YOU'VE JUST PURCHASED MORE THAN A TEXTBOOK!

Evolve Student Resources for *Ackley: Nursing Diagnosis Handbook, 11th Edition*, include the following:

- **Care Plan Constructor**
Build a comprehensive individualized care plan with ease and confidence! The Ackley, Ladwig, and Makic Care Plan Constructor allows you to access a list of common medical diagnoses, diagnostic procedures, clinical states, symptoms, and problems that are linked to 100 2015-2017 NANDA-I approved nursing care plans.
- **Case Studies**
Apply the nursing process when building a care plan. Each case study is linked to the care plan constructor for a complete study tool.
- **Review Questions for the NCLEX Exam (150 questions with answers and rationales)**
Test your knowledge with 150 multiple-choice review questions with answers and rationales!
- **Nursing Interventions Classification (NIC) and Nursing Outcomes Classification (NOC) Lists**
Choose the correct interventions to enhance patient outcomes and develop the appropriate client outcomes for your care plan by using the list of 544 NIC labels and 490 NOC labels.

NANDA International, Inc. Nursing Diagnoses: Definitions & Classifications 2015-2017, Tenth Edition. Edited by T. Heather Herdman and Shigemi Kamitsuru. 2014 NANDA International, Inc. Published 2014 by John Wiley & Sons, Ltd. Companion website: www.wiley.com/go/nursingdiagnoses. In order to make safe and effective judgments using NANDA-I diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Notices

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors, assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

In Memory of Betty J. Ackley

Dreams

*Dreams come
Dreams go
Whispers, shouts, images
Dreams come
Dreams go
Follow, follow**

Betty believed in dreams. This textbook was our dream. We set out to write the best nursing diagnosis textbook ever. Our book is now in 1400 nursing programs. It has been high on Amazon's best seller list. I think her dream is realized. From a handout to students to an international publication. Thank you, dear friend Betty.

Betty passed away in December 2014 at her home with her husband (Dale) and daughter (Dawn) present.

Betty fought a gallant battle with pancreatic cancer for nine months. She loved life, her family, and the profession of nursing. She was an active member of NANDA-I for more than two decades. She was also Professor Emeritus, Jackson Community College (Jackson, Michigan). Betty was an instructor at Jackson Community College for 34 years and was named Faculty of the Year.

Betty provided presentations on nursing diagnosis in Japan and across the United States. She wrote a column on nursing diagnosis for a Japanese journal, *Expert Nurse*. Betty was known for her work as a co-author of several textbooks on diagnoses, outcomes, and interventions. She served on several NANDA-I committees over the years, the most recent of which was as Chair of the most recent nominating committee. She recruited one of the strongest slates of nominees that NANDA-I has had in many years, due to her tireless efforts.

Betty will be remembered as a very giving person. She had an ability to help others in their time of need and provide comfort and direction for them. She was a certified instructor in aerobics, spinning, Zumba, and Pilates. For years she loved to run, and she finished two Detroit Marathons. Her passion included gardening, traveling, authoring this textbook, and watching her two grandchildren grow.

The following is a quote from Betty's husband:

Betty saw a need and was able to help fill that need by working to complete this book and see it through to publication. She was very proud of each edition of this book. She always strived to make each edition as good as it could be.

Betty was a loving daughter, grandmother, mother, and wife. She cared about people and was always helping everyone to be their very best. This book will continue to be her way of giving to the profession she loved. Nursing gave a lot to Betty, and she returned the love of nursing by writing the most helpful book she could write.

Dale Ackley

Also Dedicated to

Jerry Ladwig, my wonderful husband, who, after 51 years, is still supportive and helpful—he has been “my right-hand man” in every revision of this book. Also to my very special children, their spouses, and all of my grandchildren: Jerry, Kathy, Alexandra, Elizabeth, and Benjamin Ladwig; Christine, John, Sean, Ciara, and Bridget McMahon; Jennifer, Jim, Abby, Katelyn, Blake, and Connor Martin; Amy, Scott, Ford, and Vaughn Bertram—the greatest family anyone could ever hope for.

Gail B. Ladwig

My husband, Zlatko, and children, Alexander and Erik, whose unconditional love and support are ever present in my life. To my parents and sisters for always encouraging me to follow my passion. To Gail, for her incredible mentorship, guidance, and encouragement this past year. And finally to Betty, for believing in me and providing me with an opportunity to more fully contribute to this amazing textbook in support of nurses and the patients and families we serve.

Mary Beth Flynn Makic

*Gail Ladwig, 2015

About the Authors

Betty Ackley worked in nursing for 40 years in many capacities. She was a staff nurse on a CCU unit, medical ICU unit, respiratory ICU unit, intensive care unit, and step-down unit. She worked on a gynecological surgery floor and on an orthopedic floor, and spent many years working in oncology.

She also was in management and nursing education in a hospital, and she spent 31 years as a professor of nursing at Jackson Community College. At the college she taught medical-surgical nursing, critical care nursing, fundamentals of nursing, nursing leadership, and nutrition. In addition she served as a nursing consultant for nursing continuing education at the college. In 1996 she began the online learning program at Jackson Community College, offering an online course in nutrition. In 2000, Betty was named Faculty of the Year at her college.

Betty presented conferences nationally and internationally in the areas of nursing diagnosis, nursing process, online learning, and evidence-based nursing. She wrote NCLEX-RN questions for the national licensure examination four times and was an expert in the area of testing and NCLEX preparation.

Betty obtained her BSN from Michigan State University, MS in nursing from the University of Michigan, and education specialist degree from Michigan State University.

Betty is co-author of *Nursing Diagnosis: Guide to Planning Care*, which has been a successful text for 20 years, and co-author for four editions of *Mosby's Guide to Nursing Diagnosis*. She was also a lead co-author/editor of *Evidence-Based Nursing Care Guidelines: Medical-Surgical Interventions*. This text is designed to help nurses easily find and use evidence to provide excellence in nursing care. The text was published in 2008 and was named AJN book of the year.

Her free time was spent exercising, especially teaching Zumba and Pilates, and also taking spinning classes, kick boxing, and keeping moving. She taught classes in Total Control, a program to help women with urinary incontinence. In addition, she loved to travel, read, garden, spend time with her grandchildren, and learn anything new!

Gail Ladwig is a professor emeritus of Jackson Community College. During her tenure, she served 4 years as the Department Chairperson of Nursing and as a nurse consultant for Continuing Education. She was instrumental in starting a BSN transfer program with the University of Michigan.

Gail has taught classroom and clinical at JCC in fundamentals, med-surg, mental health, and a transfer course for BSN students. In addition, she has taught online courses in pharmacology, as well as a hybrid course (partially online) for BSN transfer students. She has also taught an online course in pathophysiology for the Medical University of South Carolina.

She worked as a staff nurse in medical-surgical nursing and intensive care for more than 20 years prior to beginning her teaching career. She was a certified critical-care nurse for several years and has a master's degree in Psychiatric Mental Health Nursing from Wayne State University. Her master's research was published in the *International Journal of Addictions*.

She has presented nationally and internationally, including Paris, Tokyo, and Puerto Rico, on many topics, including nursing diagnosis, computerized care planning, and holistic nursing topics.

Gail is co-author of *Nursing Diagnosis: Guide to Planning Care*, which has been a very successful text for more than 20 years, and she has been co-author for all editions of *Mosby's Guide to Nursing Diagnosis*, now in its fifth edition. She is also a co-author/editor of *Evidence-Based Nursing Care Guidelines: Medical-Surgical Interventions*. This text was published in 2008 and was named AJN book of the year.

Gail has been an active member and supporter of NANDA-I for many, many years.

Gail is the mother of 4 children and grandmother of 12 and loves to spend time with her grandchildren. She has been married to her husband Jerry for 51 years and is passionate about her family and the profession of nursing.

Mary Beth Flynn Makic is an associate professor at the University of Colorado, College of Nursing, Aurora, Colorado. At the college she teaches in the undergraduate and graduate programs. She is co-director of the Clinical Nurse Specialist graduate degree program at the College of Nursing. She

has worked predominately in critical care for 30 years. Mary Beth is best known for her publications and presentations, regionally and nationally, as an expert on evidence-based practice in nursing. Her practice expertise and research focuses on the care of the trauma, general surgical, and burn injured patient populations; acute wound healing; pressure ulcer prevention; and hospital-acquired conditions (HACs). She is passionate about nurses' understanding and translating current best evidence into practice to optimize patient and family outcomes. She is co-author of *Trauma Nursing: from Resuscitation through Rehabilitation* and a section editor of *American Association of Critical Care Nurses Procedure Manual for Critical Care*. She is actively involved in several professional nursing and interprofessional organizations.

Preface

Nursing Diagnosis Handbook: An Evidence-Based Guide to Planning Care is a convenient reference to help the practicing nurse or nursing student make a nursing diagnosis and write a care plan with ease and confidence. This handbook helps nurses correlate nursing diagnoses with known information about clients on the basis of assessment findings; established medical, surgical, or psychiatric diagnoses; and the current treatment plan.

Making a nursing diagnosis and planning care are complex processes that involve diagnostic reasoning and critical thinking skills. Nursing students and practicing nurses cannot possibly memorize the extensive list of defining characteristics, related factors, and risk factors for the 235 diagnoses approved by NANDA-International. There are two additional diagnoses that the authors think are significant: Hearing Loss and Vision Loss. These diagnoses are contained in Appendix E. This book correlates suggested nursing diagnoses with what nurses know about clients and offers a care plan for each nursing diagnosis.

Section I, Nursing Process, Clinical Reasoning, Nursing Diagnosis, and Evidence-Based Nursing, is divided into two parts. Part A includes an overview of the nursing process. This section provides information on how to make a nursing diagnosis and directions on how to plan nursing care. It also includes information on using clinical reasoning skills and eliciting the “client’s story.” Part B includes advanced nursing concepts: Concept mapping, QSEN (Quality and Safety Education for Nurses), Evidence-based nursing care, Quality nursing care, Patient-centered care, Safety, Informatics in nursing, Team/collaborative work with multidisciplinary team, and Root cause thinking.

In **Section II, Guide to Nursing Diagnoses**, the nurse can look up symptoms and problems and their suggested nursing diagnoses for more than 1450 client symptoms; medical, surgical, and psychiatric diagnoses; diagnostic procedures; surgical interventions; and clinical states.

In **Section III, Guide to Planning Care**, the nurse can find care plans for all nursing diagnoses suggested in Section II. We have included the suggested nursing outcomes from the Nursing Outcomes Classification (NOC) and interventions from the Nursing Interventions Classification (NIC) by the Iowa Intervention Project. We believe this work is a significant addition to the nursing process to further define nursing practice with standardized language.

Scientific rationales based on research are included for most of the interventions. This is done to make the evidence base of nursing practice apparent to the nursing student and practicing nurse.

New special features of the eleventh edition of *Nursing Diagnosis Handbook: An Evidence-Based Guide to Planning Care* include the following:

- Labeling of classic older research studies that are still relevant as Classic Evidence Based (CEB)
 - Twenty-six new nursing diagnoses recently approved by NANDA-I, along with retiring seven nursing diagnoses: Disturbed energy field, Adult failure to thrive, Readiness for enhanced immunization status, Imbalanced nutrition: more than body requirements, Risk for imbalanced nutrition: more than body requirements, Impaired environmental interpretation syndrome, and Delayed growth and development
 - Five revisions of nursing diagnoses made by NANDA-I in existing nursing diagnoses
 - **Old diagnosis:** Ineffective Self-Health management
Revised diagnosis: Ineffective Health management
 - **Old diagnosis:** Readiness for enhanced Self-Health management
Revised diagnosis: Readiness for enhanced Health management
 - **Old diagnosis:** Ineffective family Therapeutic Regimen Management
Revised diagnosis: Ineffective family Health management
 - **Old diagnosis:** Impaired individual Resilience
Revised diagnosis: Impaired Resilience
 - **Old diagnosis:** Risk for compromised Resilience
Revised diagnosis: Risk for impaired Resilience
 - Further addition of pediatric and critical care interventions to appropriate care plans
 - An associated Evolve Online Course Management System that includes a care plan constructor, critical thinking case studies, Nursing Interventions Classification (NIC) and Nursing Outcomes Classification (NOC) labels, PowerPoint slides, and review questions for the NCLEX-RN® exam
 - Appendixes for Nursing Diagnoses Arranged by Maslow’s Hierarchy of Needs, Nursing Diagnoses Arranged by Gordon’s Functional Health Patterns, Motivational Interviewing for Nurses, Wellness-Oriented Diagnostic Categories, and Nursing Care Plans for Hearing Loss and Vision Loss
- The following features of *Nursing Diagnosis Handbook: A Guide to Planning Care* are also available:
- Suggested nursing diagnoses for more than 1450 clinical entities, including signs and symptoms, medical diagnoses, surgeries, maternal-child disorders, mental health disorders, and geriatric disorders

- Labeling of nursing research as EBN (Evidence-Based Nursing) and clinical research as EB (Evidence-Based) to identify the source of evidence-based rationales
- An Evolve Online Courseware System with the Ackley-Ladwig Care Plan Constructor that helps the student or nurse write a nursing care plan
- Rationales for nursing interventions that are for the most part based on nursing research
- Nursing references identified for each care plan
- A complete list of NOC outcomes on the Evolve website
- A complete list of NIC interventions on the Evolve website
- Nursing care plans that contain many holistic interventions
- Care plans written by leading national nursing experts from throughout the United States, along with international contributors, who together represent all of the major nursing specialties and have extensive experience with nursing diagnoses and the nursing process. Care plans written by experts include:
 - **Caregiver Role Strain and Fatigue** by Dr. Barbara A. Given and Dr. Paula Riess Sherwood
 - Care plans for **Spirituality** by Dr. Lisa Burkhart
 - Care plans for **Religiosity** by Dr. Lisa Burkhart
 - **Impaired Memory** by Dr. Graham J. McDougall, Jr.
 - **Decreased Intracranial adaptive capacity and Risk for ineffective Cerebral tissue perfusion** by Dr. Laura Mcilvoy
 - **Unilateral Neglect** by Dr. Lori M. Rhudy
 - **Anxiety, Death Anxiety, and Fear** by Dr. Ruth McCaffrey
 - **Impaired Comfort** by Dr. Katharine Kolcaba
 - **Risk for Infection and Ineffective Protection** by Ruth M. Curchoe
 - **Readiness for enhanced Communication and Impaired verbal Communication** by Dr. Stacey M. Carroll
 - **Sexual dysfunction and Ineffective Sexuality pattern** by Dr. Elaine E. Steinke
- A format that facilitates analyzing signs and symptoms by the process already known by nurses, which involves using defining characteristics of nursing diagnoses to make a diagnosis
- Use of NANDA-I terminology and approved diagnoses
- An alphabetical format for Sections II and III, which allows rapid access to information
- Nursing care plans for all nursing diagnoses listed in Section II
- Specific geriatric interventions in appropriate plans of care
- Specific client/family teaching interventions in each plan of care
- Information on culturally competent nursing care included where appropriate
- Inclusion of commonly used abbreviations (e.g., AIDS, MI, CHF) and cross-references to the complete term in Section II

We acknowledge the work of NANDA-I, which is used extensively throughout this text. In some rare cases, the authors and contributors have modified the NANDA-I work to increase ease of use. The original NANDA-I work can be found in *NANDA-I Nursing Diagnoses: Definitions & Classification 2015-2017*. Several contributors are the original submitters/authors of the nursing diagnoses established by NANDA-I. These contributors include the following:

Lisa Burkhart, PhD, RN, ANEF
Impaired Religiosity; Risk for impaired Religiosity; Readiness for enhanced Religiosity; Spiritual distress; Readiness for enhanced Spiritual well-being

Katharine Kolcaba, PhD, RN
Impaired Comfort

Shelly Eisbach, PhD, PMHNP-BC, RN
Risk for compromised Resilience; Impaired individual Resilience; Readiness for enhanced Resilience

David Wilson, MS, RNC
Neonatal Jaundice

Susanne W. Gibbons, PhD, C-ANP/GNP
Self-Neglect

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CHSE, ANEF, FAAN
Impaired emancipated Decision-Making, Readiness for enhanced emancipated Decision-Making, Risk for impaired emancipated Decision-Making

Wolter Paans, MSCc, PhD, RN
Labile Emotional Control

We and the consultants and contributors trust that nurses will find this eleventh edition of *Nursing Diagnosis Handbook: An Evidence-Based Guide to Planning Care* a valuable tool that simplifies the process of identifying appropriate nursing diagnoses for clients and planning for their care, thus allowing nurses more time to provide evidence-based care that speeds each client's recovery.

Betty J. Ackley
Gail B. Ladwig
Mary Beth Flynn Makic

Acknowledgments

We would like to thank the following people at Elsevier: Sandy E. Clark, Senior Content Strategist, who supported us with this eleventh edition of the text with intelligence and kindness; Jennifer Wade, Content Development Specialist, who was a continual source of support; a special thank you to Carol O'Connell for project management of this edition; and to Melanie Cole for her support.

We acknowledge with gratitude nurses and student nurses, who are always an inspiration for us to provide fresh and accurate material. We are honored that they continue to value this text and to use it in their studies and practice.

Care has been taken to confirm the accuracy of information presented in this book. However, the authors, editors, and publisher cannot accept any responsibility for conse-

quences resulting from errors or omissions of the information in this book and make no warranty, express or implied, with respect to its contents. The reader should use practices suggested in this book in accordance with agency policies and professional standards. Every effort has been made to ensure the accuracy of the information presented in this text.

We hope you find this text useful in your nursing practice.

Betty J. Ackley

(Betty was very involved in planning and contributed much until she passed away)

Caregiver role strain

Caregiver Health Status

Physical
Cardiovascular disease, diabetes, fatigue, GI upset, headache, hypertension, rash, weight change

Behavioral
Poor eating behaviors, increased smoking, increased alcohol consumption, sleep disturbances

Emotional
Anxiety, depression, fatigue, feeling depressed, frustration, impaired individual coping, impatience, increased emotional lability, increased environmental lack of time to meet personal needs, socialization stress

Sociodemographic
Change in leisure activities, low work productivity, quitting work, or refusing career advancement to provide care, withdrawing from social life, financial distress including, but not limited to, poverty and bankruptcy

Caregiver-Care Recipient Relationship
Difficulty watching care recipient go through the illness, grief regarding changed relationship with care recipient, uncertainty regarding changed relationship with care recipient

Family Processes
Concern about family members, family conflict, family cohesion, family dysfunction

Related Factors (r/t)

Care Recipient Health Status
Admission, comorbidity, cognitive problems, depression, illness chronicity, illness severity, increasing care needs, instability of care recipient's health, problem behaviors, psychological problems, unpredictability of illness course

Caregiver Health Status
Admission (comorbidity), cognitive problems, inability to fulfill one's own expectations, inability to fulfill others' expectations, marital coping patterns, physical problems, psychological problems, unrealistic expectations of self

Caregiver-Care Recipient Relationship
History of poor relationship, mental status of elder inhibiting conversation, presence of abuse or violence, unrealistic expectations of caregiver by care recipient

Caring/Being Cared For
24-hour care responsibilities, amount of activities (including number of hours and specific activities that are stressful), complexity of activities, discharge of family members to home with significant care needs, ongoing changes in activities, unpredictability of care situations, stress of caregiving

Family Processes
History of family dysfunction, history of marginal family coping

Insights
Caregiver is not developmentally ready for caregiver role, deficient knowledge about community resources, difficulty accessing community resources, emotional strength, formal assistance, formal support, inadequate community resources (e.g., respite services, respite care, respite care), inadequate preparation for providing care, inadequate physical environment for providing care (e.g., housing, transportation, safety), inadequate transportation, inexperience with caregiving, informal assistance, informal support, insufficient financial resources, insufficient time, lack of caregiver privacy, lack of support, physical restriction

Sociodemographic
Alienation from others, competing role commitments, insufficient recreation, isolation from others, financial distress including potential loss of home and savings

• Independent **CB** = Class Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Caregiver role strain

care situation can offer financial resources, assessment of financial distributions should occur at regular intervals. Caregivers report needing information regarding financial matters during the care situation (Lisak et al., 2012).

- Help the caregiver identify competing occupational demands and potential benefits in maintaining work as a way of providing normally. Guide caregivers to seek ways to maintain employment through mechanisms such as job sharing or decreasing hours at work. (1) If employed caregivers report that work can provide a sense of fulfillment, relief, and satisfaction (Elliott & Carlson, 2011).
- Help the caregiver problem solve to meet the care recipient's needs. (1) Using a psychosocial or problem-solving intervention can decrease caregiver feelings of strain. Although it has not been shown to help with caregiver depressive symptoms (Northrup et al., 2010).

Geriatric

- Monitor the caregiver for psychological distress and signs of depression, especially if caring for a mentally impaired elder or if there is an unsatisfactory marital relationship before caregiving. (1) In the majority of family caregivers, degree of marital satisfaction is strongly linked with caregiver role strain (Grove & King, 2011).
- Assess the health of caregivers, particularly their control over chronic diseases, at regular intervals. (1) Caregivers who report feeling better have an increased risk of mortality, and that may be particularly high in elderly caregivers with comorbid conditions (Beach et al., 2006; Schulz & Beach, 1999).
- Assess the presence of and use of social support and encourage the use of secondary caregivers with elderly caregivers. (1) Caregivers are at risk for becoming overwhelmed or unable to distinguish themselves from the caregiver role, particularly in the absence of adequate social support (Pfeck et al., 2011).
- To improve the ability to provide role care, provide skills training related to direct care, perform complex monitoring tasks, supervise and interpret client expressions, assist with decision making, assist with medication adherence, provide emotional support and comfort, and coordinate care. (1) Each task demands different skills and knowledge, organization capacities, role demands, and social and psychological strengths from family members (Schwartz et al., 2000).
- Teach symptom management techniques, assessment, potential causes, triggering factors, potential alleviating factors, reassessment, particularly for fatigue, constipation, anorexia, and pain. (1) Caregivers require training to care recipient monitoring, program management, and interpretation and can benefit from a problem-solving approach (Meyer et al., 2012).

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's ability to modify health behaviors. (1) What the client considers normal and abnormal health behavior may be based on cultural perceptions (Oger & Davidson, 2008). (1) Each client should be assessed for ability to modify health behavior based on the phenomenon of communication, time, space, social organization, environmental, and biological variations (Oger & Davidson, 2008).
- Despite the importance of cultural differences in perceptions of caregiver role strain, there are certain characteristics that are distinctive to caregivers across multiple cultures. (1) Social support and caregiver's behavioral differences have been shown to be an important factor in caregiver distress across multiple cultures (Chao & Shapp, 2012; Thompson et al., 2011; Gallo & Shaver, 2010).
- Persons with different cultural backgrounds may not perceive the provision of care with equal degrees of distress. (1) A group of caregivers in Belize did not report providing care as negative, although this did conflict with physical signs of distress (Vroman & Morley, 2011).
- Recognize that cultures often play a role in identifying who will be recognized as a family caregiver and form partnerships with those groups. (1) In a study of American Indians, people who attended and participated in Native events and received traditional healing practices were more likely to be caregivers. The study also reported that gender played a role in identifying caregivers in some tribes, but not all (Gates, 2011).
- Encourage spirituality as a source of support for coping. (1) Many African-American and Latino-American spiritually, religiousness, prayer, and church-based approaches to coping resources. Successive rates, geographic location, and role associated with health care often differ across cultures. (1) Health care clients will seek health care and modify health behaviors (Oger & Davidson, 2008).
- Assess for the presence of conflicting values within the culture. (1) Values differing and acting as part of the stressor community, families with diverse cultures were found to value privacy more related to their body image and health status and to prefer this was shared in the dual-ethnicity (Schwartz, 2005).

• Independent **CB** = Class Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Caregiver role strain

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Caregiver Adaptation to Patient Individualization, Caregiver Emotional Health, Caregiver Home Care Readiness, Caregiver Lifestyle Disruption, Caregiver-Patient Relationship, Caregiver Performance, Blood Care, Caregiver Performance: Blood Care, Caregiver Physical Health, Caregiver Role Support, Caregiver Role Endurance, Caregiver Stressors, Caregiver Well-Being

Example NOC Outcome with Indicators

Caregiver Emotional Health risk plan for a patient hospitalized by a family relative: Indicators will include a standardized emotional and environmental/physical goal within 24 hours and status of Caregiver Emotional Health: 1 = severely compromised, 2 = moderately compromised, 3 = mildly compromised, 4 = not compromised [in 10 days]

Client Outcomes

Throughout the care situation, the caregiver will:

- Feel supported by health care professionals, family, and friends
- Report reduced or acceptable feelings of burden or distress
- Take part in self-care activities to maintain own physical and psychological/emotional health
- Identify resources available to help in giving care or to support the caregiver in giving care
- Verbally manifest of the care situation feel confident and competent to provide care

Throughout this care situation, the care recipient will:

- Obtain quality and safe care

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Caregiver Support

Example NIC Activities—Caregiver Support

Discuss caregiver's options if not kept options at night awake

Nursing Interventions and Rationales

- Regularly monitor signs of depression, anxiety, burden, and deteriorating physical health in the caregiver throughout the care situation, especially if the marital relationship is poor, the care recipient has cognitive or perceptual impairments, there is little social support available, the caregiver becomes embedded in the care situation, the caregiver is elderly, female, or has poor preexisting physical or emotional health. Refer to the care plan for **Hopelessness** when appropriate. (1) The incidence of depression in family caregivers is higher than that of the patient with those whose relatives (Williams & McCorkle, 2011). (1) ER Caregiving may weaken the immune system and predispose the caregiver to illness, particularly cardiac illness and poor response to acquired infections in some situations (Gallagher et al., 2008; Guinn, Haines, & Knauth-Closter, 2008; Lovell, Moss, & Whitford, 2012). Particular urgency has been shown to be at high risk for becoming distressed in work/professional care (Schwartzman, Batters, & Holopainen, 2005).
- The impact of providing care on the caregiver's emotional health should be assessed at regular intervals using a reliable and valid instrument such as the Caregiver Strain Index, Caregiver Burden Inventory, Caregiver Reaction Assessment, Survey for Caregiver Burden, and the Subjective and Objective Burden Scale (Decker et al., 2005; Yoshida et al., 1991). (1) CB & EB. Research has validated the effectiveness of a number of evaluation tools for caregivers, including the Caregiver Reaction Assessment (Gross et al., 1992), Burden Interview (Zarit et al., 1980), the Caregiver Strain Index (Robinson, 1994), and the

• Independent **CB** = Class Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

GIVE NURSING CARE

Administer nursing care following the plan of care based on the interventions.

EVALUATE NURSING CARE

Evaluate nursing care administered using either the NOC outcomes or Client Outcomes. If the outcomes were not met, and the nursing interventions were not effective, reassess the client and determine if the appropriate nursing diagnoses were made.

DOCUMENT

Document all of the previous steps using the format provided in the clinical setting.

PLAN INTERVENTIONS

Use Section III, Guide to Planning Care, to find appropriate interventions for the client. Use the Nursing Interventions as found in that section.

SECTION I Nursing Process, Clinical Reasoning, Nursing Diagnosis, and Evidence-Based Nursing, 1

An explanation of how to make a nursing diagnosis using diagnostic reasoning, which is critical thinking. Then information on how to plan care using the nursing process, standardized nursing language, and evidence-based nursing.

SECTION II Guide to Nursing Diagnosis, 17

An alphabetized list of medical, surgical, and psychiatric diagnoses; diagnostic procedures, clinical states, symptoms, and problems, with suggested nursing diagnoses. This section enables the nursing student as well as the practicing nurse to make a nursing diagnosis quickly, to save time.

SECTION III Guide to Planning Care, 121

Section III contains the actual nursing diagnosis care plans for each accepted nursing diagnosis of the North American Nursing Diagnosis Association-International (NANDA-I): the definition, defining characteristics, risk factors, related factors, suggested NOC outcomes, client outcomes, suggested NIC interventions, interventions with rationales, geriatric interventions, pediatric interventions, critical care interventions (when appropriate), home care interventions, culturally competent nursing interventions (when appropriate), and client/family teaching and discharge planning for each alphabetized nursing diagnosis.

APPENDIX A Nursing Diagnoses Arranged by Maslow's Hierarchy of Needs, 949

APPENDIX B Nursing Diagnoses Arranged by Gordon's Functional Health Patterns, 952

APPENDIX C Motivational Interviewing for Nurses, 955

APPENDIX D Wellness-Oriented Diagnostic Categories, 957

APPENDIX E Nursing Care Plans for Hearing Loss and Vision Loss, 960

SECTION

I Nursing Process, Clinical Reasoning, Nursing Diagnosis, and Evidence-Based Nursing

*Betty J. Ackley, MSN, EdS, RN, Gail B. Ladwig, MSN, RN,
Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN,
and Marina Martinez-Kratz, MS, RN, CNE*

Section I is divided into two parts. Part A includes an overview of the nursing process. This section provides information on how to make a nursing diagnosis and directions on how to plan nursing care. It also includes information on using clinical reasoning skills and eliciting the “patient’s story.” Part B includes advanced nursing concepts.

Part A: The Nursing Process: Using Clinical Reasoning Skills to Determine Nursing Diagnosis and Plan Care

1. **Assessing:** performing a nursing assessment
2. **Diagnosing:** making nursing diagnoses
3. **Planning:** formulating and writing outcome statements and determining appropriate nursing interventions based on appropriate best evidence (research)
4. **Implementing care**
5. **Evaluating the outcomes and the nursing care that has been implemented.** Make necessary revisions in care interventions as needed

Part B: Advanced Nursing Concepts

- Concept mapping
- QSEN (Quality and Safety Education for Nurses)
- Evidence-based nursing care
- Quality nursing care
- Patient-centered care
- Safety
- Informatics in nursing
- Team/collaborative work with interprofessional team

PART
A

The Nursing Process: Using Clinical Reasoning Skills to Determine Nursing Diagnoses and Plan Care

The primary goals of nursing are to (1) determine client/family responses to human problems, level of wellness, and need for assistance; (2) provide physical care, emotional care, teaching, guidance, and counseling; and (3) implement interventions aimed at prevention and assisting the client to meet his or her own needs and health-related goals. The nurse must always focus on assisting clients and families to their highest level of functioning and self-care. The care that is provided should be structured in a way that allows clients the ability to influence their health care and accomplish their self-efficacy goals. The nursing process, which is a problem-solving approach to the identification and treatment of client problems, provides a framework for assisting clients and families to their optimal level of functioning. The nursing process involves five dynamic and fluid phases: **assessment, diagnosis, planning, implementation, and evaluation.** Within each of these phases, the client and family story is embedded and is used as a foundation for knowledge, judgment, and actions brought to the client care experience. A description of the “patient’s story” and each aspect of the nursing process follow.

THE “PATIENT’S STORY”

The “patient’s story” is a term used to describe objective and subjective information about the client that describes who the client is as a person in addition to their usual medical history. Specific aspects of the story include physiological, psychological, and family characteristics; available resources; environmental and social context; knowledge; and motivation. Care is influenced, and often driven, by what the client states—verbally or through their physiologic state. The “patient’s story” is fluid and must be shared and understood throughout the client’s health care experience.

There are multiple sources for obtaining the patient’s story. The primary source for eliciting this story is through communicating directly with the client and the client’s family. It is important to understand how the illness (or wellness) state has affected the client physiologically, psychologically, and spiritually. The client’s perception of his or her health state is important to understand and may have an impact on subsequent interventions. At times, clients will be unable to tell their story verbally, but there is still much they can communicate through their physical state. The client’s family (as the client defines them) is a valuable source of information and can provide a rich perspective on the client. Other

valuable sources of the “patient’s story” include the client’s health record. Every time a piece of information is added to the health record, it becomes a part of the “patient’s story.” All nursing care is driven by the client’s story. The nurse must have a clear understanding of the story to effectively complete the nursing process. Understanding the full story also provides an avenue for identifying mutual goals with the client and family aimed at improving client outcomes and goals.

Note: The “patient’s story” is terminology that is used to describe a holistic assessment of information about the client, with the client’s and the family’s input as much as possible. In this text, we use the term “patient’s story” in quotes whenever we refer to the specific process. In all other places, we use the term *client* in place of the word *patient*; we think labeling the person as a client is more respectful and empowering for the person. *Client* is also the term that is used in the National Council Licensure Examination (NCLEX-RN) test plan ([National Council of State Boards of Nursing, 2013](#)).

Understanding the “patient’s story” is critically important, in that psychological, socioeconomic, and spiritual characteristics play a significant role in the client’s ability and desire to access health care. Also knowing and understanding the “patient’s story” is an integral first step in giving client-centered care. In today’s health care world, the focus is on the client, which leads to increased satisfaction with care. Improving the client’s health care experience is part of the Affordable Care Act and is tied to reimbursement through value-based purchasing of care: “participating hospitals are paid for inpatient acute care services based on the quality of care, not just quantity of services they provide” ([Centers for Medicare & Medicaid Services, 2014](#)).

THE NURSING PROCESS

The nursing process is an organizing framework for professional nursing practice, a critical thinking process for the nurse to use to give the best care possible to the client. It is very similar to the steps used in scientific reasoning and problem solving. This section is designed to help the nursing student learn how to use this thinking process, the nursing process. Key components of the process include the steps listed below. An easy, convenient way to remember the steps of the nursing process is to use an acronym, **ADPIE** ([Figure I-1](#)):

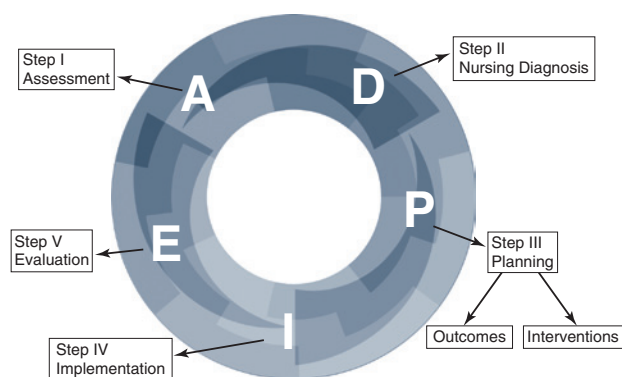

Figure I-1
Nursing process.

1. **Assess:** perform a nursing assessment
2. **Diagnose:** make nursing diagnoses
3. **Plan:** formulate and write outcome/goal statements and determine appropriate nursing interventions based on the client's reality and evidence (research)
4. **Implement care**
5. **Evaluate** the outcomes and the nursing care that has been implemented. Make necessary revisions in care interventions as needed.

The following is an overview and practical application of the steps of the nursing process. The steps are listed in the usual order in which they are performed.

STEP 1: ASSESSMENT (ADPIE)

The assessment phase of the nursing process is foundational for appropriate diagnosis, planning, and intervention. Data on all dimensions of the “patient’s story,” including biophysical, psychological, sociocultural, spiritual, and environmental characteristics, are embedded in the assessment. It involves performing a thorough holistic nursing assessment of the client. This is the first step needed to make an appropriate nursing diagnosis, and it is done using the assessment format adopted by the facility or educational institution in which the practice is situated.

The nurse assesses components of the “patient’s story” every time an assessment is performed. Often, nurses focus on the physical component of the story (e.g., temperature, blood pressure, breath sounds). This component is certainly critical, but it is only one piece. Indeed, one of the unique and wonderful aspects of nursing is the holistic theory that is applied to clients and families. Clients are active partners in the healing process. Nurses must increasingly develop the skills and systems to incorporate client preferences into care (Hess & Markee, 2014). “The challenge facing the nation, and the opportunity afforded by the Affordable Care Act, is to move from a culture of sickness to a culture of care and then to a culture of health” (Institute of Medicine, 2013). Assessment information is obtained first by completing a thorough health and medical history, and by listening to and observing

the client. To elicit as much information as possible, the nurse should use open-ended questions, rather than questions that can be answered with a simple “yes” or “no.”

In screening for depression in older clients, the following open-ended questions are useful (Lusk & Fater, 2013):

- What made you come here today?
- What do you think your problem is?
- What do you think caused your problem?
- Are you worried about anything in particular?
- What have you tried to do about the problem so far?
- What would you like me to do about your problem?
- Is there anything else you would like to discuss today?

These types of questions will encourage the client to give more information about his or her situation. Listen carefully for cues and record relevant information that the client shares. Even when the client’s physical condition or developmental age makes it impossible for them to verbally communicate with the health care team, nurses may be able to communicate with the client’s family or significant other to learn more about the client. This information that is obtained verbally from the client is considered *subjective* information.

Information is also obtained by performing a physical assessment, taking vital signs, and noting diagnostic test results. This information is considered *objective* information.

The information from all of these sources is used to formulate a nursing diagnosis. All of this information needs to be carefully documented on the forms provided by the agency or school of nursing. When recording information, the HIPAA (Health Insurance Portability and Accountability Act) (Foster, 2012) regulations need to be followed carefully. To protect client confidentiality, the client’s name should *not* be used on the student care plan. When the assessment is complete, proceed to the next step.

STEP 2: NURSING DIAGNOSIS (ADPIE)

In the diagnosis phase of the nursing process, the nurse begins clustering the information within the client story and formulates an evaluative judgment about a client’s health status. Only after a thorough analysis—which includes recognizing cues, sorting through and organizing or clustering the information, and determining client strengths and unmet needs—can an appropriate diagnosis be made. This process of thinking is called *clinical reasoning*. Clinical reasoning is a cognitive process that uses formal and informal thinking strategies to gather and analyze client information, evaluate the significance of this information, and determine the value of alternative actions (Benner, 2010). Benner (2010) describes this cognitive process as “thinking like a nurse.” Watson and Rebar (2014) referred to “noticing” as a precursor to clinical reasoning. By noticing the nurse can preempt possible risks or support subtle changes toward recovery. Noticing can be the activity that stimulates nursing action before words are exchanged, preempting need. The nurse synthesizes the

evidence while also knowing the client as part of clinical reasoning that informs client specific diagnoses (Cappelletti, Engel, & Prentice, 2014).

The nursing diagnoses that are used throughout this book are taken from North American Nursing Diagnosis Association—International (Herdman & Kamitsuru, 2014). The complete nursing diagnosis list is on the inside front cover of this text, and it can also be found on the EVOLVE website that accompanies this text. The diagnoses used throughout this text are listed in alphabetical order by the **diagnostic concept**. For example, *impaired wheelchair mobility* is found under *mobility*, not under *wheelchair* or *impaired* (Herdman & Kamitsuru, 2014).

The holistic assessment of the client helps determine the type of diagnosis that follows. For example, if during the assessment a client is noted to have unsteady gait and balance disturbance and states, “I’m concerned I will fall while walking down my stairs,” but has not fallen previously, then the client would be identified as having a “risk” nursing diagnosis.

Once the diagnosis is determined, the next step is to determine related factors and defining characteristics. The process for formulating a nursing diagnosis with related factors and defining characteristics follows. A client may have many nursing and medical diagnoses, and determining the priority with which each should be addressed requires clinical reasoning and application of knowledge.

Formulating a Nursing Diagnosis with Related Factors and Defining Characteristics

A working nursing diagnosis may have two or three parts. The two-part system consists of the nursing diagnosis and the “related to” (r/t) statement: “Related factors are factors that appear to show some type of patterned relationship with the nursing diagnosis: such factors may be described as antecedent to, associated with, relating to, contributing to, or abetting” (Herdman & Kamitsuru, 2014).

The two-part system is often used when the defining characteristics, or signs and symptoms identified in the assessment, may be obvious to those caring for the client.

The three-part system consists of the nursing diagnosis, the r/t statement, and the defining characteristics, which are “observable cues/inferences that cluster as manifestations of an actual or wellness nursing diagnosis” (Herdman & Kamitsuru, 2014).

Some nurses refer to the three-part diagnostic statement as the **PES system**:

- P** (problem)—The nursing diagnosis label: a concise term or phrase that represents a pattern of related cues. The nursing diagnosis is taken from the official NANDA-I list.
- E** (etiology)—“Related to” (r/t) phrase or etiology: related cause or contributor to the problem.
- S** (symptoms)—Defining characteristics phrase: symptoms that the nurse identified in the assessment.

Here we use the example of a beginning nursing student who is attempting to understand the nursing process and how to make a nursing diagnosis:

Problem: Use the nursing diagnosis label deficient **Knowledge** from the NANDA-I list. Remember to check the definition: “Absence or deficiency of cognitive information related to a specific topic” (Herdman & Kamitsuru, 2014).

Etiology: r/t unfamiliarity with information about the nursing process and nursing diagnosis. At this point the beginning nurse would not be familiar with available resources regarding the nursing process.

Symptoms: Defining characteristics, as evidenced by (aeb) verbalization of lack of understanding: “I don’t understand this, and I really don’t know how to make a nursing diagnosis.”

When using the **PES** system, look at the **S** first, then formulate the three-part statement. (You would have gotten the **S**, symptoms, which are defining characteristics, from your assessment.)

Therefore, the three-part nursing diagnosis is: deficient **Knowledge** r/t unfamiliarity with information about the nursing process and nursing diagnosis aeb verbalization of lack of understanding.

Types of Nursing Diagnoses

There are three different types of nursing diagnoses.

Problem-Focused Diagnosis. “A clinical judgment concerning an undesirable human response to a health condition/process that exists in an individual, family, group or community” (Herdman & Kamitsuru, 2014, p 22).

“Related factors are an integral part of all problem-focused diagnoses. They are etiologies, circumstances, facts or influences that have some type of relationship with the nursing diagnosis” (Herdman & Kamitsuru, 2014, p 26).

Example of a Problem-Focused Nursing Diagnosis. **Overweight** related to excessive intake in relation to metabolic needs, concentrating food intake at the end of the day aeb weight 20% over ideal for height and frame. Note: This is a three-part nursing diagnosis.

Risk Nursing Diagnosis. Risk nursing diagnosis is a “clinical judgment concerning the vulnerability of an individual, family, group, or community for developing an undesirable human response to health conditions/life processes” (Herdman & Kamitsuru, 2014, p 22). “The risk diagnosis is supported by risk factors that increase the vulnerability of a client, family, group, or community to an unhealthy event” (Herdman & Kamitsuru, 2014, p 26). Defining characteristics and related factors are observable cues and circumstances or influences that have some type of relationship with the nursing diagnosis that may contribute to a health problem. Identification of related factors allows nursing interventions to be implemented to address the underlying cause of a nursing diagnosis (Herdman & Kamitsuru, 2014, p 26).

Example of a Risk Nursing Diagnosis. Risk for **Overweight**: Risk factor: concentrating food at the end of the day. Note: This is a two-part nursing diagnosis.

Health Promotion Nursing Diagnosis. A clinical judgment concerning motivation and desire to increase well-being and to actualize human health potential that may be expressed by a readiness to enhance specific health behaviors or health state. Health promotion responses may exist in an individual, family, group, or community (Herdman & Kamitsuru, 2014, p 22). Health promotion is different from prevention in that health promotion focuses on being as healthy as possible, as opposed to preventing a disease or problem. The difference between health promotion and disease prevention is that the reason for the health behavior should always be a positive one. *With a health promotion diagnosis, the outcomes and interventions should be focused on enhancing health.*

Example of a Health Promotion Nursing Diagnosis. Readiness for enhanced **Nutrition** aeb expresses willingness to change eating pattern and eat healthier foods. Note: This is a two-part nursing diagnosis.

Application and Examples of Making a Nursing Diagnosis

When the assessment is complete, identify common patterns/symptoms of response to *actual or potential health problems from the assessment* and select an appropriate nursing diagnosis label using clinical reasoning skills. Use the steps with Case Study 1. (The same steps can be followed using an actual client assessment in the clinical setting or in a student assessment.)

- Highlight or underline the relevant symptoms (defining characteristics). As you review your assessment information, ask: Is this normal? Is this an ideal situation? Is this a problem for the client? You may go back and validate information with the client.
- Make a list of the symptoms (underlined or highlighted information).
- Cluster similar symptoms.
- Analyze/interpret the symptoms. (What do these symptoms mean or represent when they are together?)
- Select a nursing diagnosis label from the NANDA-I list that fits the appropriate defining characteristics and nursing diagnosis definition.

Case Study I—An Older Client with Breathing Problems

A. Underline the Symptoms (Defining Characteristics)

A 73-year-old man has been admitted to the unit with a diagnosis of chronic obstructive pulmonary disease (COPD). He states that he has “difficulty breathing when walking short distances.” He also states that his “heart feels like it is racing” (heart rate is 110 beats per minute) at the same time. He states that he is “tired all the time,” and while talking to you about

his story, he is continually wringing his hands and looking out the window.

B. List the Symptoms (Subjective and Objective)

“Difficulty breathing when walking short distances”; “heart feels like it is racing”; heart rate is 110 beats per minute; “tired all the time”; continually wringing his hands and looking out the window.

C. Cluster Similar Symptoms

“Difficulty breathing when walking short distances”
“Heart feels like it is racing”; heart rate = 110 bpm
“Tired all the time”

Continually wringing his hands
Looking out the window

D. Analyze

Interpret the Subjective Symptoms (What the Client Has Stated)

- “Difficulty breathing when walking short distances” = exertional discomfort: a defining characteristic of **Activity** intolerance
- “Heart feels like it is racing” = abnormal heart rate response to activity: a defining characteristic of **Activity** intolerance
- “Tired all the time” = verbal report of weakness: a defining characteristic of **Activity** intolerance

Interpret the Objective Symptoms (Observable Information)

- Continually wringing his hands = extraneous movement, hand/arm movements: a defining characteristic of **Anxiety**
- Looking out the window = poor eye contact, glancing about: a defining characteristic of **Anxiety**
- Heart rate = 110 beats per minute

E. Select the Nursing Diagnosis Label

In **Section II**, look up *dyspnea* (difficulty breathing) or *dysrhythmia* (abnormal heart rate or rhythm), chosen because they are high priority, and you will find the nursing diagnosis **Activity** intolerance listed with these symptoms. Is this diagnosis appropriate for this client?

To validate that the diagnosis **Activity** intolerance is appropriate for the client, turn to **Section III** and read the NANDA-I definition of the nursing diagnosis **Activity** intolerance: “Insufficient physiological or psychological energy to endure or complete required or desired daily activities” (Herdman & Kamitsuru, 2014, p 225). When reading the definition, ask, “Does this definition describe the symptoms demonstrated by the client?” “Is any more assessment information needed?” “Should I take his blood pressure or take an apical pulse rate?” If the appropriate nursing diagnosis has been selected, the definition should describe the condition that has been observed.

The client may also have defining characteristics for this particular diagnosis. Are the client symptoms that you

identified in the list of defining characteristics (e.g., verbal report of fatigue, abnormal heart rate response to activity, exertional dyspnea)?

Another way to use this text and to help validate the diagnosis is to look up the client's medical diagnosis in [Section II](#). This client has a medical diagnosis of COPD. Is Activity Intolerance listed with this medical diagnosis? Consider whether the nursing diagnosis makes sense given the client's medical diagnosis (in this case, COPD). There may be times when a nursing diagnosis is not directly linked to a medical diagnosis (e.g., ineffective **Coping**) but is nevertheless appropriate given nursing's holistic approach to the client/family.

The process of identifying significant symptoms, clustering or grouping them into logical patterns, and then choosing an appropriate nursing diagnosis involves diagnostic reasoning (critical thinking) skills that must be learned in the process of becoming a nurse. This text serves as a tool to help the learner in this process.

“Related to” Phrase or Etiology

The second part of the nursing diagnosis is the “related to” (r/t) phrase. Related factors are those that appear to show some type of patterned relationship with the nursing diagnosis. Such factors may be described as antecedent to, associated with, related to, contributing to, or abetting. Pathophysiological and psychosocial changes, such as developmental age and cultural and environmental situations, may be causative or contributing factors.

Often, a nursing diagnosis is complementary to a medical diagnosis and vice versa. Ideally the etiology (r/t statement), or cause, of the nursing diagnosis is something that can be treated independently by a nurse. When this is the case, the diagnosis is identified as an independent nursing diagnosis.

If medical intervention is also necessary, it might be identified as a collaborative nursing diagnosis. A carefully written, individualized r/t statement enables the nurse to plan nursing interventions and refer for diagnostic procedures, medical treatments, pharmaceutical interventions, and other interventions that will assist the client/family in accomplishing goals and return to a state of optimum health. Diagnoses and treatments provided by the multidisciplinary team all contribute to the client/family outcome. The coordinated effort of the team can only improve outcomes for the client/family and decrease duplication of effort and frustration among the health care team and the client/family.

The etiology is *not* the medical diagnosis. It may be the underlying issue contributing to the nursing diagnosis, but a medical diagnosis is *not* something the nurse can treat independently, without health care provider orders. In the case of the man with COPD, think about what happens when someone has COPD. How does this affect the client? What is happening to him because of this diagnosis?

For each suggested nursing diagnosis, the nurse should refer to the statements listed under the heading “Related Factors (r/t)” in [Section III](#). These r/t factors may or may not

be appropriate for the individual client. If they are not appropriate, the nurse should develop and write an r/t statement that is appropriate for the client. For the client from Case Study 1, a two-part statement could be made here:

Problem = Activity Intolerance

Etiology = r/t imbalance between oxygen supply and demand

It was already determined that the client had **Activity intolerance**. With the respiratory symptoms identified from the assessment, imbalance between oxygen supply and demand is appropriate.

Defining Characteristics Phrase

The defining characteristics phrase is the third part of the three-part diagnostic system, and it consists of the signs and symptoms that have been gathered during the assessment phase. The phrase “as evidenced by” (aeb) may be used to connect the etiology (r/t) with the defining characteristics. The use of identifying defining characteristics is similar to the process that the health care provider uses when making a medical diagnosis. For example, the health care provider who observes the following signs and symptoms—diminished inspiratory and expiratory capacity of the lungs, complaints of dyspnea on exertion, difficulty in inhaling and exhaling deeply, and sometimes chronic cough—may make the medical diagnosis of COPD. This same process is used to identify the nursing diagnosis of **Activity intolerance**.

Put It All Together: Writing the Three-Part Nursing Diagnosis Statement

Problem—Choose the label (nursing diagnosis) using the guidelines explained previously. A list of nursing diagnosis labels can be found in [Section II](#) and on the inside front cover.

Etiology—Write an r/t phrase (etiology). These can be found in [Section II](#).

Symptoms—Write the defining characteristics (signs and symptoms), or the “as evidenced by” (aeb) list. A list of the signs and symptoms associated with each nursing diagnosis can be found in [Section III](#).

Case Study 1—73-Year-Old Male Client with COPD (Continued)

Using the information from the earlier case study/example, the nursing diagnostic statement would be as follows:

Problem—**Activity intolerance**

Etiology—r/t imbalance between oxygen supply and demand

Symptoms—Verbal reports of fatigue, exertional dyspnea (“difficulty breathing when walking”), and abnormal heart rate response to activity (“racing heart”), heart rate 110 beats per minute.

Therefore, the nursing diagnostic statement for the client with COPD is **Activity intolerance** r/t imbalance between

oxygen supply and demand and verbal reports of fatigue, exertional dyspnea, and abnormal heart rate in response to activity.

Consider a second case study:

Case Study 2—Woman with Insomnia

As before, the nurse always begins with an assessment. To make the nursing diagnosis, the nurse follows the steps below.

A. Underline the Symptoms

A 45-year-old woman comes to the clinic and asks for medication to help her sleep. She states that she is worrying too much and adds, “It takes me about an hour to get to sleep, and it is very hard to fall asleep. I feel like I can’t do anything because I am so tired. My job has become very stressful because of a new boss and too much work.”

B. List the Symptoms (Subjective and Objective)

Asks for medication to help her sleep; states she is worrying about too much; “It takes me about an hour to get to sleep”; “it is very hard to fall asleep”; “I feel like I can’t do anything because I am so tired”; “My job has become very stressful because of a new boss and too much work.”

C. Cluster Similar Symptoms

Asks for medication to help her sleep
 “It takes me about an hour to get to sleep.”
 “It is very hard to fall asleep.”
 “I feel like I can’t do anything because I am so tired.”
 “I am worrying too much.”
 “My job is stressful.”
 “Too much work.”

D. Analyze/Interpret the Symptoms

Subjective Symptoms

- Asks for medication to help her sleep; “It takes me about an hour to get to sleep”; “it is very hard to fall asleep”; “I feel like I can’t do anything because I am so tired.” (All defining characteristics = verbal complaints of difficulty with sleeping.)
- States she is worrying too much (anxiety): “My job is stressful.”

Objective Symptoms

- None

E. Select a Nursing Diagnosis with Related Factors and Defining Characteristics

Look up “sleep” in Section II. Listed under the heading “Sleep pattern, disturbed” in Section II is the following information:

Insomnia (nursing diagnosis) r/t anxiety and stress

This client states she is worrying too much, which may indicate anxiety; she also recently has increased job stress.

Look up **Insomnia** in Section III. Check the definition: “A disruption in amount and quality of sleep that impairs functioning” (Herdman & Kamitsuru, 2014). Does this describe the client in the case study? What are the related factors? What are the symptoms? Write the diagnostic statement:

Problem—**Insomnia**

Etiology—r/t anxiety, stress

Symptoms—Difficulty falling asleep, “I am so tired, I can’t do anything.”

The nursing diagnostic statement is written in this format: **Insomnia** r/t anxiety and stress and (as evidenced by) difficulty falling asleep.

Note: There are more than 30 case studies available for both student and faculty use on the Evolve website that accompanies this text.

After the diagnostic statement is written, proceed to the next step: planning.

STEP 3: PLANNING (ADPIE)

The planning phase of the nursing process includes the identification of priorities, as well as the determination of appropriate client-specific outcomes and interventions. The nurse in collaboration with the client and family (as applicable) and the rest of the health care team must determine the urgency of the identified problems and prioritize client needs. *Mutual goal setting*, along with *symptom pattern recognition* and *triggers*, helps prioritize interventions and determine which interventions are going to provide the greatest impact. *Symptom pattern recognition* and/or *triggers* is a process of identifying symptoms that clients have related to their illness, understanding which symptom patterns require intervention, and identifying the associated timeframe to intervene effectively. For example, a client with heart failure is noted to gain 5 pounds overnight. Coupling this symptom with other symptoms of edema and shortness of breath while walking can be referred to as “symptom pattern recognition”—in this case, that the client is retaining fluid. The nurse, and often the client/family, recognize these symptoms as an immediate *cause* and that more action/intervention is needed to avoid a potential adverse outcome.

Nursing diagnoses should be prioritized first by immediate needs based on ABC (airway, breathing, and circulation). The highest priority should also be determined by using Maslow’s hierarchy of needs. In this hierarchy, priority is given to immediate problems that may be life-threatening (thus ABC). For example, ineffective **Airway** clearance, as evidenced by the symptoms of increased secretions and increased use of inhaler related to asthma, creates an immediate cause compared to the nursing diagnosis of **Anxiety**, a love and belonging or security need, which makes it a lesser

priority than ineffective **Airway** clearance. Refer to [Appendix A](#), Nursing Diagnoses Arranged by Maslow’s Hierarchy of Needs, for assistance in prioritizing nursing diagnoses.

The planning phase should be done—whenever possible—with the client/family and the multidisciplinary team to maximize efforts and understanding, and increase compliance with the proposed plan and outcomes. For a successful plan of care, measurable goals and outcomes, including nursing interventions, must be identified.

SMART Outcomes

When writing outcome statements, it can be helpful to use the acronym SMART, which means the outcome must be:

Specific
Measurable
Attainable
Realistic
Timed

The SMART acronym is used in business, education, and health care settings. This method assists the nurse in identifying patient outcomes more effectively.

Once priorities are established, outcomes for the client can be easily identified. Client-specific outcomes are determined based on the mutually set goals. Outcomes refer to the measurable degree of the client’s response. The client’s response/outcome may be intentional and favorable, such as leaving the hospital 2 days after surgery without any complications. The client’s outcome can be negative and unintentional, such as demonstrating a surgical site infection. Generally, outcomes are described in relation to the client’s response to interventions, for example, the client’s cough becomes more productive after the client begins using the controlled coughing technique.

Based on the “patient’s story,” the nursing assessment, the mutual goals and outcomes identified by the caregiving team and the client/family, and the clinical reasoning that the nurse uses to prioritize his or her work, the nurse then decides what interventions to employ. Based on the nurse’s clinical judgment and knowledge, nursing interventions are defined as *all treatments that a nurse performs to enhance client outcomes*.

The selection of appropriate, effective interventions can be individualized to meet the mutual goals established by the client/family. It is then the nurse’s education, experience, and skill that allow them to select and carry out interventions to meet that mutual goal.

Outcomes

After the appropriate priority setting of the nursing diagnoses and interventions is determined, outcomes are developed or examined and decided upon. This text includes standardized Nursing Outcomes Classification (NOC) outcomes written by a large team of University of Iowa College of Nursing faculty and students in conjunction with clinicians from a variety of settings ([Moorhead et al, 2013](#)). “Nursing-sensitive

outcome (NOC) is an individual, family or community state, behavior or perception that is measured along a continuum in response to nursing interventions. The outcomes are stated as concepts that reflect a client, caregiver, family, or community state, perception of behavior rather than as expected goals” ([Moorhead et al, 2013](#)).

It is very important for the nurse to *involve* the client and/or family in determining appropriate outcomes. The use of outcomes information creates a continuous feedback loop that is essential to ensuring evidence-based care and the best possible client outcomes, not only for the patient care experience, but also for improving the population’s health and reducing health care costs ([Weston & Roberts, 2013](#)). The minimum requirements for rating an outcome are when the outcome is selected (i.e., the baseline measure) and when care is completed (i.e., the discharge summary). This may be sufficient in short-stay, acute-care settings. Depending on how rapidly the client’s condition is expected to change, some settings may evaluate once a day or once a shift. Community agencies may evaluate every visit or every other visit, for example. Because measurement times are not standardized, they can be individualized for the client and the setting ([Moorhead et al, 2013](#)).

Development of appropriate outcomes can be done one of two ways: using the NOC list or developing an appropriate outcome statement, both of which are included in [Section III](#). There are suggested outcome statements for each nursing diagnosis in this text that can be used as written or modified as necessary to meet the needs of the client.

The Evolve website includes a list of additional NOC outcomes. The use of NOC outcomes can be helpful to the nurse because they contain a five-point, Likert-type rating scale that can be used to evaluate progress toward achieving the outcome. In this text, the rating scale is listed, along with some of the more common indicators; for example, see the rating scale for the outcome **Sleep** ([Table I-1](#)).

Because the NOC outcomes are specific, they enhance the nursing process by helping the nurse measure and record the outcomes before and after interventions have been performed. The nurse can choose to have clients rate their own progress using the Likert-type rating scale. This involvement can help increase client motivation to progress toward outcomes.

After client outcomes are selected or written, and *discussed* with a client, the nurse plans nursing care with the client and establishes a means that will help the client achieve the selected outcomes. The usual means are nursing interventions.

Interventions

Interventions are like roadmaps directing the best ways to provide nursing care. The more clearly a nurse writes an intervention, the easier it will be to complete the journey and arrive at the destination of desired client outcomes.

[Section III](#) includes suggested interventions for each nursing diagnosis. The interventions are identified as

TABLE I-1

Example NOC Outcome

Sleep—0004

Domain—Functional Health (I)

Care Recipient:

Class—Energy Maintenance (A)

Data Source:

Scale(s)—Severely compromised to Not compromised (a) and Severe to None (n)

Definition: Natural periodic suspension of consciousness during which the body is restored.

Outcome Target Rating: Maintain at _____ Increase to _____

Sleep Overall Rating		Severely Compromised	Substantially Compromised	Moderately Compromised	Mildly Compromised	Not Compromised	
		1	2	3	4	5	
INDICATORS:

Adapted from Moorhead S, Johnson, M, Maas ML, & Swanson E. (Eds.). (2013). *Nursing outcomes classification (NOC)* (5th ed.). St Louis: Elsevier.

independent (autonomous actions that are initiated by the nurse in response to a nursing diagnosis) or collaborative (actions that the nurse performs in collaboration with other health care professionals, and that may require a health care provider's order and may be in response to both medical and nursing diagnoses). The nurse may choose the interventions appropriate for the client and individualize them accordingly, or determine additional interventions.

This text also contains several suggested Nursing Interventions Classification (NIC) interventions for each nursing diagnosis to help the reader see how NIC is used along with NOC and nursing diagnoses. The NIC interventions are a comprehensive, standardized classification of treatments that nurses perform. The classification includes both physiological and psychosocial interventions, and covers all nursing specialties. A list of NIC interventions is included on the Evolve website. For more information about NIC interventions, refer to the NIC text (Bulechek et al, 2013).

Putting It All Together—Recording the Care Plan

The nurse must document the actual care plan, including prioritized nursing diagnostic statements, outcomes, and interventions. This may be done electronically or in writing. To ensure continuity of care, the plan must be documented and shared with all health care personnel caring for the client. This text provides rationales, most of which are research based, to validate that the interventions are appropriate and workable.

The Evolve website includes an electronic care plan constructor that can be easily accessed, updated, and individualized. Many agencies are using electronic records, and this is an ideal resource. See the inside front cover of this text for information regarding access to the Evolve website, or go to <http://evolve.elsevier.com/Ackley/NDH>.

STEP 4: IMPLEMENTATION (ADPIE)

The implementation phase includes the “carrying out” of the specific, individualized, jointly agreed upon interventions in the plan of care. Often, the interventions implemented are focused on *symptom management*, which is alleviating symptoms. Typically, nursing care does not involve “curing” the medical condition causing the symptom. Rather, nursing care focuses on caring for the client/family so they can function at their highest level.

The implementation phase of the nursing process is the point at which you actually give nursing care. You perform the interventions that have been individualized to the client. All the hard work you put into the previous steps (ADP) can now be actualized to assist the client. As the interventions are performed, make sure that they are appropriate for the client. Consider that the client who was having difficulty breathing was also older. He may need extra time to carry out any

activity. Check the rationale or research that is provided to determine why the intervention is being used. The evidence should support the individualized actions that you are implementing.

Client outcomes are achieved by the performance of the nursing interventions in collaboration with other disciplines and the client/family. During this phase, the nurse continues to assess the client to determine whether the interventions are effective and the desired outcomes are met.

STEP 5: EVALUATION (ADPIE)

The final phase of the nursing process is evaluation. Evaluation occurs not only at the end of the nursing process, but throughout the process. Evaluation of an intervention is, in essence, another nursing assessment; hence the dynamic feature of the nursing process. The nurse reassesses the client, taking into consideration where the client was before the intervention (i.e., baseline) and where the client is after the intervention. Nurses are also in a great place (at the bedside) to evaluate how clients respond to other, multidisciplinary interventions, and their assessment of the client's response is valuable to determine whether the client's plan of care needs to be altered or not. For example, the client may receive 2 mg of morphine intravenously for pain (a pharmaceutical intervention to treat pain), and the nurse is the member of the health care team who can best assess how the client responded to that medication. Did the client receive relief from pain? Did the client develop any side effects? The nurse's documented evaluation of the client's response will be very helpful to the entire health care team.

The client/family can often tell the nurse how the intervention helped or did not help. This reassessment requires the nurse to revisit the mutual outcomes/goals set earlier and ask, “Are we moving toward that goal, or does the goal seem unreachable after the intervention?” If the outcomes were not met, the nurse begins again with assessment and determines the reason they were not met. Consider the SMART acronym and Case Study 1. Were the outcomes Specific? Were the outcomes Measurable? Did the client's heart rate decrease? Did the client indicate that it was easier to breathe when walking from his bed to the bathroom? Were the outcomes Attainable and Realistic? Did he still report “being tired”? Did you allow adequate Time for a positive outcome? Also ask yourself whether you identified the correct nursing diagnosis. Should the interventions be changed? At this point, the nurse can look up any new symptoms or conditions that have been identified and adjust the care plan as needed. Decisions about implementing additional interventions may be necessary; if so, they should be made in collaboration with the client/family if possible.

In some instances, the client/family/nurse triad will establish new, achievable goals and continue to cycle through the nursing process until the mutual goals are achieved.

Another important part of the evaluation phase is documentation. The nurse should use the facility's tool for documentation and record the nursing activity that was performed as well as the results of the nursing interventions. Many facilities use problem-oriented charting, in which the nurse evaluates the care and client outcomes as part of charting. Documentation is also necessary for legal reasons, because in a legal dispute, *if it wasn't charted/recorded, it wasn't done*.

Many health care providers use critical pathways or care maps to plan nursing care. The use of nursing diagnoses should be an integral part of any critical pathway/care map to ensure that nursing care needs are being assessed and appropriate nursing interventions are planned and implemented.

PART B

Advanced Nursing Process Concepts

Conceptual Mapping and the Nursing Process

Conceptual mapping is an active learning strategy that promotes critical thinking and clinical judgment, and helps increase clinical competency (Jamison & Lis, 2014; George et al, 2014). The process involves developing a diagram or pictorial representation of newly generated ideas. A concept map begins with a central theme or concept, and then related information is diagrammed radiating from the center theme. A concept map can be used to diagram the critical thinking strategy involved in using the nursing process.

Start with a blank sheet of paper; the client should be at the center of the paper. The next step involves linking to the person, via lines, the symptoms (defining characteristics) from the assessment to help determine the appropriate nursing diagnosis.

Figure I-2 is an example of how a concept map can be used to begin the nursing diagnostic process.

After the symptoms are visualized, similar ones can be put together to formulate a nursing diagnosis using another concept map (Figure I-3).

The central theme in this concept map is the nursing diagnosis: **Activity intolerance**, with the defining characteristics/client symptoms as concepts that lead to and support the nursing diagnosis. The conceptual map can then be used as a method for determining outcomes and interventions as desired. The nursing process is a thinking process. Using conceptual mapping is a method to help the nurse or nursing student think more effectively about the client.

Quality and Safety Education for Nurses

The Quality and Safety Education for Nurses (QSEN, 2014) project represents the nursing profession's response to the five health care competencies articulated by the Institute of Medicine (2013). The QSEN project defined those five competencies for nursing and also added the competency of safety. The

objective of the QSEN project is to provide nurses with the knowledge, skills, and attitudes critical to improve the quality and safety of health care systems.

The following are the competencies that were identified.

Patient-Centered Care

The QSEN project defines patient-centered care as the ability to "recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated

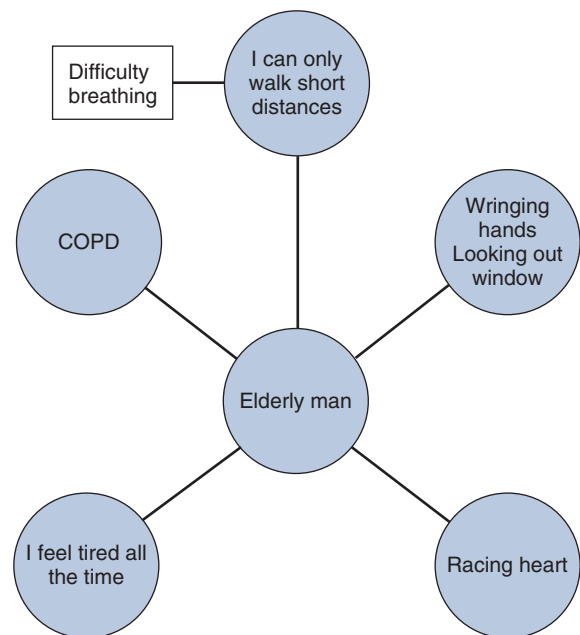

Figure I-2
Example of a concept map.

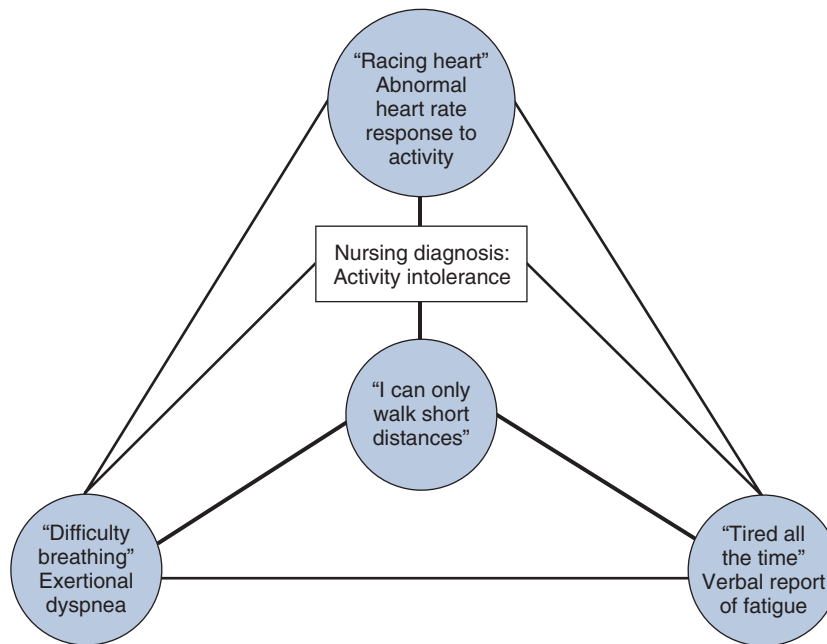

Figure I-3
Formulating a nursing diagnosis using a concept map.

care based on respect for patient’s preferences, values, and needs” (QSEN, 2014).

Patient-centered care begins with the nurse learning as much as possible about the client, including their “patient’s story” as explained in Part A of this text. The nursing process using nursing diagnosis is intrinsically all about patient-centered care. Here the client/family is a full partner in the entire process, including assessment, nursing diagnosis selection, outcomes, interventions, and evaluation. This competency is about giving care with the client and family in control as they are able, not giving care to them where the nurse is in complete control. The client, family, nurse, health care provider, and other health care workers form a team to partner with the client and family in every way possible.

Client education needs to be centered around the needs of the client, with behavior-changing techniques such as use of motivational interviewing to accomplish the defined goals. At present, too often new health information is given to clients in the form of a lecture, handout, admonishment, or direction where the client is powerless. Motivational interviewing is based on reinforcement of the client’s present thoughts and motivations on behavior change, and on respect for the client as an individual (Miller & Rollnick, 2013). This technique has been used for almost 30 years and has an extensive research base showing effectiveness. To learn more about motivational interviewing, refer to the appendix.

Addressing the unique cultural needs of clients is another example of patient-centered care. Nurses who are culturally competent base care planning on cultural awareness and

assessments that enables them to identify client values, beliefs, and preferences. Cultural awareness can ensure safe and quality outcomes for all clients by assisting clients to become “safety allies” who can alert professionals to their preferences and deviations from their usual routines (Sherwood & Zomorodi, 2014). This text provides the addition of multicultural interventions that reflect the client’s cultural preferences, values, and needs.

Patient-centered care can help nurses change attitudes toward clients, especially when caring for older clients (Pope, 2012). Caring for the retired school teacher who raised four children can be different from just caring for the client woman in Room 234 who has her call light on frequently and is incontinent of urine at too-frequent intervals.

Teamwork and Collaboration

Teamwork and collaboration are defined by the QSEN project as the ability to “function effectively within nursing and inter-professional teams, fostering open communication, mutual respect, and shared decision-making to achieve quality client care” (QSEN, 2014). Interprofessional collaboration has the potential to shift the attitudes and perceptions of health care providers so there is an increased awareness of each other’s roles, values, and disciplinary knowledge (Wilson et al, 2014). The need for collaboration by health care professionals is a reality of contemporary health care practice and is written into this text. Collaborative interventions are designated with a triangular symbol Δ . In addition, many nursing interventions are referrals to other health care personnel to best meet the client’s needs.

Evidence-Based Practice

Evidence-based practice is defined by the QSEN project as “integrat[ing] best current evidence with clinical expertise and client/family preferences and values for delivery of optimal health care” (QSEN, 2014). It is well established that evidence-based practice results in higher quality care for clients than care that is based on traditional nursing knowledge (Makic et al, 2014). Now it is imperative for each nurse and nursing student to develop clinical inquiry skills, which means the nurse continually questions whether care is being given in the best way possible based on research evidence when possible (Blazek et al, 2011). Basing nursing practice on evidence or research is a concept that has been added to the nursing process, entitled *evidence-based nursing* (EBN). EBN is a systematic process that uses current evidence in making decisions about the care of clients, including evaluation of quality and applicability of existing research, client preferences, clinical expertise, and available health care resources (Melnyk & Fineout-Overholt, 2011). To determine the best way of giving care, use of evidence-based practice is needed. To make this happen, nurses need ready access to the evidence.

This text includes evidence (research)-based rationales whenever possible. The research ranges along a continuum from a case study about a single client to a systematic review performed by experts that gives quality information to guide nursing care. Every attempt has been made to supply the most current research for the nursing interventions. In Section III, the abbreviation EBN is used when interventions have a scientific rationale supported by nursing research. The abbreviation EB is used when interventions have a scientific rationale supported by research that has been obtained from disciplines other than nursing. CEB is used as a heading for classic research that has not been replicated or is older. It may be either nursing research or research from other disciplines. Many times the CEB-labeled research will be the most important studies that have been done on that nursing issue or intervention.

When using EBN, it is vitally important that the client's concerns and individual situations be taken into consideration. The nurse must always use critical thinking when applying evidence-based guidelines to any particular nursing situation. Each client is unique in his or her needs and capabilities. To improve outcomes, clinicians and clients should collaborate to formulate a treatment plan that incorporates both evidence-based data and client preferences within the context of each client's specific clinical situation (Muhrer, 2012). This text includes both research and the nursing process. By integrating these concepts, it assists the nurse in increasing the use of evidence-based interventions in the clinical setting.

Quality Improvement

Quality improvement has been used for many years, with processes in place to ensure that the client receives appropri-

ate care. The QSEN project defines quality improvement as the ability to “use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems” (QSEN, 2014). QSEN resources supporting quality improvement initiatives are available at their website (<http://qsen.org/competencies/quality-improvement-resources-2/>). As with EBP, quality improvement initiatives need to critically examine research in supporting process changes. Research is the basis upon which best practice should be supported (Odom, 2013). It is essential for nurses to participate in the work of quality and performance improvement, which is key to attaining excellence in nursing care. As nurses are educated about performance and quality measures, they are more likely to value these activities and make quality improvement part of their nursing practice (Nelson, 2014). There is potential overlap of work in quality departments and EBN/research departments. These authors hope that the measurement of quality and quality departments in health care collaborate closely with EBN departments so that quality measurement always include relevant nursing research/evidence to effectively improve the practice of nursing.

Safety

Safety is the competency that QSEN added to the five competencies identified by the Institute of Medicine. QSEN defines safety as “minimiz[ing] risk of harm to clients and providers through both system effectiveness and individual performance” (QSEN, 2014).

Client safety is a priority when health care is delivered. Nurses are required to adhere to established standards of care as a guideline for providing safe client care. Internal standards of care are policies and procedures established by health care institutions and are based on the most relevant and current evidence. External standards of care are established by regulatory agencies (e.g., The Joint Commission), professional organizations (e.g., the American Nurses Association), and health care organizations.

