Rationale:** To prevent excessive sedation and CNS depression.
12. Monitor client's pain level and sedation level. ► **Rationale:** To check if pain level is being controlled and sedation level is within acceptable limits.

Loading PCA—Alaris Model

Procedure

1. Open syringe barrel clamp (clear piece) until it clears syringe chamber.
2. Raise drive head (gray) to fully extended position.
3. Insert syringe barrel flange between barrel flange grippers.
4. Twist gripper control clockwise, lower drive head, and lock (anchor) plunger in place with plunger grippers.

NOTE: Be sure you complete these steps according to manufacturer's directions.

5. Explain ongoing procedure to client. (You have already completed client teaching regarding pain management with use of PCA infuser.)
6. Leave PCA booklet with client for referral during pain control time.

Clinical Alert

To administer blood or any other medication incompatible with pain medication, you must establish a second IV site.

PCA Infuser Pump

PCA infuser pumps are made for home or hospital use. These special pumps allow the client to control three parameters of medication delivery:

- Stopping and starting a continuous infusion.
- Titrating the hourly dose within a preset range of milligrams per hour.
- Administering a bolus dose within preset parameters.

Priming PCA

Procedure

1. Attach administration set to syringe.
2. Prime the administration set.
 - a. Priming manually, express air from the administration tubing set.
 - b. Priming using PCA module, view screen and press **OPTIONS**, then press **PRIME SET WITH SYRINGE**.
3. Close slide when tubing set is primed. ▶ **Rationale:** Closing slide clamp maintains prime and prevents air entry.
4. Press **SYSTEM ON KEY**.
5. Select **YES** or **NO** to new client.
6. Select appropriate **PROFILE**.
7. Press **CHANNEL SELECT KEY**.
8. Set key to program position.
9. Press **CONFIRM TIME** setting.
10. Choose correct syringe type and size; choose correct medication and concentration. ▶ **Rationale:** Medication and dose must match physician's orders.
11. Press **OPTIONS KEY** to prime.
12. Press **PRIME SET WITH SYRINGE**. (See 2b above.)
13. Press and hold **PRIME KEY** to prime tubing.

NOTE: Do not prime while attached to client.

14. Press **EXIT** when priming is complete.
15. Choose desired infusion mode and follow on-screen prompts.
16. Close and lock door.
17. Attach administration set tubing to client.
18. Review settings and press **START**.

Clinical Alert

There is a high rate of errors associated with PCA according to MEDMARX error reporting system of U.S. Pharmacopeia (USP). When pumps are involved, client harm increases threefold. Most common errors are:

1. Improper dose and quantity (39%).
2. Unauthorized/wrong drug (18%).
3. Omitting a dose (18%).

The Joint Commission has issued a *Sentinel Event Warning* about client harm and death with PCA pumps. There were more than 6,000 errors reported with 460 resulting in death or some level of harm to the client.

Changing Syringe on PCA

Procedure

1. Press **PAUSE**.
2. Close tubing clamp.
3. Use key and unlock door.
4. Remove old syringe.
5. Press **SILENCE**.
6. Attach new syringe to tubing.
7. Load new syringe.
8. SET KEY to "program" position and close door.
9. Press **CHANNEL SELECT**.
10. Choose correct syringe type and size.
11. Press **CONFIRM**.
12. Press **RESTORE** if same drug and dose is issued.
13. Verify drug and concentration.
14. Verify current settings.
15. Lock door and open tubing clamp. ▶ **Rationale:** Door must be locked for PCA to begin.
16. Review settings and press **START**.

Changing Program/Mode

Procedure

1. Press CHANNEL SELECT key.
2. Press PROGRAM.
3. SET KEY to “program” position or enter authorization code.
4. Press CHANNEL SELECT key.
5. Choose desired infusion mode and follow on-screen prompts.

▲ 1 Alaris Central Processing Unit (smart pump).

▲ 2 Attach PCA module to central unit.

▲ 3 Load syringe (50 mL) into module.

Checking PCA at Shift Evaluation

Procedure

1. Press CHANNEL SELECT key.
2. Verify syringe type and size.
3. Verify drug, concentration settings, and medication use.
 - ▶ **Rationale:** Narcotics must be accounted for when used in PCA.
4. Inspect the IV site to ensure the medication is being delivered into the vein, not surrounding tissue.
5. Press START key.

4 Anchor syringe/plunger in three steps; be sure plunger is anchored according to manufacturer's directions.

5 Set key to "program" position and check drug library on screen.

6 Recheck drug selected and confirm by pressing "yes."

7 Close and lock door.

8 Pass client control button to client.

9 Check narcotic dose with a second nurse.

EVIDENCE-BASED PRACTICE

In 2007, a hospital with 9,000 PCA clients a year looked at the source of its 56 PCA-related errors:

- Misprogramming—71% (common errors were misplaced decimal)
- Wrong entering—(basal rate where bolus dose should be entered)

- Wrong selection of lockout settings
- Selecting the wrong concentration
- Confusing words (milliliter for milligram)

Source: Institute for Safe Medication Practices. (June 14, 2007). *Safety Issues with Patient-Controlled Analgesia*. Available at: www.ismp.org

Giving Bolus Dose

Procedure

1. Press CHANNEL SELECT key.
2. Press BOLUS DOSE.
3. SET KEY to “program” position or enter authorization code.
4. Enter bolus dose amount.
5. Lock door.
6. Press CONFIRM.
7. Review settings and press START.

Stopping Bolus, Loading, or PCA Dose

Procedure

1. Press CHANNEL SELECT key.
2. Press STOP bolus/loading or PCA.
3. Press YES or NO.

Dose Calculation

- The PCA infuser delivers in milliliters. The machine calculates the number of milliliters needed for the correct milligram dose. Examples: 10 mg (1 mL) every 10 minutes; 40 mg (4 mL) every 10 minutes.
- The maximum rate of administration is 20 mL/hr.

Ten Profiles of PCA Use

Pediatrics and Peds ICU
 Medical–Surgical
 Post-operative

Chronic pain, High-dose PCA
 Progressive Care
 ICU–NICU

TABLE 16-3 PCA Risks and Strategies

PCA Risks	Risk Reduction Strategies
Wrong or improper drug or dose	Standardizing the drugs for PCA use Standardizing PCA order sheets Use prefilled syringes and bags with standardized concentrations Integrating bar coding on medications for PCA use Limiting the concentration of drugs New protocols for infusion of meds
Side effects of medication—toxicity, respiratory distress, over-sedation	Continual respiratory monitoring Adding pulse oximetry (S_pO_2) and capnography ($EtCO_2$) to the same module monitoring adverse responses Monitoring level of consciousness
Improper client selection	Use standard protocol for client selection
Programming errors of meds	Safety software for dosing and safety limits Have nurses annually demonstrate entering correct PCA settings from standard orders
PCA by proxy	Proxy (intervening in established pain relief protocols) is usually family and friends intervention, so better education of family and client is indicated

Ongoing Assessment of the PCA Client

Procedure

1. Check pulse oximetry readings—when Spo₂ is less than 90% with decreased respiratory rate (less than 10), client status requires intervention.
2. Monitor respiratory status often with a prescribed time interval. ► **Rationale:** It is a key indicator of adverse response to opioid infusion.
3. Keep naloxone (Narcan) and positive pressure ventilation on hand. ► **Rationale:** These items will be needed to reverse respiratory depression due to over-sedation.
4. Check heart rate, respiratory rate, oxygen level, end-tidal CO₂ if PCA has capnography module. ► **Rationale:** These criteria are important to assess and monitor status of the client.

NOTE: Intermittent monitoring may not pick up ventilatory depression that occurs between monitoring times.

Due to PCA sentinel event warnings, recent studies suggest using side-stream capnography (together with pulse oximetry) to provide continuous recordings of heart rate, oxygen saturation, respiratory rate, and end-tidal CO₂ from which they can monitor for respiratory depression. A change in respiratory status is a leading indicator of adverse client response to opioid infusion, and capnography can detect hypoventilation. The newer PCA pumps have integrated capnography and pulse oximetry.

Teaching PCA to a Client

Preparation

1. Determine whether client is a candidate for PCA (see skill in this chapter *Qualifying the Client for PCA*).
2. Allow client to directly handle equipment and practice using a “dummy” PCA button. ► **Rationale:** This reduces fear of technology and teaches basic steps of PCA.

▲ Teach PCA procedure to client.

Procedure

1. Demonstrate how PCA device works.
 - a. Set the pump's controls to deliver pain medication.
 - b. Instruct client that if amount of medication is not sufficient to control pain, he or she may press a button to deliver an additional bolus.
 - c. Tell client that after each bolus, client must wait a minimum amount of time (usually 5–10 minutes) before delivering another dose. ► **Rationale:** This protects client from receiving too much medication.
 - d. Dose may be adjusted to maintain pain control. ► **Rationale:** When clients control their own medication dose, studies indicate usage is not excessive.
 - e. Have client explain and demonstrate PCA use before initiating therapy.
2. Clarify with client how he or she administers medication dose when pain is felt. ► **Rationale:** Self-control of pain medication has been found to be very successful with clients and less time-consuming for the nurse. There is no significant difference in amount of medication used.
3. Program PCA infuser for continuous infusion plus a bolus dose.
 - a. Establish amount of narcotic needed to control client's pain (i.e., give 1–5 mg morphine every 10 minutes until pain is relieved).
 - b. Set pump's hourly infusion rate to equal total milligrams per hour needed to control pain.

4. Reassure client that PCA will control, but not totally abolish, pain. ► **Rationale:** Continuous infusion supplemented by small boluses provides steady relief (more so than IM injections) but does not eliminate pain.
5. Teach client how to evaluate pain level on a five-point scale. If client's pain is not sufficiently relieved, medication dose is increased. ► **Rationale:** When clients know they can control their pain level, they feel less helpless and more empowered.
 - 1 = Pain relieved
 - 2 = Occasional discomfort
 - 3 = Decreased pain intensity, e.g., able to walk, cough
 - 4 = Minimal pain relief
 - 5 = No pain relief
6. Evaluate client's response to medication schedule.
 - **Rationale:** It is important to check for adverse

effects of sedation to avoid complications or necessity of revising dose parameters.

7. Reassess client's ability to control pain level and effectiveness of medication dosage to control pain.
8. Teach client importance of not letting family member (or anyone other than client) activate PCA pump.
 - **Rationale:** PCA by proxy (family members) has caused critical events of overdosing.
9. Teach client potential adverse effects (sedation, respiratory depression) if anyone other than client activates pump.
10. Instruct client to notify staff if machine malfunctions (alarm sounds or message display indicates a problem), pain is not controlled or changes in severity, or if he or she has any questions.

DOCUMENTATION for Pharmacological Pain Management

- Pain assessment: onset, pattern, description, location, intensity
- Amount and type of pain medication administered
- Sedation level of client
- Interventions, level of pain relief
- Side effects—pruritus, nausea, and vomiting
- Vital signs

- 2 = Drowsy
- 3 = Dozing intermittently
- 4 = Mostly sleeping
- 5 = Only awakens when disturbed

- Initiate new PCA administration record for each narcotic vial injector used.

For Epidural Analgesia

- Pain relief from medication
- Side effects—pruritus, nausea, and vomiting
- Condition of insertion site
- Vital signs

For PCA

- Assess and chart on client using PCA infuser every 4 hr (after initial 24 hr), unless otherwise ordered.
- Describe respirations every 2 hr and compare to baseline assessment sheet.
- Record sedation and pain legend every 4 hr. Include degree of pain relief obtained from PCA.
 - 1 = Wide awake

For PCA Record

- Chart appropriate entries throughout your shift. To determine amount of medication administered, press TOTAL DOSES and multiply by number of milliliters prescribed.
- Chart LOADING DOSE and time administered separately on medication record.
- Chart wasted narcotic—cosigned per hospital policy.
- Verify and document that calculated volume remaining and actual volume remaining in syringe are the same. Report any discrepancy and follow hospital procedure for incorrect narcotic count.

CRITICAL THINKING Application

Expected Outcomes

- Client feels competent to self-administer pain medication via PCA.
- PCA infuser works efficiently to administer medication.
- IV site used to administer PCA remains free of complications.
- Pain is assessed at the appropriate level and controlled to client's satisfaction.

Unexpected Outcomes

For Administering Pain Medication

Client says that pain medication is not helping the pain.

Client appears overly sedated.

For Epidural Analgesia

Client develops constipation from regularly administered narcotic preparations.

Client develops respiratory depression and appears to be sedated.

Client develops nausea and vomits.

Client complains of numbness in legs and motor weakness but has no pain.

Catheter insertion site is red and warm to touch, and drainage is noted.

For PCA

Alarm Alert—PCA no longer infusing.

- Medication administration for pain is monitored at an appropriate level.
- Client's anxiety level remains low or manageable around issue of pain control.
- Family and friends are educated not to interfere with pain relief protocols.

Alternative Actions

- Reassess tolerance level of client (check if client has previously been on high doses of a narcotic, thus developing a high tolerance level).
- Check that pain dose is adequate for pain management.
- Request consultation with physician to increase or change pain medication (remember, the nurse is the client's advocate).
- Hold the next pain medication until client can be evaluated—notify the physician.
- Check other drugs client is taking—there may be a synergistic effect.

- Obtain order for and administer stool softener and peristaltic stimulant.
- Encourage intake of high-fiber diet, if not contraindicated.
- Encourage adequate fluid intake.

- Check sedation level (drug may have been absorbed by systemic vasculature and epidural veins and ended up in high concentrations in the brain).
- Reduce rate of epidural and notify physician.
- Check on other drugs the client is taking—there may be a synergistic effect.
- Nursing assessment: respirations, ability to cough and deep breathe, auscultate chest, arterial blood gases.
- Check that Narcan is at the bedside—may be ordered if respirations are too slow (this drug reverses analgesia so monitor for high pain level returning).

- Assess cause of problem—consider pain, ileus, as well as reaction to drug.
- Administer antiemetics as ordered, and protect client from aspiration.
- Keep client NPO until cause of problem is discovered.

- Turn epidural infusion off until normal sensations return, then restart infusion at 2 to 4 mL/hr lower than original rate.
- Monitor for pain relief.
- Chart nursing actions and client response.
- Check temperature and vital signs and notify physician.

- Check if hourly maximum limit reached.
- Check if maximum amount of drug was delivered based on PCA programmed setting.
- Use SILENCE key to end alarm tone.
NOTE: Alarm tone will re-sound if additional dose is requested if drug has reached maximum limit.

Unexpected Outcomes

Near end of infusion, ALERT message appears on screen.

Client exhibits bradypnea, hypotension, nausea, vomiting, or dizziness.

Client experiences breakthrough pain.

Client is insecure and anxious about using PCA mode of pain control.

Medication, either type or dose, is not sufficiently controlling client's level of pain.

Client is receiving too much pain medication.

Alternative Actions

- PCA module will remain silent until syringe is empty, then alarm will sound.
- PCA module remains functional and will continue to infuse.
- Monitor sedation level—remember the goal of PCA is to control pain without sedation.
- Report to physician that medication parameters are resulting in oversedation.
- Readjust the medication or dosage level or bolus level (according to orders) so that breakthrough pain does not occur.
- Determine which steps client feels insecure about completing, and reteach procedure while demonstrating steps.
- Reevaluate medication and dose parameters with physician.
- Install bar codes on all PCA meds.
- Double-check module set-up and maintenance of pump.
- Re-educate client and family about proper use of PCA.