Client safety was identified as a priority of care by The Joint Commission through the launch of National Patient Safety Goals in 2002. The Joint Commission (2014) has established standards for improving client safety that include the need for increased handwashing, better client identification before receiving medications or treatments, and protection of suicidal clients from self-harm. Many of these safety standards have been incorporated into the care plans in this text. A safety icon is used to designate specific safety nursing interventions in this text.

Informatics

QSEN defines informatics as the nurse's ability to “use information and technology to communicate, manage knowledge, mitigate error, and support decision making” (QSEN, 2014). Informatics is now a critical part of the nurse's professional role, and every nurse must be computer literate (TIGER,

2014). Key computer proficiencies for nursing practice should include basic computer system and desktop skills, the ability to search for client information, communication using email, ability to search electronic health care databases, and use of technology for client education, client documentation, and client monitoring (Gracie, 2011; Tiger, 2014).

In addition to computer literacy, nurses must also acquire informatic knowledge that addresses client privacy and the security of health care information as it applies to the use of technology (Foster, 2012; TIGER, 2014). Because nurses document on the electronic medical record and use smartphones for access to information on medications, diagnoses, and treatments, there are constant threats to client confidentiality.

Nurses also use clinical decision support systems in many facilities that contain order sets tailored for conditions or types of clients. These systems include information vital to nurses and also may provide alerts about potentially dangerous situations that should *not* be ignored when giving client care.

Nurses need access to technology to effectively bring evidence to the client bedside, because evidence is constantly evolving and books are often out of date before they are published. Use of informatics is integral to use of EBN practice as explained previously.

EBN, safety initiatives, informatics, patient-centered care, teamwork, and quality work together in a synergistic manner lead to excellence in nursing care. Quality care needs to be more than safe; the care should result in the best outcome possible for the client. For this to happen, the client should receive care that is based on evidence of the effectiveness of the care.

The nursing process is continually evolving. This text is all about *thinking* for the nurse to help the client in any way possible. Our goal is to present state-of-the-art information to help the nurse and nursing student provide the best care possible.

SECTION

II

Guide to Nursing Diagnosis

*Betty J. Ackley, MSN, EdS, RN, Gail B. Ladwig, MSN, RN,
Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN, and Melody Zanotti, RN*

Section II is an alphabetical listing of client symptoms, client problems, medical diagnoses, psychosocial diagnoses, and clinical states. Each of these will have a list of possible nursing diagnoses. You may use this section to find suggestions for nursing diagnoses for your client.

- Assess the client using the format provided by the clinical setting.
- Locate the client's symptoms, problems, clinical state, diagnoses, surgeries, and diagnostic testing in the alphabetical listing contained in this section.
- Note suggestions given for appropriate nursing diagnoses.
- Evaluate the suggested nursing diagnoses to determine whether they are appropriate for the client and have information that was found in the assessment.
- Use Section III (which contains an alphabetized list of all NANDA-I approved nursing diagnoses) to validate this information and check the definition, related factors, and defining characteristics. Determine whether the nursing diagnosis you have selected is appropriate for the client.

List of Nursing Assessments by Letter: A

Abdominal Distention	Abdominal Hysterectomy	Abdominal Pain
Abdominal Surgery	Abdominal Trauma	Ablation, Radiofrequency Catheter
Abortion, Induced	Abortion, Spontaneous	Abruption Placentae <36 Weeks
Abscess Formation	Abuse, Child	Abuse, Spouse, Parent, or Significant Other
Accessory Muscle Use (to Breathe)	Accident Prone	Achalasia
Acid-Base Imbalances	Acidosis, Metabolic	Acidosis, Respiratory
Acne	ACS (Acute Coronary Syndrome)	Acquired Immunodeficiency Syndrome
Acromegaly	Activity Intolerance, Potential to Develop	Acute Abdominal Pain
Acute Alcohol Intoxication	Acute Back Pain	Acute Confusion
Acute Coronary Syndrome	Acute Lymphocytic Leukemia (ALL)	Acute Renal Failure/Acute Kidney Failure
Acute Respiratory Distress Syndrome	Adams-Stokes Syndrome	Addiction
Addison's Disease	Adenoidectomy	Adhesions, Lysis of
Adjustment Disorder	Adjustment Impairment	Adolescent, Pregnant
Adoption, Giving Child Up for	Adrenocortical Insufficiency	Advance Directives
Affective Disorders	Age-Related Macular Degeneration	Aggressive Behavior
Aging	Agitation	Agoraphobia
Agranulocytosis	AIDS (Acquired Immunodeficiency Syndrome)	AIDS Dementia
AIDS, Child	Airway Obstruction/Secretions	Alcohol Withdrawal
Alcoholism	Alcoholism, Dysfunctional Family Processes	Alkalosis
ALL (Acute Lymphocytic Leukemia)	Allergies	Alopecia
Altered Mental Status	ALS (Amyotrophic Lateral Sclerosis)	Alzheimer's Disease
AMD (Age-Related Macular Degeneration)	Amenorrhea	AMI (Acute Myocardial Infarction)

Amnesia	Amniocentesis	Amnionitis
Amniotic Membrane Rupture	Amputation	Amyotrophic Lateral Sclerosis (ALS)
Anal Fistula	Anaphylactic Shock	Anaphylaxis Prevention
Anasarca	Anemia	Anemia, in Pregnancy
Anemia, Sickle Cell	Anencephaly	Aneurysm, Abdominal Surgery
Aneurysm, Cerebral	Anger	Angina
Angiocardiology (Cardiac Catheterization)	Angioplasty, Coronary	Anomaly, Fetal/Newborn (Parent Dealing with)
Anorectal Abscess	Anorexia	Anorexia Nervosa
Anosmia (Smell, Loss of Ability to)	Antepartum Period	Anterior Repair, Anterior Colporrhaphy
Anticoagulant Therapy	Antisocial Personality Disorder	Anuria
Anxiety	Anxiety Disorder	Aortic Aneurysm Repair (Abdominal Surgery)
Aortic Valvular Stenosis	Aphasia	Aplastic Anemia
Apnea in Infancy	Apneustic Respirations	Appendectomy
Appendicitis	Apprehension	ARDS (Acute Respiratory Distress Syndrome)
Arrhythmia	Arterial Insufficiency	Arthritis
Arthrocentesis	Arthroplasty (Total Hip Replacement)	Arthroscopy
Ascites	Asperger's Syndrome	Asphyxia, Birth
Aspiration, Danger of	Assault Victim	Assaultive Client
Asthma	Ataxia	Atelectasis
Atherosclerosis	Athlete's Foot	ATN (Acute Tubular Necrosis)
Atrial Fibrillation	Atrial Septal Defect	Attention Deficit Disorder
Auditory Problems	Autism	Autonomic Dysreflexia
Autonomic Hyperreflexia		

A

A

Abdominal Distention

Constipation r/t decreased activity, decreased fluid intake, decreased fiber intake, pathological process

Dysfunctional **Gastrointestinal** motility r/t decreased perfusion of intestines, medication effect

Nausea r/t irritation of gastrointestinal tract

Imbalanced **Nutrition**: less than body requirements r/t nausea, vomiting

Acute **Pain** r/t retention of air, gastrointestinal secretions

Delayed **Surgical** recovery r/t retention of gas, secretions

Abdominal Hysterectomy

See *Hysterectomy*

Abdominal Pain

Dysfunctional **Gastrointestinal** motility r/t decreased perfusion, medication effect

Acute **Pain** r/t injury, pathological process

Abdominal Surgery

Constipation r/t decreased activity, decreased fluid intake, anesthesia, opioids

Dysfunctional **Gastrointestinal** motility r/t medication or anesthesia effect, trauma from surgery

Imbalanced **Nutrition**: less than body requirements r/t high metabolic needs, decreased ability to ingest or digest food

Acute **Pain** r/t surgical procedure

Ineffective peripheral **Tissue Perfusion** r/t immobility, abdominal surgery

Risk for delayed **Surgical** recovery r/t extensive surgical procedure

Risk for **Infection**: Risk factor: invasive procedure

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care*

Abdominal Trauma

Disturbed **Body Image** r/t scarring, change in body function, need for temporary colostomy

Ineffective **Breathing** pattern r/t abdominal distention, pain

Deficient **Fluid** volume r/t hemorrhage, active fluid volume loss

Dysfunctional **Gastrointestinal** motility r/t decreased perfusion

Acute **Pain** r/t abdominal trauma

Risk for **Bleeding**: Risk factor: trauma and possible contusion/rupture of abdominal organs

Risk for **Infection**: Risk factor: possible perforation of abdominal structures

Ablation, Radiofrequency Catheter

Fear r/t invasive procedure

Risk for decreased **Cardiac** tissue perfusion: Risk factor: catheterization of heart

Abortion, Induced

Compromised family **Coping** r/t unresolved feelings about decision

Acute **Pain** r/t surgical intervention

Chronic low **Self-Esteem** r/t feelings of guilt

Chronic **Sorrow** r/t loss of potential child

Risk for **Bleeding**: Risk factor: trauma from abortion

Risk for delayed **Development**: Risk factors: unplanned or unwanted pregnancy

Risk for **Infection**: Risk factors: open uterine blood vessels, dilated cervix

Risk for **Post-Trauma** syndrome: Risk factor: psychological trauma of abortion

Risk for **Spiritual** distress: Risk factor: perceived moral implications of decision

Readiness for enhanced **Knowledge**: expresses an interest in learning

Abortion, Spontaneous

Disturbed **Body Image** r/t perceived inability to carry pregnancy, produce child

Disabled family **Coping** r/t unresolved feelings about loss

Ineffective **Coping** r/t personal vulnerability

Interrupted **Family** processes r/t unmet expectations for pregnancy and childbirth

Fear r/t implications for future pregnancies

Grieving r/t loss of fetus

Acute **Pain** r/t uterine contractions, surgical intervention

Situational low **Self-Esteem** r/t feelings about loss of fetus

Chronic **Sorrow** r/t loss of potential child

Risk for **Bleeding**: Risk factor: trauma from abortion

Risk for **Infection**: Risk factors: septic or incomplete abortion of products of conception, open uterine blood vessels, dilated cervix

Risk for **Post-Trauma** syndrome: Risk factor: psychological trauma of abortion

Risk for **Spiritual** distress: Risk factor: loss of fetus

Readiness for enhanced **Knowledge**: expresses an interest in learning

Abruptio Placentae <36 Weeks

Anxiety r/t unknown outcome, change in birth plans

Death **Anxiety** r/t unknown outcome, hemorrhage, or pain

Interrupted **Family** processes r/t unmet expectations for pregnancy and childbirth

Fear r/t threat to well-being of self and fetus

Impaired **Gas** exchange: placental r/t decreased uteroplacental area

Acute **Pain** r/t irritable uterus, hypertonic uterus

Impaired **Tissue** integrity: maternal r/t possible uterine rupture

Risk for **Bleeding**: Risk factor: separation of placenta from uterus causing bleeding

Risk for disproportionate **Growth**: Risk factor: uteroplacental insufficiency

Risk for **Infection**: Risk factor: partial separation of placenta

Risk for disturbed **Maternal–Fetal** dyad: Risk factors: trauma of process, lack of energy of mother

Risk for **Shock**: Risk factor: separation of placenta from uterus

Readiness for enhanced **Knowledge**: expresses an interest in learning

Abscess Formation

Ineffective **Protection** r/t inadequate nutrition, abnormal blood profile, drug therapy, depressed immune function

Impaired **Tissue** integrity r/t altered circulation, nutritional deficit or excess

Readiness for enhanced **Knowledge**: expresses an interest in learning

Abuse, Child

See *Child Abuse*

Abuse, Spouse, Parent, or Significant Other

Anxiety r/t threat to self-concept, situational crisis of abuse

Caregiver Role Strain r/t chronic illness, self-care deficits, lack of respite care, extent of caregiving required

Impaired verbal **Communication** r/t psychological barriers of fear

Compromised family **Coping** r/t abusive patterns

Defensive **Coping** r/t low self-esteem

Dysfunctional **Family** processes r/t inadequate coping skills

Insomnia r/t psychological stress

Post-Trauma syndrome r/t history of abuse

Powerlessness r/t lifestyle of helplessness

Chronic low **Self-Esteem** r/t negative family interactions

Risk for impaired emancipated **Decision-Making**: Risk factor: inability to verbalize needs and wants

Risk for self-directed **Violence**: Risk factor: history of abuse

Accessory Muscle Use (to Breathe)

Ineffective **Breathing** pattern (See **Breathing pattern**, ineffective, Section III)

See *Asthma*; *Bronchitis*; *COPD (Chronic Obstructive Pulmonary Disease)*; *Respiratory Infections*, *Acute Childhood*

Accident Prone

Frail Elderly syndrome r/t history of falls

Acute **Confusion** r/t altered level of consciousness

Ineffective **Coping** r/t personal vulnerability, situational crises

Ineffective **Impulse** control (See **Impulse control**, ineffective, Section III)

Risk for **Injury**: Risk factor: history of accidents

Achalasia

Ineffective **Coping** r/t chronic disease

Acute **Pain** r/t stasis of food in esophagus

Impaired **Swallowing** r/t neuromuscular impairment

Risk for **Aspiration**: Risk factor: nocturnal regurgitation

Acid-Base Imbalances

Risk for **Electrolyte** imbalance: Risk factors: renal dysfunction, diarrhea, treatment-related side effects (e.g., medications, drains)

Acidosis, Metabolic

Acute **Confusion** r/t acid-base imbalance, associated electrolyte imbalance

Impaired **Memory** r/t effect of metabolic acidosis on brain function

Imbalanced **Nutrition**: less than body requirements r/t inability to ingest, absorb nutrients

Risk for **Electrolyte** imbalance: Risk factor: effect of metabolic acidosis on renal function

Risk for **Injury**: Risk factors: disorientation, weakness, stupor

Risk for decreased **Cardiac** tissue perfusion: Risk factor: dysrhythmias from hyperkalemia

Risk for **Shock**: Risk factors: abnormal metabolic state, presence of acid state impairing function, decreased tissue perfusion

Acidosis, Respiratory

Activity intolerance r/t imbalance between oxygen supply and demand

Impaired **Gas** exchange r/t ventilation-perfusion imbalance

Impaired **Memory** r/t hypoxia

Risk for decreased **Cardiac** tissue perfusion: Risk factor: dysrhythmias associated with respiratory acidosis

Acne

Disturbed **Body Image** r/t biophysical changes associated with skin disorder

Ineffective **Health** management r/t insufficient knowledge of therapeutic regimen

Impaired **Skin** integrity r/t hormonal changes (adolescence, menstrual cycle)

ACS (Acute Coronary Syndrome)

See *MI (Myocardial Infarction)*

Acquired Immunodeficiency Syndrome

See *AIDS (Acquired Immunodeficiency Syndrome)*

Acromegaly

Activity intolerance (See **Activity intolerance**, Section III)

Ineffective **Airway** clearance r/t airway obstruction by enlarged tongue

Disturbed **Body Image** r/t changes in body function and appearance

A

Impaired physical **Mobility** r/t joint pain

Risk for decreased **Cardiac** tissue perfusion: Risk factor: increased atherosclerosis from abnormal health status

Risk for unstable blood **Glucose** level: Risk factor: abnormal physical health status

Sexual dysfunction r/t changes in hormonal secretions

Risk for **Overweight**: Risk factor: energy expenditure less than energy intake

Activity Intolerance, Potential to Develop

Activity intolerance (See [Activity intolerance, Section III](#))

Acute Abdominal Pain

Deficient **Fluid** volume r/t air and fluids trapped in bowel, inability to drink

Acute **Pain** r/t pathological process

Risk for dysfunctional **Gastrointestinal** motility: Risk factor: ineffective gastrointestinal tissue perfusion

See [Abdominal Pain](#)

Acute Alcohol Intoxication

Ineffective **Breathing** pattern r/t depression of the respiratory center from excessive alcohol intake

Acute **Confusion** r/t central nervous system depression

Dysfunctional **Family** processes r/t abuse of alcohol

Risk for **Aspiration**: Risk factor: depressed reflexes with acute vomiting

Risk for **Infection**: Risk factor: impaired immune system from malnutrition associated with chronic excessive alcohol intake

Risk for **Injury**: Risk factor: chemical (alcohol)

Acute Back Pain

Anxiety r/t situational crisis, back injury

Constipation r/t decreased activity, effect of pain medication

Ineffective **Coping** r/t situational crisis, back injury

Impaired physical **Mobility** r/t pain

Acute **Pain** r/t back injury

Readiness for enhanced **Knowledge**: expresses an interest in learning

Acute Confusion

See [Confusion, Acute](#)

Acute Coronary Syndrome

Decreased **Cardiac** output r/t cardiac disorder

Risk for decreased **Cardiac** tissue perfusion (See [Cardiac tissue perfusion, risk for decreased, Section III](#))

Acute Lymphocytic Leukemia (ALL)

See [Cancer](#); [Chemotherapy](#); [Child with Chronic Condition](#); [Leukemia](#)

Acute Renal Failure/Acute Kidney Failure

See [Kidney Failure](#)

Acute Respiratory Distress Syndrome

See [ARDS \(Acute Respiratory Distress Syndrome\)](#)

Adams-Stokes Syndrome

See [Dysrhythmia](#)

Addiction

See [Alcoholism](#); [Drug Abuse](#)

Addison's Disease

Activity intolerance r/t weakness, fatigue

Disturbed **Body Image** r/t increased skin pigmentation

Deficient **Fluid** volume r/t failure of regulatory mechanisms

Imbalanced **Nutrition**: less than body requirements r/t chronic illness

Risk for **Injury**: Risk factor: weakness

Readiness for enhanced **Knowledge**: expresses an interest in learning

Adenoidectomy

Acute **Pain** r/t surgical incision

Ineffective **Airway** clearance r/t hesitation or reluctance to cough as a result of pain, fear

Nausea r/t anesthesia effects, drainage from surgery

Acute **Pain** r/t surgical incision

Risk for **Aspiration**: Risk factors: postoperative drainage, impaired swallowing

Risk for **Bleeding**: Risk factor: surgical incision

Risk for deficient **Fluid** volume: Risk factors: decreased intake as a result of painful swallowing, effects of anesthesia

Risk for imbalanced **Nutrition**: less than body requirements: Risk factor: reluctance to swallow

Readiness for enhanced **Knowledge**: expresses an interest in learning

Adhesions, Lysis of

See [Abdominal Surgery](#)

Adjustment Disorder

Anxiety r/t inability to cope with psychosocial stressor

Labile **Emotional Control** r/t emotional disturbance

Risk-prone **Health** behavior r/t assault to self-esteem

Disturbed personal **Identity** r/t psychosocial stressor (specific to individual)

Situational low **Self-Esteem** r/t change in role function

Impaired **Social** interaction r/t absence of significant others or peers

Adjustment Impairment

Risk-prone **Health** behavior (See [Health behavior, risk-prone, Section III](#))

Adolescent, Pregnant

Anxiety r/t situational and maturational crisis, pregnancy

Disturbed **Body Image** r/t pregnancy superimposed on developing body

Decisional Conflict: keeping child versus giving up child versus abortion r/t lack of experience with decision-making,

interference with decision-making, multiple or divergent sources of information, lack of support system

Disabled family Coping r/t highly ambivalent family relationships, chronically unresolved feelings of guilt, anger, despair

Ineffective Coping r/t situational and maturational crisis, personal vulnerability

Ineffective Denial r/t fear of consequences of pregnancy becoming known

Interrupted Family processes r/t unmet expectations for adolescent, situational crisis

Fear r/t labor and delivery

Deficient Knowledge r/t pregnancy, infant growth and development, parenting

Imbalanced Nutrition: less than body requirements r/t lack of knowledge of nutritional needs during pregnancy and as growing adolescent

Ineffective Role performance r/t pregnancy

Situational low Self-Esteem r/t feelings of shame and guilt about becoming or being pregnant

Impaired Social interaction r/t self-concept disturbance

Social isolation r/t absence of supportive significant others

Risk for impaired Attachment: Risk factor: anxiety associated with the parent role

Risk for delayed Development: Risk factor: unplanned or unwanted pregnancy

Risk for urge urinary Incontinence: Risk factor: pressure on bladder by growing uterus

Risk for disturbed Maternal-Fetal dyad: Risk factors: immaturity, substance use

Risk for impaired Parenting: Risk factors: adolescent parent, unplanned or unwanted pregnancy, single parent

Readiness for enhanced Childbearing process: reports appropriate prenatal lifestyle

Readiness for enhanced Knowledge: expresses an interest in learning

Adoption, Giving Child Up for

Decisional Conflict r/t unclear personal values or beliefs, perceived threat to value system, support system deficit

Ineffective Coping r/t stress of loss of child

Interrupted Family processes r/t conflict within family regarding relinquishment of child

Grieving r/t loss of child, loss of role of parent

Insomnia r/t depression or trauma of relinquishment of child

Social isolation r/t making choice that goes against values of significant others

Chronic Sorrow r/t loss of relationship with child

Risk for Spiritual distress: Risk factor: perceived moral implications of decision

Readiness for enhanced Spiritual well-being: harmony with self regarding final decision

Adrenocortical Insufficiency

Deficient Fluid volume r/t insufficient ability to reabsorb water

Ineffective Protection r/t inability to tolerate stress

Delayed Surgical recovery r/t inability to respond to stress

Risk for Shock: Risk factors: deficient fluid volume, decreased cortisol to initiate stress response to insult to body

See *Addison's Disease; Shock, Hypovolemic*

Advance Directives

Death Anxiety r/t planning for end-of-life health decisions

Decisional Conflict r/t unclear personal values or beliefs, perceived threat to value system, support system deficit

Grieving r/t possible loss of self, significant other

Readiness for enhanced Spiritual well-being: harmonious interconnectedness with self, others, higher power, God

Affective Disorders

See *Depression (Major Depressive Disorder); Dysthymic Disorder; Manic Disorder, Bipolar I; SAD (Seasonal Affective Disorder)*

Age-Related Macular Degeneration

See *Macular Degeneration*

Aggressive Behavior

Fear r/t real or imagined threat to own well-being

Risk for other-directed Violence (See *Violence, other-directed, risk for, Section III*)

Aging

Death Anxiety r/t fear of unknown, loss of self, impact on significant others

Impaired Dentition r/t ineffective oral hygiene

Risk for Frail Elderly syndrome: Risk factors: >70 years, activity intolerance, impaired vision

Grieving r/t multiple losses, impending death

Ineffective Health management r/t powerlessness

Hearing Loss r/t exposure to loud noises, aging

Functional urinary Incontinence r/t impaired vision, impaired cognition, neuromuscular limitations, altered environmental factors

Impaired Resilience r/t aging, multiple losses

Sleep deprivation r/t aging-related sleep-stage shifts

Ineffective Thermoregulation r/t aging

Vision Loss r/t aging (see *care plan in Appendix*)

Risk for Caregiver Role Strain: Risk factor: inability to handle increasing needs of significant other

Risk for Impaired emancipated Decision-Making: Risk factor: inability to process information regarding health care decisions

Risk for Injury: Risk factors: vision loss, hearing loss, decreased balance, decreased sensation in feet

Risk for Loneliness: Risk factors: inadequate support system, role transition, health alterations, depression, fatigue

A

Readiness for enhanced community **Coping**: providing social support and other resources identified as needed for elderly client

Readiness for enhanced family **Coping**: ability to gratify needs, address adaptive tasks

Readiness for enhanced **Health** management: knowledge about medication, nutrition, exercise, coping strategies

Readiness for enhanced **Knowledge**: specify need to improve health

Readiness for enhanced **Nutrition**: need to improve health

Readiness for enhanced **Relationship**: demonstrates understanding of partner's insufficient function

Readiness for enhanced **Sleep**: need to improve sleep

Readiness for enhanced **Spiritual** well-being: one's experience of life's meaning, harmony with self, others, higher power, God, environment

Readiness for enhanced **Urinary** elimination: need to improve health

Agitation

Acute **Confusion** r/t side effects of medication, hypoxia, decreased cerebral perfusion, alcohol abuse or withdrawal, substance abuse or withdrawal, sensory deprivation or overload

Sleep deprivation r/t sustained inadequate sleep hygiene, sundown syndrome

Agoraphobia

Anxiety r/t real or perceived threat to physical integrity

Ineffective **Coping** r/t inadequate support systems

Fear r/t leaving home, going out in public places

Impaired **Social** interaction r/t disturbance in self-concept

Social isolation r/t altered thought process

Agranulocytosis

Delayed **Surgical** recovery r/t abnormal blood profile

Risk for **Infection**: Risk factor: abnormal blood profile

Readiness for enhanced **Knowledge**: expresses an interest in learning

AIDS (Acquired Immunodeficiency Syndrome)

Death **Anxiety** r/t fear of premature death

Disturbed **Body Image** r/t chronic contagious illness, cachexia

Caregiver Role Strain r/t unpredictable illness course, presence of situation stressors

Diarrhea r/t inflammatory bowel changes

Interrupted **Family** processes r/t distress about diagnosis of human immunodeficiency virus (HIV) infection

Fatigue r/t disease process, stress, decreased nutritional intake

Fear r/t powerlessness, threat to well-being

Grieving: family/parental r/t potential or impending death of loved one

Grieving: individual r/t loss of physical and psychosocial well-being

Hopelessness r/t deteriorating physical condition

Imbalanced **Nutrition**: less than body requirements r/t decreased ability to eat and absorb nutrients as a result of anorexia, nausea, diarrhea; oral candidiasis

Chronic **Pain** r/t tissue inflammation and destruction

Impaired **Resilience** r/t chronic illness

Situational low **Self-Esteem** r/t crisis of chronic contagious illness

Ineffective **Sexuality** pattern r/t possible transmission of disease

Social isolation r/t self-concept disturbance, therapeutic isolation

Chronic **Sorrow** r/t chronic illness

Spiritual distress r/t challenged beliefs or moral system

Risk for deficient **Fluid** volume: Risk factors: diarrhea, vomiting, fever, bleeding

Risk for **Infection**: Risk factor: inadequate immune system

Risk for **Loneliness**: Risk factor: social isolation

Risk for impaired **Oral Mucous Membrane**: Risk factor: immunological deficit

Risk for impaired **Skin** integrity: Risk factors: immunological deficit, diarrhea

Risk for **Spiritual** distress: Risk factor: physical illness

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *AIDS, Child; Cancer; Pneumonia*

AIDS Dementia

Chronic **Confusion** r/t viral invasion of nervous system

See *Dementia*

AIDS, Child

Impaired **Parenting** r/t congenital acquisition of infection secondary to intravenous (IV) drug use, multiple sexual partners, history of contaminated blood transfusion

See *AIDS (Acquired Immunodeficiency Syndrome); Child with Chronic Condition; Hospitalized Child; Terminally Ill Child, Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/Preadolescent; Terminally Ill Child/Death of Child, Parent*

Airway Obstruction/Secretions

Ineffective **Airway** clearance (See *Airway clearance, ineffective, Section III*)

Alcohol Withdrawal

Anxiety r/t situational crisis, withdrawal

Acute **Confusion** r/t effects of alcohol withdrawal

Ineffective **Coping** r/t personal vulnerability

Dysfunctional **Family** processes r/t abuse of alcohol

Insomnia r/t effect of alcohol withdrawal, anxiety

Imbalanced **Nutrition**: less than body requirements r/t poor dietary habits

Chronic low **Self-Esteem** r/t repeated unmet expectations

Risk for deficient **Fluid** volume: Risk factors: excessive diaphoresis, agitation, decreased fluid intake

Risk for other-directed **Violence**: Risk factor: substance withdrawal

Risk for self-directed **Violence**: Risk factor: substance withdrawal

Readiness for enhanced **Knowledge**: expresses an interest in learning

Alcoholism

Anxiety r/t loss of control

Risk-prone **Health** behavior r/t lack of motivation to change behaviors, addiction

Acute **Confusion** r/t alcohol abuse

Chronic **Confusion** r/t neurological effects of chronic alcohol intake

Defensive **Coping** r/t denial of reality of addiction

Disabled family **Coping** r/t codependency issues due to alcoholism

Ineffective **Coping** r/t use of alcohol to cope with life events

Labile **Emotional Control** r/t substance abuse

Ineffective **Denial** r/t refusal to acknowledge addiction

Dysfunctional **Family** processes r/t alcohol abuse

Impaired **Home** maintenance r/t memory deficits, fatigue

Insomnia r/t irritability, nightmares, tremors

Impaired **Memory** r/t alcohol abuse

Self-Neglect r/t effects of alcohol abuse

Imbalanced **Nutrition**: less than body requirements r/t anorexia, inappropriate diet with increased carbohydrates

Powerlessness r/t alcohol addiction

Ineffective **Protection** r/t malnutrition, sleep deprivation

Chronic low **Self-Esteem** r/t failure at life events

Social isolation r/t unacceptable social behavior, values

Risk for **Injury**: Risk factor: alteration in sensory or perceptual function

Risk for **Loneliness**: Risk factor: unacceptable social behavior

Risk for other-directed **Violence**: Risk factors: reactions to substances used, impulsive behavior, disorientation, impaired judgment

Risk for self-directed **Violence**: Risk factors: reactions to substances used, impulsive behavior, disorientation, impaired judgment

Alcoholism, Dysfunctional Family Processes

Dysfunctional **Family** processes (See **Family** processes, **dysfunctional**, Section III)

Alkalosis

See *Metabolic Alkalosis*

ALL (Acute Lymphocytic Leukemia)

See *Cancer; Chemotherapy; Child with Chronic Condition; Leukemia*

Allergies

Latex Allergy response r/t hypersensitivity to natural rubber latex

Risk for **Allergy** response: Risk factors: chemical factors, dander, environmental substances, foods, insect stings, medications

Risk for **Latex Allergy** response: Risk factor: repeated exposure to products containing latex

Readiness for enhanced **Knowledge**: expresses an interest in learning

Alopecia

Disturbed **Body Image** r/t loss of hair, change in appearance

Readiness for enhanced **Knowledge**: expresses an interest in learning

Altered Mental Status

See *Confusion, Acute; Confusion, Chronic; Memory Deficit*

ALS (Amyotrophic Lateral Sclerosis)

See *Amyotrophic Lateral Sclerosis (ALS)*

Alzheimer's Disease

Caregiver role strain r/t duration and extent of caregiving required

Chronic **Confusion** r/t loss of cognitive function

Compromised family **Coping** r/t interrupted family processes

Frail Elderly syndrome r/t alteration in cognitive functioning

Impaired **Home** maintenance r/t impaired cognitive function, inadequate support systems

Hopelessness r/t deteriorating condition

Insomnia r/t neurological impairment, daytime naps

Impaired **Memory** r/t neurological disturbance

Impaired physical **Mobility** r/t severe neurological dysfunction

Self-Neglect r/t loss of cognitive function

Powerlessness r/t deteriorating condition

Self-Care deficit: specify r/t loss of cognitive function, psychological impairment

Social isolation r/t fear of disclosure of memory loss

Wandering r/t cognitive impairment, frustration, physiological state

Risk for chronic functional **Constipation**: Risk factor: impaired cognitive functioning

Risk for **Injury**: Risk factor: confusion

Risk for **Loneliness**: Risk factor: potential social isolation

Risk for **Relocation** stress syndrome: Risk factors: impaired psychosocial health, decreased health status

Risk for other-directed **Violence**: Risk factors: frustration, fear, anger, loss of cognitive function

Readiness for enhanced **Knowledge**: Caregiver: expresses an interest in learning

See *Dementia*

AMD (Age-Related Macular Degeneration)

See *Macular Degeneration*

A

Amenorrhea

Imbalanced **Nutrition**: less than body requirements r/t inadequate food intake

See *Sexuality, Adolescent*

AMI (Acute Myocardial Infarction)

See *MI (Myocardial Infarction)*

Amnesia

Acute **Confusion** r/t alcohol abuse, delirium, dementia, drug abuse

Dysfunctional **Family** processes r/t alcohol abuse, inadequate coping skills

Impaired **Memory** r/t excessive environmental disturbance, neurological disturbance

Post-Trauma syndrome r/t history of abuse, catastrophic illness, disaster, accident

Amniocentesis

Anxiety r/t threat to self and fetus, unknown future

Decisional Conflict r/t choice of treatment pending results of test

Risk for **Infection**: Risk factor: invasive procedure

Amnionitis

See *Chorioamnionitis*

Amniotic Membrane Rupture

See *Premature Rupture of Membranes*

Amputation

Disturbed **Body Image** r/t negative effects of amputation, response from others

Grieving r/t loss of body part, future lifestyle changes

Impaired physical **Mobility** r/t musculoskeletal impairment, limited movement

Acute **Pain** r/t surgery, phantom limb sensation

Chronic **Pain** r/t surgery, phantom limb sensation

Ineffective peripheral **Tissue Perfusion** r/t impaired arterial circulation

Impaired **Skin** integrity r/t poor healing, prosthesis rubbing

Risk for **Bleeding**: Risk factor: vulnerable surgical site

Risk for Impaired **Tissue** integrity: Risk factor: mechanical factors impacting site

Readiness for enhanced **Knowledge**: expresses an interest in learning

Amyotrophic Lateral Sclerosis (ALS)

Death **Anxiety** r/t impending progressive loss of function leading to death

Ineffective **Breathing** pattern r/t compromised muscles of respiration

Impaired verbal **Communication** r/t weakness of muscles of speech, deficient knowledge of ways to compensate and alternative communication devices

Decisional Conflict: ventilator therapy r/t unclear personal values or beliefs, lack of relevant information

Impaired **Resilience** r/t perceived vulnerability

Chronic **Sorrow** r/t chronic illness

Impaired **Swallowing** r/t weakness of muscles involved in swallowing

Impaired spontaneous **Ventilation** r/t weakness of muscles of respiration

Risk for **Aspiration**: Risk factor: impaired swallowing

Risk for **Spiritual** distress: Risk factor: chronic debilitating condition

See *Neurologic Disorders*

Anal Fistula

See *Hemorrhoidectomy*

Anaphylactic Shock

Deficient **Fluid** volume r/t compromised regulatory mechanism

Ineffective **Airway** clearance r/t laryngeal edema, bronchospasm

Latex Allergy response r/t abnormal immune mechanism response

Impaired spontaneous **Ventilation** r/t acute airway obstruction from anaphylaxis process

Anaphylaxis Prevention

Risk for **Allergy** response (See **Allergy** response, risk for, Section III)

Anasarca

Excess **Fluid** volume r/t excessive fluid intake, cardiac/renal dysfunction, loss of plasma proteins

Risk for impaired **Skin** integrity: Risk factor: impaired circulation to skin from edema

See *Anasarca*

Anemia

Anxiety r/t cause of disease

Impaired **Comfort** r/t feelings of always being cold from decreased hemoglobin and decreased metabolism

Fatigue r/t decreased oxygen supply to the body, increased cardiac workload

Impaired **Memory** r/t change in cognition from decreased oxygen supply to the body

Delayed **Surgical** recovery r/t decreased oxygen supply to body, increased cardiac workload

Risk for **Bleeding** (See **Bleeding**, risk for, Section III)

Risk for **Injury**: Risk factor: alteration in peripheral sensory perception

Readiness for enhanced **Knowledge**: expresses an interest in learning

Anemia, in Pregnancy

Anxiety r/t concerns about health of self and fetus

Fatigue r/t decreased oxygen supply to the body, increased cardiac workload

Risk for **delayed Development**: Risk factor: reduction in the oxygen-carrying capacity of blood

Risk for **Infection**: Risk factor: reduction in oxygen-carrying capacity of blood

Risk for disturbed **Maternal–Fetal** dyad: Risk factor: compromised oxygen transport

Readiness for enhanced **Knowledge**: expresses an interest in learning

Anemia, Sickle Cell

See *Anemia; Sickle Cell Anemia/Crisis*

Anencephaly

See *Neural Tube Defects*

Aneurysm, Abdominal Surgery

Risk for deficient **Fluid** volume: Risk factor: hemorrhage r/t potential abnormal blood loss

Risk for **Infection**: Risk factor: invasive procedure

Risk for ineffective **Gastrointestinal** perfusion (See **Gastrointestinal perfusion, ineffective, risk for, Section III**)

Risk for ineffective **Renal** perfusion: Risk factor: prolonged ischemia of kidneys

See *Abdominal Surgery*

Aneurysm, Cerebral

See *Craniectomy/Craniotomy; Subarachnoid Hemorrhage*

Anger

Anxiety r/t situational crisis

Defensive **Coping** r/t inability to acknowledge responsibility for actions and results of actions

Labile **Emotional Control** r/t stressors

Fear r/t environmental stressor, hospitalization

Grieving r/t significant loss

Risk-prone **Health** behavior r/t assault to self-esteem, disability requiring change in lifestyle, inadequate support system

Powerlessness r/t health care environment

Risk for compromised **Human Dignity**: Risk factors: inadequate participation in decision-making, perceived dehumanizing treatment, perceived humiliation, exposure of the body, cultural incongruity

Risk for **Post-Trauma** syndrome: Risk factor: inadequate social support

Risk for other-directed **Violence**: Risk factors: history of violence, rage reaction

Risk for self-directed **Violence**: Risk factors: history of violence, history of abuse, rage reaction

Angina

Activity intolerance r/t acute pain, dysrhythmias

Anxiety r/t situational crisis

Decreased **Cardiac** output r/t myocardial ischemia, medication effect, dysrhythmia

Ineffective **Coping** r/t personal vulnerability to situational crisis of new diagnosis, deteriorating health

Ineffective **Denial** r/t deficient knowledge of need to seek help with symptoms

Grieving r/t pain, loss of health

Acute **Pain** r/t myocardial ischemia

Ineffective **Sexuality** pattern r/t disease process, medications, loss of libido

Readiness for enhanced **Knowledge**: expresses an interest in learning

Angiocardiology (Cardiac Catheterization)

See *Cardiac Catheterization*

Angioplasty, Coronary

Fear r/t possible outcome of interventional procedure

Ineffective peripheral **Tissue Perfusion** r/t vasospasm, hematoma formation

Risk for **Bleeding**: Risk factors: possible damage to coronary artery, hematoma formation

Risk for decreased **Cardiac** tissue perfusion: Risk factors: ventricular ischemia, dysrhythmias

Readiness for enhanced **Knowledge**: expresses an interest in learning

Anomaly, Fetal/Newborn (Parent Dealing with)

Anxiety r/t threat to role functioning, situational crisis

Decisional Conflict: interventions for fetus or newborn r/t lack of relevant information, spiritual distress, threat to value system

Disabled family **Coping** r/t chronically unresolved feelings about loss of perfect baby

Ineffective **Coping** r/t personal vulnerability in situational crisis

Interrupted **Family** processes r/t unmet expectations for perfect baby, lack of adequate support systems

Fear r/t real or imagined threat to baby, implications for future pregnancies, powerlessness

Grieving r/t loss of ideal child

Hopelessness r/t long-term stress, deteriorating physical condition of child, lost spiritual belief

Deficient **Knowledge** r/t limited exposure to situation

Impaired **Parenting** r/t interruption of bonding process

Powerlessness r/t complication threatening fetus or newborn

Parental **Role** conflict r/t separation from newborn, intimidation with invasive or restrictive modalities, specialized care center policies

Situational low **Self-Esteem** r/t perceived inability to produce a perfect child

Social isolation r/t alterations in child's physical appearance, altered state of wellness

Chronic **Sorrow** r/t loss of ideal child, inadequate bereavement support

A

Spiritual distress r/t test of spiritual beliefs

Risk for impaired **Attachment**: Risk factor: ill infant unable to effectively initiate parental contact as result of altered behavioral organization

Risk for disorganized **Infant** behavior: Risk factor: congenital disorder

Risk for impaired **Parenting**: Risk factors: interruption of bonding process; unrealistic expectations for self, infant, or partner; perceived threat to own emotional survival; severe stress; lack of knowledge

Risk for **Spiritual** distress: Risk factor: lack of normal child to raise and carry on family name

Anorectal Abscess

Disturbed **Body Image** r/t odor and drainage from rectal area

Acute **Pain** r/t inflammation of perirectal area

Risk for **Constipation**: Risk factor: fear of painful elimination

Readiness for enhanced **Knowledge**: expresses an interest in learning

Anorexia

Deficient **Fluid** volume r/t inability to drink

Imbalanced **Nutrition**: less than body requirements r/t loss of appetite, nausea, vomiting, laxative abuse

Delayed **Surgical** recovery r/t inadequate nutritional intake

Risk for delayed **Surgical** recovery: Risk factor: inadequate nutritional intake

Anorexia Nervosa

Activity intolerance r/t fatigue, weakness

Disturbed **Body Image** r/t misconception of actual body appearance

Constipation r/t lack of adequate food, fiber, and fluid intake

Defensive **Coping** r/t psychological impairment, eating disorder

Disabled family **Coping** r/t highly ambivalent family relationships

Ineffective **Denial** r/t fear of consequences of therapy, possible weight gain

Diarrhea r/t laxative abuse

Interrupted **Family** processes r/t situational crisis

Ineffective family **Health** management r/t family conflict, excessive demands on family associated with complexity of condition and treatment

Imbalanced **Nutrition**: less than body requirements r/t inadequate food intake, excessive exercise

Chronic low **Self-Esteem** r/t repeated unmet expectations

Ineffective **Sexuality** pattern r/t loss of libido from malnutrition

Risk for **Infection**: Risk factor: malnutrition resulting in depressed immune system

Risk for **Spiritual** distress: Risk factor: low self-esteem

See *Maturational Issues, Adolescent*

Anosmia (Smell, Loss of Ability to)

Imbalanced **Nutrition**: less than body requirements r/t loss of appetite associated with loss of smell

Antepartum Period

See *Pregnancy, Normal; Prenatal Care, Normal*

Anterior Repair, Anterior Colporrhaphy

Urinary Retention r/t edema of urinary structures

Risk for urge urinary **Incontinence**: Risk factor: trauma to bladder

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Vaginal Hysterectomy*

Anticoagulant Therapy

Risk for **Bleeding**: Risk factor: altered clotting function from anticoagulant

Risk for deficient **Fluid** volume: hemorrhage: Risk factor: altered clotting mechanism

Readiness for enhanced **Knowledge**: expresses an interest in learning

Antisocial Personality Disorder

Defensive **Coping** r/t excessive use of projection

Ineffective **Coping** r/t frequently violating the norms and rules of society

Labile **Emotional Control** r/t psychiatric disorder

Hopelessness r/t abandonment

Impaired **Social** interaction r/t sociocultural conflict, chemical dependence, inability to form relationships

Spiritual distress r/t separation from religious or cultural ties

Ineffective **Health** management r/t excessive demands on family

Risk for **Loneliness**: Risk factor: inability to interact appropriately with others

Risk for impaired **Parenting**: Risk factors: inability to function as parent or guardian, emotional instability

Risk for **Self-Mutilation**: Risk factors: self-hatred, depersonalization

Risk for other-directed **Violence**: Risk factor: history of violence, altered thought patterns

Anuria

See *Kidney Failure*

Anxiety

See *Anxiety, Section III*

Anxiety Disorder

Ineffective **Activity** planning r/t unrealistic perception of events

Anxiety r/t unmet security and safety needs

Death **Anxiety** r/t fears of unknown, powerlessness

Decisional Conflict r/t low self-esteem, fear of making a mistake

Defensive **Coping** r/t overwhelming feelings of dread

Disabled family **Coping** r/t ritualistic behavior, actions
 Ineffective **Coping** r/t inability to express feelings appropriately
 Ineffective **Denial** r/t overwhelming feelings of hopelessness, fear, threat to self

Insomnia r/t psychological impairment, emotional instability
 Impaired **Mood** regulation r/t functional impairment, impaired social functioning, alteration in sleep pattern

Labile **Emotional Control** r/t emotional instability

Powerlessness r/t lifestyle of helplessness

Self-Care deficit r/t ritualistic behavior, activities

Sleep deprivation r/t prolonged psychological discomfort

Risk for **Spiritual** distress: Risk factor: psychological distress

Readiness for enhanced **Knowledge**: expresses an interest in learning

Aortic Aneurysm Repair (Abdominal Surgery)

See *Abdominal Surgery; Aneurysm, Abdominal Surgery*

Aortic Valvular Stenosis

See *Congenital Heart Disease/Cardiac Anomalies*

Aphasia

Anxiety r/t situational crisis of aphasia

Impaired verbal **Communication** r/t decrease in circulation to brain

Ineffective **Coping** r/t loss of speech

Ineffective **Health** maintenance r/t deficient knowledge regarding information on aphasia and alternative communication techniques

Aplastic Anemia

Activity intolerance r/t imbalance between oxygen supply and demand

Fear r/t ability to live with serious disease

Risk for **Bleeding**: Risk factor: inadequate clotting factors

Risk for **Infection**: Risk factor: inadequate immune function

Readiness for enhanced **Knowledge**: expresses an interest in learning

Apnea in Infancy

See *Premature Infant (Child); Premature Infant (Parent); SIDS (Sudden Infant Death Syndrome)*

Apneustic Respirations

Ineffective **Breathing** pattern r/t perception or cognitive impairment, neurological impairment

See *Apneustic Respirations*

Appendectomy

Deficient **Fluid** volume r/t fluid restriction, hypermetabolic state, nausea, vomiting

Acute **Pain** r/t surgical incision

Delayed **Surgical** recovery r/t rupture of appendix

Risk for **Infection**: Risk factors: perforation or rupture of appendix, surgical incision, peritonitis

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Hospitalized Child; Surgery, Postoperative Care*

Appendicitis

Deficient **Fluid** volume r/t anorexia, nausea, vomiting

Acute **Pain** r/t inflammation

Risk for **Infection**: Risk factor: possible perforation of appendix

Readiness for enhanced **Knowledge**: expresses an interest in learning

Apprehension

Anxiety r/t threat to self-concept, threat to health status, situational crisis

Death **Anxiety** r/t apprehension over loss of self, consequences to significant others

ARDS (Acute Respiratory Distress Syndrome)

Ineffective **Airway** clearance r/t excessive tracheobronchial secretions

Death **Anxiety** r/t seriousness of physical disease

Impaired **Gas** exchange r/t damage to alveolar capillary membrane, change in lung compliance

Impaired spontaneous **Ventilation** r/t damage to alveolar capillary membrane

See *Ventilated Client, Mechanically*

Arrhythmia

See *Dysrhythmia*

Arterial Insufficiency

Ineffective peripheral **Tissue Perfusion** r/t interruption of arterial flow

Delayed **Surgical** recovery r/t ineffective tissue perfusion

Arthritis

Activity intolerance r/t chronic pain, fatigue, weakness

Disturbed **Body Image** r/t ineffective coping with joint abnormalities

Impaired physical **Mobility** r/t joint impairment

Chronic **Pain** r/t progression of joint deterioration

Self-Care deficit: specify r/t pain with movement, damage to joints

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *JRA (Juvenile Rheumatoid Arthritis)*

Arthrocentesis

Acute **Pain** r/t invasive procedure

Arthroplasty (Total Hip Replacement)

See *Total Joint Replacement (Total Hip/Total Knee/Shoulder); Surgery, Perioperative; Surgery, Postoperative Care; Surgery, Preoperative Care*

A

Arthroscopy

Impaired physical **Mobility** r/t surgical trauma of knee

Readiness for enhanced **Knowledge**: expresses an interest in learning

Ascites

Ineffective **Breathing** pattern r/t increased abdominal girth

Imbalanced **Nutrition**: less than body requirements r/t loss of appetite

Chronic **Pain** r/t altered body function

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Ascites; Cancer; Cirrhosis*

Asperger's Syndrome

Ineffective **Relationship** r/t poor communication skills, lack of empathy

See *Autism*

Asphyxia, Birth

Ineffective **Breathing** pattern r/t depression of breathing reflex secondary to anoxia

Ineffective **Coping** r/t uncertainty of child outcome

Fear (parental) r/t concern over safety of infant

Impaired **Gas** exchange r/t poor placental perfusion, lack of initiation of breathing by newborn

Grieving r/t loss of perfect child, concern of loss of future abilities

Impaired spontaneous **Ventilation** r/t brain injury

Risk for impaired **Attachment**: Risk factors: ill infant who is unable to initiate parental contact, hospitalization in critical care environment

Risk for delayed **Development**: Risk factor: lack of oxygen to brain

Risk for disproportionate **Growth**: Risk factor: lack of oxygen to brain

Risk for disorganized **Infant** behavior: Risk factor: lack of oxygen to brain

Risk for **Injury**: Risk factor: lack of oxygen to brain

Risk for ineffective **Cerebral** tissue perfusion: Risk factor: poor placental perfusion or cord compression resulting in lack of oxygen to brain

Aspiration, Danger of

Risk for **Aspiration** (See *Aspiration, risk for, Section III*)

Assault Victim

Post-Trauma syndrome r/t assault

Rape-Trauma syndrome r/t rape

Impaired **Resilience** r/t frightening experience, post-trauma stress response

Risk for **Post-Trauma** syndrome: Risk factors: perception of event, inadequate social support, unsupportive environment, diminished ego strength, duration of event

Risk for **Spiritual** distress: Risk factors: physical, psychological stress

Assaultive Client

Risk for **Injury**: Risk factors: confused thought process, impaired judgment

Risk for other-directed **Violence**: Risk factors: paranoid ideation, anger

Asthma

Activity intolerance r/t fatigue, energy shift to meet muscle needs for breathing to overcome airway obstruction

Ineffective **Airway** clearance r/t tracheobronchial narrowing, excessive secretions

Anxiety r/t inability to breathe effectively, fear of suffocation

Disturbed **Body Image** r/t decreased participation in physical activities

Ineffective **Breathing** pattern r/t anxiety

Ineffective **Coping** r/t personal vulnerability to situational crisis

Ineffective **Health** management (See *Health management, ineffective, in Section III*)

Impaired **Home** maintenance r/t deficient knowledge regarding control of environmental triggers

Sleep deprivation r/t ineffective breathing pattern, cough

Readiness for enhanced **Health** management (See *Health management, readiness for enhanced, in Section III*)

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Child with Chronic Condition; Hospitalized Child*

Ataxia

Anxiety r/t change in health status

Disturbed **Body Image** r/t staggering gait

Impaired physical **Mobility** r/t neuromuscular impairment

Risk for **Falls**: Risk factors: gait alteration, instability

Atelectasis

Ineffective **Breathing** pattern r/t loss of functional lung tissue, depression of respiratory function or hypoventilation because of pain

Impaired **Gas** exchange r/t decreased alveolar-capillary surface

Anxiety r/t alteration in respiratory pattern

See *Atelectasis*

Atherosclerosis

See *MI (Myocardial Infarction); CVA (Cerebrovascular Accident); Peripheral Vascular Disease (PVD)*

Athlete's Foot

Impaired **Skin** integrity r/t effects of fungal agent

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Itching; Pruritus*

ATN (Acute Tubular Necrosis)

See *Kidney Failure*

Atrial Fibrillation

See *Dysrhythmia*

Atrial Septal Defect

See *Congenital Heart Disease/Cardiac Anomalies*

Attention Deficit Disorder

Risk-prone **Health** behavior r/t intense emotional state
 Disabled family **Coping** r/t significant person with chronically unexpressed feelings of guilt, anxiety, hostility, and despair
 Ineffective **Impulse** control r/t (See **Impulse control, ineffective, Section III**)
 Chronic low **Self-Esteem** r/t difficulty in participating in expected activities, poor school performance
Social isolation r/t unacceptable social behavior
 Risk for delayed **Development**: Risk factor: behavior disorders
 Risk for **Falls**: Risk factor: rapid non-thinking behavior
 Risk for **Loneliness**: Risk factor: social isolation
 Risk for impaired **Parenting**: Risk factor: lack of knowledge of factors contributing to child's behavior
 Risk for **Spiritual** distress: Risk factor: poor relationships

Auditory Problems

See *Hearing Impairment*

Autism

Impaired verbal **Communication** r/t speech and language delays
 Compromised family **Coping** r/t parental guilt over etiology of disease, inability to accept or adapt to child's condition, inability to help child and other family members seek treatment
 Disturbed personal **Identity** r/t inability to distinguish between self and environment, inability to identify own body as separate from those of other people, inability to integrate concept of self
Self-Neglect r/t impaired socialization
 Impaired **Social** interaction r/t communication barriers, inability to relate to others, failure to develop peer relationships
 Risk for delayed **Development**: Risk factor: autism
 Risk for **Loneliness**: Risk factor: difficulty developing relationships with other people
 Risk for **Self-Mutilation**: Risk factor: autistic state
 Risk for other-directed **Violence**: Risk factors: frequent destructive rages toward others secondary to extreme response to changes in routine, fear of harmless things
 Risk for self-directed **Violence**: Risk factors: frequent destructive rages toward self, secondary to extreme response to changes in routine, fear of harmless things

See *Child with Chronic Condition*

Autonomic Dysreflexia

Autonomic Dysreflexia r/t bladder distention, bowel distention, noxious stimuli

Risk for **Autonomic Dysreflexia**: Risk factors: bladder distention, bowel distention, noxious stimuli

Autonomic Hyperreflexia

See *Autonomic Dysreflexia*

B

Baby Care

Readiness for enhanced **Childbearing** process: demonstrates appropriate feeding and baby care techniques, along with attachment to infant and providing a safe environment
Anxiety r/t situational crisis, back injury
 Ineffective **Coping** r/t situational crisis, back injury
 Impaired physical **Mobility** r/t pain
 Acute **Pain** r/t back injury
 Chronic **Pain** r/t back injury
 Risk for **Constipation**: Risk factors: decreased activity, side effect of pain medication
 Risk for **Disuse** syndrome: Risk factor: severe pain
 Readiness for enhanced **Knowledge**: expresses an interest in learning

Bacteremia

Risk for **Infection**: Risk factor: compromised immune system
 Risk for **Shock**: Risk factor: development of systemic inflammatory response from presence of bacteria in bloodstream
 See *Infection; Infection, Potential for*

Barrel Chest

See *Aging (if appropriate); COPD (Chronic Obstructive Pulmonary Disease)*

Bathing/Hygiene Problems

Impaired **Mobility** r/t chronic physically limiting condition
Self-Neglect (See **Self-Neglect, Section III**)
 Bathing **Self-Care** deficit (See **Self-Care deficit, bathing, Section III**)

Battered Child Syndrome

Dysfunctional **Family** processes r/t inadequate coping skills
Sleep deprivation r/t prolonged psychological discomfort
 Chronic **Sorrow** r/t situational crises
 Risk for **Post-Trauma** syndrome: Risk factors: physical abuse, incest, rape, molestation
 Risk for **Self-Mutilation**: Risk factors: feelings of rejection, dysfunctional family
 Risk for **Suicide**: Risk factor: childhood abuse
 See *Child Abuse*

List of Nursing Assessments by Letter: B

Baby Care	Bacteremia	Barrel Chest
Bathing/Hygiene Problems	Battered Child Syndrome	Battered Person
Bedbugs, Infestation	Bed Mobility, Impaired	Bed Rest, Prolonged
Bedsores	Bedwetting	Bell's Palsy
Benign Prostatic Hypertrophy	Bereavement	Biliary Atresia
Biliary Calculus	Biliary Obstruction	Bilirubin Elevation in Neonate
Biopsy	Bioterrorism	Bipolar Disorder I (Most Recent Episode, Depressed or Manic)
Birth Asphyxia	Birth Control	Bladder Cancer
Bladder Distention	Bladder Training	Bladder Training, Child
Bleeding Tendency	Blepharoplasty	Blindness
Blood Disorder	Blood Pressure Alteration	Blood Sugar Control
Blood Transfusion	Body Dysmorphic Disorder	Body Image Change
Body Temperature, Altered	Bone Marrow Biopsy	Borderline Personality Disorder
Boredom	Botulism	Bowel Incontinence
Bowel Obstruction	Bowel Resection	Bowel Sounds, Absent or Diminished
Bowel Sounds, Hyperactive	Bowel Training	Bowel Training, Child
BPH (Benign Prostatic Hypertrophy)	Bradycardia	Bradypnea
Brain Injury	Brain Surgery	Brain Tumor
Braxton Hicks Contractions	Breast Biopsy	Breast Cancer
Breast Examination, Self	Breast Lumps	Breast Pumping
Breastfeeding, Effective	Breastfeeding, Ineffective	Breastfeeding, Interrupted
Breast Milk, Insufficient	Breath Sounds, Decreased or Absent	Breathing Pattern Alteration
Breech Birth	Bronchitis	Bronchopulmonary Dysplasia
Bronchoscopy	Bruits, Carotid	Bryant's Traction
Buck's Traction	Buerger's Disease	Bulimia
Bunion	Bunionectomy	Burn Risk
Burns	Bursitis	Bypass Graft

Battered Person

See *Abuse, Spouse, Parent, or Significant Other*

Bedbugs, Infestation

Impaired **Home** maintenance r/t deficient knowledge regarding prevention of bedbug infestation

Impaired **Skin** integrity r/t bites of bedbugs

See *Itching; Pruritus*

Bed Mobility, Impaired

Impaired bed **Mobility** (See **Mobility, bed, impaired, Section III**)

Bed Rest, Prolonged

Deficient **Diversional** activity r/t prolonged bed rest

Impaired bed **Mobility** r/t neuromuscular impairment

Social isolation r/t prolonged bed rest

Risk for chronic functional **Constipation**: Risk factor: insufficient physical activity

Risk for **Disuse** syndrome: Risk factor: prolonged immobility

Risk for **Frail Elderly** syndrome: Risk factor: prolonged immobility

Risk for **Loneliness**: Risk factor: prolonged bed rest

Risk for **Overweight**: Risk factor: energy expenditure below energy intake

Risk for **Pressure** ulcer: Risk factor: prolonged immobility

Bedsore

See *Pressure Ulcer*

Bedwetting

Ineffective **Health** maintenance r/t unachieved developmental level, neuromuscular immaturity, diseases of the urinary system

Bell's Palsy

Disturbed **Body Image** r/t loss of motor control on one side of face

Imbalanced **Nutrition**: less than body requirements r/t difficulty with chewing

Acute **Pain** r/t inflammation of facial nerve

Risk for **Injury** (eye): Risk factors: decreased tears, decreased blinking of eye

Readiness for enhanced **Knowledge**: expresses an interest in learning

Benign Prostatic Hypertrophy

See *BPH (Benign Prostatic Hypertrophy); Prostatic Hypertrophy*

Bereavement

Grieving r/t loss of significant person

Insomnia r/t grief

Risk for complicated **Grieving**: Risk factor: emotional instability, lack of social support

Risk for **Spiritual** distress: Risk factor: death of a loved one

Biliary Atresia

Anxiety r/t surgical intervention, possible liver transplantation
Impaired **Comfort** r/t inflammation of skin, itching

Imbalanced **Nutrition**: less than body requirements r/t decreased absorption of fat and fat-soluble vitamins, poor feeding

Risk for **Bleeding**: Risk factors: vitamin K deficiency, altered clotting mechanisms

Risk for ineffective **Breathing** pattern: Risk factors: enlarged liver, development of ascites

Risk for impaired **Skin** integrity: Risk factor: pruritus

See *Child with Chronic Condition; Cirrhosis (as complication); Hospitalized Child; Terminally Ill: Child, Adolescent; Infant/Toddler; Preschool Child; School-Age Child/Preadolescent; Death of Child, Parent*

Biliary Calculus

See *Cholelithiasis*

Biliary Obstruction

See *Jaundice*

Bilirubin Elevation in Neonate

Neonatal **Jaundice** (See **Jaundice, Neonatal, Section III**)

Biopsy

Fear r/t outcome of biopsy

Readiness for enhanced **Knowledge**: expresses an interest in learning

Bioterrorism

Contamination r/t exposure to bioterrorism

Risk for **Infection**: Risk factor: exposure to harmful biological agent

Risk for **Post-Trauma** syndrome: Risk factor: perception of event of bioterrorism

Bipolar Disorder I (Most Recent Episode, Depressed or Manic)

Ineffective **Activity** planning r/t unrealistic perception of events

Fatigue r/t psychological demands

Risk-prone **Health** behavior r/t low state of optimism

Ineffective **Health** maintenance r/t lack of ability to make good judgments regarding ways to obtain help

Self-Care deficit: specify r/t depression, cognitive impairment

Chronic low **Self-Esteem** r/t repeated unmet expectations

Social isolation r/t ineffective coping

Risk for complicated **Grieving**: Risk factor: lack of previous resolution of former grieving response

Risk for **Loneliness**: Risk factors: stress, conflict

Risk for **Spiritual** distress: Risk factor: mental illness

Risk for **Suicide**: Risk factors: psychiatric disorder, poor support system

See *Depression (Major Depressive Disorder); Manic Disorder, Bipolar I*

Birth Asphyxia

See *Asphyxia, Birth*

Birth Control

See *Contraceptive Method*

Bladder Cancer

Urinary Retention r/t clots obstructing urethra

See *Cancer; TURP (Transurethral Resection of the Prostate)*

Bladder Distention

Urinary Retention r/t high urethral pressure caused by weak detrusor, inhibition of reflex arc, blockage, strong sphincter

Bladder Training

Disturbed **Body Image** r/t difficulty maintaining control of urinary elimination

Functional urinary **Incontinence** r/t altered environment; sensory, cognitive, mobility deficit

Stress urinary **Incontinence** r/t degenerative change in pelvic muscles and structural supports

Urge urinary **Incontinence** r/t decreased bladder capacity, increased urine concentration, overdistention of bladder

Readiness for enhanced **Knowledge**: expresses an interest in learning

Bladder Training, Child

See *Toilet Training*

Bleeding Tendency

Risk for **Bleeding** (See **Bleeding**, risk for, Section III)

Risk for delayed **Surgical** recovery: Risk factor: bleeding tendency

Blepharoplasty

Disturbed **Body Image** r/t effects of surgery

Readiness for enhanced **Knowledge**: expresses an interest in learning

Blindness

Interrupted **Family** processes r/t shift in health status of family member (change in visual acuity)

Impaired **Home** maintenance r/t decreased vision

Ineffective **Role** performance r/t alteration in health status (change in visual acuity)

Self-Care deficit: specify r/t inability to see to be able to perform activities of daily living

Vision Loss r/t impaired sensory reception, transmission, or integration (see *care plan in Appendix*)

Risk for delayed **Development**: Risk factor: vision impairment

Risk for **Injury**: Risk factor: sensory dysfunction

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Vision Impairment*

Blood Disorder

Ineffective **Protection** r/t abnormal blood profile

Risk for **Bleeding**: Risk factor: abnormal blood profile

See *ITP (Idiopathic Thrombocytopenic Purpura), Hemophilia, Lacerations, Shock, Hypovolemic*

Blood Pressure Alteration

See *Hypotension; HTN (Hypertension)*

Blood Sugar Control

Risk for unstable blood **Glucose** level (See **Glucose** level, blood, unstable, risk for, Section III)

Blood Transfusion

Anxiety r/t possibility of harm from transfusion

See *Anemia*

Body Dysmorphic Disorder

Anxiety r/t perceived defect of body

Disturbed **Body Image** r/t overinvolvement in physical appearance

Chronic low **Self-Esteem** r/t lack of self valuing because of perceived body defects

Social isolation r/t distancing self from others because of perceived self body defects

Risk for **Suicide**: Risk factor: perceived defects of body affecting self-valuing and hopes

Body Image Change

Disturbed **Body Image** (See **Body Image**, disturbed, Section III)

Body Temperature, Altered

Ineffective **Thermoregulation** (See **Thermoregulation**, ineffective, Section III)

Bone Marrow Biopsy

Fear r/t unknown outcome of results of biopsy

Acute **Pain** r/t bone marrow aspiration

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *disease necessitating bone marrow biopsy (e.g., Leukemia)*

Borderline Personality Disorder

Ineffective **Activity** planning r/t unrealistic perception of events

Anxiety r/t perceived threat to self-concept

Defensive **Coping** r/t difficulty with relationships, inability to accept blame for own behavior

Ineffective **Coping** r/t use of maladjusted defense mechanisms (e.g., projection, denial)

Powerlessness r/t lifestyle of helplessness

Social isolation r/t immature interests

Ineffective family **Health** management r/t manipulative behavior of client

Risk for **Caregiver Role Strain**: Risk factors: inability of care receiver to accept criticism, care receiver taking advantage of others to meet own needs or having unreasonable expectations

Risk for **Self-Mutilation**: Risk factors: ineffective coping, feelings of self-hatred

Risk for **Spiritual** distress: Risk factor: poor relationships associated with abnormal behaviors

Risk for self-directed **Violence**: Risk factors: feelings of need to punish self, manipulative behavior

Boredom

Deficient **Diversional** activity r/t environmental lack of diversional activity

Impaired **Mood** regulation r/t emotional instability

Social isolation r/t altered state of wellness

Botulism

Deficient **Fluid** volume r/t profuse diarrhea

Readiness for enhanced **Knowledge**: expresses an interest in learning

Bowel Incontinence

Bowel **Incontinence** r/t decreased awareness of need to defecate, loss of sphincter control, fecal impaction

Readiness for enhanced **Knowledge**: expresses an interest in learning

Bowel Obstruction

Constipation r/t decreased motility, intestinal obstruction

Deficient **Fluid** volume r/t inadequate fluid volume intake, fluid loss in bowel

Imbalanced **Nutrition**: less than body requirements r/t nausea, vomiting

Acute **Pain** r/t pressure from distended abdomen

Bowel Resection

See *Abdominal Surgery*

Bowel Sounds, Absent or Diminished

Constipation r/t decreased or absent peristalsis

Deficient **Fluid** volume r/t inability to ingest fluids, loss of fluids in bowel

Delayed **Surgical** recovery r/t inability to obtain adequate nutritional status

Risk for dysfunctional **Gastrointestinal** motility (See **Gastrointestinal** motility, dysfunctional, risk for, Section III)

Bowel Sounds, Hyperactive

Diarrhea r/t increased gastrointestinal motility

Bowel Training

Bowel **Incontinence** r/t loss of control of rectal sphincter

Readiness for enhanced **Knowledge**: expresses an interest in learning

Bowel Training, Child

See *Toilet Training*

BPH (Benign Prostatic Hypertrophy)

Ineffective **Health** maintenance r/t deficient knowledge regarding self-care with prostatic hypertrophy

Insomnia r/t nocturia

Urinary Retention r/t obstruction of urethra

Risk for urge urinary **Incontinence**: Risk factors: detrusor muscle instability with impaired contractility, involuntary sphincter relaxation

Risk for **Infection**: Risk factors: urinary residual after voiding, bacterial invasion of bladder

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Prostatic Hypertrophy*

Bradycardia

Decreased **Cardiac** output r/t slow heart rate supplying inadequate amount of blood for body function

Risk for ineffective **Cerebral** tissue perfusion: Risk factors: decreased cardiac output secondary to bradycardia, vagal response

Readiness for enhanced **Knowledge**: expresses an interest in learning

Bradypnea

Ineffective **Breathing** pattern r/t neuromuscular impairment, pain, musculoskeletal impairment, perception or cognitive impairment, anxiety, fatigue or decreased energy, effects of drugs

See *Sleep apnea* (See **Airway** clearance, ineffective, Section III)

Brain Injury

See *Intracranial Pressure, Increased*

Brain Surgery

See *Craniectomy/Craniotomy*

Brain Tumor

Acute **Confusion** r/t pressure from tumor

Fear r/t threat to well-being

Grieving r/t potential loss of physiosocial-psychosocial well-being

Decreased **Intracranial** adaptive capacity r/t presence of brain tumor

Acute **Pain** r/t pressure from tumor

Vision Loss r/t tumor growth compressing optic nerve and/or brain tissue

Risk for **Injury**: Risk factors: sensory-perceptual alterations, weakness

Risk for **Hyperthermia**: Risk factor: loss of thermoregulation with hypothalamic dysfunction

See *Cancer; Chemotherapy; Child with Chronic Condition; Craniectomy/Craniotomy; Hospitalized Child; Radiation Therapy; Terminally Ill Child, Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/Preadolescent; Terminally Ill Child/Death of Child, Parent*

Braxton Hicks Contractions

Activity intolerance r/t increased contractions with increased gestation

Anxiety r/t uncertainty about beginning labor

Fatigue r/t lack of sleep

Stress urinary **Incontinence** r/t increased pressure on bladder with contractions

Insomnia r/t contractions when lying down

Ineffective **Sexuality** pattern r/t fear of contractions associated with loss of infant

Breast Biopsy

Fear r/t potential for diagnosis of cancer

Risk for **Spiritual** distress: Risk factor: fear of diagnosis of cancer

Readiness for enhanced **Knowledge**: expresses an interest in learning

Breast Cancer

Death **Anxiety** r/t diagnosis of cancer

Ineffective **Coping** r/t treatment, prognosis

Fear r/t diagnosis of cancer

Sexual dysfunction r/t loss of body part, partner's reaction to loss

Chronic **Sorrow** r/t diagnosis of cancer, loss of body integrity

Risk for **Spiritual** distress: Risk factor: fear of diagnosis of cancer

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Cancer; Chemotherapy; Mastectomy; Radiation Therapy*

Breast Examination, Self

See *SBE (Self-Breast Examination)*

Breast Lumps

Fear r/t potential for diagnosis of cancer

Readiness for enhanced **Knowledge**: expresses an interest in learning

Breast Pumping

Risk for **Infection**: Risk factors: possible contaminated breast pump, incomplete emptying of breast

Risk for impaired **Skin** integrity: Risk factor: high suction

Readiness for enhanced **Knowledge**: expresses an interest in learning

Breastfeeding, Effective

Readiness for enhanced **Breastfeeding** (See **Breastfeeding, readiness for enhanced**, Section III)

Breastfeeding, Ineffective

Ineffective **Breastfeeding** (See **Breastfeeding, ineffective**, Section III)

See *Infant Feeding Pattern, Ineffective; Painful Breasts, Engorgement; Painful Breasts, Sore Nipples*

Breastfeeding, Interrupted

Interrupted **Breastfeeding** (See **Breastfeeding, interrupted**, Section III)

Breast Milk, Insufficient

Insufficient **Breast Milk** (See **Breast Milk, insufficient**, Section III)

Breath Sounds, Decreased or Absent

See *Atelectasis; Pneumothorax*

Breathing Pattern Alteration

Ineffective **Breathing** pattern r/t neuromuscular impairment, pain, musculoskeletal impairment, perception or cognitive impairment, anxiety, decreased energy or fatigue

Breech Birth

Fear: maternal r/t danger to infant, self

Impaired **Gas** exchange: fetal r/t compressed umbilical cord

Risk for **Aspiration**: fetal: Risk factor: birth of body before head

Risk for delayed **Development**: Risk factor: compressed umbilical cord

Risk for impaired **Tissue** integrity: fetal: Risk factor: difficult birth

Risk for impaired **Tissue** integrity: maternal: Risk factor: difficult birth

Bronchitis

Ineffective **Airway** clearance r/t excessive thickened mucus secretion

Readiness for enhanced **Health** management: wishes to stop smoking

Readiness for enhanced **Knowledge**: expresses an interest in learning

Bronchopulmonary Dysplasia

Activity intolerance r/t imbalance between oxygen supply and demand

Excess **Fluid** volume r/t sodium and water retention

Imbalanced **Nutrition**: less than body requirements r/t poor feeding, increased caloric needs as a result of increased work of breathing

See *Child with Chronic Condition; Hospitalized Child; Respiratory Conditions of the Neonate*

Bronchoscopy

Risk for **Aspiration**: Risk factor: temporary loss of gag reflex

Risk for **Injury**: Risk factors: complication of pneumothorax, laryngeal edema, hemorrhage (if biopsy done)

Bruits, Carotid

Risk for ineffective **Cerebral** tissue perfusion: Risk factors: interruption of carotid blood flow to brain

Bryant's Traction

See *Traction and Casts*

Buck's Traction

See *Traction and Casts*

Buerger's Disease

See *Peripheral Vascular Disease (PVD)*

Bulimia

Disturbed **Body Image** r/t misperception about actual appearance, body weight

Compromised family **Coping** r/t chronically unresolved feelings of guilt, anger, hostility

Defensive **Coping** r/t eating disorder

Diarrhea r/t laxative abuse

C

Fear r/t food ingestion, weight gain

Imbalanced **Nutrition**: less than body requirements r/t induced vomiting, excessive exercise, laxative abuse

Powerlessness r/t urge to purge self after eating

Chronic low **Self-Esteem** r/t lack of positive feedback

See *Maturational Issues, Adolescent*

Bunion

Readiness for enhanced **Knowledge**: expresses an interest in learning

Bunionectomy

Impaired physical **Mobility** r/t sore foot

Impaired **Walking** r/t pain associated with surgery

Risk for **Infection**: Risk factors: surgical incision, advanced age

Readiness for enhanced **Knowledge**: expresses an interest in learning

Burn Risk

Risk for **Thermal** injury (See **Thermal injury, risk for, Section III**)

Burns

Anxiety r/t burn injury, treatments

Disturbed **Body Image** r/t altered physical appearance

Deficient **Diversional** activity r/t long-term hospitalization

Fear r/t pain from treatments, possible permanent disfigurement

Deficient **Fluid** volume r/t loss of protective skin

Grieving r/t loss of bodily function, loss of future hopes and plans

Hypothermia r/t impaired skin integrity

Impaired physical **Mobility** r/t pain, musculoskeletal impairment, contracture formation

Imbalanced **Nutrition**: less than body requirements r/t increased metabolic needs, anorexia, protein and fluid loss

Acute **Pain** r/t burn injury, treatments

Chronic **Pain** r/t burn injury, treatments

Ineffective peripheral **Tissue Perfusion** r/t circumferential burns, impaired arterial/venous circulation

Post-Trauma syndrome r/t life-threatening event

Impaired **Skin** integrity r/t injury of skin

Delayed **Surgical** recovery r/t ineffective tissue perfusion

Risk for ineffective **Airway** clearance: Risk factors: potential tracheobronchial obstruction, edema

Risk for deficient **Fluid** volume: Risk factors: loss from skin surface, fluid shift

Risk for **Infection**: Risk factors: loss of intact skin, trauma, invasive sites

Risk for **Peripheral Neurovascular** dysfunction: Risk factor: eschar formation with circumferential burn

Risk for **Post-Trauma** syndrome: Risk factors: perception, duration of event that caused burns

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Hospitalized Child; Safety, Childhood*

Bursitis

Impaired physical **Mobility** r/t inflammation in joint

Acute **Pain** r/t inflammation in joint

Bypass Graft

See *Coronary Artery Bypass Grafting (CABG)*

C

CABG (Coronary Artery Bypass Grafting)

See *Coronary Artery Bypass Grafting (CABG)*

Cachexia

Frail Elderly syndrome r/t fatigue, feeding self-care deficit

Imbalanced **Nutrition**: less than body requirements r/t inability to ingest food because of physiological factors

Risk for **Infection**: Risk factor: inadequate nutrition

Calcium Alteration

See *Hypercalcemia; Hypocalcemia*

Cancer

Activity intolerance r/t side effects of treatment, weakness from cancer

Death **Anxiety** r/t unresolved issues regarding dying

Disturbed **Body Image** r/t side effects of treatment, cachexia

Decisional Conflict r/t selection of treatment choices, continuation or discontinuation of treatment, “do not resuscitate” decision

Constipation r/t side effects of medication, altered nutrition, decreased activity

Compromised family **Coping** r/t prolonged disease or disability progression that exhausts supportive ability of significant others

Ineffective **Coping** r/t personal vulnerability in situational crisis, terminal illness

Ineffective **Denial** r/t complicated grieving process

Fear r/t serious threat to well-being

Grieving r/t potential loss of significant others, high risk for infertility

Ineffective **Health** maintenance r/t deficient knowledge regarding prescribed treatment

Hopelessness r/t loss of control, terminal illness

Insomnia r/t anxiety, pain

Impaired physical **Mobility** r/t weakness, neuromusculoskeletal impairment, pain

List of Nursing Assessments by Letter: C

CABG (Coronary Artery Bypass Grafting)	Cachexia	Calcium Alteration
Cancer	Candidiasis, Oral	Capillary Refill Time, Prolonged
Carbon Monoxide Poisoning	Cardiac Arrest	Cardiac Catheterization
Cardiac Disorders	Cardiac Disorders in Pregnancy	Cardiac Dysrhythmia
Cardiac Output, Decreased	Cardiac Tamponade	Cardiogenic Shock
Cardiovascular Function: Risk for Impaired	Caregiver Role Strain	Carious Teeth
Carotid Endarterectomy	Carpal Tunnel Syndrome	Carpopedal Spasm
Casts	Cataract Extraction	Cataracts
Catatonic Schizophrenia	Catheterization, Urinary	Cavities in Teeth
Celiac Disease	Cellulitis	Cellulitis, Periorbital
Central Line Insertion	Cerebral Aneurysm	Cerebral Palsy
Cerebral Perfusion	Cerebrovascular Accident (CVA)	Cervicitis
Cesarean Delivery	Chemical Dependence	Chemotherapy
Chest Pain	Chest Tubes	Cheyne-Stokes Respiration
CHF (Congestive Heart Failure)	Chickenpox	Child Abuse
Childbearing Problems	Child Neglect	Child with Chronic Condition
Childbirth	Chills	Chlamydia Infection
Chloasma	Choking or Coughing with Eating	Cholecystectomy
Cholelithiasis	Chorioamnionitis	Chronic Confusion
Chronic Functional Constipation	Chronic Lymphocytic Leukemia	Chronic Obstructive Pulmonary Disease (COPD)
Chronic Pain	Chronic Renal Failure (Chronic kidney disease)	Chvostek's Sign
Circumcision	Cirrhosis	Cleft Lip/Cleft Palate
Clotting Disorder	Cocaine Abuse	Cocaine Baby

Codependency	Cold, Viral	Colectomy
Colitis	Collagen Disease	Colostomy
Colporrhaphy, Anterior	Coma	Comfort, Loss of
Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice, Impetigo)	Communication	Communication Problems
Community Coping	Community Health Problems	Compartment Syndrome
Compulsion	Conduction Disorders (Cardiac)	Confusion, Acute
Confusion, Chronic	Confusion, Possible	Congenital Heart Disease/Cardiac Anomalies
Congestive Heart Failure (CHF)/Heart Failure (HF)	Conjunctivitis	Consciousness, Altered Level of
Constipation	Constipation, Chronic Functional	Constipation, Perceived
Constipation, Risk for	Contamination	Continent Ileostomy (Kock Pouch)
Contraceptive Method	Convulsions	COPD (Chronic Obstructive Pulmonary Disease)
Coping	Coping Problems	Corneal Injury
Corneal Reflex, Absent	Corneal Transplant	Coronary Artery Bypass Grafting (CABG)
Costovertebral Angle Tenderness	Cough, Ineffective	Crack Abuse
Crack Baby	Crackles in Lungs, Coarse	Crackles in Lungs, Fine
Craniectomy/Craniotomy	Crepitation, Subcutaneous	Crisis
Crohn's Disease	Croup	Cryosurgery for Retinal Detachment
Cushing's Syndrome	Cuts (Wounds)	CVA (Cerebrovascular Accident)
Cyanosis, Central with Cyanosis of Oral Mucous Membranes	Cyanosis, Peripheral with Cyanosis of Nail Beds	Cystic Fibrosis
Cystitis	Cystocele	Cystoscopy

Imbalanced **Nutrition**: less than body requirements r/t loss of appetite, difficulty swallowing, side effects of chemotherapy, obstruction by tumor

Impaired **Oral Mucous Membrane** r/t chemotherapy, effects of radiation, oral pH changes, decreased oral secretions

Chronic **Pain** r/t metastatic cancer

Powerlessness r/t treatment, progression of disease

Ineffective **Protection** r/t cancer suppressing immune system

Ineffective **Role** performance r/t change in physical capacity, inability to resume prior role

Self-Care deficit: specify r/t pain, intolerance to activity, decreased strength

Impaired **Skin** integrity r/t immunological deficit, immobility

Social isolation r/t hospitalization, lifestyle changes

Chronic **Sorrow** r/t chronic illness of cancer

Spiritual distress r/t test of spiritual beliefs

Risk for **Bleeding**: Risk factor: bone marrow depression from chemotherapy

Risk for **Disuse** syndrome: Risk factors: immobility, fatigue

Risk for impaired **Home** maintenance: Risk factor: lack of familiarity with community resources

Risk for **Infection**: Risk factor: inadequate immune system

Risk for compromised **Resilience**: Risk factors: multiple stressors, pain, chronic illness

Risk for **Spiritual** distress: Risk factor: physical illness of cancer

Readiness for enhanced **Knowledge**: expresses an interest in learning

Readiness for enhanced **Spiritual** well-being: desire for harmony with self, others, higher power, God, when faced with serious illness

See *Chemotherapy; Child with Chronic Condition; Hospitalized Child; Leukemia; Radiation Therapy; Terminally Ill Child, Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/ Preadolescent; Terminally Ill Child/Death of Child, Parent*

Candidiasis, Oral

Readiness for enhanced **Knowledge**: expresses an interest in learning

Impaired **Oral Mucous Membrane** r/t overgrowth of infectious agent, depressed immune function

Acute **Pain** r/t oral condition

Capillary Refill Time, Prolonged

Impaired **Gas** exchange r/t ventilation perfusion imbalance

Ineffective peripheral **Tissue Perfusion** r/t interruption of arterial flow

See *Shock, Hypovolemic*

Carbon Monoxide Poisoning

See *Smoke Inhalation*

Cardiac Arrest

Post-Trauma syndrome r/t experiencing serious life event

See *Dysrhythmia, MI*

Cardiac Catheterization

Fear r/t invasive procedure, uncertainty of outcome of procedure

Risk for **Injury**: hematoma: Risk factor: invasive procedure

Risk for decreased **Cardiac** tissue perfusion: Risk factors: ventricular ischemia, dysrhythmia

Risk for **Peripheral Neurovascular** dysfunction: Risk factor: vascular obstruction

Risk for Impaired **Tissue** integrity: Risk factor: invasive procedure

Readiness for enhanced **Knowledge**: expresses an interest in learning postprocedure care, treatment, and prevention of coronary artery disease

Cardiac Disorders

Decreased **Cardiac** output r/t cardiac disorder

Risk for decreased **Cardiac** tissue perfusion: Risk factor: cardiac disorder

See *specific cardiac disorder*

Cardiac Disorders in Pregnancy

Activity intolerance r/t cardiac pathophysiology, increased demand for cardiac output because of pregnancy, weakness, fatigue

Death **Anxiety** r/t potential danger of condition

Compromised family **Coping** r/t prolonged hospitalization or maternal incapacitation that exhausts supportive capacity of significant others

Ineffective **Coping** r/t personal vulnerability

Interrupted **Family** processes r/t hospitalization, maternal incapacitation, changes in roles

Fatigue r/t physiological, psychological, and emotional demands

Fear r/t potential maternal effects, potential poor fetal or maternal outcome

Powerlessness r/t illness-related regimen

Ineffective **Role** performance r/t changes in lifestyle, expectations from disease process with superimposed pregnancy

Situational low **Self-Esteem** r/t situational crisis, pregnancy

Social isolation r/t limitations of activity, bed rest or hospitalization, separation from family and friends

Risk for decreased **Cardiac** tissue perfusion: Risk factor: strain on compromised heart from work of pregnancy, delivery

Risk for delayed **Development**: Risk factor: poor maternal oxygenation

Risk for deficient **Fluid** volume: Risk factor: sudden changes in circulation after delivery of placenta

Risk for excess **Fluid** volume: Risk factors: compromised regulatory mechanism with increased afterload, preload, circulating blood volume

Risk for impaired **Gas** exchange: Risk factor: pulmonary edema

Risk for disproportionate **Growth**: Risk factor: poor maternal oxygenation

Risk for disturbed **Maternal–Fetal** dyad: Risk factor: compromised oxygen transport

Risk for compromised **Resilience**: Risk factors: multiple stressors, fear

C

Risk for **Spiritual** distress: Risk factor: fear of diagnosis for self and infant

Readiness for enhanced **Knowledge**: expresses an interest in learning

Cardiac Dysrhythmia

See *Dysrhythmia*

Cardiac Output, Decreased

Decreased **Cardiac** output r/t cardiac dysfunction

Decreased **Cardiac** output (See **Cardiac output, decreased**, Section III)

Oliguria r/t cardiac dysfunction

Risk for decreased **Cardiac** output (See **Cardiac output, risk for decreased**, Section III)

Cardiac Tamponade

Decreased **Cardiac** output r/t fluid in pericardial sac

See *Pericarditis*

Cardiogenic Shock

See *Shock, Cardiogenic*

Cardiovascular Function: Risk for Impaired

Risk for Impaired **Cardiovascular** Function (See **impaired Cardiovascular function, risk for**, Section III)

Caregiver Role Strain

Caregiver Role Strain (See **Caregiver Role Strain**, Section III)

Risk for compromised **Resilience**: Risk factor: stress of prolonged caregiving

Carious Teeth

See *Cavities in Teeth*

Carotid Endarterectomy

Fear r/t surgery in vital area

Risk for ineffective **Airway** clearance: Risk factor: hematoma compressing trachea

Risk for **Bleeding**: Risk factor: possible hematoma formation, trauma to region

Risk for ineffective **Cerebral** tissue perfusion: Risk factors: hemorrhage, clot formation

Readiness for enhanced **Knowledge**: expresses an interest in learning

Carpal Tunnel Syndrome

Impaired physical **Mobility** r/t neuromuscular impairment

Chronic **Pain** r/t unrelieved pressure on median nerve

Self-Care deficit: bathing, dressing, feeding r/t pain

Carpopedal Spasm

See *Hypocalcemia*

Casts

Deficient **Diversional** activity r/t physical limitations from cast
Impaired physical **Mobility** r/t limb immobilization

Self-Care deficit: bathing, dressing, feeding r/t presence of cast(s) on upper extremities

Self-Care deficit: toileting r/t presence of cast(s) on lower extremities

Impaired **Walking** r/t cast(s) on lower extremities, fracture of bones

Risk for **Peripheral Neurovascular** dysfunction: Risk factors: mechanical compression from cast, trauma from fracture

Risk for impaired **Skin** integrity: Risk factor: unrelieved pressure on skin from cast

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Traction and Casts*

Cataract Extraction

Anxiety r/t threat of permanent vision loss, surgical procedure

Vision Loss r/t edema from surgery (*see care plan in Appendix*)

Risk for **Injury**: Risk factors: increased intraocular pressure, accommodation to new visual field

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Vision Impairment*

Cataracts

Vision Loss r/t impaired sensory input (*see care plan in Appendix*)

See *Vision Impairment*

Catatonic Schizophrenia

Impaired verbal **Communication** r/t cognitive impairment

Impaired **Memory** r/t cognitive impairment

Impaired physical **Mobility** r/t cognitive impairment, maintenance of rigid posture, inappropriate or bizarre postures

Imbalanced **Nutrition**: less than body requirements r/t decrease in outside stimulation, loss of perception of hunger, resistance to instructions to eat

Social isolation r/t inability to communicate, immobility

See *Schizophrenia*

Catheterization, Urinary

Risk for **Infection**: Risk factor: invasive procedure

Readiness for enhanced **Knowledge**: expresses an interest in learning

Cavities in Teeth

Impaired **Dentition** r/t ineffective oral hygiene, barriers to self-care, economic barriers to professional care, nutritional deficits, dietary habits

Celiac Disease

Diarrhea r/t malabsorption of food, immune effects of gluten on gastrointestinal system

Imbalanced **Nutrition**: less than body requirements r/t malabsorption due to immune effects of gluten

Readiness for enhanced **Knowledge**: expresses an interest in learning

Cellulitis

Acute **Pain** r/t inflammatory changes in tissues from infection

Impaired **Tissue** integrity r/t inflammatory process damaging skin and underlying tissue

Ineffective peripheral **Tissue Perfusion** r/t edema of extremities

Risk for **Vascular Trauma**: Risk factor: infusion of antibiotics

Readiness for enhanced **Knowledge**: expresses an interest in learning

Cellulitis, Periorbital

Acute **Pain** r/t edema and inflammation of skin/tissues

Impaired **Skin** integrity r/t inflammation or infection of skin, tissues

Vision Loss r/t decreased visual field secondary to edema of eyelids (see *care plan in Appendix*)

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Hospitalized Child*

Central Line Insertion

Risk for **Infection**: Risk factor: invasive procedure

Risk for **Vascular Trauma** (See **Vascular Trauma**, risk for, Section III)

Readiness for enhanced **Knowledge**: expresses an interest in learning

Cerebral Aneurysm

See *Craniectomy/Craniotomy; Intracranial Pressure, Increased; Subarachnoid Hemorrhage*

Cerebral Palsy

Impaired verbal **Communication** r/t impaired ability to articulate or speak words because of facial muscle involvement

Deficient **Diversional** activity r/t physical impairments, limitations on ability to participate in recreational activities

Impaired physical **Mobility** r/t spasticity, neuromuscular impairment or weakness

Imbalanced **Nutrition**: less than body requirements r/t spasticity, feeding or swallowing difficulties

Self-Care deficit: specify r/t neuromuscular impairments, sensory deficits

Impaired **Social** interaction r/t impaired communication skills, limited physical activity, perceived differences from peers

Chronic **Sorrow** r/t presence of chronic disability

Risk for **Falls**: Risk factor: impaired physical mobility

Risk for **Injury**: Risk factors: muscle weakness, inability to control spasticity

Risk for impaired **Parenting**: Risk factor: caring for child with overwhelming needs resulting from chronic change in health status

Risk for **Spiritual** distress: Risk factor: psychological stress associated with chronic illness

See *Child with Chronic Condition*

Cerebral Perfusion

Risk for ineffective **Cerebral** tissue perfusion (See **Cerebral tissue perfusion, ineffective, risk for**, Section III)

Cerebrovascular Accident (CVA)

See *CVA (Cerebrovascular Accident)*

Cervicitis

Ineffective **Health** maintenance r/t deficient knowledge regarding care and prevention of condition

Ineffective **Sexuality** pattern r/t abstinence during acute stage

Risk for **Infection**: Risk factors: spread of infection, recurrence of infection

Cesarean Delivery

Disturbed **Body Image** r/t surgery, unmet expectations for childbirth

Interrupted **Family** processes r/t unmet expectations for childbirth

Fear r/t perceived threat to own well-being, outcome of birth

Impaired physical **Mobility** r/t pain

Acute **Pain** r/t surgical incision

Ineffective **Role** performance r/t unmet expectations for childbirth

Situational low **Self-Esteem** r/t inability to deliver child vaginally

Risk for **Bleeding**: Risk factor: surgery

Risk for imbalanced **Fluid** volume: Risk factors: loss of blood, fluid shifts

Risk for **Infection**: Risk factor: surgical incision

Risk for **Urinary Retention**: Risk factor: regional anesthesia

Readiness for enhanced **Childbearing** process: a pattern of preparing for, maintaining, and strengthening care of newborn

Readiness for enhanced **Knowledge**: expresses an interest in learning

Chemical Dependence

See *Alcoholism; Drug Abuse; Cocaine Abuse; Substance Abuse*

Chemotherapy

Death **Anxiety** r/t chemotherapy not accomplishing desired results

Disturbed **Body Image** r/t loss of weight, loss of hair

Fatigue r/t disease process, anemia, drug effects

Nausea r/t effects of chemotherapy

Imbalanced **Nutrition**: less than body requirements r/t side effects of chemotherapy

Impaired **Oral Mucous Membrane** r/t effects of chemotherapy

Ineffective **Protection** r/t suppressed immune system, decreased platelets

Risk for **Bleeding**: Risk factors: tumor eroding blood vessel, stress effects on gastrointestinal system

Risk for **Infection**: Risk factor: immunosuppression

Risk for **Vascular Trauma**: Risk factor: infusion of irritating medications

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Cancer*

Chest Pain

Fear r/t potential threat of death

Acute **Pain** r/t myocardial injury, ischemia

Risk for decreased **Cardiac** tissue perfusion: Risk factor: ventricular ischemia

See *Angina; MI (Myocardial Infarction)*

Chest Tubes

Ineffective **Breathing** pattern r/t asymmetrical lung expansion secondary to pain

Impaired **Gas** exchange r/t decreased functional lung tissue

Acute **Pain** r/t presence of chest tubes, injury

Risk for **Injury**: Risk factor: presence of invasive chest tube

Cheyne-Stokes Respiration

Ineffective **Breathing** pattern r/t critical illness

See *Heart Failure*

CHF (Congestive Heart Failure)

See *Heart Failure*

Chickenpox

See *Communicable Diseases, Childhood*

Child Abuse

Interrupted **Family** processes r/t inadequate coping skills

Fear r/t threat of punishment for perceived wrongdoing

Insomnia r/t hypervigilance, fear

Imbalanced **Nutrition**: less than body requirements r/t inadequate caretaking

Acute **Pain** r/t physical injuries

Impaired **Parenting** r/t psychological impairment, physical or emotional abuse of parent, substance abuse, unrealistic expectations of child

Post-Trauma syndrome r/t physical abuse, incest, rape, molestation

Chronic low **Self-Esteem** r/t lack of positive feedback, excessive negative feedback

Impaired **Skin** integrity r/t altered nutritional state, physical abuse

Social isolation: family imposed r/t fear of disclosure of family dysfunction and abuse

Risk for delayed **Development**: Risk factors: shaken baby syndrome, abuse

Risk for disproportionate **Growth**: Risk factor: abuse

Risk for **Poisoning**: Risk factors: inadequate safeguards, lack of proper safety precautions, accessibility of illicit substances because of impaired home maintenance

Risk for **Suffocation**: Risk factors: unattended child, unsafe environment

Risk for **Trauma**: Risk factors: inadequate precautions, cognitive or emotional difficulties

Childbearing Problems

Ineffective **Childbearing** process (See **Childbearing process, ineffective**, Section III)

Risk for ineffective **Childbearing** process: See **Childbearing process, risk for ineffective**, Section III)

Child Neglect

See *Child Abuse; Failure to Thrive, Nonorganic*

Child with Chronic Condition

Activity intolerance r/t fatigue associated with chronic illness

Compromised family **Coping** r/t prolonged overconcern for child; distortion of reality regarding child's health problem, including extreme denial about its existence or severity

Disabled family **Coping** r/t prolonged disease or disability progression that exhausts supportive capacity of significant others

Ineffective **Coping**: child r/t situational or maturational crises

Decisional Conflict r/t treatment options, conflicting values

Deficient **Diversional** activity r/t immobility, monotonous environment, frequent or lengthy treatments, reluctance to participate, self-imposed social isolation

Interrupted **Family** processes r/t intermittent situational crisis of illness, disease, hospitalization

Ineffective **Health** maintenance r/t exhausting family resources (finances, physical energy, support systems)

Impaired **Home** maintenance r/t overtaxed family members (e.g., exhausted, anxious)

Hopelessness: child r/t prolonged activity restriction, long-term stress, lack of involvement in or passively allowing care as a result of parental overprotection

Insomnia: child or parent r/t time-intensive treatments, exacerbation of condition, 24-hour care needs

Deficient **Knowledge** r/t knowledge or skill acquisition regarding health practices, acceptance of limitations, promotion of maximal potential of child, self-actualization of rest of family

Imbalanced **Nutrition**: less than body requirements r/t anorexia, fatigue from physical exertion

Risk for **Overweight** r/t effects of steroid medications on appetite

Chronic **Pain** r/t physical, biological, chemical, or psychological factors

Powerlessness: child r/t health care environment, illness-related regimen, lifestyle of learned helplessness

Parental Role conflict r/t separation from child as a result of chronic illness, home care of child with special needs, interruptions of family life resulting from home care regimen

Chronic low **Self-Esteem** r/t actual or perceived differences; peer acceptance; decreased ability to participate in physical, school, and social activities

Ineffective **Sexuality** pattern: parental r/t disrupted relationship with sexual partner

Impaired **Social** interaction r/t developmental lag or delay, perceived differences

Social isolation: family r/t actual or perceived social stigmatization, complex care requirements

Chronic **Sorrow** r/t developmental stages and missed opportunities or milestones that bring comparisons with social or personal norms, unending caregiving as reminder of loss

Risk for delayed **Development**: Risk factor: chronic illness

Risk for disproportionate **Growth**: Risk factor: chronic illness

Risk for **Infection**: Risk factor: debilitating physical condition

Risk for impaired **Parenting**: Risk factors: impaired or disrupted bonding, caring for child with perceived overwhelming care needs

Readiness for enhanced family **Coping**: impact of crisis on family values, priorities, goals, or relationships; changes in family choices to optimize wellness

Childbirth

Readiness for enhanced **Childbearing** process (See **Childbearing** process, readiness for enhanced, Section III)

See *Labor, Normal; Postpartum, Normal Care*

Chills

Hyperthermia r/t infectious process

Chlamydia Infection

See *STD (Sexually Transmitted Disease)*

Chloasma

Disturbed **Body Image** r/t change in skin color

Choking or Coughing with Eating

Impaired **Swallowing** r/t neuromuscular impairment

Risk for **Aspiration**: Risk factors: depressed cough and gag reflexes

Cholecystectomy

Imbalanced **Nutrition**: less than body requirements r/t high metabolic needs, decreased ability to digest fatty foods

Acute **Pain** r/t trauma from surgery

Risk for deficient **Fluid** volume: Risk factors: restricted intake, nausea, vomiting

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Abdominal Surgery*

Cholelithiasis

Nausea r/t obstruction of bile

Imbalanced **Nutrition**: less than body requirements r/t anorexia, nausea, vomiting

Acute **Pain** r/t obstruction of bile flow, inflammation in gallbladder

Readiness for enhanced **Knowledge**: expresses an interest in learning

Chorioamnionitis

Anxiety r/t threat to self and infant

Grieving r/t guilt about potential loss of ideal pregnancy and birth

Hyperthermia r/t infectious process

Situational low **Self-Esteem** r/t guilt about threat to infant's health

Risk for **Infection**: Risk factors: infection transmission from mother to fetus; infection in fetal environment

Chronic Confusion

See *Confusion, Chronic*

Chronic Functional Constipation

(See **Constipation**, chronic functional, section III)

(See **Constipation**, chronic functional, risk for, section III)

Chronic Lymphocytic Leukemia

See *Cancer; Chemotherapy; Leukemia*

Chronic Obstructive Pulmonary Disease (COPD)

See *COPD (Chronic Obstructive Pulmonary Disease)*

Chronic Pain

See *Pain, Chronic*

Chronic Renal Failure (Chronic kidney disease)

See *Renal Failure*

Chvostek's Sign

See *Hypocalcemia*

Circumcision

Acute **Pain** r/t surgical intervention

Risk for **Bleeding**: Risk factor: surgical trauma

Risk for **Infection**: Risk factor: surgical wound

Readiness for enhanced **Knowledge**: parent: expresses an interest in learning

Cirrhosis

Chronic **Confusion** r/t chronic organic disorder with increased ammonia levels, substance abuse

Defensive **Coping** r/t inability to accept responsibility to stop substance abuse

Fatigue r/t malnutrition

Ineffective **Health** maintenance r/t deficient knowledge regarding correlation between lifestyle habits and disease process

Nausea r/t irritation to gastrointestinal system

Imbalanced **Nutrition**: less than body requirements r/t loss of appetite, nausea, vomiting

Chronic **Pain** r/t liver enlargement

Chronic low **Self-Esteem** r/t chronic illness

Chronic **Sorrow** r/t presence of chronic illness

Risk for **Bleeding**: Risk factors: impaired blood coagulation, bleeding from portal hypertension

Risk for **Injury**: Risk factors: substance intoxication, potential delirium tremens

Risk for impaired **Oral Mucous Membrane**: Risk factors: altered nutrition, inadequate oral care

Risk for impaired **Skin** integrity: Risk factors: altered nutritional state, altered metabolic state

Cleft Lip/Cleft Palate

Ineffective **Airway** clearance r/t common feeding and breathing passage, postoperative laryngeal, incisional edema

Ineffective **Breastfeeding** r/t infant anomaly

Impaired verbal **Communication** r/t inadequate palate function, possible hearing loss from infected eustachian tubes

Fear: parental r/t special care needs, surgery

Grieving r/t loss of perfect child

Ineffective infant **Feeding** pattern r/t cleft lip, cleft palate

Impaired physical **Mobility** r/t imposed restricted activity, use of elbow restraints

Impaired **Oral Mucous Membrane** r/t surgical correction

Acute **Pain** r/t surgical correction, elbow restraints

Impaired **Skin** integrity r/t incomplete joining of lip, palate ridges

Chronic **Sorrow** r/t birth of child with congenital defect

Risk for **Aspiration**: Risk factor: common feeding and breathing passage

Risk for disturbed **Body Image**: Risk factors: disfigurement, speech impediment

Risk for delayed **Development**: Risk factor: inadequate nutrition resulting from difficulty feeding

Risk for deficient **Fluid** volume: Risk factor: inability to take liquids in usual manner

Risk for disproportionate **Growth**: Risk factor: inability to feed with normal techniques

Risk for **Infection**: Risk factors: invasive procedure, disruption of eustachian tube development, aspiration

Readiness for enhanced **Knowledge**: parent: expresses an interest in learning

Clotting Disorder

Fear r/t threat to well-being

Risk for **Bleeding**: Risk factor: impaired clotting

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Anticoagulant Therapy*; *DIC (Disseminated Intravascular Coagulation)*; *Hemophilia*

Cocaine Abuse

Ineffective **Breathing** pattern r/t drug effect on respiratory center

Chronic **Confusion** r/t excessive stimulation of nervous system by cocaine

Ineffective **Coping** r/t inability to deal with life stresses

Risk for decreased **Cardiac** tissue perfusion r/t increase in sympathetic response in the body damaging the heart

See *Drug Abuse*; *Substance Abuse*

Cocaine Baby

See *Crack Baby*; *Infant of Substance-Abusing Mother*

Codependency

Caregiver Role Strain r/t codependency

Impaired verbal **Communication** r/t psychological barriers

Ineffective **Coping** r/t inadequate support systems

Decisional Conflict r/t support system deficit

Ineffective **Denial** r/t unmet self-needs

Powerlessness r/t lifestyle of helplessness

Cold, Viral

Readiness for enhanced **Comfort** (See **Comfort**, readiness for enhanced, Section III)

Readiness for enhanced **Knowledge**: expresses an interest in learning

Colectomy

Constipation r/t decreased activity, decreased fluid intake

Imbalanced **Nutrition**: less than body requirements r/t high metabolic needs, decreased ability to ingest or digest food

Acute **Pain** r/t recent surgery

Risk for **Infection**: Risk factor: invasive procedure

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Abdominal Surgery*

Colitis

Diarrhea r/t inflammation in colon

Deficient **Fluid** volume r/t frequent stools

Acute **Pain** r/t inflammation in colon

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Crohn's Disease*; *Inflammatory Bowel Disease (Child and Adult)*

Collagen Disease

See *specific disease (e.g., lupus erythematosus; JRA [juvenile rheumatoid arthritis]); Congenital Heart Disease/Cardiac Anomalies*

Colostomy

Disturbed **Body Image** r/t presence of stoma, daily care of fecal material

Ineffective **Sexuality** pattern r/t altered body image, self-concept

Social isolation r/t anxiety about appearance of stoma and possible leakage of stool

Risk for **Constipation**: Risk factor: inappropriate diet

Risk for **Diarrhea**: Risk factor: inappropriate diet

Risk for impaired **Skin** integrity: Risk factor: irritation from bowel contents

Readiness for enhanced **Knowledge**: expresses an interest in learning

Colporrhaphy, Anterior

See *Vaginal Hysterectomy*

Coma

Death **Anxiety**: significant others r/t unknown outcome of coma state

Interrupted **Family** processes r/t illness or disability of family member

Functional urinary **Incontinence** r/t presence of comatose state

Self-Care deficit: r/t neuromuscular impairment

Ineffective family **Health** management r/t complexity of therapeutic regimen

Risk for **Aspiration**: Risk factors: impaired swallowing, loss of cough or gag reflex

Risk for **Disuse** syndrome: Risk factor: altered level of consciousness impairing mobility

Risk for **Hypothermia**: Risk factors: Inactivity, possible pharmaceutical agents, possible hypothalamic injury

Risk for **Injury**: Risk factor: potential seizure activity

Risk for corneal **Injury**: Risk factor: suppressed corneal reflex

Risk for urinary tract **Injury**: Risk factor: long-term use of urinary catheter

Risk for impaired **Oral Mucous Membrane**: Risk factors: dry mouth, inability to do own mouth care

Risk for **Pressure** ulcer: Risk factor: prolonged immobility

Risk for impaired **Skin** integrity: Risk factor: immobility

Risk for **Spiritual** distress: significant others: Risk factors: loss of ability to relate to loved one, unknown outcome of coma

Risk for impaired **Tissue** integrity: Risk factor: impaired physical mobility

See *Head Injury, Subarachnoid Hemorrhage, Increased Intracranial Pressure*

Comfort, Loss of

Impaired **Comfort** (See **Comfort**, impaired, Section III)

Readiness for enhanced **Comfort** (See **Comfort**, readiness for enhanced, Section III)

Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice, Impetigo)

Impaired **Comfort** r/t pruritus, inflammation or infection of skin, subdermal organisms

Deficient **Diversional** activity r/t imposed isolation from peers, disruption in usual play activities, fatigue, activity intolerance

Ineffective **Health** maintenance r/t nonadherence to appropriate immunization schedules, lack of prevention of transmission of infection

Acute **Pain** r/t impaired skin integrity, edema

Risk for **Infection**: transmission to others: Risk factor: contagious organisms

See *Meningitis/Encephalitis, Respiratory Infections, Acute Childhood; Reye's Syndrome*

Communication

Readiness for enhanced **Communication** (See **Communication**, readiness for enhanced, Section III)

Communication Problems

Impaired verbal **Communication** (See **Communication**, verbal, impaired, Section III)

Community Coping

Ineffective community **Coping** (See **Coping**, community, ineffective, Section III)

Readiness for enhanced community **Coping**: community sense of power to manage stressors, social supports available, resources available for problem solving

Community Health Problems

Deficient community **Health** (See **Health**, deficient, community, Section III)

Compartment Syndrome

Fear r/t possible loss of limb, damage to limb

Acute **Pain** r/t pressure in compromised body part

Ineffective peripheral **Tissue Perfusion** r/t increased pressure within compartment

Compulsion

See *OCD (Obsessive-Compulsive Disorder)*

Conduction Disorders (Cardiac)

See *Dysrhythmia*

Confusion, Acute

Acute **Confusion** r/t older than 70 years of age with hospitalization, alcohol abuse, delirium, dementia, drug abuse

Frail Elderly syndrome r/t impaired memory

Confusion, Chronic

Chronic **Confusion** r/t dementia, Korsakoff's psychosis, multi-infarct dementia, cerebrovascular accident, head injury

Frail Elderly syndrome r/t impaired memory

Impaired **Memory** r/t fluid and electrolyte imbalance, neurological disturbances, excessive environmental disturbances, anemia, acute or chronic hypoxia, decreased cardiac output

Impaired **Mood** regulation r/t emotional instability

See *Alzheimer's Disease; Dementia*

Confusion, Possible

Risk for acute **Confusion**: Risk factor (See **Confusion**, acute, risk for, Section III)

Congenital Heart Disease/Cardiac Anomalies

Activity intolerance r/t fatigue, generalized weakness, lack of adequate oxygenation

Ineffective **Breathing** pattern r/t pulmonary vascular disease
 Decreased **Cardiac** output r/t cardiac dysfunction
 Excess **Fluid** volume r/t cardiac dysfunction, side effects of medication

C Impaired **Gas** exchange r/t cardiac dysfunction, pulmonary congestion

Imbalanced **Nutrition**: less than body requirements r/t fatigue, generalized weakness, inability of infant to suck and feed, increased caloric requirements

Risk for delayed **Development**: Risk factor: inadequate oxygen and nutrients to tissues

Risk for deficient **Fluid** volume: Risk factor: side effects of diuretics

Risk for disproportionate **Growth**: Risk factor: inadequate oxygen and nutrients to tissues

Risk for disorganized **Infant** behavior: Risk factor: invasive procedures

Risk for **Poisoning**: Risk factor: potential toxicity of cardiac medications

Risk for ineffective **Thermoregulation**: Risk factor: neonatal age

See *Child with Chronic Condition; Hospitalized Child*

Congestive Heart Failure (CHF)/Heart Failure (HF)

See *CHF (Congestive Heart Failure)*

Conjunctivitis

Acute **Pain** r/t inflammatory process

Vision Loss r/t change in visual acuity resulting from inflammation

Consciousness, Altered Level of

Acute **Confusion** r/t alcohol abuse, delirium, dementia, drug abuse, head injury

Chronic **Confusion** r/t multi-infarct dementia, Korsakoff's psychosis, head injury, cerebrovascular accident, neurological deficit, **Frail Elderly** syndrome

Functional urinary **Incontinence** r/t neurological dysfunction

Decreased **Intracranial** adaptive capacity r/t brain injury

Impaired **Memory** r/t neurological disturbances

Self-Care deficit: specify r/t neuromuscular impairment

Risk for **Aspiration**: Risk factors: impaired swallowing, loss of cough or gag reflex

Risk for **Disuse** syndrome: Risk factor: impaired mobility resulting from altered level of consciousness

Risk for **Falls**: Risk factor: diminished mental status

Risk for impaired **Oral Mucous Membrane**: Risk factors: dry mouth, interrupted oral care

Risk for ineffective **Cerebral** tissue perfusion: Risk factors: increased intracranial pressure, altered cerebral perfusion

Risk for impaired **Skin** integrity: Risk factor: immobility

See *Coma, Head Injury, Subarachnoid Hemorrhage, Increased Intracranial Pressure*

Constipation

Constipation (See [Constipation, Section III](#))

Constipation, Chronic Functional

Constipation (See [Constipation, chronic functional, Section III](#))

Constipation, Perceived

Perceived **Constipation** (See [perceived Constipation, Section III](#))

Constipation, Risk for

Risk for **Constipation** (See [Constipation, risk for, Section III](#))

Risk for chronic functional **Constipation** (See [Constipation, chronic functional, risk for, Section III](#))

Contamination

Contamination (See [Contamination, Section III](#))

Risk for **Contamination** (See [Contamination, risk for, Section III](#))

Continent Ileostomy (Kock Pouch)

Ineffective **Coping** r/t stress of disease, exacerbations caused by stress

Imbalanced **Nutrition**: less than body requirements r/t malabsorption from disease process

Risk for **Injury**: Risk factors: failure of valve, stomal cyanosis, intestinal obstruction

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Abdominal Surgery, Crohn's Disease*

Contraceptive Method

Decisional Conflict: method of contraception r/t unclear personal values or beliefs, lack of experience or interference with decision-making, lack of relevant information, support system deficit

Ineffective **Sexuality** pattern r/t fear of pregnancy

Readiness for enhanced **Health** management: requesting information about available and appropriate birth control methods

Convulsions

Anxiety r/t concern over controlling convulsions

Impaired **Memory** r/t neurological disturbance

Risk for **Aspiration**: Risk factor: impaired swallowing

Risk for delayed **Development**: Risk factor: seizures

Risk for **Injury**: Risk factor: seizure activity

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Seizure Disorders, Adult; Seizure Disorders, Childhood*

COPD (Chronic Obstructive Pulmonary Disease)

Activity intolerance r/t imbalance between oxygen supply and demand

Ineffective **Airway** clearance r/t bronchoconstriction, increased mucus, ineffective cough, infection

Anxiety r/t breathlessness, change in health status

Death **Anxiety** r/t seriousness of medical condition, difficulty being able to “catch breath,” feeling of suffocation

Interrupted **Family** processes r/t role changes

Impaired **Gas** exchange r/t ventilation-perfusion inequality

Ineffective **Health** management (See **Health management, ineffective**, Section III)

Imbalanced **Nutrition**: less than body requirements r/t decreased intake because of dyspnea, unpleasant taste in mouth left by medications, increased need for calories from work of breathing

Powerlessness r/t progressive nature of disease

Self-Care deficit: r/t fatigue from the increased work of breathing

Chronic low **Self-Esteem** r/t chronic illness

Sleep deprivation r/t breathing difficulties when lying down

Impaired **Social** interaction r/t social isolation because of oxygen use, activity intolerance

Chronic **Sorrow** r/t presence of chronic illness

Risk for **Infection**: Risk factor: stasis of respiratory secretions

Readiness for enhanced **Health** management (See **Health management, readiness for enhanced**, Section III)

Coping

Readiness for enhanced **Coping** (See **Coping, readiness for enhanced**, Section III)

Coping Problems

Compromised family **Coping** (see **Coping, compromised family**, Section III)

Defensive **Coping** (See **Coping, defensive**, Section III)

Disabled family **Coping** (See **Coping, disabled family**, Section III)

Ineffective **Coping** (See **Coping, ineffective**, Section III)

Ineffective community **Coping** (see **Coping, ineffective community**, Section III)

Corneal Injury

Risk for corneal **Injury** (See **corneal Injury, risk for**, Section III)

Corneal Reflex, Absent

Risk for **Injury**: Risk factors: accidental corneal abrasion, drying of cornea

Corneal Transplant

Risk for **Infection**: Risk factors: invasive procedure, surgery

Readiness for enhanced **Health** management: describes need to rest and avoid strenuous activities during healing phase

Coronary Artery Bypass Grafting (CABG)

Decreased **Cardiac** output r/t dysrhythmia, depressed cardiac function, change in preload, contractility or afterload

Fear r/t outcome of surgical procedure

Deficient **Fluid** volume r/t intraoperative blood loss, use of diuretics in surgery

Acute **Pain** r/t traumatic surgery

Risk for **Perioperative Positioning** injury: Risk factors: hypothermia, extended supine position

Risk for Impaired **Tissue** integrity: Risk Factor: surgical procedure

Readiness for enhanced **Knowledge**: expresses an interest in learning

Costovertebral Angle Tenderness

See *Kidney Stone; Pyelonephritis*

Cough, Ineffective

Ineffective **Airway** clearance r/t decreased energy, fatigue, normal aging changes

See *Bronchitis; COPD (Chronic Obstructive Pulmonary Disease); Pulmonary Edema*

Crack Abuse

See *Cocaine Abuse; Drug Abuse; Substance Abuse*

Crack Baby

Disorganized **Infant** behavior r/t prematurity, drug withdrawal, lack of attachment

Risk for impaired **Attachment**: Risk factors: parent's inability to meet infant's needs, substance abuse

Risk for disturbed **Maternal-Fetal** dyad: Risk factor: substance abuse

See *Infant of Substance-Abusing Mother*

Crackles in Lungs, Coarse

Ineffective **Airway** clearance r/t excessive secretions in airways, ineffective cough

See *Heart Failure, Pneumonia, Pulmonary Edema*

Crackles in Lungs, Fine

Ineffective **Breathing** pattern r/t fatigue, surgery, decreased energy

See *Bronchitis or Pneumonia (if from pulmonary infection); CHF (Congestive Heart Failure) (if cardiac in origin); Infection*

Craniectomy/Craniotomy

Frail Elderly syndrome r/t alteration in cognition

Fear r/t threat to well-being

Decreased **Intracranial** adaptive capacity r/t brain injury, intracranial hypertension

Impaired **Memory** r/t neurological surgery

Acute **Pain** r/t recent brain surgery, increased intracranial pressure

Risk for ineffective **Cerebral** tissue perfusion: Risk factors: cerebral edema, increased intracranial pressure

Risk for **Injury**: Risk factor: potential confusion

See *Coma (if relevant)*

Crepitation, Subcutaneous

See *Pneumothorax*

Crisis

Anxiety r/t threat to or change in environment, health status, interaction patterns, situation, self-concept, or role functioning; threat of death of self or significant other

Death Anxiety r/t feelings of hopelessness associated with crisis
Compromised family **Coping** r/t situational or developmental crisis

Ineffective **Coping** r/t situational or maturational crisis

Fear r/t crisis situation

Grieving r/t potential significant loss

Impaired individual **Resilience** r/t onset of crisis

Situational low **Self-Esteem** r/t perception of inability to handle crisis

Stress overload (See **Stress overload**, Section III)

Risk for **Spiritual** distress: Risk factors: physical or psychological stress, natural disasters, situational losses, maturational losses

Crohn's Disease

Anxiety r/t change in health status

Ineffective **Coping** r/t repeated episodes of diarrhea

Diarrhea r/t inflammatory process

Ineffective **Health** maintenance r/t deficient knowledge regarding management of disease

Imbalanced **Nutrition**: less than body requirements r/t diarrhea, altered ability to digest and absorb food

Acute **Pain** r/t increased peristalsis

Powerlessness r/t chronic disease

Risk for deficient **Fluid** volume: Risk factor: abnormal fluid loss with diarrhea

Croup

See *Respiratory Infections, Acute Childhood*

Cryosurgery for Retinal Detachment

See *Retinal Detachment*

Cushing's Syndrome

Activity intolerance r/t fatigue, weakness

Disturbed **Body Image** r/t change in appearance from disease process

Excess **Fluid** volume r/t failure of regulatory mechanisms

Sexual dysfunction r/t loss of libido

Impaired **Skin** integrity r/t thin vulnerable skin from effects of increased cortisol

Risk for **Infection**: Risk factor: suppression of immune system caused by increased cortisol levels

Risk for **Injury**: Risk factors: decreased muscle strength, brittle bones

Readiness for enhanced **Knowledge**: expresses an interest in learning

Cuts (Wounds)

See *Lacerations*

CVA (Cerebrovascular Accident)

Anxiety r/t situational crisis, change in physical or emotional condition

Disturbed **Body Image** r/t chronic illness, paralysis

Caregiver Role Strain r/t cognitive problems of care receiver, need for significant home care

Impaired verbal **Communication** r/t pressure damage, decreased circulation to brain in speech center informational sources

Chronic **Confusion** r/t neurological changes

Constipation r/t decreased activity

Ineffective **Coping** r/t disability

Interrupted **Family** processes r/t illness, disability of family member

Frail Elderly syndrome r/t alteration in cognitive functioning

Grieving r/t loss of health

Impaired **Home** maintenance r/t neurological disease affecting ability to perform activities of daily living

Functional urinary **Incontinence** r/t neurological dysfunction

Reflex urinary **Incontinence** r/t loss of feeling to void

Impaired **Memory** r/t neurological disturbances

Impaired physical **Mobility** r/t loss of balance and coordination

Unilateral Neglect r/t disturbed perception from neurological damage

Self-Care deficit: specify r/t decreased strength and endurance, paralysis

Impaired **Social** interaction r/t limited physical mobility, limited ability to communicate

Impaired **Swallowing** r/t neuromuscular dysfunction

Impaired **Transfer Ability** r/t limited physical mobility

Vision Loss r/t pressure damage to visual centers in the brain (see *care plan in Appendix*)

Impaired **Walking** r/t loss of balance and coordination

Risk for **Aspiration**: Risk factors: impaired swallowing, loss of gag reflex

Risk for chronic functional **Constipation**: Risk factor: immobility

Risk for **Disuse** syndrome: Risk factor: paralysis

Risk for **Falls**: Risk factor: paralysis, decreased balance

Risk for **Injury**: Risk factors: vision loss, decreased tissue perfusion with loss of sensation

Risk for ineffective **Cerebral** tissue perfusion: Risk factor: clot, emboli, or hemorrhage from cerebral vessel

Risk for impaired **Skin** integrity: Risk factor: immobility

Readiness for enhanced **Knowledge**: expresses an interest in learning

Cyanosis, Central with Cyanosis of Oral Mucous Membranes

Impaired **Gas** exchange r/t alveolar-capillary membrane changes

Cyanosis, Peripheral with Cyanosis of Nail Beds

Ineffective peripheral **Tissue Perfusion** r/t interruption of arterial flow, severe vasoconstriction, cold temperatures

Cystic Fibrosis

Activity intolerance r/t imbalance between oxygen supply and demand

Ineffective **Airway** clearance r/t increased production of thick mucus

Anxiety r/t dyspnea, oxygen deprivation

Disturbed **Body Image** r/t changes in physical appearance, treatment of chronic lung disease (clubbing, barrel chest, home oxygen therapy)

Impaired **Gas** exchange r/t ventilation-perfusion imbalance

Impaired **Home** maintenance r/t extensive daily treatment, medications necessary for health

Imbalanced **Nutrition**: less than body requirements r/t anorexia; decreased absorption of nutrients, fat; increased work of breathing

Chronic **Sorrow** r/t presence of chronic disease

Risk for **Caregiver Role Strain**: Risk factors: illness severity of care receiver, unpredictable course of illness

Risk for deficient **Fluid** volume: Risk factors: decreased fluid intake, increased work of breathing

Risk for **Infection**: Risk factors: thick, tenacious mucus; harboring of bacterial organisms; immunocompromised state

Risk for **Spiritual** distress: Risk factor: presence of chronic disease

See *Child with Chronic Condition; Hospitalized Child; Terminally Ill Child, Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/Preadolescent; Terminally Ill Child/Death of Child, Parent*

Cystitis

Acute **Pain**: dysuria r/t inflammatory process in bladder and urethra

Impaired **Urinary** elimination: frequency r/t urinary tract infection

Urge urinary **Incontinence**: Risk factor: infection in bladder

Readiness for enhanced **Knowledge**: expresses an interest in learning

Cystocele

Stress urinary **Incontinence** r/t prolapsed bladder

Readiness for enhanced **Knowledge**: expresses an interest in learning

Cystoscopy

Urinary Retention r/t edema in urethra obstructing flow of urine

Risk for **Infection**: Risk factor: invasive procedure

Readiness for enhanced **Knowledge**: expresses an interest in learning

D

Deafness

Impaired verbal **Communication** r/t impaired hearing

Hearing Loss r/t alteration in sensory reception, transmission, integration

Risk for delayed **Development**: Risk factor: impaired hearing

Risk for **Injury**: Risk factor: alteration in sensory perception

Death

Risk for **Sudden Infant Death** syndrome (SIDS) (See **Sudden Infant Death** syndrome, risk for, Section III)

Death, Oncoming

Death **Anxiety** r/t unresolved issues surrounding dying

Compromised family **Coping** r/t client's inability to provide support to family

Ineffective **Coping** r/t personal vulnerability

Fear r/t threat of death

Grieving r/t loss of significant other

Powerlessness r/t effects of illness, oncoming death

Social isolation r/t altered state of wellness

Spiritual distress r/t intense suffering

Readiness for enhanced **Spiritual** well-being: desire of client and family to be in harmony with each other and higher power, God

See *Terminally Ill Child, Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/Preadolescent; Terminally Ill Child/Death of Child, Parent*

Decisions, Difficulty Making

Decisional Conflict r/t support system deficit, perceived threat to value system, multiple or divergent sources of information, lack of relevant information, unclear personal values or beliefs

Readiness for enhanced **Decision-Making** (See **Decision-Making**, readiness for enhanced, Section III)

Decubitus Ulcer

See *Pressure Ulcer*

Deep Vein Thrombosis (DVT)

See *DVT (Deep Vein Thrombosis)*

Defensive Behavior

Defensive **Coping** r/t nonacceptance of blame, denial of problems or weakness

Ineffective **Denial** r/t inability to face situation realistically

Dehiscence, Abdominal

Fear r/t threat of death, severe dysfunction

Acute **Pain** r/t stretching of abdominal wall

Impaired **Skin** integrity r/t altered circulation, malnutrition, opening in incision

List of Nursing Assessments by Letter: D

Deafness	Death	Death, Oncoming
Decisions, Difficulty Making	Decubitus Ulcer	Deep Vein Thrombosis (DVT)
Defensive Behavior	Dehiscence, Abdominal	Dehydration
Delirium	Delirium Tremens (DT)	Delivery
Delusions	Dementia	Denial of Health Status
Dental Caries	Depression (Major Depressive Disorder)	Dermatitis
Despondency	Destructive Behavior Toward Others	Developmental Concerns
Diabetes in Pregnancy	Diabetes Insipidus	Diabetes Mellitus
Diabetes Mellitus, Juvenile (IDDM Type 1)	Diabetic Coma	Diabetic Ketoacidosis
Diabetic Retinopathy	Dialysis	Diaphragmatic Hernia
Diarrhea	DIC (Disseminated Intravascular Coagulation)	Digitalis Toxicity
Dignity, Loss of	Dilation and Curettage (D&C)	Dirty Body (for Prolonged Period)
Discharge Planning	Discomforts of Pregnancy	Dislocation of Joint
Dissecting Aneurysm	Disseminated Intravascular Coagulation (DIC)	Dissociative Identity Disorder (Not Otherwise Specified)
Distress	Disuse Syndrome, Potential to Develop	Diversional Activity, Lack of
Diverticulitis	Dizziness	Domestic Violence
Down Syndrome	Dress Self (Inability to)	Dribbling of Urine
Drooling	Dropout from School	Drug Abuse
Drug Withdrawal	Dry Eye	DT (Delirium Tremens)
DVT (Deep Vein Thrombosis)	Dying Client	Dysfunctional Eating Pattern
Dysfunctional Family Unit	Dysfunctional Ventilatory Weaning	Dysmenorrhea
Dyspareunia	Dyspepsia	Dysphagia
Dysphasia	Dyspnea	Dysrhythmia
Dysthymic Disorder	Dystocia	Dysuria

Delayed **Surgical** recovery r/t altered circulation, malnutrition, opening in incision

Impaired **Tissue** integrity r/t exposure of abdominal contents to external environment

Risk for deficient **Fluid** volume: Risk factor: altered circulation associated with opening of wound and exposure of abdominal contents

Risk for **Infection**: Risk factors: loss of skin integrity, open surgical wound

Dehydration

Deficient **Fluid** volume r/t active fluid volume loss

Impaired **Oral Mucous Membrane** r/t decreased salivation, fluid deficit

Risk for chronic functional **Constipation**: Risk factor: decreased fluid volume

Risk for imbalanced body **Temperature**: Risk factor: hyperthermia due to sensible water loss

See *Burns, Heat Stroke, Vomiting, Diarrhea*

Delirium

Acute **Confusion** r/t effects of medication, response to hospitalization, alcohol abuse, substance abuse, sensory deprivation or overload, infection, polypharmacy

Impaired **Memory** r/t delirium

Sleep deprivation r/t sustained inadequate sleep hygiene

Risk for **Injury**: Risk factor: altered level of consciousness

Delirium Tremens (DT)

See *Alcohol Withdrawal*

Delivery

See *Labor, Normal*

Delusions

Impaired verbal **Communication** r/t psychological impairment, delusional thinking

Acute **Confusion** r/t alcohol abuse, delirium, dementia, drug abuse

Ineffective **Coping** r/t distortion and insecurity of life events

Fear r/t content of intrusive thoughts

Risk for other-directed **Violence**: Risk factor: delusional thinking

Risk for self-directed **Violence**: Risk factor: delusional thinking

Dementia

Chronic **Confusion** r/t neurological dysfunction

Interrupted **Family** processes r/t disability of family member

Frail Elderly syndrome r/t alteration in cognitive functioning

Impaired **Home** maintenance r/t inadequate support system, neurological dysfunction

Imbalanced **Nutrition**: less than body requirements r/t neurological impairment

Functional urinary **Incontinence** r/t neurological dysfunction

Insomnia r/t neurological impairment, naps during the day

Impaired physical **Mobility** r/t alteration in cognitive function

Self-Neglect r/t cognitive impairment

Self-Care deficit: specify r/t psychological or neuromuscular impairment

Chronic **Sorrow**: Significant other r/t chronic long-standing disability, loss of mental function

Impaired **Swallowing** r/t neuromuscular changes associated with long-standing dementia

Risk for **Caregiver Role Strain**: Risk factors: number of caregiving tasks, duration of caregiving required

Risk for Chronic Functional **Constipation**: Risk factor: decreased fluid intake

Risk for **Falls**: Risk factor: diminished mental status

Risk for **Frail Elderly** syndrome: Risk factors: cognitive impairment

Risk for **Injury**: Risk factors: confusion, decreased muscle coordination

Risk for impaired **Skin** integrity: Risk factors: altered nutritional status, immobility

Denial of Health Status

Ineffective **Denial** r/t lack of perception about the health status effects of illness

Ineffective **Health** management r/t denial of seriousness of health situation

Dental Caries

Impaired **Dentition** r/t ineffective oral hygiene, barriers to self-care, economic barriers to professional care, nutritional deficits, dietary habits

Ineffective **Health** maintenance r/t lack of knowledge regarding prevention of dental disease

Depression (Major Depressive Disorder)

Death **Anxiety** r/t feelings of lack of self-worth

Constipation r/t inactivity, decreased fluid intake

Fatigue r/t psychological demands

Ineffective **Health** maintenance r/t lack of ability to make good judgments regarding ways to obtain help

Hopelessness r/t feeling of abandonment, long-term stress

Impaired **Mood** Regulation r/t emotional instability

Insomnia r/t inactivity

Self-Neglect r/t depression, cognitive impairment

Powerlessness r/t pattern of helplessness

Chronic low **Self-Esteem** r/t repeated unmet expectations

Sexual dysfunction r/t loss of sexual desire

Social isolation r/t ineffective coping

Chronic **Sorrow** r/t unresolved grief

Risk for complicated **Grieving**: Risk factor: lack of previous resolution of former grieving response

Risk for **Suicide**: Risk factor: grieving, hopelessness

Dermatitis

Anxiety r/t situational crisis imposed by illness

Impaired **Comfort** r/t itching

Impaired **Skin** integrity r/t side effect of medication, allergic reaction

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Itching*

Despondency

Hopelessness r/t long-term stress

See *Depression (Major Depressive Disorder)*

Destructive Behavior Toward Others

Risk-prone **Health** behavior r/t intense emotional state

Ineffective **Coping** r/t situational crises, maturational crises, disturbance in pattern of appraisal of threat

Risk for other-directed **Violence** (See **Violence, other-directed, risk for, Section III**)

Developmental Concerns

Risk for delayed **Development** (See **Development, delayed, risk for, Section III**)

See *Growth and Development Lag*

Diabetes in Pregnancy

See *Gestational Diabetes (Diabetes in Pregnancy)*

Diabetes Insipidus

Deficient **Fluid** volume r/t inability to conserve fluid

Ineffective **Health** maintenance r/t deficient knowledge regarding care of disease, importance of medications

Diabetes Mellitus

Ineffective **Health** maintenance r/t complexity of therapeutic regimen

Ineffective **Health** management (See **Health management, ineffective, Section III**)

Imbalanced **Nutrition**: less than body requirements r/t inability to use glucose (type 1 [insulin-dependent] diabetes)

Risk for **Overweight** r/t excessive intake of nutrients (type 2 diabetes)

Ineffective peripheral **Tissue** perfusion r/t impaired arterial circulation

Powerlessness r/t perceived lack of personal control

Sexual dysfunction r/t neuropathy associated with disease

Vision Loss r/t ineffective tissue perfusion of retina

Risk for unstable blood **Glucose** level (See **Glucose level, blood, unstable, risk for, Section III**)

Risk for **Infection**: Risk factors: hyperglycemia, impaired healing, circulatory changes

Risk for **Injury**: Risk factors: hypoglycemia or hyperglycemia from failure to consume adequate calories, failure to take insulin

Risk for dysfunctional **Gastrointestinal** motility: Risk factor: complication of diabetes

Risk for impaired **Skin** integrity: Risk factor: loss of pain perception in extremities

Risk for delayed **Surgical** recovery: Risk factor: impaired healing due to circulatory changes

Readiness for enhanced **Health** management (See **Health management, readiness for enhanced, Section III**)

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Hyperglycemia; Hypoglycemia*

Diabetes Mellitus, Juvenile (IDDM Type I)

Risk-prone **Health** behavior r/t inadequate comprehension, inadequate social support, low self-efficacy, impaired adjustment attributable to adolescent maturational crises

Disturbed **Body Image** r/t imposed deviations from biophysical and psychosocial norm, perceived differences from peers

Impaired **Comfort** r/t insulin injections, peripheral blood glucose testing

Ineffective **Health** maintenance r/t (See **Health maintenance, ineffective, Section III**)

Imbalanced **Nutrition**: less than body requirements r/t inability of body to adequately metabolize and use glucose and nutrients, increased caloric needs of child to promote growth and physical activity participation with peers

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Diabetes Mellitus; Child with Chronic Condition; Hospitalized Child*

Diabetic Coma

Acute **Confusion** r/t hyperglycemia, presence of excessive metabolic acids

Deficient **Fluid** volume r/t hyperglycemia resulting in polyuria

Ineffective **Health** management r/t lack of understanding of preventive measures, adequate blood sugar control

Risk for unstable blood **Glucose** level (See **Glucose level, blood, unstable, risk for, Section III**)

Risk for **Infection**: Risk factors: hyperglycemia, changes in vascular system

See *Diabetes Mellitus*

Diabetic Ketoacidosis

See *Ketoacidosis, Diabetic*

Diabetic Retinopathy

Grieving r/t loss of vision

Ineffective **Health** maintenance r/t deficient knowledge regarding preserving vision with treatment if possible, use of low-vision aids

Vision Loss r/t change in sensory reception

See *Vision Impairment; Blindness*

Dialysis

See *Hemodialysis; Peritoneal Dialysis*

Diaphragmatic Hernia

See *Hiatal Hernia*

Diarrhea

Diarrhea r/t infection, change in diet, gastrointestinal disorders, stress, medication effect, impaction

Deficient **Fluid** volume r/t excessive loss of fluids in liquid stools

Risk for **Electrolyte** imbalance: Risk factor: effect of loss of electrolytes from frequent stools

DIC (Disseminated Intravascular Coagulation)

Fear r/t threat to well-being

Deficient **Fluid** volume: hemorrhage r/t depletion of clotting factors

Risk for **Bleeding**: Risk factors: microclotting within vascular system, depleted clotting factors

Risk for ineffective **Gastrointestinal** perfusion (See **Gastrointestinal perfusion, ineffective, risk for, Section III**)

Digitalis Toxicity

Decreased **Cardiac** output r/t drug toxicity affecting cardiac rhythm, rate

Ineffective **Health** management r/t deficient knowledge regarding action, appropriate method of administration of digitalis

Dignity, Loss of

Risk for compromised **Human Dignity** (See **Human Dignity, compromised, risk for, Section III**)

Dilation and Curettage (D&C)

Acute **Pain** r/t uterine contractions

Risk for **Bleeding**: Risk factor: surgical procedure

Risk for **Infection**: Risk factor: surgical procedure

Risk for ineffective **Sexuality** pattern: Risk factors: painful coitus, fear associated with surgery on genital area

Readiness for enhanced **Knowledge**: expresses an interest in learning

Dirty Body (for Prolonged Period)

Self-Neglect r/t mental illness, substance abuse, cognitive impairment

Discharge Planning

Impaired **Home Maintenance** r/t family member's disease or injury interfering with home maintenance

Deficient **Knowledge** r/t lack of exposure to information for home care

Relocation stress syndrome: Risk factors: insufficient predeparture counseling, insufficient support system, unpredictability of experience

Readiness for enhanced **Knowledge**: expresses an interest in learning

Discomforts of Pregnancy

Disturbed **Body Image** r/t pregnancy-induced body changes

Impaired **Comfort** r/t enlarged abdomen, swollen feet

Fatigue r/t hormonal, metabolic, body changes

Stress urinary **Incontinence** r/t enlarged uterus, fetal movement

Insomnia r/t psychological stress, fetal movement, muscular cramping, urinary frequency, shortness of breath

Nausea r/t hormone effect

Acute **Pain**: headache r/t hormonal changes of pregnancy

Acute **Pain**: leg cramps r/t nerve compression, calcium/phosphorus/potassium imbalance

Risk for **Constipation**: Risk factors: decreased intestinal motility, inadequate fiber in diet

Risk for **Injury**: Risk factors: faintness and/or syncope caused by vasomotor lability or postural hypotension, venous stasis in lower extremities

Dislocation of Joint

Acute **Pain** r/t dislocation of a joint

Self-Care deficit: r/t inability to use a joint

Risk for **Injury**: Risk factor: unstable joint

Dissecting Aneurysm

Fear r/t threat to well-being

See *Abdominal Surgery; Aneurysm, Abdominal Surgery*

Disseminated Intravascular Coagulation (DIC)

See *DIC (Disseminated Intravascular Coagulation)*

Dissociative Identity Disorder (Not Otherwise Specified)

Anxiety r/t psychosocial stress

Ineffective **Coping** r/t personal vulnerability in crisis of accurate self-perception

Disturbed personal **Identity** r/t inability to distinguish self caused by multiple personality disorder, depersonalization, disturbance in memory

Impaired **Memory** r/t altered state of consciousness

See *Multiple Personality Disorder (Dissociative Identity Disorder)*

Distress

Anxiety r/t situational crises, maturational crises

Death **Anxiety** r/t denial of one's own mortality or impending death

Disuse Syndrome, Potential to Develop

Risk for **Disuse** syndrome: Risk factors: paralysis, mechanical immobilization, prescribed immobilization, severe pain, altered level of consciousness

Diversional Activity, Lack of

Deficient **Diversional** activity r/t environmental lack of diversional activity as in frequent hospitalizations, lengthy treatments

Diverticulitis

Constipation r/t dietary deficiency of fiber and roughage

Diarrhea r/t increased intestinal motility caused by inflammation

Deficient Knowledge r/t diet needed to control disease, medication regimen

Imbalanced Nutrition: less than body requirements r/t loss of appetite

Acute Pain r/t inflammation of bowel

Risk for deficient **Fluid Volume:** Risk factor: diarrhea

Dizziness

Decreased **Cardiac** output r/t alteration in heart rate and rhythm, altered stroke volume

Deficient Knowledge r/t actions to take to prevent or modify dizziness and prevent falls

Impaired physical **Mobility** r/t dizziness

Risk for **Falls:** Risk factor: difficulty maintaining balance

Risk for ineffective **Cerebral** tissue perfusion: Risk factor: interruption of cerebral arterial blood flow

Domestic Violence

Impaired verbal **Communication** r/t psychological barriers of fear

Compromised family **Coping** r/t abusive patterns

Defensive **Coping** r/t low self-esteem

Dysfunctional **Family** processes r/t inadequate coping skills

Fear r/t threat to self-concept, situational crisis of abuse

Insomnia r/t psychological stress

Post-Trauma syndrome r/t history of abuse

Powerlessness r/t lifestyle of helplessness

Situational low **Self-Esteem** r/t negative family interactions

Risk for compromised **Resilience:** Risk factor: effects of abuse

Risk for other-directed **Violence:** Risk factor: history of abuse

Down Syndrome

See *Child with Chronic Condition; Intellectual Disability*

Dress Self (Inability to)

Dressing **Self-Care** deficit r/t intolerance to activity, decreased strength and endurance, pain, discomfort, perceptual or cognitive impairment, neuromuscular impairment, musculoskeletal impairment, depression, severe anxiety

Dribbling of Urine

Overflow urinary **Incontinence** r/t degenerative changes in pelvic muscles and urinary structures

Stress urinary **Incontinence** r/t degenerative changes in pelvic muscles and urinary structures

Drooling

Impaired **Swallowing** r/t neuromuscular impairment, mechanical obstruction

Risk for **Aspiration:** Risk factor: impaired swallowing

Dropout from School

Impaired individual **Resilience** (See **Resilience, individual, impaired, Section III**)

Anxiety r/t conflict about life goals

Ineffective **Coping** r/t inadequate resources

Drug Abuse

Anxiety r/t threat to self-concept, lack of control of drug use

Risk-prone **Health** behavior r/t addiction

Ineffective **Coping** r/t situational crisis

Ineffective **Denial** r/t use of drugs affecting quality of own life and that of significant others

Insomnia r/t effects of drugs

Imbalanced Nutrition: less than body requirements r/t poor eating habits

Powerlessness r/t feeling unable to change patterns of drug abuse

Impaired individual **Resilience** (See **Resilience, individual, impaired, Section III**)

Sexual dysfunction r/t actions and side effects of drug abuse

Sleep deprivation r/t prolonged psychological discomfort

Impaired **Social** interaction r/t disturbed thought processes from drug abuse

Spiritual distress r/t separation from religious, cultural ties

Risk for **Injury:** Risk factors: hallucinations, drug effects

Risk for other-directed **Violence:** Risk factor: poor impulse control

See *Cocaine Abuse; Substance Abuse*

Drug Withdrawal

Anxiety r/t physiological withdrawal

Acute **Confusion** r/t effects of substance withdrawal

Ineffective **Coping** r/t situational crisis, withdrawal

Insomnia r/t effects of medication/substance withdrawal

Imbalanced Nutrition: less than body requirements r/t poor eating habits

Risk for other-directed **Violence:** Risk factors: poor impulse control, hallucinations

Risk for self-directed **Violence:** Risk factors: poor impulse control, hallucinations

See *Drug Abuse*

Dry Eye

Risk for dry **Eye:** Risk factors: (See **dry Eye, risk for, Section III**)

Risk for Corneal **Injury:** Risk factor: suppressed corneal reflex

Readiness for enhanced **Knowledge:** expresses an interest in learning

See *Conjunctivitis; Keratoconjunctivitis Sicca*

DT (Delirium Tremens)

See *Alcohol Withdrawal*

DVT (Deep Vein Thrombosis)

Constipation r/t inactivity, bed rest

Impaired physical **Mobility** r/t pain in extremity

Acute **Pain** r/t vascular inflammation, edema

Ineffective peripheral **Tissue** perfusion r/t deficient knowledge of aggravating factors

Delayed **Surgical** recovery r/t impaired physical mobility

Readiness for enhanced **Knowledge**: expresses an interest in learning

Risk for imbalanced body **Temperature**: Risk factor: inactivity
See *Anticoagulant Therapy*

Dying Client

See *Terminally Ill Adult; Terminally Ill Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/Preadolescent; Terminally Ill Child/Death of Child, Parent*

Dysfunctional Eating Pattern

Imbalanced **Nutrition**: less than body requirements r/t psychological factors

Risk for **Overweight**: Risk factor: psychological factors

See *Anorexia Nervosa; Bulimia; Maturational Issues, Adolescent; Obesity*

Dysfunctional Family Unit

See *Family Problems*

Dysfunctional Ventilatory Weaning

Dysfunctional **Ventilatory** weaning response r/t physical, psychological, situational factors

Dysmenorrhea

Nausea r/t prostaglandin effect

Acute **Pain** r/t cramping from hormonal effects

Readiness for enhanced **Knowledge**: expresses an interest in learning

Dyspareunia

Sexual **Dysfunction** r/t lack of lubrication during intercourse, alteration in reproductive organ function

Dyspepsia

Anxiety r/t pressures of personal role

Acute **Pain** r/t gastrointestinal disease, consumption of irritating foods

Readiness for enhanced **Knowledge**: expresses an interest in learning

Dysphagia

Impaired **Swallowing** r/t neuromuscular impairment

Risk for **Aspiration**: Risk factor: loss of gag or cough reflex

Dysphasia

Impaired verbal **Communication** r/t decrease in circulation to brain

Impaired social **Interaction** r/t difficulty in communicating

Dyspnea

Activity intolerance r/t imbalance between oxygen supply and demand

Ineffective **Breathing** pattern r/t compromised cardiac or pulmonary function, decreased lung expansion, neurological impairment affecting respiratory center, extreme anxiety

Fear r/t threat to state of well-being, potential death

Impaired **Gas** exchange r/t alveolar-capillary damage

Insomnia r/t difficulty breathing, positioning required for effective breathing

Sleep deprivation r/t ineffective breathing pattern

Dysrhythmia

Activity intolerance r/t decreased cardiac output

Decreased **Cardiac** output r/t alteration in heart rate, rhythm

Fear r/t threat of death, change in health status

Risk for ineffective **Cerebral** tissue perfusion: Risk factor: decreased blood supply to the brain from dysrhythmia

Readiness for enhanced **Knowledge**: expresses an interest in learning

Dysthymic Disorder

Ineffective **Coping** r/t impaired social interaction

Ineffective **Health** maintenance r/t inability to make good judgments regarding ways to obtain help

Insomnia r/t anxious thoughts

Chronic low **Self-Esteem** r/t repeated unmet expectations

Ineffective **Sexuality** pattern r/t loss of sexual desire

Social isolation r/t ineffective coping

See *Depression (Major Depressive Disorder)*

Dystocia

Anxiety r/t difficult labor, deficient knowledge regarding normal labor pattern

Ineffective **Coping** r/t situational crisis

Fatigue r/t prolonged labor

Grieving r/t loss of ideal labor experience

Acute **Pain** r/t difficult labor, medical interventions

Powerlessness r/t perceived inability to control outcome of labor

Risk for **Bleeding**: Risk factor: hemorrhage secondary to uterine atony

Risk for ineffective **Cerebral** tissue perfusion (fetal): Risk factor: difficult labor and birth

Risk for delayed **Development** (Infant): Risk factor: difficult labor and birth

Risk for disproportionate **Growth**: Risk factor: difficult labor and birth

Risk for **Infection**: Risk factor: prolonged rupture of membranes

Risk for impaired **Tissue** integrity (maternal and fetal): Risk factor: difficult labor

Dysuria

Impaired **Urinary** elimination r/t infection/inflammation of the urinary tract

Risk for urge urinary **Incontinence**: Risk factor: detrusor hyperreflexia from infection in the urinary tract

Acute **Pain** r/t infection/inflammation of the urinary tract

E

ECMO (Extracorporeal Membrane Oxygenator)

Death **Anxiety** r/t emergency condition, hemorrhage

Decreased **Cardiac** output r/t altered contractility of the heart

Impaired **Gas** exchange (See **Gas** exchange, impaired, Section III)

See *Respiratory Conditions of the Neonate*

E. coli Infection

Fear r/t serious illness, unknown outcome

Deficient **Knowledge** r/t how to prevent disease; care of self with serious illness

See *Gastroenteritis; Gastroenteritis, Child; Hospitalized Child*

Ear Surgery

Acute **Pain** r/t edema in ears from surgery

Hearing Loss r/t invasive surgery of ears, dressings

Risk for delayed **Development**: Risk factor: hearing impairment

Risk for **Falls**: Risk factor: dizziness from excessive stimuli to vestibular apparatus

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Hospitalized Child*

Earache

Acute **Pain** r/t trauma, edema, infection

Hearing Loss r/t altered sensory reception, transmission

Ebola Virus Disease

Fear r/t serious threat to well-being

Ineffective **Health** maintenance r/t knowledge deficit regarding transmission, symptoms, and treatment

Social isolation r/t fear of incurable disease

Deficient **Fluid** volume r/t active fluid loss, vomiting, diarrhea, and failure of regulatory mechanisms

Risk for **Infection**: Risk factor: lack of knowledge concerning transmission of disease

Eclampsia

Interrupted **Family** processes r/t unmet expectations for pregnancy and childbirth

Fear r/t threat of well-being to self and fetus

Risk for **Aspiration**: Risk factor: seizure activity

Risk for ineffective **Cerebral** tissue perfusion: fetal: Risk factor: uteroplacental insufficiency

Risk for delayed **Development**: Risk factor: uteroplacental insufficiency

Risk for excess **Fluid** volume: Risk factor: decreased urine output as a result of renal dysfunction

Risk for disproportionate **Growth**: Risk factor: uteroplacental insufficiency

ECT (Electroconvulsive Therapy)

Decisional Conflict r/t lack of relevant information

Fear r/t real or imagined threat to well-being

Impaired **Memory** r/t effects of treatment

See *Depression (Major Depressive Disorder)*

Ectopic Pregnancy

Death **Anxiety** r/t emergency condition, hemorrhage

Disturbed **Body Image** r/t negative feelings about body and reproductive functioning

Fear r/t threat to self, surgery, implications for future pregnancy

Acute **Pain** r/t stretching or rupture of implantation site

Ineffective **Role** performance r/t loss of pregnancy

Situational low **Self-Esteem** r/t loss of pregnancy, inability to carry pregnancy to term

Chronic **Sorrow** r/t loss of pregnancy, potential loss of fertility

Risk for **Bleeding**: Risk factor: possible rupture of implantation site, surgical trauma

Risk for ineffective **Coping**: Risk factor: loss of pregnancy

Risk for interrupted **Family** processes: Risk factor: situational crisis

Risk for **Infection**: Risk factors: traumatized tissue, surgical procedure

Risk for **Spiritual** distress: Risk factor: grief process

Eczema

Disturbed **Body Image** r/t change in appearance from inflamed skin

Impaired **Comfort**: pruritus r/t inflammation of skin

Impaired **Skin** integrity r/t side effect of medication, allergic reaction

Readiness for enhanced **Knowledge**: expresses an interest in learning

ED (Erectile Dysfunction)

See *Erectile Dysfunction (ED); Impotence*

Edema

Excess **Fluid** volume r/t excessive fluid intake, cardiac dysfunction, renal dysfunction, loss of plasma proteins

Ineffective **Health** maintenance r/t deficient knowledge regarding treatment of edema

Risk for impaired **Skin** integrity: Risk factors: impaired circulation, fragility of skin

See *Heart Failure, Kidney Failure*

Elder Abuse

See *Abuse, Spouse, Parent, or Significant Other*

List of Nursing Assessments by Letter: E

ECMO (Extracorporeal Membrane Oxygenator)	<i>E. coli</i> Infection	Ear Surgery
Earache	Ebola Virus Disease	Eclampsia
ECT (Electroconvulsive Therapy)	Ectopic Pregnancy	Eczema
ED (Erectile Dysfunction)	Edema	Elder Abuse
Elderly	Electroconvulsive Therapy	Electrolyte Imbalance
Emancipated Decision-Making, Impaired	Emaciated Person	Embolectomy
Emboli	Embolism in Leg or Arm	Emesis
Emotional Problems	Empathy	Emphysema
Emptiness	Encephalitis	Endocardial Cushion Defect
Endocarditis	Endometriosis	Endometritis
Enuresis	Environmental Interpretation Problems	Epididymitis
Epiglottitis	Epilepsy	Episiotomy
Epistaxis	Epstein-Barr Virus	Erectile Dysfunction (ED)
Esophageal Varices	Esophagitis	ETOH Withdrawal
Evisceration	Exhaustion	Exposure to Hot or Cold Environment
External Fixation	Extracorporeal Membrane Oxygenator (ECMO)	Eye Discomfort
Eye Surgery		