NOTE: Refer to Table 16-3 PCA Risks and Strategies on page 538.

GERONTOLOGIC Considerations

The Incidence of Pain in the Elderly Has Not Been Well Studied and This Population Presents Several Pain Management Problems

- Elderly people often suffer acute and chronic painful diseases or have multiple diseases, thus they often have more than one source of pain.
- Elderly are at increased risk for drug as well as disease interactions.
- Studies show the incidence of pain is twofold higher in those over 60. Acutely painful conditions affect the elderly disproportionately (herpes zoster, arthritis, polymyalgia rheumatica, peripheral vascular disease).
- Elderly may have impaired senses (vision, hearing) and an impaired ability to express themselves.

Pain Assessment Is More Complex and Difficult With the Elderly

- The elderly may report pain differently (not as clearly) than younger clients due to physiologic, psychologic, and cultural changes associated with aging.
- Clinicians often hold the mistaken belief that the elderly have increased pain thresholds; they may be more stoic about experiencing, and thus reporting, pain.

- Cognitive impairment (which may occur in as many as 50% of the institutionalized elderly) may interfere greatly with the assessment of pain. Even though behavior may be assessed (restlessness, groaning, agitation), it is nonspecific and subject to interpretation.
- See Gerontologic Considerations for Medications in Chapter 18 for specific guidelines for drug use with the elderly.

Traditional Approaches to Pain Control May Not Work With the Elderly

- Universal use of pain protocols may not be possible with visual, hearing, and motor impairments.
- Clients may report pain initially, but recall (due to cognitive impairment) may not be possible.
- Pain assessment may require frequent monitoring. Monitoring may have major implications for quality of care and quality of life, so facilities with limited staff may result in poor pain control in the elderly.
- The elderly are at risk for over- and undertreatment. Adverse drug reactions are more prevalent with the elderly.
- Attitudes among healthcare professionals may also impede appropriate care (partially due to belief that acute and chronic pain are a normal component of aging).

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- Noninvasive pain management techniques can be delegated to any staff member who feels comfortable performing and/or has experience in using touch (massage) or relaxation techniques. If TENS is used for pain control, the nurse must understand the basic principles of how this method works.
- The nurse, RN or LVN/LPN, is the primary individual who is responsible for pain management. He or she does this through the nurse–client relationship by becoming the client's advocate. Therefore, a professional nurse must manage the client's pain in order to identify the intensity, codify the degree, and evaluate the response to pain medication and intervene as necessary with the physician to change the medication protocol.
- Administration of epidural narcotic analgesia *must* be done by an RN and, in many hospitals, the nurse must have special certification. This skill may *not* be delegated to a nonprofessional staff member.
- Initial administration of PCA must be done by an RN or experienced LVN/PN. It may not be delegated to a UAP, nor may the UAP administer a booster dose.

- PCA may be managed and taught to the client by an RN or LVN/LPN *if* two parameters exist: (1) The Nurse Practice Act and agency protocol in the state allows it, and (2) the nurse has the information and experience to qualify the client and teach the procedure (under physician's orders). Nonprofessional staff may *not* perform this skill.

Communication Matrix

- It is critically important that the RN inform all staff where epidural narcotic analgesia is being used.
- Safety precautions (written labels) *must* be placed in the appropriate places, such as “Epidural Protocol Client” at the head of the bed, and the catheter labeled “Epidural Catheter” to avoid injuring the client.
- It is also imperative that the RN communicate to other nurses through the client's written records, labeling the IV line, and verbally through report that the client is receiving epidural anesthesia, and that the IV line be placed as far as possible from the epidural catheter. If an epidural catheter is mistaken for an IV line, it could be a *fatal* mistake.
- Because the nurse is the client's advocate in pain control, he or she must receive adequate feedback from all staff who interact with the client so that a viable pain management program can be implemented. It is the nurse's responsibility to inform the auxiliary staff caring for the client to report how the client is managing pain.

CRITICAL THINKING Strategies

Scenario 1

The client assigned to you has a diagnosis of advanced Alzheimer's disease and cancer with bone metastases. He is a 65-year-old man recently hospitalized. You know he is in pain, but he is unable to relate the degree of pain clearly to the staff or his family.

1. What is the most appropriate method of assessing pain in this client?
2. When considering this client, what is unique about the pain assessment in this situation?
3. What are some possible plans/goals to deal with this client's pain?
4. What are some of the risks in implementing the plan?

Scenario 2

The client has a PCA in place but constantly complains that the pain medication is not working. When asked if he uses the bolus dose, he says that he is constantly “locked out.”

1. What further assessment, if any, is necessary with this client?
2. Describe the goals and strategies you would devise to handle this situation.

3. What are the best actions you can carry out to meet these goals?

Scenario 3

A female client has been admitted to the nursing unit with the diagnosis of acute abdominal pain. You are assigned to admit her to room 113. The chart only contains the following demographic data: lives locally, is 28 years old, recently married. Her husband is at the bedside and is very concerned with his wife's pain. As you walk in the room to complete the admission process, she is writhing in pain and crying loudly.

1. To prepare for the admission interview, what will you do first? Why?
2. State how you will ask the client to describe her pain.
3. What questions might be appropriate to ask regarding the abdominal pain?
4. What assessment data is priority for this client?
5. How is this information utilized in the development of a client plan of care?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

- Which of the following theories of pain is the most recent and accepted as the most likely explanation of pain?
 - Pattern theory.
 - Specificity theory.
 - Endorphin theory.
 - Gate control theory.

- Which of the following characteristics are most important when you are measuring the degree of pain?

Select all that apply.

- Location.
 - Intensity.
 - Quality.
 - Pain pathway.
 - Pattern.
 - Amount of pain relief needed.
- What is the best explanation of why pain is now considered the fifth vital sign?
 - Pain is as important to assess as blood pressure and other vital signs.
 - Considered as a vital sign, pain will be measured and documented when other vital signs are taken.
 - As a vital sign, the presence of pain will result in an intervention.
 - As a vital sign, assessing pain allows the effectiveness of pain management to be measured.
 - The primary purpose of using a nonpharmacological method of pain relief over a pharmacological one is that it:
 - Is noninvasive.
 - Works better.
 - Works faster.
 - Is preferred by clients and physicians.
 - When a client is receiving epidural narcotic analgesia, the priority safety issue is:
 - Respiratory depression.
 - Checking that the apnea monitor is working.
 - Assessing for migration of the catheter.
 - Mistaking the epidural catheter for an IV catheter.
 - Which of the following is the most important rationale for qualifying a client for patient-controlled analgesia (PCA)?
 - To determine whether this pain method will relieve the client's pain.

- To evaluate whether the client is mentally alert and able to comply with the instructions.
- To assess the level of pain the client is experiencing.
- To assess whether the client's pain is chronic.

- You are assigned to care for a client receiving PCA. When you assess the client, you find that he is experiencing bradypnea, hypotension, and nausea. What is the priority intervention?
 - Assess the medication level.
 - Determine whether the medication is relieving the client's pain.
 - Monitor client's sedation level and request that the physician evaluate dose parameters.
 - Terminate the PCA.

- When monitoring a client with PCA, which of the following are common dangers when IV pumps are involved?

Select all that apply.

- Improper dose and quantity.
 - Unauthorized/wrong drug.
 - Poor pain relief results.
 - Omitting a dose.
 - Drug administration by proxy.
- You have a client who is to receive epidural narcotic analgesia. As a team leader, you may safely assign this client to which of the following staff members?
 - An LVN/PN or an RN.
 - A nonprofessional.
 - Any staff member.
 - Only an RN.
 - A client with recurrent acute pain is instructed on pain management. Successful compliance to the plan is reflected by which of the following statements?
 - "I take the pain medication faithfully every 4 hours."
 - "The best time to take my medication is after I shower and dress."
 - "The medication works best when I take it soon after the pain begins."
 - "I take the pain medication whenever the pain is a 7 on the scale of 10."

17

Alternative Therapies and Stress Management

LEARNING OBJECTIVES

1. Define the term *stress* according to Hans Selye.
2. Discuss the psychologic effect of stress on the body.
3. Describe the body's physiologic response to stress, and include at least two body systems.
4. List at least three different categories of stressors.
5. Identify at least five danger signals of stress.
6. Discuss a specific alternative method used to control stress.
7. Discuss complementary and alternative medicine (CAM) and how it can be applied to nursing.
8. Choose two alternative therapies, discuss the major components, and relate how you use them with clients.
9. Practice breathing techniques and discuss how you would teach this to a client.
10. Discuss why herbs could be dangerous.
11. List two herbs that could be dangerous when taken with a specific medication.

TERMINOLOGY

Adaptive reaction a response by which the person attempts to improve or alter his or her condition in relation to the environment.

Alleviate to make more bearable; reduce (pain, grief, or suffering).

Anxiety a state of uneasiness and distress; diffuse apprehension.

Apathy indifference; insensibility; without emotion; sluggish.

Apprehension a fearful or uneasy anticipation of the future; dread.

Ataraxia the absence of all anxiety.

Autonomic nervous system the part of the nervous system that regulates the functioning of internal organs and glands; it controls such functions as digestion, respiration, and cardiovascular activity.

Cerebral cortex the extensive outer layer of gray tissue of the cerebral hemispheres (brain), responsible for higher nervous functions.

Complementary/alternative medicine (CAM) a set of practices that encompass many treatments and ideologies outside of mainstream medicine.

Coping mechanisms means by which an individual adjusts or adapts to a threat or a challenge; actions that assist in maintaining homeostasis.

Defense mechanisms conscious or unconscious processes used to protect oneself from threats or to alleviate anxiety.

Dynamics of homeostasis danger or its symbols, whether internal or external, resulting in the activation of the sympathetic nervous system and the adrenal medulla. The organism prepares for fight or flight.

Emotional strong feelings, as of joy and sorrow.

Fight or flight one's immediate response to stress that is, although archaic and often inappropriate, part of our central nervous system's biologic heritage.

General adaptation syndrome a general theory of stress response formulated by Dr. Hans Selye; describes the action of stress response in three stages: the alarm reaction, the stage of resistance, and the stage of exhaustion.

Hallucination false perception having no relation to reality and not accounted for by external stimuli.

Health the state of physical, psychologic, and sociologic well-being.

Herbal preparations the use of plants to make medicines used for healing various conditions.

Holistic a way of looking at individuals and organisms as a whole rather than a sum of the parts.

Homeostasis the maintenance of a constant state in the internal environment through self-regulatory techniques that preserve an organism's ability to adapt to stress.

Hypertension a condition in which the client has a higher blood pressure than judged to be normal.

Illness a state characterized by the malfunction of the biopsychosocial organism.

Insomnia inability to sleep.

Lifestyle the manner in which one is accustomed to living.

Meditation the act of reflecting on or pondering; contemplation.

Musculoskeletal pertaining to the muscles and the skeleton.

Pain a sensation in which a person experiences discomfort, distress, or suffering.

Parasympathetic nervous system a division of the autonomic nervous system that regulates acetylcholine and conserves energy expenditure; it slows down the system.

Perspective subjective evaluation of relative significance; a view.

Psychogenic of mental origin.

Relaxation a lessening of tension or activity in a part.

Stamina constitutional energy; strength; endurance.

Stress a nonspecific response of the body to any internal or external event or change that impinges on a person's system and creates a demand.

Stressor a specific demand that gives rise to a coping response.

Sympathetic nervous system a division of the autonomic nervous system that controls energy expenditure and mobilizes for action when confronted with a threat.

Tachycardia abnormally rapid heart action; above 100 beats per minute.

Tranquilizer a drug that acts to reduce tension and anxiety without interfering with normal mental activity.

Wellness a state of physical, psychological, and sociologic well-being of a whole person. Synonym for health.

STRESS

Stress is a universal phenomenon; all human beings in all cultures experience it as a part of their everyday existence. Although stress is a natural component of life, it can sap energy and contribute to the presence of disease. The concept of stress has been with us since the beginning of time, but it was not until William Osler and Walter Cannon began their investigations in the early 1900s that stress was actually linked to illness. By 1950, Hans Selye, a Canadian endocrinologist and biologist, scientifically demonstrated that stress plays a major role in certain diseases, such as gastric ulcers and high blood pressure. Since Selye's early research, authorities from medicine as well as all areas of science have studied and written thousands of articles on this subject. With the undeniable fact that stress affects an individual's total life, nurses should have a basic understanding of this phenomenon, its effect on humans, how humans cope and adapt to stress, and how the nurse can deal

with his or her own stress and help clients deal with theirs. To examine stress and its influence on human beings in this culture, we have to examine the total scope of life experience. The stress of life is life itself according to Dr. Barbara Brown, a nurse-author.

Western medicine is entering an era of transformation. The whole context of the medical profession is changing. Clients and professionals alike are examining alternatives to traditional patterns of treatment and are devising new modes of healthcare delivery. These changes are occurring at a time when the healthcare system in this country, and indeed the world, desperately needs a new structure to deal with health and illness.

Perhaps the greatest impetus for these changes has developed in response to new knowledge about the role of stress in our lives. Selye, the acknowledged expert on stress, believed that efforts to manage and find cures for diseases is ineffective

as an approach to wellness. He and other prominent scientists think that a viable answer is to examine our ability to cope and adapt to stress. Arnold Fox, MD, stated that stress is either the main cause or a strong contributing factor in all diseases of humankind. In fact, most scientists now attribute 70%–80% of all diseases to stress and lifestyle.

The view that disease is caused by invading microorganisms, or that ill people are merely victims, or even that all disease can be cured by modern science, is misleading and limiting. New definitions of existing problems necessitate finding new solutions. The current emphasis on stress is relevant to our times, and nurses need to recognize and understand stress and its influence on individuals, on the profession, and, most particularly, on clients.

Stress is a difficult term to define precisely, for it does not have a single specific source or one definite response. Selye stated that stress may be viewed as the common denominator of all the body's adaptive reactions. Stress may be grief as well as joy, pleasure as well as unhappiness, cold as well as heat, fear as well as elation. In fact, stress covers the total range of mental, emotional, and physical demands on the body and causes the body to respond with predictable biochemical and general adaptation changes. If the body is in a state of balance and the whole organism functions in harmony, the body is healthy. Stress can be defined as a state of arousal or agitation that throws the body out of balance. Although a certain amount of stress is necessary for survival, when it becomes prolonged and intense, our adaptive responses weary, and the negative aspects begin to take their toll on our bodies and our minds. When this occurs, it can be said that disease has overtaken the body and an unhealthy state exists.

The Effect of Stress

Physiologically, stress may be viewed as the experience an individual has when the demands placed on the body exceed the ability to cope, and the body is thrown out of balance. Chemically, stress initiates certain bodily processes, such as the “fight-or-flight” mechanism, which result in a threat to homeostasis. Early in the 1900s, Walter Cannon, a Harvard physiologist, coined the term *homeostasis*. As a result of his work, certain adjustment mechanisms of the body, such as blood sugar level, temperature, and hydration, were identified. According to Cannon, the stress response resulted in these mechanisms being activated, which in turn threw the body out of balance.

Rather than a specific response, Hans Selye focused on a general adaptation process as a response to stress. This process is the body's attempt to adapt and maintain homeostasis. Selye further defined stress as the rate of wear and tear on the body and stated that the only freedom from stress is death.