Elderly

See *Aging; Frail Elderly Syndrome*

Electroconvulsive Therapy

See *ECT (Electroconvulsive Therapy)*

Electrolyte Imbalance

Risk for **Electrolyte** imbalance (See **Electrolyte imbalance**, risk for, Section III)

Emancipated Decision-Making, Impaired

Risk for impaired emancipated **Decision-Making**: Risk factor: inability or unwillingness to verbalize needs and wants

Readiness for enhanced emancipated **Decision-Making**

Emaciated Person

Frail Elderly syndrome r/t living alone, malnutrition, alteration in cognitive functioning

Imbalanced **Nutrition**: less than body requirements r/t inability to ingest food, digest food, absorb nutrients because of biological, psychological, economic factors

Embolectomy

Fear r/t threat of great bodily harm from embolus

Ineffective peripheral **Tissue Perfusion** r/t presence of embolus

Risk for **Bleeding**: Risk factors: postoperative complication, surgical area

See *Surgery, Postoperative Care*

Emboli

See *Pulmonary Embolism*

Embolism in Leg or Arm

Ineffective peripheral **Tissue Perfusion** r/t arterial obstruction from clot

See *Deep Vein Thrombosis*

Emesis

Nausea (See **Nausea**, Section III)

See *Vomiting*

Emotional Problems

See *Coping Problems*

Empathy

Readiness for enhanced community **Coping**: social supports, being available for problem solving

Readiness for enhanced family **Coping**: basic needs met, desire to move to higher level of health

Readiness for enhanced **Spiritual Well-Being**: desire to establish interconnectedness through spirituality

Emphysema

See *COPD (Chronic Obstructive Pulmonary Disease)*

Emptiness

Social isolation r/t inability to engage in satisfying personal relationships

Chronic **Sorrow** r/t unresolved grief

Spiritual distress r/t separation from religious or cultural ties

Encephalitis

See *Meningitis/Encephalitis*

Endocardial Cushion Defect

See *Congenital Heart Disease/Cardiac Anomalies*

Endocarditis

Activity intolerance r/t reduced cardiac reserve, prescribed bed rest

Decreased **Cardiac** output r/t inflammation of lining of heart and change in structure of valve leaflets, increased myocardial workload

Risk for imbalanced **Nutrition**: less than body requirements: Risk factors: fever, hypermetabolic state associated with fever

Risk for ineffective **Cerebral** tissue perfusion: Risk factor: possible presence of emboli in cerebral circulation

Risk for ineffective peripheral **Tissue** perfusion: Risk factor: possible presence of emboli in peripheral circulation

Readiness for enhanced **Knowledge**: expresses an interest in learning

Endometriosis

Grieving r/t possible infertility

Nausea r/t prostaglandin effect

Acute **Pain** r/t onset of menses with distention of endometrial tissue

Sexual dysfunction r/t painful intercourse

Readiness for enhanced **Knowledge**: expresses an interest in learning

Endometritis

Anxiety r/t, fear of unknown

Ineffective **Thermoregulation** r/t infectious process

Acute **Pain** r/t infectious process in reproductive tract

Readiness for enhanced **Knowledge**: expresses an interest in learning

Enuresis

Ineffective **Health** maintenance r/t unachieved developmental task, neuromuscular immaturity, diseases of urinary system

See *Toilet Training*

Environmental Interpretation Problems

(See **chronic Confusion**)

Epididymitis

Anxiety r/t situational crisis, pain, threat to future fertility

Acute **Pain** r/t inflammation in scrotal sac

Ineffective **Sexuality** pattern r/t edema of epididymis and testes

Readiness for enhanced **Knowledge**: expresses an interest in learning

Epiglottitis

See *Respiratory Infections, Acute Childhood (Croup, Epiglottitis, Pertussis, Pneumonia, Respiratory Syncytial Virus)*

Epilepsy

Anxiety r/t threat to role functioning

Ineffective **Health** management r/t deficient knowledge regarding seizure control

Impaired **Memory** r/t seizure activity

Risk for **Aspiration**: Risk factors: impaired swallowing, excessive secretions

Risk for delayed **Development**: Risk factor: seizure disorder

Risk for **Injury**: Risk factor: environmental factors during seizure

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Seizure Disorders, Adult; Seizure Disorders, Childhood*

Episiotomy

Anxiety r/t fear of pain

Disturbed **Body Image** r/t fear of resuming sexual relations

Impaired physical **Mobility** r/t pain, swelling, tissue trauma

Acute **Pain** r/t tissue trauma

Sexual dysfunction r/t altered body structure, tissue trauma

Impaired **Skin** integrity r/t perineal incision

Risk for **Infection**: Risk factor: tissue trauma

Epistaxis

Fear r/t large amount of blood loss

Risk for deficient **Fluid** volume: Risk factor: excessive blood loss

Epstein-Barr Virus

See *Mononucleosis*

Erectile Dysfunction (ED)

Situational low **Self-Esteem** r/t physiological crisis, inability to practice usual sexual activity

Sexual dysfunction r/t altered body function

Readiness for enhanced **Knowledge**: information regarding treatment for erectile dysfunction

See *Impotence*

Esophageal Varices

Fear r/t threat of death from hematemesis

Risk for **Bleeding**: Risk factor: portal hypertension, distended variceal vessels that can easily rupture

See *Cirrhosis*

Esophagitis

Acute **Pain** r/t inflammation of esophagus

Readiness for enhanced **Knowledge**: expresses an interest in learning

ETOH Withdrawal

See *Alcohol Withdrawal*

Evisceration

See *Dehiscence, Abdominal*

Exhaustion

Impaired individual **Resilience** (See **Resilience, individual, impaired, Section III**)

Disturbed **Sleep** pattern (See **Sleep pattern, disturbed, Section III**)

Exposure to Hot or Cold Environment

Hyperthermia r/t exposure to hot environment, abnormal reaction to anesthetics

Hypothermia r/t exposure to cold environment

Risk for imbalanced **Body** temperature: Risk factors: extremes of environmental temperature; inappropriate clothing for environmental temperature

External Fixation

Disturbed **Body Image** r/t trauma, change to affected part

Risk for **Infection**: Risk factor: presence of pins inserted into bone

See *Fracture*

Extracorporeal Membrane Oxygenator (ECMO)

See *ECMO (Extracorporeal Membrane Oxygenator)*

Eye Discomfort

Risk for dry **Eye** (See **Eye, dry, risk for, Section III**)

Risk for corneal **Injury**: Risk factors: exposure of the eyeball, blinking less than five times per minute

Eye Surgery

Anxiety r/t possible loss of vision

Self-Care deficit: specify r/t impaired vision

Vision Loss r/t surgical procedure, eye pathology

Risk for **Injury**: Risk factor: impaired vision

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Hospitalized Child; Vision Impairment*

F

Failure to Thrive, Child

Disorganized **Infant** behavior (See **Infant behavior, disorganized, Section III**)

Insomnia r/t inconsistency of caretaker; lack of quiet, consistent environment

Imbalanced **Nutrition**: less than body requirements r/t inadequate type or amounts of food for infant or child, inappropriate feeding techniques

Impaired **Parenting** r/t lack of parenting skills, inadequate role modeling

Chronic low **Self-Esteem**: parental r/t feelings of inadequacy, support system deficiencies, inadequate role model

List of Nursing Assessments by Letter: F

Failure to Thrive, Child	Falls, Risk for	Family Problems
Family Process	Fatigue	Fear
Febrile Seizures	Fecal Impaction	Fecal Incontinence
Feeding Problems, Newborn	Femoral Popliteal Bypass	Fetal Alcohol Syndrome
Fetal Distress/Nonreassuring Fetal Heart Rate Pattern	Fever	Fibrocystic Breast Disease
Filthy Home Environment	Financial Crisis in the Home Environment	Fistulectomy
Flail Chest	Flashbacks	Flat Affect
Flesh-Eating Bacteria (Necrotizing Fasciitis)	Fluid Balance	Fluid Volume Deficit
Fluid Volume Excess	Fluid Volume Imbalance, Risk for	Food Allergies
Foodborne Illness	Food Intolerance	Foreign Body Aspiration
Formula Feeding of Infant	Fracture	Fractured Hip
Frail Elderly Syndrome	Frequency of Urination	Friendship
Frostbite	Frothy Sputum	Fusion, Lumbar

Social isolation r/t limited support systems, self-imposed situation

Risk for impaired **Attachment**: Risk factor: inability of parents to meet infant's needs

Risk for delayed **Development** (See **Development, delayed, risk for, Section III**)

Risk for disproportionate **Growth** (See **Growth, disproportionate, risk for, Section III**)

Falls, Risk for

Risk for **Falls** (See **Falls, risk for, Section III**)

Family Problems

Compromised family **Coping** (See **Coping, family, compromised, Section III**)

Disabled family **Coping** (See **Coping, family, disabled, Section III**)

Interrupted **Family Processes** r/t situation transition and/or crises, developmental transition and/or crises

Ineffective family **Health** management (See **family Health management, ineffective, Section III**)

Readiness for enhanced family **Coping**: needs sufficiently gratified, adaptive tasks effectively addressed to enable goals of self-actualization to surface

Family Process

Dysfunctional **Family** processes (See **Family processes, dysfunctional, Section III**)

Interrupted **Family** processes (See **Family processes, interrupted, Section III**)

Readiness for enhanced **Family** processes (See **Family processes, readiness for enhanced, Section III**)

Readiness for enhanced **Relationship** (See **Relationship, readiness for enhanced, Section III**)

Fatigue

Fatigue (See **Fatigue, Section III**)

Fear

Death **Anxiety** r/t fear of death

Fear r/t identifiable physical or psychological threat to person

Febrile Seizures

See *Seizure Disorders, Childhood (Epilepsy, Febrile Seizures, Infantile Spasms)*

Fecal Impaction

See *Impaction of Stool*

(See **Constipation, Section III**)

(See **Constipation, chronic functional, Section III**)

Fecal Incontinence

Bowel **Incontinence** r/t neurological impairment, gastrointestinal disorders, anorectal trauma, weakened perineal muscles

Feeding Problems, Newborn

Ineffective **Breastfeeding** (See **Breastfeeding, ineffective, Section III**)

Insufficient **Breastfeeding** (See **Breastfeeding, insufficient, Section III**)

Disorganized **Infant** behavior r/t prematurity, immature neurological system

Ineffective infant **Feeding** pattern r/t prematurity, neurological impairment or delay, oral hypersensitivity, prolonged nothing-by-mouth status

Impaired **Swallowing** r/t prematurity

Risk for delayed **Development**: Risk factor: inadequate nutrition

Risk for deficient **Fluid** volume: Risk factor: inability to take in adequate amount of fluids

Risk for disproportionate **Growth**: Risk factor: feeding problems

Femoral Popliteal Bypass

Anxiety r/t threat to or change in health status

Acute **Pain** r/t surgical trauma, edema in surgical area

Ineffective peripheral **Tissue Perfusion** r/t impaired arterial circulation

Risk for **Bleeding**: Risk factor: surgery on arteries

Risk for **Infection**: Risk factor: invasive procedure

Fetal Alcohol Syndrome

See *Infant of Substance-Abusing Mother*

Fetal Distress/Nonreassuring Fetal Heart Rate Pattern

Fear r/t threat to fetus

Ineffective peripheral **Tissue Perfusion**: fetal r/t interruption of umbilical cord blood flow

Fever

Ineffective **Thermoregulation** r/t infectious process

Risk for Imbalanced body **Temperature**: Risk factors: acute brain injury; pharmaceutical agent

Fibrocystic Breast Disease

See *Breast Lumps*

Filthy Home Environment

Impaired **Home** maintenance (See **Home maintenance, impaired, Section III**)

Self-Neglect r/t mental illness, substance abuse, cognitive impairment

Financial Crisis in the Home Environment

Impaired **Home** maintenance r/t insufficient finances

Fistulectomy

See *Hemorrhoidectomy*

Flail Chest

Ineffective **Breathing** pattern r/t chest trauma

Fear r/t difficulty breathing

Impaired **Gas** exchange r/t loss of effective lung function

Impaired spontaneous **Ventilation** r/t paradoxical respirations

Flashbacks

Post-Trauma syndrome r/t catastrophic event

Flat Affect

Hopelessness r/t prolonged activity restriction creating isolation, failing or deteriorating physiological condition, long-term stress, abandonment, lost belief in transcendent values or higher power or God

Risk for **Loneliness**: Risk factors: social isolation, lack of interest in surroundings

See *Depression (Major Depressive Disorder)*; *Dysthymic Disorder*

Flesh-Eating Bacteria (Necrotizing Fasciitis)

See *Necrotizing Fasciitis (Flesh-Eating Bacteria)*

Fluid Balance

Readiness for enhanced **Fluid** balance (See **Fluid** balance, readiness for enhanced, Section III)

Fluid Volume Deficit

Deficient **Fluid** volume r/t active fluid loss, vomiting, diarrhea, failure of regulatory mechanisms

Risk for **Shock**: Risk factors: hypovolemia, sepsis, systemic inflammatory response syndrome (SIRS)

Fluid Volume Excess

Excess **Fluid** volume r/t compromised regulatory mechanism, excess sodium intake

Fluid Volume Imbalance, Risk for

Risk for imbalanced **Fluid** volume: Risk factor: major invasive surgeries

Food Allergies

Diarrhea r/t immune effects of offending food on gastrointestinal system

Risk for **Allergy** response: Risk factor: specific foods

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Anaphylactic Shock if relevant*

Foodborne Illness

Diarrhea r/t infectious material in gastrointestinal tract

Deficient **Fluid** volume r/t active fluid loss from vomiting and diarrhea

Deficient **Knowledge** r/t care of self with serious illness, prevention of further incidences of foodborne illness

Nausea r/t contamination irritating stomach

Risk for dysfunctional **Gastrointestinal** motility: Risk factor: contaminated food

See *Gastroenteritis*; *Gastroenteritis, Child*; *Hospitalized Child*; *E. coli Infection*

Food Intolerance

Risk for dysfunctional **Gastrointestinal** motility: Risk factor: food intolerance

Foreign Body Aspiration

Ineffective **Airway** clearance r/t obstruction of airway

Ineffective **Health** maintenance r/t parental deficient knowledge regarding high-risk items

Risk for **Suffocation**: Risk factor: inhalation of small objects

See *Safety, Childhood*

Formula Feeding of Infant

Grieving: maternal r/t loss of desired breastfeeding experience

Risk for **Constipation**: infant: Risk factor: iron-fortified formula

Risk for **Infection**: infant: Risk factors: lack of passive maternal immunity, supine feeding position, contamination of formula

Readiness for enhanced **Knowledge**: expresses an interest in learning

Fracture

Deficient **Diversional** activity r/t immobility

Impaired physical **Mobility** r/t limb immobilization

Acute **Pain** r/t muscle spasm, edema, trauma

Post-Trauma syndrome r/t catastrophic event

Impaired **Walking** r/t limb immobility

Risk for ineffective peripheral **Tissue Perfusion**: Risk factors: immobility, presence of cast

Risk for **Peripheral Neurovascular** dysfunction: Risk factors: mechanical compression, treatment of fracture

Risk for impaired **Skin** integrity: Risk factors: immobility, presence of cast

Readiness for enhanced **Knowledge**: expresses an interest in learning

Fractured Hip

See *Hip Fracture*

Frail Elderly Syndrome

Activity intolerance r/t sensory changes

Risk for **Frail Elderly** syndrome (see **Frail Elderly syndrome, risk for**, Section III)

Risk for **Injury**: Risk factors: impaired vision, impaired gait

Risk for **Powerlessness**: Risk factor: inability to maintain independence

Frequency of Urination

Stress urinary **Incontinence** r/t degenerative change in pelvic muscles and structural support

Urge urinary **Incontinence** r/t decreased bladder capacity, irritation of bladder stretch receptors causing spasm, alcohol, caffeine, increased fluids, increased urine concentration, over-distended bladder

Impaired **Urinary** elimination r/t urinary tract infection

Urinary retention r/t high urethral pressure caused by weak detrusor, inhibition of reflex arc, strong sphincter, blockage

Friendship

Readiness for enhanced **Relationship**: expresses desire to enhance communication between partners

Frostbite

Acute **Pain** r/t decreased circulation from prolonged exposure to cold

Ineffective peripheral **Tissue Perfusion** r/t damage to extremities from prolonged exposure to cold

Impaired **Tissue** integrity r/t freezing of skin and tissues

See *Hypothermia*

Frothy Sputum

See *CHF (Congestive Heart Failure); Pulmonary Edema; Seizure Disorders, Adult; Seizure Disorders, Childhood (Epilepsy, Febrile Seizures, Infantile Spasms)*

Fusion, Lumbar

Anxiety r/t fear of surgical procedure, possible recurring problems

Impaired physical **Mobility** r/t limitations from surgical procedure, presence of brace

Acute **Pain** r/t discomfort at bone donor site, surgical operation

Risk for **Injury**: Risk factor: improper body mechanics

Risk for **Perioperative Positioning** injury: Risk factor: immobilization during surgery

Readiness for enhanced **Knowledge**: expresses an interest in learning

G

Gag Reflex, Depressed or Absent

Impaired **Swallowing** r/t neuromuscular impairment

Risk for **Aspiration**: Risk factors: depressed cough or gag reflex

Gallop Rhythm

Decreased **Cardiac** output r/t decreased contractility of heart

Gallstones

See *Cholelithiasis*

Gang Member

Impaired individual **Resilience** (See **Resilience, individual, impaired, Section III**)

Gangrene

Fear r/t possible loss of extremity

Ineffective peripheral **Tissue** perfusion r/t obstruction of arterial flow

See *Diabetes Mellitus, Peripheral Vascular Disease*

Gas Exchange, Impaired

Impaired **Gas** exchange r/t ventilation-perfusion imbalance

Gastric Ulcer

See *GI Bleed (Gastrointestinal Bleeding); Ulcer, Peptic (Duodenal or Gastric)*

Gastritis

Imbalanced **Nutrition**: less than body requirements r/t vomiting, inadequate intestinal absorption of nutrients, restricted dietary regimen

Acute **Pain** r/t inflammation of gastric mucosa

Risk for deficient **Fluid** volume: Risk factors: excessive loss from gastrointestinal tract from vomiting, decreased intake

Gastroenteritis

Diarrhea r/t infectious process involving intestinal tract

Deficient **Fluid** volume r/t excessive loss from gastrointestinal tract from diarrhea, vomiting

Nausea r/t irritation to gastrointestinal system

Imbalanced **Nutrition**: less than body requirements r/t vomiting, inadequate intestinal absorption of nutrients, restricted dietary intake

Acute **Pain** r/t increased peristalsis causing cramping

Risk for **Electrolyte** imbalance: Risk factor: loss of gastrointestinal fluids high in electrolytes

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Gastroenteritis, Child*

Gastroenteritis, Child

Impaired **Skin** integrity: diaper rash r/t acidic excretions on perineal tissues

Readiness for enhanced **Knowledge**: expresses an interest in learning

Acute **Pain** r/t increased peristalsis causing cramping

See *Gastroenteritis; Hospitalized Child*

Gastroesophageal Reflux (GERD)

Ineffective **Airway** clearance r/t reflux of gastric contents into esophagus and tracheal or bronchial tree

Ineffective **Health** maintenance r/t deficient knowledge regarding anti-reflux regimen (e.g., positioning, change in diet)

Acute **Pain** r/t irritation of esophagus from gastric acids

Risk for **Aspiration**: Risk factor: entry of gastric contents in tracheal or bronchial tree

Gastroesophageal Reflux, Child

Ineffective **Airway** clearance r/t reflux of gastric contents into esophagus and tracheal or bronchial tree

Anxiety: parental r/t possible need for surgical intervention

Deficient **Fluid** volume r/t persistent vomiting

Imbalanced **Nutrition**: less than body requirements r/t poor feeding, vomiting

Risk for **Aspiration**: Risk factor: entry of gastric contents in tracheal or bronchial tree

Risk for impaired **Parenting**: Risk factors: disruption in bonding as a result of irritable or inconsolable infant; lack of sleep for parents

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Child with Chronic Condition; Hospitalized Child*

List of Nursing Assessments by Letter: G

Gag Reflex, Depressed or Absent	Gallop Rhythm	Gallstones
Gang Member	Gangrene	Gas Exchange, Impaired
Gastric Ulcer	Gastritis	Gastroenteritis
Gastroenteritis, Child	Gastroesophageal Reflux (GERD)	Gastroesophageal Reflux, Child
Gastrointestinal Bleeding (GI Bleed)	Gastrointestinal Hemorrhage	Gastrointestinal Surgery
Gastroschisis/Omphalocele	Gastrostomy	Genital Herpes
Genital Warts	GERD	Gestational Diabetes (Diabetes in Pregnancy)
GI Bleed (Gastrointestinal Bleeding)	Gingivitis	Glaucoma
Glomerulonephritis	Gluten Allergy	Gonorrhea
Gout	Grandiosity	Grand Mal Seizure
Grandparents Raising Grandchildren	Graves' Disease	Grieving
Grieving, Complicated	Groom Self (Inability to)	Growth and Development Lag
Guillain-Barré Syndrome	Guilt	

Gastrointestinal Bleeding (GI Bleed)

See *GI Bleed (Gastrointestinal Bleeding)*

Gastrointestinal Hemorrhage

See *GI Bleed (Gastrointestinal Bleeding)*

Gastrointestinal Surgery

Risk for **Injury**: Risk factor: inadvertent insertion of nasogastric tube through gastric incision line

Risk for ineffective **Gastrointestinal** perfusion (See **Gastrointestinal** perfusion, ineffective, risk for, Section III)

See *Abdominal Surgery*

Gastroschisis/Omphalocele

Ineffective **Airway** clearance r/t complications of anesthetic effects

Impaired **Gas** exchange r/t effects of anesthesia, subsequent atelectasis

Grieving r/t threatened loss of infant, loss of perfect birth or infant because of serious medical condition

Risk for deficient **Fluid** volume: Risk factors: inability to feed because of condition, subsequent electrolyte imbalance

Risk for **Infection**: Risk factor: disrupted skin integrity with exposure of abdominal contents

Risk for **Injury**: Risk factors: disrupted skin integrity, ineffective protection

Gastrostomy

Risk for impaired **Skin** integrity: Risk factor: presence of gastric contents on skin

See *Tube Feeding*

Genital Herpes

See *Herpes Simplex II*

Genital Warts

See *STD (Sexually Transmitted Disease)*

GERD

See *Gastroesophageal Reflux (GERD)*

Gestational Diabetes (Diabetes in Pregnancy)

Anxiety r/t threat to self and/or fetus

Impaired **Nutrition**: less than body requirements r/t decreased insulin production and glucose uptake in cells

Risk for **Overweight**: fetal: r/t excessive glucose uptake

Impaired **Nutrition**: more than body requirements: fetal r/t excessive glucose uptake

Risk for delayed **Development**: fetal: Risk factor: endocrine disorder of mother

Risk for unstable blood **Glucose**: Risk factor: excessive intake of carbohydrates

Risk for disproportionate **Growth**: fetal: Risk factor: endocrine disorder of mother

Risk for disturbed **Maternal–Fetal** dyad: Risk factor: impaired glucose metabolism

Risk for impaired **Tissue** integrity: fetal: Risk factors: large infant, congenital defects, birth injury

Risk for impaired **Tissue** integrity: maternal: Risk factor: delivery of large infant

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Diabetes Mellitus*

GI Bleed (Gastrointestinal Bleeding)

Fatigue r/t loss of circulating blood volume, decreased ability to transport oxygen

Fear r/t threat to well-being, potential death

Deficient **Fluid** volume r/t gastrointestinal bleeding, hemorrhage

Imbalanced **Nutrition**: less than body requirements r/t nausea, vomiting

Acute **Pain** r/t irritated mucosa from acid secretion

Risk for ineffective **Coping**: Risk factors: personal vulnerability in crisis, bleeding, hospitalization

Readiness for enhanced **Knowledge**: expresses an interest in learning

Gingivitis

Impaired **Oral Mucous Membrane** r/t ineffective oral hygiene

Glaucoma

Deficient **Knowledge** r/t treatment and self-care for disease

Vision Loss r/t untreated increased intraocular pressure (see *care plan in Appendix*)

See *Vision Impairment*

Glomerulonephritis

Excess **Fluid** volume r/t renal impairment

Imbalanced **Nutrition**: less than body requirements r/t anorexia, restrictive diet

Acute **Pain** r/t edema of kidney

Readiness for enhanced **Knowledge**: expresses an interest in learning

Gluten Allergy

See *Celiac Disease*

Gonorrhea

Acute **Pain** r/t inflammation of reproductive organs

Risk for **Infection**: Risk factor: spread of organism throughout reproductive organs

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *STD (Sexually Transmitted Disease)*

Gout

Impaired physical **Mobility** r/t musculoskeletal impairment

Chronic **Pain** r/t inflammation of affected joint

Readiness for enhanced **Knowledge**: expresses an interest in learning

Grandiosity

Defensive **Coping** r/t inaccurate perception of self and abilities

Grand Mal Seizure

See *Seizure Disorders, Adult; Seizure Disorders, Childhood (Epilepsy, Febrile Seizures, Infantile Spasms)*

Grandparents Raising Grandchildren

Anxiety r/t change in role status

Decisional Conflict r/t support system deficit

Parental **Role** conflict r/t change in parental role

Compromised family **Coping** r/t family role changes

Interrupted **Family** processes r/t family roles shift

Ineffective **Role** performance r/t role transition, aging

Ineffective family **Health** management r/t excessive demands on individual or family

Risk for impaired **Parenting**: Risk factor: role strain

Risk for **Powerlessness**: Risk factors: role strain, situational crisis, aging

Risk for **Spiritual** distress: Risk factor: life change

Readiness for enhanced **Parenting**: physical and emotional needs of children are met

Graves' Disease

See *Hyperthyroidism*

Grieving

Grieving r/t anticipated or actual significant loss, change in life status, style, or function

Grieving, Complicated

Complicated **Grieving** r/t expected or sudden death of a significant other with whom there was a volatile relationship, emotional instability, lack of social support

Risk for complicated **Grieving**: Risk factors: death of a significant other with whom there was a volatile relationship, emotional instability, lack of social support

Groom Self (Inability to)

Bathing **Self-Care** deficit (See [Self-Care deficit, bathing, Section III](#))

Dressing **Self-Care** deficit (See [Self-Care deficit, dressing, Section III](#))

Growth and Development Lag

Risk for disproportionate **Growth** (See [Growth, disproportionate, risk for, Section III](#))

Guillain-Barré Syndrome

Impaired **Spontaneous Ventilation** r/t weak respiratory muscles

Risk for **Aspiration** r/t ineffective cough; depressed gag reflex

See *Neurologic Disorders*

Guilt

Grieving r/t potential loss of significant person, animal, prized material possession, change in life role

Impaired individual **Resilience** (See [Resilience, individual, impaired, Section III](#))

Situational low **Self-Esteem** r/t unmet expectations of self

Risk for complicated **Grieving**: Risk factors: actual loss of significant person, animal, prized material possession, change in life role

Risk for **Post-Trauma** syndrome: Risk factor: exaggerated sense of responsibility for traumatic event

Readiness for enhanced **Spiritual** well-being: desire to be in harmony with self, others, higher power or God

H

HINI

See *Influenza*

Hair Loss

Disturbed **Body Image** r/t psychological reaction to loss of hair

Imbalanced **Nutrition**: less than body requirements r/t inability to ingest food because of biological, psychological, economic factors

Halitosis

Impaired **Dentition** r/t ineffective oral hygiene

Impaired **Oral Mucous Membrane** r/t ineffective oral hygiene

Hallucinations

Anxiety r/t threat to self-concept

Acute **Confusion** r/t alcohol abuse, delirium, dementia, mental illness, drug abuse

Ineffective **Coping** r/t distortion and insecurity of life events

Risk for **Self-Mutilation**: Risk factor: command hallucinations

Risk for other-directed **Violence**: Risk factors: catatonic excitement, manic excitement, rage or panic reactions, response to violent internal stimuli

Risk for self-directed **Violence**: Risk factors: catatonic excitement, manic excitement, rage or panic reactions, response to violent internal stimuli

Head Injury

Ineffective **Breathing** pattern r/t pressure damage to breathing center in brainstem

Acute **Confusion** r/t increased intracranial pressure

Decreased **Intracranial** adaptive capacity r/t increased intracranial pressure

Risk for ineffective **Cerebral** tissue perfusion: Risk factors: effects of increased intracranial pressure, trauma to brain

Vision Loss r/t pressure damage to sensory centers in brain (*see care plan in Appendix*)

See *Neurologic Disorders*

List of Nursing Assessments by Letter: H

H1N1	Hair Loss	Halitosis
Hallucinations	Head Injury	Headache
Health Behavior, Risk-Prone	Health Maintenance Problems	Health-Seeking Person
Hearing Impairment	Heart Attack	Heartburn
Heart Failure	Heart Surgery	Heat Stroke
Hematemesis	Hematuria	Hemianopia
Hemiplegia	Hemodialysis	Hemodynamic Monitoring
Hemolytic Uremic Syndrome	Hemophilia	Hemoptysis
Hemorrhage	Hemorrhoidectomy	Hemorrhoids
Hemothorax	Hepatitis	Hernia
Herniated Disk	Herniorrhaphy	Herpes in Pregnancy
Herpes Simplex I	Herpes Simplex II	Herpes Zoster
HHNS (Hyperosmolar Hyperglycemic Nonketotic Syndrome)	Hiatal Hernia	Hip Fracture
Hip Replacement	Hirschsprung's Disease	Hirsutism
Hitting Behavior	HIV (Human Immunodeficiency Virus)	Hodgkin's Disease
Homelessness	Home Maintenance Problems	Hope
Hopelessness	Hospitalized Child	Hostile Behavior
HTN (Hypertension)	Human Immunodeficiency Virus (HIV)	Humiliating Experience
Huntington's Disease	Hydrocele	Hydrocephalus
Hygiene, Inability to Provide Own	Hyperactive Syndrome	Hyperbilirubinemia (Infant)
Hypercalcemia	Hypercapnia	Hyperemesis Gravidarum
Hyperglycemia	Hyperkalemia	Hypernatremia
Hyperosmolar Hyperglycemic Nonketotic Syndrome (HHNS)	Hyperphosphatemia	Hypersensitivity to Slight Criticism

Hypertension (HTN)	Hyperthermia	Hyperthyroidism
Hyperventilation	Hypocalcemia	Hypoglycemia
Hypokalemia	Hypomagnesemia	Hypomania
Hyponatremia	Hypoplastic Left Lung	Hypotension
Hypothermia	Hypothyroidism	Hypovolemic Shock
Hypoxia	Hysterectomy	

Headache

Acute Pain r/t lack of knowledge of pain control techniques or methods to prevent headaches

Ineffective Health management r/t lack of knowledge, identification, elimination of aggravating factors

Health Behavior, Risk-Prone

Risk-prone **Health behavior**: Risk factors (See **Health behavior, risk-prone, Section III**)

Health Maintenance Problems

Ineffective Health maintenance (See **Health maintenance, ineffective, Section III**)

Ineffective Health management (See **Health management, ineffective, Section III**)

Health-Seeking Person

Readiness for enhanced **Health management** (See **Health management, readiness for enhanced, Section III**)

Hearing Impairment

Impaired verbal **Communication** r/t inability to hear own voice

Hearing Loss (See **Hearing Loss, Section III**)

Social isolation r/t difficulty with communication

Heart Attack

See *MI (Myocardial Infarction)*

Heartburn

Nausea r/t gastrointestinal irritation

Acute Pain: heartburn r/t inflammation of stomach and esophagus

Risk for imbalanced **Nutrition**: less than body requirements: Risk factor: pain after eating

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Gastroesophageal Reflux (GERD)*

Heart Failure

Activity intolerance r/t weakness, fatigue

Decreased **Cardiac output** r/t impaired cardiac function, increased preload, decreased contractility, increased afterload

Constipation r/t activity intolerance

Fatigue r/t disease process with decreased cardiac output

Fear r/t threat to one's own well-being

Excess **Fluid volume** r/t impaired excretion of sodium and water

Impaired **Gas exchange** r/t excessive fluid in interstitial space of lungs

Powerlessness r/t illness-related regimen

Risk for **Shock** (cardiogenic): Risk factors: decreased contractility of heart, increased afterload

Readiness for enhanced **Health management** (See **Health management, readiness for enhanced, Section III**)

See *Child with Chronic Condition; Congenital Heart Disease/ Cardiac Anomalies; Hospitalized Child*

Heart Surgery

See *Coronary Artery Bypass Grafting (CABG)*

Heat Stroke

Deficient **Fluid volume** r/t profuse diaphoresis from high environmental temperature

Hyperthermia r/t vigorous activity, high environmental temperature, inappropriate clothing

Hematemesis

See *GI Bleed (Gastrointestinal Bleeding)*

Hematuria

See *Kidney Stone; UTI (Urinary Tract Infection)*

Hemianopia

Anxiety r/t change in vision

Unilateral Neglect r/t effects of disturbed perceptual abilities

Visual Loss r/t impaired sensory reception, transmission, integration

Risk for **Injury**: Risk factor: disturbed sensory perception

Hemiplegia

Anxiety r/t change in health status

Disturbed **Body Image** r/t functional loss of one side of body

Impaired physical **Mobility** r/t loss of neurological control of involved extremities

Self-Care deficit: specify: r/t neuromuscular impairment

Impaired **Sitting** r/t partial paralysis

Impaired **Standing** r/t partial paralysis

Impaired **Transfer ability** r/t partial paralysis

Unilateral Neglect r/t effects of disturbed perceptual abilities

Impaired **Walking** r/t loss of neurological control of involved extremities

Risk for **Falls**: Risk factor: impaired mobility

Risk for impaired **Skin integrity**: Risk factors: alteration in sensation, immobility; pressure over bony prominence

See *CVA (Cerebrovascular Accident)*

Hemodialysis

Ineffective Coping r/t situational crisis

Interrupted **Family processes** r/t changes in role responsibilities as a result of therapy regimen

Excess **Fluid volume** r/t renal disease with minimal urine output

Powerlessness r/t treatment regimen

Risk for **Caregiver Role Strain**: Risk factor: complexity of care receiver treatment

Risk for **Electrolyte imbalance**: Risk factor: effect of metabolic state on kidney function

Risk for deficient **Fluid volume**: Risk factor: excessive removal of fluid during dialysis

Risk for **Infection**: Risk factors: exposure to blood products, risk for developing hepatitis B or C, impaired immune system

Risk for **Injury**: Risk factors: clotting of blood access, abnormal surface for blood flow

Risk for impaired **Tissue** integrity: Risk factor: mechanical factor associated with fistula formation

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Renal Failure; Renal Failure, Child with Chronic Condition*

Hemodynamic Monitoring

Risk for **Infection**: Risk factor: invasive procedure

Risk for **Injury**: Risk factors: inadvertent wedging of catheter, dislodgment of catheter, disconnection of catheter

Risk for impaired **Tissue** integrity: Risk factor: invasive procedure

See *Shock; Cardiogenic, Hypovolemic, Septic, Systemic Inflammatory Response Syndrome (SIRS)*

Hemolytic Uremic Syndrome

Fatigue r/t decreased red blood cells

Fear r/t serious condition with unknown outcome

Deficient **Fluid** volume r/t vomiting, diarrhea

Nausea r/t effects of uremia

Risk for **Injury**: Risk factors: decreased platelet count, seizure activity

Risk for impaired **Skin** integrity: Risk factor: diarrhea

See *Hospitalized Child; Renal Failure, Acute/Chronic, Child*

Hemophilia

Fear r/t high risk for AIDS infection from contaminated blood products

Impaired physical **Mobility** r/t pain from acute bleeds, imposed activity restrictions, joint pain

Acute **Pain** r/t bleeding into body tissues

Risk for **Bleeding**: Risk factors: deficient clotting factors, child's developmental level, age-appropriate play, inappropriate use of toys or sports equipment

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Child with Chronic Condition; Hospitalized Child; Maturation Issues, Adolescent*

Hemoptysis

Fear r/t serious threat to well-being

Risk for ineffective **Airway** clearance: Risk factor: obstruction of airway with blood and mucus

Risk for deficient **Fluid** volume: Risk factor: excessive loss of blood

Hemorrhage

Fear r/t threat to well-being

Deficient **Fluid** volume r/t massive blood loss

See *Hypovolemic Shock*

Hemorrhoidectomy

Anxiety r/t embarrassment, need for privacy

Constipation r/t fear of pain with defecation

Acute **Pain** r/t surgical procedure

Urinary Retention r/t pain, anesthetic effect

Risk for **Bleeding**: Risk factors: inadequate clotting, trauma from surgery

Readiness for enhanced **Knowledge**: expresses an interest in learning

Hemorrhoids

Impaired **Comfort** r/t itching in rectal area

Constipation r/t painful defecation, poor bowel habits

Impaired **Sitting** r/t pain and pressure

Readiness for enhanced **Knowledge**: expresses an interest in learning

Hemothorax

Deficient **Fluid** volume r/t blood in pleural space

See *Pneumothorax*

Hepatitis

Activity intolerance r/t weakness or fatigue caused by infection

Deficient **Diversional** activity r/t isolation

Fatigue r/t infectious process, altered body chemistry

Imbalanced **Nutrition**: less than body requirements r/t anorexia, impaired use of proteins and carbohydrates

Acute **Pain** r/t edema of liver, bile irritating skin

Social isolation r/t treatment-imposed isolation

Risk for deficient **Fluid** volume: Risk factor: excessive loss of fluids from vomiting and diarrhea

Readiness for enhanced **Knowledge**: expresses an interest in learning

Hernia

See *Hiatal Hernia; Inguinal Hernia Repair*

Herniated Disk

See *Low Back Pain*

Herniorrhaphy

See *Inguinal Hernia Repair*

Herpes in Pregnancy

Fear r/t threat to fetus, impending surgery

Situational low **Self-Esteem** r/t threat to fetus as a result of disease process

Risk for **Infection** (infant): Risk factors: transplacental transfer during primary herpes, exposure to active herpes during birth process

See *Herpes Simplex II*

Herpes Simplex I

Impaired **Oral Mucous Membrane** r/t inflammatory changes in mouth

Herpes Simplex II

Ineffective **Health** maintenance r/t deficient knowledge regarding treatment, prevention, spread of disease

Acute **Pain** r/t active herpes lesion

Situational low **Self-Esteem** r/t expressions of shame or guilt

Sexual dysfunction r/t disease process

Impaired **Tissue** integrity r/t active herpes lesion

Impaired **Urinary** elimination r/t pain with urination

Herpes Zoster

See *Shingles*

HHNS (Hyperosmolar Hyperglycemic Nonketotic Syndrome)

See *Hyperosmolar Hyperglycemic Nonketotic Syndrome (HHNS)*

Hiatal Hernia

Ineffective **Health** maintenance r/t deficient knowledge regarding care of disease

Nausea r/t effects of gastric contents in esophagus

Imbalanced **Nutrition**: less than body requirements r/t pain after eating

Acute **Pain** r/t gastroesophageal reflux

Hip Fracture

Acute **Confusion** r/t sensory overload, sensory deprivation, medication side effects, advanced age, pain

Constipation r/t immobility, opioids, anesthesia

Fear r/t outcome of treatment, future mobility, present helplessness

Impaired physical **Mobility** r/t surgical incision, temporary absence of weight bearing, pain when walking

Acute **Pain** r/t injury, surgical procedure, movement

Powerlessness r/t health care environment

Self-Care deficit: specify r/t musculoskeletal impairment

Impaired **Transfer** ability r/t immobilization of hip

Impaired **Walking** r/t temporary absence of weight bearing

Risk for **Bleeding**: Risk factors: postoperative complication, surgical blood loss

Risk for **Infection**: Risk factor: invasive procedure

Risk for **Injury**: Risk factors: activities such as greater than 90-degree flexion of hips that can result in dislodged prosthesis, unsteadiness when ambulating

Risk for **Perioperative Positioning** injury: Risk factors: immobilization, muscle weakness, emaciation

Risk for **Peripheral Neurovascular** dysfunction: Risk factors: trauma, vascular obstruction, fracture

Risk for impaired **Skin** integrity: Risk factor: immobility

Hip Replacement

See *Total Joint Replacement (Total Hip/Total Knee/Shoulder)*

Hirschsprung's Disease

Constipation: bowel obstruction r/t inhibited peristalsis as a result of congenital absence of parasympathetic ganglion cells in distal colon

Grieving r/t loss of perfect child, birth of child with congenital defect even though child expected to be normal within 2 years

Imbalanced **Nutrition**: less than body requirements r/t anorexia, pain from distended colon

Acute **Pain** r/t distended colon, incisional postoperative pain

Impaired **Skin** integrity r/t stoma, potential skin care problems associated with stoma

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Hospitalized Child*

Hirsutism

Disturbed **Body Image** r/t excessive hair

Hitting Behavior

Acute **Confusion** r/t dementia, alcohol abuse, drug abuse, delirium

Risk for other-directed **Violence** (See **Violence, other-directed, risk for, Section III**)

HIV (Human Immunodeficiency Virus)

Fear r/t possible death

Ineffective **Protection** r/t depressed immune system

See *AIDS (Acquired Immunodeficiency Syndrome)*

Hodgkin's Disease

See *Anemia; Cancer; Chemotherapy*

Homelessness

Impaired **Home** maintenance r/t impaired cognitive or emotional functioning, inadequate support system, insufficient finances

Home Maintenance Problems

Impaired **Home** maintenance (See **Home maintenance, impaired, Section III**)

Self-Neglect r/t mental illness, substance abuse, cognitive impairment

Powerlessness r/t interpersonal interactions

Risk for **Trauma**: Risk factor: being in high-crime neighborhood

Hope

Readiness for enhanced **Hope** (See **Hope, readiness for enhanced, Section III**)

Hopelessness

Hopelessness (See **Hopelessness, Section III**)

Hospitalized Child

Activity intolerance r/t fatigue associated with acute illness

Anxiety: separation (child) r/t familiar surroundings and separation from family and friends

Compromised family **Coping** r/t possible prolonged hospitalization that exhausts supportive capacity of significant people

Ineffective **Coping**: parent r/t possible guilt regarding hospitalization of child, parental inadequacies

Deficient **Diversional** activity r/t immobility, monotonous environment, frequent or lengthy treatments, reluctance to participate, therapeutic isolation, separation from peers

Interrupted **Family** processes r/t situational crisis of illness, disease, hospitalization

Fear r/t deficient knowledge or maturational level with fear of unknown, mutilation, painful procedures, surgery

Hopelessness: child r/t prolonged activity restriction, uncertain prognosis

Insomnia: child or parent r/t 24-hour care needs of hospitalization

Acute Pain r/t treatments, diagnostic or therapeutic procedures, disease process

Powerlessness: child r/t health care environment, illness-related regimen

Risk for impaired **Attachment**: Risk factor: separation

Risk for delayed **Development**: regression: Risk factors: disruption of normal routine, unfamiliar environment or caregivers, developmental vulnerability of young children

Risk for **Injury**: Risk factors: unfamiliar environment, developmental age, lack of parental knowledge regarding safety (e.g., side rails, IV site/pole)

Risk for imbalanced **Nutrition**: less than body requirements: Risk factors: anorexia, absence of familiar foods, cultural preferences

Readiness for enhanced family **Coping**: impact of crisis on family values, priorities, goals, relationships in family

See *Child with Chronic Condition*

Hostile Behavior

Risk for other-directed **Violence**: Risk factor: antisocial personality disorder

HTN (Hypertension)

Ineffective **Health** management (See **Health management, ineffective**, Section III)

Readiness for enhanced **Health** management (See **Health management, readiness for enhanced**, Section III)

Risk for **Overweight**: Risk factor: lack of knowledge of relationship between diet and disease process

Human Immunodeficiency Virus (HIV)

See *AIDS (Acquired Immunodeficiency Syndrome)*; *HIV (Human Immunodeficiency Virus)*

Humiliating Experience

Risk for compromised **Human Dignity** (See **Human Dignity, compromised, risk for**, Section III)

Huntington's Disease

Decisional Conflict r/t whether to have children

See *Neurologic Disorders*

Hydrocele

Acute Pain r/t severely enlarged hydrocele

Ineffective **Sexuality** pattern r/t recent surgery on area of scrotum

Hydrocephalus

Decisional Conflict r/t unclear or conflicting values regarding selection of treatment modality

Interrupted **Family** processes r/t situational crisis

Imbalanced **Nutrition**: less than body requirements r/t inadequate intake as a result of anorexia, nausea, vomiting, feeding difficulties

Risk for delayed **Development**: Risk factor: sequelae of increased intracranial pressure

Risk for disproportionate **Growth**: Risk factor: sequelae of increased intracranial pressure

Risk for **Infection**: Risk factor: sequelae of invasive procedure (shunt placement)

Risk for ineffective **Cerebral** tissue perfusion: Risk factors: interrupted flow, hypervolemia of cerebral ventricles

Risk for **Falls**: Risk factors: acute illness, alteration in cognitive functioning

See *Normal Pressure Hydrocephalus (NPH)*; *Child with Chronic Condition*; *Hospitalized Child*; *Mental Retardation (if appropriate)*; *Premature Infant (Child)*; *Premature Infant (Parent)*

Hygiene, Inability to Provide Own

Frail Elderly syndrome r/t living alone

Self-Neglect (See **Self-Neglect**, Section III)

Bathing **Self-Care** deficit (See **Self-Care deficit, bathing**, Section III)

Hyperactive Syndrome

Decisional Conflict r/t multiple or divergent sources of information regarding education, nutrition, medication regimens; willingness to change own food habits; limited resources

Parental **Role** conflict: when siblings present r/t increased attention toward hyperactive child

Compromised family **Coping** r/t unsuccessful strategies to control excessive activity, behaviors, frustration, anger

Ineffective **Impulse** control r/t disorder of development, environment that might cause frustration or irritation

Ineffective **Role** performance: parent r/t stressors associated with dealing with hyperactive child, perceived or projected blame for causes of child's behavior, unmet needs for support or care, lack of energy to provide for those needs

Chronic low **Self-Esteem** r/t inability to achieve socially acceptable behaviors; frustration; frequent reprimands, punishment, or scolding for uncontrolled activity and behaviors; mood fluctuations and restlessness; inability to succeed academically; lack of peer support

Impaired **Social** interaction r/t impulsive and overactive behaviors, concomitant emotional difficulties, distractibility and excitability

Risk for delayed **Development**: Risk factor: behavior disorders

Risk for impaired **Parenting**: Risk factor: disruptive or uncontrollable behaviors of child

Risk for other-directed **Violence**: parent or child: Risk factors: frustration with disruptive behavior, anger, unsuccessful relationships

Hyperbilirubinemia (Infant)

Anxiety: parent r/t threat to infant, unknown future

Parental **Role** conflict r/t interruption of family life because of care regimen

Neonatal **Jaundice** r/t abnormal breakdown of red blood cells following birth

Imbalanced **Nutrition**: less than body requirements (infant) r/t disinterest in feeding because of jaundice-related lethargy

Risk for disproportionate **Growth**: infant: Risk factor: disinterest in feeding because of jaundice-related lethargy

Risk for imbalanced body **Temperature**: infant: Risk factor: phototherapy

Risk for **Injury**: infant: Risk factors: kernicterus, phototherapy lights

Hypercalcemia

Decreased **Cardiac** output r/t bradycardia

Impaired physical **Mobility** r/t decreased muscle tone

Imbalanced **Nutrition**: less than body requirements r/t gastrointestinal manifestations of hypercalcemia (nausea, anorexia, ileus)

Risk for **Disuse** syndrome: Risk factor: comatose state impairing mobility

Hypercapnia

Fear r/t difficulty breathing

Impaired **Gas** exchange r/t ventilation-perfusion imbalance, retention of carbon dioxide

See *ARDS, COPD, Sleep Apnea*,

Hyperemesis Gravidarum

Anxiety r/t threat to self and infant, hospitalization

Deficient **Fluid** volume r/t excessive vomiting

Impaired **Home** maintenance r/t chronic nausea, inability to function

Nausea r/t hormonal changes of pregnancy

Imbalanced **Nutrition**: less than body requirements r/t excessive vomiting

Powerlessness r/t health care regimen

Social isolation r/t hospitalization

Risk for **Electrolyte** imbalance: Risk factor: vomiting

Hyperglycemia

Ineffective **Health** management r/t complexity of therapeutic regimen, decisional conflicts, economic difficulties, unresponsive family, insufficient cues to action, deficient knowledge, mistrust, lack of acknowledgment of seriousness of condition

Risk for unstable blood **Glucose** level (See **Glucose** level, blood, unstable, risk for, Section III)

See *Diabetes Mellitus*

Hyperkalemia

Risk for **Activity** intolerance: Risk factor: muscle weakness

Risk for decreased **Cardiac** tissue perfusion: Risk factor: abnormal electrolyte level affecting heart rate and rhythm

Risk for excess **Fluid** volume: Risk factor: untreated renal failure

Hypernatremia

Risk for deficient **Fluid** volume: Risk factors: abnormal water loss, inadequate water intake

Hyperosmolar Hyperglycemic Nonketotic Syndrome (HHNS)

Acute **Confusion** r/t dehydration, electrolyte imbalance

Deficient **Fluid** volume r/t polyuria, hyperglycemia, inadequate fluid intake

Risk for **Electrolyte** imbalance: Risk factor: effect of metabolic state on kidney function

Risk for **Injury**: seizures: Risk factors: hyperosmolar state, electrolyte imbalance

See *Diabetes Mellitus; Diabetes Mellitus, Juvenile (IDDM Type 1)*

Hyperphosphatemia

Deficient **Knowledge** r/t dietary changes needed to control phosphate levels

See *Renal Failure*

Hypersensitivity to Slight Criticism

Defensive **Coping** r/t situational crisis, psychological impairment, substance abuse

Hypertension (HTN)

See *HTN (Hypertension)*

Risk for decreased **Cardiac** output: Risk factors: decreased contractility and altered conductivity associated with myocardial damage

Risk for impaired **Cardiovascular** function: Risk factors: obesity, inadequate physical activity and failure to alter diet

Hyperthermia

Hyperthermia (See **Hyperthermia**, Section III)

Hyperthyroidism

Anxiety r/t increased stimulation, loss of control

Diarrhea r/t increased gastric motility

Insomnia r/t anxiety, excessive sympathetic discharge

Imbalanced **Nutrition**: less than body requirements r/t increased metabolic rate, increased gastrointestinal activity

Risk for **Injury**: eye damage: Risk factor: protruding eyes without sufficient lubrication

Readiness for enhanced **Knowledge**: expresses an interest in learning

Hyperventilation

Ineffective **Breathing** pattern r/t anxiety, acid-base imbalance
See *Anxiety Disorder, Dyspnea, Heart Failure*

Hypocalcemia

Activity intolerance r/t neuromuscular irritability
Ineffective **Breathing** pattern r/t laryngospasm
Imbalanced **Nutrition**: less than body requirements r/t effects of vitamin D deficiency, renal failure, malabsorption, laxative use

Hypoglycemia

Acute **Confusion** r/t insufficient blood glucose to brain
Ineffective **Health** management r/t deficient knowledge regarding disease process, self-care
Imbalanced **Nutrition**: less than body requirements r/t imbalance of glucose and insulin level
Risk for unstable blood **Glucose** level (See **Glucose level, blood, unstable, risk for, Section III**)

See *Diabetes Mellitus; Diabetes Mellitus, Juvenile (IDDM Type 1)*

Hypokalemia

Activity intolerance r/t muscle weakness
Risk for decreased **Cardiac** tissue perfusion: Risk factor: possible dysrhythmia from electrolyte imbalance

Hypomagnesemia

Imbalanced **Nutrition**: less than body requirements r/t deficient knowledge of nutrition, alcoholism

See *Alcoholism*

Hypomania

Insomnia r/t psychological stimulus

See *Manic Disorder, Bipolar I*

Hyponatremia

Acute **Confusion** r/t electrolyte imbalance
Excess **Fluid** volume r/t excessive intake of hypotonic fluids
Risk for **Injury**: Risk factors: seizures, new onset of confusion

Hypoplastic Left Lung

See *Congenital Heart Disease/Cardiac Anomalies*

Hypotension

Decreased **Cardiac** output r/t decreased preload, decreased contractility

Risk for deficient **Fluid** volume: Risk factor: excessive fluid loss

Risk for ineffective **Cerebral** tissue perfusion: Risk factors: hypovolemia, decreased contractility, decreased afterload

Risk for ineffective **Gastrointestinal** perfusion (See **Gastrointestinal perfusion, ineffective, risk for, Section III**)

Risk for ineffective **Renal** perfusion: Risk factor: prolonged ischemia of kidneys

Risk for **Shock** (See **Shock, risk for, Section III**)

See *Dehydration, Heart Failure, MI*

Hypothermia

Hypothermia (See **Hypothermia, Section III**)

Risk for **Hypothermia** (see **Hypothermia, risk for, Section III**)

Hypothyroidism

Activity intolerance r/t muscular stiffness, shortness of breath on exertion

Constipation r/t decreased gastric motility

Impaired **Gas** exchange r/t respiratory depression

Impaired **Skin** integrity r/t edema, dry or scaly skin

Risk for **Overweight**: Risk factor: decreased metabolic process

Hypovolemic Shock

See *Shock, Hypovolemic*

Hypoxia

Acute **Confusion** r/t decreased oxygen supply to brain

Fear r/t breathlessness

Impaired **Gas** exchange r/t altered oxygen supply, inability to transport oxygen

Risk for **Shock** (See **Shock, risk for, Section III**)

Hysterectomy

Constipation r/t opioids, anesthesia, bowel manipulation during surgery

Ineffective **Coping** r/t situational crisis of surgery

Grieving r/t change in body image, loss of reproductive status

Acute **Pain** r/t surgical injury

Sexual dysfunction r/t disturbance in self-concept

Urinary retention r/t edema in area, anesthesia, opioids, pain

Risk for **Bleeding**: Risk factor: surgical procedure

Risk for **Constipation**: Risk factors: opioids, anesthesia, bowel manipulation during surgery

Risk for ineffective peripheral **Tissue** perfusion: Risk factor: deficient knowledge of aggravating factors

Readiness for enhanced **Knowledge**: Expresses an interest in learning

See *Surgery, Perioperative; Surgery, Preoperative; Surgery, Postoperative*

IBS (Irritable Bowel Syndrome)

Constipation r/t low-residue diet, stress

Diarrhea r/t increased motility of intestines associated with disease process, stress

Ineffective **Health** management r/t deficient knowledge, powerlessness

Chronic **Pain** r/t spasms, increased motility of bowel

Risk for **Electrolyte** imbalance: Risk factor: diarrhea

Readiness for enhanced **Health** management: expresses desire to manage illness and prevent onset of symptoms

List of Nursing Assessments by Letter: I

IBS (Irritable Bowel Syndrome)	ICD (Implantable Cardioverter/Defibrillator)	IDDM (Insulin-Dependent Diabetes)
Identity Disturbance/Problems	Idiopathic Thrombocytopenic Purpura (ITP)	Ileal Conduit
Ileostomy	Ileus	Immobility
Immunization	Immunosuppression	Impaction of Stool
Imperforate Anus	Impaired Sitting	Impaired Standing
Impetigo	Implantable Cardioverter/Defibrillator (ICD)	Impotence
Impulsiveness	Inactivity	Incompetent Cervix
Incontinence of Stool	Incontinence of Urine	Indigestion
Induction of Labor	Infant Apnea	Infant Behavior
Infant Care	Infant Feeding Pattern, Ineffective	Infant of Diabetic Mother
Infant of Substance-Abusing Mother (Fetal Alcohol Syndrome, Crack Baby, Other Drug Withdrawal Infants)	Infantile Polyarteritis	Infection
Infection, Potential for	Infertility	Inflammatory Bowel Disease (Child and Adult)
Influenza	Inguinal Hernia Repair	Injury
Insanity	Insomnia	Insulin Shock
Intellectual Disability	Intermittent Claudication	Internal Cardioverter/Defibrillator (ICD)
Internal Fixation	Interstitial Cystitis	Intervertebral Disk Excision
Intestinal Obstruction	Intestinal Perforation	Intoxication
Intraaortic Balloon Counterpulsation	Intracranial Pressure, Increased	Intrauterine Growth Retardation
Intravenous Therapy	Intubation, Endotracheal or Nasogastric	Iodine Reaction with Diagnostic Testing
Irregular Pulse	Irritable Bowel Syndrome (IBS)	Isolation
Itching	ITP (Idiopathic Thrombocytopenic Purpura)	

ICD (Implantable Cardioverter/Defibrillator)

Anxiety r/t possible dysrhythmia, threat of death
 Decreased **Cardiac** output r/t possible dysrhythmia
 Readiness for enhanced **Knowledge:** expresses an interest in learning

IDDM (Insulin-Dependent Diabetes)

See *Diabetes Mellitus*

Identity Disturbance/Problems

Disturbed personal **Identity** r/t situational crisis, psychological impairment, chronic illness, pain
 Risk for disturbed personal **Identity** (See **Identity, personal, risk for disturbed in Section III**)

Idiopathic Thrombocytopenic Purpura (ITP)

See *ITP (Idiopathic Thrombocytopenic Purpura)*

Ileal Conduit

Disturbed **Body Image** r/t presence of stoma
 Ineffective **Health** management r/t new skills required to care for appliance and self
 Ineffective **Sexuality** pattern r/t altered body function and structure
Social isolation r/t alteration in physical appearance, fear of accidental spill of urine
 Risk for **Latex Allergy** response: Risk factor: repeated exposures to latex associated with treatment and management of disease
 Risk for impaired **Skin** integrity: Risk factor: difficulty obtaining tight seal of appliance
 Readiness for enhanced **Knowledge:** expresses an interest in learning

Ileostomy

Disturbed **Body Image** r/t presence of stoma
Diarrhea r/t dietary changes, alteration in intestinal motility
 Deficient **Knowledge** r/t limited practice of stoma care, dietary modifications
 Ineffective **Sexuality** pattern r/t altered body function and structure
Social isolation r/t alteration in physical appearance, fear of accidental spill of ostomy contents
 Risk for impaired **Skin** integrity: Risk factors: difficulty obtaining tight seal of appliance, caustic drainage
 Readiness for enhanced **Knowledge:** expresses an interest in learning

Ileus

Deficient **Fluid** volume r/t loss of fluids from vomiting, fluids trapped in bowel
 Dysfunctional **Gastrointestinal** motility r/t effects of surgery, decreased perfusion of intestines, medication effect, immobility
Nausea r/t gastrointestinal irritation

Acute **Pain** r/t pressure, abdominal distention
 Readiness for enhanced **Knowledge:** expresses an interest in learning

Immobility

Ineffective **Breathing** pattern r/t inability to deep breathe in supine position
 Acute **Confusion:** elderly r/t sensory deprivation from immobility
Constipation r/t immobility
 Risk for **Frail Elderly** syndrome: Risk factors: low physical activity, bed rest
 Impaired physical **Mobility** r/t medically imposed bed rest
 Ineffective peripheral **Tissue Perfusion** r/t interruption of venous flow
Powerlessness r/t forced immobility from health care environment
 Impaired **Walking** r/t limited physical mobility, deconditioning of body
 Risk for **Disuse** syndrome: Risk factor: immobilization
 Risk for impaired **Skin** integrity: Risk factors: pressure over bony prominences, shearing forces when moved; pressure from devices
 Risk for Impaired **Tissue** Integrity: Risk factors: mechanical factors from pressure over bony prominences, shearing forces when moved; pressure from devices
 Risk for **Overweight:** Risk factor: energy expenditure less than energy intake
 Readiness for enhanced **Knowledge:** expresses an interest in learning

Immunization

See *Readiness for enhanced Health management, Section III*

Immunosuppression

Risk for **Infection:** Risk factors: immunosuppression; exposure to disease outbreak
 Impaired **Social** interaction r/t therapeutic isolation

Impaction of Stool

Constipation r/t decreased fluid intake, less than adequate amounts of fiber and bulk-forming foods in diet, medication effect, or immobility

Imperforate Anus

Anxiety r/t ability to care for newborn
 Deficient **Knowledge** r/t home care for newborn
 Impaired **Skin** integrity r/t pruritus

Impaired Sitting

Impaired physical **Mobility** r/t musculoskeletal, cognitive, or neuromuscular disorder

Impaired Standing

Activity intolerance r/t insufficient physiological or psychological energy
Powerlessness r/t loss of function

Impetigo

Impaired **Skin** integrity r/t infectious disease

Readiness for enhanced **Knowledge**: expresses an interest in learning

See *Communicable Diseases, Childhood*

Implantable Cardioverter/Defibrillator (ICD)

See *ICD (Implantable Cardioverter/Defibrillator)*

Impotence

Situational low **Self-Esteem** r/t physiological crisis, inability to practice usual sexual activity

Sexual dysfunction r/t altered body function

Readiness for enhanced **Knowledge**: treatment information for erectile dysfunction

See *Erectile Dysfunction (ED)*

Impulsiveness

Ineffective **Impulse** control r/t (See **Impulse control, ineffective** in Section III)

Inactivity

Activity intolerance r/t imbalance between oxygen supply and demand, sedentary lifestyle, weakness, immobility

Hopelessness r/t deteriorating physiological condition, long-term stress, social isolation

Impaired physical **Mobility** r/t intolerance to activity, decreased strength and endurance, depression, severe anxiety, musculoskeletal impairment, perceptual or cognitive impairment, neuromuscular impairment, pain, discomfort

Risk for **Constipation**: Risk factor: insufficient physical activity

Incompetent Cervix

See *Premature Dilation of the Cervix (Incompetent Cervix)*

Incontinence of Stool

Disturbed **Body Image** r/t inability to control elimination of stool

Bowel **Incontinence** r/t decreased awareness of need to defecate, loss of sphincter control

Toileting **Self-Care** deficit r/t cognitive impairment, neuromuscular impairment, perceptual impairment, weakness

Situational low **Self-Esteem** r/t inability to control elimination of stool

Risk for impaired **Skin** integrity: Risk factor: presence of stool

Incontinence of Urine

Functional urinary **Incontinence** r/t altered environment; sensory, cognitive, or mobility deficits

Overflow urinary **Incontinence** r/t relaxation of pelvic muscles and changes in urinary structures

Reflex urinary **Incontinence** r/t neurological impairment

Stress urinary **Incontinence** (See **Incontinence, urinary, stress**, Section III)

Urge urinary **Incontinence** (See **Incontinence, urinary, urge**, Section III)

Toileting **Self-Care** deficit r/t cognitive impairment

Situational low **Self-Esteem** r/t inability to control passage of urine

Risk for impaired **Skin** integrity: Risk factor: presence of urine on perineal skin

Indigestion

Nausea r/t gastrointestinal irritation

Imbalanced **Nutrition**: less than body requirements r/t discomfort when eating

Induction of Labor

Anxiety r/t medical interventions, powerlessness

Decisional Conflict r/t perceived threat to idealized birth

Ineffective **Coping** r/t situational crisis of medical intervention in birthing process

Acute **Pain** r/t contractions

Situational low **Self-Esteem** r/t inability to carry out normal labor

Risk for **Injury**: maternal and fetal: Risk factors: hypertonic uterus, potential prematurity of newborn

Readiness for enhanced **Family** processes: family support during induction of labor

Infant Apnea

See *Premature Infant (Child); Respiratory Conditions of the Neonate; SIDS (Sudden Infant Death Syndrome)*

Infant Behavior

Disorganized **Infant** behavior r/t pain, oral/motor problems, feeding intolerance, environmental overstimulation, lack of containment or boundaries, prematurity, invasive or painful procedures

Risk for disorganized **Infant** behavior: Risk factors: pain, oral/motor problems, environmental overstimulation, lack of containment or boundaries

Readiness for enhanced organized **Infant** behavior: stable physiologic measures, use of some self-regulatory measures

Infant Care

Readiness for enhanced **Childbearing** process: a pattern of preparing for, maintaining, and strengthening care of newborn infant

Infant Feeding Pattern, Ineffective

Ineffective infant **Feeding** pattern r/t prematurity, neurological impairment or delay, oral hypersensitivity, prolonged nothing-by-mouth order

Infant of Diabetic Mother

Decreased **Cardiac** output r/t cardiomegaly

Deficient **Fluid** volume r/t increased urinary excretion and osmotic diuresis

Imbalanced **Nutrition**: less than body requirements r/t hypotonia, lethargy, poor sucking, postnatal metabolic changes from hyperglycemia to hypoglycemia and hyperinsulinism

Risk for delayed **Development**: Risk factor: prolonged and severe postnatal hypoglycemia

Risk for impaired **Gas exchange**: Risk factors: increased incidence of cardiomegaly, prematurity

Risk for unstable blood **Glucose level**: Risk factor: metabolic change from hyperglycemia to hypoglycemia and hyperinsulinism

Risk for disproportionate **Growth**: Risk factor: prolonged and severe postnatal hypoglycemia

Risk for disturbed **Maternal–Fetal dyad**: Risk factor: impaired glucose metabolism

See *Premature Infant (Child)*; *Respiratory Conditions of the Neonate*

Infant of Substance-Abusing Mother (Fetal Alcohol Syndrome, Crack Baby, Other Drug Withdrawal Infants)

Ineffective **Airway clearance** r/t pooling of secretions from the lack of adequate cough reflex, effects of viral or bacterial lower airway infection as a result of altered protective state

Interrupted **Breastfeeding** r/t use of drugs or alcohol by mother

Diarrhea r/t effects of withdrawal, increased peristalsis from hyperirritability

Ineffective infant **Feeding pattern** r/t uncoordinated or ineffective sucking reflex

Disorganized **Infant behavior** r/t exposure and or withdrawal from toxic substances (alcohol and drugs)

Ineffective **Childbearing process** r/t inconsistent prenatal health visits, suboptimal maternal nutrition, substance abuse

Insomnia r/t hyperirritability or hypersensitivity to environmental stimuli

Imbalanced **Nutrition**: less than body requirements r/t feeding problems; uncoordinated or ineffective suck and swallow; effects of diarrhea, vomiting, or colic associated with maternal substance abuse

Impaired **Parenting** r/t impaired or absent attachment behaviors, inadequate support systems

Risk for delayed **Development**: Risk factor: substance abuse

Risk for disproportionate **Growth**: Risk factor: substance abuse

Risk for **Infection**: skin, meningeal, respiratory: Risk factor: stress effects of withdrawal

See *Cerebral Palsy*; *Child with Chronic Condition*; *Crack Baby*; *Failure to Thrive, Nonorganic*; *Hospitalized Child*; *Hyperactive Syndrome*; *Premature Infant (Child)*; *SIDS (Sudden Infant Death Syndrome)*

Infantile Polyarteritis

See *Kawasaki Disease*

Infection

Hyperthermia r/t increased metabolic rate

Ineffective **Protection** r/t inadequate nutrition, abnormal blood profiles, drug therapies, treatments

Impaired **Social interaction** r/t therapeutic isolation

Risk for **Vascular Trauma**: Risk factor: infusion of antibiotics

Infection, Potential for

Risk for **Infection** (See *Infection, risk for, Section III*)

Infertility

Ineffective **Health management** r/t deficient knowledge about infertility

Powerlessness r/t infertility

Chronic **Sorrow** r/t inability to conceive a child

Spiritual distress r/t inability to conceive a child

Inflammatory Bowel Disease (Child and Adult)

Ineffective **Coping** r/t repeated episodes of diarrhea

Diarrhea r/t effects of inflammatory changes of the bowel

Deficient **Fluid volume** r/t frequent and loose stools

Imbalanced **Nutrition**: less than body requirements r/t anorexia, decreased absorption of nutrients from gastrointestinal tract

Acute **Pain** r/t abdominal cramping and anal irritation

Impaired **Skin integrity** r/t frequent stools, development of anal fissures

Social isolation r/t diarrhea

See *Child with Chronic Condition*; *Crohn's Disease*; *Hospitalized Child*; *Maturational Issues, Adolescent*

Influenza

Deficient **Fluid volume** r/t inadequate fluid intake

Ineffective **Health management** r/t lack of knowledge regarding preventive immunizations

Ineffective **Thermoregulation** r/t infectious process

Acute **Pain** r/t inflammatory changes in joints

Readiness for enhanced **Knowledge**: information to prevent or treat influenza

Inguinal Hernia Repair

Impaired physical **Mobility** r/t pain at surgical site and fear of causing hernia to rupture

Acute **Pain** r/t surgical procedure

Urinary retention r/t possible edema at surgical site

Risk for **Infection**: Risk factor: surgical procedure

Injury

Risk for **Falls**: Risk factors: orthostatic hypotension, impaired physical mobility, diminished mental status

Risk for **Injury**: Risk factor: environmental conditions interacting with client's adaptive and defensive resources

Risk for corneal **Injury**: Risk factors: blinking less than five times per minute, mechanical ventilation, pharmaceutical agent, prolonged hospitalization

Risk for **Thermal injury**: Risk factors: cognitive impairment, inadequate supervision, developmental level

Risk for urinary tract **Injury**: Risk factor: inflammation and/or infection from long-term use of urinary catheter

Insanity

See *Mental Illness, Psychosis*

Insomnia

(See **Insomnia**, Section III)

Insulin Shock

See *Hypoglycemia*

Intellectual Disability

Impaired verbal **Communication** r/t developmental delay
 Interrupted **Family** processes r/t crisis of diagnosis and situational transition

Grieving r/t loss of perfect child, birth of child with congenital defect or subsequent head injury

Deficient community **Health** r/t lack of programs to address developmental deficiencies

Impaired **Home** maintenance r/t insufficient support systems

Self-Neglect r/t learning disability

Self-Care deficit: bathing, dressing, feeding, toileting r/t perceptual or cognitive impairment

Self-Mutilation r/t inability to express tension verbally

Social isolation r/t delay in accomplishing developmental tasks

Spiritual distress r/t chronic condition of child with special needs

Stress overload r/t intense, repeated stressor (chronic condition)

Impaired **Swallowing** r/t neuromuscular impairment

Risk for ineffective **Activity** planning r/t inability to process information

Risk for delayed **Development**: Risk factor: cognitive or perceptual impairment

Risk for disproportionate **Growth**: Risk factor: mental retardation

Risk for impaired **Religiosity**: Risk factor: social isolation

Risk for **Self-Mutilation**: Risk factors: separation anxiety, depersonalization

Readiness for enhanced family **Coping**: adaptation and acceptance of child's condition and needs

See *Child with Chronic Condition; Safety, Childhood*

Intermittent Claudication

Deficient **Knowledge** r/t lack of knowledge of cause and treatment of peripheral vascular diseases

Acute **Pain** r/t decreased circulation to extremities with activity

Ineffective peripheral **Tissue Perfusion** r/t interruption of arterial flow

Risk for **Injury**: Risk factor: tissue hypoxia

Readiness for enhanced **Knowledge**: prevention of pain and impaired circulation

See *Peripheral Vascular Disease (PVD)*

Internal Cardioverter/Defibrillator (ICD)

See *ICD (Implantable Cardioverter/Defibrillator)*

Internal Fixation

Impaired **Walking** r/t repair of fracture

Risk for **Infection**: Risk factors: traumatized tissue, broken skin

See *Fracture*

Interstitial Cystitis

Acute **Pain** r/t inflammatory process

Impaired **Urinary** elimination r/t inflammation of bladder

Risk for **Infection**: Risk factor: suppressed inflammatory response

Readiness for enhanced **Knowledge**: expresses an interest in learning

Intervertebral Disk Excision

See *Laminectomy*

Intestinal Obstruction

See *Ileus, Bowel Obstruction*

Intestinal Perforation

See *Peritonitis*

Intoxication

Anxiety r/t loss of control of actions

Acute **Confusion** r/t alcohol abuse

Ineffective **Coping** r/t use of mind-altering substances as a means of coping

Impaired **Memory** r/t effects of alcohol on mind

Risk for **Aspiration**: Risk factors: diminished mental status, vomiting

Risk for **Falls**: Risk factor: diminished mental status

Risk for other-directed **Violence**: Risk factor: inability to control thoughts and actions

Intraaortic Balloon Counterpulsation

Anxiety r/t device providing cardiovascular assistance

Decreased **Cardiac** output r/t heart dysfunction needing counterpulsation

Compromised family **Coping** r/t seriousness of significant other's medical condition

Impaired physical **Mobility** r/t restriction of movement because of mechanical device

Risk for **Peripheral Neurovascular** dysfunction: Risk factors: vascular obstruction of balloon catheter, thrombus formation, emboli, edema

Risk for **Infection**: Risk factor: invasive procedure

Risk for impaired **Tissue** integrity: Risk factor: invasive procedure

Intracranial Pressure, Increased

Ineffective **Breathing** pattern r/t pressure damage to breathing center in brainstem

Acute **Confusion** r/t increased intracranial pressure

Decreased **Intracranial** adaptive capacity r/t sustained increase in intracranial pressure

Impaired **Memory** r/t neurological disturbance

Vision Loss r/t pressure damage to sensory centers in brain

Risk for ineffective **Cerebral** tissue perfusion: Risk factors: body position, cerebral vessel circulation deficits

See *Head Injury, Subarachnoid Hemorrhage*

Intrauterine Growth Retardation

Anxiety: maternal r/t threat to fetus

Ineffective **Coping:** maternal r/t situational crisis, threat to fetus

Impaired **Gas** exchange r/t insufficient placental perfusion

Imbalanced **Nutrition:** less than body requirements r/t insufficient placenta

Situational low **Self-Esteem:** maternal r/t guilt about threat to fetus

Spiritual distress r/t unknown outcome of fetus

Risk for **Powerlessness:** Risk factor: unknown outcome of fetus

Intravenous Therapy

Risk for **Vascular Trauma:** Risk factor: infusion of irritating chemicals

Intubation, Endotracheal or Nasogastric

Disturbed **Body Image** r/t altered appearance with mechanical devices

Impaired verbal **Communication** r/t endotracheal tube

Imbalanced **Nutrition:** less than body requirements r/t inability to ingest food because of the presence of tubes

Impaired **Oral Mucous Membrane** r/t presence of tubes

Acute **Pain** r/t presence of tube

Iodine Reaction with Diagnostic Testing

Risk for adverse reaction to iodinated **Contrast Media** (See [reaction to iodinated Contrast Media](#), risk for adverse, Section III)

Irregular Pulse

See *Dysrhythmia*

Irritable Bowel Syndrome (IBS)

See *IBS (Irritable Bowel Syndrome)*

Isolation

Impaired individual **Resilience** (See [Resilience, individual, impaired](#), Section III)

Social isolation (See [Social isolation](#), Section III)

Itching

Impaired **Comfort** r/t inflammation of skin causing itching

Risk for impaired **Skin** integrity: Risk factor: scratching, dry skin

ITP (Idiopathic Thrombocytopenic Purpura)

Deficient **Diversional** activity r/t activity restrictions, safety precautions

Ineffective **Protection** r/t decreased platelet count

Risk for **Bleeding:** Risk factors: decreased platelet count, developmental level, age-appropriate play

See *Hospitalized Child*

J

Jaundice

Imbalanced **Nutrition**, less than body requirements r/t decreased appetite with liver disorder

Risk for **Bleeding:** Risk factor: impaired liver function

Risk for impaired **Liver** function: Risk factors: possible viral infection, medication effect

Risk for impaired **Skin** integrity: Risk factors: pruritus, itching

See *Cirrhosis; Hepatitis*

Jaundice, Neonatal

Neonatal **Jaundice** (See [Jaundice, neonatal](#), Section III)

Risk for ineffective **Gastrointestinal** perfusion: Risk factor: liver dysfunction

Readiness for enhanced **Health** management (parents): expresses desire to manage treatment: assessment of jaundice when infant is discharged from the hospital, when to call the physician, and possible preventive measures such as frequent breastfeeding

See *Hyperbilirubinemia*

Jaw Pain and Heart Attacks

See *Angina; Chest Pain; MI (Myocardial Infarction)*

Jaw Surgery

Deficient **Knowledge** r/t emergency care for wired jaws (e.g., cutting bands and wires), oral care

Imbalanced **Nutrition:** less than body requirements r/t jaws wired closed, difficulty eating

Acute **Pain** r/t surgical procedure

Impaired **Swallowing** r/t edema from surgery

Risk for **Aspiration:** Risk factor: wired jaws

Jittery

Anxiety r/t unconscious conflict about essential values and goals, threat to or change in health status

Death **Anxiety** r/t unresolved issues relating to end of life

Risk for **Post-Trauma** syndrome: Risk factors: occupation, survivor's role in event, inadequate social support

Jock Itch

Ineffective **Health** management r/t prevention and treatment of disorder

Impaired **Skin** integrity r/t moisture and irritating or tight-fitting clothing

See *Itching*

Joint Dislocation

See *Dislocation of Joint*

List of Nursing Assessments by Letter: J

Jaundice	Jaundice, Neonatal	Jaw Pain and Heart Attacks
Jaw Surgery	Jittery	Jock Itch
Joint Dislocation	Joint Pain	Joint Replacement
JRA (Juvenile Rheumatoid Arthritis)		

Joint Pain

See *Arthritis; Bursitis; JRA (Juvenile Rheumatoid Arthritis); Osteoarthritis; Rheumatoid Arthritis*

Joint Replacement

Risk for **Peripheral Neurovascular** dysfunction: Risk factor: orthopedic surgery

Risk for impaired **Tissue** integrity: Risk factor: invasive procedure

See *Total Joint Replacement (Total Hip/Total Knee/Shoulder)*

JRA (Juvenile Rheumatoid Arthritis)

Impaired **Comfort** r/t altered health status

Fatigue r/t chronic inflammatory disease

Impaired physical **Mobility** r/t pain, restricted joint movement

Acute Pain r/t swollen or inflamed joints, restricted movement, physical therapy

Self-Care deficit: feeding, bathing, dressing, toileting r/t restricted joint movement, pain

Risk for compromised **Human Dignity**: Risk factors: perceived intrusion by clinicians, invasion of privacy

Risk for **Injury**: Risk factors: impaired physical mobility, splints, adaptive devices, increased bleeding potential from antiinflammatory medications

Risk for compromised **Resilience**: Risk factor: chronic condition

Risk for situational low **Self-Esteem**: Risk factor: disturbed body image

Risk for impaired **Skin** integrity: Risk factors: splints, adaptive devices

See *Child with Chronic Condition; Hospitalized Child*

K

Kaposi's Sarcoma

Risk for complicated **Grieving**: Risk factor: loss of social support

Risk for impaired **Religiosity**: Risk factors: illness/hospitalization, ineffective coping

Risk for impaired **Resilience**: Risk factor: serious illness

See *AIDS (Acquired Immunodeficiency Syndrome)*

Kawasaki Disease

Anxiety: parental r/t progression of disease, complications of arthritis, and cardiac involvement

Impaired **Comfort** r/t altered health status

Hyperthermia r/t inflammatory disease process

Imbalanced **Nutrition**: less than body requirements r/t impaired oral mucous membranes

Impaired **Oral Mucous Membrane** r/t inflamed mouth and pharynx; swollen lips that become dry, cracked, fissured

Acute Pain r/t enlarged lymph nodes; erythematous skin rash that progresses to desquamation, peeling, denuding of skin

Impaired **Skin** integrity r/t inflammatory skin changes

Risk for imbalanced **Fluid** volume: Risk factor: hypovolemia

Risk for decreased **Cardiac** tissue perfusion: Risk factor: cardiac involvement

See *Hospitalized Child*

Keloids

Disturbed **Body Image** r/t presence of scar tissue at site of a healed skin injury

Readiness for enhanced **Health** management: desire to have information to manage condition

Keratoconjunctivitis Sicca (Dry Eye Syndrome)

Risk for dry **Eye**: Risk factors: aging, staring at a computer screen for long intervals

Risk for **Infection**: Risk factor: dry eyes that are more vulnerable to infection

Risk for corneal **Injury**: Risk factors: dry eye; exposure of the eyeball

Vision Loss r/t dry eye resulting in film or obstruction of vision (see *care plan in Appendix*)

See *Conjunctivitis*

Keratoplasty

See *Corneal Transplant*

Ketoacidosis, Alcoholic

See *Alcohol Withdrawal; Alcoholism*

Ketoacidosis, Diabetic

Deficient **Fluid** volume r/t excess excretion of urine, nausea, vomiting, increased respiration

Impaired **Memory** r/t fluid and electrolyte imbalance

Imbalanced **Nutrition**: less than body requirements r/t body's inability to use nutrients

Risk for unstable blood **Glucose** level: Risk factor: deficient knowledge of diabetes management (e.g., action plan)

Risk for **Powerlessness**: Risk factor: illness-related regimen

Risk for impaired **Resilience**: Risk factor: complications of disease

See *Diabetes Mellitus*

Keyhole Heart Surgery

See *MIDCAB (Minimally Invasive Direct Coronary Artery Bypass)*

Kidney Disease Screening

Risk for ineffective **Renal** perfusion: Risk factors: hypovolemia, hypertension, alteration in metabolism

Readiness for enhanced **Health** management: seeks information for screening

Kidney Failure

Activity intolerance r/t effects of anemia, heart failure

Death **Anxiety** r/t unknown outcome of disease

Decreased **Cardiac** output r/t effects of heart failure, elevated potassium levels interfering with conduction system

Impaired **Comfort** r/t pruritus

List of Nursing Assessments by Letter: K

Kaposi's Sarcoma	Kawasaki Disease	Keloids
Keratoconjunctivitis Sicca (Dry Eye Syndrome)	Keratoplasty	Ketoacidosis, Alcoholic
Ketoacidosis, Diabetic	Keyhole Heart Surgery	Kidney Disease Screening
Kidney Failure	Kidney Failure Acute/Chronic, Child	Kidney Failure, Nonoliguric
Kidney Stone	Kidney Transplantation, Donor	Kidney Transplantation, Recipient
Kidney Transplant	Kidney Tumor	Kissing Disease
Knee Replacement	Knowledge	Knowledge, Deficient
Kock Pouch	Korsakoff's Syndrome	

Ineffective **Coping** r/t depression resulting from chronic disease

Fatigue r/t effects of chronic uremia and anemia

Excess **Fluid** volume r/t decreased urine output, sodium retention, inappropriate fluid intake

Ineffective **Health** management r/t complexity of health care regimen, inadequate number of cues to action, perceived barriers, powerlessness

Imbalanced **Nutrition**: less than body requirements r/t anorexia, nausea, vomiting, altered taste sensation, dietary restrictions

Impaired **Oral Mucous Membrane** r/t irritation from nitrogenous waste products

Chronic **Sorrow** r/t chronic illness

Spiritual distress r/t dealing with chronic illness

Impaired **Urinary** elimination r/t effects of disease, need for dialysis

Risk for **Electrolyte** imbalance: Risk factor: renal dysfunction

Risk for **Infection**: Risk factor: altered immune functioning

Risk for **Injury**: Risk factors: bone changes, neuropathy, muscle weakness

Risk for impaired **Oral Mucous Membrane**: Risk factors: dehydration, effects of uremia

Risk for **Powerlessness**: Risk factor: chronic illness

Risk for **Sepsis**: Risk factor: infection

Kidney Failure Acute/Chronic, Child

Disturbed **Body Image** r/t growth retardation, bone changes, visibility of dialysis access devices (shunt, fistula), edema

Deficient **Diversional Activity** r/t immobility during dialysis

See *Child with Chronic Condition; Hospitalized Child*

Kidney Failure, Nonliguric

Anxiety r/t change in health status

Risk for deficient **Fluid** volume: Risk factor: loss of large volumes of urine

See *Kidney Failure*

Kidney Stone

Acute **Pain** r/t obstruction from kidney calculi

Impaired **Urinary** elimination: urgency and frequency r/t anatomical obstruction, irritation caused by stone

Risk for **Infection**: Risk factor: obstruction of urinary tract with stasis of urine

Readiness for enhanced **Knowledge**: expresses an interest in learning about prevention of stones

Kidney Transplantation, Donor

Impaired emancipated **Decision-Making** r/t harvesting of kidney from traumatized donor

Moral Distress r/t conflict among decision makers, end-of-life decisions, time constraints for decision-making

Spiritual distress r/t grieving from loss of significant person

Readiness for enhanced **Communication**: expressing thoughts and feelings about situation

Readiness for enhanced family **Coping**: decision to allow organ donation

Readiness for enhanced emancipated **Decision-Making**: expresses desire to enhance understanding and meaning of choices

Readiness for enhanced **Resilience**: decision to donate organs

Readiness for enhanced **Spirituality**: inner peace resulting from allowance of organ donation

See *Nephrectomy*

Kidney Transplantation, Recipient

Anxiety r/t possible rejection, procedure

Ineffective **Health** maintenance r/t long-term home treatment after transplantation, diet, signs of rejection, use of medications

Deficient **Knowledge** r/t specific nutritional needs, possible paralytic ileus, fluid or sodium restrictions

Impaired **Urinary** elimination r/t possible impaired renal function

Risk for **Bleeding**: Risk factor: surgical procedure

Risk for **Infection**: Risk factor: use of immunosuppressive therapy to control rejection

Risk for ineffective **Renal** perfusion: Risk factor: transplanted kidney

Risk for **Shock**: Risk factor: possible hypovolemia

Risk for **Spiritual** distress: Risk factor: obtaining transplanted kidney from someone's traumatic loss

Readiness for enhanced **Spiritual** well-being: acceptance of situation

Kidney Transplant

Ineffective **Protection** r/t immunosuppressive therapy

Risk for ineffective **Renal** perfusion: Risk factor: complications from transplant procedure

Readiness for enhanced **Decision-making**: expresses desire to enhance understanding of choices

Readiness for enhanced **Family** processes: adapting to life without dialysis

Readiness for enhanced **Health** management: desire to manage the treatment and prevention of complications after transplantation

Readiness for enhanced **Spiritual** well-being: heightened coping, living without dialysis

See *Kidney Failure, Kidney Transplantation, Donor; Kidney Transplantation, Recipient; Nephrectomy; Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care*

Kidney Tumor

See *Wilms' Tumor*

Kissing Disease

See *Mononucleosis*

Knee Replacement

See *Total Joint Replacement (Total Hip/Total Knee/Shoulder)*

Knowledge

Readiness for enhanced **Knowledge** (See **Knowledge, readiness for enhanced**, Section III)

Knowledge, Deficient

Ineffective **Health** maintenance r/t lack of or significant alteration in communication skills (written, verbal, and/or gestural)

Deficient **Knowledge** (See **Knowledge, deficient**, Section III)

Readiness for enhanced **Knowledge** (See **Knowledge, readiness for enhanced**, Section III)

Kock Pouch

See *Continent Ileostomy (Kock Pouch)*

Korsakoff's Syndrome

Acute **Confusion** r/t alcohol abuse

Dysfunctional **Family** processes r/t alcoholism as possible cause of syndrome

Impaired **Memory** r/t neurological changes associated with excessive alcohol intake

Self-Neglect r/t cognitive impairment from chronic alcohol abuse

Risk for **Falls**: Risk factor: cognitive impairment from chronic alcohol abuse

Risk for **Injury**: Risk factors: sensory dysfunction, lack of coordination when ambulating from chronic alcohol abuse

Risk for impaired **Liver** function: Risk factor: substance abuse (alcohol)

Risk for imbalanced **Nutrition**: less than body requirements: Risk factor: lack of adequate balanced intake from chronic alcohol abuse

L

Labor, Induction of

See *Induction of Labor*

Labor, Normal

Anxiety r/t fear of the unknown, situational crisis

Impaired **Comfort** r/t labor

Fatigue r/t childbirth

Deficient **Knowledge** r/t lack of preparation for labor

Labor **Pain** r/t uterine contractions, stretching of cervix and birth canal

Impaired **Tissue** integrity r/t passage of infant through birth canal, episiotomy

Risk for ineffective **Childbearing** process (See **Childbearing process**, Section III)

Risk for **Falls**: Risk factors: excessive loss or shift in intravascular fluid volume, orthostatic hypotension

Risk for deficient **Fluid** volume: Risk factor: excessive loss of blood

Risk for **Infection**: Risk factors: multiple vaginal examinations, tissue trauma, prolonged rupture of membranes

Risk for **Injury**: fetal: Risk factor: hypoxia

Risk for **Post-Trauma** syndrome: Risk factors: trauma or violence associated with labor pains, medical or surgical interventions, history of sexual abuse

Readiness for enhanced **Childbearing** process: responds appropriately, is proactive, bonds with infant, uses support systems

Readiness for enhanced family **Coping**: significant other provides support during labor

Readiness for enhanced **Health** management: prenatal care and childbirth education birth process

Readiness for enhanced **Power**: expresses readiness to enhance participation in choices regarding treatment during labor

Labor Pain

Labor **Pain** r/t uterine contractions, stretching of cervix and birth canal

Labyrinthitis

Ineffective **Health** management r/t delay in seeking treatment for respiratory and ear infections

Risk for **Injury** r/t dizziness

Readiness for enhanced **Health** management: management of episodes

See *Ménière's Disease*

Lacerations

Readiness for enhanced **Health** management: appropriate care of injury

Risk for **Infection**: Risk factor: broken skin

Risk for **Trauma**: Risk factor: children playing with dangerous objects

Lactation

See *Breastfeeding, Ineffective; Breastfeeding, Interrupted; Breastfeeding, Readiness for Enhanced*

Lactic Acidosis

Decreased **Cardiac** output r/t altered heart rate/rhythm, preload, and contractility

Risk for **Electrolyte** imbalance: Risk factor: impaired regulatory mechanism

Risk for decreased **Cardiac** tissue perfusion: Risk factor: hypoxia

See *Ketoacidosis, Diabetes Mellitus*

Lactose Intolerance

Readiness for enhanced **Knowledge**: interest in identifying lactose intolerance, treatment, and substitutes for milk products

See *Abdominal Distention; Diarrhea*

Laminectomy

Anxiety r/t change in health status, surgical procedure

Impaired **Comfort** r/t surgical procedure

Deficient **Knowledge** r/t appropriate postoperative and post-discharge activities

List of Nursing Assessments by Letter: L

Labor, Induction of	Labor, Normal	Labor Pain
Labyrinthitis	Lacerations	Lactation
Lactic Acidosis	Lactose Intolerance	Laminectomy
Language Impairment	Laparoscopic Laser Cholecystectomy	Laparoscopy
Laparotomy	Large Bowel Resection	Laryngectomy
Laser Surgery	LASIK Eye Surgery (Laser-Assisted in Situ Keratomileusis)	Latex Allergy
Laxative Abuse	Lead Poisoning	Left Heart Catheterization
Legionnaires' Disease	Lens Implant	Lethargy/Listlessness
Leukemia	Leukopenia	Level of Consciousness, Decreased
Lice	Lifestyle, Sedentary	Lightheadedness
Limb Reattachment Procedures	Liposuction	Lithotripsy
Liver Biopsy	Liver Cancer	Liver Disease
Liver Function	Liver Transplant	Living Will
Lobectomy	Loneliness	Loose Stools (Bowel Movements)
Loss of Bladder Control	Loss of Bowel Control	Lou Gehrig's Disease
Low Back Pain	Low Blood Pressure	Low Blood Sugar
Lower GI Bleeding	Lumbar Puncture	Lumpectomy
Lung Cancer	Lung Surgery	Lupus Erythematosus
Lyme Disease	Lymphedema	Lymphoma

Impaired physical **Mobility** r/t neuromuscular impairment

Acute **Pain** r/t localized inflammation and edema

Urinary retention r/t competing sensory impulses, effects of opioids or anesthesia

Risk for **Bleeding**: Risk factor: surgery

Risk for **Infection**: Risk factor: invasive procedure, surgery

Risk for **Perioperative Positioning** injury: Risk factor: prone position

See *Surgery, Perioperative; Surgery, Postoperative; Surgery, Preoperative*

Language Impairment

See *Speech Disorders*

Laparoscopic Laser Cholecystectomy

See *Cholecystectomy; Laser Surgery*

Laparoscopy

Urge urinary **Incontinence** r/t pressure on the bladder from gas

Acute **Pain**: shoulder r/t gas irritating the diaphragm

Risk for ineffective **Gastrointestinal** perfusion: Risk factor: complications from procedure

Laparotomy

See *Abdominal Surgery*

Large Bowel Resection

See *Abdominal Surgery*

Laryngectomy

Ineffective **Airway** clearance r/t surgical removal of glottis, decreased humidification

Death **Anxiety** r/t unknown results of surgery

Disturbed **Body Image** r/t change in body structure and function

Impaired **Comfort** r/t surgery

Impaired verbal **Communication** r/t removal of larynx

Interrupted **Family** processes r/t surgery, serious condition of family member, difficulty communicating

Grieving r/t loss of voice, fear of death

Ineffective **Health** management r/t deficient knowledge regarding self-care with laryngectomy

Imbalanced **Nutrition**: less than body requirements r/t absence of oral feeding, difficulty swallowing, increased need for fluids

Impaired **Oral Mucous Membrane** r/t absence of oral feeding

Chronic **Sorrow** r/t change in body image

Impaired **Swallowing** r/t edema, laryngectomy tube

Risk for **Electrolyte** imbalance: Risk factor: fluid imbalance

Risk for complicated **Grieving**: Risk factors: loss, major life event

Risk for compromised **Human Dignity**: Risk factor: inability to communicate

Risk for **Infection**: Risk factors: invasive procedure, surgery

Risk for **Powerlessness**: Risk factors: chronic illness, change in communication

Risk for impaired **Resilience**: Risk factor: change in health status

Risk for situational low **Self-Esteem**: Risk factor: disturbed body image

Laser Surgery

Impaired **Comfort** r/t surgery

Constipation r/t laser intervention in vulval and perianal areas
Deficient **Knowledge** r/t preoperative and postoperative care associated with laser procedure

Acute **Pain** r/t heat from laser

Risk for **Bleeding**: Risk factor: surgery

Risk for **Infection**: Risk factor: delayed heating reaction of tissue exposed to laser

Risk for **Injury**: Risk factor: accidental exposure to laser beam

LASIK Eye Surgery (Laser-Assisted in Situ Keratomileusis)

Impaired **Comfort** r/t surgery

Decisional Conflict r/t decision to have surgery

Risk for **Infection**: Risk factor: invasive procedure/surgery

Readiness for enhanced **Health** management: surgical procedure preoperative and postoperative teaching and expectations

Latex Allergy

Latex Allergy response (See [Latex Allergy response, Section III](#))

Risk for **Latex Allergy** response (See [Latex Allergy response, risk for, Section III](#))

Readiness for enhanced **Knowledge**: prevention and treatment of exposure to latex products

Laxative Abuse

Perceived **Constipation** r/t health belief, faulty appraisal, impaired thought processes

Lead Poisoning

Contamination r/t flaking, peeling paint in presence of young children

Impaired **Home** maintenance r/t presence of lead paint

Risk for delayed **Development**: Risk factor: lead poisoning

Left Heart Catheterization

See *Cardiac Catheterization*

Legionnaires' Disease

Contamination r/t contaminated water in air-conditioning systems

See *Pneumonia*

Lens Implant

See *Cataract Extraction; Vision Impairment*

Lethargy/Listlessness

Frail Elderly syndrome r/t alteration in cognitive function

Fatigue r/t decreased metabolic energy production

Insomnia r/t internal or external stressors

Risk for ineffective **Cerebral** tissue perfusion: Risk factor: carbon dioxide retention and/or lack of oxygen supply to brain

Leukemia

Ineffective **Protection** r/t abnormal blood profile

Fatigue r/t abnormal blood profile and/or side effects of chemotherapy treatment

Risk for imbalanced **Fluid** volume: Risk factors: nausea, vomiting, bleeding, side effects of treatment

Risk for **Infection**: Risk factor: ineffective immune system

Risk for impaired **Resilience**: Risk factor: serious illness

See *Cancer; Chemotherapy*

Leukopenia

Ineffective **Protection** r/t leukopenia

Risk for **Infection**: Risk factor: low white blood cell count

Level of Consciousness, Decreased

See *Confusion, Acute; Confusion, Chronic*

Lice

Impaired **Comfort** r/t inflammation, pruritus

Readiness for enhanced **Health** management: preventing and treating infestation

Impaired **Home** maintenance r/t close unsanitary, overcrowded conditions

Self-Neglect r/t lifestyle

See *Communicable Diseases, Childhood*

Lifestyle, Sedentary

Sedentary lifestyle (See *Sedentary lifestyle, Section III*)

Risk for ineffective peripheral **Tissue Perfusion**: Risk factor: lack of movement

Lightheadedness

See *Dizziness; Vertigo*

Limb Reattachment Procedures

Anxiety r/t unknown outcome of reattachment procedure, use and appearance of limb

Disturbed **Body Image** r/t unpredictability of function and appearance of reattached body part

Grieving r/t unknown outcome of reattachment procedure

Spiritual distress r/t anxiety about condition

Stress overload r/t multiple coexisting stressors, physical demands

Risk for **Bleeding**: Risk factor: severed vessels

Risk for **Perioperative Positioning** injury: Risk factor: immobilization

Risk for **Peripheral Neurovascular** dysfunction: Risk factors: trauma, orthopedic and neurovascular surgery, compression of nerves and blood vessels

Risk for **Powerlessness**: Risk factor: unknown outcome of procedure

Risk for impaired **Religiosity**: Risk factors: suffering, hospitalization

See *Surgery, Postoperative Care*

Liposuction

Disturbed **Body Image** r/t dissatisfaction with unwanted fat deposits in body

Risk for impaired **Resilience**: Risk factor: body image disturbance

Readiness for enhanced **Decision-Making**: expresses desire to make decision regarding liposuction

Readiness for enhanced **Self-Concept**: satisfaction with new body image

See *Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care*

Lithotripsy

Readiness for enhanced **Health** management: expresses desire for information related to procedure and aftercare and prevention of stones

See *Kidney Stone*

Liver Biopsy

Anxiety r/t procedure and results

Risk for deficient **Fluid** volume: Risk factor: hemorrhage from biopsy site

Risk for **Infection**: Risk factor: invasive procedure

Risk for **Powerlessness**: Risk factor: inability to control outcome of procedure

Liver Cancer

Risk for **Bleeding**: Risk factor: liver dysfunction

Risk for **Falls**: Risk factor: confusion associated with liver dysfunction

Risk for ineffective **Gastrointestinal** perfusion: Risk factor: liver dysfunction

Risk for impaired **Liver** function: Risk factor: disease process

Risk for impaired **Resilience**: Risk factor: serious illness

See *Cancer; Chemotherapy; Radiation Therapy*

Liver Disease

See *Cirrhosis; Hepatitis*

Liver Function

Risk for impaired **Liver** function (See *Liver function, impaired, risk for, Section III*)

Liver Transplant

Impaired **Comfort** r/t surgical pain

Decisional Conflict r/t acceptance of donor liver

Ineffective **Protection** r/t immunosuppressive therapy

Risk for impaired **Liver** function: Risk factors: possible rejection, infection

Readiness for enhanced **Family** processes: change in physical needs of family member

Readiness for enhanced **Health** management: desire to manage the treatment and prevention of complications after transplantation

Readiness for enhanced **Spiritual** well-being: heightened coping
See *Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care*

Living Will

Moral Distress r/t end-of-life decisions

Readiness for enhanced **Decision-Making**: expresses desire to enhance understanding of choices for decision making

Readiness for enhanced **Relationship**: shares information with others

Readiness for enhanced **Religiosity**: request to meet with religious leaders or facilitators

Readiness for enhanced **Resilience**: uses effective communication

Readiness for enhanced **Spiritual** well-being: acceptance of and preparation for end of life

See *Advance Directives*

Lobectomy

See *Thoracotomy*

Loneliness

Spiritual distress r/t loneliness, social alienation

Risk for **Loneliness** (See **Loneliness, risk for, Section III**)

Risk for impaired **Religiosity**: Risk factor: lack of social interaction

Readiness for enhanced **Hope**: expresses desire to enhance interconnectedness with others

Readiness for enhanced **Relationship**: expresses satisfaction with complementary relationship between partners

Loose Stools (Bowel Movements)

Diarrhea r/t increased gastric motility

Risk for dysfunctional **Gastrointestinal** motility (See **Gastrointestinal** motility, dysfunctional, risk for, Section III)

See *Diarrhea*

Loss of Bladder Control

See *Incontinence of Urine*

Loss of Bowel Control

See *Incontinence of Stool*

Lou Gehrig's Disease

See *Amyotrophic Lateral Sclerosis (ALS)*

Low Back Pain

Impaired **Comfort** r/t back pain

Ineffective **Health** maintenance r/t deficient knowledge regarding self-care with back pain

Impaired physical **Mobility** r/t back pain

Chronic **Pain** r/t degenerative processes, musculotendinous strain, injury, inflammation, congenital deformities

Urinary Retention r/t possible spinal cord compression

Risk for **Powerlessness**: Risk factor: living with chronic pain

Readiness for enhanced **Health** management: expresses desire for information to manage pain

Low Blood Pressure

See *Hypotension*

Low Blood Sugar

See *Hypoglycemia*

Lower GI Bleeding

See *GI Bleed (Gastrointestinal Bleeding)*

Lumbar Puncture

Anxiety r/t invasive procedure and unknown results

Deficient **Knowledge** r/t information about procedure

Acute **Pain** r/t possible loss of cerebrospinal fluid

Risk for ineffective **Cerebral** tissue perfusion: Risk factor: treatment-related side effects

Risk for **Infection**: Risk factor: invasive procedure

Lumpectomy

Decisional Conflict r/t treatment choices

Readiness for enhanced **Knowledge**: preoperative and postoperative care

Readiness for enhanced **Spiritual** well-being: hope of benign diagnosis

See *Cancer*

Lung Cancer

See *Cancer; Chemotherapy; Radiation Therapy; Thoracotomy*

Lung Surgery

See *Thoracotomy*

Lupus Erythematosus

Disturbed **Body Image** r/t change in skin, rash, lesions, ulcers, mottled erythema

Fatigue r/t increased metabolic requirements

Ineffective **Health** maintenance r/t deficient knowledge regarding medication, diet, activity

Acute **Pain** r/t inflammatory process

Powerlessness r/t unpredictability of course of disease

Impaired **Religiosity** r/t ineffective coping with disease

Chronic **Sorrow** r/t presence of chronic illness

Spiritual distress r/t chronicity of disease, unknown etiology

Risk for decreased **Cardiac** tissue perfusion: Risk factor: altered circulation

Risk for impaired **Resilience**: Risk factor: chronic disease

Risk for impaired **Skin** integrity: Risk factors: chronic inflammation, edema, altered circulation

Lyme Disease

Impaired **Comfort** r/t inflammation

Fatigue r/t increased energy requirements

Deficient **Knowledge** r/t lack of information concerning disease, prevention, treatment

Acute **Pain** r/t inflammation of joints, urticaria, rash

Risk for decreased **Cardiac** output: Risk factor: dysrhythmia

Risk for **Powerlessness**: Risk factor: possible chronic condition

Lymphedema

Disturbed **Body Image** r/t change in appearance of body part with edema

Excess **Fluid** volume r/t compromised regulatory system; inflammation, obstruction, or removal of lymph glands

Deficient **Knowledge** r/t management of condition

Risk for **Infection**: Risk factors: abnormal lymphatic system allowing stasis of fluids with decreased resistance to infection

Risk for situational low **Self-Esteem**: Risk factor: disturbed body image

Lymphoma

See *Cancer*

M

M

Macular Degeneration

Ineffective **Coping** r/t visual loss

Compromised family **Coping** r/t deteriorating vision of family member

Risk-prone **Health** behavior r/t deteriorating vision while trying to maintain usual lifestyle

Hopelessness r/t deteriorating vision

Sedentary lifestyle r/t visual loss

Self-Neglect r/t change in vision

Social isolation r/t inability to drive because of visual changes

Vision Loss r/t impaired visual function

Risk for **Falls**: Risk factor: visual difficulties

Risk for **Injury**: Risk factor: inability to distinguish traffic lights and safety signs

Risk for **Powerlessness**: Risk factor: deteriorating vision

Risk for impaired **Religiosity**: Risk factor: possible lack of transportation to church

Risk for impaired **Resilience**: Risk factor: changing vision

Readiness for enhanced **Health** management: appropriate choices of daily activities for meeting the goals of a treatment program

Magnetic Resonance Imaging (MRI)

See *MRI (Magnetic Resonance Imaging)*

Major Depressive Disorder

See *Depression (Major Depressive Disorder)*

Malabsorption Syndrome

Diarrhea r/t lactose intolerance, gluten sensitivity, resection of small bowel

Dysfunctional **Gastrointestinal** motility r/t disease state

Deficient **Knowledge** r/t lack of information about diet and nutrition

Imbalanced **Nutrition**: less than body requirements r/t inability of body to absorb nutrients because of physiological factors

Risk for **Electrolyte** imbalance: Risk factors: hypovolemia, hyponatremia, hypokalemia

Risk for imbalanced **Fluid** volume: Risk factors: diarrhea, hypovolemia

Risk for disproportionate **Growth**: Risk factor: malnutrition from malabsorption

See *Abdominal Distention*

Maladaptive Behavior

See *Crisis; Post-Trauma Syndrome; Suicide Attempt*

Malaise

See *Fatigue*

Malaria

Contamination r/t geographic area

Risk for **Contamination**: Risk factors: increased environmental exposure (not wearing protective clothing, not using insecticide or repellent on skin and in room in areas where infected mosquitoes are present); inadequate defense mechanisms (inappropriate use of prophylactic regimen)

Risk for impaired **Liver** function: Risk factor: complications of disease

Readiness for enhanced community **Coping**: uses resources available for problem solving

Readiness for enhanced **Health** management: expresses desire to enhance immunization status /vaccination status

Readiness for enhanced **Resilience**: immunization status

See *Anemia*

Male Infertility

See *Erectile Dysfunction (ED); Infertility*

Malignancy

See *Cancer*

Malignant Hypertension (Arteriolar Nephrosclerosis)

Decreased **Cardiac** output r/t altered afterload, altered contractility

Fatigue r/t disease state, increased blood pressure

Excess **Fluid** volume r/t decreased kidney function

Risk for ineffective **Cerebral** tissue perfusion: Risk factor: elevated blood pressure damaging cerebral vessels

Risk for acute **Confusion**: Risk factors: increased blood urea nitrogen or creatinine levels

Risk for imbalanced **Fluid** volume: Risk factors: hypertension, altered kidney function

Risk for ineffective **Renal** perfusion: Risk factor: elevated blood pressure damaging the kidney

List of Nursing Assessments by Letter: M

Macular Degeneration	Magnetic Resonance Imaging (MRI)	Major Depressive Disorder
Malabsorption Syndrome	Maladaptive Behavior	Malaise
Malaria	Male Infertility	Malignancy
Malignant Hypertension (Arteriolar Nephrosclerosis)	Malignant Hyperthermia	Malnutrition
Mammography	Manic Disorder, Bipolar I	Manipulative Behavior
Marfan Syndrome	Mastectomy	Mastitis
Maternal Infection	Maturation Issues, Adolescent	Maze III Procedure
MD (Muscular Dystrophy)	Measles (Rubeola)	Meconium Aspiration
Meconium Delayed	Melanoma	Melena
Memory Deficit	Ménière's Disease	Meningitis/Encephalitis
Meningocele	Menopause	Menorrhagia
Mental Illness	Metabolic Acidosis	Metabolic Alkalosis
Metastasis	Methicillin-Resistant <i>Staphylococcus aureus</i> (MRSA)	MI (Myocardial Infarction)
MIDCAB (Minimally Invasive Direct Coronary Artery Bypass)	Midlife Crisis	Migraine Headache
Milk Intolerance	Minimally Invasive Direct Coronary Bypass (MIDCAB)	Miscarriage
Mitral Stenosis	Mitral Valve Prolapse	Mobility, Impaired Bed
Mobility, Impaired Physical	Mobility, Impaired Wheelchair	Modified Radical Mastectomy
Mononucleosis	Mood Disorders	Moon Face
Moral/Ethical Dilemmas	Morning Sickness	Motion Sickness
Mottling of Peripheral Skin	Mourning	Mouth Lesions
MRI (Magnetic Resonance Imaging)	MRSA (Methicillin-Resistant <i>Staphylococcus aureus</i>)	Mucocutaneous Lymph Node Syndrome
Mucous Membrane, Impaired Oral	Multi-Infarct Dementia	Multiple Gestations

Multiple Personality Disorder (Dissociative Identity Disorder)	Multiple Sclerosis (MS)	Mumps
Murmurs	Muscular Atrophy/Weakness	Muscular Dystrophy (MD)
MVC (Motor Vehicle Crash)	Myasthenia Gravis	Mycoplasma Pneumonia
Myelocele	Myelomeningocele	Myocardial Infarction (MI)
Myocarditis	Myringotomy	Myxedema

Readiness for enhanced **Health** management: expresses desire to manage the illness, high blood pressure

Malignant Hyperthermia

Hyperthermia r/t anesthesia reaction associated with inherited condition

Risk for ineffective **Renal** perfusion: Risk factors: hyperthermia and muscle destruction (rhabdomyolysis)

Readiness for enhanced **Health** management: knowledge of risk factors

Malnutrition

Insufficient **Breast Milk** r/t (See **Breast Milk**, insufficient, Section III)

Frail Elderly syndrome r/t undetected malnutrition

Deficient **Knowledge** r/t misinformation about normal nutrition, social isolation, lack of food preparation facilities

Imbalanced **Nutrition**: less than body requirements r/t inability to ingest food, digest food, or absorb nutrients because of biological, psychological, or economic factors; institutionalization (i.e., lack of menu choices)

Ineffective **Protection** r/t inadequate nutrition

Ineffective **Health** management r/t inadequate nutrition

Self-Neglect r/t inadequate nutrition

Risk for disproportionate **Growth**: Risk factor: malnutrition

Risk for **Powerlessness**: Risk factor: possible inability to provide adequate nutrition

Mammography

Readiness for enhanced **Health** management: follows guidelines for screening

Readiness for enhanced **Resilience**: responsibility for self-care

Manic Disorder, Bipolar I

Anxiety r/t change in role function

Ineffective **Coping** r/t situational crisis

Ineffective **Denial** r/t fear of inability to control behavior

Interrupted **Family** processes r/t family member's illness

Risk-prone **Health** behavior r/t low self-efficacy

Ineffective **Health** management r/t unpredictability of client, excessive demands on family, chronic illness, social support deficit

Impaired **Home** maintenance r/t altered psychological state, inability to concentrate

Disturbed personal **Identity** r/t manic state

Insomnia r/t constant anxious thoughts

Imbalanced **Nutrition**: less than body requirements r/t lack of time and motivation to eat, constant movement

Impaired individual **Resilience** r/t psychological disorder

Ineffective **Role** performance r/t impaired social interactions

Self-Neglect r/t manic state

Sleep deprivation r/t hyperagitated state

Risk for ineffective **Activity** planning r/t inability to process information

Risk for **Caregiver Role Strain**: Risk factor: unpredictability of condition

Risk for imbalanced **Fluid** volume: Risk factor: hypovolemia

Risk for **Powerlessness**: Risk factor: inability to control changes in mood

Risk for **Spiritual** distress: Risk factor: depression

Risk for **Suicide**: Risk factor: bipolar disorder

Risk for self-directed **Violence**: Risk factors: hallucinations, delusions

Risk for other-directed **Violence**: Risk factor: pathologic intoxication

Readiness for enhanced **Hope**: expresses desire to enhance problem-solving goals

Manipulative Behavior

Defensive **Coping** r/t superior attitude toward others

Ineffective **Coping** r/t inappropriate use of defense mechanisms

Self-Mutilation r/t use of manipulation to obtain nurturing relationship with others

Self-Neglect r/t maintaining control

Impaired **Social** interaction r/t self-concept disturbance

Risk for **Loneliness**: Risk factor: inability to interact appropriately with others

Risk for situational low **Self-Esteem**: Risk factor: history of learned helplessness

Risk for **Self-Mutilation**: Risk factor: inability to cope with increased psychological or physiological tension in healthy manner

Marfan Syndrome

Decreased **Cardiac** output r/t dilation of the aortic root, dissection or rupture of the aorta

Risk for decreased **Cardiac** tissue perfusion: Risk factor: heart-related complications from Marfan syndrome

Readiness for enhanced **Health** management: describes reduction of risk factors

See *Mitral Valve Prolapse*; *Scoliosis*

Mastectomy

Disturbed **Body Image** r/t loss of sexually significant body part

Impaired **Comfort** r/t altered body image; difficult diagnosis

Death **Anxiety** r/t threat of mortality associated with breast cancer

Fatigue r/t increased metabolic requirements

Fear r/t change in body image, prognosis

Deficient **Knowledge** r/t self-care activities

Nausea r/t chemotherapy

Acute **Pain** r/t surgical procedure

Sexual dysfunction r/t change in body image, fear of loss of femininity

Chronic **Sorrow** r/t disturbed body image, unknown long-term health status

Spiritual distress r/t change in body image

Risk for **Infection**: Risk factors: surgical procedure, broken skin

Risk for impaired physical **Mobility**: Risk factors: nerve or muscle damage, pain

Risk for **Post-Trauma** syndrome: Risk factors: loss of body part, surgical wounds

Risk for **Powerlessness**: Risk factor: fear of unknown outcome of procedure

Risk for impaired **Resilience**: Risk factor: altered body image

See *Cancer; Modified Radical Mastectomy; Surgery, Perioperative; Surgery, Postoperative; Surgery, Preoperative*

Mastitis

Anxiety r/t threat to self, concern over safety of milk for infant

Ineffective **Breastfeeding** r/t breast pain, conflicting advice from health care providers

Deficient **Knowledge** r/t antibiotic regimen, comfort measures

Acute **Pain** r/t infectious disease process, swelling of breast tissue

Ineffective **Role** performance r/t change in capacity to function in expected role

Maternal Infection

Ineffective **Protection** r/t invasive procedures, traumatized tissue

See *Postpartum, Normal Care*

Maturational Issues, Adolescent

Ineffective **Coping** r/t maturational crises

Risk-prone **Health** behavior r/t inadequate comprehension, negative attitude toward health care

Interrupted **Family** processes r/t developmental crises of adolescence resulting from challenge of parental authority and values, situational crises from change in parental marital status

Deficient **Knowledge**: potential for enhanced health maintenance r/t information misinterpretation, lack of education regarding age-related factors

Impaired **Social** interaction r/t ineffective, unsuccessful, or dysfunctional interaction with peers

Social isolation r/t perceived alteration in physical appearance, social values not accepted by dominant peer group

Risk for Ineffective **Activity** planning: Risk factor: unrealistic perception of personal competencies

Risk for disturbed personal **Identity**: Risk factor: maturational issues

Risk for **Injury**: Risk factor: thrill-seeking behaviors

Risk for chronic low **Self-Esteem**: Risk factor: lack of sense of belonging in peer group

Risk for situational low **Self-Esteem**: Risk factor: developmental changes

Readiness for enhanced **Communication**: expressing willingness to communicate with parental figures

Readiness for enhanced **Relationship**: expresses desire to enhance communication with parental figures

See *Sexuality, Adolescent; Substance Abuse (if relevant)*

Maze III Procedure

See *Dysrhythmia; Open Heart Surgery*

MD (Muscular Dystrophy)

See *Muscular Dystrophy (MD)*

Measles (Rubeola)

See *Communicable Diseases, Childhood*

Meconium Aspiration

See *Respiratory Conditions of the Neonate*

Meconium Delayed

Risk for neonatal **Jaundice**: Risk factor: delayed meconium

Melanoma

Disturbed **Body Image** r/t altered pigmentation, surgical incision

Fear r/t threat to well-being

Ineffective **Health** maintenance r/t deficient knowledge regarding self-care and treatment of melanoma

Acute **Pain** r/t surgical incision

Chronic **Sorrow** r/t disturbed body image, unknown long-term health status

Readiness for enhanced **Health** management: describes reduction of risk factors; protection from sunlight's ultraviolet rays

See *Cancer*

Melena

Fear r/t presence of blood in feces

Risk for imbalanced **Fluid** volume: Risk factor: hemorrhage

See *GI Bleed (Gastrointestinal Bleeding)*

Memory Deficit

Impaired **Memory** (See **Memory, impaired, Section III**)

Ménière's Disease

Risk for **Injury**: Risk factor: symptoms of disease

Readiness for enhanced **Health** management: expresses desire to manage illness

See *Dizziness; Nausea; Vertigo*

Meningitis/Encephalitis

Ineffective **Airway** clearance r/t seizure activity

Impaired **Comfort** r/t altered health status

Excess **Fluid** volume r/t increased intracranial pressure, syndrome of inappropriate secretion of antidiuretic hormone

Decreased **Intracranial** adaptive capacity r/t sustained increase in intracranial pressure

Impaired **Mobility** r/t neuromuscular or central nervous system insult

Acute **Pain** r/t biological injury

Risk for **Aspiration**: Risk factor: seizure activity

Risk for acute **Confusion**: Risk factor: infection of brain

Risk for **Falls**: Risk factors: neuromuscular dysfunction and confusion

Risk for **Injury**: Risk factor: seizure activity

Risk for impaired **Resilience**: Risk factor: illness

Risk for **Shock**: Risk factor: infection

Risk for ineffective **Cerebral tissue perfusion**: Risk factors: cerebral tissue edema and inflammation of meninges, increased intracranial pressure; infection

See *Hospitalized Child*

Meningocele

See *Neural Tube Defects*

Menopause

Impaired **Comfort** r/t symptoms associated with menopause

Insomnia r/t hormonal shifts

Impaired **Memory** r/t change in hormonal levels

Sexual dysfunction r/t menopausal changes

Ineffective **Sexuality pattern** r/t altered body structure, lack of lubrication, lack of knowledge of artificial lubrication

Ineffective **Thermoregulation** r/t changes in hormonal levels

Risk for urge urinary **Incontinence**: Risk factor: changes in hormonal levels affecting bladder function

Risk for **Overweight**: Risk factor: change in metabolic rate caused by fluctuating hormone levels

Risk for **Powerlessness**: Risk factor: changes associated with menopause

Risk for impaired **Resilience**: Risk factor: menopause

Risk for situational low **Self-Esteem**: Risk factors: developmental changes, menopause

Readiness for enhanced **Health management**: verbalized desire to manage menopause

Readiness for enhanced **Self-Care**: expresses satisfaction with body image

Readiness for enhanced **Spiritual well-being**: desire for harmony of mind, body, and spirit

Menorrhagia

Fear r/t loss of large amounts of blood

Risk for deficient **Fluid volume**: Risk factor: excessive loss of menstrual blood

Mental Illness

Defensive **Coping** r/t psychological impairment, substance abuse

Ineffective **Coping** r/t situational crisis, coping with mental illness

Compromised family **Coping** r/t lack of available support from client

Disabled family **Coping** r/t chronically unexpressed feelings of guilt, anxiety, hostility, or despair

Ineffective **Denial** r/t refusal to acknowledge abuse problem, fear of the social stigma of disease

Risk-prone **Health behavior** r/t low self-efficacy

Disturbed personal **Identity** r/t psychoses

Ineffective **Relationship** r/t effects of mental illness in partner relationship

Chronic **Sorrow** r/t presence of mental illness

Stress overload r/t multiple coexisting stressors

Ineffective family **Health management** r/t chronicity of condition, unpredictability of client, unknown prognosis

Risk for **Loneliness**: Risk factor: social isolation

Risk for **Powerlessness**: Risk factor: lifestyle of helplessness

Risk for impaired **Resilience**: Risk factor: chronic illness

Risk for chronic low **Self-Esteem**: Risk factor: presence of mental illness/repeated negative reinforcement

Metabolic Acidosis

See *Ketoacidosis, Alcoholic; Ketoacidosis, Diabetic; Risk for Shock; Risk for Sepsis*

Metabolic Alkalosis

Deficient **Fluid volume** r/t fluid volume loss, vomiting, gastric suctioning, failure of regulatory mechanisms

Metastasis

See *Cancer*

Methicillin-Resistant *Staphylococcus aureus* (MRSA)

See *MRSA (Methicillin-Resistant Staphylococcus aureus)*

MI (Myocardial Infarction)

Activity intolerance r/t imbalance between oxygen supply and demand

Anxiety r/t threat of death, possible change in role status

Death **Anxiety** r/t seriousness of medical condition

Constipation r/t decreased peristalsis from decreased physical activity, medication effect, change in diet

Ineffective family **Coping** r/t spouse or significant other's fear of partner loss

Ineffective **Denial** r/t fear, deficient knowledge about heart disease

Interrupted **Family processes** r/t crisis, role change

Fear r/t threat to well-being

Ineffective **Health maintenance** r/t deficient knowledge regarding self-care and treatment

Acute **Pain** r/t myocardial tissue damage from inadequate blood supply

Situational low **Self-Esteem** r/t crisis of MI

Ineffective **Sexuality pattern** r/t fear of chest pain, possibility of heart damage

Risk for **Powerlessness**: Risk factor: acute illness

Risk for **Shock**: Risk factors: hypotension, myocardial dysfunction, hypoxia

Risk for **Spiritual distress**: Risk factor: physical illness

Risk for decreased **Cardiac** output: Risk factors: alteration in heart rate, rhythm, and contractility

Risk for decreased **Cardiac** tissue perfusion: Risk factors: coronary artery spasm, hypertension, hypotension, hypoxia

Readiness for enhanced **Knowledge**: expresses an interest in learning about condition

See *Angioplasty (Coronary); Coronary Artery Bypass Grafting (CABG)*

MIDCAB (Minimally Invasive Direct Coronary Artery Bypass)

Risk for **Bleeding**: Risk factor: surgery

Readiness for enhanced **Health** management: preoperative and postoperative care associated with surgery

Risk for **Infection**: Risk factor: surgical procedure

See *Angioplasty, Coronary; Coronary Artery Bypass Grafting (CABG)*

Midlife Crisis

Ineffective **Coping** r/t inability to deal with changes associated with aging

Powerlessness r/t lack of control over life situation

Spiritual distress r/t questioning beliefs or value system

Risk for disturbed personal **Identity**

Risk for chronic low **Self-Esteem**: Risk factor: ineffective coping with loss

Readiness for enhanced **Relationship**: meets goals for lifestyle change

Readiness for enhanced **Spiritual** well-being: desire to find purpose and meaning to life

Migraine Headache

Ineffective **Health** maintenance r/t deficient knowledge regarding prevention and treatment of headaches

Readiness for enhanced **Health** management: expresses desire to manage illness

Acute **Pain**: headache r/t vasodilation of cerebral and extracerebral vessels

Risk for impaired **Resilience**: Risk factors: chronic illness, disabling pain

Milk Intolerance

See *Lactose Intolerance*

Minimally Invasive Direct Coronary Bypass (MIDCAB)

See *MIDCAB (Minimally Invasive Direct Coronary Artery Bypass)*

Miscarriage

See *Pregnancy Loss*

Mitral Stenosis

Activity intolerance r/t imbalance between oxygen supply and demand

Anxiety r/t possible worsening of symptoms, activity intolerance, fatigue

Decreased **Cardiac** output r/t incompetent heart valves, abnormal forward or backward blood flow, flow into a dilated chamber, flow through an abnormal passage between chambers

Fatigue r/t reduced cardiac output

Ineffective **Health** maintenance r/t deficient knowledge regarding self-care with disorder

Risk for decreased **Cardiac** tissue perfusion: Risk factor: incompetent heart valve

Risk for **Infection**: Risk factors: invasive procedure, risk for endocarditis

Mitral Valve Prolapse

Anxiety r/t symptoms of condition: palpitations, chest pain

Fatigue r/t abnormal catecholamine regulation, decreased intravascular volume

Fear r/t lack of knowledge about mitral valve prolapse, feelings of having heart attack

Ineffective **Health** maintenance r/t deficient knowledge regarding methods to relieve pain and treat dysrhythmia and shortness of breath, need for prophylactic antibiotics before invasive procedures

Acute **Pain** r/t mitral valve regurgitation

Risk for ineffective **Cerebral** tissue perfusion: Risk factor: postural hypotension

Risk for **Infection**: Risk factor: invasive procedures

Risk for **Powerlessness**: Risk factor: unpredictability of onset of symptoms

Readiness for enhanced **Knowledge**: expresses interest in learning about condition

Mobility, Impaired Bed

Impaired bed **Mobility** (See *Mobility, bed, impaired, Section III*)

Mobility, Impaired Physical

Impaired physical **Mobility** (See *Mobility, physical, impaired, Section III*)

Risk for **Falls**: Risk factor: impaired physical mobility

Mobility, Impaired Wheelchair

Impaired wheelchair **Mobility** (See *Mobility, wheelchair, impaired, Section III*)

Modified Radical Mastectomy

Impaired emancipated **Decision-Making**

Readiness for enhanced **Communication**: willingness to enhance communication

See *Mastectomy*

Mononucleosis

Activity intolerance r/t generalized weakness

Impaired **Comfort** r/t sore throat, muscle aches

Fatigue r/t disease state, stress

Ineffective **Health** maintenance r/t deficient knowledge concerning transmission and treatment of disease

Acute **Pain** r/t enlargement of lymph nodes, oropharyngeal edema

Impaired **Swallowing** r/t enlargement of lymph nodes, oropharyngeal edema

Risk for **Injury**: Risk factor: possible rupture of spleen

Risk for **Loneliness**: Risk factor: social isolation

Mood Disorders

Caregiver Role Strain r/t overwhelming needs of care receiver, unpredictability of mood alterations

Labile **Emotional Control** r/t (See **Labile Emotional Control, Section III**)

Risk-prone **Health** behavior r/t hopelessness, altered locus of control

Impaired **Mood** regulation r/t (See **Mood regulation, impaired, Section III**)

Self-Neglect r/t inability to care for self

Social isolation r/t alterations in mental status

Risk for situational low **Self-Esteem**: Risk factor: unpredictable changes in mood

Readiness for enhanced **Communication**: expresses feelings

See *specific disorder: Depression (Major Depressive Disorder); Dysthymic Disorder; Hypomania; Manic Disorder, Bipolar I*

Moon Face

Disturbed **Body Image** r/t change in appearance from disease and medication(s)

Risk for situational low **Self-Esteem**: Risk factor: change in body image

See *Cushing's Syndrome*

Moral/Ethical Dilemmas

Impaired emancipated **Decision-Making** r/t questioning personal values and belief, which alter decision

Moral Distress r/t conflicting information guiding moral or ethical decision-making

Risk for **Powerlessness**: Risk factor: lack of knowledge to make a decision

Risk for **Spiritual** distress: Risk factor: moral or ethical crisis

Readiness for enhanced emancipated **Decision-Making**: expresses desire to enhance congruency of decisions with personal values and goals

Readiness for enhanced **Religiosity**: requests assistance in expanding religious options

Readiness for enhanced **Resilience**: vulnerable state

Readiness for enhanced **Spiritual** well-being: request for interaction with others regarding difficult decisions

Morning Sickness

See *Hyperemesis Gravidarum; Pregnancy, Normal*

Motion Sickness

See *Labyrinthitis*

Mottling of Peripheral Skin

Ineffective peripheral **Tissue Perfusion** r/t interruption of arterial flow, decreased circulating blood volume

Risk for **Shock**: Risk factor: inadequate circulation to perfuse body

Mourning

See *Grieving*

Mouth Lesions

See *Mucous Membrane, Impaired Oral*

MRI (Magnetic Resonance Imaging)

Anxiety r/t fear of being in closed spaces

Readiness for enhanced **Health** management: describes reduction of risk factors associated with exam

Deficient **Knowledge** r/t unfamiliarity with information resources; exam information

Readiness for enhanced **Knowledge**: expresses interest in learning about exam

MRSA (Methicillin-Resistant Staphylococcus aureus)

Impaired **Skin** integrity r/t infection

Delayed **Surgical** recovery r/t infection

Ineffective **Thermoregulation** r/t severe infection stimulating immune system

Impaired **Tissue** integrity r/t wound, infection

Risk for **Loneliness**: Risk factor: physical isolation

Risk for impaired **Resilience**: Risk factor: illness

Risk for **Shock**: Risk factor: sepsis

Mucocutaneous Lymph Node Syndrome

See *Kawasaki Disease*

Mucous Membrane, Impaired Oral

Impaired **Oral Mucous Membrane** (See **Oral Mucous Membrane, impaired, Section III**)

Multi-Infarct Dementia

See *Dementia*

Multiple Gestations

Anxiety r/t uncertain outcome of pregnancy

Death **Anxiety** r/t maternal complications associated with multiple gestations

Insufficient **Breast Milk** r/t multiple births

Ineffective **Childbearing** process r/t unavailable support system

Fatigue r/t physiological demands of a multifetal pregnancy and/or care of more than one infant

Impaired **Home** maintenance r/t fatigue

Stress urinary **Incontinence** r/t increased pelvic pressure

Insomnia r/t impairment of normal sleep pattern; parental responsibilities

Deficient **Knowledge** r/t caring for more than one infant

Neonatal **Jaundice** r/t feeding pattern not well established

Deficient **Knowledge** r/t caring for more than one infant

Imbalanced **Nutrition**: less than body requirements r/t physiological demands of a multifetal pregnancy

Stress overload r/t multiple coexisting stressors, family demands

Impaired **Walking** r/t increased uterine size

Risk for ineffective **Breastfeeding**: Risk factors: lack of support, physical demands of feeding more than one infant

Risk for delayed **Development**: fetus: Risk factor: multiple gestations

Risk for disproportionate **Growth**: fetus: Risk factor: multiple gestations

Risk for neonatal **Jaundice**: Risk factors: abnormal weight loss, prematurity, feeding pattern not well-established

Readiness for enhanced **Childbearing** process: demonstrates appropriate care for infants and mother

Readiness for enhanced **Family** processes: family adapting to change with more than one infant

Multiple Personality Disorder (Dissociative Identity Disorder)

Anxiety r/t loss of control of behavior and feelings

Disturbed **Body Image** r/t psychosocial changes

Defensive **Coping** r/t unresolved past traumatic events, severe anxiety

Ineffective **Coping** r/t history of abuse

Hopelessness r/t long-term stress

Disturbed personal **Identity** r/t severe child abuse

Chronic low **Self-Esteem** r/t rejection, failure

Risk for **Self-Mutilation**: Risk factor: need to act out to relieve stress

Readiness for enhanced **Communication**: willingness to discuss problems associated with condition

See *Dissociative Identity Disorder (Not Otherwise Specified)*

Multiple Sclerosis (MS)

Ineffective **Activity** planning r/t unrealistic perception of personal competence

Ineffective **Airway** clearance r/t decreased energy or fatigue

Impaired physical **Mobility** r/t neuromuscular impairment

Self-Neglect r/t functional impairment

Powerlessness r/t progressive nature of disease

Self-Care deficit: specify r/t neuromuscular impairment

Sexual dysfunction r/t biopsychosocial alteration of sexuality

Chronic **Sorrow** r/t loss of physical ability

Spiritual distress r/t perceived hopelessness of diagnosis

Urinary Retention r/t inhibition of the reflex arc

Risk for **Disuse** syndrome: Risk factor: physical immobility

Risk for **Injury**: Risk factors: altered mobility, sensory dysfunction

Risk for imbalanced **Nutrition**: less than body requirements: Risk factors: impaired swallowing, depression

Risk for **Powerlessness**: Risk factor: chronic illness

Risk for impaired **Religiosity**: Risk factor: illness

Risk for **Thermal Injury**: Risk factor: neuromuscular impairment

Readiness for enhanced **Health** management: expresses a desire to manage condition

Readiness for enhanced **Self-Care**: expresses desire to enhance knowledge of strategies and responsibility for self-care

Readiness for enhanced **Spiritual** well-being: struggling with chronic debilitating condition

See *Neurologic Disorders*

Mumps

See *Communicable Diseases, Childhood*

Murmurs

Decreased **Cardiac** output r/t altered preload/afterload

Risk for decreased **Cardiac** tissue perfusion: Risk factor: incompetent valve

Risk for **Fatigue**: Risk factor: decreased cardiac output

Muscular Atrophy/Weakness

Risk for **Disuse** syndrome: Risk factor: impaired physical mobility

Risk for **Falls**: Risk factor: impaired physical mobility

Muscular Dystrophy (MD)

Activity intolerance r/t fatigue, muscle weakness

Ineffective **Activity** planning r/t unrealistic perception of personal competence

Ineffective **Airway** clearance r/t muscle weakness and decreased ability to cough

Constipation r/t immobility

Fatigue r/t increased energy requirements to perform activities of daily living

Impaired physical **Mobility** r/t muscle weakness and development of contractures

Imbalanced **Nutrition**: less than body requirements r/t impaired swallowing or chewing

Self-Care deficit: feeding, bathing, dressing, toileting r/t muscle weakness and fatigue

Self-Neglect r/t functional impairment

Impaired **Transfer** ability r/t muscle weakness

Impaired **Walking** r/t muscle weakness

Risk for **Aspiration**: Risk factor: impaired swallowing

Risk for decreased **Cardiac** tissue perfusion: Risk factor: hypoxia associated with cardiomyopathy

Risk for **Disuse** syndrome: Risk factor: complications of immobility

Risk for **Falls**: Risk factor: muscle weakness

Risk for **Infection**: Risk factor: pooling of pulmonary secretions as a result of immobility and muscle weakness

Risk for **Injury**: Risk factors: muscle weakness and unsteady gait

Risk for **Overweight**: Risk factor: inactivity

Risk for **Powerlessness**: Risk factor: chronic condition
 Risk for impaired **Religiosity**: Risk factor: illness
 Risk for impaired **Resilience**: Risk factor: chronic illness
 Risk for situational low **Self-Esteem**: Risk factor: presence of chronic condition
 Readiness for enhanced **Self-Concept**: acceptance of strength and abilities
 Risk for impaired **Skin** integrity: Risk factors: immobility, braces, or adaptive devices
 See *Child with Chronic Condition; Hospitalized Child*

MVC (Motor Vehicle Crash)

See *Fracture; Head Injury; Injury; Pneumothorax*

Myasthenia Gravis

Ineffective **Airway** clearance r/t decreased ability to cough and swallow
 Interrupted **Family** processes r/t crisis of dealing with diagnosis
Fatigue r/t paresthesia, aching muscles, weakness of muscles
 Impaired physical **Mobility** r/t defective transmission of nerve impulses at the neuromuscular junction
 Imbalanced **Nutrition**: less than body requirements r/t difficulty eating and swallowing
 Impaired **Swallowing** r/t neuromuscular impairment
 Risk for **Caregiver Role Strain**: Risk factors: severity of illness of client, overwhelming needs of client
 Risk for impaired **Religiosity**: Risk factor: illness
 Risk for impaired **Resilience**: Risk factor: new diagnosis of chronic, serious illness
 Readiness for enhanced **Spiritual** well-being: heightened coping with serious illness
 See *Neurologic Disorders*

Mycoplasma Pneumonia

See *Pneumonia*

Myelocele

See *Neural Tube Defects*

Myelomeningocele

See *Neural Tube Defects*

Myocardial Infarction (MI)

See *MI (Myocardial Infarction)*

Myocarditis

Activity intolerance r/t reduced cardiac reserve and prescribed bed rest
 Decreased **Cardiac** output r/t altered preload/afterload
 Deficient **Knowledge** r/t treatment of disease
 Risk for decreased **Cardiac** tissue perfusion: Risk factors: hypoxia, hypovolemia, cardiac tamponade
 Readiness for enhanced **Knowledge**: treatment of disease
 See *Heart Failure, if appropriate*

Myringotomy

Fear r/t hospitalization, surgical procedure
 Ineffective **Health** maintenance r/t deficient knowledge regarding care after surgery
 Acute **Pain** r/t surgical procedure
 Risk for **Infection**: Risk factor: invasive procedure
 See *Ear Surgery*

Myxedema

See *Hypothyroidism*

N

Narcissistic Personality Disorder

Defensive **Coping** r/t grandiose sense of self
 Impaired emancipated **Decision-Making** r/t lack of realistic problem-solving skills
 Interrupted **Family** processes r/t taking advantage of others to achieve own goals
 Risk-prone **Health** behavior r/t low self-efficacy
 Disturbed personal **Identity** r/t psychological impairment
 Ineffective **Relationship** r/t lack of mutual support/respect between partners
 Impaired individual **Resilience** r/t psychological disorders
 Impaired **Social** interaction r/t self-concept disturbance
 Risk for **Loneliness**: Risk factors: emotional deprivation, social isolation

Narcolepsy

Anxiety r/t fear of lack of control over falling asleep
 Disturbed **Sleep** pattern r/t uncontrollable desire to sleep
 Risk for **Trauma**: Risk factor: falling asleep during potentially dangerous activity
 Readiness for enhanced **Sleep**: expresses willingness to enhance sleep

Narcotic Use

See *Opiate Use (preferred terminology)*

Nasogastric Suction

Impaired **Oral Mucous Membrane** r/t presence of nasogastric tube
 Risk for **Electrolyte** imbalance: Risk factor: loss of gastrointestinal fluids that contain electrolytes
 Risk for imbalanced **Fluid** volume: Risk factor: loss of gastrointestinal fluids without adequate replacement
 Risk for dysfunctional **Gastrointestinal** motility: Risk factor: decreased intestinal motility

Nausea

Nausea (See [Nausea, Section III](#))

Near-Drowning

Ineffective **Airway** clearance r/t aspiration of fluid

List of Nursing Assessments by Letter: N

Narcissistic Personality Disorder	Narcolepsy	Narcotic Use
Nasogastric Suction	Nausea	Near-Drowning
Nearsightedness	Nearsightedness; Corneal Surgery	Neck Vein Distention
Necrosis, Kidney Tubular; Necrosis, Acute Tubular	Necrotizing Enterocolitis	Negative Feelings About Self
Neglect, Unilateral	Neglectful Care of Family Member	Neonatal Jaundice
Neonate	Neoplasm	Nephrectomy
Nephrostomy, Percutaneous	Nephrotic Syndrome	Neural Tube Defects (Meningocele, Myelomeningocele, Spina Bifida, Anencephaly)
Neuralgia	Neuritis (Peripheral Neuropathy)	Neurogenic Bladder
Neurologic Disorders	Neuropathy, Peripheral	Neurosurgery
Newborn, Normal	Newborn, Postmature	Newborn, Small for Gestational Age (SGA)
Nicotine Addiction	NIDDM (Non-Insulin-Dependent Diabetes Mellitus)	Nightmares
Nipple Soreness	Nocturia	Nocturnal Myoclonus
Nocturnal Paroxysmal Dyspnea	Noncompliance	Non-Insulin-Dependent Diabetes Mellitus (NIDDM)
Normal Pressure Hydrocephalus (NPH)	Norovirus	NSTEMI (non-ST-elevation myocardial infarction)
Nursing	Nutrition	Nutrition, Imbalanced

Aspiration r/t aspiration of fluid into lungs

Fear: parental r/t possible death of child, possible permanent and debilitating sequelae

Impaired **Gas exchange** r/t laryngospasm, holding breath, aspiration, inflammation

Grieving r/t potential death of child, unknown sequelae, guilt about accident

Ineffective **Health maintenance** r/t parental deficient knowledge regarding safety measures appropriate for age

Hypothermia r/t central nervous system injury, prolonged submersion in cold water

Risk for delayed **Development:** Risk factors: hypoxemia, cerebral anoxia

Risk for disproportionate **Growth:** Risk factor: exposure to violence

Risk for complicated **Grieving:** Risk factors: potential death of child, unknown sequelae, guilt about accident

Risk for **Infection:** Risk factors: aspiration, invasive monitoring

Risk for ineffective **Cerebral tissue perfusion:** Risk factor: hypoxia

Readiness for enhanced **Spiritual well-being:** struggle with survival of life-threatening situation

See *Child with Chronic Condition; Hospitalized Child; Safety, Childhood; Terminally Ill Child/Death of Child, Parent*

Nearsightedness

Readiness for enhanced **Health management:** need for correction of myopia

Nearsightedness; Corneal Surgery

See *LASIK Eye Surgery (Laser-Assisted in Situ Keratomileusis)*

Neck Vein Distention

Decreased **Cardiac output** r/t decreased contractility of heart resulting in increased preload

Excess **Fluid volume** r/t excess fluid intake, compromised regulatory mechanisms

See *Congestive Heart Failure; Heart Failure*

Necrosis, Kidney Tubular; Necrosis, Acute Tubular

See *Kidney Failure*

Necrotizing Enterocolitis

Ineffective **Breathing pattern** r/t abdominal distention, hypoxia

Diarrhea r/t infection

Deficient **Fluid volume** r/t vomiting, gastrointestinal bleeding

Neonatal **Jaundice** r/t feeding pattern not well-established

Imbalanced **Nutrition:** less than body requirements r/t decreased ability to absorb nutrients, decreased perfusion to gastrointestinal tract

Risk for dysfunctional **Gastrointestinal motility:** Risk factor: infection

Risk for ineffective **Gastrointestinal perfusion:** Risk factors: shunting of blood away from mesenteric circulation and toward vital organs as a result of perinatal stress, hypoxia

Risk for **Infection:** Risk factors: bacterial invasion of gastrointestinal tract, invasive procedures

See *Hospitalized Child; Premature Infant (Child)*

Negative Feelings About Self

Chronic low **Self-Esteem** r/t long-standing negative self-evaluation

Self-Neglect r/t negative feelings

Readiness for enhanced **Self-Concept:** expresses willingness to enhance self-concept

Neglect, Unilateral

Unilateral Neglect (See [Unilateral Neglect, Section III](#))

Neglectful Care of Family Member

Caregiver Role Strain r/t overwhelming care demands of family member, lack of social or financial support

Disabled family **Coping** r/t highly ambivalent family relationships, lack of respite care

Interrupted **Family processes** r/t situational transition or crisis

Deficient **Knowledge** r/t care needs

Impaired individual **Resilience** r/t vulnerability from neglect

Risk for compromised **Human Dignity:** Risk factor: inadequate participation in decision-making

Neonatal Jaundice

Neonatal **Jaundice** (See [neonatal Jaundice, Section III](#))

Neonate

Readiness for enhanced **Childbearing process:** appropriate care of newborn

See *Newborn, Normal; Newborn, Postmature; Newborn, Small for Gestational Age (SGA)*

Neoplasm

Fear r/t possible malignancy

See *Cancer*

Nephrectomy

Anxiety r/t surgical recovery, prognosis

Ineffective **Breathing pattern** r/t location of surgical incision

Constipation r/t lack of return of peristalsis

Acute **Pain** r/t incisional discomfort

Spiritual distress r/t chronic illness

Risk for **Bleeding:** Risk factor: surgery

Risk for imbalanced **Fluid volume:** Risk factors: vascular losses, decreased intake

Risk for **Infection:** Risk factors: invasive procedure, lack of deep breathing because of location of surgical incision

Risk for ineffective **Renal perfusion:** Risk factor: kidney disease

Nephrostomy, Percutaneous

Acute **Pain** r/t invasive procedure

Impaired **Urinary** elimination r/t nephrostomy tube

Risk for **Infection**: Risk factor: invasive procedure

Nephrotic Syndrome

Activity intolerance r/t generalized edema

Disturbed **Body Image** r/t edematous appearance and side effects of steroid therapy

Excess **Fluid** volume r/t edema resulting from oncotic fluid shift caused by serum protein loss and kidney retention of salt and water

Imbalanced **Nutrition**: less than body requirements r/t anorexia, protein loss

Imbalanced **Nutrition**: more than body requirements r/t increased appetite attributable to steroid therapy

Social isolation r/t edematous appearance

Risk for **Infection**: Risk factor: altered immune mechanisms caused by disease and effects of steroids

Risk for ineffective **Renal** perfusion: Risk factor: kidney disease

Risk for impaired **Skin** integrity: Risk factor: edema

See *Child with Chronic Condition; Hospitalized Child*

Neural Tube Defects (Meningocele, Myelomeningocele, Spina Bifida, Anencephaly)

Chronic functional **Constipation** r/t immobility or less than adequate mobility

Grieving r/t loss of perfect child, birth of child with congenital defect

Reflex urinary **Incontinence** r/t neurogenic impairment

Total urinary **Incontinence** r/t neurogenic impairment

Urge urinary **Incontinence** r/t neurogenic impairment

Impaired **Mobility** r/t neuromuscular impairment

Chronic low **Self-Esteem** r/t perceived differences, decreased ability to participate in physical and social activities at school

Impaired **Skin** integrity r/t incontinence

Risk for delayed **Development**: Risk factor: inadequate nutrition

Risk for disproportionate **Growth**: Risk factor: congenital disorder

Risk for **Latex Allergy** response: Risk factor: multiple exposures to latex products

Risk for imbalanced **Nutrition**: more than body requirements: Risk factors: diminished, limited, or impaired physical activity

Risk for **Powerlessness**: Risk factor: debilitating disease

Risk for impaired **Skin** integrity: lower extremities: Risk factor: decreased sensory perception

Readiness for enhanced family **Coping**: effective adaptive response by family members

Readiness for enhanced **Family** processes: family supports each other

See *Child with Chronic Condition; Premature Infant (Child)*

Neuralgia

See *Trigeminal Neuralgia*

Neuritis (Peripheral Neuropathy)

Activity intolerance r/t pain with movement

Ineffective **Health** maintenance r/t deficient knowledge regarding self-care with neuritis

Acute **Pain** r/t stimulation of affected nerve endings, inflammation of sensory nerves

See *Neuropathy, Peripheral*

Neurogenic Bladder

Reflex urinary **Incontinence** r/t neurological impairment

Urinary Retention r/t interruption in the lateral spinal tracts

Risk for **Latex Allergy** response: Risk factor: repeated exposures to latex associated with possible repeated catheterizations

Neurologic Disorders

Ineffective **Airway** clearance r/t perceptual or cognitive impairment, decreased energy, fatigue

Acute **Confusion** r/t dementia, alcohol abuse, drug abuse, delirium

Ineffective **Coping** r/t disability requiring change in lifestyle

Interrupted **Family** processes r/t situational crisis, illness, or disability of family member

Grieving r/t loss of usual body functioning

Impaired **Home** maintenance r/t client's or family member's disease

Risk for corneal **Injury**: Risk factor: lack of spontaneous blink reflex

Impaired **Memory** r/t neurological disturbance

Impaired physical **Mobility** r/t neuromuscular impairment

Imbalanced **Nutrition**: less than body requirements r/t impaired swallowing, depression, difficulty feeding self

Powerlessness r/t progressive nature of disease

Self-Care deficit: specify r/t neuromuscular dysfunction

Sexual dysfunction r/t biopsychosocial alteration of sexuality

Social isolation r/t altered state of wellness

Impaired **Swallowing** r/t neuromuscular dysfunction

Risk for **Disuse** syndrome: Risk factors: physical immobility, neuromuscular dysfunction

Risk for **Injury**: Risk factors: altered mobility, sensory dysfunction, cognitive impairment

Risk for ineffective **Cerebral** tissue perfusion: Risk factor: cerebral disease/injury

Risk for impaired **Religiosity**: Risk factor: life transition

Risk for impaired **Skin** integrity: Risk factors: altered sensation, altered mental status, paralysis

See *specific condition: Alcohol Withdrawal; Amyotrophic Lateral Sclerosis (ALS); CVA (Cerebrovascular Accident); Delirium; Dementia; Guillain-Barré Syndrome; Head Injury; Huntington's Disease; Spinal Cord Injury; Myasthenia Gravis; Muscular Dystrophy; Parkinson's Disease*

Neuropathy, Peripheral

Chronic **Pain** r/t damage to nerves in the peripheral nervous system as a result of medication side effects, vitamin deficiency, or diabetes

Ineffective **Thermoregulation** r/t decreased ability to regulate body temperature

Risk for **Injury**: Risk factors: lack of muscle control, decreased sensation

Risk for impaired **Skin** integrity: Risk factor: poor perfusion

Risk for **Thermal** Injury r/t nerve damage

See *Peripheral Vascular Disease (PVD)*

Neurosurgery

See *Craniectomy/Craniotomy*

Newborn, Normal

Breastfeeding r/t normal oral structure and gestational age greater than 34 weeks

Ineffective **Thermoregulation** r/t immaturity of neuroendocrine system

Risk for **Sudden Infant Death** syndrome: Risk factors: lack of knowledge regarding infant sleeping in prone or side-lying position, prenatal or postnatal infant smoke exposure, infant overheating or overwrapping, loose articles in the sleep environment

Risk for **Infection**: Risk factors: open umbilical stump, immature immune system

Risk for **Injury**: Risk factors: immaturity, need for caretaking

Readiness for enhanced **Childbearing** process: appropriate care of newborn

Readiness for enhanced organized **Infant** behavior: demonstrates adaptive response to pain

Readiness for enhanced **Parenting**: providing emotional and physical needs of infant

Newborn, Postmature

Hypothermia r/t depleted stores of subcutaneous fat

Impaired **Skin** integrity r/t cracked and peeling skin as a result of decreased vernix

Risk for ineffective **Airway** clearance: Risk factor: meconium aspiration

Risk for unstable blood **Glucose** level: Risk factor: depleted glycogen stores

Newborn, Small for Gestational Age (SGA)

Neonatal **Jaundice** r/t neonate age and difficulty feeding

Imbalanced **Nutrition**: less than body requirements r/t history of placental insufficiency

Ineffective **Thermoregulation** r/t decreased brown fat, subcutaneous fat

Risk for delayed **Development**: Risk factor: history of placental insufficiency

Risk for disproportionate **Growth**: Risk factor: history of placental insufficiency

Risk for **Injury**: Risk factors: hypoglycemia, perinatal asphyxia, meconium aspiration

Risk for **Sudden Infant Death** syndrome: Risk factor: low birth weight

Nicotine Addiction

Risk-prone **Health** behavior r/t smoking

Ineffective **Health** maintenance r/t lack of ability to make a judgment about smoking cessation

Risk for impaired **Skin** integrity: Risk factor: poor tissue perfusion associated with nicotine