Selye's *general adaptation syndrome* occurs in three stages. The first stage, the *alarm stage*, occurs when the generalized response throughout the body responds to stressors, such as trauma, infection, pain, cold, heat, and fear. The purpose of the alarm reaction is to mobilize the body's defenses to meet the stressor. Biochemically, during the alarm stage, the adrenal

cortex produces the anti-inflammatory hormones, the adrenocorticotropic hormones (cortisone and cortisol), and the proinflammatory hormones (aldosterone and desoxycorticosterone). This is called the shock phase because it is when the autonomic nervous system comes into full play.

The second stage, *resistance*, occurs when the body's defenses are mobilized to produce hormones to cope with the alarm stage. The body chemistry either repels or adapts to the stressor. During this phase the organism may be successful in adapting to the stressor, and, if so, the biochemical changes resulting from the alarm phase return to the prealarm stage. Any life change causes alarm and resistance, and the stress accrued through life reduces the body's adaptive abilities.

The *final stage* occurs when the stress is prolonged and the body can no longer cope effectively. The result is exhaustion, and the body may become ill with disease. The organism's adaptive abilities are depleted, and the organism loses its ability to deal with the stress. The organism goes into shock, and if the stress is not alleviated, the result may be death of the organism. The general adaptation syndrome varies widely in intensity. Reaction to positive stimuli, such as getting married or a job promotion, also activates a stress response. The response may, however, result in less damage than a negative stressor, even though it does temporarily throw the body out of balance. Furthermore, a person does not respond with the same intensity to all negative stressors. For example, one doesn't respond with the same degree of intensity to jumping in a cold pool as to turning a corner and seeing a man with a gun.

The *local adaptive syndrome* is the manifestation of stress in a limited part of the body. The body responds locally to the stressor, such as a burn or cut to a finger. The local response may also trigger a general response if the ability of the body to respond to the specific area is greatly affected by the condition of the whole organism. An upper respiratory infection causes a much different response within a healthy child than in a child with cystic fibrosis. The better the organism as a whole adapts to stress, the more effective the local adaptive response.

Individual Responses to Stress

Responses to stress, then, can be categorized into several different patterns: the *physiologic response*, in which there is loss or gain in weight over time, hormone levels increase, blood pressure increases, or possibly a somatoform (psychosomatic) symptom appears; the *psychologic response*, which may also result in a psychosomatic illness or psychiatric manifestations, such as depression, mania, withdrawal from reality, or anxiety; and, the *behavioral response*, in which one hits out, becomes aggressive (fights), or withdraws; one may also become immobilized, or turn inward (physical or emotional flight). The *interpersonal mode* can reflect stress when communication effectiveness decreases, relationships deteriorate, trust in others diminishes, and the ability to form and maintain close, intimate, loving ties with another person decreases. Finally, the affective response may be present when one's emotions are affected so that anxiety is high and

TABLE 17-1 Selye's Stress Adaptation Syndrome

Stage	General Function	Interpersonal	Behavioral	Affective	Cognitive	Physiological
1 Alarm reaction	Mobilization of body defenses	Interpersonal communication effectiveness decreases	Task oriented Increased restlessness Apathy Regression Crying	Feelings of anger, suspiciousness, helplessness Anxiety level increases	Alert Thinking becomes narrow and concrete Symptoms of thought blocking, forgetfulness, and decreased productivity	Muscle tension Increase in epinephrine and cortisone Stimulation of adrenal cortex and lymph glands Increase in blood pressure, pulse, blood glucose
2 Stage of resistance	Adaptation to stresses Resistance increases	Interpersonal communication self-oriented Uses interpersonal relationships to meet own needs	Automatic behaviors Self-oriented behaviors Fight or flight behavior apparent	Increased use of defense mechanisms Emotional responses may be automatic or exaggerated	Thought processes more habitual than problem-solving oriented	Hormonal levels return to prealarm stage if adaptation occurs Physiological responses return to normal or are channeled into psychosomatic symptoms
3 Stage of exhaustion	Depletion or exhaustion of organs and resources Loss of ability to resist stress	Disintegration of personal interactions Communication skills ineffective and disorganized Self-oriented	Restless, withdrawn, agitated; may become violent or self-destructive Diminished productivity	Depressed, flat or inappropriate affect Exaggerated or inappropriate use of defense mechanisms Decreased ability to cope	Thought disorganization, hallucinations, preoccupation Reduced intellectual processes	Exhaustion, with increased demands on organism Adrenal cortex hormone depletion Death, if stress is continuous and excessive

emotions are unstable, labile, unpredictable, and inappropriate to the situation. All of the above-mentioned modes of response relate to the negative elements of response patterns. Of course, these modes can be used in a positive way so that stress becomes nondetrimental. There is no way to eliminate stress completely, but individuals can learn to minimize the harmful effects and use their response modes in a positive way.

Stressors may be chemical, physical, developmental, and emotional. Graduating from nursing school, being promoted, failing to be promoted, having arguments, and playing a tough game of racquetball are all stressful events and require adaptation and change at some level. By understanding stress, we can more easily identify stress factors and their effects on clients who need or seek health care. Whether a client is having a baby, undergoing open-heart surgery, or seeking counseling for emotional problems, each of these individuals is experiencing stress in his or her own particular manner. How the individual adapts or fails to adapt depends on several factors: personality and emotional makeup and past experiences in dealing with stress (response repertoire).

People are able to create many different forms of disease as well as emotional and spiritual scars. And the more we use up our reserves of adaptation energy, the more likely we are to age and hasten our death. In fact, Selye warned that there is no evidence that the basic reserves of energy for adaptation can be

restored. These may be genetically programmed. The more reserves we use handling everyday stress, the less we have for major crises or for growing older. The latest research indicates that there is a direct relationship between the amount of stress encountered in everyday life and aging.

Stress and Disease

Stress and an individual's method of handling it have been associated with the risk of developing heart disease, cancer, and other illnesses. Although stress is an inevitable part of life, excessive amounts of it can contribute to poor health. When one goes through a very stressful period, it is important to work through that stress, rather than ignore it.

The mechanisms by which stress leads to disease may differ for heart disease and cancer. Perceived stress leads to a release of adrenaline, cortisol, and other hormones within the body. These substances, in turn, increase the heart rate, blood pressure, cholesterol level, and platelet stickiness. When stress becomes chronic, these physiologic changes can accelerate atherosclerosis, the process that causes coronary heart disease.

Individuals with Type A behavior are known to be at increased risk of heart disease. Type A behavior is defined as having a constant sense of time urgency and a feeling of free-floating anger at the world in general. These behavior patterns can be seen as a maladaptive way of dealing with chronic

TABLE 17-2 Signals of Stress

Physiologic	
Fatigue, lethargy	Pain—backache, teeth grinding
Muscle tension—neck, back, legs, and so forth	Excessive sweating
Frequent headaches—tension, migraine	Heart problems—palpitations, racing, variable heartbeat, chest pain
Shaking, trembling, spasms	Breathing complications—hyperventilation
Cold extremities, poor circulation	High blood pressure
Digestion disturbances—acid, nausea, gas, cramps, colitis	Skin eruptions—rash, hives, itching, eczema, acne
Eating disorders—compulsive eating, loss of appetite	Sexual difficulties—impotence, low libido (desire), nonorgasmic, elimination disorders—diarrhea, constipation, vaginitis
Sleep problems—insomnia, nightmares, excessive sleep, early awakenings	Amenorrhea (absence of menstrual period)
Psychologic	
Anxiety	Confusion
Panic disorder	Helplessness
Depression	Apathy
Pessimism	Alienation
Melancholy	Isolation
Impatience	Numbness
Anger	Self-consciousness
Irritability	Purposelessness
Boredom	
Behavioral Indicators	
Restlessness	Indecisiveness
Loss of memory, poor concentration	Tardiness
Nervous mannerisms—tics, grimaces, finger tapping, hair twisting	Inflexibility
Speech difficulties—stuttering, stammering	Nonproductivity
Hyperactivity	Poor problem solving
Disorganization	Alcohol and drug abuse
Passivity	Phobic responses
Aggressiveness	Overeating

stress. The famous study of the causative factors in heart disease, the Framingham study, examined many aspects of heart disease. Results revealed that males who were classified as Type A developed chest pains three times as often as their more peaceful Type B counterparts. Another fascinating conclusion was that those who remained calm and serene (Type B personalities) rarely developed high cholesterol levels regardless of their diet.

Chronic stress causes changes in the immune system that can interfere with its ability to recognize and destroy cancerous cells. Several researchers have shown that cancer clients have a characteristic personality pattern years before the cancers are diagnosed. Part of this personality pattern involves difficulty dealing with stress and turning conflict inward instead of confronting it directly.

It is important to remember that the stress syndrome can be both positive and negative. Any change or alteration in the balance of life can create stress. The Holmes and Rahe stress scale is an excellent example of the varying conditions in life that result in stress. (See Holmes and Rahe's Social Readjustment Rating Scale in *Instructor's Manual for Clinical Nursing Skills*, 8th ed.) We are all unique individuals, and we respond differently to various stressors. Thus it does not matter whether the stress is positive or negative, light or severe. What matters is how we develop adaptive mechanisms to cope with these stressors. The ability to cope or solve a problem can be translated as the ability to withstand stress and create life experiences that do not work against us. The implications of stress theory—that by being able to withstand stress, by coping with it, diluting it when it occurs,

Danger Signals of Stress

- Depression, lack of interest in life
- Uncontrolled hyperactive behavior
- Lack of concentration, inability to focus
- Feelings of unreality
- Loss of control, emotional instability
- Pervasive high anxiety level
- Physical manifestations
 - Irregular heartbeats
 - Tremors, tics
 - Gastrointestinal disturbance
 - Skin disturbance
 - Changes in respiratory patterns
- Insomnia
- Disease
- Increased dependence on alcohol, drugs
- Feelings of dread

or eliminating it, we can actually affect our life—are tremendously exciting. It means that we are not doomed to inevitable illness later in life, nor are we preprogrammed for premature aging. In fact, every individual controls his or her own health. To quote the *Journal of the American Medical Association*, “Nature did not intend us to grow old and ill; we were designed to die young in old age but free of disease.” In other words, even when we are old we should feel “young” (healthy) and be free of disease.

Stress and a Satisfying Life

Understanding stress teaches you critical principles for creating a healthy and satisfying life. Consider the following principles, and reflect on how you can use stress in your life to positive advantage.

- **Stress does not come from the outside; you generate it totally within yourself.** In Hans Selye’s definition, stress is the nonspecific reaction to any demand. An upcoming exam may be a stressor; your reaction may or may not be stress. A specific response to the exam (assuming you want to get a good grade in the course) is to study extra hard. But nonspecific reactions, which do not serve specifically to resolve the imbalance of having an upcoming exam and wanting to do well, may also include a certain amount of fear, even panic. You might eat more, smoke cigarettes, pace the floor, or have difficulty sleeping. You yourself, not the exam, have generated these reactions—they are the symptoms of stress.
- **You cannot see stress directly; you can only experience its symptoms.** No one can see love, but we all know its symptoms: the fluttering heart, butterflies in the stomach, inability to concentrate on other things, tendency to think about a loved one all the time. You must discover

Alternative Methods to Reduce Stress

- Biofeedback
- Massage
- Progressive muscle relaxation
- Meditation
- Audio tapes on stress reduction, music
- Yoga, t’ai chi
- Physical exercise
- Friends or groups to discuss feelings

Along with coping with one’s own stress, it is the responsibility of the nurse to be aware that clients suffer from stress phenomena and that part of the nurse’s role is to assist clients to adapt and cope with stress.

Guidelines for Implementing Stress Objectives in Nursing

The nurse must have an understanding of the role of stress.

- Understand and accept the theory of stress—what it is and what effect it has on the body.
- Be aware of how stress manifests: tiredness, apathy, frequent illness, lack of interest or liveliness, unwillingness to seek out new challenges, inability to cope with change, and many other symptoms.

your personal characteristic symptoms of stress. You might overeat or get headaches or skin rashes. You might become short-tempered. Learn to recognize your symptoms as not actual problems but bodily warning lights signaling an imbalance. Merely seeking immediate relief from the symptoms through drugs, sex, or other distractions is like painting over the warning light to keep it from bothering you. You must look deeper within your system to discover and correct the imbalance.

- **Your attitude plays a significant role in illness and wellness.** While working at the University of Chicago with professionals who experienced constant pressure, researcher Susanne Kobasa demonstrated that the primary difference between those who became ill and those who stayed well was attitude. Those who stayed well tended to be committed to their jobs, viewed problems as challenges not obstacles, and felt a sense of control—they believed their actions and presence actually made a difference. Your attitude, beliefs, and conceptualization of what is happening to you determine your internal reaction to those events and, therefore, determine your stress level.

The challenge is to shift your attitudes so that you look for the positive side of events—not a phoney positive attitude that turns one into a “Pollyanna” who fails to recognize painful situations or major problems, but a “can do” attitude.

- **Stress is essential to everything you enjoy.** We all love the feeling of victory, and this feeling of achievement is proportional to the challenge. Think about what makes you feel happiest, most excited and enthusiastic. Having your team win a football game in the final two minutes is more exciting and memorable than when the team wins by a large margin over a poor team. When you have learned a subject well, how much better it feels to handle successfully a challenging set of final exam problems rather than a bunch of boring multiple-choice questions that test only a small part of what you’ve learned in the course.

Coping with stress requires exploring the inner you, utilizing and reinforcing your creativity, skill, and strength. Stressful events and periods in our lives can help us grow to be better able to make the most of our lives. Learning to truly celebrate your successes will increase your joy, personal satisfaction, and enthusiasm.

- **A healthy life is a balance of stress and relaxation.** In nature, stress and tension alternate with relaxation. Your heart contracts and relaxes to keep your blood flowing. Your breath enters and leaves. Your busy, complex world provides plenty of stress; most of us must work diligently to find relaxation techniques and time to balance this stress. Few aspects of our culture really encourage us to acknowledge the importance of relaxation. Can you imagine one of your professors, as the assignment is being collected, asking if you made sure to do your 20-minute meditation last night?
- **You must take responsibility for your own life, including its stress.** Only you can really make your life better. No one else can feel or deal with your symptoms of stress. Take responsibility for dealing effectively with stressors. Focus on wellness, not illness. Practice self-awareness, self-education, and self-responsibility. Create a stress management program, motivate yourself to follow it, and update it regularly until it becomes an automatic part of your life.

Emmett E. Miller, MD

Source Emmett E. Miller, MD, is a leading practitioner of psychophysiological medicine, which relates mental processes to physical health and optimal performance. Dr. Miller has developed a unique series of self-improvement audio tapes and experiential videotapes relating to stress management, self-improvement, and health and wellness. He is a frequent guest speaker at health conferences and workshops. Dr. Miller maintains a private practice in hypnotherapy, preventive medicine, and psychotherapy in Los Altos, California.

- Recognize the factors that increase stress, both positive and negative (illness, hospitalization, pain, marriage, family pressures, etc.).
- Assist in making a plan and implementing it, designing specific actions to reduce stress, such as relaxation methods, meditation, exercise.
- Work out a plan with the individual about how to control, alter, or change stressors in his or her life.

The nurse may carry out specific behaviors in the hospital setting to reduce stress.