Powerlessness r/t perceived lack of control over ability to give up nicotine

Readiness for enhanced emancipated **Decision-Making**: expresses desire to enhance understanding and meaning of choices

Readiness for enhanced **Health** management: expresses desire to learn measures to stop smoking

NIDDM (Non-Insulin-Dependent Diabetes Mellitus)

Readiness for enhanced **Health** management: expresses desire for information on exercise and diet to manage diabetes

See *Diabetes Mellitus*

Nightmares

Post-Trauma syndrome r/t disaster, war, epidemic, rape, assault, torture, catastrophic illness, or accident

Nipple Soreness

Impaired **Comfort** r/t physical condition

See *Painful Breasts; Sore Nipples, Breastfeeding*

Nocturia

Urge urinary **Incontinence** r/t decreased bladder capacity, irritation of bladder stretch receptors causing spasm, alcohol, caffeine, increased fluids, increased urine concentration, overdistention of bladder

Impaired **Urinary** elimination r/t sensory motor impairment, urinary tract infection

Risk for **Powerlessness**: Risk factor: inability to control nighttime voiding

Nocturnal Myoclonus

See *Restless Leg Syndrome; Stress*

Nocturnal Paroxysmal Dyspnea

See *PND (Paroxysmal Nocturnal Dyspnea)*

Noncompliance

Ineffective **Health** management (See **Health management, ineffective, Section III**)

Non-Insulin-Dependent Diabetes Mellitus (NIDDM)

See *Diabetes Mellitus*

Normal Pressure Hydrocephalus (NPH)

Impaired verbal **Communication** r/t obstruction of flow of cerebrospinal fluid affecting speech

Acute **Confusion** r/t increased intracranial pressure caused by obstruction to flow of cerebrospinal fluid

Impaired **Memory** r/t neurological disturbance

Risk for ineffective **Cerebral** tissue perfusion: Risk factor: fluid pressing on the brain

Risk for **Falls**: Risk factor: unsteady gait as a result of obstruction of cerebrospinal fluid

Norovirus

See *Viral Gastroenteritis*

NSTEMI (non-ST-elevation myocardial infarction)

See *MI (Myocardial Infarction)*

Nursing

See *Breastfeeding, Effective; Breastfeeding, Ineffective; Breastfeeding, Interrupted*

Nutrition

Readiness for enhanced **Nutrition** (See **Nutrition**, readiness for enhanced, Section III)

Nutrition, Imbalanced

Imbalanced **Nutrition**: less than body requirements (See **Nutrition**: less than body requirements, imbalanced, Section III)

Obesity (See **Obesity**, Section III)

Overweight (See **Overweight**, Section III)

Risk for **Overweight** (See **Overweight**, risk for, Section III)

Obesity

Disturbed **Body Image** r/t eating disorder, excess weight

Risk-prone **Health** behavior: r/t negative attitude toward health care

Obesity (See **Obesity**, Section III)

Chronic low **Self-Esteem** r/t ineffective coping, overeating

Risk for ineffective peripheral **Tissue Perfusion**: Risk factor: sedentary lifestyle

Readiness for enhanced **Nutrition**: expresses willingness to enhance nutrition

OBS (Organic Brain Syndrome)

See *Organic Mental Disorders; Dementia*

Obsessive-Compulsive Disorder (OCD)

See *OCD (Obsessive-Compulsive Disorder)*

Obstruction, Bowel

See *Bowel Obstruction*

Obstructive Sleep Apnea

Insomnia r/t blocked airway

Obesity r/t excessive intake related to metabolic need

See *PND (Paroxysmal Nocturnal Dyspnea)*

OCD (Obsessive-Compulsive Disorder)

Ineffective **Activity** planning r/t unrealistic perception of events

Anxiety r/t threat to self-concept, unmet needs

Impaired emancipated **Decision-Making** r/t inability to make a decision for fear of reprisal

Disabled family **Coping** r/t family process being disrupted by client's ritualistic activities

Ineffective **Coping** r/t expression of feelings in an unacceptable way, ritualistic behavior

Risk-prone **Health** behavior r/t inadequate comprehension associated with repetitive thoughts

Powerlessness r/t unrelenting repetitive thoughts to perform irrational activities

Impaired individual **Resilience** r/t psychological disorder

Risk for situational low **Self-Esteem**: Risk factor: inability to control repetitive thoughts and actions

ODD (Oppositional Defiant Disorder)

Anxiety r/t feelings of anger and hostility toward authority figures

Ineffective **Coping** r/t lack of self-control or perceived lack of self-control

Disabled **Family** coping r/t feelings of anger, hostility; defiant behavior toward authority figures

Risk-prone **Health** behavior r/t multiple stressors associated with condition

Ineffective **Impulse** control r/t anger/compunction to engage in disruptive behaviors

Chronic or situational low **Self-Esteem** r/t poor self-control and disruptive behaviors

Impaired **Social** interaction r/t being touchy or easily annoyed, blaming others for own mistakes, constant trouble in school

Social isolation r/t unaccepted social behavior

Ineffective family **Health** management r/t difficulty in limit setting and managing oppositional behaviors

Risk for ineffective **Activity** planning: Risk factors: unrealistic perception of events, hedonism, insufficient social support

Risk for impaired **Parenting**: Risk factors: children's difficult behaviors and inability to set limits

Risk for **Powerlessness**: Risk factor: inability to deal with difficult behaviors

Risk for **Spiritual** distress: Risk factors: anxiety and stress in dealing with difficult behaviors

Risk for other-directed **Violence**: Risk factors: history of violence, threats of violence against others, history of antisocial behavior, history of indirect violence

Older Adult

See *Aging*

List of Nursing Assessments by Letter: O

Obesity	OBS (Organic Brain Syndrome)	Obsessive-Compulsive Disorder (OCD)
Obstruction, Bowel	Obstructive Sleep Apnea	OCD (Obsessive-Compulsive Disorder)
ODD (Oppositional Defiant Disorder)	Older Adult	Oliguria
Omphalocele	Oophorectomy	OPCAB (Off-Pump Coronary Artery Bypass)
Open Heart Surgery	Open Reduction of Fracture with Internal Fixation (Femur)	Opiate Use
Opportunistic Infection	Oppositional Defiant Disorder (ODD)	Oral Mucous Membrane, Impaired
Oral Thrush	Orchitis	Organic Mental Disorders
Orthopedic Traction	Orthopnea	Orthostatic Hypotension
Osteoarthritis	Osteomyelitis	Osteoporosis
Ostomy	Otitis Media	Ovarian Carcinoma

Oliguria

Deficient **Fluid** volume r/t active fluid loss, failure of regulatory mechanism, inadequate intake

See *Cardiac Output, Decreased; Kidney Failure; Shock, Hypovolemic*

Omphalocele

See *Gastroschisis/Omphalocele*

Oophorectomy

Risk for ineffective **Sexuality** pattern: Risk factor: altered body function

See *Surgery, Perioperative; Surgery, Postoperative; Surgery, Preoperative*

OPCAB (Off-Pump Coronary Artery Bypass)

See *Angioplasty, Coronary; Coronary Artery Bypass Grafting (CABG)*

Open Heart Surgery

Risk for decreased **Cardiac** tissue perfusion: Risk factor: cardiac surgery

See *Coronary Artery Bypass Grafting (CABG); Dysrhythmia*

Open Reduction of Fracture with Internal Fixation (Femur)

Anxiety r/t outcome of corrective procedure

Impaired physical **Mobility** r/t postoperative position, abduction of leg, avoidance of acute flexion

Powerlessness r/t loss of control, unanticipated change in lifestyle

Risk for **Infection**: Risk factor: surgical procedure

Risk for **Perioperative Positioning** injury: Risk factor: immobilization

Risk for **Peripheral Neurovascular** dysfunction: Risk factors: mechanical compression, orthopedic surgery, immobilization

See *Surgery, Postoperative Care*

Opiate Use

Chronic **Pain** syndrome r/t prolonged use of opiates

Risk for **Constipation**: Risk factor: effects of opiates on peristalsis

See *Drug Abuse; Drug Withdrawal*

Opportunistic Infection

Delayed **Surgical** recovery r/t abnormal blood profiles, impaired healing

Risk for **Infection**: Risk factor: abnormal blood profiles

See *AIDS (Acquired Immunodeficiency Syndrome); HIV (Human Immunodeficiency Virus)*

Oppositional Defiant Disorder (ODD)

See *ODD (Oppositional Defiant Disorder)*

Oral Mucous Membrane, Impaired

Impaired **Oral Mucous Membrane** (See *Oral Mucous Membrane, impaired, Section III*)

Oral Thrush

See *Candidiasis, Oral*

Orchitis

Readiness for enhanced **Health** management: follows recommendations for mumps vaccination

See *Epididymitis*

Organic Mental Disorders

Frail Elderly syndrome r/t alteration in cognitive function

Impaired **Social** interaction r/t disturbed thought processes

Risk for disturbed personal **Identity**: Risk factor: delusions/fluctuating perceptions of stimuli

Risk for **Infection**: Risk factor: surgical procedure

See *Dementia*

Orthopedic Traction

Ineffective **Role** performance r/t limited physical mobility

Impaired **Social** interaction r/t limited physical mobility

Impaired **Transfer** ability r/t limited physical mobility

Risk for impaired **Religiosity**: Risk factor: immobility

See *Traction and Casts*

Orthopnea

Ineffective **Breathing** pattern r/t inability to breathe with head of bed flat

Decreased **Cardiac** output r/t inability of heart to meet demands of body

Orthostatic Hypotension

See *Dizziness*

Osteoarthritis

Acute **Pain** r/t movement

Impaired **Walking** r/t inflammation and damage to joints

See *Arthritis*

Osteomyelitis

Deficient **Diversional** activity r/t prolonged immobilization, hospitalization

Fear: parental r/t concern regarding possible growth plate damage caused by infection, concern that infection may become chronic

Ineffective **Health** maintenance r/t continued immobility at home, possible extensive casts, continued antibiotics

Impaired physical **Mobility** r/t imposed immobility as a result of infected area

Acute **Pain** r/t inflammation in affected extremity

Ineffective **Thermoregulation** r/t infectious process

Risk for **Constipation**: Risk factor: immobility

Risk for **Infection**: Risk factor: inadequate primary and secondary defenses

Risk for impaired **Skin** integrity: Risk factor: irritation from splint or cast

See *Hospitalized Child*

Osteoporosis

Deficient **Knowledge** r/t diet, exercise, need to abstain from alcohol and nicotine

Impaired physical **Mobility** r/t pain, skeletal changes

Imbalanced **Nutrition**: less than body requirements r/t inadequate intake of calcium and vitamin D

Acute **Pain** r/t fracture, muscle spasms

Risk for **Injury**: fracture: Risk factors: lack of activity, risk of falling resulting from environmental hazards, neuromuscular disorders, diminished senses, cardiovascular responses to drugs

Risk for **Powerlessness**: Risk factor: debilitating disease

Readiness for enhanced **Health** management: expresses desire to manage the treatment of illness and prevent complications

Ostomy

See *Child with Chronic Condition; Colostomy; Ileal Conduit; Ileostomy*

Otitis Media

Acute **Pain** r/t inflammation, infectious process

Risk for delayed **Development**: speech and language: Risk factor: frequent otitis media

Risk for **Infection**: Risk factors: eustachian tube obstruction, traumatic eardrum perforation, infectious disease process

Readiness for enhanced **Knowledge**: information on treatment and prevention of disease

Ovarian Carcinoma

Death **Anxiety** r/t unknown outcome, possible poor prognosis

Fear r/t unknown outcome, possible poor prognosis

Ineffective **Health Maintenance** r/t deficient knowledge regarding self-care, treatment of condition

Readiness for enhanced **Family Processes**: family functioning meets needs of client

Readiness for enhanced **Resilience**: participates in support groups

See *Chemotherapy; Hysterectomy; Radiation Therapy*

P

Pacemaker

Anxiety r/t change in health status, presence of pacemaker

Death **Anxiety** r/t worry over possible malfunction of pacemaker

Deficient **Knowledge** r/t self-care program, when to seek medical attention

Acute **Pain** r/t surgical procedure

Risk for **Bleeding**: Risk factor: surgery

Risk for decreased **Cardiac** tissue perfusion: Risk factor: pacemaker malfunction

Risk for **Infection**: Risk factors: invasive procedure, presence of foreign body (catheter and generator)

Risk for **Powerlessness**: Risk factor: presence of electronic device to stimulate heart

Readiness for enhanced **Health** management: appropriate health care management of pacemaker

Paget's Disease

Disturbed **Body Image** r/t possible enlarged head, bowed tibias, kyphosis

Deficient **Knowledge** r/t appropriate diet high in protein and calcium, mild exercise

Chronic **Sorrow** r/t chronic condition with altered body image

Risk for **Trauma**: fracture: Risk factor: excessive bone destruction

Pain, Acute

Acute **Pain** (See **Pain, acute**, Section III)

Pain, Chronic

Chronic **Pain** (See **Pain, chronic**, Section III)

Painful Breasts, Engorgement

Acute **Pain** r/t distention of breast tissue

Ineffective **Role** performance r/t change in physical capacity to assume role of breastfeeding mother

Impaired **Tissue** integrity r/t excessive fluid in breast tissues

Risk for ineffective **Breastfeeding**: Risk factors: pain, infant's inability to latch on to engorged breast

Risk for **Infection**: Risk factor: milk stasis

Painful Breasts, Sore Nipples

Insufficient **Breast Milk** r/t long breastfeeding time/pain response

Ineffective **Breastfeeding** r/t pain

Acute **Pain** r/t cracked nipples

Ineffective **Role** performance r/t change in physical capacity to assume role of breastfeeding mother

Impaired **Skin** integrity r/t mechanical factors involved in suckling, breastfeeding management

Risk for **Infection**: Risk factor: break in skin

Pallor of Extremities

Ineffective peripheral **Tissue Perfusion** r/t interruption of vascular flow

See *Shock; Peripheral Vascular disease (PVD)*

Palpitations (Heart Palpitations)

See *Dysrhythmia*

Pancreatic Cancer

Death **Anxiety** r/t possible poor prognosis of disease process

Ineffective family **Coping** r/t poor prognosis

Fear r/t poor prognosis of the disease

List of Nursing Assessments by Letter: P

Pacemaker	Paget's Disease	Pain, Acute
Pain, Chronic	Painful Breasts, Engorgement	Painful Breasts, Sore Nipples
Pallor of Extremities	Palpitations (Heart Palpitations)	Pancreatic Cancer
Pancreatitis	Panic Disorder (Panic Attacks)	Paralysis
Paralytic Ileus	Paranoid Personality Disorder	Paraplegia
Parathyroidectomy	Parent Attachment	Parental Role Conflict
Parenting	Parenting, Impaired	Parenting, Risk for Impaired
Paresthesia	Parkinson's Disease	Paroxysmal Nocturnal Dyspnea (PND)
Patent Ductus Arteriosus (PDA)	Patient-Controlled Analgesia (PCA)	Patient Education
PCA (Patient-Controlled Analgesia)	Pectus Excavatum	Pediculosis
PEG (Percutaneous Endoscopic Gastrostomy)	Pelvic Inflammatory Disease (PID)	Penile Prosthesis
Peptic Ulcer	Percutaneous Transluminal Coronary Angioplasty (PTCA)	Pericardial Friction Rub
Pericarditis	Periodontal Disease	Perioperative Hypothermia
Perioperative Positioning	Peripheral Neuropathy	Peripheral Neurovascular Dysfunction
Peripheral Vascular Disease (PVD)	Peritoneal Dialysis	Peritonitis
Pernicious Anemia	Persistent Fetal Circulation	Personal Identity Problems
Personality Disorder	Pertussis (Whooping Cough)	Pesticide Contamination
Petechiae	Petit Mal Seizure	Pharyngitis
Phenylketonuria (PKU)	Pheochromocytoma	Phlebitis
Phobia (Specific)	Photosensitivity	Physical Abuse
Pica	PID (Pelvic Inflammatory Disease)	PIH (Pregnancy-Induced Hypertension/Preeclampsia)
Piloerection	Pimples	Pink Eye
Pinworms	Pituitary Tumor, Benign	PKU (Phenylketonuria)
Placenta Abruptio	Placenta Previa	Plantar Fasciitis

Pleural Effusion	Pleural Friction Rub	Pleural Tap
Pleurisy	PMS (Premenstrual Tension Syndrome)	PND (Paroxysmal Nocturnal Dyspnea)
Pneumonectomy	Pneumonia	Pneumothorax
Poisoning, Risk for	Poliomyelitis	Polydipsia
Polyphagia	Polyuria	Postoperative Care
Postpartum Depression	Postpartum Hemorrhage	Postpartum, Normal Care
Post-Trauma Syndrome	Post-Trauma Syndrome, Risk for	Post-Traumatic Stress Disorder (PTSD)
Potassium, Increase/Decrease	Power/Powerlessness	Preeclampsia
Pregnancy, Cardiac Disorders	Pregnancy-Induced Hypertension/Preeclampsia (PIH)	Pregnancy Loss
Pregnancy, Normal	Premature Dilation of the Cervix (Incompetent Cervix)	Premature Infant (Child)
Premature Infant (Parent)	Premature Rupture of Membranes	Premenstrual Tension Syndrome (PMS)
Prenatal Care, Normal	Prenatal Testing	Preoperative Teaching
Pressure Ulcer	Preterm Labor	Problem-Solving Dysfunction
Projection	Prolapsed Umbilical Cord	Prostatectomy
Prostatic Hypertrophy	Prostatitis	Pruritus
Psoriasis	Psychosis	PTCA (Percutaneous Transluminal Coronary Angioplasty)
PTSD (Posttraumatic Stress Disorder)	Pulmonary Edema	Pulmonary Embolism
Pulmonary Stenosis	Pulse Deficit	Pulse Oximetry
Pulse Pressure, Increased	Pulse Pressure, Narrowed	Pulses, Absent or Diminished Peripheral
Purpura	Pyelonephritis	Pyloric Stenosis
Pyloromyotomy (Pyloric Stenosis Repair)		

Grieving r/t shortened life span

Deficient **Knowledge** r/t disease-induced diabetes, home management

Spiritual distress r/t poor prognosis

Risk for impaired **Liver** function: Risk factor: complications from underlying disease

See *Cancer; Chemotherapy; Radiation Therapy; Surgery, Perioperative; Surgery, Postoperative; Surgery, Preoperative*

Pancreatitis

Ineffective **Breathing** pattern r/t splinting from severe pain, disease process and inflammation

Ineffective **Denial** r/t ineffective coping, alcohol use

Diarrhea r/t decrease in pancreatic secretions resulting in steatorrhea

Deficient **Fluid** volume r/t vomiting, decreased fluid intake, fever, diaphoresis, fluid shifts

Ineffective **Health** maintenance r/t deficient knowledge concerning diet, alcohol use, medication

Nausea r/t irritation of gastrointestinal system

Imbalanced **Nutrition**: less than body requirements r/t inadequate dietary intake, increased nutritional needs as a result of acute illness, increased metabolic needs caused by increased body temperature, disease process

Acute **Pain** r/t irritation and edema of the inflamed pancreas

Chronic **Sorrow** r/t chronic illness

Readiness for enhanced **Comfort**: expresses desire to enhance comfort

Panic Disorder (Panic Attacks)

Ineffective **Activity** planning r/t unrealistic perception of events

Anxiety r/t situational crisis

Ineffective **Coping** r/t personal vulnerability

Risk-prone **Health** behavior r/t low self-efficacy

Disturbed personal **Identity** r/t situational crisis

Post-Trauma syndrome r/t previous catastrophic event

Social isolation r/t fear of lack of control

Risk for **Loneliness**: Risk factor: inability to socially interact because of fear of losing control

Risk for **Post-Trauma** syndrome: Risk factors: perception of the event, diminished ego strength

Risk for **Powerlessness**: Risk factor: ineffective coping skills

Readiness for enhanced **Coping**: seeks problem-oriented and emotion-oriented strategies to manage condition

See *Anxiety; Anxiety Disorder*

Paralysis

Disturbed **Body Image** r/t biophysical changes, loss of movement, immobility

Impaired **Comfort** r/t prolonged immobility

Constipation r/t effects of spinal cord disruption, inadequate fiber in diet

Ineffective **Health** maintenance r/t deficient knowledge regarding self-care with paralysis

Impaired **Home** maintenance r/t physical disability

Reflex urinary **Incontinence** r/t neurological impairment

Impaired physical **Mobility** r/t neuromuscular impairment

Impaired wheelchair **Mobility** r/t neuromuscular impairment

Self-Neglect r/t functional impairment

Powerlessness r/t illness-related regimen

Self-Care deficit: specify r/t neuromuscular impairment

Sexual dysfunction r/t loss of sensation, biopsychosocial alteration

Chronic **Sorrow** r/t loss of physical mobility

Impaired **Transfer** ability r/t paralysis

Risk for **Autonomic Dysreflexia**: Risk factor: cause of paralysis

Risk for **Disuse** syndrome: Risk factor: paralysis

Risk for **Falls**: Risk factor: paralysis

Risk for **Injury**: Risk factors: altered mobility, sensory dysfunction

Risk for **Latex Allergy** response: Risk factor: possible repeated urinary catheterizations

Risk for **Post-Trauma** syndrome: Risk factor: event causing paralysis

Risk for impaired **Religiosity**: Risk factors: immobility, possible lack of transportation

Risk for impaired **Resilience**: Risk factor: chronic disability

Risk for situational low **Self-Esteem**: Risk factor: change in body image and function

Risk for impaired **Skin** integrity: Risk factors: altered circulation, altered sensation, immobility

Readiness for enhanced **Self-Care**: expresses desire to enhance knowledge and responsibility for strategies for self-care

See *Child with Chronic Condition; Hemiplegia; Hospitalized Child; Neural Tube Defects; Spinal Cord Injury*

Paralytic Ileus

Constipation r/t decreased gastrointestinal motility

Deficient **Fluid** volume r/t loss of fluids from vomiting, retention of fluid in bowel

Dysfunctional **Gastrointestinal** motility r/t recent abdominal surgery, electrolyte imbalance

Nausea r/t gastrointestinal irritation

Acute **Pain** r/t pressure, abdominal distention, presence of nasogastric tube

See *Bowel Obstruction*

Paranoid Personality Disorder

Ineffective **Activity** planning r/t unrealistic perception of events

Anxiety r/t uncontrollable intrusive, suspicious thoughts

Risk-prone **Health** behavior r/t intense emotional state

Disturbed personal **Identity** r/t difficulty with reality testing

Impaired individual **Resilience** r/t psychological disorder

Chronic low **Self-Esteem** r/t inability to trust others

Social isolation r/t inappropriate social skills

Risk for **Loneliness**: Risk factor: social isolation

Risk for other-directed **Violence**: Risk factor: being suspicious of others and their actions

Paraplegia

See *Spinal Cord Injury*

Parathyroidectomy

Anxiety r/t surgery

Risk for ineffective **Airway** clearance: Risk factors: edema or hematoma formation, airway obstruction

Risk for **Bleeding**: Risk factor: surgery

Risk for impaired verbal **Communication**: Risk factors: possible laryngeal damage, edema

Risk for **Infection**: Risk factor: surgical procedure

See *Hypocalcemia*

Parent Attachment

Risk for impaired **Attachment** (See **Attachment**, impaired, risk for, Section III)

Readiness for enhanced **Childbearing** process: demonstrates appropriate care of newborn

See *Parental Role Conflict*

Parental Role Conflict

Parental **Role** conflict (See **Role conflict**, parental, Section III)

Ineffective **Relationship** r/t unrealistic expectations

Chronic **Sorrow** r/t difficult parent–child relationship

Risk for **Spiritual** distress: Risk factor: altered relationships

Readiness for enhanced **Parenting**: willingness to enhance parenting

Parenting

Readiness for enhanced **Parenting** (See **Parenting**, readiness for enhanced, Section III)

Parenting, Impaired

Impaired **Parenting** (See **Parenting**, impaired, Section III)

Chronic **Sorrow** r/t difficult parent–child relationship

Risk for **Spiritual** distress: Risk factor: altered relationships

Parenting, Risk for Impaired

Risk for impaired **Parenting** (See **Parenting**, impaired, risk for, Section III)

See *Parenting, Impaired*

Paresthesia

Risk for **Injury**: Risk factors: inability to feel temperature changes, pain

Risk for impaired **Skin** integrity: Risk factor: impaired sensation

Risk for **Thermal** injury: Risk factor: neuromuscular impairment

Parkinson's Disease

Impaired verbal **Communication** r/t decreased speech volume, slowness of speech, impaired facial muscles

Constipation r/t weakness of muscles, lack of exercise, inadequate fluid intake, decreased autonomic nervous system activity

Frail Elderly syndrome r/t chronic illness

Imbalanced **Nutrition**: less than body requirements r/t tremor, slowness in eating, difficulty in chewing and swallowing

Chronic **Sorrow** r/t loss of physical capacity

Risk for **Injury**: Risk factors: tremors, slow reactions, altered gait

See *Neurologic Disorders*

Paroxysmal Nocturnal Dyspnea (PND)

See *PND (Paroxysmal Nocturnal Dyspnea)*

Patent Ductus Arteriosus (PDA)

See *Congenital Heart Disease/Cardiac Anomalies*

Patient-Controlled Analgesia (PCA)

See *PCA (Patient-Controlled Analgesia)*

Patient Education

Deficient **Knowledge** r/t lack of exposure to information misinterpretation, unfamiliarity with information resources to manage illness

Readiness for enhanced emancipated **Decision-Making**: expresses desire to enhance understanding of choices for decision-making

Readiness for enhanced **Knowledge** (specify): interest in learning

Readiness for enhanced **Health** management: expresses desire for information to manage the illness

PCA (Patient-Controlled Analgesia)

Deficient **Knowledge** r/t self-care of pain control

Nausea r/t side effects of medication

Risk for **Injury**: Risk factors: possible complications associated with PCA

Risk for **Vascular Trauma**: Risk factors: insertion site and length of insertion time

Readiness for enhanced **Knowledge**: appropriate management of PCA

Pectus Excavatum

See *Marfan Syndrome*

Pediculosis

See *Lice*

PEG (Percutaneous Endoscopic Gastrostomy)

See *Tube Feeding*

Pelvic Inflammatory Disease (PID)

See *PID (Pelvic Inflammatory Disease)*

Penile Prosthesis

Ineffective **Sexuality** pattern r/t use of penile prosthesis

Risk for **Infection**: Risk factor: invasive surgical procedure

Risk for situational low **Self-Esteem**: Risk factor: ineffective sexuality pattern

Readiness for enhanced **Health** management: seeks information regarding care and use of prosthesis

See *Erectile Dysfunction (ED)*; *Impotence*

Peptic Ulcer

See *Ulcer, Peptic (Duodenal or Gastric)*

Percutaneous Transluminal Coronary Angioplasty (PTCA)

See *Angioplasty, Coronary*

Pericardial Friction Rub

Decreased **Cardiac** output

Acute **Pain** r/t inflammation, effusion

Risk for decreased **Cardiac** tissue perfusion: Risk factors: inflammation in pericardial sac, fluid accumulation compressing heart

Pericarditis

Activity intolerance r/t reduced cardiac reserve, prescribed bed rest

Decreased **Cardiac** output r/t impaired cardiac function from inflammation of pericardial sac

Risk for decreased **Cardiac** tissue perfusion: Risk factor: inflammation in pericardial sac

Deficient **Knowledge** r/t unfamiliarity with information sources

Risk for imbalanced **Nutrition**: less than body requirements: Risk factors: fever, hypermetabolic state associated with fever

Acute **Pain** r/t biological injury, inflammation

Periodontal Disease

Risk for impaired **Oral Mucous Membranes** (See **Oral Mucous Membranes**, impaired, risk for, Section III)

Perioperative Hypothermia

Risk for **Perioperative Hypothermia** (See **Perioperative Hypothermia**, risk for, Section III)

Perioperative Positioning

Risk for **Perioperative Positioning** injury (See **Perioperative Positioning** injury, risk for, Section III)

Peripheral Neuropathy

See *Neuropathy, Peripheral*

Peripheral Neurovascular Dysfunction

Risk for **Peripheral Neurovascular** dysfunction (See **Peripheral Neurovascular** dysfunction, risk for, Section III)

See *Neuropathy, Peripheral*; *Peripheral Vascular Disease (PVD)*

Peripheral Vascular Disease (PVD)

Ineffective **Health** maintenance r/t deficient knowledge regarding self-care and treatment of disease

Chronic **Pain**: intermittent claudication r/t ischemia

Ineffective peripheral **Tissue Perfusion** r/t disease process

Risk for **Falls**: Risk factor: altered mobility

Risk for **Injury**: Risk factors: tissue hypoxia, altered mobility, altered sensation

Risk for **Peripheral Neurovascular** dysfunction: Risk factor: possible vascular obstruction

Risk for impaired **Tissue** integrity: Risk factor: altered circulation or sensation

Readiness for enhanced **Health** management: self-care and treatment of disease

See *Neuropathy, Peripheral*; *Peripheral Neurovascular Dysfunction*

Peritoneal Dialysis

Ineffective **Breathing** pattern r/t pressure from dialysate

Impaired **Comfort** r/t instillation of dialysate, temperature of dialysate

Impaired **Home** maintenance r/t complex home treatment of client

Deficient **Knowledge** r/t treatment procedure, self-care with peritoneal dialysis

Chronic **Sorrow** r/t chronic disability

Risk for ineffective **Coping**: Risk factor: disability requiring change in lifestyle

Risk for unstable blood **Glucose** level: Risk factors: increased concentrations of glucose in dialysate, ineffective medication management

Risk for imbalanced **Fluid** volume: Risk factor: medical procedure

Risk for **Infection**: peritoneal: Risk factors: invasive procedure, presence of catheter, dialysate

Risk for **Powerlessness**: Risk factors: chronic condition and care involved

See *Child with Chronic Condition*; *Hemodialysis*; *Hospitalized Child*; *Kidney Failure*; *Kidney Failure, Acute/Chronic, Child*

Peritonitis

Ineffective **Breathing** pattern r/t pain, increased abdominal pressure

Constipation r/t decreased oral intake, decrease of peristalsis

Deficient **Fluid** volume r/t retention of fluid in bowel with loss of circulating blood volume

Nausea r/t gastrointestinal irritation

Imbalanced **Nutrition**: less than body requirements r/t nausea, vomiting

Acute **Pain** r/t inflammation and infection of gastrointestinal system

Risk for dysfunctional **Gastrointestinal** motility: Risk factor: gastrointestinal disease

Pernicious Anemia

Diarrhea r/t malabsorption of nutrients

Fatigue r/t imbalanced nutrition: less than body requirements

Impaired **Memory** r/t lack of adequate red blood cells

Nausea r/t altered oral mucous membrane; sore tongue, bleeding gums

Imbalanced **Nutrition**: less than body requirements r/t lack of appetite associated with nausea and altered oral mucous membrane

Impaired **Oral Mucous Membrane** r/t vitamin deficiency; inability to absorb vitamin B₁₂ associated with lack of intrinsic factor

Risk for **Falls**: Risk factors: dizziness, lightheadedness

Risk for **Peripheral Neurovascular** dysfunction: Risk factor: anemia

Persistent Fetal Circulation

See *Congenital Heart Disease/Cardiac Anomalies*

Personal Identity Problems

Disturbed personal **Identity** (See **Identity**, personal, disturbed, Section III)

Risk for disturbed personal **Identity** (See **disturbed personal Identity**, risk for, Section III)

Personality Disorder

Ineffective **Activity** planning r/t unrealistic perception of events

Impaired individual **Resilience** r/t psychological disorder

See *specific disorder: Antisocial Personality Disorder; Borderline Personality Disorder; OCD (Obsessive-Compulsive Disorder); Paranoid Personality Disorder*

Pertussis (Whooping Cough)

Risk for impaired emancipated **Decision-Making** r/t whether to administer usual childhood vaccinations

See *Respiratory Infections, Acute Childhood*

Pesticide Contamination

Contamination r/t use of environmental contaminants; pesticides

Risk for **Allergy** response r/t repeated exposure to pesticides

Risk for disproportionate **Growth**: Risk factor: environmental contamination

Petechiae

See *Anticoagulant Therapy; Clotting Disorder; DIC (Disseminated Intravascular Coagulation); Hemophilia*

Petit Mal Seizure

Readiness for enhanced **Health** management: wears medical alert bracelet; limits hazardous activities such as driving, swimming, working at heights, operating equipment

See *Epilepsy*

Pharyngitis

See *Sore Throat*

Phenylketonuria (PKU)

See *PKU (Phenylketonuria)*

Pheochromocytoma

Anxiety r/t symptoms from increased catecholamines—headache, palpitations, sweating, nervousness, nausea, vomiting, syncope

Ineffective **Health** maintenance r/t deficient knowledge regarding treatment and self-care

Insomnia r/t high levels of catecholamines

Nausea r/t increased catecholamines

Risk for decreased **Cardiac** tissue perfusion: Risk factor: hypertension

See *Surgery, Perioperative; Surgery, Postoperative; Surgery, Preoperative*

Phlebitis

See *Thrombophlebitis*

Phobia (Specific)

Fear r/t presence or anticipation of specific object or situation

Powerlessness r/t anxiety about encountering unknown or known entity

Impaired individual **Resilience** r/t psychological disorder

Readiness for enhanced **Power**: expresses readiness to enhance identification of choices that can be made for change

See *Anxiety; Anxiety Disorder; Panic Disorder (Panic Attacks)*

Photosensitivity

Ineffective **Health** maintenance r/t deficient knowledge regarding medications inducing photosensitivity

Risk for dry **Eye**: Risk factors: pharmaceutical agents, sunlight exposure

Risk for impaired **Skin** integrity: Risk factor: exposure to sun

Physical Abuse

See *Abuse, Child; Abuse, Spouse, Parent, or Significant Other*

Pica

Anxiety r/t stress

Imbalanced **Nutrition**: less than body requirements r/t eating nonnutritive substances

Impaired **Parenting** r/t lack of supervision, food deprivation

Risk for **Constipation**: Risk factor: presence of undigestible materials in gastrointestinal tract

Risk for dysfunctional **Gastrointestinal** motility: Risk factor: abnormal eating behavior

Risk for **Infection**: Risk factor: ingestion of infectious agents via contaminated substances

Risk for **Poisoning**: Risk factor: ingestion of substances containing lead

See *Anemia*

PID (Pelvic Inflammatory Disease)

Ineffective **Health** maintenance r/t deficient knowledge regarding self-care, treatment of disease

Acute **Pain** r/t biological injury; inflammation, edema, congestion of pelvic tissues

Ineffective **Sexuality** pattern r/t medically imposed abstinence from sexual activities until acute infection subsides, change in reproductive potential

Risk for **Infection**: Risk factors: insufficient knowledge to avoid exposure to pathogens; proper hygiene, nutrition, other health habits

See *Maturational Issues, Adolescent; STD (Sexually Transmitted Disease)*

PIH (Pregnancy-Induced Hypertension/Preeclampsia)

Anxiety r/t fear of the unknown, threat to self and infant, change in role functioning

Death **Anxiety** r/t threat of preeclampsia

Deficient **Diversional** activity r/t bed rest

Interrupted **Family** processes r/t situational crisis

Impaired **Home** maintenance r/t bed rest

Deficient **Knowledge** r/t lack of experience with situation

Impaired physical **Mobility** r/t medically prescribed limitations

Impaired **Parenting** r/t prescribed bed rest

Powerlessness r/t complication threatening pregnancy, medically prescribed limitations

Ineffective **Role** performance r/t change in physical capacity to assume role of pregnant woman or resume other roles

Situational low **Self-Esteem** r/t loss of idealized pregnancy

Impaired **Social** interaction r/t imposed bed rest

Risk for imbalanced **Fluid** volume: Risk factors: hypertension, altered kidney function

Risk for **Injury**: fetal: Risk factors: decreased uteroplacental perfusion, seizures

Risk for **Injury**: maternal: Risk factors: vasospasm, high blood pressure

Readiness for enhanced **Knowledge**: exhibits desire for information on managing condition

Piloerection

Hypothermia r/t exposure to cold environment

Pimples

See *Acne*

Pink Eye

See *Conjunctivitis*

Pinworms

Impaired **Comfort** r/t itching

Impaired **Home** maintenance r/t inadequate cleaning of bed linen and toilet seats

Insomnia r/t discomfort

Readiness for enhanced **Health** management: proper hand-washing; short, clean fingernails; avoiding hand, mouth, nose contact with unwashed hands; appropriate cleaning of bed linen and toilet seats

Pituitary Tumor, Benign

See *Cushing's Disease*

PKU (Phenylketonuria)

Risk for delayed **Development**: Risk factors: not following strict dietary program; eating foods extremely low in phenylalanine; avoiding eggs, milk, any foods containing aspartame (e.g., NutraSweet)

Readiness for enhanced **Health** management: testing for PKU and following prescribed dietary regimen

Placenta Abruptio

Death **Anxiety** r/t threat of mortality associated with bleeding

Fear r/t threat to self and fetus

Ineffective **Health** maintenance r/t deficient knowledge regarding treatment and control of hypertension associated with placenta abruptio

Acute **Pain**: abdominal/back r/t premature separation of placenta before delivery

Risk for **Bleeding**: Risk factor: placenta abruptio

Risk for deficient **Fluid** volume: Risk factor: maternal blood loss

Risk for **Powerlessness**: Risk factors: complications of pregnancy and unknown outcome

Risk for **Shock**: Risk factor: hypovolemia

Risk for **Spiritual** distress: Risk factor: fear from unknown outcome of pregnancy

Placenta Previa

Death **Anxiety** r/t threat of mortality associated with bleeding

Disturbed **Body Image** r/t negative feelings about body and reproductive ability, feelings of helplessness

Ineffective **Coping** r/t threat to self and fetus

Deficient **Diversional** activity r/t long-term hospitalization

Interrupted **Family** processes r/t maternal bed rest, hospitalization

Fear r/t threat to self and fetus, unknown future

Impaired **Home** maintenance r/t maternal bed rest, hospitalization

Impaired physical **Mobility** r/t medical protocol, maternal bed rest

Ineffective **Role** performance r/t maternal bed rest, hospitalization

Situational low **Self-Esteem** r/t situational crisis

Spiritual distress r/t inability to participate in usual religious rituals, situational crisis

Risk for **Bleeding**: Risk factor: placenta previa

Risk for **Constipation**: Risk factors: bed rest, pregnancy

Risk for deficient **Fluid** volume: Risk factor: maternal blood loss

Risk for imbalanced **Fluid** volume: Risk factor: maternal blood loss

Risk for **Injury**: fetal and maternal: Risk factors: threat to uteroplacental perfusion, hemorrhage

Risk for disturbed **Maternal-Fetal** dyad: Risk factor: complication of pregnancy

Risk for impaired **Parenting**: Risk factors: maternal bed rest, hospitalization

Risk for ineffective peripheral **Tissue Perfusion**: placental: Risk factors: dilation of cervix, loss of placental implantation site

Risk for **Powerlessness**: Risk factors: complications of pregnancy, unknown outcome

Risk for **Shock**: Risk factor: hypovolemia

Plantar Fasciitis

Impaired **Comfort** r/t inflamed structures of feet

Impaired physical **Mobility** r/t discomfort

Acute **Pain** r/t inflammation

Chronic **Pain** r/t inflammation

Pleural Effusion

Ineffective **Breathing** pattern r/t pain

Excess **Fluid** volume r/t compromised regulatory mechanisms; heart, liver, or kidney failure

Acute **Pain** r/t inflammation, fluid accumulation

Pleural Friction Rub

Ineffective **Breathing** pattern r/t pain

Acute **Pain** r/t inflammation, fluid accumulation

Pleural Tap

See *Pleural Effusion*

Pleurisy

Ineffective **Breathing** pattern r/t pain

Impaired **Gas** exchange r/t ventilation perfusion imbalance

Acute **Pain** r/t pressure on pleural nerve endings associated with fluid accumulation or inflammation

Impaired **Walking** r/t activity intolerance, inability to “catch breath”

Risk for ineffective **Airway** clearance: Risk factors: increased secretions, ineffective cough because of pain

Risk for **Infection**: Risk factor: exposure to pathogens

PMS (Premenstrual Tension Syndrome)

Fatigue r/t hormonal changes

Excess **Fluid** volume r/t alterations of hormonal levels inducing fluid retention

Deficient **Knowledge** r/t methods to deal with and prevent syndrome

Acute **Pain** r/t hormonal stimulation of gastrointestinal structures

Risk for **Powerlessness**: Risk factors: lack of knowledge and ability to deal with symptoms

Risk for impaired **Resilience**: Risk factor: PMS symptoms

Readiness for enhanced **Communication**: willingness to express thoughts and feelings about PMS

Readiness for enhanced **Health** management: desire for information to manage and prevent symptoms

PND (Paroxysmal Nocturnal Dyspnea)

Anxiety r/t inability to breathe during sleep

Ineffective **Breathing** pattern r/t increase in carbon dioxide levels, decrease in oxygen levels

Insomnia r/t suffocating feeling from fluid in lungs on awakening from sleep

Sleep deprivation r/t inability to breathe during sleep

Risk for decreased **Cardiac** tissue perfusion: Risk factor: hypoxia

Risk for **Powerlessness**: Risk factor: inability to control nocturnal dyspnea

Readiness for enhanced **Sleep**: expresses willingness to learn measures to enhance sleep

Pneumonectomy

See *Thoracotomy*

Pneumonia

Activity intolerance r/t imbalance between oxygen supply and demand

Ineffective **Airway** clearance r/t inflammation and presence of secretions

Impaired **Gas** exchange r/t decreased functional lung tissue

Ineffective **Health** management r/t deficient knowledge regarding self-care and treatment of disease

Imbalanced **Nutrition**: less than body requirements r/t loss of appetite

Impaired **Oral Mucous Membrane** r/t dry mouth from mouth breathing, decreased fluid intake

Ineffective **Thermoregulation** r/t infectious process

Risk for acute **Confusion**: Risk factors: underlying illness, hypoxia

Risk for deficient **Fluid** volume: Risk factor: inadequate intake of fluids

Risk for **Vascular Trauma**: Risk factor: irritation from intravenous antibiotics

See *Respiratory Infections, Acute Childhood*

Pneumothorax

Fear r/t threat to own well-being, difficulty breathing

Impaired **Gas** exchange r/t ventilation-perfusion imbalance, decreased functional lung tissue

Acute **Pain** r/t recent injury, coughing, deep breathing

Risk for **Injury**: Risk factor: possible complications associated with closed chest drainage system

See *Chest Tubes*

Poisoning, Risk for

Risk for **Poisoning** (See **Poisoning**, risk for, Section III)

Poliomyelitis

See *Paralysis*

Polydipsia

Readiness for enhanced **Fluid** balance: excessive thirst gone when diabetes is controlled

See *Diabetes Mellitus*

Polyphagia

Readiness for enhanced **Nutrition**: knowledge of appropriate diet for diabetes

See *Diabetes Mellitus*

Polyuria

Readiness for enhanced **Urinary** elimination: willingness to learn measures to enhance urinary elimination

See *Diabetes Mellitus*

Postoperative Care

See *Surgery, Postoperative*

Postpartum Depression

Anxiety r/t new responsibilities of parenting

Disturbed **Body Image** r/t normal postpartum recovery

Ineffective **Childbearing** process r/t depression/lack of support system

Ineffective **Coping** r/t hormonal changes

Fatigue r/t childbirth, postpartum state, crying child

Risk-prone **Health** behavior r/t lack of support systems

Impaired **Home** maintenance r/t fatigue, care of newborn

Hopelessness r/t stress, exhaustion

Deficient **Knowledge** r/t lifestyle changes

Impaired **Parenting** r/t hormone-induced depression

Ineffective **Role** performance r/t new responsibilities of parenting

Sexual dysfunction r/t fear of another pregnancy, postpartum pain, lochia flow

Sleep deprivation r/t environmental stimulation of newborn

Impaired **Social** interaction r/t change in role functioning

Risk for disturbed personal **Identity** r/t role change/depression/inability to cope

Risk for situational low **Self-Esteem**: Risk factor: decreased power over feelings of sadness

Risk for **Spiritual** distress: Risk factors: altered relationships, social isolation

Readiness for enhanced **Hope**: expresses desire to enhance hope and interconnectedness with others

See *Depression (Major Depressive Disorder)*

Postpartum Hemorrhage

Activity intolerance r/t anemia from loss of blood

Death **Anxiety** r/t threat of mortality associated with bleeding

Disturbed **Body Image** r/t loss of ideal childbirth

Insufficient **Breast Milk** r/t fluid volume depletion

Interrupted **Breastfeeding** r/t separation from infant for medical treatment

Decreased **Cardiac** output r/t hypovolemia

Fear r/t threat to self, unknown future

Deficient **Fluid** volume r/t uterine atony, loss of blood

Impaired **Home** maintenance r/t lack of stamina

Deficient **Knowledge** r/t lack of exposure to situation

Acute **Pain** r/t nursing and medical interventions to control bleeding

Ineffective peripheral **Tissue Perfusion** r/t hypovolemia

Risk for **Bleeding**: Risk factor: postpartum complications

Risk for impaired **Childbearing**: Risk factor: postpartum complication

Risk for imbalanced **Fluid** volume: Risk factor: maternal blood loss

Risk for **Infection**: Risk factors: loss of blood, depressed immunity

Risk for impaired **Parenting**: Risk factor: weakened maternal condition

Risk for **Powerlessness**: Risk factor: acute illness

Risk for **Shock**: Risk factor: hypovolemia

Postpartum, Normal Care

Anxiety r/t change in role functioning, parenting

Effective **Breastfeeding** r/t basic breastfeeding knowledge, support of partner and health care provider

Fatigue r/t childbirth, new responsibilities of parenting, body changes

Acute **Pain** r/t episiotomy, lacerations, bruising, breast engorgement, headache, sore nipples, epidural or intravenous site, hemorrhoids

Sexual dysfunction r/t recent childbirth

Impaired **Tissue** integrity r/t episiotomy, lacerations

Sleep deprivation r/t care of infant

Impaired **Urinary** elimination r/t effects of anesthesia, tissue trauma

Risk for **Constipation**: Risk factors: hormonal effects on smooth muscles, fear of straining with defecation, effects of anesthesia

Risk for **Infection**: Risk factors: tissue trauma, blood loss

Readiness for enhanced family **Coping**: adaptation to new family member

Readiness for enhanced **Hope**: desire to increase hope

Readiness for enhanced **Parenting**: expresses willingness to enhance parenting skills

Post-Trauma Syndrome

Post-Trauma syndrome (See **Post-Trauma** syndrome, Section III)

Post-Trauma Syndrome, Risk for

Risk for **Post-Trauma** syndrome (See **Post-Trauma** syndrome, risk for, Section III)

Post-Traumatic Stress Disorder (PTSD)

See *PTSD (Post-Traumatic Stress Disorder)*

Potassium, Increase/Decrease

See *Hyperkalemia; Hypokalemia*

Power/Powerlessness

Powerlessness (See **Powerlessness**, Section III)

Risk for **Powerlessness** (See **Powerlessness**, risk for, Section III)

Readiness for enhanced **Power** (See **Power**, readiness for enhanced, Section III)

Preeclampsia

See *PIH (Pregnancy-Induced Hypertension/Preeclampsia)*

Pregnancy, Cardiac Disorders

See *Cardiac Disorders in Pregnancy*

Pregnancy-Induced Hypertension/ Preeclampsia (PIH)

See *PIH (Pregnancy-Induced Hypertension/Preeclampsia)*

Pregnancy Loss

Anxiety r/t threat to role functioning, health status, situational crisis

Compromised family **Coping** r/t lack of support by significant other because of personal suffering

Ineffective **Coping** r/t situational crisis

Grieving r/t loss of pregnancy, fetus, or child

Acute **Pain** r/t surgical intervention

Ineffective **Role** performance r/t inability to assume parenting role

Ineffective **Sexuality** pattern r/t self-esteem disturbance resulting from pregnancy loss and anxiety about future pregnancies

Chronic **Sorrow** r/t loss of a fetus or child

Spiritual distress r/t intense suffering from loss of child

Risk for deficient **Fluid** volume: Risk factor: blood loss

Risk for complicated **Grieving**: Risk factor: loss of pregnancy

Risk for **Infection**: Risk factor: retained products of conception

Risk for **Powerlessness**: Risk factor: situational crisis

Risk for ineffective **Relationship**: Risk factor: poor communication skills in dealing with the loss

Risk for **Spiritual** distress: Risk factor: intense suffering

Readiness for enhanced **Communication**: willingness to express feelings and thoughts about loss

Readiness for enhanced **Hope**: expresses desire to enhance hope

Readiness for enhanced **Spiritual** well-being: desire for acceptance of loss

Pregnancy, Normal

Anxiety r/t unknown future, threat to self secondary to pain of labor

Disturbed **Body Image** r/t altered body function and appearance

Interrupted **Family** processes r/t developmental transition of pregnancy

Fatigue r/t increased energy demands

Fear r/t labor and delivery

Deficient **Knowledge** r/t primiparity

Nausea r/t hormonal changes of pregnancy

Imbalanced **Nutrition**: less than body requirements r/t growing fetus, nausea

Imbalanced **Nutrition**: more than body requirements r/t deficient knowledge regarding nutritional needs of pregnancy

Sleep deprivation r/t uncomfortable pregnancy state

Impaired **Urinary** elimination r/t frequency caused by increased pelvic pressure and hormonal stimulation

Risk for **Constipation**: Risk factor: pregnancy

Risk for **Sexual** dysfunction: Risk factors: altered body function, self-concept, body image with pregnancy

Readiness for enhanced **Childbearing** process: appropriate prenatal care

Readiness for enhanced family **Coping**: satisfying partner relationship, attention to gratification of needs, effective adaptation to developmental tasks of pregnancy

Readiness for enhanced **Family** processes: family adapts to change

Readiness for enhanced **Health** management: seeks information for prenatal self care

Readiness for enhanced **Nutrition**: desire for knowledge of appropriate nutrition during pregnancy

Readiness for enhanced **Parenting**: expresses willingness to enhance parenting skills

Readiness for enhanced **Relationship**: meeting developmental goals associated with pregnancy

Readiness for enhanced **Spiritual** well-being: new role as parent

See *Discomforts of Pregnancy*

Premature Dilatation of the Cervix (Incompetent Cervix)

Ineffective **Activity** planning r/t unrealistic perception of events

Ineffective **Coping** r/t bed rest, threat to fetus

Deficient **Diversional** activity r/t bed rest

Fear r/t potential loss of infant

Grieving r/t potential loss of infant

Deficient **Knowledge** r/t treatment regimen, prognosis for pregnancy

Impaired physical **Mobility** r/t imposed bed rest to prevent preterm birth

Powerlessness r/t inability to control outcome of pregnancy

Ineffective **Role** performance r/t inability to continue usual patterns of responsibility

Situational low **Self-Esteem** r/t inability to complete normal pregnancy

Sexual dysfunction r/t fear of harm to fetus

Impaired **Social** interaction r/t bed rest

Risk for **Infection**: Risk factor: invasive procedures to prevent preterm birth

Risk for **Injury**: fetal: Risk factors: preterm birth, use of anesthetics

Risk for **Injury**: maternal: Risk factor: surgical procedures to prevent preterm birth (e.g., cerclage)

Risk for impaired **Resilience**: Risk factor: complication of pregnancy

Risk for **Spiritual** distress: Risk factors: physical/psychological stress

Premature Infant (Child)

Insufficient **Breast Milk** r/t ineffective sucking, latching on of the infant

Impaired **Gas** exchange r/t effects of cardiopulmonary insufficiency

Disorganized **Infant** behavior r/t prematurity

Insomnia r/t noisy and noxious intensive care environment

Neonatal **Jaundice** r/t infant experiences difficulty making transition to extrauterine life

Imbalanced **Nutrition**: less than body requirements r/t delayed or understimulated rooting reflex, easy fatigue during feeding, diminished endurance

Impaired **Swallowing** r/t decreased or absent gag reflex, fatigue

Ineffective **Thermoregulation** r/t large body surface/weight ratio, immaturity of thermal regulation, state of prematurity

Risk for delayed **Development**: Risk factor: prematurity

Risk for disproportionate **Growth**: Risk factor: prematurity

Risk for **Infection**: Risk factors: inadequate, immature, or undeveloped acquired immune response

Risk for **Injury**: Risk factor: prolonged mechanical ventilation, retinopathy of prematurity (ROP) secondary to 100% oxygen environment

Risk for neonatal **Jaundice**: Risk factor: late preterm birth

Readiness for enhanced organized **Infant** behavior: use of some self-regulatory measures

Premature Infant (Parent)

Ineffective **Breastfeeding** r/t disrupted establishment of effective pattern secondary to prematurity or insufficient opportunities

Decisional Conflict r/t support system deficit, multiple sources of information

Compromised family **Coping** r/t disrupted family roles and disorganization, prolonged condition exhausting supportive capacity of significant persons

Grieving r/t loss of perfect child possibly leading to complicated grieving

Complicated **Grieving** (prolonged) r/t unresolved conflicts

Parental **Role** conflict r/t expressed concerns, expressed inability to care for child's physical, emotional, or developmental needs

Chronic **Sorrow** r/t threat of loss of a child, prolonged hospitalization

Spiritual distress r/t challenged belief or value systems regarding moral or ethical implications of treatment plans

Risk for impaired **Attachment**: Risk factors: separation, physical barriers, lack of privacy

Risk for disturbed **Maternal–Fetal** dyad: Risk factor: complication of pregnancy

Risk for **Powerlessness**: Risk factor: inability to control situation

Risk for impaired **Resilience**: Risk factor: premature infant

Risk for **Spiritual** distress: Risk factor: challenged belief or value systems regarding moral or ethical implications of treatment plans

Readiness for enhanced **Family** process: adaptation to change associated with premature infant

See *Child with Chronic Condition; Hospitalized Child*

Premature Rupture of Membranes

Anxiety r/t threat to infant's health status

Disturbed **Body Image** r/t inability to carry pregnancy to term

Ineffective **Coping** r/t situational crisis

Grieving r/t potential loss of infant

Situational low **Self-Esteem** r/t inability to carry pregnancy to term

Risk for ineffective **Childbearing** process: Risk factor: complication of pregnancy

Risk for **Infection**: Risk factor: rupture of membranes

Risk for **Injury**: fetal: Risk factor: risk of premature birth

Premenstrual Tension Syndrome (PMS)

See *PMS (Premenstrual Tension Syndrome)*

Prenatal Care, Normal

Readiness for enhanced **Childbearing** process: appropriate prenatal lifestyle

Readiness for enhanced **Knowledge**: appropriate prenatal care

Readiness for enhanced **Spiritual** well-being: new role as parent

See *Pregnancy, Normal*

Prenatal Testing

Anxiety r/t unknown outcome, delayed test results

Acute **Pain** r/t invasive procedures

Risk for **Infection**: Risk factor: invasive procedures during amniocentesis or chorionic villus sampling

Risk for **Injury**: fetal r/t invasive procedures

Preoperative Teaching

See *Surgery, Preoperative Care*

Pressure Ulcer

Impaired bed **Mobility** r/t intolerance to activity, pain, cognitive impairment, depression, severe anxiety, severity of illness

Imbalanced **Nutrition**: less than body requirements r/t limited access to food, inability to absorb nutrients because of biological factors, anorexia

Acute **Pain** r/t tissue destruction, exposure of nerves

Impaired **Skin** integrity: stage I or II pressure ulcer r/t physical immobility, mechanical factors, altered circulation, skin irritants, excessive moisture

Impaired **Tissue** integrity: stage III or IV pressure ulcer r/t altered circulation, impaired physical mobility, excessive moisture

Risk for **Infection**: Risk factors: physical immobility, mechanical factors (shearing forces, pressure, restraint, altered circulation, skin irritants, excessive moisture, open wound)

Risk for **Pressure ulcer** (See **Pressure ulcer, risk for**, Section III)

Preterm Labor

Anxiety r/t threat to fetus, change in role functioning, change in environment and interaction patterns, use of tocolytic drugs

Ineffective **Coping** r/t situational crisis, preterm labor

Deficient **Diversional** activity r/t long-term hospitalization

Grieving r/t loss of idealized pregnancy, potential loss of fetus

Impaired **Home** maintenance r/t medical restrictions

Impaired physical **Mobility** r/t medically imposed restrictions

Ineffective **Role** performance r/t inability to carry out normal roles secondary to bed rest or hospitalization, change in expected course of pregnancy

Situational low **Self-Esteem** r/t threatened ability to carry pregnancy to term

Sexual dysfunction r/t actual or perceived limitation imposed by preterm labor and/or prescribed treatment, separation from partner because of hospitalization

Sleep deprivation r/t change in usual pattern secondary to contractions, hospitalization, treatment regimen

Impaired **Social** interaction r/t prolonged bed rest or hospitalization

Risk for **Injury**: fetal: Risk factors: premature birth, immature body systems

Risk for **Injury**: maternal: Risk factor: use of tocolytic drugs

Risk for **Powerlessness**: Risk factor: lack of control over preterm labor

Risk for **Vascular Trauma**: Risk factor: intravenous medication

Readiness for enhanced **Childbearing** process: appropriate prenatal lifestyle

Readiness for enhanced **Comfort**: expresses desire to enhance relaxation

Readiness for enhanced **Communication**: willingness to discuss thoughts and feelings about situation

Problem-Solving Dysfunction

Defensive **Coping** r/t situational crisis

Impaired Emancipated **Decision-Making** r/t problem solving dysfunction

Risk for chronic low **Self-Esteem**: Risk factor: repeated failures

Readiness for enhanced **Communication**: willing to share ideas with others

Readiness for enhanced **Relationship**: shares information and ideas between partners

Readiness for enhanced **Resilience**: identifies available resources

Readiness for enhanced **Spiritual** well-being: desires to draw on inner strength and find meaning and purpose to life

Projection

Anxiety r/t threat to self-concept

Defensive **Coping** r/t inability to acknowledge that own behavior may be a problem, blaming others

Chronic low **Self-Esteem** r/t failure

Impaired **Social** interaction r/t self-concept disturbance, confrontational communication style

Risk for **Loneliness**: Risk factor: blaming others for problems

See *Paranoid Personality Disorder*

Prolapsed Umbilical Cord

Fear r/t threat to fetus, impending surgery

Ineffective peripheral **Tissue Perfusion**: fetal r/t interruption in umbilical blood flow

Risk for ineffective **Cerebral** tissue perfusion: fetal: Risk factor: cord compression

Risk for **Injury**: maternal: Risk factor: emergency surgery

Prostatectomy

See *TURP (Transurethral Resection of the Prostate)*

Prostatic Hypertrophy

Ineffective **Health** maintenance r/t deficient knowledge regarding self-care and prevention of complications

Sleep deprivation r/t nocturia

Urinary Retention r/t obstruction

Risk for **Infection**: Risk factors: urinary residual after voiding, bacterial invasion of bladder

See *BPH (Benign Prostatic Hypertrophy)*

Prostatitis

Impaired **Comfort** r/t inflammation

Ineffective **Health** maintenance r/t deficient knowledge regarding treatment

Urge urinary **Incontinence** r/t irritation of bladder

Ineffective **Protection** r/t depressed immune system

Pruritus

Impaired **Comfort** r/t itching

Deficient **Knowledge** r/t methods to treat and prevent itching

Risk for impaired **Skin** integrity: Risk factor: scratching from pruritus

Psoriasis

Disturbed **Body Image** r/t lesions on body

Impaired **Comfort** r/t irritated skin

Ineffective **Health** maintenance r/t deficient knowledge regarding treatment modalities

Powerlessness r/t lack of control over condition with frequent exacerbations and remissions

Impaired **Skin** integrity r/t lesions on body

Psychosis

Ineffective **Activity** planning r/t compromised ability to process information

Ineffective **Health** maintenance r/t cognitive impairment, ineffective individual and family coping

Self-Neglect r/t mental disorder

Impaired individual **Resilience** r/t psychological disorder

Situational low **Self-Esteem** r/t excessive use of defense mechanisms (e.g., projection, denial, rationalization)

Risk for disturbed personal **Identity**: Risk factor: psychosis

Impaired **Mood** regulation r/t psychosis

Risk for **Post-Trauma** syndrome: Risk factor: diminished ego strength

See *Schizophrenia*

PTCA (Percutaneous Transluminal Coronary Angioplasty)

See *Angioplasty, Coronary*

PTSD (Posttraumatic Stress Disorder)

Anxiety r/t exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event

Chronic **Sorrow** r/t chronic disability (e.g., physical, mental)

Death **Anxiety** r/t psychological stress associated with traumatic event

Ineffective **Breathing** pattern r/t hyperventilation associated with anxiety

Ineffective **Coping** r/t extreme anxiety

Ineffective **Impulse** control r/t thinking of initial trauma experience

Insomnia r/t recurring nightmares

Post-Trauma syndrome r/t exposure to a traumatic event

Sleep deprivation r/t nightmares interrupting sleep associated with traumatic event

Spiritual distress r/t feelings of detachment or estrangement from others

Risk for impaired **Resilience**: Risk factor: chronicity of existing crisis

Risk for **Powerlessness**: Risk factors: flashbacks, reliving event

Risk for ineffective **Relationship**: Risk factor: stressful life events

Risk for self- or other-directed **Violence**: Risk factors: fear of self or others

Readiness for enhanced **Comfort**: expresses desire to enhance relaxation

Readiness for enhanced **Communication**: willingness to express feelings and thoughts

Readiness for enhanced **Spiritual** well-being: desire for harmony after stressful event

Pulmonary Edema

Anxiety r/t fear of suffocation

Ineffective **Airway** clearance r/t presence of tracheobronchial secretions

Decreased **Cardiac** output r/t increased preload, ineffective forward perfusion

Impaired **Gas** exchange r/t extravasation of extravascular fluid in lung tissues and alveoli

Ineffective **Health** maintenance r/t deficient knowledge regarding treatment regimen

Sleep deprivation r/t inability to breathe

Risk for acute **Confusion**: Risk factor: hypoxia

See *Heart Failure*

Pulmonary Embolism

Anxiety r/t fear of suffocation

Decreased **Cardiac** output r/t right ventricular failure secondary to obstructed pulmonary artery

Fear r/t severe pain, possible death

Impaired **Gas** exchange r/t altered blood flow to alveoli secondary to embolus

Deficient **Knowledge** r/t activities to prevent embolism, self-care after diagnosis of embolism

Acute **Pain** r/t biological injury, lack of oxygen to cells

Ineffective peripheral **Tissue Perfusion** r/t deep vein thrombus formation

See *Anticoagulant Therapy*

Pulmonary Stenosis

See *Congenital Heart Disease/Cardiac Anomalies*

Pulse Deficit

Risk for Decreased **Cardiac** output r/t dysrhythmia

See *Dysrhythmia*

Pulse Oximetry

Readiness for enhanced **Knowledge**: information about treatment regimen

See *Hypoxia*

Pulse Pressure, Increased

See *Intracranial Pressure, Increased*

Pulse Pressure, Narrowed

See *Shock, Hypovolemic*

Pulses, Absent or Diminished Peripheral

Ineffective peripheral **Tissue Perfusion** r/t interruption of arterial flow

Risk for **Peripheral Neurovascular** dysfunction: Risk factors: fractures, mechanical compression, orthopedic surgery trauma, immobilization, burns, vascular obstruction

Purpura

See *Clotting Disorder*

Pyelonephritis

Ineffective **Health** maintenance r/t deficient knowledge regarding self-care, treatment of disease, prevention of further urinary tract infections

Acute **Pain** r/t inflammation and irritation of urinary tract

Disturbed **Sleep** pattern r/t urinary frequency

Impaired **Urinary** elimination r/t irritation of urinary tract

Risk for ineffective **Renal** perfusion: Risk factor: infection

Pyloric Stenosis

Imbalanced **Nutrition**: less than body requirements r/t vomiting secondary to pyloric sphincter obstruction

Acute **Pain** r/t abdominal fullness

Risk for decreased **Fluid** volume: Risk factors: vomiting, dehydration

See *Hospitalized Child*

Pyloromyotomy (Pyloric Stenosis Repair)

See *Surgery Preoperative, Perioperative, Postoperative*

R

RA (Rheumatoid Arthritis)

See *Rheumatoid Arthritis (RA)*

Rabies

Ineffective **Health** maintenance r/t deficient knowledge regarding care of wound, isolation, and observation of infected animal

Acute **Pain** r/t multiple immunization injections

Risk for ineffective **Cerebral** tissue perfusion: Risk factor: rabies virus

Radial Nerve Dysfunction

Acute **Pain** r/t trauma to hand or arm

See *Neuropathy, Peripheral*

Radiation Therapy

Activity intolerance r/t fatigue from possible anemia

Disturbed **Body Image** r/t change in appearance, hair loss

Diarrhea r/t irradiation effects

Fatigue r/t malnutrition from lack of appetite, nausea, and vomiting; side effect of radiation

Deficient **Knowledge** r/t what to expect with radiation therapy, how to do self-care

Nausea r/t side effects of radiation

Imbalanced **Nutrition**: less than body requirements r/t anorexia, nausea, vomiting, irradiation of areas of pharynx and esophagus

Impaired **Oral Mucous Membrane** r/t irradiation effects

Ineffective **Protection** r/t suppression of bone marrow

Risk for impaired **Oral Mucous Membranes**: Risk factor: Radiation treatments

Risk for **Powerlessness**: Risk factors: medical treatment and possible side effects

Risk for impaired **Resilience**: Risk factor: radiation treatment

Risk for impaired **Skin** integrity: Risk factor: irradiation effects

Risk for **Spiritual** distress: Risk factors: radiation treatment, prognosis

Radical Neck Dissection

See *Laryngectomy*

Rage

Risk-prone **Health** behavior r/t multiple stressors

Labile Emotional Control r/t psychiatric disorders and mood disorders

Impaired individual **Resilience** r/t poor impulse control

Stress overload r/t multiple coexisting stressors

Risk for **Self-Mutilation**: Risk factor: command hallucinations

Risk for **Suicide**: Risk factor: desire to kill self

Risk for other-directed **Violence**: Risk factors: panic state, manic excitement, organic brain syndrome

Rape-Trauma Syndrome

Rape-Trauma syndrome (See *Rape-Trauma syndrome, Section III*)

Chronic **Sorrow** r/t forced loss of virginity

Risk for ineffective **Childbearing** process r/t to trauma and violence

Risk for **Post-Trauma** syndrome: Risk factor: trauma or violence associated with rape

Risk for **Powerlessness**: Risk factor: inability to control thoughts about incident

Risk for ineffective **Relationship** r/t to trauma and violence

Risk for chronic low **Self-Esteem** r/t perceived lack of respect from others/feeling violated

Risk for **Spiritual** distress: Risk factor: forced loss of virginity

Rash

Impaired **Comfort** r/t pruritus

Impaired **Skin** integrity r/t mechanical trauma

Risk for **Infection**: Risk factors: traumatized tissue, broken skin

Risk for **Latex Allergy** response: Risk factor: allergy to products associated with latex

Rationalization

Defensive **Coping** r/t situational crisis, inability to accept blame for consequences of own behavior

Ineffective **Denial** r/t fear of consequences, actual or perceived loss

Impaired individual **Resilience** r/t psychological disturbance

Risk for **Post-Trauma** syndrome: Risk factor: survivor's role in event

Readiness for enhanced **Communication**: expresses desire to share thoughts and feelings

Readiness for enhanced **Spiritual** well-being: possibility of seeking harmony with self, others, higher power, God

Rats, Rodents in Home

Impaired **Home** maintenance r/t lack of knowledge, insufficient finances

List of Nursing Assessments by Letter: R

RA (Rheumatoid Arthritis)	Rabies	Radial Nerve Dysfunction
Radiation Therapy	Radical Neck Dissection	Rage
Rape-Trauma Syndrome	Rash	Rationalization
Rats, Rodents in Home	Raynaud's Disease	RDS (Respiratory Distress Syndrome)
Rectal Fullness	Rectal Lump	Rectal Pain/Bleeding
Rectal Surgery	Rectocele Repair	Reflex Incontinence
Regression	Regretful	Rehabilitation
Relationship	Relaxation Techniques	Religiosity
Religious Concerns	Relocation Stress Syndrome	Respiratory Acidosis
Respiratory Conditions of the Neonate (Respiratory Distress Syndrome [RDS], Meconium Aspiration, Diaphragmatic Hernia)	Respiratory Distress	Respiratory Distress Syndrome (RDS)
Respiratory Infections, Acute Childhood (Croup, Epiglottitis, Pertussis, Pneumonia, Respiratory Syncytial Virus)	Respiratory Syncytial Virus	Restless Leg Syndrome
Retarded Growth and Development	Retching	Retinal Detachment
Retinopathy, Diabetic	Retinopathy of Prematurity (ROP)	Rh Factor Incompatibility
Rhabdomyolysis	Rheumatic Fever	Rheumatoid Arthritis (RA)
Rib Fracture	Ridicule of Others	Ringworm of Body
Ringworm of Nails	Ringworm of Scalp	Roaches, Invasion of Home with
Role Performance, Altered	ROP (Retinopathy of Prematurity)	RSV (Respiratory Syncytial Virus)
Rubella	Rubor of Extremities	Ruptured Disk

Risk for **Allergy** response r/t repeated exposure to environmental contamination

See *Filthy Home Environment*

Raynaud's Disease

Deficient **Knowledge** r/t lack of information about disease process, possible complications, self-care needs regarding disease process and medication

Ineffective peripheral **Tissue Perfusion** r/t transient reduction of blood flow

Acute **Pain** r/t transient reduction in blood flow

RDS (Respiratory Distress Syndrome)

See *Respiratory Conditions of the Neonate*

Rectal Fullness

Chronic functional **Constipation** r/t decreased activity level, decreased fluid intake, inadequate fiber in diet, decreased peristalsis, side effects of antidepressant or antipsychotic therapy

Risk for chronic functional **Constipation**: Risk factor: habitual denial of or ignoring urge to defecate

Rectal Lump

See *Hemorrhoids*

Rectal Pain/Bleeding

Chronic functional **Constipation** r/t pain on defecation

Deficient **Knowledge** r/t possible causes of rectal bleeding, pain, treatment modalities

Acute **Pain** r/t pressure of defecation

Risk for **Bleeding**: Risk factor: rectal disease

Rectal Surgery

See *Hemorrhoidectomy*

Rectocele Repair

Chronic functional **Constipation** r/t painful defecation

Ineffective **Health** maintenance r/t deficient knowledge of post-operative care of surgical site, dietary measures, exercise to prevent constipation

Acute **Pain** r/t surgical procedure

Urinary retention r/t edema from surgery

Risk for **Bleeding**: Risk factor: surgery

Risk for **Infection**: Risk factors: surgical procedure, possible contamination of area with feces

Reflex Incontinence

Reflex urinary **Incontinence** (See **Incontinence**, urinary, reflex, Section III)

Regression

Anxiety r/t threat to or change in health status

Defensive **Coping** r/t denial of obvious problems, weaknesses

Self-Neglect r/t functional impairment

Powerlessness r/t health care environment

Impaired individual **Resilience** r/t psychological disturbance

Ineffective **Role** performance r/t powerlessness over health status

See *Hospitalized Child; Separation Anxiety*

Regretful

Anxiety r/t situational or maturational crises

Death **Anxiety** r/t feelings of not having accomplished goals in life

Risk for **Spiritual** distress: Risk factor: inability to forgive

Rehabilitation

Ineffective **Coping** r/t loss of normal function

Impaired physical **Mobility** r/t injury, surgery, psychosocial condition warranting rehabilitation

Self-Care deficit: specify r/t impaired physical mobility

Risk for **Falls**: Risk factor: physical deconditioning

Readiness for enhanced **Comfort**: expresses desire to enhance feeling of comfort

Readiness for enhanced **Self-Concept**: accepts strengths and limitations

Readiness for enhanced **Health Management**: expresses desire to manage rehabilitation

Relationship

Ineffective **Relationship** (See **ineffective Relationship**, Section III)

Readiness for enhanced **Relationship** (See **Risk for enhanced Relationship** see Section III)

Relaxation Techniques

Anxiety r/t situational crisis

Readiness for enhanced **Comfort**: expresses desire to enhance relaxation

Readiness for enhanced **Health** management: desire to manage illness

Readiness for enhanced **Religiosity**: requests religious materials or experiences

Readiness for enhanced **Resilience**: desire to enhance resilience

Readiness for enhanced **Self-Concept**: willingness to enhance self-concept

Readiness for enhanced **Spiritual** well-being: seeking comfort from higher power

Religiosity

Impaired **Religiosity** (See **Religiosity, impaired**, Section III)

Risk for impaired **Religiosity** (See **Religiosity, impaired**, risk for, Section III)

Readiness for enhanced **Religiosity** (See **Religiosity, readiness for enhanced**, Section III)

Religious Concerns

Spiritual distress r/t separation from religious or cultural ties

Risk for impaired **Religiosity**: Risk factors: ineffective support, coping, caregiving

Risk for **Spiritual** distress: Risk factors: physical or psychological stress

Readiness for enhanced **Spiritual** well-being: desire for increased spirituality

Relocation Stress Syndrome

Relocation stress syndrome (See [Relocation stress syndrome, Section III](#))

Risk for **Relocation** stress syndrome (See [Relocation stress syndrome, risk for, Section III](#))

Respiratory Acidosis

See [Acidosis, Respiratory](#)

Respiratory Conditions of the Neonate (Respiratory Distress Syndrome [RDS], Meconium Aspiration, Diaphragmatic Hernia)

Ineffective **Airway** clearance r/t sequelae of attempts to breathe in utero resulting in meconium aspiration

Fatigue r/t increased energy requirements and metabolic demands

Impaired **Gas** exchange r/t decreased surfactant, immature lung tissue

Dysfunctional **Ventilator** weaning response r/t immature respiratory system

Risk for **Infection**: Risk factors: tissue destruction or irritation as a result of aspiration of meconium fluid

See [Bronchopulmonary Dysplasia](#); [Hospitalized Child](#); [Premature Infant, Child](#)

Respiratory Distress

See [Dyspnea](#)

Respiratory Distress Syndrome (RDS)

See [Respiratory Conditions of the Neonate](#)

Respiratory Infections, Acute Childhood (Croup, Epiglottitis, Pertussis, Pneumonia, Respiratory Syncytial Virus)

Activity intolerance r/t generalized weakness, dyspnea, fatigue, poor oxygenation

Ineffective **Airway** clearance r/t excess tracheobronchial secretions

Ineffective **Breathing** pattern r/t inflamed bronchial passages, coughing

Fear r/t oxygen deprivation, difficulty breathing

Deficient **Fluid** volume r/t insensible losses (fever, diaphoresis), inadequate oral fluid intake

Impaired **Gas** exchange r/t insufficient oxygenation as a result of inflammation or edema of epiglottis, larynx, bronchial passages

Imbalanced **Nutrition**: less than body requirements r/t anorexia, fatigue, generalized weakness, poor sucking and breathing coordination, dyspnea

Ineffective **Thermoregulation** r/t infectious process

Risk for **Aspiration**: Risk factors: inability to coordinate breathing, coughing, sucking