- Identify the stressors affecting the client now.
- Counsel the client and family on the theory of stress; together, examine how the client’s particular stressors affect his or her lifestyle.
- Reinforce the client’s adaptive process by meeting his or her needs, listening to concerns, administering care, and providing emotional support.
- Assist the client to alter adaptive behaviors to cope more effectively with stress.
- Remember that laughter decreases stress, so maintain a light rather than a depressed or morbid attitude.

A NEW PARADIGM FOR HEALTH

The way the Western world views health is undergoing a change. Even the terms we use to describe health are changing; new terms, like *holistic health* and *alternative, unconventional*, or

complementary medicine are being heard more frequently in both medical and nonmedical circles. In the past, good health meant the absence of disease. The new definition of health goes beyond physical health to encompass the health of the whole person, including mental, emotional, and spiritual health. The World Health Organization (WHO) formulated a new definition of health in 1970 that has significantly influenced the medical model of health care. WHO described health as “a state of complete physical, mental, and social well-being, not merely the absence of disease or infirmity.” What made this definition innovative is that it took into account the mind as well as the body. In fact, this new interpretation of health almost enters the spiritual dimension. Though critics have pointed out that by this definition no one is truly healthy, it is the beginning of a view of health as an open system in a holistic framework. A holistic redefinition of health emphasizes high-level wellness or going beyond the absence of disease toward one’s maximum health potential. This section focuses on the connection among mind, body, spirit, and environment and discusses how one can use this connection to reach the possible highest level of health and wellness.

A Holistic Approach to Health

From the 1990s into the new century, we are witnessing a significant growth in many dimensions of health. As shown in a recent Gallup survey completed for *American Health Magazine*, many people in society now include a very broad range of issues in the concept of personal health. Certainly their top health concern is still oriented toward personal health—“staying free of disease.” The third-highest priority, however—“living in an environment

with clean air and water”—expresses a much more global health perspective. Many of their top concerns show not only physical status but also mental and emotional status as important components of personal health. Today’s significant health goals may even include having a positive outlook on life and sharing love with friends and family. Wellness can be thought of as a state of being; holistic health is the means of achieving it.

The term *holistic* implies wholeness; a harmonious individual that integrates mind, body, and spirit into a functioning unit. A holistic stress model implies modifying all parts of one’s life so that stress is both encountered and alleviated from an integrated perspective.

In the modern era, holistic medicine postulates a constant interchange between mind and body, psyche and soul. Carl Jung was one of the first physicians and therapists to discuss the prevention of illness in terms of using one’s inner resources. He discussed the inner self and themes of self-renewal in relation to growth, spirituality, and health. As our body of research knowledge grows, more and more physicians are employing spiritual growth techniques as a health tool. For example, Dr. Carl Simonton has been using meditation and imagery as adjunct therapy for clients with cancer and has shown that clients recover faster and have less pain when guided imagery is used. He has also demonstrated that cancer clients showed a heightened immune response. Dr. Joan Borysenko at the Harvard Mind–Body Clinic is also using meditation as a medical tool; Dr. Norman Shealy, founder of the American Holistic Medical Association and the Shealy Institute for Comprehensive Pain and Healthcare, has used alternative methods of health care for many years. The current literature, much of it authored by prominent healthcare providers, exemplifies today’s trend toward the holistic, or alternative, model.

The holistic paradigm suggests that the body, psyche, and environment are one and interact as an open system. This idea can assist us to view our client’s health as well as our personal health from a new dimension. In the holistic view, health care includes three types of actions: disease and injury prevention, treatment, and health promotion.

There are more than 200 alternative modalities—from bee sting therapy for multiple sclerosis to essential healing oils. Some probably do not work, except for a placebo effect, but others definitely are being shown by research to work. An example is stress reduction for heart disease and angina.

Alternative treatments may include treatments that require involvement on the client’s part, such as changes in eating patterns and other lifestyle behaviors; or physical treatments, such as acupuncture or vitamin therapy. The client is counseled to take the initiative and assume responsibility for his or her own health, and the role of the nurse and physician is to guide clients to various healthcare options. Truly holistic treatment involves an integrated assessment of all aspects of health.

COMPLEMENTARY AND ALTERNATIVE MEDICINE (CAM)

The terms “complementary” and “alternative” medicine are often used interchangeably, even though they may have slightly different meanings. Complementary medicine refers more

directly to treatment methods, such as acupuncture, nutrition, and physiotherapy, that complement mainstream medicine and are often used in conjunction with it. Alternative medicine, on the other hand, refers to treatment modalities that exist outside of the established medical system (for example, herbalism, massage, and naturopathic medicine).

Alternative, or complementary, medicine is not nearly as unknown, untried, or unaccepted as traditional physicians believed. For the first time, in 1993, physicians learned, through the *New England Journal of Medicine*, that Americans made 425 million visits to alternative providers, compared with 388 million visits to all other mainstream primary care physicians. Many physicians, on learning the results of this survey, were stunned because they had no idea Americans were seeking alternative therapies in such numbers. Now it is estimated that Americans spent an estimated \$33.9 billion out-of-pocket on CAM products and services in 2007, which totals 11.2% of all out-of-pocket healthcare spending. The most commonly used therapies include prayer, natural products such as herbs and oils, deep breathing exercises, meditation, and chiropractic care. Research notes that 38% of those using alternative care chose to do so because they felt conventional treatment would not help them with their health problems. Researchers also say that women and those with higher education are more apt to use complementary medicine.

The National Institutes of Health (NIH), a conservative, scientifically based organization, gave nearly \$130 million in 2010 to the National Center for Complementary and Alternative Medicine. This office was founded because of congressional pressure to investigate new approaches to the degenerative diseases killing Americans. It is one of 27 NIH centers.

Several national insurance companies now reimburse their clients for selected alternative treatments. Among the companies are Blue Cross–Blue Shield, Alliance for Alternatives in Health Care, Inc., Oxford Health Plan, and Aetna US Life. Alternative treatments reimbursed include acupuncture, massage therapy, and body therapies such as Rolfing, chiropractic, stress reduction, and homeopathic therapy.

Legal Implications of Alternative Therapy

Several bills were passed in the U.S. House of Representatives and the Senate that will allow authorized healthcare providers to give alternative treatments, provided the client is fully informed about the type of treatment, the risks and benefits, and conventional therapy that is available. Written consent is necessary only if the therapy is invasive (acupuncture) or can cause the client harm.

If the client does request information about alternative approaches to illness, the nurse should discuss this request with the client’s physician and unit manager or supervisor. The nurse may even contact the client advocate or ombudsman and ask them to talk with the client and honor the request. In many states, there are staff personnel and physicians who are open to alternative therapy and even encourage the client’s right to take responsibility for their own health. In such a situation, the personnel may work as a team in conjunction with

the client to explore all of the available treatment options, including alternative therapy.

Over the past few years, many hospitals have opened alternative clinics so that clients who wish to combine mainstream medicine with alternative treatment methods can do so. A national poll completed in 2007 showed that 40% of hospitals offered at least one CAM therapy. Another interesting statistic, showing a trend toward including alternative treatment methods in traditional therapies, is that CAM courses have become a requirement in almost 90% of medical schools in the United States. This is for the academic year 2007–2008, compared with 30% for the 2001–2002 year. Integrated programs in hospitals are being customized to meet the needs of both the hospital's clients and the community; thus this appears to be the direction of health care in the country today.

Alternative Treatment Methods

A new direction in alternative medicine is called *integrative medicine*, a blending of the best of conventional methods with high-tech and alternative therapies. This method combines drugs, surgery, high-tech treatments, and mind–body practices, as well as alternative treatments. It remains client-centered.

Following is a short sampling of the more than 200 alternative treatment methods that may be used alone or in tandem with conventional medical treatments. Alternative methods may be classified as lifestyle (holistic medicine; nutrition), botanical (homeopathy, herbal, aromatherapy), energy/manipulative (chiropractic, acupressure and acupuncture, reflexology, massage), and mind–body (meditation, guided imagery, biofeedback, color healing, and hypnotherapy).

Acupuncture An ancient Chinese method of relieving pain and treating disease, acupuncture is based on the belief that energy, or *qi*, flows along 12 lines or meridians in the body, creating a balance between two principles of nature called yin and yang. Each meridian is connected to a particular organ or system. It is believed that lack of energy flow or blocked energy along the meridians leads to illness or disease. Acupuncture treatment involves inserting sharp needles under the skin along the meridian lines, thereby unblocking energy, stimulating flow, and restoring balance and health of internal organs. Since the 1960s in the United States, Chinese doctors, as well as some U.S. physicians, have performed major surgery with acupuncture as the only anesthetic.

Applied Kinesiology Applied kinesiology is a form of evaluation based on the theory that the condition of a person's muscles reflects certain internal disorders or problems. Body imbalances or disorders are identified when certain muscle groups are tested and appear weak. Certain foods, medications, or herbs are held in a person's hand or placed next to their skin. If the substance is not appropriate for the body, the muscles respond to testing by appearing weak. When the substance is removed, the muscles regain their strength. Based on identifying weak muscles, various treatments, such as vitamins, herbs, diet therapy, acupressure, or chiropractic, are suggested.

Aromatherapy Essential oils are the aromatic liquids extracted from herbs, plants, and flowers. These oils have been

used to treat various conditions and have been an important part of medical lore for thousands of years. For example, there are 188 references to essential oils in the Bible. Modern aromatherapy became known in the 1930s, but it was not until the 1990s that aromatherapy emerged as a major mode of alternative treatment.

Essential oils can be included in the genre of vibrational therapy because specific oils have their own vibrational level or life force and, as such, work differently in the body. Dr. Robert Becker, in his book *The Body Electric*, discusses the fact that the human body has an average electrical frequency and the health of a person depends on their particular body frequency. Research at the State University in Cheney, Washington, determined that the average body frequency is 62–68 hertz (Hz). When the frequency drops, the immune system is compromised and various illnesses may ensue. Based on this research, scientists found that pollutants lower the body frequency. For example, canned or processed foods have a frequency of zero, fresh produce 15 Hz, and essential oils start at 52 Hz and go as high as 320 Hz (which is organic, pure rose oil). Essential oils have the ability to penetrate the human body through either the skin or olfactory receptors. Supporters of this form of alternative therapy believe that essential oils are a most effective healing agent and they are noninvasive. Examples of commonly used oils are lemon and thyme oil, used to kill strep, staph, and TB; lavender, used as a relaxing or sleep-enhancing oil; and peppermint, used to aid digestion. This mode of treatment would be used to supplement, not replace, other treatment methods.

Ayurveda A form of medicine that originated in India, ayurveda, meaning the science of life, has been practiced in India for over 5,000 years and has just recently become known in the West. This system is based on the concept of three metabolic body types: slim, athletic, and heavy. Each body type utilizes food and herbs in a different way; thus treatment includes dietary changes, herbs, and exercise, as well as specific practices, such as yoga, meditation, massage with herbal remedies, and medicated inhalations. This form of medicine has recently gained popularity in the West after several Indian physicians opened clinics based on this system of treatment. Notable among them is Dr. Deepak Chopra, an endocrinologist, who has written many popular books on the subject.

Biofeedback This technique employs an instrument to monitor physiologic processes of the body and to “feed back” measurements to the individual being monitored. A scale, thermometer, and pulse monitor are common feedback devices, as are more technically sophisticated machines having electronic sensors and digital readouts. Recent research has confirmed that many people can influence or control their autonomic processes (heart rate, blood pressure, temperature, digestive functions, etc.). As the client becomes more adept at controlling body responses, the need to use monitoring devices decreases—and the mental skills can be used independently.

Chiropractic Originating in ancient Greece and literally meaning “done by the hands,” chiropractic suggests that one cause of disease and dysfunction in the body is a misalignment of the spinal column that interferes with proper nerve function.

These conditions cause or contribute to some diseases and lower the body's resistance to others. Spinal adjustments and manipulation restore structural integrity, thus enabling the body to heal itself. Studies have shown that chiropractic can relieve pain and structural disorders in the joints and muscles. The focus of treatment is general and includes correction of such disorders as headaches; allergies; pain in the back, hip, or spinal column; or gastrointestinal problems.

Energy Medicine This contemporary aspect of health views the human body as comprised of electronic vibrations. Interventions involving the energy field will interface with environmental, spiritual, and vibrational aspects of healing. Special high and low frequencies of sound and light are already being used for healing. For example, sound therapy is used to speed healing through a cast; full-spectrum light frequencies are being used to affect moods such as seasonal affective disorder (SAD). Other examples of energy/vibrational/frequency healing are Reiki healing, in which the healer has progressed through two or three weekend education levels; Therapeutic Touch, the founders of which are Dolores Krieger and Janet Mentgen, also entails learning the techniques via a seminar or educational program; and energy healing, which may be the transmission of the healer's energy into the client's body, or the empowerment of the client to heal herself/himself. Documented studies have shown that certain individuals have this ability to transmit healing energy to others. In fact, a special photographic process called Kirlian photography has shown the energy moving from healer to client.

Herbal Medicine There is a growing interest in herbal products, as more and more clients become interested in healing themselves.

For more information on herbs and plants, see Table 17-3.

Homeopathy Based on the work of the German physician Dr. Samuel Hahnemann in the early 1800s, homeopathy is a system of treatment that rests on the theory that extremely minute doses of certain substances, usually herbal or chemical, cause a response in a person that mimics a particular disease. These substances, or homeopathic remedies, are administered to a person with a disease exhibiting a similar symptom pattern, stimulating the body's natural healing response. This is called "treatment by similars, or like cures like." The practice of homeopathy is becoming more popular; there is even a software package designed to assist physicians in the homeopathic diagnosis and treatment of disease.

Massage Of all the alternative treatments, massage may be the oldest form of medicine known to man. Historical records indicate that the Chinese, in 3000 B.C., wrote about massage, and both the Greeks and Romans considered massage a therapy. Massage was introduced to the United States in 1877 by Dr. S. Mitchell, and schools of massage proliferated in both the United States and Britain.

With the introduction of electrical treatments, the application of massage began to diminish as a part of recommended physiotherapy. However, today, the application of touch to the skin to relieve tension in muscles, ligaments, tendons, and joints is an accepted nonpharmacological approach to decrease pain.

Naturopathy Founded almost 100 years ago, this form of medicine includes natural therapeutics such as nutrition, herbs, homeopathy, massage, exercise, and even acupuncture. Drugs are not in this repertoire. Naturopathy school of thought believes that diseases are the body's attempt to heal itself through release of impurities. Treatments are designed to increase the client's "vital force" by eliminating toxins, thus allowing the body to heal.

Nutrition The holistic approach dictates that an individual pay close attention to nutritional status as a critical component of wellness. Research strongly points to diet as a major contributor to health or disease. This is especially so when a person has a diet of high saturated fat, refined sugars, additives, preservatives, or junk food. It is also current thinking that a high-carbohydrate diet contributes to obesity. Nutrition can also play a major role in prevention of disease; more and more emphasis is currently being placed on the role of antioxidants (vitamins C, E, beta-carotene, pycnogenol, etc.) in preventing such diseases as cancer and heart disease.

There is much controversy today over whether the average American consumes a diet that provides enough of the essential nutrients to prevent disease and aging. The pro argument group says that if you follow the USDA Revised Food Pyramid, you do not need to supplement your diet. (See Chapter 19.) The opposing argument says that the quality of food today (unless you are eating a majority of organic/natural foods) is so deficient in nutrients that you cannot sustain a healthy diet.

To follow preventive guidelines for better health, most alternative physicians and healthcare workers advocate supplementing diet with a broad-based multiple vitamin/mineral capsule daily, preferably with natural, food-based (not synthetic) nutrients. This prescription would include basic vitamins, all the minerals (including trace minerals), antioxidants, essential fatty acids (Omega 3 and 6), the carotinoids, coenzyme Q10, nutrients for the eyes such as lycopene and lutein, and bioflavonoids.

Prayer and Spirituality in Health People have used both prayer and spiritual practices for thousands of years. These two areas are currently included in the arena of alternative medicine because it is built on a foundation of mind-body-spirit.

In a major survey of complementary medicine, when prayer was included in the definition, 62% had used this practice for dealing with a health problem. In fact, research shows that it is the therapy most commonly used among all alternative therapies. In one study at Harvard Medical School, analyzed data on the use of prayer showed that among 3,055 participants, 57% used prayer for health concerns or specific medical conditions and 75% prayed for wellness. (See Evidenced-Based Practice, page 557.)

Reflexology Also called "zone therapy," reflexology is a method of treatment that proposes that diseases and organ dysfunction can be both diagnosed and treated by pressing on certain areas of the hands or feet. Each area of the body is represented by a corresponding area on the feet or hands; pressing on specific points is said to stimulate blood, nutrient, and energy flow to the diseased area of the body.

Relaxation and Visualization Stress experts have carefully studied the effects of deep relaxation on the mind and

▲ Sound and visualization are alternative treatment methods.

body. They found that individuals who regularly practice relaxation exercises experience less stress than people who don't. The relaxation response is actually the physiologic opposite of the stress response. People adept at invoking the relaxation response use their minds to control their autonomic nervous system—oxygen consumption, respiratory rate, heart rate, blood pressure, and muscle tension. Their alpha brain waves, the waves associated with feelings of well-being, increase. Effective body relaxation techniques have existed for centuries. Several have gained significant popularity in recent years. In the United States, about 12% of adults use deep breathing exercises and 8% use meditation as complementary to their health care. The following short descriptions should familiarize you with the leading techniques.

1. **Deep Breathing:** Emphasized by virtually all relaxation exercises, deep breathing is a key to reducing stress. When you are tense, your breathing becomes rapid, irregular, and shallow. Healthy *deep* breathing increases the amount of oxygen in your blood, cleanses your system of carbon dioxide and other waste chemicals, relaxes your muscles, increases the endorphin release, and encourages your heart rate to return to normal. Learning to take deep, slow, full breaths and exhale completely effects mastery of this key relaxation technique. B. K. S. Iyengar, a world-class yoga teacher, suggests a breathing technique for stress reduction. Try it and instruct your clients in this technique.
 - Inhale as you normally do.
 - Exhale as you normally do.
 - Pause as long as comfortable.
 - Repeat the first three steps.

Simple? Yes. Effective? Yes. This technique allows lungs to empty more completely, continuing the normal exhalation process. Why is this simple exercise effective? Because the completed exhalation enables the mind to quiet—a rest from the jumble of one thought upon another. Iyengar says that if you learn this “secret,” you can control stress. It also provides the foundation for meditation.

2. **Autogenic Training:** In this form of relaxation, warmth and heaviness are visualized: two physical sensations associated with the relaxed state. The warmth represents increased blood flow throughout the body, and heaviness is perceived as relaxation of the skeletal muscles. During progressive relaxation, specific muscles or groups of muscles are tensed and released throughout the body. This technique is especially effective for clients who are fearful and stressed.
3. **Meditation:** Originating thousands of years ago, meditation is based on Eastern cultures and religions. The effects of meditation are similar to those associated with deep relaxation. Meditation is the process of bringing the mind to stillness. It sounds easy, but if you have tried meditation, you know from experience how difficult and frustrating this process can be. There are many methods of meditation, from the traditional transcendental meditation (TM) and Zen meditation to the repetition of a word such as “one,” advocated by Dr. Herbert Benson of Harvard University. TM is a structured form of meditation popularized in the United States in the 1960s by Maharishi Mahesh Yogi. In TM, a mantra is selected (a word or sound) that is repeated mentally while the person is seated quietly in a tranquil place.

Perhaps the easiest meditation technique is to sit in a comfortable position with the spine straight (the lotus position is perfect if the legs can stand it), eyes closed, and to relax. While meditating, one concentrates on relaxing the muscles and organs throughout the body, then focuses on breathing. One is to inhale fully, then exhale, watching the breath come out “in one’s mind’s eye.” If a thought comes in, it should be made to slip away and one should continue inhaling and exhaling. No thoughts should be allowed to rush in to break the concentration.

4. **Visualization:** Visualization is a proven technique for healing, stress management, and positive goal attainment. When a mental picture is created, the body responds as if it were a real experience. Visualization can assist a client to feel more confident in circumstances filled with uncertainties. It can also assist with reducing pain. Teach the client to first relax (through one of the techniques mentioned in this chapter), then deep breathe, and finally to see the pain in the mind’s eye becoming less and less severe.

T'ai Chi Ch'uan This slow, graceful Chinese technique for relaxation is actually a system to both stimulate and balance subtle life energies. Thirty minutes a day devoted to the gentle, flowing movements of t'ai chi is relaxing, centering, and invigorating—a great way to relax and an interesting alternative to energetic Western exercise.

Yoga Yoga is an ancient Indian discipline that begins with postures, or asanas, that stretch and strengthen muscles.

It progresses to meditative relaxation or breathing techniques. Yoga is not sport or exercise as such; nor does it have to be a religion. The system is devised completely for health and well-being. The best way to begin yoga is to find an experienced teacher who can correct postures and guide the individual through the breathing and relaxation exercises.

All cultures from ancient times onward have used herbs to cure illness. Indeed, many drugs commonly used today are derived from herbs. Nearly one-fourth of all medications have at least one ingredient that is plant-based. The WHO estimates that 80% of the world population includes herbal medicines as part of their health practices.

Other countries are far ahead of the United States in integrating herbal products into mainstream medicine. WHO's *Guidelines for the Assessment of Herbal Medicine* state that historical use is a valid way to document safety and efficacy in the absence of scientific evidence to the contrary. European herbs are among the world's best-studied medicines. Some are even prescribed by physicians in Europe because they are so effective in treating diseases. In the United States, more and more holistic physicians are incorporating herbs into their medical practice, both because they are effective and because they have far fewer side effects than drugs.

Following is a listing of the most common herbs used today.

TABLE 17-3 The Most Common Herbs and Plants and What They Can Do for You

Aloe

A plant that has been used for centuries. It is a proven healer for skin problems and burns and has been used for gastrointestinal distress and as a daily tonic.

Bilberry

A European berry used by British Royal Air Force pilots flying night missions during World War II for improving night vision. This berry also relieves eye strain and helps to prevent eye disorders.

Black Cohosh

A remarkable herb for females because it helps to maintain normal hormone balance, especially during menopause. This herb is powerful and will increase the effect of synthetic hormones.

Cayenne

Anyone who has eaten a chili pepper has experienced the power of cayenne pepper. Capsaicin, the main ingredient, is used topically as a pain reliever and is useful for arthritis. This herb also reduces inflammation and increases circulation.

Chamomile

Produced from the chamomile flowers, this herb renews the skin or, used in a tea, is helpful for digestive upset or insomnia.

Echinacea

A favorite herb because of its immune-boosting properties. It is very effective for colds, flu, and coughs. It is not good to use on a long-term basis.

Elderberry

An ancient remedy for colds and one of the best herbal medicines for the flu. It is available in capsule, tincture, or extract form.

Feverfew

Many holistic physicians recommend this herb as a preventive measure for migraine headaches. Studies have shown that feverfew decreases the severity and intensity of headaches.

Garlic

A common plant Italians love to use in cooking, but it is also a remedy for many disorders. Garlic keeps immunity high, lowers cholesterol, and can be used for ear infections.

Ginger

A medicinal as well as a cooking herb that is useful for nausea, stomach upset, and intestinal gas. Also, taken after meals, it helps digestion and reduces allergies.

Ginkgo

Traced back in time to the age of dinosaurs, this amazing tree is the oldest known species in existence. The many uses include improving circulation, helping memory and attention deficit disorder, relieving tinnitus, and accelerating stroke recovery.

Ginseng

American, Chinese, and Siberian are all forms of this famous root. The Chinese form (Panax) is a warming herb that can increase energy and sex drive. American and Siberian forms are cooling herbs that fight fatigue and decrease stress. This herb also helps to normalize blood pressure and cholesterol.

Goldenseal

Extracted from a root, this bitter herb is excellent for colds, sore throats, ear infections, and as a cream useful for skin infections.

TABLE 17-3 The Most Common Herbs and Plants and What They Can Do for You (Continued)**Green Tea**

The leaves of this plant have become very popular because they contain some of the most powerful antioxidants known which help the body to eliminate free radicals. Used as a tea, tincture, tablet or capsule, this herb can be taken as a cancer preventive or detoxification agent.

Hawthorn

A tonic made from berries, hawthorn can be used for a variety of heart disorders—lowering blood pressure, congestive heart failure, angina, and cardiomyopathy. Clients should seek medical consultation when using it with other heart medications.

Milk Thistle

Liver disease is one of the country's major health problems. This seed, known for its restoration of liver function, is one of the best-studied herbs for liver disease. Silymarin is the main ingredient in milk thistle. It is one of the most liver-protecting substances known to protect intact liver cells.

Pau D'Arco

Extracted from the bark of a tree in the Amazon Rain Forest, this potion in tea or capsule form, has amazing uses—for infections, cancer, killing parasites or candida overgrowth.

Saw Palmetto

Made from berries grown on a small palm tree, this extract is a popular substance for men with an enlarged prostate. It relieves symptoms of benign prostatic hyperplasia and has been confirmed as the most researched and helpful substance for the prostate.

St. John's Wort

This herb, from which both the flowers and whole plant are used, enhance the production of key neurotransmitters. It works for mild to moderate depression and to decrease stress. With considerably fewer side effects than antidepressant drugs, it should not be used with pharmaceutical medications.

Turmeric

Known and used for centuries as a basic ingredient in Indian cooking, turmeric (from curcuma) is best used as an anti-inflammatory herb. It is also useful for arthritis, as a digestive aid, and for its antitumor qualities.

Valerian

A root that is used to relax nerves, promote peaceful feelings, and assist in sleeping. It is also used for spasms and pain.

HERB-DRUG INTERACTIONS

Millions of Americans are using herbal preparations instead of prescription and over-the-counter drugs. Other millions are combining herbs and medications. A survey by *Prevention* magazine in 2000 estimated that more than 50 million persons were using herbal remedies, and there are even more using them now.

Since use of herbs among nonprofessionals has greatly increased in the past few years, healthcare professionals must be aware of the potential danger, especially when combined with medications. In addition there is no regulation, standardization, quality control, or even efficacy with herbal preparations. When

nurses are completing admission assessments, questions should include asking about herbal preparations the client is now taking. The following table of herb-drug interactions will cover some of the most popular herbs and their interactions with specific drugs.

EVIDENCE-BASED PRACTICE

Herbal Remedies and Interaction With Drugs

A review of herbal remedies and their interactions with drugs found that warfarin was the drug most likely to be involved in adverse effects. St. John's wort was the herbal remedy most likely to cause an adverse interaction with other drugs.

Source: Fugh-Berman, E. (2003). *Natural medicine comprehensive database*.

TABLE 17-4 Herb-Drug Interactions Chart

Herb	Action	Side Effects	Drug Interaction	Drugs Affected
Black Cohosh	An herb for females, especially during menopause for hot flashes—maintains healthy levels of luteinizing hormone Decreases menstrual discomfort Sedative, diuretic Lowers blood pressure	Overdose may cause nausea, vomiting, headache, dizziness, tremors, and depressed heart rate	Increase effects of drugs—especially synthetic hormones Clients with congestive heart failure and pregnant women should not use this herb	Hormone replacement therapy (HRT) Contraceptives Heart/cardiac medications

(Continued)

TABLE 17-4 Herb–Drug Interactions Chart (Continued)

Herb	Action	Side Effects	Drug Interaction	Drugs Affected
Echinacea	Immunostimulant Treatment for colds (URIs) and influenza Bladder infections Blood purifier Helps preserve white cells during radiation treatment	Possible, but not common: nausea, vomiting, diarrhea, heartburn, skin rash, allergic reactions	Stimulates immune system—may alter effect of certain drugs; do not use with clients using immunosuppressants, or those who have AIDS, TB, or are pregnant	Anabolic steroids Amiodarone Methotrexate Ketoconazole
Ephedra (Ma Huang)	Promotes weight loss and acts as a stimulant (asthma) Considered toxic by FDA	Stimulant, insomnia, headaches, nervousness, seizures, death	Heart attack, seizure or death Additive effect; increased thermogenesis (related to stimulants/coffee) Elevation of BP (related to MAO inhibitors) Reduces drug action—may cause arrhythmias Increased steroid drug clearance may reduce effectiveness	Decongestants (Actifed, Dristan, Sinutab, Sudafed) Stimulants—caffeine MAO inhibitors Beta-blockers Cardiac glycosides Steroids (anti-inflammatories)
Feverfew	Eases pain and nausea of migraine headaches Prevents blood vessel spasms Interferes with action of platelets (which clump together to form clots) Lowers blood pressure	Gastrointestinal symptoms, nervousness, insomnia, and tiredness	Severe bleeding Pregnant women, children under age 2, and people taking drugs as listed should not take this herb	Anticoagulants—Warfarin Aspirin NSAIDs (ibuprofen)
Garlic	Contains allicin, natural antibiotic—effective against bacteria and viruses Lowers total cholesterol and increases HDL Reduces blood pressure Reduces blood clot formation (when arteries are narrowed)	Intestinal problems—upset stomach, heartburn, garlic odor	Excessive thinning of blood (bleeding) when used with blood thinners. Those who have blood disorders should use this herb conservatively	Anticoagulants—Warfarin Coumadin Aspirin Antihypertensives Saquinavir
Ginger	Relieves nausea associated with seasickness, motion sickness, or anesthesia Digestive aid; increased secretion of bile Reduces side effects of chemotherapy Reduces congestion and fevers Supports cardiovascular system	Heartburn	Excessive thinning of blood (bleeding) when used with blood thinners Interferes with platelet action Increases gut absorption (may increase drug bioavailability)	Anticoagulants—Warfarin Take cautiously with all cardiac or diabetic medications; Antihypertensives
Ginkgo Biloba	Improves circulation by thinning blood Enhances flow of oxygen and blood to brain Improves memory and mental function (dementia) May delay progression of Alzheimer's (jury still out) Asthma	Headache Indigestion, nausea, vomiting Nervousness Allergic skin reactions	Anticoagulant effect and may cause spontaneous or excessive bleeding Those with blood clotting disorders should not take this drug	Anticoagulants Coumadin Warfarin Aspirin NSAIDs Cox-2—inhibitors Anticonvulsants Vitamin K antagonists Diuretics Thiazides

TABLE 17-4 Herb–Drug Interactions Chart (Continued)