Risk for **Infection**: transmission to others: Risk factor: virulent infectious organisms

Risk for **Injury** (to pregnant others): Risk factors: exposure to aerosolized medications (e.g., ribavirin, pentamidine), resultant potential fetal toxicity

Risk for **Suffocation**: Risk factors: inflammation of larynx, epiglottis

See [Hospitalized Child](#)

Respiratory Syncytial Virus

See [Respiratory Infections, Acute Childhood](#)

Restless Leg Syndrome

Disturbed **Sleep** pattern r/t leg discomfort during sleep relieved by frequent leg movement

Chronic **Pain** r/t leg discomfort

See [Stress](#)

Retarded Growth and Development

See [Growth and Development Lag](#)

Retching

Nausea r/t chemotherapy, postsurgical anesthesia, irritation to gastrointestinal system, stimulation of neuropharmacological mechanisms

Imbalanced **Nutrition**: less than body requirements r/t inability to ingest food

Risk for **Fatigue**: Risk factor: stress of retching, muscle contractions

Retinal Detachment

Anxiety r/t change in vision, threat of loss of vision

Deficient **Knowledge** r/t symptoms, need for early intervention to prevent permanent damage

Vision Loss r/t impaired visual acuity

Risk for impaired **Home** maintenance: Risk factors: postoperative care, activity limitations, care of affected eye

Risk for impaired **Resilience**: Risk factor: possible loss of vision

See [Vision Impairment](#)

Retinopathy, Diabetic

See [Diabetic Retinopathy](#)

Retinopathy of Prematurity (ROP)

Risk for **Injury**: Risk factors: prolonged mechanical ventilation, ROP secondary to 100% oxygen environment

See [Retinal Detachment](#)

Rh Factor Incompatibility

Anxiety r/t unknown outcome of pregnancy

Neonatal **Jaundice** r/t Rh factor incompatibility

Deficient **Knowledge** r/t treatment regimen from lack of experience with situation

Powerlessness r/t perceived lack of control over outcome of pregnancy

Risk for **Injury: fetal:** Risk factors: intrauterine destruction of red blood cells, transfusions

Risk for neonatal **Jaundice** r/t Rh factor incompatibility

Readiness for enhanced **Health** management: prenatal care, compliance with diagnostic and treatment regimen

Rhabdomyolysis

Ineffective **Coping** r/t seriousness of condition

Impaired physical **Mobility** r/t myalgia and muscle weakness

Risk for deficient **Fluid** volume: Risk factor: reduced blood flow to kidneys

Risk for ineffective **Renal** perfusion: Risk factor: possible kidney failure from obstruction of kidney

Risk for **Shock:** Risk factor: hypovolemia

Readiness for enhanced **Health** management: seeks information to avoid condition

See *Kidney Failure*

Rheumatic Fever

See *Endocarditis*

Rheumatoid Arthritis (RA)

Imbalanced **Nutrition:** less than body requirements r/t loss of appetite

Chronic **Pain** r/t joint inflammation

Risk for impaired **Resilience:** Risk factor: chronic, painful, progressive disease

See *Arthritis; JRA (Juvenile Rheumatoid Arthritis)*

Rib Fracture

Ineffective **Breathing** pattern r/t fractured ribs

Acute **Pain** r/t movement, deep breathing

Impaired **Gas** exchange r/t ventilation-perfusion imbalance, decreased depth of ventilation

Ridicule of Others

Defensive **Coping** r/t situational crisis, psychological impairment, substance abuse

Risk for **Post-Trauma** syndrome: Risk factor: perception of event

Ringworm of Body

Impaired **Comfort** r/t pruritus

Impaired **Skin** integrity r/t presence of macules associated with fungus

See *Itching; Pruritus*

Ringworm of Nails

Disturbed **Body Image** r/t appearance of nails, removed nails

Ringworm of Scalp

Disturbed **Body Image** r/t possible hair loss (alopecia)

See *Itching; Pruritus*

Roaches, Invasion of Home with

Impaired **Home** maintenance r/t lack of knowledge, insufficient finances

See *Filthy Home Environment*

Role Performance, Altered

Ineffective **Role** performance (See **Role** performance, ineffective, Section III)

ROP (Retinopathy of Prematurity)

See *Retinopathy of Prematurity (ROP)*

RSV (Respiratory Syncytial Virus)

See *Respiratory Infection, Acute Childhood*

Rubella

See *Communicable Diseases, Childhood*

Rubor of Extremities

Ineffective peripheral **Tissue Perfusion** r/t interruption of arterial flow

See *Peripheral Vascular Disease (PVD)*

Ruptured Disk

See *Low Back Pain*

S

SAD (Seasonal Affective Disorder)

Readiness for enhanced **Resilience:** uses SAD lights during winter months

See *Depression (Major Depressive Disorder)*

Sadness

Complicated **Grieving** r/t actual or perceived loss

Impaired **Mood** regulation r/t chronic illness (See **Mood** regulation, impaired, Section III)

Spiritual distress r/t intense suffering

Risk for **Powerlessness:** Risk factor: actual or perceived loss

Risk for **Spiritual** distress: Risk factor: loss of loved one

Readiness for enhanced **Communication:** willingness to share feelings and thoughts

Readiness for enhanced **Spiritual** well-being: desire for harmony after actual or perceived loss

See *Depression (Major Depressive Disorder); Major Depressive Disorder*

Safe Sex

Readiness for enhanced **Health** management: takes appropriate precautions during sexual activity to keep from contracting sexually transmitted disease

See *Sexuality, Adolescent; STD (Sexually Transmitted Disease)*

Safety, Childhood

Deficient **Knowledge:** potential for enhanced health maintenance r/t parental knowledge and skill acquisition regarding appropriate safety measures

List of Nursing Assessments by Letter: S

SAD (Seasonal Affective Disorder)	Sadness	Safe Sex
Safety, Childhood	Salmonella	Salpingectomy
Sarcoidosis	SARS (Severe Acute Respiratory Syndrome)	SBE (Self-Breast Examination)
Scabies	Scared	Schizophrenia
Sciatica	Scoliosis	Sedentary Lifestyle
Seizure Disorders, Adult	Seizure Disorders, Childhood (Epilepsy, Febrile Seizures, Infantile Spasms)	Self-Breast Examination (SBE)
Self-Care	Self-Care Deficit, Bathing	Self-Care Deficit, Dressing
Self-Care Deficit, Feeding	Self-Care Deficit, Toileting	Self-Concept
Self-Destructive Behavior	Self-Esteem, Chronic Low	Self-Esteem, Situational Low
Self-Mutilation	Senile Dementia	Separation Anxiety
Sepsis, Child	Septicemia	Severe Acute Respiratory Syndrome (SARS)
Sexual Dysfunction	Sexuality, Adolescent	Sexuality Pattern, Ineffective
Sexually Transmitted Disease (STD)	Shaken Baby Syndrome	Shakiness
Shame	Shingles	Shivering
Shock, Cardiogenic	Shock, Hypovolemic	Shock, Septic
Shoulder Repair	Sickle Cell Anemia/Crisis	SIDS (Sudden Infant Death Syndrome)
Sitting Problems	Situational Crisis	SJS (Stevens-Johnson Syndrome)
Skin Cancer	Skin Disorders	Skin Turgor, Change in Elasticity
Sleep	Sleep Apnea	Sleep Deprivation
Sleep Problems	Sleep Pattern, Disturbed, Parent/Child	Slurring of Speech
Small Bowel Resection	Smell, Loss of Ability to	Smoke Inhalation
Smoking Behavior	Social Interaction, Impaired	Social Isolation
Sociopathic Personality	Sodium, Decrease/Increase	Somatization Disorder

Sore Nipples, Breastfeeding	Sore Throat	Sorrow
Spastic Colon	Speech Disorders	Spina Bifida
Spinal Cord Injury	Spinal Fusion	Spiritual Distress
Spiritual Well-Being	Splenectomy	Sprains
Standing Problems	Stapedectomy	Stasis Ulcer
STD (Sexually Transmitted Disease)	STEMI (ST-Elevation Myocardial Infarction)	Stent (Coronary Artery Stent)
Sterilization Surgery	Stertorous Respirations	Stevens-Johnson Syndrome (SJS)
Stillbirth	Stoma	Stomatitis
Stone, Kidney	Stool, Hard/Dry	Straining with Defecation
Strep Throat	Stress	Stress Urinary Incontinence
Stridor	Stroke	Stuttering
Subarachnoid Hemorrhage	Substance Abuse	Substance Abuse, Adolescent
Substance Abuse in Pregnancy	Sucking Reflex	Sudden Infant Death Syndrome (SIDS)
Suffocation, Risk for	Suicide Attempt	Support System, Inadequate
Suppression of Labor	Surgery, Perioperative Care	Surgery, Postoperative Care
Surgery, Preoperative Care	Surgical Recovery, Delayed	Suspected Child Abuse and Neglect (SCAN), Child
Suspected Child Abuse and Neglect (SCAN), Parent	Suspicion	Swallowing Difficulties
Swine Flu (H1N1)	Syncope	Syphilis
Systemic Lupus Erythematosus		

Risk for **Aspiration** (See **Aspiration, risk for, Section III**)

Risk for **Injury**: Risk factors: developmental age, altered home maintenance

Risk for impaired **Parenting**: Risk factors: lack of available and effective role model, lack of knowledge, misinformation from other family members (old wives' tales)

Risk for **Poisoning**: Risk factors: use of lead-based paint; presence of asbestos or radon gas; drugs not locked in cabinet; household products left in accessible area (bleach, detergent, drain cleaners, household cleaners); alcohol and perfume within reach of child; presence of poisonous plants; atmospheric pollutants

Risk for **Thermal injury**: Risk factor: inadequate supervision

Readiness for enhanced **Childbearing process**: expresses appropriate knowledge for care of child

Salmonella

Impaired **Home maintenance** r/t improper preparation or storage of food, lack of safety measures when caring for pet reptile

Risk for **Shock**: Risk factors: hypovolemia, diarrhea, sepsis

Readiness for enhanced **Health management**: avoiding improperly prepared or stored food, wearing gloves when handling pet reptiles or their feces

See *Gastroenteritis; Gastroenteritis, Child*

Salpingectomy

Decisional Conflict r/t sterilization procedure

Grieving r/t possible loss from tubal pregnancy

Risk for impaired **Urinary elimination**: Risk factor: trauma to ureter during surgery

See *Hysterectomy; Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care*

Sarcoidosis

Anxiety r/t change in health status

Impaired **Gas exchange** r/t ventilation-perfusion imbalance

Ineffective **Health maintenance** r/t deficient knowledge regarding home care and medication regimen

Acute **Pain** r/t possible disease affecting joints

Ineffective **Protection** r/t immune disorder

Risk for decreased **Cardiac tissue perfusion**: Risk factor: dysrhythmias

Risk for impaired **Skin integrity**: Risk factor: immunological disorder

SARS (Severe Acute Respiratory Syndrome)

Risk for **Infection**: Risk factor: increased environmental exposure (travelers in close proximity to infected persons, traveling when a fever is present)

Readiness for enhanced **Knowledge**: information regarding travel and precautions to avoid exposure to SARS

See *Pneumonia*

SBE (Self-Breast Examination)

Readiness for enhanced **Health management**: desires to have information about SBE

Readiness for enhanced **Knowledge**: self-breast examination

Scabies

See *Communicable Diseases, Childhood*

Scared

Anxiety r/t threat of death, threat to or change in health status

Death Anxiety r/t unresolved issues surrounding end-of-life decisions

Fear r/t hospitalization, real or imagined threat to own well-being

Impaired individual **Resilience** r/t violence

Readiness for enhanced **Communication**: willingness to share thoughts and feelings

Schizophrenia

Ineffective **Activity planning** r/t compromised ability to process information

Anxiety r/t unconscious conflict with reality

Impaired verbal **Communication** r/t psychosis, disorientation, inaccurate perception, hallucinations, delusions

Ineffective **Coping** r/t inadequate support systems, unrealistic perceptions, inadequate coping skills, disturbed thought processes, impaired communication

Deficient **Diversional activity** r/t social isolation, possible regression

Interrupted **Family processes** r/t inability to express feelings, impaired communication

Fear r/t altered contact with reality

Ineffective **Health maintenance** r/t cognitive impairment, ineffective individual and family coping, lack of material resources

Ineffective family **Health management** r/t chronicity and unpredictability of condition

Impaired **Home maintenance** r/t impaired cognitive or emotional functioning, insufficient finances, inadequate support systems

Hopelessness r/t long-term stress from chronic mental illness

Disturbed personal **Identity** r/t psychiatric disorder

Impaired **Memory** r/t psychosocial condition

Imbalanced **Nutrition**: less than body requirements r/t fear of eating, lack of awareness of hunger, disinterest toward food

Impaired individual **Resilience** r/t psychological disorder

Self-Care deficit: specify r/t loss of contact with reality, impairment of perception

Self-Neglect r/t psychosis

Sleep deprivation r/t intrusive thoughts, nightmares

Impaired **Social interaction** r/t impaired communication patterns, self-concept disturbance, disturbed thought processes

Social isolation r/t lack of trust, regression, delusional thinking, repressed fears

Chronic **Sorrow** r/t chronic mental illness

Spiritual distress r/t loneliness, social alienation

Risk for **Caregiver Role Strain**: Risk factors: bizarre behavior of client, chronicity of condition

Risk for compromised **Human Dignity**: Risk factor: stigmatizing label

Risk for **Loneliness**: Risk factor: inability to interact socially

Risk for **Post-Trauma** syndrome: Risk factor: diminished ego strength

Risk for **Powerlessness**: Risk factor: intrusive, distorted thinking

Risk for impaired **Religiosity**: Risk factors: ineffective coping, lack of security

Risk for **Suicide**: Risk factor: psychiatric illness

Risk for self-directed **Violence**: Risk factors: lack of trust, panic, hallucinations, delusional thinking

Risk for other-directed **Violence**: Risk factor: psychotic disorder

Readiness for enhanced **Hope**: expresses desire to enhance interconnectedness with others and problem-solve to meet goals

Readiness for enhanced **Power**: expresses willingness to enhance participation in choices for daily living and health and enhance knowledge for participation in change

Sciatica

See *Neuropathy, Peripheral*

Scoliosis

Risk-prone **Health** behavior r/t lack of developmental maturity to comprehend long-term consequences of noncompliance with treatment procedures

Disturbed **Body Image** r/t use of therapeutic braces, postsurgery scars, restricted physical activity

Impaired **Comfort** r/t altered health status and body image

Impaired **Gas** exchange r/t restricted lung expansion as a result of severe presurgery curvature of spine, immobilization

Ineffective **Health** maintenance r/t deficient knowledge regarding treatment modalities, restrictions, home care, postoperative activities

Impaired physical **Mobility** r/t restricted movement, dyspnea caused by severe curvature of spine

Acute **Pain** r/t musculoskeletal restrictions, surgery, reambulation with cast or spinal rod

Impaired **Skin** integrity r/t braces, casts, surgical correction

Chronic **Sorrow** r/t chronic disability

Risk for **Infection**: Risk factor: surgical incision

Risk for **Perioperative Positioning** injury: Risk factor: prone position

Risk for impaired **Resilience**: Risk factor: chronic condition

Readiness for enhanced **Health** management: desires knowledge regarding treatment for condition

See *Hospitalized Child; Maturational Issues, Adolescent*

Sedentary Lifestyle

Activity intolerance r/t sedentary lifestyle

Sedentary lifestyle (See [Sedentary lifestyle, Section III](#))

Obesity (See [Obesity, Section III](#))

Overweight (See [Overweight, Section III](#))

Risk for **Overweight** (See [Overweight, Section III](#))

Risk for ineffective peripheral **Tissue Perfusion**: Risk factor: insufficient knowledge of aggravating factors (e.g., immobility, obesity)

Readiness for enhanced **Coping**: seeking knowledge of new strategies to adjust to sedentary lifestyle

Seizure Disorders, Adult

Acute **Confusion** r/t postseizure state

Social isolation r/t unpredictability of seizures, community-imposed stigma

Risk for ineffective **Airway** clearance: Risk factor: accumulation of secretions during seizure

Risk for **Falls**: Risk factor: uncontrolled seizure activity

Risk for **Powerlessness**: Risk factor: possible seizure

Risk for impaired **Resilience**: Risk factor: chronic illness

Readiness for enhanced **Knowledge**: anticonvulsive therapy

Readiness for enhanced **Self-Care**: expresses desire to enhance knowledge and responsibility for self-care

See *Epilepsy*

Seizure Disorders, Childhood (Epilepsy, Febrile Seizures, Infantile Spasms)

Ineffective **Health** maintenance r/t lack of knowledge regarding anticonvulsive therapy, fever reduction (febrile seizures)

Social isolation r/t unpredictability of seizures, community-imposed stigma

Risk for ineffective **Airway** clearance: Risk factor: accumulation of secretions during seizure

Risk for delayed **Development**: Risk factors: effects of seizure disorder, parental overprotection

Risk for disproportionate **Growth**: Risk factors: congenital disorder, malnutrition

Risk for **Falls**: Risk factor: possible seizure

Risk for **Injury**: Risk factors: uncontrolled movements during seizure, falls, drowsiness caused by anticonvulsants

See *Epilepsy*

Self-Breast Examination (SBE)

See *SBE (Self-Breast Examination)*

Self-Care

Readiness for enhanced **Self-Care** (See [Self-Care, readiness for enhanced, Section III](#))

Self-Care Deficit, Bathing

Bathing **Self-Care** deficit (See [Self-Care deficit, bathing, Section III](#))

Self-Care Deficit, Dressing

Dressing **Self-Care** deficit (See **Self-Care** deficit, dressing, Section III)

Self-Care Deficit, Feeding

Feeding **Self-Care** deficit (See **Self-Care** deficit, feeding, Section III)

Self-Care Deficit, Toileting

Toileting **Self-Care** deficit (See **Self-Care** deficit, toileting, Section III)

Self-Concept

Readiness for enhanced **Self-Concept** (See **Self-Concept**, readiness for enhanced, Section III)

Self-Destructive Behavior

Post-Trauma syndrome r/t unresolved feelings from traumatic event

Risk for **Self-Mutilation**: Risk factors: feelings of depression, rejection, self-hatred, depersonalization; command hallucinations

Risk for **Suicide**: Risk factor: history of self-destructive behavior

Risk for self-directed **Violence**: Risk factors: panic state, history of child abuse, toxic reaction to medication

Self-Esteem, Chronic Low

Chronic low **Self-Esteem** (See **Self-Esteem**, low, chronic, Section III)

Risk for disturbed personal **Identity**: Risk factor: chronic low self-esteem

Self-Esteem, Situational Low

Situational low **Self-Esteem** (See **Self-Esteem**, low, situational, Section III)

Risk for situational low **Self-Esteem** (See **Self-Esteem**, low, situational, risk for, Section III)

Self-Mutilation

Ineffective **Impulse** control r/t ineffective management of anxiety

Self-Mutilation (See **Self-Mutilation**, Section III)

Risk for **Self-Mutilation** (See **Self-Mutilation**, risk for, Section III)

Senile Dementia

Ineffective **Relationship** r/t cognitive changes in one partner

Sedentary lifestyle r/t lack of interest in movement

See *Dementia*

Separation Anxiety

Ineffective **Coping** r/t maturational and situational crises, vulnerability related to developmental age, hospitalization, separation from family and familiar surroundings, multiple caregivers

Insomnia r/t separation for significant others

Risk for impaired **Attachment**: Risk factor: separation

See *Hospitalized Child*

Sepsis, Child

Impaired **Gas** exchange r/t pulmonary inflammation associated with disease process

Imbalanced **Nutrition**: less than body requirements r/t anorexia, generalized weakness, poor sucking reflex

Delayed **Surgical** recovery r/t presence of infection

Ineffective **Thermoregulation** r/t infectious process, septic shock

Ineffective peripheral **Tissue Perfusion** r/t arterial or venous blood flow exchange problems, septic shock

Risk for deficient **Fluid** volume: Risk factor: inflammation leading to decreased systemic vascular resistance

Risk for impaired **Skin** integrity: Risk factor: desquamation caused by disseminated intravascular coagulation

See *Hospitalized Child; Premature Infant, Child*

Septicemia

Imbalanced **Nutrition**: less than body requirements r/t anorexia, generalized weakness

Ineffective peripheral **Tissue Perfusion** r/t decreased systemic vascular resistance

Risk for deficient **Fluid** volume: Risk factors: vasodilation of peripheral vessels, leaking of capillaries

Risk for **Shock**: Risk factors: hypotension, hypovolemia

See *Sepsis, Child; Shock, Septic*

Severe Acute Respiratory Syndrome (SARS)

See *SARS (Severe Acute Respiratory Syndrome); Pneumonia*

Sexual Dysfunction

Sexual dysfunction (See **Sexual** dysfunction, Section III)

Ineffective **Relationship** r/t reported sexual dissatisfaction between partners

Chronic **Sorrow** r/t loss of ideal sexual experience, altered relationships

Risk for chronic low **Self-Esteem**

See *Erectile Dysfunction (ED)*

Sexuality, Adolescent

Disturbed **Body Image** r/t anxiety caused by unachieved developmental milestone (puberty) or deficient knowledge regarding reproductive maturation with expressed concerns regarding lack of growth of secondary sex characteristics

Impaired emancipated **Decision-Making**: sexual activity r/t undefined personal values or beliefs, multiple or divergent sources of information, lack of relevant information

Ineffective **Impulse** control r/t denial of consequences of actions

Deficient **Knowledge**: potential for enhanced health maintenance r/t multiple or divergent sources of information or lack of relevant information regarding sexual transmission of disease, contraception, prevention of toxic shock syndrome

See *Maturational Issues, Adolescent*

Sexuality Pattern, Ineffective

Ineffective **Sexuality** pattern (See [Sexuality pattern, ineffective, Section III](#))

Sexually Transmitted Disease (STD)

See *STD (Sexually Transmitted Disease)*

Shaken Baby Syndrome

Decreased intracranial **Adaptive** capacity r/t brain injury

Impaired **Parenting** r/t stress, history of being abusive

Impaired individual **Resilience** r/t poor impulse control

Stress overload r/t intense repeated family stressors, family violence

Risk for other-directed **Violence**: Risk factors: history of violence against others, perinatal complications

See *Child Abuse; Suspected Child Abuse and Neglect (SCAN), Child; Suspected Child Abuse and Neglect (SCAN), Parent*

Shakiness

Anxiety r/t situational or maturational crisis, threat of death

Shame

Situational low **Self-Esteem** r/t inability to deal with past traumatic events, blaming of self for events not in one's control

Shingles

Acute **Pain** r/t vesicular eruption along the nerves

Ineffective **Protection** r/t abnormal blood profiles

Social isolation r/t altered state of wellness, contagiousness of disease

Risk for **Infection**: Risk factor: tissue destruction

See *Itching*

Shivering

Impaired **Comfort** r/t altered health status

Fear r/t serious threat to health status

Hypothermia r/t exposure to cool environment

Ineffective **Thermoregulation** r/t serious infectious process resulting in immune response of fever

See *Shock, Septic*

Shock, Cardiogenic

Decreased **Cardiac** output r/t decreased myocardial contractility, dysrhythmia

Shock, Hypovolemic

Deficient **Fluid** volume r/t abnormal loss of fluid, trauma, third spacing

Shock, Septic

Deficient **Fluid** volume r/t abnormal loss of intravascular fluid, pooling of blood in peripheral circulation, overwhelming inflammatory response

Ineffective **Protection** r/t inadequately functioning immune system

See *Sepsis, Child; Septicemia*

Shoulder Repair

Self-Care deficit: bathing, dressing, feeding r/t immobilization of affected shoulder

Risk for **Perioperative Positioning** injury: Risk factor: immobility

See *Surgery, Preoperative; Surgery, Perioperative; Surgery, Postoperative; Total Joint Replacement (Total Hip/Total Knee/Shoulder)*

Sickle Cell Anemia/Crisis

Activity intolerance r/t fatigue, effects of chronic anemia

Deficient **Fluid** volume r/t decreased intake, increased fluid requirements during sickle cell crisis, decreased ability of kidneys to concentrate urine

Impaired physical **Mobility** r/t pain, fatigue

Acute **Pain** r/t viscous blood, tissue hypoxia

Ineffective peripheral **Tissue Perfusion** r/t effects of red cell sickling, infarction of tissues

Risk for decreased **Cardiac** tissue perfusion: Risk factors: effects of red cell sickling, infarction of tissues

Risk for disproportionate **Growth**: Risk factor: chronic illness

Risk for **Infection**: Risk factor: alterations in splenic function

Risk for impaired **Resilience**: Risk factor: chronic illness

Risk for ineffective cerebral **Tissue** perfusion: Risk factors: effects of red cell sickling, infarction of tissues

Risk for ineffective **Gastrointestinal** perfusion: Risk factors: coagulopathy, sickle cell anemia.

See *Child with Chronic Condition; Hospitalized Child*

SIDS (Sudden Infant Death Syndrome)

Anxiety: parental worry r/t life-threatening event

Interrupted **Family** processes r/t stress as a result of special care needs of infant with apnea

Grieving r/t potential loss of infant

Insomnia: parental/infant r/t home apnea monitoring

Deficient **Knowledge**: potential for enhanced health maintenance r/t knowledge or skill acquisition of cardiopulmonary resuscitation and home apnea monitoring

Impaired **Resilience** r/t sudden loss

Risk for **Sudden Infant Death** syndrome (See [Sudden Infant Death syndrome, risk for, Section III](#))

Risk for **Powerlessness**: Risk factor: unanticipated life-threatening event

See *Terminally Ill Child/Death of Child, Parent*

Sitting Problems

Impaired **Sitting** (See [Sitting, impaired, Section III](#))

Situational Crisis

Ineffective **Coping** r/t situational crisis

Interrupted **Family** processes r/t situational crisis

Risk for ineffective **Activity** planning: Risk factor: inability to process information

Risk for disturbed personal **Identity**: Risk factor: situational crisis

Readiness for enhanced **Communication**: willingness to share feelings and thoughts

Readiness for enhanced **Religiosity**: requests religious material and/or experiences

Readiness for enhanced **Resilience**: desire to enhance resilience

Readiness for enhanced **Spiritual** well-being: desire for harmony following crisis

SJS (Stevens-Johnson Syndrome)

See *Stevens-Johnson Syndrome (SJS)*

Skin Cancer

Ineffective **Health** maintenance r/t deficient knowledge regarding self-care with skin cancer

Ineffective **Protection** r/t weakened immune system

Impaired **Tissue** integrity r/t abnormal cell growth in skin, treatment of skin cancer

Readiness for enhanced **Health** management: follows preventive measures

Readiness for enhanced **Knowledge**: self-care to prevent and treat skin cancer

Skin Disorders

Impaired **Skin** integrity (See **Skin** integrity, impaired, Section III)

Skin Turgor, Change in Elasticity

Deficient **Fluid** volume r/t active fluid loss

Sleep

Readiness for enhanced **Sleep** (See **Sleep**, readiness for enhanced, Section III)

Sleep Apnea

Ineffective **Breathing** pattern r/t obesity, substance abuse, enlarged tonsils, smoking, or neurological pathology such as a brain tumor

Sleep Deprivation

Fatigue r/t lack of sleep

Sleep deprivation (See **Sleep** deprivation, Section III)

Sleep Problems

Insomnia (See **Insomnia**, Section III)

Sleep Pattern, Disturbed, Parent/Child

Insomnia: child r/t anxiety or fear

Insomnia: parent r/t parental responsibilities, stress

See *Suspected Child Abuse and Neglect (SCAN), Child and Parent*

Slurring of Speech

Impaired verbal **Communication** r/t decrease in circulation to brain, brain tumor, anatomical defect, cleft palate

Situational low **Self-Esteem** r/t speech impairment

See *Communication Problems*

Small Bowel Resection

See *Abdominal Surgery*

Smell, Loss of Ability to

Risk for **Injury**: Risk factors: inability to detect gas fumes, smoke smells

See *Anosmia*

Smoke Inhalation

Ineffective **Airway** clearance r/t smoke inhalation

Impaired **Gas** exchange r/t ventilation-perfusion imbalance

Risk for acute **Confusion**: Risk factor: decreased oxygen supply

Risk for **Infection**: Risk factors: inflammation, ineffective airway clearance, pneumonia

Risk for **Poisoning**: Risk factor: exposure to carbon monoxide

Readiness for enhanced **Health** management: functioning smoke detectors and carbon monoxide detectors in home and work, escape route planned and reviewed

See *Atelectasis; Burns; Pneumonia*

Smoking Behavior

Insufficient **Breast Milk** r/t smoking

Risk-prone **Health** behavior r/t smoking

Ineffective **Health** maintenance r/t denial of effects of smoking, lack of effective support for smoking withdrawal

Readiness for enhanced **Knowledge**: expresses interest in smoking cessation

Risk for dry **Eye**: Risk factor: smoking

Risk for ineffective peripheral **Tissue Perfusion**: Risk factor: effect of nicotine

Risk for **Thermal** injury: Risk factor: unsafe smoking behavior

Social Interaction, Impaired

Impaired **Social** interaction (See **Social** interaction, impaired, Section III)

Social Isolation

Social isolation (See **Social** isolation, Section III)

Sociopathic Personality

See *Antisocial Personality Disorder*

Sodium, Decrease/Increase

See *Hyponatremia; Hypernatremia*

Somatization Disorder

Anxiety r/t unresolved conflicts channeled into physical complaints or conditions

Ineffective **Coping** r/t lack of insight into underlying conflicts

Ineffective **Denial** r/t displaced psychological stress to physical symptoms

Nausea r/t anxiety

Chronic **Pain** r/t unexpressed anger, multiple physical disorders, depression

Impaired individual **Resilience** r/t possible psychological disorders

Sore Nipples, Breastfeeding

Ineffective **Breastfeeding** r/t deficient knowledge regarding correct feeding procedure

See *Painful Breasts, Sore Nipples*

Sore Throat

Impaired **Comfort** r/t sore throat

Deficient **Knowledge** r/t treatment, relief of discomfort

Impaired **Oral Mucous Membrane** r/t inflammation or infection of oral cavity

Impaired **Swallowing** r/t irritation of oropharyngeal cavity

Sorrow

Grieving r/t loss of significant person, object, or role

Chronic **Sorrow** (See **Sorrow, chronic**, Section III)

Readiness for enhanced **Communication**: expresses thoughts and feelings

Readiness for enhanced **Spiritual well-being**: desire to find purpose and meaning of loss

Spastic Colon

See *IBS (Irritable Bowel Syndrome)*

Speech Disorders

Anxiety r/t difficulty with communication

Impaired verbal **Communication** r/t anatomical defect, cleft palate, psychological barriers, decrease in circulation to brain

Spina Bifida

See *Neural Tube Defects*

Spinal Cord Injury

Deficient **Diversional** activity r/t long-term hospitalization, frequent lengthy treatments

Fear r/t powerlessness over loss of body function

Complicated **Grieving** r/t loss of usual body function

Sedentary lifestyle r/t lack of resources or interest

Impaired wheelchair **Mobility** r/t neuromuscular impairment

Impaired **Standing** r/t spinal cord injury

Urinary Retention r/t inhibition of reflex arc

Risk for **Latex Allergy** response: Risk factor: continuous or intermittent catheterization

Risk for **Autonomic Dysreflexia**: Risk factors: bladder or bowel distention, skin irritation, deficient knowledge of patient and caregiver

Risk for ineffective **Breathing** pattern: Risk factor: neuromuscular impairment

Risk for **Infection**: Risk factors: chronic disease, stasis of body fluids

Risk for **Loneliness**: Risk factor: physical immobility

Risk for **Powerlessness**: Risk factor: loss of function

Risk for **Pressure** ulcer: Risk factor: immobility and decreased sensation

See *Child with Chronic Condition; Hospitalized Child; Neural Tube Defects; Paralysis*

Spinal Fusion

Impaired bed **Mobility** r/t impaired ability to turn side to side while keeping spine in proper alignment

Impaired physical **Mobility** r/t musculoskeletal impairment associated with surgery, possible back brace

Readiness for enhanced **Knowledge**: expresses interest in information associated with surgery

See *Acute Back; Back Pain; Scoliosis; Surgery, Preoperative Care; Surgery, Perioperative Care; Surgery, Postoperative Care*

Spiritual Distress

Spiritual distress (See **Spiritual** distress, Section III)

Risk for chronic low **Self-Esteem**: Risk factor: unresolved spiritual issues

Risk for **Spiritual** distress (See **Spiritual** distress, risk for, Section III)

Spiritual Well-Being

Readiness for enhanced **Spiritual** well-being (See **Spiritual** well-being, readiness for enhanced, Section III)

Splenectomy

See *Abdominal Surgery*

Sprains

Acute **Pain** r/t physical injury

Impaired physical **Mobility** r/t injury

Impaired **Walking** r/t injury

Standing Problems

Impaired **Standing** (see **Impaired Standing**, Section III)

Stapedectomy

Hearing Loss r/t edema from surgery

Acute **Pain** r/t headache

Risk for **Falls**: Risk factor: dizziness

Risk for **Infection**: Risk factor: invasive procedure

Stasis Ulcer

Impaired **Tissue** integrity r/t chronic venous congestion

Risk for **Infection**: Risk factor: open wound

See *CHF (Congestive Heart Failure); Varicose Veins*

STD (Sexually Transmitted Disease)

Impaired **Comfort** r/t infection

Fear r/t altered body function, risk for social isolation, fear of incurable illness

Ineffective **Health** maintenance r/t deficient knowledge regarding transmission, symptoms, treatment of STD

Ineffective **Sexuality** pattern r/t illness, altered body function, need for abstinence to heal

Social isolation r/t fear of contracting or spreading disease

Risk for **Infection**: spread of infection: Risk factor: lack of knowledge concerning transmission of disease

Readiness for enhanced **Knowledge**: seeks information regarding prevention and treatment of STDs

See *Maturational Issues, Adolescent; PID (Pelvic Inflammatory Disease)*

STEMI (ST-Elevation Myocardial Infarction)

See *MI (Myocardial Infarction)*

Stent (Coronary Artery Stent)

Risk for **Injury**: Risk factor: complications associated with stent placement

Risk for decreased **Cardiac** tissue perfusion: Risk factor: possible restenosis

Risk for **Vascular Trauma**: Risk factors: insertion site, catheter width

Readiness for enhanced **Decision-Making**: expresses desire to enhance risk-benefit analysis, understanding and meaning of choices, and decisions regarding treatment

See *Angioplasty, Coronary; Cardiac Catheterization*

Sterilization Surgery

Decisional Conflict r/t multiple or divergent sources of information, unclear personal values or beliefs

See *Surgery, Preoperative Care; Surgery, Perioperative Care; Surgery, Postoperative Care; Tubal Ligation; Vasectomy*

Stertorous Respirations

Ineffective **Airway** clearance r/t pharyngeal obstruction

Stevens-Johnson Syndrome (SJS)

Impaired **Oral Mucous Membrane** r/t immunocompromised condition associated with allergic medication reaction

Acute **Pain** r/t painful skin lesions and painful mucosa lesions

Impaired **Skin** integrity r/t allergic medication reaction

Risk for deficient **Fluid** volume: Risk factors: factors affecting fluid needs (hypermetabolic state, fever), excessive losses through normal routes (vomiting and diarrhea)

Risk for **Infection**: Risk factor: sloughing skin

Risk for impaired **Liver** function: Risk factor: impaired immune response

Stillbirth

See *Pregnancy Loss*

Stoma

See *Colostomy; Ileostomy*

Stomatitis

Impaired **Oral Mucous Membrane** r/t pathological conditions of oral cavity; side effects of chemotherapy

Risk for impaired **Oral Mucous Membranes** (See *impaired Oral Mucous Membranes, risk for, Section III*)

Stone, Kidney

See *Kidney Stone*

Stool, Hard/Dry

Chronic functional **Constipation** r/t inadequate fluid intake, inadequate fiber intake, decreased activity level, decreased gastric motility

Straining with Defecation

Chronic functional **Constipation** r/t less than adequate fluid intake, less than adequate dietary intake

Risk for decreased **Cardiac** output: Risk factor: vagal stimulation with dysrhythmia resulting from Valsalva maneuver

Strep Throat

Risk for **Infection**: Risk factor: exposure to pathogen

See *Sore Throat*

Stress

Anxiety r/t feelings of helplessness, feelings of being threatened

Ineffective **Coping** r/t ineffective use of problem-solving process, feelings of apprehension or helplessness

Fear r/t powerlessness over feelings

Stress overload r/t intense or multiple stressors

Readiness for enhanced **Communication**: shows willingness to share thoughts and feelings

Readiness for enhanced **Spiritual** well-being: expresses desire for harmony and peace in stressful situation

See *Anxiety*

Stress Urinary Incontinence

Stress urinary **Incontinence** r/t degenerative change in pelvic muscles

Stridor

Ineffective **Airway** clearance r/t obstruction, tracheobronchial infection, trauma

Stroke

See *CVA (Cerebrovascular Accident)*

Stuttering

Anxiety r/t impaired verbal communication

Impaired verbal **Communication** r/t anxiety, psychological problems

Subarachnoid Hemorrhage

Acute **Pain**: headache r/t irritation of meninges from blood, increased intracranial pressure

Risk for ineffective **Cerebral** tissue perfusion: Risk factor: bleeding from cerebral vessel

See *Intracranial Pressure, Increased*

Substance Abuse

Compromised family **Coping** r/t codependency issues

Defensive **Coping** r/t substance abuse

Disabled family **Coping** r/t differing coping styles between support persons

Ineffective **Coping** r/t use of substances to cope with life events
 Ineffective **Denial** r/t refusal to acknowledge substance abuse problem

Dysfunctional **Family** processes r/t substance abuse

Deficient community **Health** r/t prevention and control of illegal substances in community

Ineffective **Impulse** control r/t addictive process

Ineffective **Relationship** r/t inability for well-balanced collaboration between partners

Insomnia r/t irritability, nightmares, tremors

Risk for impaired **Attachment**: Risk factor: substance abuse

Risk for disturbed personal **Identity**: Risk factor: ingestion/inhalation of toxic chemicals

Risk for chronic low **Self-Esteem**: Risk factors: perceived lack of respect from others, repeated failures, repeated negative reinforcement

Risk for **Thermal** injury: Risk factor: intoxication with drugs or alcohol

Risk for **Vascular Trauma**: Risk factor: chemical irritant self injected into veins

Risk for self-directed **Violence**: Risk factors: reactions to substances used, impulsive behavior, disorientation, impaired judgment

Risk for other-directed **Violence**: Risk factor: access to weapon

Readiness for enhanced **Coping**: seeking social support and knowledge of new strategies

Readiness for enhanced **Self-Concept**: accepting strengths and limitations

See *Alcoholism; Drug Abuse; Maturational Issues, Adolescent*

Substance Abuse, Adolescent

See *Alcohol Withdrawal; Maturational Issues, Adolescent; Substance Abuse*

Substance Abuse in Pregnancy

Ineffective **Childbearing** process r/t substance abuse

Defensive **Coping** r/t denial of situation, differing value system

Ineffective **Health** management r/t addiction

Deficient **Knowledge** r/t lack of exposure to information regarding effects of substance abuse in pregnancy

Risk for impaired **Attachment**: Risk factors: substance abuse, inability of parent to meet infant's or own personal needs

Risk for **Infection**: Risk factors: intravenous drug use, lifestyle

Risk for **Injury**: fetal: Risk factor: effects of drugs on fetal growth and development

Risk for **Injury**: maternal: Risk factor: drug or alcohol use

Risk for impaired **Parenting**: Risk factor: lack of ability to meet infant's needs due to addiction with use of alcohol or drugs

See *Alcoholism; Drug Abuse; Substance Abuse*

Sucking Reflex

Effective **Breastfeeding** r/t regular and sustained sucking and swallowing at breast

Sudden Infant Death Syndrome (SIDS)

See *SIDS (Sudden Infant Death Syndrome)*

Suffocation, Risk for

Risk for **Suffocation** (See **Suffocation**, risk for, Section III)

Suicide Attempt

Risk-prone **Health** behavior r/t low self-efficacy

Ineffective **Coping** r/t anger, complicated grieving

Hopelessness r/t perceived or actual loss, substance abuse, low self-concept, inadequate support systems

Ineffective **Impulse** control r/t inability to modulate stress, anxiety

Post-Trauma syndrome r/t history of traumatic events, abuse, rape, incest, war, torture

Impaired individual **Resilience** r/t poor impulse control

Situational low **Self-Esteem** r/t guilt, inability to trust, feelings of worthlessness or rejection

Social isolation r/t inability to engage in satisfying personal relationships

Spiritual distress r/t hopelessness, despair

Risk for **Post-Trauma** syndrome: Risk factor: survivor's role in suicide attempt

Risk for **Suicide** (See **Suicide**, risk for, Section III)

Readiness for enhanced **Communication**: willingness to share thoughts and feelings

Readiness for enhanced **Spiritual** well-being: desire for harmony and inner strength to help redefine purpose for life

See *Violent Behavior*

Support System, Inadequate

Readiness for enhanced family **Coping**: ability to adapt to tasks associated with care, support of significant other during health crisis

Readiness for enhanced **Family** processes: activities support the growth of family members

Readiness for enhanced **Parenting**: children or other dependent person(s) expressing satisfaction with home environment

Suppression of Labor

See *Preterm Labor; Tocolytic Therapy*

Surgery, Perioperative Care

Risk for imbalanced **Fluid** volume: Risk factor: surgery

Risk for **Perioperative Hypothermia**: Risk factors: inadequate covering of client, cold surgical room

Risk for **Perioperative Positioning** injury: Risk factors: predisposing condition, prolonged surgery

Surgery, Postoperative Care

Activity intolerance r/t pain, surgical procedure

Anxiety r/t change in health status, hospital environment

Deficient **Knowledge** r/t postoperative expectations, lifestyle changes

Nausea r/t manipulation of gastrointestinal tract, postsurgical anesthesia

Imbalanced Nutrition: less than body requirements r/t anorexia, nausea, vomiting, decreased peristalsis

Ineffective peripheral Tissue Perfusion r/t hypovolemia, circulatory stasis, obesity, prolonged immobility, decreased coughing, decreased deep breathing

Acute Pain r/t inflammation or injury in surgical area

Delayed Surgical recovery r/t extensive surgical procedure, postoperative surgical infection

Urinary retention r/t anesthesia, pain, fear, unfamiliar surroundings, client's position

Risk for Bleeding: Risk factor: surgical procedure

Risk for ineffective Breathing pattern: Risk factors: pain, location of incision, effects of anesthesia or opioids

Risk for Constipation: Risk factors: decreased activity, decreased food or fluid intake, anesthesia, pain medication

Risk for imbalanced Fluid volume: Risk factors: hypermetabolic state, fluid loss during surgery, presence of indwelling tubes, fluids used to distend organ structures being absorbed into body

Risk for Infection: Risk factors: invasive procedure, pain, anesthesia, location of incision, weakened cough as a result of aging

Surgery, Preoperative Care

Anxiety r/t threat to or change in health status, situational crisis, fear of the unknown

Insomnia r/t anxiety about upcoming surgery

Deficient Knowledge r/t preoperative procedures, postoperative expectations

Readiness for enhanced Knowledge: shows understanding of preoperative and postoperative expectations for self-care

Surgical Recovery, Delayed

Delayed Surgical recovery (See [Surgical recovery, delayed, Section III](#))

Risk for delayed Surgical recovery (See [Surgical recovery, delayed, risk for, Section III](#))

Suspected Child Abuse and Neglect (SCAN), Child

Ineffective Activity planning r/t lack of family support

Anxiety: child r/t threat of punishment for perceived wrongdoing

Deficient community Health r/t inadequate reporting and follow-up of SCAN

Disturbed personal Identity r/t dysfunctional family processes

Rape-Trauma syndrome r/t altered lifestyle because of abuse, changes in residence

Risk for impaired Resilience: Risk factor: adverse situation

Readiness for enhanced community Coping: obtaining resources to prevent child abuse, neglect

See [Child Abuse](#); [Hospitalized Child](#); [Maturational Issues, Adolescent](#)

Suspected Child Abuse and Neglect (SCAN), Parent

Disabled family Coping r/t dysfunctional family, underdeveloped nurturing parental role, lack of parental support systems or role models

Dysfunctional Family processes r/t inadequate coping skills

Ineffective Health maintenance r/t deficient knowledge of parenting skills as result of unachieved developmental tasks

Impaired Home maintenance r/t disorganization, parental dysfunction, neglect of safe and nurturing environment

Ineffective Impulse control r/t projection of anger, frustration onto child

Impaired Parenting r/t unrealistic expectations of child; lack of effective role model; unmet social, emotional, or maturational needs of parents; interruption in bonding process

Impaired individual Resilience r/t poor impulse control

Chronic low Self-Esteem r/t lack of successful parenting experiences

Risk for other-directed Violence: parent to child: Risk factors: inadequate coping mechanisms, unresolved stressors, unachieved maturational level by parent

Suspicion

Disturbed personal Identity r/t psychiatric disorder

Powerlessness r/t repetitive paranoid thinking

Impaired Social interaction r/t disturbed thought processes, paranoid delusions, hallucinations

Risk for self-directed Violence: Risk factor: inability to trust

Risk for other-directed Violence: Risk factor: impulsiveness

Swallowing Difficulties

Impaired Swallowing (See [Swallowing, impaired, Section III](#))

Swine Flu (H1N1)

See [Influenza](#)

Syncope

Anxiety r/t fear of falling

Impaired physical Mobility r/t fear of falling

Ineffective Health management r/t lack of knowledge in how to prevent syncope

Social isolation r/t fear of falling

Risk for decreased Cardiac output: Risk factor: dysrhythmia

Risk for Falls: Risk factor: syncope

Risk for Injury: Risk factors: altered sensory perception, transient loss of consciousness, risk for falls

Risk for ineffective Cerebral tissue perfusion: Risk factor: interruption of blood flow

Syphilis

See [STD \(Sexually Transmitted Disease\)](#)

Systemic Lupus Erythematosus

See [Lupus Erythematosus](#)

List of Nursing Assessments by Letter: T

T & A (Tonsillectomy and Adenoidectomy)	Tachycardia	Tachypnea
Tardive Dyskinesia	Taste Abnormality	TB (Pulmonary Tuberculosis)
TBI (Traumatic Brain Injury)	TD (Traveler's Diarrhea)	Temperature, Decreased
Temperature, High	Temperature Regulation, Impaired	TEN (Toxic Epidermal Necrolysis)
Tension	Terminally Ill Adult	Terminally Ill Child, Adolescent
Terminally Ill Child, Infant/Toddler	Terminally Ill Child, Preschool Child	Terminally Ill Child, School-Age Child/Preadolescent
Terminally Ill Child/Death of Child, Parent	Tetralogy of Fallot	Tetraplegia
Thermoregulation, Ineffective	Thoracentesis	Thoracotomy
Thought Disorders	Thrombocytopenic Purpura	Thrombophlebitis
Thyroidectomy	TIA (Transient Ischemic Attack)	Tic Disorder
Tinea Capitis	Tinea Corporis	Tinea Cruris
Tinea Pedis	Tinea Unguium (Onychomycosis)	Tinnitus
Tissue Damage, Corneal	Tissue Damage, Integumentary	Tissue Perfusion, Peripheral
Toileting Problems	Toilet Training	Tonsillectomy and Adenoidectomy (T & A)
Toothache	Total Anomalous Pulmonary Venous Return	Total Joint Replacement (Total Hip/ Total Knee/Shoulder)
Total Parenteral Nutrition (TPN)	Tourette's Syndrome (TS)	Toxemia
Toxic Epidermal Necrolysis (TEN) (Erythema Multiforme)	TPN (Total Parenteral Nutrition)	Tracheoesophageal Fistula
Tracheostomy	Traction and Casts	Transfer Ability
Transient Ischemic Attack (TIA)	Transposition of Great Vessels	Transurethral Resection of the Prostate (TURP)

e26 List of Nursing Assessments by Letter: T

Trauma in Pregnancy	Trauma, Risk for	Traumatic Brain Injury (TBI)
Traumatic Event	Traveler's Diarrhea (TD)	Trembling of Hands
Tricuspid Atresia	Trigeminal Neuralgia	Truncus Arteriosus
TS (Tourette's Syndrome)	TSE (Testicular Self-Examination)	Tubal Ligation
Tube Feeding	Tuberculosis (TB)	TURP (Transurethral Resection of the Prostate)

T

T & A (Tonsillectomy and Adenoidectomy)

Ineffective **Airway** clearance r/t hesitation or reluctance to cough because of pain

Deficient **Knowledge**: potential for enhanced health maintenance r/t insufficient knowledge regarding postoperative nutritional and rest requirements, signs and symptoms of complications, positioning

Nausea r/t gastric irritation, pharmaceuticals, anesthesia

Acute Pain r/t surgical incision

Risk for **Aspiration**: Risk factors: postoperative drainage and impaired swallowing

Risk for deficient **Fluid** volume: Risk factors: decreased intake because of painful swallowing, effects of anesthesia (nausea, vomiting), hemorrhage

Risk for imbalanced **Nutrition**: less than body requirements: Risk factors: hesitation or reluctance to swallow

Tachycardia

See *Dysrhythmia*

Tachypnea

Ineffective **Breathing** pattern r/t pain, anxiety, hypoxia

See *cause of Tachypnea*

Tardive Dyskinesia

Ineffective **Health** management r/t complexity of therapeutic regimen or medication

Deficient **Knowledge** r/t cognitive limitation in assimilating information relating to side effects associated with neuroleptic medications

Risk for **Injury**: Risk factor: drug-induced abnormal body movements

Taste Abnormality

Frail Elderly syndrome r/t chronic illness

TB (Pulmonary Tuberculosis)

Ineffective **Airway** clearance r/t increased secretions, excessive mucus

Ineffective **Breathing** pattern r/t decreased energy, fatigue

Fatigue r/t disease state

Impaired **Gas** exchange r/t disease process

Ineffective **Health** management r/t deficient knowledge of prevention and treatment regimen

Impaired **Home** maintenance management r/t client or family member with disease

Ineffective **Thermoregulation** r/t presence of infection

Risk for **Infection**: Risk factor: insufficient knowledge regarding avoidance of exposure to pathogens

Readiness for enhanced **Health** management: takes medications according to prescribed protocol for prevention and treatment

TBI (Traumatic Brain Injury)

Interrupted **Family** processes r/t traumatic injury to family member

Chronic **Sorrow** r/t change in health status and functional ability

Risk for **Post-Trauma** syndrome: Risk factor: perception of event causing TBI

Risk for impaired **Religiosity**: Risk factor: impaired physical mobility

Risk for impaired **Resilience**: Risk factor: crisis of injury

See *Head Injury; Neurologic Disorders*

TD (Traveler's Diarrhea)

Diarrhea r/t travel with exposure to different bacteria, viruses

Risk for deficient **Fluid** volume: Risk factors: excessive loss of fluids, diarrhea

Risk for **Infection**: Risk factors: insufficient knowledge regarding avoidance of exposure to pathogens (water supply, iced drinks, local cheeses, ice cream, undercooked meat, fish and shellfish, uncooked vegetables, unclean eating utensils, improper handwashing)

Temperature, Decreased

Hypothermia r/t exposure to cold environment

Temperature, High

Hyperthermia r/t neurological damage, disease condition with high temperature, excessive heat, inflammatory response

Temperature Regulation, Impaired

Ineffective **Thermoregulation** r/t trauma, illness, cerebral injury

TEN (Toxic Epidermal Necrolysis)

See *Toxic Epidermal Necrolysis (TEN)*

Tension

Anxiety r/t threat to or change in health status, situational crisis

Readiness for enhanced **Communication**: expresses willingness to share feelings and thoughts

See *Stress*

Terminally Ill Adult

Death Anxiety r/t unresolved issues relating to death and dying

Risk for **Spiritual** distress: Risk factor: impending death

Readiness for enhanced **Religiosity**: requests religious material and/or experiences

Readiness for enhanced **Spiritual** well-being: desire to achieve harmony of mind, body, spirit

See *Terminally Ill Child/Death of Child, Parent*

Terminally Ill Child, Adolescent

Disturbed **Body Image** r/t effects of terminal disease, already critical feelings of group identity and self-image

Ineffective **Coping** r/t inability to establish personal and peer identity because of the threat of being different or not being healthy, inability to achieve maturational tasks

Impaired **Social** interaction r/t forced separation from peers

See *Child with Chronic Condition; Hospitalized Child, Terminally Ill Child/Death of Child, Parent*

Terminally Ill Child, Infant/Toddler

Ineffective **Coping** r/t separation from parents and familiar environment from inability to understand dying process

See *Child with Chronic Condition, Terminally Ill Child/Death of Child, Parent*

Terminally Ill Child, Preschool Child

Fear r/t perceived punishment, bodily harm, feelings of guilt caused by magical thinking (i.e., believing that thoughts cause events)

See *Child with Chronic Condition, Terminally Ill Child/Death of Child, Parent*

Terminally Ill Child, School-Age Child/Preadolescent

Fear r/t perceived punishment, body mutilation, feelings of guilt

See *Child with Chronic Condition, Terminally Ill Child/Death of Child, Parent*

Terminally Ill Child/Death of Child, Parent

Compromised family **Coping** r/t inability or unwillingness to discuss impending death and feelings with child or support child through terminal stages of illness

Decisional Conflict r/t continuation or discontinuation of treatment, do-not-resuscitate decision, ethical issues regarding organ donation

Ineffective **Denial** r/t complicated grieving

Interrupted **Family** processes r/t situational crisis

Grieving r/t death of child

Hopelessness r/t overwhelming stresses caused by terminal illness

Insomnia r/t grieving process

Impaired **Parenting** r/t risk for overprotection of surviving siblings

Powerlessness r/t inability to alter course of events

Impaired **Social** interaction r/t complicated grieving

Social isolation: imposed by others r/t feelings of inadequacy in providing support to grieving parents

Social isolation: self-imposed r/t unresolved grief, perceived inadequate parenting skills

Spiritual distress r/t sudden and unexpected death, prolonged suffering before death, questioning the death of youth, questioning the meaning of one's own existence

Risk for complicated **Grieving**: Risk factors: prolonged, unresolved, obstructed progression through stages of grief and mourning

Risk for impaired **Resilience**: Risk factor: impending death

Readiness for enhanced family **Coping**: impact of crisis on family values, priorities, goals, or relationships; expressed interest or desire to attach meaning to child's life and death

Tetralogy of Fallot

See *Congenital Heart Disease/Cardiac Anomalies*

Tetraplegia

Autonomic dysreflexia r/t bladder or bowel distention, skin irritation, infection, deficient knowledge of patient and caregiver

Grieving r/t loss of previous functioning

Powerlessness r/t inability to perform previous activities

Impaired **Sitting** r/t paralysis of extremities

Impaired spontaneous **Ventilation** r/t loss of innervation of respiratory muscles, respiratory muscle fatigue

Risk for **Aspiration**: Risk factor: inadequate ability to protect airway from neurological damage

Risk for **Infection**: Risk factor: urinary stasis

Risk for impaired **Skin** integrity: Risk factor: physical immobilization and decreased sensation

Risk for ineffective **Thermoregulation**: Risk factors: inability to move to increase temperature, possible presence of infection to increase temperature

Thermoregulation, Ineffective

Ineffective **Thermoregulation** (See [Thermoregulation, ineffective, Section III](#))

Thoracentesis

See *Pleural Effusion*

Thoracotomy

Activity intolerance r/t pain, imbalance between oxygen supply and demand, presence of chest tubes

Ineffective **Airway** clearance r/t drowsiness, pain with breathing and coughing

Ineffective **Breathing** pattern r/t decreased energy, fatigue, pain

Deficient **Knowledge** r/t self-care, effective breathing exercises, pain relief

Acute **Pain** r/t surgical procedure, coughing, deep breathing

Risk for **Bleeding**: Risk factor: surgery

Risk for **Infection**: Risk factor: invasive procedure

Risk for **Injury**: Risk factor: disruption of closed-chest drainage system

Risk for **Perioperative Positioning** injury: Risk factors: lateral positioning, immobility

Risk for **Vascular Trauma**: Risk factors: chemical irritant; antibiotics

Thought Disorders

See *Schizophrenia*

Thrombocytopenic Purpura

See *ITP (Idiopathic Thrombocytopenic Purpura)*

Thrombophlebitis

See *DVT*

Thyroidectomy

Risk for ineffective **Airway** clearance r/t edema or hematoma formation, airway obstruction

Risk for impaired verbal **Communication**: Risk factors: edema, pain, vocal cord or laryngeal nerve damage

Risk for **Injury**: Risk factor: possible parathyroid damage or removal

See *Surgery, Preoperative Care; Surgery, Perioperative Care; Surgery, Postoperative Care*

TIA (Transient Ischemic Attack)

Acute **Confusion** r/t hypoxia

Readiness for enhanced **Health** management: obtains knowledge regarding treatment prevention of inadequate oxygenation

See *Syncope*

Tic Disorder

See *Tourette's Syndrome (TS)*

Tinea Capitis

Impaired **Comfort** r/t inflammation from skin irritation

See *Ringworm of Scalp*

Tinea Corporis

See *Ringworm of Body*

Tinea Cruris

See *Jock Itch; Itching; Pruritus*

Tinea Pedis

See *Athlete's Foot; Itching; Pruritus*

Tinea Unguium (Onychomycosis)

See *Ringworm of Nails*

Tinnitus

Ineffective **Health** maintenance r/t deficient knowledge regarding self-care with tinnitus

Hearing Loss r/t ringing in ears obscuring hearing

Tissue Damage, Corneal

Risk for corneal **Injury** (See *corneal Injury, risk for, Section III*)

Tissue Damage, Integumentary

Impaired **Tissue** integrity (See *Tissue integrity, impaired, Section III*)

Risk for impaired **Tissue** integrity (See *Tissue integrity, impaired, risk for, Section III*)

Tissue Perfusion, Peripheral

Ineffective peripheral **Tissue Perfusion** (See *Tissue Perfusion, peripheral, ineffective, Section III*)

Risk for ineffective peripheral **Tissue Perfusion** (See *Tissue Perfusion, peripheral, ineffective, risk for, Section III*)

Toileting Problems

Toileting **Self-Care** deficit r/t impaired transfer ability, impaired mobility status, intolerance of activity, neuromuscular impairment, cognitive impairment

Impaired **Transfer** ability r/t neuromuscular deficits

Toilet Training

Deficient **Knowledge**: parent r/t signs of child's readiness for training

Risk for **Constipation**: Risk factor: withholding stool

Risk for **Infection**: Risk factor: withholding urination

Tonsillectomy and Adenoidectomy (T & A)

See *T & A (Tonsillectomy and Adenoidectomy)*

Toothache

Impaired **Dentition** r/t ineffective oral hygiene, barriers to self-care, economic barriers to professional care, nutritional deficits, lack of knowledge regarding dental health

Acute **Pain** r/t inflammation, infection

Total Anomalous Pulmonary Venous Return

See *Congenital Heart Disease/Cardiac Anomalies*

Total Joint Replacement (Total Hip/Total Knee/Shoulder)

Disturbed **Body Image** r/t large scar, presence of prosthesis

Impaired physical **Mobility** r/t musculoskeletal impairment, surgery, prosthesis

Risk for **Injury**: neurovascular: Risk factors: altered peripheral tissue perfusion, impaired mobility, prosthesis

Risk for **Peripheral Neurovascular** dysfunction r/t immobilization, surgical procedure

Ineffective peripheral **Tissue** perfusion r/t surgery

See *Surgery, Preoperative Care; Surgery, Perioperative Care; Surgery, Postoperative Care*

Total Parenteral Nutrition (TPN)

See *TPN (Total Parenteral Nutrition)*

Tourette's Syndrome (TS)

Hopelessness r/t inability to control behavior

Impaired individual **Resilience** r/t uncontrollable behavior

Risk for situational low **Self-Esteem**: Risk factors: uncontrollable behavior, motor and phonic tics

See *Attention Deficit Disorder*

Toxemia

See *PIH (Pregnancy-Induced Hypertension/Preeclampsia)*

Toxic Epidermal Necrolysis (TEN) (Erythema Multiforme)

Death **Anxiety** r/t uncertainty of prognosis

See *Stevens-Johnson Syndrome (SJS)*

TPN (Total Parenteral Nutrition)

Imbalanced **Nutrition**: less than body requirements r/t inability to digest food or absorb nutrients as a result of biological or psychological factors

Risk for **Electrolyte** imbalance: Risk factor: need for regulation of electrolytes in TPN fluids

Risk for excess **Fluid** volume: Risk factor: rapid administration of TPN

Risk for unstable blood **Glucose** level: Risk factor: high glucose levels in TPN to be regulated according to blood glucose levels

Risk for **Infection**: Risk factors: concentrated glucose solution, invasive administration of fluids

Risk for **Vascular Trauma**: Risk factors: insertion site, length of treatment time

Tracheoesophageal Fistula

Ineffective **Airway** clearance r/t aspiration of feeding because of inability to swallow

Imbalanced **Nutrition**: less than body requirements r/t difficulties swallowing

Risk for **Aspiration**: Risk factor: common passage of air and food

Risk for **Vascular Trauma**: Risk factors: venous medications and site

See *Respiratory Conditions of the Neonate; Hospitalized Child*

Tracheostomy

Ineffective **Airway** clearance r/t increased secretions, mucous plugs

Anxiety r/t impaired verbal communication, ineffective airway clearance

Disturbed **Body Image** r/t abnormal opening in neck

Impaired verbal **Communication** r/t presence of mechanical airway

Deficient **Knowledge** r/t self-care, home maintenance management

Acute **Pain** r/t edema, surgical procedure

Risk for **Aspiration**: Risk factor: presence of tracheostomy

Risk for **Bleeding**: Risk factor: surgical incision

Risk for **Infection**: Risk factors: invasive procedure, pooling of secretions

Traction and Casts

Constipation r/t immobility

Deficient **Diversional** activity r/t immobility

Impaired physical **Mobility** r/t imposed restrictions on activity because of bone or joint disease injury

Acute **Pain** r/t immobility, injury, or disease

Self-Care deficit: feeding, dressing, bathing, toileting r/t degree of impaired physical mobility, body area affected by traction or cast

Impaired **Transfer** ability r/t presence of traction, casts

Risk for **Disuse** syndrome: Risk factor: mechanical immobilization

See *Casts*

Transfer Ability

Impaired **Transfer** ability (See **Transfer** ability, impaired, Section III)

Transient Ischemic Attack (TIA)

See *TIA (Transient Ischemic Attack)*

Transposition of Great Vessels

See *Congenital Heart Disease/Cardiac Anomalies*

Transurethral Resection of the Prostate (TURP)

See *TURP (Transurethral Resection of the Prostate)*

Trauma in Pregnancy

Anxiety r/t threat to self or fetus, unknown outcome

Deficient **Knowledge** r/t lack of exposure to situation

Acute **Pain** r/t trauma

Impaired **Skin** integrity r/t trauma

Risk for **Bleeding**: Risk factor: trauma

Risk for deficient **Fluid** volume: Risk factor: fluid loss

Risk for **Infection**: Risk factor: traumatized tissue

Risk for **Injury**: fetal: Risk factor: premature separation of placenta

Risk for disturbed **Maternal–Fetal** dyad: Risk factor: complication of pregnancy

Trauma, Risk for

Risk for **Trauma** (See **Trauma**, risk for, Section III)

Traumatic Brain Injury (TBI)

See *TBI (Traumatic Brain Injury); Intracranial Pressure, Increased*

Traumatic Event

Post-Trauma syndrome r/t previously experienced trauma

Traveler's Diarrhea (TD)

See *TD (Traveler's Diarrhea)*

Trembling of Hands

Fear r/t threat to or change in health status, threat of death, situational crisis

Tricuspid Atresia

See *Congenital Heart Disease/Cardiac Anomalies*

Trigeminal Neuralgia

Ineffective **Health** management r/t deficient knowledge regarding prevention of stimuli that trigger pain

Imbalanced **Nutrition**: less than body requirements r/t pain when chewing

Acute **Pain** r/t irritation of trigeminal nerve

Risk for corneal **Injury**: Risk factor: possible decreased corneal sensation

Truncus Arteriosus

See *Congenital Heart Disease/Cardiac Anomalies*

TS (Tourette's Syndrome)

See *Tourette's Syndrome (TS)*

TSE (Testicular Self-Examination)

Readiness for enhanced **Health** management: seeks information regarding self-examination

Tubal Ligation

Decisional Conflict r/t tubal sterilization

See *Laparoscopy*

Tube Feeding

Risk for **Aspiration**: Risk factors: improperly administered feeding, improper placement of tube, improper positioning of client during and after feeding, excessive residual feeding or lack of digestion, altered gag reflex

Risk for deficient **Fluid** volume: Risk factor: inadequate water administration with concentrated feeding

Risk for imbalanced **Nutrition**: less than body requirements: Risk factors: intolerance to tube feeding, inadequate calorie replacement to meet metabolic needs

Tuberculosis (TB)

See *TB (Pulmonary Tuberculosis)*

TURP (Transurethral Resection of the Prostate)

Deficient **Knowledge** r/t postoperative self-care, home maintenance management

Acute **Pain** r/t incision, irritation from catheter, bladder spasms, kidney infection

Urinary retention r/t obstruction of urethra or catheter with clots

Risk for **Bleeding**: Risk factor: surgery

Risk for deficient **Fluid** volume: Risk factors: fluid loss, possible bleeding

Risk for urge urinary **Incontinence**: Risk factor: edema from surgical procedure

Risk for **Infection**: Risk factors: invasive procedure, route for bacteria entry

U

U

Ulcer, Peptic (Duodenal or Gastric)

Fatigue r/t loss of blood, chronic illness

Ineffective **Health** maintenance r/t lack of knowledge regarding health practices to prevent ulcer formation

Nausea r/t gastrointestinal irritation

Acute **Pain** r/t irritated mucosa from acid secretion

Risk for ineffective **Gastrointestinal** perfusion: Risk factor: ulcer

See *GI Bleed (Gastrointestinal Bleeding)*

Ulcerative Colitis

See *Inflammatory Bowel Disease (Child and Adult)*

Ulcers, Stasis

See *Stasis Ulcer*

Unilateral Neglect of One Side of Body

Unilateral Neglect (See **Unilateral Neglect**, Section III)

Unsanitary Living Conditions

Impaired **Home** maintenance r/t impaired cognitive or emotional functioning, lack of knowledge, insufficient finances, addiction

Risk for **Allergy** response: Risk factor: exposure to environmental contaminants

Urgency to Urinate

Urge urinary **Incontinence** (See **Incontinence**, urinary, urge, Section III)

Risk for urge urinary **Incontinence** (See **Incontinence**, urinary, urge, risk for, Section III)

Urinary Catheter

Risk for urinary tract **Injury**: Risk factors: confused client, long-term use of catheter, large retention balloon or catheter, perirectal burn injured client

Urinary Diversion

See *Ileal Conduit*

Urinary Elimination, Impaired

Impaired **Urinary** elimination (See **Urinary** elimination, impaired, Section III)

Urinary Incontinence

See *Incontinence of Urine*

Urinary Retention

Urinary Retention (See **Urinary Retention**, Section III)

Urinary Tract Infection (UTI)

See *UTI (Urinary Tract Infection)*

Urolithiasis

See *Kidney Stone*

Uterine Atony in Labor

See *Dystocia*

Uterine Atony in Postpartum

See *Postpartum Hemorrhage*

Uterine Bleeding

See *Hemorrhage; Postpartum Hemorrhage; Shock, Hypovolemic*

UTI (Urinary Tract Infection)

Ineffective **Health** maintenance r/t deficient knowledge regarding methods to treat and prevent UTIs, prolonged use of indwelling urinary catheter

Acute **Pain**: dysuria r/t inflammatory process in bladder

Impaired **Urinary** elimination: frequency r/t urinary tract infection

Risk for urge urinary **Incontinence**: Risk factor: hyperreflexia from cystitis

Risk for ineffective **Renal** perfusion: Risk factor: infection

List of Nursing Assessments by Letter: U

Ulcer, Peptic (Duodenal or Gastric)	Ulcerative Colitis	Ulcers, Stasis
Unilateral Neglect of One Side of Body	Unsanitary Living Conditions	Urgency to Urinate
Urinary Catheter	Urinary Diversion	Urinary Elimination, Impaired
Urinary Incontinence	Urinary Retention	Urinary Tract Infection (UTI)
Urolithiasis	Uterine Atony in Labor	Uterine Atony in Postpartum
Uterine Bleeding	UTI (Urinary Tract Infection)	

List of Nursing Assessments by Letter: V

VAD (Ventricular Assist Device)	Vaginal Hysterectomy	Vaginitis
Vagotomy	Value System Conflict	Varicose Veins
Vascular Dementia (Formerly Called Multiinfarct Dementia)	Vascular Obstruction, Peripheral	Vasectomy
Venereal Disease	Ventilated Client, Mechanically	Ventricular Assist Device (VAD)
Ventricular Fibrillation	Vertigo	Violent Behavior
Viral Gastroenteritis	Vision Impairment	Vomiting
VTE (Venous Thromboembolism)		

V

VAD (Ventricular Assist Device)

See *Ventricular Assist Device (VAD)*

Vaginal Hysterectomy

Urinary retention r/t edema at surgical site

Risk for urge urinary **Incontinence**: Risk factors: edema, congestion of pelvic tissues

Risk for **Infection**: Risk factor: surgical site

Risk for **Perioperative Positioning injury**: Risk factor: lithotomy position

Vaginitis

Impaired **Comfort** r/t pruritus, itching

Ineffective **Health maintenance** r/t deficient knowledge regarding self-care with vaginitis

Ineffective **Sexuality** pattern r/t abstinence during acute stage, pain

Vagotomy

See *Abdominal Surgery*

Value System Conflict

Decisional Conflict r/t unclear personal values or beliefs

Spiritual distress r/t challenged value system

Readiness for enhanced **Spiritual well-being**: desire for harmony with self, others, higher power, God

Varicose Veins

Ineffective **Health maintenance** r/t deficient knowledge regarding health care practices, prevention, treatment regimen

Chronic **Pain** r/t impaired circulation

Ineffective peripheral **Tissue Perfusion** r/t venous stasis

Risk for impaired **Tissue integrity**: Risk factor: altered peripheral tissue perfusion

Vascular Dementia (Formerly Called Multiinfarct Dementia)

See *Dementia*

Vascular Obstruction, Peripheral

Anxiety r/t lack of circulation to body part

Acute **Pain** r/t vascular obstruction

Ineffective peripheral **Tissue Perfusion** r/t interruption of circulatory flow

Risk for **Peripheral Neurovascular dysfunction**: Risk factor: vascular obstruction

Vasectomy

Decisional Conflict r/t surgery as method of permanent sterilization

Venereal Disease

See *STD (Sexually Transmitted Disease)*

Ventilated Client, Mechanically

Ineffective **Airway clearance** r/t increased secretions, decreased cough and gag reflex

Ineffective **Breathing pattern** r/t decreased energy and fatigue as a result of possible altered nutrition: less than body requirements, neurological disease or damage

Impaired verbal **Communication** r/t presence of endotracheal tube, inability to phonate

Fear r/t inability to breathe on own, difficulty communicating

Impaired **Gas exchange** r/t ventilation-perfusion imbalance

Powerlessness r/t health treatment regimen

Social isolation r/t impaired mobility, ventilator dependence

Impaired spontaneous **Ventilation** r/t metabolic factors, respiratory muscle fatigue

Dysfunctional **Ventilatory weaning response** r/t psychological, situational, physiological factors

Risk for **Falls**: Risk factors: impaired mobility, decreased muscle strength

Risk for **Infection**: Risk factors: presence of endotracheal tube, pooled secretions

Risk for pressure **Ulcer**: Risk factor: decreased mobility

Risk for impaired **Resilience**: Risk factor: illness

See *Child with Chronic Condition; Hospitalized Child; Respiratory Conditions of the Neonate*

Ventricular Assist Device (VAD)

Anxiety r/t possible failure of device

Risk for **Infection**: Risk factor: device insertion site

Risk for **Vascular Trauma**: Risk factor: insertion site

Readiness for enhanced **Decision-Making**: expresses desire to enhance the understanding of the meaning of choices regarding implanting a ventricular assist device

See *Open Heart Surgery*

Ventricular Fibrillation

See *Dysrhythmia*

Vertigo

See *Syncope*

Violent Behavior

Risk for other-directed **Violence** (See **Violence, other-directed, risk for, Section III**)

Risk for self-directed **Violence** (See **Violence, self-directed, risk for, Section III**)

Viral Gastroenteritis

Diarrhea r/t infectious process, Norovirus

Deficient **Fluid volume** r/t vomiting, diarrhea

Ineffective **Health management** r/t inadequate handwashing

See *Gastroenteritis, Child*

Vision Impairment

Fear r/t loss of sight

Social isolation r/t altered state of wellness, inability to see

Vision Loss r/t impaired visual function; integration; reception; and or transmission

Risk for impaired **Resilience**: Risk factor: presence of new crisis
See *Blindness; Cataracts; Glaucoma*

Vomiting

Nausea r/t chemotherapy, postsurgical anesthesia, irritation to the gastrointestinal system, stimulation of neuropharmacological mechanisms

Imbalanced **Nutrition**: less than body requirements r/t inability to ingest food

Risk for **Electrolyte** imbalance: Risk factor: vomiting

VTE (Venous Thromboembolism)

See *DVT (Deep Vein Thrombosis)*

W

Walking Impairment

Impaired **Walking** (See *Walking, impaired, Section III*)

Wandering

Wandering (See *Wandering, Section III*)

Weakness

Fatigue r/t decreased or increased metabolic energy production

Risk for **Falls**: Risk factor: weakness

Weight Gain

Overweight (See *Overweight, Section III*)

Weight Loss

Imbalanced **Nutrition**: less than body requirements r/t inability to ingest food because of biological, psychological, economic factors

Wellness-Seeking Behavior

Readiness for enhanced **Health** management: expresses desire for increased control of health practice

Wernicke-Korsakoff Syndrome

See *Korsakoff's Syndrome*

West Nile Virus

See *Meningitis/Encephalitis*

Wheelchair Use Problems

Impaired wheelchair **Mobility** (See *Mobility, wheelchair, impaired, Section III*)

Wheezing

Ineffective **Airway** clearance r/t tracheobronchial obstructions, secretions

Wilms' Tumor

Chronic functional **Constipation** r/t obstruction associated with presence of tumor

Acute **Pain** r/t pressure from tumor

See *Chemotherapy; Hospitalized Child; Radiation Therapy; Surgery, Preoperative Care; Surgery, Perioperative Care; Surgery, Postoperative Care*

Withdrawal from Alcohol

See *Alcohol Withdrawal*

Withdrawal from Drugs

See *Drug Withdrawal*

Wound Debridement

Acute **Pain** r/t debridement of wound

Impaired **Tissue** integrity r/t debridement, open wound

Risk for **Infection**: Risk factors: open wound, presence of bacteria

Wound Dehiscence, Evisceration

Fear r/t client fear of body parts "falling out," surgical procedure not going as planned

Disturbed **Body Image** r/t change in body structure and wound appearance

Imbalanced **Nutrition**: less than body requirements r/t inability to digest nutrients, need for increased protein for healing

Risk for deficient **Fluid** volume: Risk factors: inability to ingest nutrients, obstruction, fluid loss

Risk for **Injury**: Risk factor: exposed abdominal contents

Risk for delayed **Surgical** recovery: Risk factors: separation of wound, exposure of abdominal contents

Wound Infection

Disturbed **Body Image** r/t open wound

Imbalanced **Nutrition**: less than body requirements r/t biological factors, infection, fever

Ineffective **Thermoregulation** r/t infection in wound resulting in fever

Impaired **Tissue** integrity r/t wound, presence of infection

Risk for imbalanced **Fluid** volume: Risk factor: increased metabolic rate

Risk for **Infection**: spread of: Risk factor: imbalanced nutrition: less than body requirements

Risk for delayed **Surgical** recovery: Risk factor: presence of infection

Wounds, Open

See *Lacerations*

SECTION

III

Guide to Planning Care

Section III is a collection of NANDA-I nursing diagnosis care plans. The care plans are arranged alphabetically by diagnostic concept. They contain definitions, defining characteristics, and related factors if appropriate. Risk Diagnoses, however, only contain “risk factors.” Care plans include suggested outcomes and interventions for all nursing diagnoses.