Herb	Action	Side Effects	Drug Interaction	Drugs Affected
Siberian Ginseng	Tonic, boosts energy and stamina Reduces stress, fatigue Improves sexual performance, regulates hormones Strengthens immune system Raise “good” cholesterol, HDL Protects against heart attacks Preventative for aging Improves blood sugar and diabetic symptoms (could reduce amount of insulin needed)	Insomnia, hypertension Diarrhea Low blood glucose Allergy symptoms Increased alcohol clearance Affects insulin level	Increases anticoagulant effect and bleeding Headache, manic behavior may occur when other drugs are taken Monitoring effect of drug may be difficult—may increase digoxin levels Stimulates alcohol metabolism Those who have blood clotting problems, high blood pressure, asthma, emphysema, and children and pregnant women should not take this herb	Anticoagulants Warfarin Coumadin Aspirin NSAIDs Nardil (MAO inhibitor) Digoxin (Lanoxin) Alcohol Insulin Antidepressants (phenelzine sulfate)
Kava Kava	Sedative effect to treat anxiety	GI problems, liver problems (even liver failure has been reported) Allergic skin reaction	Sedation, and even coma when taken with certain drugs	Alprazolam Sleeping meds Antipsychotics Alcohol Xanax (antidepressant) Drugs treating Parkinson’s disease
Licorice Root	Helps steroid drug withdrawal Helps to heal gastric ulcers Diuretic effect	Raises blood pressure Headache Lethargy Cardiac dysfunction	Potentiates drug levels and offsets effects of NSAIDs Antibiotics reduce herb activity Diuretic effect could result in decreased potassium leading to electrolyte imbalance Increased sensitivity to digoxin or other cardiac glycosides Women who are pregnant or nursing, and people with glaucoma, hypertension, stroke, or heart disease should not take this herb	Corticosteroids Thiazides Oral contraceptives Antibiotics
Saw Palmetto	Supports health of prostate gland, benign prostatic hypertrophy (BPH) Improves urine flow Maintains healthy testosterone metabolism Anti-inflammatory	Relatively few: mild nausea, gastro intestinal disturbance, hypertension, headache	The safety profile of this herb is very good—no known drug interactions	
Silymarin (Milk Thistle)	Increases liver detox capacity in general Supports liver function Protects liver from drug damage	Nausea, GI disturbance	Reduces drug toxicity to liver and protects liver from drug damage Reduces toxic side effects of chemotherapy Potentially dangerous for transplant clients—reduces levels of immunosuppressives	Aspirin Alcohol Chemotherapy

(Continued)

TABLE 17-4 Herb–Drug Interactions Chart (Continued)

Herb	Action	Side Effects	Drug Interaction	Drugs Affected
St. John's Wort	Relieves mild to moderate depression by countering monamine oxidase (avoid same foods as if taking MAO inhibitor drug) Immune-stimulating properties—useful with AIDS because it is antiviral Helps bruises and hemorrhoids	Dry mouth, dizziness, fatigue, digestive problems (fewer side effects than prescription antidepressants) Sensitivity to light	Decreases immunosuppressant therapy Additive serotonin-like effects—serotonin syndrome (serious condition: fever, dizziness, sweating, etc.) Could affect action of epilepsy drugs Clients with hypertension and those on immunosuppressive therapy should not use this herb	Tetracyclines Cyclosporin Digoxin Oral contraceptives Zoloft and antidepressants Other SSRIs Anticonvulsants Warfarin
Valerian	Quiets and calms neurological system Promotes sleep Used for headache, anxiety, and nervousness	Restlessness, headache, giddiness, nausea, and blurred vision	Effect may be altered by alcohol or barbiturates—use cautiously Not for children under 2 years Effect may be enhanced with sleeping tablets Additive effect—may be used to wean off drugs (diazepam)	Alcohol Barbiturates Sleeping tablets Benzodiazepines

Top five herbs your clients take but do not tell their physician:

- Black Cohosh
- Echinacea
- Ginkgo Biloba
- Saw Palmetto
- St. John's Wort

Source: Crock, R. (2003, September). Herbal medicine consultant.

CULTURAL AWARENESS

Allowing for a religious or spiritual component in the care plan will enhance the client's ability to cope. Benson (1997) found that when religious beliefs were added to relaxation response procedures, worries and fears improved greatly.

Source: Fontaine, K. (2000). *Healing practices*. Upper Saddle River, NJ: Prentice Hall.

NURSING DIAGNOSES

The following nursing diagnoses may be appropriate to include in a client care plan when the components are related to decreasing stress and promoting adaptation.

NURSING DIAGNOSIS	RELATED FACTORS
Anxiety	Increased stress; for instance, illness, trauma, loss
Defensive Coping	Denial of problem, rationalization of failure, such as increased demands on individual
Ineffective Coping	High stress on person; for example, individual inability to adapt, length and duration of stressor
Disturbed Energy Field	Decreased immune response, increased stress level, poor integration of mind–body energy.
Ineffective Health Maintenance	High stress level, from illness, abuse, or psychologic factors
Deficient Knowledge	Lack of exposure to alternative methods, lack of interest in change (Relaxation Techniques)
Acute or Chronic Pain	Trauma, immobility, illness, or disease
Trauma, Risk for	Reexperiencing a traumatic event, exhibiting altered lifestyle, psychic numbness
Disturbed Sleep Pattern	Stressful thoughts, anxiety
Social Isolation	Maladaptive coping to stressor, such as long-term or high level of stress

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. Remember to wash your hands or use antibacterial gel before and after each and every client contact.

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to TJC standards.

Stress and Adaptation

Nursing Process Data

ASSESSMENT Data Base

- Identify the client who demonstrates stressed behavior.
- Evaluate, with the client, the past and present stressors that the client has experienced.
- Evaluate the stressors' effect on the client's body and signs of distress in the body.
- Examples of physiological stress effects:
 - Cardiovascular system:* increased pulse and blood pressure, evidence of angina, arrhythmias, migraine headaches, disturbance of heat and cold mechanisms
 - Gastrointestinal system:* ulcers, ulcerative colitis, constipation or diarrhea, imbalance in sugar absorption
 - Musculoskeletal system:* backache, tension headaches, arthritis, proneness to accidents
 - Autoimmune system:* infections, flu, allergies, rheumatoid arthritis, cancer
- Assess client's level of energy and the degree to which it is depleted.
- Evaluate client's awareness of thoughts, attitudes, values, and beliefs that influence stress response and adaptation.
- Assess present level of distress in the client's body.
- Assess possible causes of stress that are affecting client:
 - Environmental stressors:* input overload, such as sights, sounds, smells; actions and demands of others in the environment; or monotony
 - Physical stressors:* hunger, heat or cold, dangerous environment, injury, or pain
 - Emotional stressors:* loss of something of value, frustrations of needs and drives, threats to self-concept
 - Psychosocial stressors:* Conflicting cultural values (e.g., the American values of competition and assertiveness vs the need to be dependent)

Future shock: physiologic and psychological stress resulting from an overload of the organism's adaptive systems and decision-making processes brought about by too rapidly changing values and technology

Cultural shock: stress developing in response to the transition from a familiar environment to unfamiliar one; involves unfamiliarity with communication, technology, customs, attitudes, and beliefs (e.g., immigrating, being confined in a hospital or prison); crowding, and urban life

Job choice and the work environment (About 80% of the workers in our country are estimated to be unhappy in their jobs.)

- Assess the factors that influence how the client responds to stress:
 - Characteristics of the stressful event:* magnitude, intensity, duration
 - Client's biologic and psychologic inclinations*
 - Appropriateness of support system*
- Life changes according to a stress scale (Holmes & Rahe, 1967).
- Assess current coping strategies.

PLANNING Objectives

- To identify presence of stress in client
- To identify how stress affects the body
- To identify the current sources that result in stressed behavior
- To determine the client's response to stress
- To evaluate stress interventions that have a positive effect on stressed client

IMPLEMENTATION Procedures

- Determining the Effect of Stress 562
- Determining Response Patterns 562
- Managing Stress 563
- Manipulating the Environment to Reduce Stress 563
- Teaching Coping Strategies 563
- Managing Stress Using a Holistic Model 564
- Teaching Controlled Breathing 565
- Teaching Body Relaxation 565
- Using Meditation as an Alternative Therapy 566

Prepare for success with NCLEX®-style practice questions
and Skill Checklists

EVALUATION Expected Outcomes

- Client is able to evaluate the general stressors and identify sources of stress in his or her life.
- Client is aware of response patterns to stress and is able to alter patterns appropriately.
- Client is aware of body–mind stress and its influence on his or her body.
- Client is able to reduce environmental stressors.
- Client is able to identify and alleviate stress caused by mental concerns.

Critical Thinking Application 566

- Expected Outcomes 566
- Unexpected Outcomes 566
- Alternative Actions 566

Determining the Effect of Stress**Hans Selye's Definition of Stress**

- Stress is a specific syndrome that consists of all nonspecifically induced changes within the biologic system.
- The body is the common denominator of all adaptive responses.
- Stress is manifested by measurable changes in the body.
- Stress causes a multiplicity of changes in the body.

Procedure

1. Identify client's stress tolerance level.
 - a. Recognize the body's alarm signals (see major signals in assessment).

- b. Assess signal correctly as signifying high level of stress.
2. Discuss the concept of stress to elicit understanding of the effect on client.
 - **Rationale:** Stress may be physical, chemical, or emotional and may cause bodily or mental tension that may be a factor in disease causation.
3. Encourage client to feel free to discuss life patterns that relate to stress.
4. Discuss the effect of stress. ► **Rationale:** Directing the conversation to the emotional, mental, and social sources of stress assists the client in examining its total effect and promotes self-awareness.
5. Assist the client in formulating a plan to reduce or eliminate at least some sources of stress. ► **Rationale:** Promotes client self-empowerment.

Determining Response Patterns**Procedure**

1. Evaluate adaptation factors that influence stress management.
 - a. *Age:* adaptation is greatest in youth and young middle life and least at the extremes of life.
 - b. *Environment:* does environment support managing stress?
 - c. *Time:* the client can more easily adapt to stress over a period of time than suddenly.
 - d. *Flexibility:* degree of flexibility of the individual influences survival.
 - e. *Expenditure of energy:* the individual usually uses the adaptation mechanism that is most economic in terms of energy.
 - f. *Presence of illness:* disease decreases the person's capacity to adapt to stress.

2. Assess the effects of stress on the client.
 - a. Feelings resulting from stress:
 1. Anxiety.
 2. Anger.
 3. Helplessness and hopelessness.
 4. Guilt, shame and disgust.
 5. Fear and frustration.
 6. Depression.
 - b. Behaviors resulting from stress:
 1. Apathy, regression, withdrawal.
 2. Crying, demanding.
 3. Physical illness.
 4. Hostility, manipulation.
 5. Senseless violence, lashing out.

EVIDENCE-BASED PRACTICE

The Opposite of a Stress Response

In many studies, Herbert Benson, MD, author of *The Relaxation Response*, found that the opposite of a stress response (physiological response) can be achieved by completing only two steps: repeating a prayer, word, sound, phrase, or movement, and disregarding all other thoughts (as in meditation, yoga, etc.).

Source: Benson, H. (1984). *The relaxation response*. New York: Times Books.

Managing Stress

Procedure

1. Discuss the client's body response to stress.
 - a. The body's response to stress is a self-preservation mechanism that automatically and immediately becomes activated in times of danger.
 - b. Assist client to understand response patterns.
2. Teach client to be aware of stress sensations in his or her body—recognize physical symptoms.
3. Suggest that client frequently monitor thought patterns to identify those thoughts that cause automatic tensing responses (tight muscles, increase in heartbeat, butterflies in stomach).
4. Assist client to decide whether these thoughts are essential to survival or if they can be changed, eliminated, or replaced.
5. Assist client in planning to set aside periods each day for self-stress evaluation.
6. Provide problem-solving assistance so the client can examine new, more appropriate response patterns.
7. Refer client to resources (therapy classes, books, relaxation tapes) that will assist in developing new responses.

EVIDENCE-BASED PRACTICE

Managing Stress

The results of 153 studies on stress management were analyzed to determine whether there was consensus in definitions and therapy protocols. Most studies endorsed either a cognitive-behavioral approach to stress-coping skills (77%) (examples are problem-focused skills, self-monitoring of stress intensity, record keeping, time management, assertiveness training) or a less structured approach, breathing, relaxation, imagery, meditation, yoga, and massage therapy (85%).

Source: Ong, L., Linden, W., & Young, S. (2004). Stress management, what is it? *Journal of Psychosomatic Research*, 56(1), 133–137.

Manipulating the Environment to Reduce Stress

Procedure

1. Modify client's external environment so that adaptation responses are within his or her capacity.
2. Support the efforts of the client to adapt or to respond.
3. Provide client with the materials required to maintain constancy of his or her environment.
4. Understand the body's mechanisms for accommodating stress.
5. Prevent additional stress.
6. Reduce external stimuli and input through senses.
7. Reduce or increase physical activity depending on the cause of and response to stress.

Teaching Coping Strategies

Procedure

1. Analyze client's stress status.
 - a. Estimate total amount of stress client is experiencing—too high a level of stress indicates need for intervention.
 - b. Recognize where in body or mind the stress is manifesting.
2. Discuss various options for reducing stress—which alternatives fit with client.
3. Suggest client use diversion methods of coping.
 - a. *Physical diversion*: jogging, swimming, cooking, cleaning.
 - b. *Mental diversion*: reading, painting, going to a movie, or simply thinking about a pleasant memory.

4. Plan with client how to use rest as a way to cope with stress.
 - a. Vacation, leave of absence from job, frequent naps.
 - b. Eliminate or decrease major stressors so result is rest from stress input.
 - c. Plan with client how to manage time so that input can be reduced and goals limited.
5. Teach client how to use concentration, body relaxation, breathing, or meditation techniques to relieve mind stress.
6. Remind client that laughter is a great tranquilizer and healer as well as a stress reducer, and assist client to plan how to use this method.

Suggestions for Coping With Stress

- Rank tasks to be completed, and identify activities that need to be accomplished.
- Forget unimportant details; do not try to remember too many things. Concentrate on the essential issues and details.
- Eliminate past unpleasant events from the mind and focus on the present.
- Do not cling to unpleasant experiences and emotions that impair emotional ability to respond to here and now.
- Discard habit of anticipating negative outcomes, which is often worse than the actual event.
- Do not yearn for things relating to the past or the future; focus attention on present desires.

Managing Stress Using a Holistic Model

Procedure

1. Manage stress through exercise.
 - a. Poor physical condition becomes a stressor—this state contributes to lethargy, a constant fatigue level, and low resistance for illness and lessens adaptive responses.
 - b. Good physical condition results in stamina, reserves necessary to withstand stress, and protection against unpredictable stress periods.
 - c. Exercise prepares the body physically for stress caused by environmental conditions.
 - d. Consistent exercise prepares body to handle stress emotionally.
2. Manage stress through diet.
 - a. Certain foods and drug substances (caffeine, alcohol, sugar, junk foods, preservatives, tobacco) are potent stressors to our bodies.
 - b. Consuming high-stress foods results in negative body changes, such as hypertension, high cholesterol, labile blood sugar levels, and a rapid, bounding pulse rate.
 - c. Consuming a low-stress diet results in more energy and stamina to cope with stress. Teach client that a low-stress diet includes reducing saturated fat and limiting protein intake to 10%–15% of consumed calories. Remainder of intake should be raw or barely cooked vegetables, fruits, whole grains, nuts, low-fat dairy products, and plenty of liquids. Eliminate sodas, caffeine products, and most alcohol. Exclude refined sugars and carbohydrates and convenience or processed foods.
 - d. Encourage the use of vitamin supplements: vitamin C, B-complex, mineral supplements. Assist client to examine diet and experiment with different vitamin–mineral supplements.
3. Manage stress by altering lifestyle patterns.
 - a. Counsel clients to eliminate unnecessary stressors in their life—change parts of life that are particularly stressful.
 - b. Assist client to develop personal methods for coping with stress: walking in the woods, painting, listening to music, reading, or practicing yoga.
 - c. Encourage client to assess lifestyle periodically and alter habits as necessary to reduce stress.
4. Manage stress through use of prayer and/or meditation.

EVIDENCE-BASED PRACTICE

Prayer as Alternative Medicine

According to a survey by the National Institutes of Health (NIH) of more than 31,000 adults, prayer is the most commonly used alternative medicine. Fifty-five percent of Americans use prayer for health reasons: 52% prayed for their own health, 31% asked others to pray for them, and 23% prayed for health in a prayer group.

Teaching Controlled Breathing

Procedure

1. Instruct client to sit so that his or her back is well supported, with spine straight but not rigid.
2. Have client place feet flat on floor and place hands on legs.
3. If client is lying down, have him or her place hands at side.
4. Suggest client find a comfortable position, close eyes, and take a deep, slow breath through nostrils.
5. Continue giving the client the following instructions.
 - a. Extend your abdominal muscles.
 - b. Hold your breath for the count of four. Then very slowly release the air through slightly parted lips, making a “whoosh” sound.
 - c. When you think that all the air is out, hold your stomach in to push out even more air.
 - d. Repeat this breathing pattern several times so that your body relaxes.
 - e. Breathe in through your nostrils to the count of four—1-2-3-4. Hold it—1-2-3-4—and expel the breath all the way out slowly, slowly releasing the air through your mouth.
 - f. As the air goes out, feel all of the tension drain out with it.
 - g. Now double the count and breathe in slowly, filling your lungs all the way to the top to the count of eight. 1-2-3-4-5-6-7-8. Hold it—1-2-3-4—and now slowly release the breath—5-6-7-8.
 - h. Again breathe in slowly to the count of 10 and count for the client—1-2-3-4-5-6-7-8-9-10. Hold it to the count of eight—1-2-3-4-5-6-7-8—and slowly release the air through your mouth to the count of 10—1-2-3-4-5-6-7-8-9-10. Pause.
 - i. Continue with your regular breathing pattern, letting the air breathe for you.
6. Stop the process by having the client open his or her eyes.

▲ Find a quiet room to teach relaxation process.

If you are motivated to learn CAM techniques, there are numerous classes available. In fact, to implement certain CAM therapies such as Reiki, therapeutic touch, acupressure, or acupuncture, you will need specialized classes/training.

Teaching Body Relaxation

Procedure

1. Place client in a comfortable position.
 - a. Have client sit so that back is well supported and spine is straight. Have client put both feet on the floor and hold hands comfortably in lap.
 - b. If sitting is uncomfortable, have client lie on a bed and support areas of the body so that he or she is comfortable.
2. Instruct client to concentrate on each key muscle of the body, tensing and relaxing each muscle until it is totally relaxed.
 3. Ask client to tense and release the muscles in the left toes, left foot, left calf, left thigh, and left leg.
 4. Now have the client continue the process on the right leg, trunk, upper torso, arms, shoulders, neck, and face. Then have the client check to see that every muscle is relaxed.
 5. Ask the client to check for tight areas, any tension, any uncomfortable areas or sensations and then to let it all go. Ask the client if he or she is willing to let all of the tension go.
 6. Ask client to practice being totally relaxed.

Using Meditation as an Alternative Therapy

Procedure

1. Meditation is the process of relaxing the body and focusing and quieting the mind. The essence of this method depends on the ability to concentrate on an object, a word, or nothing at all.
2. The process of meditation begins with slow, quiet breathing and deep muscle relaxation. (See *Alleviating Stress Using Controlled Breathing and Body Relaxation*.)
3. Instruct the client in meditation techniques—suggest books or tapes that focus on meditation.
4. Encourage the client to begin meditation—suggest positive outcomes.
 - a. During meditation, there is a decrease in oxygen consumption, blood pressure, pulse rate, respiration, brain wave activity, and blood lactate level (high in anxious people).
 - b. Research indicates that meditation has a measurable effect on stress-related conditions.

DOCUMENTATION for Stress and Adaptation

- Identification of stressed behavior observed in client
- Separation of physical from emotional and environmental stressors
- How client is responding to stress
- Pertinent verbalizations of client related to stress
- Nursing interventions related to stress reduction

CRITICAL THINKING Application

Expected Outcomes

- Client is able to evaluate the general stressors and identify sources of stress in his or her life.
- Client is aware of response patterns to stress and is able to alter patterns appropriately.
- Client is aware of body–mind stress and its influence on his or her body.
- Client is able to reduce environmental stressors.
- Client is able to identify and alleviate stress caused by mental concerns.

Unexpected Outcomes

Client moves into the stage of exhaustion, and stress becomes dangerous to health.

Alternative Actions

- Immediately take measures to remove stressors through medication, complete rest, and so forth.
- Implement specific stress-reducing measures, such as relaxation processes, visualization, and biofeedback.
- Attempt to elicit feelings of client before giving information about the role of stress and effect on one's body.
- Refer client to resources, articles, and knowledgeable persons who can discuss the effect of stress and the importance of eliminating stressors.

Client refuses to acknowledge that stress is affecting his or her life.

GERONTOLOGIC Considerations

The Influence of Stress on Aging is Significant and Affects Response and Coping Ability

- Nearly 23% of older people living in the community have some degree of disability.
- Elderly have less resistance to stressors: mental, emotional, environmental, and physical.
- Homeostatic imbalance is more common in the elderly and causes additional stress on the body.
- Adaptation to stress lessens with age (depends in part on genetic makeup and personal learning to deal with life crises).
- Many elderly suffer from depression.
- Nursing care should focus on adaptive responses to stress—assist client to develop mechanisms to deal with the stress of illness and hospitalization.

Risk Factors That Influence Stress Levels and Psychosocial Adaptation

- Lowered economic resources
- Unanticipated events such as death of a spouse
- Poor coping mechanisms
- Unrealistic appraisal of conditions
- Physical illness

Symptoms to Evaluate That Indicate High Stress Levels

- Insomnia
- High anxiety level

- Abuse of drugs, alcohol, or tobacco
- Hypertension, tachycardia, irregular heartbeat
- Depression, chronic fatigue
- Chronic pain
- Physical complaints
- Lack of any pleasure in life

MANAGEMENT Guidelines

Each state legislates a Nurse Practice Act for RNs and LVN/LPNs. Healthcare facilities are responsible for establishing and implementing policies and procedures that conform to their state's regulations. Verify the regulations and role parameters for each healthcare worker in your facility.

Delegation

- Stress assessment should be completed by an RN or LVN with experience evaluating stress in clients and one who understands Selye's model of stress.
- An LVN/LPN assigned to a client who needs coping strategies for stress should check the care plan with an RN or team leader.

- Teaching a client body relaxation, controlled breathing, or meditation should be done by an experienced nurse—RN or LVN/LPN.

Communication Matrix

- Integrating stress reduction and coping strategies into a client's care plan should be shared by the total staff interacting with the client to maintain a consistent approach.
- The staff approach should have outcome behaviors designated so that the strategies can be evaluated as to effectiveness and efficacy for the client.

CRITICAL THINKING Strategies

Scenario 1

Robert Warren is 40 years old and works as an administrative assistant for a senator in Washington, D.C. Before his admission to the hospital, he had no history of heart trouble and had no other major health problems. He is overweight by 30 pounds, complains of difficulty sleeping for several years, and has admitted to several brief depressive episodes that he has handled by either working longer hours or becoming intoxicated with alcohol. He does admit to overuse of alcohol on a daily basis.

Robert complains of burnout related to his work. Although he admires and supports his boss, he also competes with him and secretly believes he would make a better senator. Another area of concern is his marriage, which he says is dull except for an explosive argument every few weeks. Robert has been having affairs with other women regularly for the past few years. He and his wife have no children. Robert's admission diagnosis is acute myocardial infarction.

1. What are the consequences of Robert's adhering to this lifestyle behavior?
2. Which assessment parameters for stress are important for this client? Be specific about the areas of stress in the assessment.

3. In what ways can you assist this client to improve his coping with stress? (Robert's nutrition and exercise plans are deferred because he is currently in a cardiac rehabilitation program which daily monitors his diet and exercise.)
4. How might you test the result of stress reduction behaviors?

Scenario 2

The nurse is admitting a 60-year-old client to the unit. He is scheduled to undergo a series of tests to determine why he is fatigued, dizzy, and has constant digestive complaints. He had one seizure and was started on Dilantin until a diagnosis is made. As the admitting RN, you are completing an assessment.

1. Excluding the physical assessment parameters and signs and symptoms, what additional assessments will you make?
2. Based on the information you receive from the client, what teaching does this client require?

NCLEX® Review Questions

Unless otherwise specified, choose only one (1) answer.

1. Which of the following terms indicate signals of stress the nurse should be aware of?
Choose all that apply.
 1. Fatigue, lethargy
 2. Eating disorder
 3. Anxiety
 4. Anger
 5. Restlessness
2. Which of the following is the best definition of holistic when referring to a holistic approach to health?
 1. The term implies wholeness.
 2. Holistic refers to the whole body, including mind and psyche.
 3. The term parallels wellness and means if the person is holistic, they are healthy.
 4. The term suggests that the body, mind, and spirit are one and interacts as an open system with the environment.
3. The World Health Organization (WHO) estimates that 80% of the world's population uses which of the following alternative practices as a part of their health care?
 1. Herbal medicine
 2. Chiropractic
 3. Energy medicine
 4. Homeopathy
4. Which of the following adaptation factors influence stress management?
Choose all that apply.
 1. Age
 2. Environment
 3. Degree of flexibility of the individual
 4. Religion
 5. Presence of illness
 6. Expenditure of energy needed
5. Which of the following is a therapeutic suggestion for coping with stress?
 1. Pay attention to unimportant details.
 2. Rank tasks to be completed in order of importance.
 3. Consider unpleasant past events and figure out what went wrong.
 4. Anticipate negative outcomes before they occur.
6. What is the best rationale for including nutrition/diet as an alternative treatment method.
 1. Diet is a major contributor to health or disease.
 2. Nutrition influences how long we live.
 3. Diet can cure disease.
 4. The quality of food influences well-being.
7. A client requests information about alternative treatments. Choose the most appropriate response.
 1. "I think that you should ask your doctor about this."
 2. "Perhaps it would be better to stick to mainstream medicine."
 3. "Let's get your doctor and my supervisor together to discuss your question."
 4. "I'll bring you information about alternative treatments."
8. Which of the following statements fit into Hans Selye's definition of stress?
 1. Stress is a specific syndrome.
 2. Stress is manifested by specific changes in the body.
 3. Stress can only be controlled by changes in thought patterns.
 4. Stress causes a multiplicity of changes in the body.
9. Which one of the following statements about stress is inaccurate?
 1. Chronic stress causes changes in the immune system.
 2. Stressors may be chemical, physical, developmental, or emotional.
 3. The stress syndrome can be both positive and negative.
 4. The danger signals of stress are easy to observe.
10. A client tells the nurse that he is constantly under stress. The nurse could teach the client a stress reduction technique such as:
 1. Counting to 10 before getting angry.
 2. Sitting relaxed and quiet, clearing the mind, and breathing deeply.
 3. Jumping up and down on a trampoline.
 4. Saying a mantra or one word over and over again.

18

Medication Administration

LEARNING OBJECTIVES

1. Explain the concepts of drug absorption, distribution, biotransformation, and excretion.
2. List the seven parts of a medication order.
3. State the “five rights” for administering medications.
4. Describe the medication cart and its purpose.
5. Identify three nursing actions to prevent medication errors.
6. Outline steps for applying a transdermal medication.
7. List factors to assess before applying medications to the skin or mucous membranes.
8. Describe steps for instilling eyedrops.
9. Outline the process of eye and ear irrigations.
10. Contrast the procedure for instilling ear medication in adults and children.
11. Outline steps used when preparing parenteral medications.
12. Demonstrate correct calculation and preparation of a complex medication order.
13. Compare insulin types, their onset, peak, and duration of action.
14. List four important factors to assess when administering parenteral medications.
15. State four techniques to alleviate pain with parenteral injections.
16. Describe the Z-track method of intramuscular injection.
17. List steps for inserting a rectal or vaginal suppository.

TERMINOLOGY

Absorption the passage of a substance from administration site into the bloodstream.

Actuation propellant-driven medication dose.

Addictive causing enslavement to some habit.

Adverse reaction undesirable, usually unpredictable medication effect; may be immediate or take months to develop.

Allergy an antigen–antibody reaction or hypersensitivity to a substance.

Anaphylaxis a shock state due to an antigen/antibody reaction to a foreign substance (e.g., medication).

Anesthesia partial or complete loss of sensation with or without loss of consciousness as a result of injury, disease, or administration of a drug.

Aseptic sterile; condition free from germs and infection.

Aspirate to remove by suction.

Biotransformation metabolic conversion of a drug into inactive metabolites that are readily excreted from the body.

Bronchodilation dilation of the airways.

Cerumen protective secretion produced by the outer ear canal.

Circulation movement of blood in a circular course, exiting through the aorta and coming back into the heart via the venae cavae.

Compatible able to mix with another substance without destructive changes.

Congestion the presence of an excessive amount of blood or fluid in an organ or in tissue.

Contaminate to soil, stain, or pollute; to render impure.

Contraindication any circumstance indicating the inappropriateness of a form of treatment otherwise advisable.

Dosage the amount of medicine to be administered to a client at one time.

Drug any substance that, when taken into the living organism, may modify one or more of its functions.

Dyspnea a subjective feeling of difficulty in breathing.

Ecchymosis irregularly formed hemorrhagic area of the skin; a bruise.

Enteral administration administration through the gastrointestinal tract via a tube, catheter, or stoma to deliver nutrients/medications distal to the oral cavity.

Generic common or general name for a drug as opposed to a brand name.

Instillation slowly pouring or dropping a liquid into a cavity or onto a surface.

Intradermal within the dermal layer of the skin; injection here used for testing allergies, immune responses.

Intramuscular within a muscle; injected medication is rapidly absorbed due to rich vascular supply.

Intravenous administration into a vein for immediate drug action.

MAR medication administration record.

Medicine a drug or remedy.

Metabolism the biological process of changing a substance so that it (a) is less active, and (b) can be excreted.

Narcotic a controlled substance that depresses the central nervous system, thus relieving pain and producing sedation.

Nebulizer a device for breaking a drug into small particles to produce a mist or fog for inhalation.

Ophthalmic topical route for administering eye medications.

Otic topical route for administering ear medications.

Parenteral absorption route for administering medications other than the GI tract requiring injection.

Peristalsis a progressive, wavelike movement that occurs involuntarily in the intestines of the body.

Side effect predictable, unavoidable secondary effects produced by the medication at the usual dose (e.g., constipation, nausea, drowsiness).

Subcutaneous third layer of skin, which contains fat, with few blood and lymph vessels; route for injected medication. Results in slower absorption.

Sublingual under the tongue.

Systemic pertinent to the whole body rather than one specific area.

Therapeutic having medicinal or healing properties.

Tonicity state of normal tension (e.g., muscular) or normal osmolality (body fluid).

PHARMACOLOGIC AGENTS

The term “medication” refers to approved therapeutic (pharmacologic) agents applied to or introduced into the body to produce specific local or systemic physiologic effects. Medications are chemical compounds that are produced in a pharmaceutical laboratory and prescribed by a physician to be administered to a client to prevent, treat, or cure illness. These agents should be differentiated from over-the-counter (OTC) products such as vitamins, minerals, nutritional supplements, and botanical agents (herbs, phytomedicines), which also affect the body. While such OTC products are available to the public and commonly used for self-treatment, they are not officially regulated or monitored in the United States. It is important to assess the client’s use of pharmaceutical agents as well as over-the-counter products or supplements, since there is potential for dangerous interactive effects.

Pharmacologic agents have a generic (patented official) name (e.g., acetaminophen), and a trade or brand name (created by the particular manufacturer) which is capitalized (e.g., Tylenol). Generic formulations are usually less expensive than brand-name products.

BIOLOGIC EFFECTS OF DRUGS

The ultimate effect of a drug is influenced by four biologic processes: absorption, distribution, metabolism (biotransformation), and excretion. These processes determine the onset, duration, and intensity of a drug’s action.

Absorption This process refers to the movement of the drug from the administration site into the bloodstream. The route of administration determines whether or not a drug is confined to one area of the body to exert a *local effect*, or is absorbed by the vascular system and distributed to body tissues for a *systemic effect*. The oral route (PO, per os) is most frequently used for drug administration. Drugs may be given PO to exert a local effect (e.g., cough medicine, antacid), but more commonly the drug dissolves and is absorbed by the GI tract to exert a systemic effect. Liquid forms are absorbed more quickly. Most drugs are absorbed in the small intestine via the large vascular mucosal surface. The alkaline environment of the intestines enhances this absorption process. GI absorption is influenced by the pH, the presence or absence of food, concomitant ingestion of other drugs, solubility of the drug, and

blood flow to the absorption site. In general, bioavailability of oral drugs is decreased because after absorption, the drug is circulated to the liver (first pass) and metabolized before reaching the circulation.

Medications applied “topically” to the skin (dermal) or eye (ophthalmic) or into the ear canal (otic) are often administered for local action. The skin is also used for transdermal (percutaneous) absorption of drugs by diffusion via patches, which release a medication continuously into capillaries of the epidermis for a systemic effect.

Mucous membranes provide a variety of convenient sites for drug administration to achieve a local or systemic effect by absorption. Sites include sublingual and buccal areas, the nose or respiratory tract (by inhalation), the eye, vagina, and rectum.

The parenteral route (by injection) provides the most direct, reliable, rapid drug absorption. Methods of parenteral administration include intradermal (ID), subcutaneous (Sub Q), intramuscular (IM), and intravenous (IV). Site selection depends on the drug, its action, and client factors. For example, a client with a severe allergic reaction receives epinephrine IV (directly into the bloodstream) because this route bypasses the process of absorption and provides immediate distribution and drug action in an emergency situation.

Distribution Distribution refers to the process by which a drug is transported by the blood to the site of action. Some of the drug binds to plasma protein and may compete with other drugs for this storage site. The rest is transported in “free” form through the circulation. It is the “free” form that is pharmacologically active. The “free” drug crosses cell membranes and as it is metabolized and excreted, the protein-bound drug is freed for action. Lipid-soluble drugs are distributed to and stored in fat and then released slowly into the bloodstream when drug administration is discontinued. The distribution process requires adequate cardiac output and tissue perfusion, while the rate of diffusion is influenced by the drug’s protein-binding capacity, its solubility, the amount of drug in the plasma, and the presence of physiologic barriers such as the blood–brain and placental barriers.

Metabolism Metabolism or biotransformation refers to the enzymatic process by which a “free” drug is converted to an inactive and harmless form that can be excreted. Most drugs are metabolized in the liver, where some drugs are converted

into metabolites that are more pharmacologically effective than their “parent” form. Some drugs given orally are significantly inactivated by “first passing” through the liver before entering the general circulation to be transported to the site of action. Oral doses of these drugs must be higher than parenteral doses, and some drugs totally inactivated by “first pass” must be given parenterally. Other sites of drug metabolism include the lungs, kidney, plasma, and intestinal mucosa.

Excretion This is the final process by which the drug is eliminated from the body. The kidneys are the most important route of excretion because they eliminate both the pure drug as well as metabolites of the parent drug. During excretion, substances are filtered through the glomeruli, secreted by the tubules, and then either reabsorbed by the tubules or directly excreted and eliminated through urine. Other routes of excretion include the lungs (by exhalation), GI tract, saliva, sweat, and breast milk.

Medication biodynamic processes and the individual client’s response to drug therapy are influenced by many factors, including a client’s body weight, body mass index, age, sex, acid–base and fluid and electrolyte balance, biorhythms, and general health and nutritional status. In addition, ethnic origin and genetic and immunologic factors affect biodynamics, as do psychological, emotional, and environmental influences. The term “drug polymorphism” is applied to these variations in clients’ response to medications.

ADMINISTERING MEDICATIONS SAFELY

A medication must have physician’s order or prescription before it can be legally administered to a client. If a written order is illegible or is questionable for any reason, the physician must be notified for clarification. In many agencies it is the pharmacist’s responsibility to contact the prescriber to clarify unclear or questionable orders. Since verbal (using words) orders may be written or spoken, it is important to specify the mode of communication. If a medication order is spoken aloud (VO) or over the phone (TO), there is greater risk of error. Verbal (spoken) orders should not be taken if the prescriber is present and the chart is available, nor are they appropriate for complex therapeutic protocols (e.g., chemotherapy).

If the order is communicated by telephone, always repeat the order to avoid misinterpretation. Have the prescriber spell out the name of the medication and dosage, and have another person listen to the order as well. Get the prescriber’s phone number, then record the order onto the client’s chart directly (rather than transcribing from scrap paper). This order must be signed by the prescriber within 24 hr. Some agencies restrict telephone orders to emergencies only. To avoid error, it is better to have the prescriber e-mail or fax the medication order.

Medication orders may be *routine* (administered as ordered until discontinued by the prescriber), *one-time-only*, “*stat*” (immediately), or PRN (administered when the client needs the medication within the specified time interval, e.g., q4h). The continued validity of any medication order should be evaluated since prescribers sometimes forget to

Seven Parts of Medication Orders

- Client’s name
- Date medication was ordered
- Name of medication
- Medication dosage
- Route of administration and any special instruction for administration
- Time and frequency medication is to be given
- Signature of individual ordering the drug

Common communication breakdowns leading to medication errors include:

- Unapproved or unclear abbreviations (see box, p. 628)
- Illegible writing
- Misplaced or unnoticed decimals (e.g., .2 rather than 0.2)
- “Verbal orders”
- Incomplete orders

Source: Institute for Safe Medication Practices. www.ismp.org.

discontinue medications no longer appropriate for the client’s condition.

While the physician prescribes the medication and the pharmacist dispenses it, the nurse is responsible for validating, preparing, and administering medications safely and in accordance with agency policies and procedures. The nurse should understand why the particular medication is prescribed for the particular client and clarify concerns about its use. The nurse who prepares the medication must also give it to the client, then document the medication, time, dosage, and route on the client’s record. In addition, the nurse assesses and documents the client’s response to the drug administered. If the client is allergic to a medication, an anaphylactic reaction may occur. This is a life-threatening medical emergency requiring immediate administration of epinephrine.

Safe administration requires adherence to the “Six Rights” (originally five) each time a medication is given in order to decrease the risk of a medication error.

Safety Precautions

When administering medications, follow established safety rules, known as “The Six Rights.” These rules are to be carried out each time you give a medication to a client.

The Six Rights

- **Right medication.** Compare medication container label to the medication sheet (MAR) **three** times (when obtaining the medication, when preparing the medication, and after preparation). Note medication expiration date. Know action, dosage, and method of administration. Know side effects of the medication and any *allergies* the client might have.
- **Right client.** Check the room and bed number and client’s Ident-A-Band: validate correct client with two identifiers other than room number (e.g., stated name and date of birth).

- **Right time.** Medication given 30–45 minutes before or after time ordered is acceptable (according to agency policy).
- **Right method or route of administration.** If a change in route is indicated, request new orders from physician.
- **Right dose.** Validate calculations of divided doses with another nurse. Have another nurse double-check your preparation of insulin, potassium chloride, morphine, hydromorphone HCl, heparin, and warfarin sodium (The Joint Commission high-alert drugs). Know the usual dose and question any dose outside safe range.
- **Documentation.** After administration may be considered to be the sixth right; the nurse should document the name of the drug, the dose and route, time administered, and the client’s response to the medication administered.

In the event of a medication error, the physician must be notified immediately so that potential adverse client outcomes can be prevented or minimized. Follow your agency’s unusual occurrence or variance reporting procedure to facilitate audits that help identify and rectify sources of medication errors.

Some agents within drug classes are more effective than others for different populations. Asians metabolize psychotropic

agents more slowly than other ethnic groups, so lower doses may be indicated.

The nurse should obtain a list of each client’s current medications as well as any alternative therapies used so that possible untoward interactions can be prevented.

CULTURAL AWARENESS

Cultural and genetic factors affect how a client reacts to medications. Physiologic rhythms, use of alcohol, and stress may either inhibit or accelerate drug biodynamics.

Cultural acceptance factors include values and beliefs, educational level, previous experiences, family influence, and physician/client relationship.

The concomitant use of “natural” remedies can also alter the client’s response to drug therapy.

One genetic factor noted to differ among ethnic groups is variation in metabolic pathways that may accelerate or slow drug metabolism. It is also thought that the pathophysiology of various disease states may differ among populations based on genetic determination. For example, black clients respond differently to different antihypertensives than whites do. Blacks respond better to diuretics than they do to beta-blockers and angiotensin-converting enzyme (ACE) inhibitors for hypertension.

NURSING DIAGNOSES

The following nursing diagnoses are appropriate to use on client care plans when the components relate to a client who requires treatment with medications.

NURSING DIAGNOSIS	RELATED FACTORS
Ineffective Health Maintenance	Lack of education or readiness to learn, cognitive impairment, lack of equipment, inadequate support systems, inadequate financial resources, religious beliefs, cultural beliefs/values
Enhanced Self Health Management, Readiness for	Client seeks supervision and practices self-administration of MDI/DPI Client expresses interest in use of insulin pump/delivery system and seeks counseling for diabetes management with Certified Diabetes Educator Client seeks supervision and practices self-injection of anticoagulant before discharge
Risk for Injury	Altered clotting factors due to anticoagulant therapy Altered regulatory function due to side effects of medications (e.g., drowsiness) Altered biochemical function due to interactive effects of prescribed or nonprescribed medications/herbal supplements/vitamins Allergic/anaphylactic reaction to administered medication Medication error on part of nursing staff
Deficient Knowledge	Inadequate understanding of condition, medication regimen or self-care skills Inadequate understanding of rationale for follow-up laboratory monitoring related to prescribed medications
Ineffective Therapeutic Regimen Management	Impaired ability to perform tasks, side effects of therapy, nontherapeutic environment, denial of condition, lack of information or finances, poor self-esteem, nonsupportive family

CLEANSE HANDS The single most important nursing action to decrease the incidence of hospital-based infections is hand hygiene. Remember to wash your hands or use antibacterial gel before and after each and every client contact.

IDENTIFY CLIENT Before every procedure, introduce yourself and check two forms of client identification, not including room number. These actions prevent errors and conform to The Joint Commission standards.

Chapter 18

UNIT 1

Medication Preparation

Nursing Process Data

ASSESSMENT Data Base

- Validate medication to be given with physician's order and client's MAR.
- Know desired therapeutic action of the drug, side effects, and adverse reactions.
- Assess for potential drug interaction with client's other medications or contraindication to administration (allergy, lab data, vital signs, unsafe dose).
- Identify route for drug administration.
- Recognize need to calculate drug dosage and seek verification of calculation by another nurse.
- Validate drug and dosage of certain critical drugs with another nurse or pharmacist.

PLANNING Objectives

- To understand the drug's action and rationale for administration to the client (desired therapeutic effect)
- To prepare the appropriate medication to be given by the correct route
- To have another nurse double-check dosage calculations and preparation of high-alert medications
- To anticipate potential side effects or adverse client reactions and be prepared to take corrective actions

IMPLEMENTATION Procedures

- Preparing for Medication Administration 575
- Converting Dosage Systems 576
- Calculating Dosages 577
- Using the Narcotic Control System 577
- Using an Automated Dispensing System 578
- Administering Medication Protocol 580

EVALUATION Expected Outcomes

- Rationale for medication administration is clear.
- Client's MAR matches physician's orders.
- Dosage calculations are accurate.
- Medication sign-out sheet matches remaining stock.
- Medication is administered according to the "Six Rights."

Critical Thinking Application 583

- Expected Outcomes 583
- Unexpected Outcomes 583
- Alternative Actions 583

Pearson Nursing Student Resources

Find additional review materials at
nursing.pearsonhighered.com

Prepare for success with NCLEX®-style practice questions
and Skill Checklists

Preparing for Medication Administration

Equipment

- Reference resource (e.g., *Physicians' Desk Reference*, pharmacology textbook, drug handbook)
- Calculator (if indicated)
- Medication administration record sheet (MAR)
- Client's chart

Procedure

1. Check physician's orders and client's MAR for medications client is to receive (drug, dosage, route of administration, time intervals).
2. Identify any unfamiliar drugs.
3. Research unfamiliar drugs using appropriate reference.
 - a. Generic and trade name.
 - b. Drug classification and major uses.
 - c. Pharmacologic actions.
 - d. Safe dosage, route, and time of administration.
 - e. Side effects; adverse reactions.
 - f. Nursing implications.
 - g. Complete client teaching as needed.

Clinical Alert

Individual drugs are designed to be administered by specific route—be sure to check drug labels for appropriate route of administration.

4. Review client's record for allergies, lab data, any factor (e.g., NPO status, planned procedures) that contraindicates administration of ordered medications.

▲ Check physician's order against medication administration record (MAR).

5. Check client's daily MAR with previous day's MAR every 24 hr for each drug's dosage, route, and time to be given. ► **Rationale:** Pharmacy produces each daily MAR sheet. Any new medications, discontinued medication, or altered dosage must be identified and verified with the physician's orders.
6. Validate carefully that MAR is consistent with physician's most recent order for each medication. ► **Rationale:** Some medication dosages are adjusted on a daily basis. Errors in transmission of intentions may occur between physician, pharmacy, and client's MAR.
7. Perform hand hygiene.
8. Take medication to client's room.
9. Open medication cart; take out client's medication drawer.
10. Starting at the top of the MAR, check each medication in order against the medication packages in the client's drawer.

Alternately, obtain client's medication from the automated dispensing system.

11. Retrieve medication to be given and compare drug label with MAR. ► **Rationale:** This is a safety check to ensure the right medication is selected.
12. Inspect label for expiration date, and ensure that medication is indicated for ordered route of administration. ► **Rationale:** Different preparations of the same medication are used for different routes of administration.

Clinical Alert

If client assessment is indicated before administering drug to client (e.g., BP), make note on wrapper as a reminder to do so.