MAKING AN ACCURATE NURSING DIAGNOSIS

Verify the accuracy of the previously suggested nursing diagnoses (from Section II) or from alphabetized list (inside back cover) for the client.

STEPS

- Read the definition for the suggested nursing diagnosis and determine if it is appropriate.
- Compare the Defining Characteristics with the symptoms that were identified from the client data collected.

or

- Compare the Risk Factors with the factors that were identified from the client data collected.

WRITING OUTCOMES STATEMENTS AND NURSING INTERVENTIONS

After selecting the appropriate nursing diagnosis, use this section to write outcomes and interventions:

STEPS

- Use the Client Outcomes/Nursing Interventions as written by the authors and contributors (select ones that are appropriate for your client).

or

- Use the NOC/NIC outcomes and interventions (as appropriate for your client).
- Read the rationales; the majority of rationales are based on nursing or clinical research that validates the efficacy of the interventions. Every attempt has been made to utilize current references; however, some significant research has not been replicated. Important research studies that are older than 5 years are included because they are the only evidence available. They are designated as **CEB** (Classic Evidence-Based).

Following these steps, you will be able to write an evidence-based nursing care plan.

- Follow this care plan to administer nursing care to the client.
- Document all steps and evaluate and update the care plan as needed.

List of Nursing Diagnoses by Letter: A

Activity intolerance	Risk for Activity intolerance	Ineffective Activity planning
Risk for Ineffective Activity planning	Ineffective Airway clearance	Risk for Allergy response
Anxiety	Death Anxiety	Risk for Aspiration
Risk for impaired Attachment	Autonomic Dysreflexia	Risk for Autonomic Dysreflexia

Activity intolerance *Lorraine Duggan, MSN, ACNP-BC*

NANDA-I

Definition

Insufficient physiological or psychological energy to endure or complete required or desired daily activities

Defining Characteristics

Abnormal blood pressure response to activity; abnormal heart rate response to activity; ECG change (e.g., arrhythmia, conduction abnormality, ischemia); exertional discomfort; exertional dyspnea; fatigue; generalized weakness

Related Factors (r/t)

Bed rest; generalized weakness; imbalance between oxygen supply/demand; immobility; sedentary lifestyle

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Activity Tolerance; Endurance; Energy Conservation; Self-Care: Instrumental Activities of Daily Living (IADLs)

Example NOC Outcome with Indicators

Activity Tolerance as evidenced by the following indicators: Oxygen saturation with activity/Pulse rate with activity/Respiratory rate with activity/Blood pressure with activity/Electrocardiogram findings/Skin color/Walking distance. (Rate the outcome and indicators of **Activity Tolerance**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Participate in prescribed physical activity with appropriate changes in heart rate, blood pressure, and breathing rate; maintain monitor patterns (rhythm and ST segment) within normal limits
- State symptoms of adverse effects of exercise and report onset of symptoms immediately
- Maintain normal skin color; skin is warm and dry with activity
- Verbalize an understanding of the need to gradually increase activity based on testing, tolerance, and symptoms
- Demonstrate increased tolerance to activity

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Activity Therapy; Energy Management; Exercise Therapy: Ambulation

Example NIC Activities—Energy Management

Monitor cardiorespiratory response to activity; Monitor location and nature of discomfort or pain during movement/activity

Nursing Interventions and Rationales

- Determine cause of Activity intolerance (see Related Factors) and determine whether cause is physical, psychological, or motivational. **QSEN**: *As nurses we are called upon to assure higher levels of safety and quality for our clients by our governments, professional organizations, and hospital administrations. It is essential that we implement evidence-based nursing care strategies to reduce avoidable errors in care so that clinical outcomes improve (Vollman, 2013).*

- If mainly on bed rest, minimize cardiovascular deconditioning by positioning the client in an upright position several times daily if possible. **CEB:** *With bed rest there is a shift of fluids from the extremities to the thoracic cavity from the loss of gravitational stress. Positioning in an upright position helps maintain optimal fluid distribution and maintain orthostatic tolerance (Perme & Chandrashekar, 2009).*
- Assess the client daily for appropriateness of activity and bed rest orders. Mobilize the client as soon as possible. **EB:** *Mobilization is a cost-effective and simple method of maintaining stable cardiovascular parameters (i.e., blood pressure, heart rate), countering orthostatic intolerance, and reducing the risk of secondary problems in clients during long-term immobilization (Wieser, 2014).*
- If the client is mostly immobile, consider use of a transfer chair: a chair that becomes a stretcher. **CEB:** *Using a transfer chair where the client is pulled onto a flat surface and then seated upright in the chair can help previously immobile clients get out of bed (Perme & Chandrashekar, 2009).*
- When appropriate, gradually increase activity, allowing the client to assist with positioning, transferring, and self-care as able. Progress the client from sitting in bed to dangling, to standing, to ambulation. Always have the client dangle at the bedside before standing to evaluate for postural hypotension. **EB:** *A reduction in plasma volume associated with bed rest impacts the physiological responses of autonomic control of circulation (Dorantes-Mendez et al, 2013).*
- When getting a client up, observe for symptoms of intolerance such as nausea, pallor, dizziness, visual dimming, and impaired consciousness, as well as changes in vital signs; manual blood pressure monitoring is best. *When an adult rises to the standing position, blood pools in the lower extremities; symptoms of central nervous system hypoperfusion may occur, including feelings of weakness, nausea, headache, lightheadedness, dizziness, blurred vision, fatigue, tremulousness, palpitations, and impaired cognition. EBN:* *Automatic devices cannot reliably detect or rule out orthostatic hypotension, indicating that nurses need to use manual devices to take accurate postural blood pressures for optimal client care (Dind et al, 2011).*
- If the client has symptoms of postural hypotension, such as dizziness, lightheadedness, or pallor, take precautions, such as dangling the client and applying leg compression stockings before the client stands. **EB:** *Put graduated compression stockings on the client or use lower limb compression bandaging, if ordered, to return blood to the heart and brain. Have the client dangle at the side of the bed with legs hanging over the edge of the bed, flexing and extending the feet several times after sitting up, then standing slowly with someone holding the client. If the client becomes lightheaded or dizzy, return him to bed immediately (Tibaldi et al, 2014).*
- Perform range-of-motion (ROM) exercises if the client is unable to tolerate activity or is mostly immobile. See care plan for Risk for **Disuse** syndrome.
- Monitor and record the client's ability to tolerate activity: note pulse rate, blood pressure, respiratory pattern, dyspnea, use of accessory muscles, and skin color before, during, and after the activity. If the following signs and symptoms of cardiac decompensation develop, activity should be stopped immediately:
 - Onset of chest discomfort or pain
 - Dyspnea
 - Palpitations
 - Excessive fatigue
 - Lightheadedness, confusion, ataxia, pallor, cyanosis, nausea, or any peripheral circulatory insufficiency
 - Dysrhythmia
 - Exercise hypotension
 - Excessive rise in blood pressure
 - Inappropriate bradycardia
 - Increased heart rate
 - Decreased oxygen saturation

The above are symptoms of intolerance to activity and continuation of activity may result in client harm (Goldman, 2011).

- ▲ Instruct the client to stop the activity immediately and report to the health care provider if the client is experiencing the following symptoms: new or worsened intensity or increased frequency of discomfort; tightness or pressure in chest, back, neck, jaw, shoulders, and/or arms; palpitations; dizziness; weakness; unusual and extreme fatigue; excessive air hunger. *Pulse rate and arterial blood oxygenation indicate cardiac/exercise tolerance; pulse oximetry identifies hypoxia (Goldman, 2011).*

- Observe and document skin integrity several times a day. **Activity intolerance**, if resulting in immobility, may lead to pressure ulcers. Mechanical pressure, moisture, friction, and shearing forces all predispose to their development. Refer to the care plan Risk for impaired **Skin** integrity.
- Assess for constipation. If present, refer to care plan for **Constipation**. **Activity intolerance** is associated with increased risk of **Constipation**.
- ▲ Refer the client to physical therapy to help increase activity levels and strength.
- ▲ Consider a dietitian referral to assess nutritional needs related to **Activity intolerance**; provide nutrition as indicated. If the client is unable to eat food, use enteral or parenteral feedings as needed.
- Recognize that malnutrition causes significant morbidity due to the loss of lean body mass.
- Provide emotional support and encouragement to the client to gradually increase activity. Work with the client to set mutual goals that increase activity levels. Fear of breathlessness, pain, or falling may decrease willingness to increase activity. **EB**: *In clients with Parkinson's disease, motivations for exercising included hope that exercise would slow the disease or prevent a decline in function, feeling better with exercise, belief that exercise is beneficial, and encouragement from family members (Ene et al, 2011).*
- ▲ Observe for pain before activity. If possible, treat pain before activity and ensure that the client is not heavily sedated. *Pain restricts the client from achieving a maximal activity level and is often exacerbated by movement.*
- ▲ Obtain any necessary assistive devices or equipment needed before ambulating the client (e.g., walkers, canes, crutches, portable oxygen).
- ▲ Use a gait walking belt when ambulating the client. **CEB**: *Gait belts improve the caregiver's grasp, reducing the incidence of injuries in clients and nurses (Nelson et al, 2003).*
- ▲ Use evidence-based practices for safe client handling to reduce the risk of injury for both clients and health care workers (Elmitsky et al, 2014).

Activity Intolerance Due to Respiratory Disease

- If the client is able to walk and has chronic obstructive pulmonary disease (COPD), use the traditional 6-minute walk distance to evaluate ability to walk.
- ▲ Ensure that the chronic pulmonary client has oxygen saturation testing with exercise. Use supplemental oxygen to keep oxygen saturation 90% or above or as prescribed with activity. *Oxygen therapy can improve exercise ability and long-term administration of oxygen can increase survival in clients with COPD (Gold Report, 2012).*
- Monitor a respiratory client's response to activity by observing for symptoms of respiratory intolerance, such as increased dyspnea, loss of ability to control breathing rhythmically, use of accessory muscles, nasal flaring, appearance of facial distress, and skin tone changes such as pallor and cyanosis.
- Instruct and assist the client with COPD in using conscious, controlled breathing techniques during exercise, including pursed-lip breathing, and inspiratory muscle use.
- ▲ Evaluate the client's nutritional status. Refer to a dietitian if indicated. Use nutritional supplements to increase nutritional level if needed.
- ▲ For the client in the intensive care unit, consider mobilizing the client with passive exercise. **Ebn**: *Nurses should consider incorporating at least 20 minutes of passive exercise early in the plan of care for critically ill clients treated with mechanical ventilation so that opportunities to improve client outcomes are not missed (Amidei & Sole, 2013).*
- ▲ Refer the COPD client to a pulmonary rehabilitation program. **EB**: *Pulmonary rehabilitation is a highly effective and safe intervention to reduce hospital admissions and mortality and to improve health-related quality of life in clients with COPD who have recently suffered an exacerbation (Puhan et al, 2009).*

Activity Intolerance Due to Cardiovascular Disease

- If the client is able to walk and has heart failure, consider use of the 6-minute walk test to determine physical ability.
- Allow for periods of rest before and after planned exertion periods such as meals, baths, treatments, and physical activity.
- ▲ Refer to a heart failure program or cardiac rehabilitation program for education, evaluation, and guided support to increase activity and rebuild life. **EB**: *Exercise-based cardiac rehabilitation is effective in reducing total and cardiovascular mortality and hospital admissions (Heran et al, 2011).*
- ▲ Refer to a community support program that includes support of significant others.

- ▲ **EB:** Contemporary studies now suggest that behavior change and multifactorial risk factor modification—especially smoking cessation and more intensive measures to control hyperlipidemia with diet, drugs, and exercise—may slow, halt, or even reverse (albeit modestly) the otherwise inexorable progression of atherosclerotic CHD (Spring, 2013).
- See care plan for Decreased **Cardiac** output for further interventions.

Pediatric

- Focus interview questions toward exercise tolerance specifically including any history of asthma exacerbations. **EB:** Cardiopulmonary deconditioning should be considered as an important differential diagnosis for breathlessness among obese adolescents. Some of these children may need pulmonary rehabilitation if difficulty breathing is the perceived reason for not exercising (Shim et al, 2013).

Geriatric

- Slow the pace of care. Allow the client extra time to carry out physical activities. *Slow gait in older adults may be related to fear of falling, decreased strength in muscles, reduced balance or visual acuity, knee flexion contractures, and foot pain.* **QSEN:** Older patients with chronic cardiac conditions are more vulnerable to falls and injuries. Cardiovascular conditions, prevalent in older people, are also the frequent cause of potentially harmful fall injuries in this group. The need to identify the fall risk-related factors that cluster with arrhythmia and syncope is relevant, in that it will potentially reduce patients' risk for falls and fall injuries (Belita et al, 2013).
- Encourage families to help/allow an older client to be independent in whatever activities possible. **EB:** Physical activity and cognitive exercise may improve memory and executive functions in older people with mild cognitive impairment (Teixeira et al, 2012).
- ▲ Assess for swaying, poor balance, weakness, and fear of falling while older clients stand/walk. Refer to physical therapy if appropriate. **CEB:** Fear of falling and repeat falling is common in the older population. Balance rehabilitation provides individualized treatment for persons with various deficits associated with balance (Studer, 2008). Refer to the care plan for Risk for **Falls** and Impaired **Walking**.
- ▲ Initiate ambulation by simply ambulating a patient a few steps from bed to chair, once a health care provider's out-of-bed order is obtained. **EBN:** Lack of ambulation and deconditioning effects of bed rest are one of the most predictable causes of loss of independent ambulation in hospitalized older persons. Nurses have been identified as the professional most capable of promoting walking independence in the hospital setting (Doherty-King & Bowers, 2013).
- ▲ Evaluate medications the client is taking to see if they could be causing **Activity** intolerance. **EB:** Medications such as beta-blockers; lipid lowering agents, which can damage muscle; antipsychotics, which have a common side effect of orthostatic hypotension; some antihypertensives; and lowering the blood pressure to normal in older adults can result in decreased functioning (Society, 2012).
- ▲ If heart disease is causing **Activity** intolerance, refer the client for cardiac rehabilitation.
- ▲ Refer the disabled older client to physical therapy for functional training including gait training, stepping, and sit-to-stand exercises, or for strength training. **CEB:** A Cochrane review found that progressive resistance strength training to improve function is effective in older clients (Liu & Latham, 2009).

Home Care

- ▲ Begin discharge planning as soon as possible with the case manager or social worker to assess the need for home support systems and the need for community or home health services. **EB:** Home-based exercise appears more effective in increasing daily ambulatory activity in the community setting than supervised exercise in clients with intermittent claudication (Gardner et al, 2011).
- ▲ Assess the home environment for factors that contribute to decreased activity tolerance such as stairs or distance to the bathroom. Refer the client for occupational therapy, if needed, to assist the client in restructuring the home and ADL patterns. *During hospitalization, clients and families often estimate energy requirements at home inaccurately because the hospital's availability of staff support distorts the level of care that will be needed.*
- ▲ Refer the client for physical therapy for strength training and possible weight training to regain strength, increase endurance, and improve balance. If the client is homebound, the physical therapist can also initiate cardiac rehabilitation.
- Encourage progress with positive feedback. *The client's experience should be validated within expected norms. Recognition of progress enhances motivation.*

- Teach the client/family the importance of and methods for setting priorities for activities, especially those having a high energy demand (e.g., home/family events). Instruct in realistic expectations.
- Encourage routine low-level exercise periods such as a daily short walk or chair exercises. **EB:** *Older adults participating in low levels of regular exercise can establish and maintain a home-based exercise program that yields immediate and long-term physical and affective benefits (Teri et al, 2011).*
- Provide the client/family with resources such as senior centers, exercise classes, educational and recreational programs, and volunteer opportunities that can aid in promoting socialization and appropriate activity. *Social isolation can be an outcome of and contribute to Activity intolerance.* **EB:** *Community-based resistance training and dietary modifications can improve body composition, muscle strength, and physical function in overweight and obese older adults (Straight et al, 2011).*
- Instruct the client and family in the importance of maintaining proper nutrition.
- Instruct the client in use of dietary supplements as indicated. *Illness may suppress appetite, leading to inadequate nutrition.*
- ▲ Refer to medical social services as necessary to assist the family in adjusting to major changes in patterns of living because of **Activity** intolerance.
- ▲ Assess the need for long-term supports for optimal activity tolerance of priority activities (e.g., assistive devices, oxygen, medication, catheters, massage), especially for a hospice client. Evaluate intermittently.
- ▲ Refer to home health aide services to support the client and family through changing levels of activity tolerance. Introduce aide support early. Instruct the aide to promote independence in activity as tolerated.
- Allow terminally ill clients and their families to guide care. Control by the client or family respects their autonomy and promotes effective coping.
- Provide increased attention to comfort and dignity of the terminally ill client in care planning. *Interventions should be provided as much for psychological effect as for physiological support. For example, oxygen may be more valuable as a support to the client's psychological comfort than as a booster of oxygen saturation.*
- ▲ Institute case management of frail elderly to support continued independent living.

Client/Family Teaching and Discharge Planning

- Instruct the client on techniques for avoiding **Activity** intolerance, such as controlled breathing techniques.
- Teach the client techniques to decrease dizziness from postural hypotension when standing up.
- Help client with energy conservation and work simplification techniques in ADLs.
- Describe to the client the symptoms of **Activity** intolerance, including which symptoms to report to the physician.
- Explain to the client how to use assistive devices, oxygen, or medications before or during activity.
- Help the client set up an activity log to record exercise and exercise tolerance.

Risk for Activity intolerance

Betty J. Ackley, MSN, EdS, RN, and Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

NANDA-I

Definition

Vulnerable to insufficient physiological or psychological energy to endure or complete required or desired daily activities, which may compromise health

Risk Factors

Circulatory problems; History of previous intolerance; Inexperience with an activity; Physical deconditioning; Respiratory condition

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan for **Activity** intolerance.

Ineffective Activity planning

Annie Muller, DNP, APN-BC, and Gail B. Ladwig, MSN, RN

NANDA-I

Definition

Inability to prepare for a set of actions fixed in time and under certain conditions

Defining Characteristics

Absence of plan; excessive anxiety about a task to be undertaken; insufficient organizational skills; insufficient resources (e.g., financial social, knowledge); pattern of failure; pattern of procrastination; unmet goals for chosen activity; worry about a task to be undertaken

Related Factors

Flight behavior when faced with proposed solution; hedonism; insufficient information processing ability; insufficient social support; unrealistic perception of event; unrealistic perception of personal abilities

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cognition; Cognition Orientation; Concentration; Decision-Making; Information Processing; Memory

Example NOC Outcome with Indicators

Cognition as evidenced by the following indicators: Communication clear and appropriate for age/Comprehension of the meaning of situations/Information processing/Alternatives weighed when making decisions. (Rate the outcome and indicators of **Cognition**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Patient Outcomes

Patient Will (Specify Time Frame)

- Verbalize need for self-directed activity
- Choose the health care option that fits his or her lifestyle within an appropriate amount of time that allows enactment of the choice
- Describe how the chosen option fits into current lifestyle before or after the decision has been made
- Verbalize the need for a behavioral change to improve physical activity

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Anxiety Reduction; Behavior Management; Behavior Modification; Calming Technique; Coping Enhancement; Decision-Making Support; Life Skills Enhancement; Planning Assistance; Sequence Guidance

Example NIC Activities—Coping Enhancement

Assist client in developing an objective appraisal of the event; Explore with client previous methods of dealing with life problems

Nursing Interventions and Rationales

- Ask the client how he or she perceives the situation in order to gather his personal vision of the problem and how they envisage their self-involvement. Specify the goals. *Clients and caregivers may have different priorities on what is important (Junius-Walker et al, 2011).*
 - Identify the informational needs of the client: understanding of the client's state of health, supervision of client's treatment if he or she is receiving treatment, diet, and important telephone numbers. **EBN:** *This study of clients with stage 4 chronic kidney disease validated the need for an individual assessment to determine the unique informational needs of each person (Lewis et al, 2010).*
 - Tackle the client's fears and worries and encourage him to make a cognitive reconstruction. Use "desire thinking." Drill and repeat: "I can change false ideas that make me believe that I am unable to carry out (achieve) my plan." **EBN:** *Desire thinking is a voluntary cognitive process involving verbal and imaginal elaboration of a desired target. Recent research has highlighted the role of desire thinking in the maintenance of addictive, eating, and impulse control disorders (Caselli & Spada, 2011).*
- Client verbalizes need for behavioral change for improved physical activity. **EB:** *This study reflects how combining planning and coping planning of a client's self-worth can be beneficial in promoting an exercise program for those individuals who lack self-esteem (Kroon et al, 2014).*
- Encourage clients to verbalize the need for physical activity to help reduce role overload. **EB:** *This study demonstrated the need for planning activities for those individuals who were experiencing a role overload in life to allow them time for leisure activities (Lovell & Butler, 2015).*
- ▲ Determine as fairly as possible the success factors needed for the planning and success of the project: financial resources; the family situation; prior medical, psychiatric, and psychosocial conditions; material resources; and the ability to manage stress. **EBN:** *Discussions identifying resources help to handle past resources, the functional solutions of everyday life, favorable changes, exceptions and differences in everyday*

life, the availability of support, and the prospects of future. By noting and providing feedback to families, the nurse offers families a new perspective on themselves (Häggman-Laitila et al, 2010).

Pediatric

- Begin activity planning in preschool-aged children of working parents. **EB:** *This study focused on the inactivity of migrant workers' preschool-aged children and the need to have a more structured and planned activity for the migrant worker. The focus was on the child because not much is known and very little research has been done. Also, there is a wide disparity of health in this population. The results showed very little physical activity was encouraged by parents and there was a great need for intervention to help with developing future healthy lifestyle for reducing potential long-term health problems (Grzywacz et al, 2014).*
- Establish a contract. **EBN:** *This study of adolescents with type 1 diabetes indicated that behavioral contracts may be an important adjunct to reduce nagging and improve outcomes with behavioral changes (Carroll et al, 2011).*
- Provide support to the schools for physical activities in all venues of schools. **EB:** *Depending on the location of the school and the available resources, schools may promote a physical activity program that is beneficial and available to the student. Schools with few resources have limited staff available, which can be a barrier to promoting a healthy lifestyle to the adolescent student. (Hobin et al, 2013).*

Geriatric

- Plan activities for older clients. **EB:** *In a study of stroke clients, it was found that physical activity may improve quality of life, physical function, and self-worth (Walter et al, 2015).*
- Plan activities for older clients with impaired mental function. **EB:** *In this study, it was found that clients with impaired mental function are often limited in their ability to become involved with planned physical activity; therefore, staff are needed to intervene and assist with the planned activity (Koring et al, 2012).*

Multicultural

- Provide literature and information in the appropriate language for the client who speaks little to no English. **EB:** *This study was able to show those clients who did not speak English fluently were not adequately prepared or educated to the needs for physical activity. Nor were they well represented in the study to show that culture was represented in understanding about cognitive health and risks of Alzheimer's disease (Rose et al, 2013).*
- Preplanning educational programs for the culturally diverse population needs to be developed. **EB:** *Low level of preplanning and poor organization of physical activities for the culturally diverse causes a loss of participation by those involved due to lack of understanding the concepts involved (Jeong et al, 2015).*

Home Care

- Have a preplanned activity exercise for the home client with a debilitating musculoskeletal disease to help improve functional status. **EB:** *This study showed an improvement for those clients who were homebound due to a musculoskeletal disorder, thereby improving their personal commitment to exercise for increasing their functional ability by gaining some muscle strength and range of motion (Hideyuki & Hitoshi, 2014).*
- Assess the home environment for barriers that can impact the client's motivation to be a participant in the activity planned. **EB:** *The research study done on homebound older adults showed that the client knew and understood the need for planned physical activity, but were not motivated to participate because they thought their age was a barrier. The idea is to teach the older client; while age may be a factor in some types of activity planning or exercise, there are many ways to adapt to the activity that can be accommodating to the client's ability (Burton et al, 2013).*
- For additional interventions, refer to care plans **Anxiety**, Readiness for enhanced family **Coping**, Readiness for enhanced **Decision-Making**, **Fear**, Readiness for enhanced **Hope**, Readiness for enhanced **Power**, Readiness for enhanced **Spiritual** well-being, and Readiness for enhanced **Health** management.

Risk for Ineffective Activity planning *Gail B. Ladwig, MSN, RN*

NANDA-I

Definition

Vulnerable to an inability to prepare for a set of actions fixed in time and under certain conditions, which may compromise health

Risk Factors

Flight behavior when faced with proposed solution; hedonism; insufficient information processing ability; insufficient social support; pattern of procrastination; unrealistic perception of event; unrealistic perception of personal abilities

NOC, NIC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to ineffective Activity planning.

Ineffective Airway clearance *Debra Siela, PhD, RN, CCNS, ACNS-BC, CCRN-K, CNE, RRT*

NANDA-I

Definition

Inability to clear secretions or obstructions from the respiratory tract to maintain a clear airway

Defining Characteristics

Absent cough; adventitious breath sounds; alteration in respiratory pattern; alteration in respiratory rate; cyanosis; difficulty verbalizing; diminished breath sounds; dyspnea; excessive sputum; ineffective cough; orthopnea; restlessness; wide-eyed look

Related Factors (r/t)

Environmental

Exposure to smoke; second-hand smoke; smoking

Obstructed Airway

Airway spasm; chronic obstructive pulmonary disease; exudate in the alveoli; excessive mucus; foreign body in airway; hyperplasia of bronchial walls; presence of artificial airway; retained secretions

Physiological

Allergic airways; asthma; infection; neuromuscular impairment

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Aspiration Prevention; Respiratory Status: Airway Patency, Gas Exchange, Ventilation

Example NOC Outcome with Indicators

Respiratory Status: Ventilation as evidenced by the following indicators: Respiratory rate/Respiratory rhythm/Depth of inspiration/Chest expansion symmetrical/Ease of breathing/Tidal volume/Vital capacity (Rate each indicator of **Respiratory Status: Ventilation**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

- Demonstrate effective coughing and clear breath sounds
- Maintain a patent airway at all times
- Explain methods useful to enhance secretion removal
- Explain the significance of changes in sputum to include color, character, amount, and odor
- Identify and avoid specific factors that inhibit effective airway clearance

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Airway Management; Airway Suctioning; Cough Enhancement

Example NIC Activities—Airway Management

Instruct how to cough effectively; Auscultate breath sounds, noting areas of decreased or absent ventilation and presence of adventitious sounds

Nursing Interventions and Rationales

- Auscultate breath sounds every 1 to 4 hours. *Breath sounds are normally clear or scattered fine crackles at bases, which clear with deep breathing. The presence of coarse crackles during late inspiration indicates fluid in the airway; wheezing indicates an airway obstruction (Fauci et al, 2008).*
- Monitor respiratory patterns, including rate, depth, and effort. *A normal respiratory rate for an adult without dyspnea is 12 to 16 breaths per minute (Bickley & Szilagy, 2012). With secretions in the airway, the respiratory rate will increase.*
- Monitor blood gas values and pulse oxygen saturation levels as available. An oxygen saturation of less than 90% (normal: 95% to 100%) or a partial pressure of oxygen of less than 80 mm Hg (normal: 80 to 100 mm Hg) indicates significant oxygenation problems (Schultz, 2011).
- ▲ Administer oxygen as ordered. *Oxygen administration has been shown to correct hypoxemia (Wong & Elliott, 2009).*
- Position the client to optimize respiration (e.g., head of bed elevated 30 to 45 degrees). *An upright position allows for maximal lung expansion; lying flat causes abdominal organs to shift toward the chest, which crowds the lungs and makes it more difficult to breathe. EB: In a mechanically ventilated client, there is a decreased incidence of ventilator-associated pneumonia if the client is positioned at a 30- to 45-degree semi-recumbent position rather than a supine position (Siela, 2010; Bell, 2011; Johanna Briggs Institute, 2014).*

- Help the client deep breathe and perform controlled coughing. Have the client inhale deeply, hold breath for several seconds, and cough two or three times with mouth open while tightening the upper abdominal muscles. **CEB:** *Controlled coughing uses the diaphragmatic muscles, making the cough more forceful and effective (Gosselink et al, 2008).*
- If the client has obstructive lung disease, such as chronic obstructive pulmonary disease (COPD), cystic fibrosis, or bronchiectasis, consider helping the client use the forced expiratory technique, the “huff cough.” The client does a series of coughs while saying the word “huff.” *This technique prevents the glottis from closing during the cough and is effective in clearing secretions (Bhowmik et al, 2009; Gosselink et al, 2008; GOLD, 2015).*
- ▲ Encourage the client to use an incentive spirometer. Recognize that controlled coughing and deep breathing may be just as effective as incentive spirometry (Gosselink et al, 2008).
- Encourage activity and ambulation as tolerated. If the client cannot be ambulated, turn the client from side to side at least every 2 hours. *Body movement helps mobilize secretions.* (See interventions for impaired **Gas** exchange for further information on positioning a respiratory patient.)
- Encourage fluid intake of up to 2500 mL/day within cardiac or renal reserve. *Fluids help minimize mucosal drying and maximize ciliary action to move secretions.*
- ▲ Administer medications such as bronchodilators or inhaled steroids as ordered. Watch for side effects such as tachycardia or anxiety with bronchodilators, or inflamed pharynx with inhaled steroids. *Bronchodilators decrease airway resistance, improve the efficiency of respiratory movements, improve exercise tolerance, and can reduce symptoms of dyspnea on exertion (Barnett, 2008).* *Pharmacologic therapy in COPD is used to reduce symptoms, reduce the frequency and severity of exacerbation, and improve health strategies and exercise tolerance (GOLD, 2015).*
- ▲ Provide percussion, vibration, and oscillation as appropriate (Gosselink et al, 2008).
- Observe sputum, noting color, odor, and volume. *Normal sputum is clear or gray and minimal; abnormal sputum is green, yellow, or bloody; malodorous; and often copious. The presence of purulent sputum during a COPD exacerbation can be sufficient indication for starting empirical antibiotic treatment. Notify health care provider of purulent sputum (GOLD, 2015).*

Critical Care

- ▲ In intubated patients, body positioning and mobilization may optimize airway secretion clearance. An early mobility and walking program can promote weaning from ventilator support as a patient’s overall strength and endurance improve (Gosselink et al, 2008; Perme & Chandrashekar, 2009).
- ▲ *Early mobility and physical rehabilitation can reduce muscle weakness, mechanical ventilation duration, intensive care unit stay, and hospital stay (Mendez-Tellez & Needham, 2012; Spruit et al, 2013).* *The Awakening and Breathing Coordination, Delirium Monitoring and Management, and Early Mobility (ABCDE) bundle has criteria to determine when patients are candidates for early mobility (Balas et al, 2012).* An early mobility and walking program can promote weaning from ventilator support as a patient’s overall strength and endurance improve (Gosselink et al, 2008; Perme & Chandrashekar, 2009).
- If the client is intubated and is stable, consider getting the client up to sit at the edge of the bed, transfer to a chair, or walk as appropriate, if an effective interdisciplinary team is developed to keep the client safe. *For every week of bedrest, muscle strength can decrease 20%; early ambulation also helped patients develop a positive outlook (Perme & Chandrashekar, 2009).*
- ▲ If the client is intubated, consider use of kinetic therapy, using a kinetic bed that slowly moves the client with 40-degree turns. *Rotational therapy may decrease the incidence of pulmonary complications in high-risk patients with increasing ventilator support requirements, who are at risk for ventilator-associated pneumonia, and with clinical indications for acute lung injury or acute respiratory distress syndrome with worsening Pao₂:FIO₂ ratio, presence of fluffy infiltrates via chest radiograph concomitant with pulmonary edema, and refractory hypoxemia (Bein et al, 2012).*
- Reposition the client as needed. Use rotational or kinetic bed therapy in clients for whom side-to-side turning is contraindicated or difficult. **EBN:** *Changing position frequently decreases the incidence of atelectasis, pooling of secretions, and resultant pneumonia (Burns, 2011).* **EB/EBN:** *Continuous, lateral rotational therapy has been shown to improve oxygenation and decrease the incidence of VAP (Burns, 2011).*
- When suctioning an endotracheal tube or tracheostomy tube for a client on a ventilator, do the following:

- Explain the process of suctioning beforehand and ensure the client is not in pain or overly anxious. *Suctioning can be a frightening experience; an explanation along with adequate pain relief or needed sedation can reduce stress, anxiety, and pain (Chulay & Seckel, 2011).*
- Hyperoxygenate before and between endotracheal suction sessions. *Studies have demonstrated that hyperoxygenation may help prevent oxygen desaturation in a suctioned client (Chulay & Seckel, 2011; Pedersen et al, 2009; Siela, 2010).*
- Suction for less than 15 seconds. *Studies demonstrated that because of a drop in the partial pressure of oxygen with suctioning, that preferably no more than 10 seconds be used actually suctioning, with the entire procedure taking 15 seconds (Chulay & Seckel, 2011; Pedersen et al, 2009).*
- Use a closed, in-line suction system. Closed in-line suctioning has minimal effects on heart rate, respiratory rate, tidal volume, and oxygen saturation (Chulay & Seckel, 2011; Seymour et al, 2009).
- Avoid saline instillation during suctioning. **EBN:** *Repeated studies have demonstrated that saline instillation before suctioning has an adverse effect on oxygen saturation in both adults and children (Chulay & Seckel, 2011; Rauen et al, 2008; Pedersen et al, 2009; Siela, 2010).*
- *Use of a subglottic suctioning endotracheal tube reduces the incidence of ventilator-associated pneumonia (VAP) or ventilator-associated complications (Hass et al, 2014).*
- *Use of nonstick endotracheal tubes can reduce the formation of biofilm and hence VAP (Haas et al, 2014).*
- Document results of coughing and suctioning, particularly client tolerance and secretion characteristics such as color, odor, and volume (Chulay & Seckel, 2011).

Pediatric

- Educate parents about the risk factors for ineffective airway clearance such as foreign body ingestion and passive smoke exposure.
- See the care plan Risk for **Suffocation** for more interventions on choking. **EB:** *Passive smoke exposure significantly increases the risk of respiratory infections in children (Chatzimicael et al, 2008).*
- Educate children and parents on the importance of adherence to peak expiratory flow monitoring for asthma self-management.
- Educate parents and other caregivers that cough and cold medication bought over the counter are not safe for a child younger than 2 unless specifically ordered by a health care provider. *Over-the-counter cold and cough medications are no longer recommended for children younger than age 2 unless recommended by a health care provider. Minimal data exist to support their effectiveness, and overuse can cause harm (Woo, 2008).*

Geriatric

- Encourage ambulation as tolerated without causing exhaustion. *Immobility is often harmful to older adults because it decreases ventilation and increases stasis of secretions, leading to atelectasis or pneumonia.*
- Actively encourage older adults to deep breathe and cough. *Cough reflexes are blunted, and coughing is decreased in older adults.*
- Ensure adequate hydration within cardiac and renal reserves. *Older adults are prone to dehydration and therefore more viscous secretions, because they frequently use diuretics or laxatives and forget to drink adequate amounts of water.*

Home Care

- Some of the above interventions may be adapted for home care use.
- ▲ Begin discharge planning as soon as possible with case manager or social worker to assess need for home support systems, assistive devices, and community or home health services.
- Assess home environment for factors that exacerbate airway clearance problems (e.g., presence of allergens, lack of adequate humidity in air, poor air flow, stressful family relationships).
- Assess affective climate within family and family support system. *Problems with respiratory function and resulting anxiety can provoke anger and frustration in the client. Feelings may be displaced onto caregiver and require intervention to ensure continued caregiver support.* Refer to care plan for **Caregiver Role Strain**.
- Refer to GOLD guidelines for management of home care and indications of hospital admission criteria. <http://www.goldcopd.org/>.

- When respiratory procedures are being implemented, explain equipment and procedures to family members and caregivers, and provide needed emotional support. *Family members assuming responsibility for respiratory monitoring often find this stressful. They may not have been able to assimilate fully any instructions provided by hospital staff.*
- When electrically based equipment for respiratory support is being implemented, evaluate home environment for electrical safety, proper grounding, and so on. Ensure that notification is sent to the local utility company, the emergency medical team, and police and fire departments.
- Provide family with support for care of a client with chronic or terminal illness. *Breathing difficulty can provoke extreme anxiety, which can interfere with the client's ability or willingness to adhere to the treatment plan.*
- Refer to care plan for **Anxiety**. *Witnessing breathing difficulties and facing concerns of dealing with chronic or terminal illness can create fear in caregiver. Fear inhibits effective coping.* Refer to care plan for **Powerlessness**.
- Instruct the client to avoid exposure to persons with upper respiratory infections, to avoid crowds of people, and wash hands after each exposure to groups of people, or public places.
- ▲ Determine client adherence to medical regimen. Instruct the client and family in importance of reporting effectiveness of current medications to health care provider. *Inappropriate use of medications (too much or too little) can influence amount of respiratory secretions.*
- Teach the client when and how to use inhalant or nebulizer treatments at home.
- Teach the client/family importance of maintaining regimen and having “as-needed” drugs easily accessible at all times. *Success in avoiding emergency or institutional care may rest solely on medication compliance or availability.*
- Instruct the client and family in the importance of maintaining proper nutrition, adequate fluids, rest, and behavioral pacing for energy conservation and rehabilitation.
- Instruct in use of dietary supplements as indicated. *Illness may suppress appetite, leading to inadequate nutrition. Supplements will allow clients to eat with minimal energy consumption.*
- Identify an emergency plan, including criteria for use. *Ineffective airway clearance can be life-threatening.*
- ▲ Refer for home health aide services for assistance with activities of daily living (ADLs). *Clients with decreased oxygenation and copious respiratory secretions are often unable to maintain energy for ADLs.*
- ▲ Assess family for role changes and coping skills. Refer to medical social services as necessary. *Clients with decreased oxygenation are unable to maintain role activities and therefore experience frustration and anger, which may pose a threat to family integrity. Family counseling to adapt to role changes may be needed.*
- ▲ For the client dying at home with a terminal illness, if the “death rattle” is present with gurgling, rattling, or crackling sounds in the airway with each breath, recognize that anticholinergic medications can often help control symptoms, if given early in the process. *Anticholinergic medications can help decrease the accumulation of secretions, but do not decrease existing secretions. This medication must be administered early in the process to be effective (Hipp & Letizia, 2009; Fielding & Long, 2014).*
- ▲ For the client with a death rattle, nursing care includes turning to mobilize secretions, keeping the head of the bed elevated for postural drainage of secretions, and avoiding suctioning. *Suctioning is a distressing and painful event for clients and families, and is rarely effective in decreasing the death rattle (Hipp & Letizia, 2009; Fielding & Long, 2014).*

Client/Family Teaching and Discharge Planning

- ▲ Teach the importance of not smoking. Refer to a smoking cessation program, and encourage clients who relapse to keep trying to quit. Ensure that the client receives appropriate medications to support smoking cessation from the primary health care provider. **EB**: *A systemic review of research demonstrated that the combination of medications and an intensive, prolonged counseling program supporting smoking cessation were effective in promoting long-term abstinence from smoking (Fiore et al, 2008).* A Cochrane review found that use of the antidepressant medications increased the rate of smoking withdrawal two to three times more than smoking withdrawal without use of medications (Hughes et al, 2014).
- ▲ Teach the client how to use a flutter clearance device if ordered, which vibrates to loosen mucus and gives positive pressure to keep airways open (Bhowmik et al, 2009; Gosselink et al, 2008). **CEB**: *A study demonstrated that use of the mucus clearance device had improved exercise performance compared with COPD clients who use a sham device (Wolkove et al, 2004).* A Cochrane review found that there was no clear

evidence that oscillation was more or less effective than other forms of physiotherapy for airway clearance in cystic fibrosis (Morrison & Agnew, 2009).

- ▲ Teach the client how to use peak expiratory flow rate (PEFR) meter if ordered and when to seek medical attention if PEFR reading drops. Also teach how to use metered dose inhalers and self-administer inhaled corticosteroids as ordered following precautions to decrease side effects.
- Teach the client how to deep breathe and cough effectively. **CEB:** *Controlled coughing uses the diaphragmatic muscles, making the cough more forceful and effective (Gosselink et al, 2008).*
- Teach the client/family to identify and avoid specific factors that exacerbate ineffective airway clearance, including known allergens and especially smoking (if relevant) or exposure to secondhand smoke.
- Educate the client and family about the significance of changes in sputum characteristics, including color, character, amount, and odor. *With this knowledge, the client and family can identify early the signs of infection and seek treatment before acute illness occurs.*
- Teach the client/family the importance of taking antibiotics as prescribed, consuming all tablets until the prescription has run out. *Taking the entire course of antibiotics helps eradicate bacterial infection, which decreases lingering, chronic infection.*
- Teach the family of the dying client in hospice with a death rattle that rarely are clients aware of the fluid that has accumulated, and help them find evidence of comfort in the client's nonverbal behavior (Hipp & Letizia, 2009; Fielding & Long, 2014).

Risk for Allergy response *Gail B. Ladwig, MSN, RN, and Marina Martinez-Kratz, MS, RN, CNE*

NANDA-I

Definition

Vulnerable to exaggerated immune response or reaction to substances which may compromise health

Risk Factors

Allergy to insect sting; exposure to allergen (e.g., pharmaceutical agent); exposure to environmental allergen (e.g., dander, dust, mold, pollen); exposure to toxic chemical; food allergy (e.g., avocado, banana, chestnut, kiwi, peanut, shellfish, mushroom, tropical fruit); repeated exposure to allergen-producing environmental substance

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Allergic Response: Systemic; Immune Hypersensitivity Response; Knowledge: Health Behavior, Risk Control, Risk Detection; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Immune Hypersensitivity Response as evidenced by the following indicators: Respiratory, cardiac, gastrointestinal, renal and neurological function status IER/Free of allergic reactions. (Rate each indicator of **Immune Hypersensitivity Response**: 1 = not controlled, 2 = slightly controlled, 3 = moderately controlled, 4 = well controlled, 5 = very well controlled [see Section I].) IER, In expected range.

Client Outcomes

Client Will (Specify Time Frame)

- State risk factors for allergies
- Demonstrate knowledge of plan to treat allergic reaction

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Allergy Management; Environmental Risk Protection

Example NIC Activity

Place an allergy band on client

Nursing Interventions and Rationales

- A careful history is important in detecting allergens and avoidance of allergen. **EB**: *Spice allergy is rare but spices are widely used and may be in cosmetics. The diagnoses depend on a good history and well-designed testing; treatment is strict avoidance (Chen & Bahna, 2011). Food allergy is among the most common of the allergic disorders. If food allergy or lactose intolerance is suspected, workup should include a detailed allergy-focused clinical history to determine whether the adverse reaction is typically an immediate*

(IgE-mediated) or more delayed-type (non-IgE-mediated) allergic reaction, or whether it may be lactose intolerance, a form of nonallergic hypersensitivity (Waddell, 2011).

- Obtain a precise history of allergies, as well as medications taken and foods ingested before surgery. **EBN:** A thorough nursing assessment of allergies supports and improves the plan of care by identifying the patient's risk factors (Cochico, 2012).
- ▲ Teach the client about correct use of the injectable epinephrine and have the client do a return demonstration. **EB:** Recent research on the correct use of the injectable epinephrine showed that 84% of the patients were unable to do correctly (Bonds et al, 2015).
- ▲ Carefully assess the client for allergies. Below is information that is important for clients with allergies. Refer for immediate treatment if anaphylaxis is suspected.

Causes

Common allergens include animal dander; bee stings or stings from other insects; foods, especially nuts, fish, and shellfish; insect bites; medications; plants; pollens

Symptoms

Common symptoms of a mild allergic reaction include hives (especially over the neck and face), itching, nasal congestion, rashes, watery, red eyes

Symptoms of a moderate or severe reaction include cramps or pain in the abdomen, chest discomfort or tightness, diarrhea, difficulty breathing, difficulty swallowing, dizziness or lightheadedness, fear or feeling of apprehension or anxiety, flushing or redness of the face, nausea and vomiting, palpitations, swelling of the face, eyes, or tongue, weakness, wheezing, unconsciousness

First Aid

For a mild to moderate reaction: Calm and reassure the person having the reaction, because anxiety can worsen symptoms.

1. Try to identify the allergen and have the person avoid further contact with it. If the allergic reaction is from a bee sting, scrape the stinger off the skin with something firm (e.g., fingernail or plastic credit card). Do not use tweezers; squeezing the stinger will release more venom.
2. Apply cool compresses and over-the-counter hydrocortisone cream for itchy rash.
3. Watch for signs of increasing distress.
4. Get medical help. For a mild reaction, a health care provider may recommend over-the-counter medications (e.g., antihistamines).

For a Severe Allergic Reaction (Anaphylaxis)

1. Check the person's airway, breathing, and circulation (the ABCs of Basic Life Support). A warning sign of dangerous throat swelling is a very hoarse or whispered voice, or coarse sounds when the person is breathing in air. If necessary, begin rescue breathing and cardiopulmonary resuscitation.
2. Call 911.
3. Calm and reassure the person.
4. If the allergic reaction is from a bee sting, scrape the stinger off the skin with something firm (e.g., fingernail or plastic credit card). Do not use tweezers; squeezing the stinger will release more venom.
5. If the person has emergency allergy medication on hand, help the person take or inject the medication. Avoid oral medication if the person is having difficulty breathing.
6. Take steps to prevent shock. Have the person lie flat, raise the person's feet about 12 inches, and cover him or her with a coat or blanket. Do NOT place the person in this position if a head, neck, back, or leg injury is suspected or if it causes discomfort.

Do NOT

- Do NOT assume that any allergy shots the person has already received will provide complete protection.
- Do NOT place a pillow under the person's head if he or she is having trouble breathing. This can block the airways.
- Do NOT give the person anything by mouth if the person is having trouble breathing.

When to Contact a Medical Professional

Call for immediate medical emergency assistance if:

- The person is having a severe allergic reaction—always call 911. Do not wait to see if the reaction is getting worse.
- The person has a history of severe allergic reactions (check for a medical ID tag).

Prevention

Avoid triggers such as foods and medications that have caused an allergic reaction (even a mild one) in the past. Ask detailed questions about ingredients when you are eating away from home. Carefully examine ingredient labels.

- If you have a child who is allergic to certain foods, introduce one new food at a time in small amounts so you can recognize an allergic reaction.
- People who know that they have had serious allergic reactions should wear a medical ID tag.
- Preoperative patients should be closely assessed for allergies to soybeans and eggs. **EBN:** *Allergies to soybeans and eggs contraindicate the use of propofol, a short-acting hypnotic commonly used in anesthesia (Cochico, 2012).*
- ▲ If you have a history of serious allergic reactions, carry emergency medications (e.g., a chewable form of diphenhydramine and injectable epinephrine or a bee sting kit) according to your health care provider's instructions.
- Do not use your injectable epinephrine on anyone else. They may have a condition (e.g., a heart problem) that could be negatively affected by this drug. **EB:** *Although first-time exposure may only produce a mild reaction, repeated exposures may lead to more serious reactions. Once a person has had an exposure or an allergic reaction (is sensitized), even a very limited exposure to a very small amount of allergen can trigger a severe reaction. Most severe allergic reactions occur within seconds or minutes after exposure to the allergen. However, some reactions can occur after several hours, particularly if the allergen causes a reaction after it has been eaten. In very rare cases, reactions develop after 24 hours.*
- Anaphylaxis is a sudden and severe allergic reaction that occurs within minutes of exposure. Immediate medical attention is needed for this condition. Without treatment, anaphylaxis can get worse very quickly and lead to death within 15 minutes (*Medline Plus, 2012*).
- ▲ Refer the client for skin testing to confirm IgE-mediated allergic response. **EB:** *Identifying clients who are less sensitive is important, so that they can be started on immunotherapy. An informal survey of low-reacting clients treated with immunotherapy showed a high degree of success (Boyles & John, 2011). Allergy testing serves to confirm an allergic trigger suspected on the basis of history (Sicherer & Wood, 2012).*
- See care plans for **Latex Allergy** response and Risk for **Latex Allergy** response.

Pediatric

- ▲ Teach parents and children with allergies to peanuts and tree nuts to avoid them and to identify them. **EB:** *Dietary avoidance is the primary management of these allergies and requires the ability to identify peanuts or tree nuts. Treatment of nut allergies with dietary avoidance should include education for both adults and children on identification of peanuts and tree nuts (Hostetler et al, 2012).*
- ▲ Teach parents and children with asthma about modifiable risk factors, which include allergy triggers. **EB:** *Attention to these allergy triggers will improve asthma control and reduce the burden of disease (Schatz, 2012).*
- ▲ Counsel parents to limit infant exposure to traffic-related air pollution. **EB:** *Recent research demonstrates that higher traffic-related air pollution exposure during infancy was associated with higher hyperactivity scores in children (Newman et al, 2013).*
- ▲ Suspect FPIES (food protein-induced enterocolitis syndrome) in formula-fed infants with repetitive emesis, diarrhea, dehydration, and lethargy 1 to 5 hours after ingesting the offending food (the most common are cow's milk, soy, and rice). Remove the offending food. **EB:** *Early recognition of FPIES and removal of the offending food is important to prevent misdiagnosis and mismanagement of symptoms from other causes. Close follow-up is required to determine when foods may be added back into the diet. FPIES typically occurs before 6 months of age. Diagnosis is made by history and physician-supervised oral food challenges (Leonard & Nowak-Węgrzyn, 2011).*
- ▲ Children should be screened for seafood allergies and avoid seafood and any foods containing seafood if an allergy is detected. **EB:** *Seafood allergy is now a leading cause of anaphylaxis in both the United States and Australia. This study confirmed a seafood as common and important cause of food allergy in Australian children, presenting with a high rate of anaphylaxis (Turner et al, 2011).*

Anxiety Ruth McCaffrey, DNP, ARNP, FNP-BC, GNP-BC, FAAN

NANDA-I

Definition

Vague, uneasy feeling of discomfort or dread accompanied by an autonomic response (the source often nonspecific or unknown to the individual); a feeling of apprehension caused by anticipation of danger. It is an alerting sign that warns of impending danger and enables the individual to take measures to deal with threat

Defining Characteristics

Behavioral

Decrease in productivity; extraneous movement; fidgeting; glancing about; hypervigilance; insomnia; poor eye contact; restlessness; scanning behavior; worry about change in life event

Affective

Anguish; apprehensiveness; distress; fear; feelings of inadequacy; helplessness; increase in wariness; irritability; jitteriness; overexcitement; rattled; regretful; self-focused; uncertain; worried

Physiological

Facial tension; hand tremors; increased perspiration; increased tension; shakiness; trembling; voice quivering

Sympathetic

Alteration in respiratory pattern; anorexia; brisk reflexes; cardiovascular excitation; diarrhea; dry mouth; facial flushing; heart palpitations; increase in blood pressure; increase in heart rate; increase in respiratory rate; pupil dilation; superficial vasoconstriction; twitching; weakness

Parasympathetic

Abdominal pain; alteration in sleep pattern; decrease in heart rate; decreased blood pressure; diarrhea; faintness; fatigue; nausea; tingling in extremities; urinary frequency; urinary hesitancy; urinary urgency

Cognitive

Alteration in attention; alteration in concentration; awareness of physiological symptoms; blocking of thoughts; confusion; decrease in perceptual field; diminished ability to learn; diminished ability to problem solve; fear; forgetfulness; preoccupation; rumination; tendency to blame others

A

Related Factors (r/t)

Conflict about life goals; exposure to toxin; family history of anxiety; heredity; interpersonal contagion; interpersonal transmission; major change (e.g., economic status, environment, health status, role function, role status); maturational crisis; situational crisis; stressors; substance abuse; threat of death; threat to current status; unmet needs; value conflict

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Aggression Self-Restraint; Anxiety Level; Anxiety Self-Control; Coping; Impulse Self-Control

Example NOC Outcome with Indicators

Anxiety Self-Control as evidenced by the following indicators: Eliminates precursors of anxiety/Monitors physical manifestations of anxiety/Controls anxiety response (Rate the outcome and indicators of **Anxiety Self-Control**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

- Identify and verbalize symptoms of anxiety
- Identify, verbalize, and demonstrate techniques to control anxiety
- Verbalize absence of or decrease in subjective distress
- Have vital signs that reflect baseline or decreased sympathetic stimulation
- Have posture, facial expressions, gestures, and activity levels that reflect decreased distress
- Demonstrate improved concentration and accuracy of thoughts
- Demonstrate return of basic problem-solving skills
- Demonstrate increased external focus
- Demonstrate some ability to reassure self

NIC (Nursing Interventions Classification)**Suggested NIC Intervention**

Anxiety Reduction

Example NIC Activities—Anxiety Reduction

Use calm, reassuring approach; Explain all procedures, including sensations likely to be experienced during the procedure

Nursing Interventions and Rationales

- Assess the client's level of anxiety and physical reactions to anxiety (e.g., tachycardia, tachypnea, nonverbal expressions of anxiety). Consider using the Hamilton Anxiety Scale, which grades 14 symptoms on a scale of 0 (not present) to 4 (very severe). Symptoms evaluated are mood, tension, fear, insomnia, concentration, worry, depressed mood, somatic complaints, and cardiovascular, respiratory, gastrointestinal, genitourinary, autonomic, and behavioral symptoms. **EBN**: *Generalized anxiety disorder (GAD) is the most common anxiety with a 12-month prevalence of 3.1% in population-based survey and between 5.3% and 7.6% among patients who visit primary care offices. The highest rate of GAD (7.7%) occurs in persons 45 to 49 years of age, and the lowest rate (3.6%) occurs in persons 60 years and older. Women are almost twice as likely as men to be diagnosed with GAD over their lifetime (Kavan et al, 2009).*
- Rule out withdrawal from alcohol, sedatives, or smoking as the cause of anxiety. **EB**: *Military personnel sent to war zones have higher levels of depression that are often exacerbated by alcohol and sedative use (Gale et al, 2010). When withdrawing from either sedatives or alcohol, participants in this study demonstrated elevated levels of anxiety and nervousness (McCabe et al, 2011).*
- Use empathy to encourage the client to interpret the anxiety symptoms as normal. **EBN**: *The way a nurse interacts with a client influences his/her quality of life. Providing psychological and social support can reduce*

the symptoms and problems associated with anxiety (Wagner & Bear, 2009). In another study, patients undergoing couples therapy felt significantly more trust and responded with more success to those therapists who provided empathetic and compassionate responses and suggestions (Benson et al, 2012).

- If irrational thoughts or fears are present, offer the client accurate information and encourage him or her to talk about the meaning of the events contributing to the anxiety. **EBN:** In one study providing cancer patients with accurate information about their disease, prognosis and outcomes significantly reduced their anxiety and increased empowerment (Lauzier et al, 2014).
- Encourage the client to use positive self-talk. **EBN:** Reducing negative self-talk and increasing positive self-talk can be beneficial for all types of anxiety (Hill, 2010). One research study showed that self-talk strengthens both actual behavior performance and prospective behavioral intentions (Dolcos & Albarracin, 2014).
- Intervene when possible to remove sources of anxiety. **EBN:** Removing or reducing sources of stress and anxiety among clients has been shown to decrease hypertension and comorbid conditions (Lobjanidze et al, 2010).
- Explain all activities, procedures, and issues that involve the client; use nonmedical terms and calm, slow speech. Do this in advance of procedures when possible, and validate the client's understanding. **EBN:** In one study, preoperative information reduced the anxiety of clients undergoing surgery under regional anesthesia (Jiala et al, 2010).
- ▲ Use massage therapy to reduce anxiety. **EBN:** Massage was shown to be an excellent method for reducing anxiety (Labrique-Walusis et al, 2010).
- ▲ Consider massage therapy for preoperative clients. **EBN:** Patients were highly satisfied with massage, and no major barriers to implementing massage therapy were identified. Massage therapy may be an important component of the healing experience for patients after cardiovascular surgery (Sutshall et al, 2010).
- Use therapeutic touch and healing touch techniques. **EBN:** One study showed that Reiki therapeutic touch reduced anxiety and pain (Sagkal, et al, 2013).
- Use guided imagery to decrease anxiety. **EBN:** Anxiety was decreased with the use of guided imagery during an intervention for postoperative pain (Thomas & Sethares, 2010).
- Suggest yoga to the client. **EB:** Yoga and massage lessened anxiety in burn patients (Parlak et al, 2010). Seven days' intensive residential yoga program reduces pain, anxiety, and depression, and improves spinal mobility in lower back pain (Tekur et al, 2012).
- Provide clients with a means to listen to music of their choice or audiotapes. **EBN:** Music can provide an effective method of reducing potentially harmful physiological responses arising from anxiety (Korhan et al, 2011). Among ICU patients receiving acute ventilatory support for respiratory failure, patient directed music resulted in greater reduction in anxiety compared with usual care, but not compared with NCH (noise cancelling headphones). Concurrently, patient directed music resulted in greater reduction in sedation frequency compared with usual care (Chlan et al, 2013).

Pediatric

- The above interventions may be adapted for the pediatric client.

Geriatric

- ▲ Monitor the client for depression. Use appropriate interventions and referrals. **EB:** GAD is a common and disabling disorder in later life that is highly comorbid with mood, anxiety, and personality disorders; psychiatric comorbidity is associated with an increased risk for medical conditions in this population. Considering that late-life GAD is associated with impaired quality of life but low levels of professional help-seeking, increased effort is needed to help individuals with this disorder to access effective treatments (Mackenzie et al, 2011).
- Older adults report less worry than younger adults. **EB:** Generalized anxiety disorder is a common diagnosis in older adults (Heinz et al, 2011).
- Observe for adverse changes if antianxiety drugs are taken. **EB:** Older adults are notably vulnerable to adverse drug reactions, particularly during unexpected hospitalizations (Bilyeu et al, 2011).
- Mindfulness meditation is successful in mediating anxiety. **EBN:** Mediation analyses indicated that mindfulness fully mediated changes in acute anxiety symptoms, and partially mediated changes in worry and trait anxiety. These researchers concluded that mindful based stress reduction exercises are an effective treatment for anxiety disorders and related symptoms (Vollestad et al, 2011).

Multicultural

- Assess for the presence of culture-bound anxiety states. **EBN:** *Prevalence and expression of social anxiety/seasonal affective disorder (SAD) depends on the particular culture. Asian cultures typically show the lowest rates, whereas Russian and United States samples show the highest rates, of SAD (Hoffman et al, 2010).*
- Identify how anxiety is manifested in the culturally diverse client. **EBN:** *Clinical presentation of anxiety disorders, with respect to symptom presentation and the interpretation of symptoms, varies across cultures. A difference in catastrophic cognitions about anxiety symptoms across cultures is hypothesized to be a key aspect of cross-cultural variation in the anxiety disorders (Marques et al, 2011).*
- For diverse clients experiencing preoperative anxiety, provide music of their choice. **EBN:** *This exploratory study demonstrated the positive impact of live music as a holistic patient intervention directed toward reducing pain, anxiety, and muscle tension during the preoperative, intraoperative, and postoperative periods (Sand-Jecklin & Emerson, 2010).*

Home Care

- The above interventions may be adapted for home care use.
- ▲ Assess for suicidal ideation. Implement emergency plan as indicated. **EBN:** *Suicidal ideation may occur in response to co-occurring depression or a sense of hopelessness over severe anxiety symptoms or once antidepressant medications have been started (Mitchell et al, 2009).* See care plan for Risk for **Suicide**.
- Assess for influence of anxiety on medical regimen. **EBN:** *Anxiety can affect a patient's ability to complete their medical regimen as prescribed, including taking medications, exercise, diet, and follow up therapies (Hynninen et al, 2010).*
- Assess for presence of depression. **EBN:** *Clinician report generally had the most favorable sensitivity and specificity for measuring depressive symptoms and treatment recommendations, respectively (Henry et al, 2014).*
- Assist family to be supportive of the client in the face of anxiety symptoms. **EBN:** *Supporting the formal and informal caregivers of a patient with anxiety as well as the patient may improve overall patient outcomes and allows the family to fully understand the problems the patient is experiencing (Kang et al, 2011).*
- ▲ Consider referral for the prescription of antianxiety or antidepressant medications for clients who have panic disorder (PD) or other anxiety-related psychiatric disorders. **EBN:** *The use of antidepressants, especially SSRI medications, is effective in many cases of anxiety (Katzman, 2009).*
- ▲ Assist the client/family to institute medication regimen appropriately. Instruct in side effects, importance of taking medications as ordered, and effects to report immediately to health care provider. **EBN:** *Patient interviews revealed that patients' values and beliefs, barriers to treatment, and prior medication-taking behavior were of primary importance in understanding medication discontinuance (Garavalia et al, 2011).*
- ▲ Refer for psychiatric home health care services for client reassurance and implementation of a therapeutic regimen. **EBN:** *Providing home health services for patients with anxiety increases self efficacy and reduces symptoms of anxiety, stress, and depression (Shelby et al, 2009).*

Client/Family Teaching and Discharge Planning

- ▲ Teach use of appropriate community resources in emergency situations (e.g., suicidal thoughts), such as hotlines, emergency departments, law enforcement, and judicial systems. **EB:** *Identification and sharing of best practices associated with emergency and community services would provide an opportunity for improvement in care for families dealing with anxiety and depression (Weiss et al, 2012).*
- Teach the client/family the symptoms of anxiety. **EBN:** *Teach families to have a general understanding of what is happening to the patient with anxiety and help them to accept assistance to overcome their anxiety (Smith et al, 2011).*
- Teach the client techniques to self-manage anxiety. **EBN:** *Computerized self-help treatments have been shown to be a less-intensive, cost-effective way to deliver empirically validated treatments for a variety of psychological problems (Newman et al, 2011).*
- Teach the client to visualize or fantasize about the absence of anxiety or pain, successful experience of the situation, resolution of conflict, or outcome of procedure. **EBN:** *Use of guided imagery has been useful for reducing anxiety (Tyron & McKay, 2009).*

- Teach relationship between a healthy physical and emotional lifestyle and a realistic mental attitude. **EBN:** *Some aspects of healthy lifestyle for anxiety disorders include identifying unhealthy relationships, building a strong support system, and adopting general healthy lifestyle habits (Smith et al, 2011).*

Death Anxiety *Ruth McCaffrey, DNP, ARNP, FNP-BC, GNP-BC, FAAN*

NANDA-I

Definition

Vague uneasy feeling of discomfort or dread generated by perceptions of a real or imagined threat to one's existence

Defining Characteristics

Concern about strain on the caregiver; deep sadness; fear of developing terminal illness; fear of loss of mental abilities when dying; fear of pain related to dying; fear of premature death; fear of prolonged dying process; fear of suffering related to dying; fear of the dying process; negative thoughts related to death and dying; powerlessness; worried about the impact of one's death on significant other

Related Factors (r/t)

Anticipation of adverse consequences of anesthesia; anticipation of impact of death on others; anticipation of pain; anticipation of suffering; confronting the reality of terminal disease; discussions on topic of death; experiencing dying process; near-death experience; nonacceptance of own mortality; observations related to death; perceived imminence of death; uncertainty about encountering a higher power; uncertainty about life after death; uncertainty about the existence of a higher power; uncertainty of prognosis

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Dignified Life Closure; Fear; Self-Control; Health Beliefs: Perceived Threat

Example NOC Outcome with Indicators

Dignified Life Closure as evidenced by the following indicators: Expresses readiness for death/Resolves important issues/ Shares feelings about dying/Discusses spiritual concerns. (Rate the outcome and indicators of **Dignified Life Closure**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State concerns about impact of death on others
- Express feelings associated with dying
- Seek help in dealing with feelings
- Discuss realistic goals
- Use prayer or other religious practice for comfort

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Dying Care; Grief Work Facilitation; Spiritual Support

Example NIC Activities—Dying Care

Communicate willingness to discuss death; Support client and family through stages of grief

Nursing Interventions and Rationales

- ▲ Assess the psychosocial maturity of the individual. **EB:** *In a large study, females scored higher on death anxiety than males. Additional tests reported that life satisfaction, an altering consciousness coping style, and avoidance coping was significantly related to risk for developing a stress-related illness when faced with the death of a loved one (Moore, 2013).*
- ▲ Assess clients for pain and provide pain relief measures. **EBN:** *Providing pain management and pain relief measures is the factor that most improves dying clients' quality of life at the end of life. Pain management should be a first priority for care providers during this time (Zhang et al, 2012).*
- Assess client for fears related to death. **EBN:** *Unbearable suffering is the outcome of an intensive process associated with death anxiety. According to clients, hopelessness is an essential element of unbearable suffering. Physical issues and feelings of loss may cause suffering during this time. Personality characteristics and biographical aspects greatly influence the burden of suffering. Unbearable suffering that accompanies death anxiety can only be understood in the continuum of the client's perspectives of the past and present, and expectations of the future (Dees et al, 2011).*
- Assist clients with life planning: consider and redefine main life goals, focus on areas of strength and/or goals that will provide satisfaction, adopt realistic goals, and recognize those that are impossible to achieve. **EB:** *Advance planning improves end of life care and client and family satisfaction, and reduces stress, anxiety, and depression in surviving relatives (Detering et al, 2010).*
- Assist clients with life review and reminiscence. **EB:** *When challenges emerged, the participants implemented "the search to find an acceptable and satisfying completion to this life," engaging family members, friends, and the hospice team in an effort to relieve discomfort and regain a degree of control (McSherry, 2011).*
- Provide music of the client's choosing. **EBN:** *Traditionally, music has played an important role in human culture and has had a powerful influence on human behavior. Music has a unique capacity for immersing an individual to such a degree that the closeness can be felt and painful aloneness may be alleviated (Chi & Young, 2011).*
- Provide social support for families, understanding what is most important to families who are caring for clients at the end of life. **EBN:** *When nurses make the intensive care unit a comfortable place for the dying patients and their loved ones, we also make the patients' deaths comfortable for us (Millner et al, 2009).*
- Encourage clients to pray. **EBN:** *Mindfulness and prayer allow for a step back from thoughts, increased coping for those who are dying, and their families (Monroe et al, 2012).*

Geriatric

- Carefully assess older adults for issues regarding death anxiety. **EB:** *Older adults in this study and review were more fearful for others than of the dying process. Women were more afraid of death of loved ones and of the consequences of their own death on those loved ones than were men (Azaiza et al, 2011).*
- Provide back massage for clients who have anxiety regarding issues such as death. **EBN:** *Back massage significantly reduced anxiety in the study population. Systolic BP decreased to a greater degree in the male participants, particularly in those with greater levels of anxiety and higher systolic BP (Chen et al, 2013).*
- Refer to care plan for **Grieving**.

Multicultural

- Assist clients to identify with their culture and its values. **EB/EBN:** *Christians scored significantly lower for death anxiety than both nonreligious and Muslim groups, and Muslims scored significantly higher than the nonreligious group (Gareth & McAdie, 2009).*
- Refer to care plans for **Anxiety** and **Grieving**.

Home Care

- The above interventions may be adapted for home care.
- Identify times and places when anxiety is greatest. Provide for psychological support at those times, using such strategies as personal contact, telephone contact, diversionary activities, or therapeutic self. **EBN:** *Participants across conditions reported similar levels of anxiety, suggesting that promoting an interest in sustained contact can be accomplished without reducing anxiety, but rather by shielding individuals from the negative effects of anxiety during social interactions (Stern & West, 2014).*

- Support religious beliefs; encourage the client to participate in services and activities of choice. **EBN:** *Enhancing the psychosocial and spiritual well-being of cancer patients can reduce their death anxiety and promote better quality of life (Shukla & Rishi, 2014).*
- ▲ Refer to medical social services or mental health services, including support groups as appropriate (e.g., anticipatory grieving groups from hospice, visiting volunteers of hospice). **EB:** *Preparatory grief was found to reduce emotional stress. Experience with hospice focused on the intense preoccupation with the dying, loneliness, tearfulness, cognitive dysfunction, irritability, anger, and social withdrawal. This study found that talking mobilizes strength to cope with the situation (Asa & Agneta, 2012).*
- Encourage the client to verbalize feelings to family/caregivers, counselors, and self. Identify the client's preferences for end-of-life care; provide assistance in honoring preferences as much as practicable. **EB:** *Music may be an effective tool for reviewing one's life, through which a client moves toward acceptance of death by giving meaning to his or her life. Near the end of life, prescriptive music may be used during bedside vigils to accompany the client in the transition from life to death (Black & Thompson, 2012).*
- ▲ Assist the client in making contact with death-related planning organizations, if appropriate, such as the Cremation Society and funeral homes. **EB:** *Advanced care planning is important to older clients. However, when clients are not accepting of death or if death is outside of the client's understanding, it can be difficult to work on advanced care planning. Nurses should explore whether the client accepts dying as a likely outcome and assess the client's fears of dying and need for control before attempting any planning (Piers et al, 2013).*
- Refer to care plan for **Powerlessness**.

Client/Family Teaching and Discharge Planning

- Promote more effective communication to family members engaged in the caregiving role. Encourage them to talk to their loved one about areas of concern. Both caregivers and care receivers often avoid discussing areas of concern. **EBN:** *Encouraging loved ones to discuss their wishes and areas of concern will assist the family during the grieving process; they will know the wishes of the dying family member and can carry them out as much as possible (Webb & Guarino, 2011).*
- Allow family members to be physically close to their dying loved one, giving them permission, instruction, and opportunities to touch. Keep family members informed. **EBN:** *A novel approach at one VA hospital was to use Skype as a tool for client and family/friend communication. This was especially useful when clinical symptoms, functional status, financial concerns, and geographic limitations prohibited in-person visits. It was very satisfying to both family/friends and clients (Brecher, 2012).*

Risk for Aspiration *Debra Siela, PhD, RN, CCNS, ACNS-BC, CCRN-K, CNE, RRT*

NANDA-I

Definition

Vulnerable to entry of gastrointestinal secretions, oropharyngeal secretions, solids, or fluids to the tracheo-bronchial passages, which may compromise health

Risk Factors

Barrier to elevating upper body; decrease in gastrointestinal motility; decrease in level of consciousness; delayed gastric emptying; depressed gag reflex; enteral feedings; facial surgery; facial trauma; impaired ability to swallow; incompetent lower esophageal sphincter; increase in gastric residual; increase in intragastric pressure; ineffective cough; neck surgery; neck trauma; oral surgery; oral trauma; presence of oral/nasal tube (e.g., tracheal, feeding); treatment regimen; wired jaw

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Aspiration Prevention; Respiratory Status: Ventilation; Swallowing Status

Example NOC Outcome with Indicators

Aspiration Prevention as evidenced by the following indicators: Avoids risk factors/Maintains oral hygiene/Positions self upright for eating and drinking/Selects foods according to swallowing ability/Selects foods and fluid of proper consistency/Remains upright for 30 minutes after eating. (Rate the outcome and indicators of **Aspiration Prevention**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = continually demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain patent airway and clear lung sounds
- Swallow and digest oral, nasogastric, or gastric feeding without aspiration

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Aspiration Precautions

Example NIC Activities—Airway Management

Monitor level of consciousness, cough reflex, gag reflex, and swallowing ability; Check nasogastric or gastrostomy residual before feeding

Nursing Interventions and Rationales

- Monitor respiratory rate, depth, and effort. Note any signs of aspiration such as dyspnea, cough, cyanosis, wheezing, hoarseness, foul-smelling sputum, or fever. If new onset of symptoms, perform oral suction and notify provider immediately. **CEB/EB**: Signs of aspiration should be detected as soon as possible to prevent further aspiration and to initiate treatment that can be lifesaving (Buckley & Cabrera, 2011;

• = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Swaminathan et al, 2015). Because of laryngeal pooling and residue in clients with dysphagia, silent aspiration may occur (*Metheny, 2011b*).

- Auscultate lung sounds frequently and before and after feedings; note any new onset of crackles or wheezing. **CEB:** *With decreased symptoms of pneumonia, an increased respiratory rate and/or crackles may be the first sign of pneumonia (Metheny, 2011b).*
- Take vital signs frequently, noting onset of a fever, increased respiratory rate, and increased heart rate.
- Before initiating oral feeding, check client's gag reflex and ability to swallow by feeling the laryngeal prominence as the client attempts to swallow (*Rees, 2013*). If client is having problems swallowing, see nursing interventions for Impaired **Swallowing**.
- If client needs to be fed, feed slowly and allow adequate time for chewing and swallowing. **CEB:** *Slowed feeding allows time for more deliberate swallowing, reducing aspiration (Rees, 2013).*
- When feeding client, watch for signs of impaired swallowing or aspiration, including coughing, choking, and spitting food.
- Have suction machine available when feeding high-risk clients. If aspiration does occur, suction immediately. *A client with aspiration needs immediate suctioning and may need further lifesaving interventions such as intubation and mechanical ventilation (Rees, 2013).*
- Keep the head of the bed (HOB) elevated at 30 to 45 degrees, preferably with the client sitting up in a chair at 90 degrees when feeding. Keep head elevated for an hour after eating. **EBP:** *Decreased gastric reflux occurs at both 30- and 45-degree HOB elevation. Thus, gastric fed patients should be maintained at the highest HOB elevation that is comfortable to prevent aspiration (Metheny & Franz, 2013).*
- Note presence of nausea, vomiting, or diarrhea. Treat nausea promptly with antiemetics.
- If the client shows symptoms of nausea and vomiting, position on side. *The side-lying position can help the client expel the vomitus and decrease the risk for aspiration (Chard, 2013).*
- Assess the abdomen and listen to bowel sounds frequently, noting if they are decreased, absent, or hyperactive. *Decreased or absent bowel sounds can indicate an ileus with possible vomiting and aspiration; increased high-pitched bowel sounds can indicate a mechanical bowel obstruction with possible vomiting and aspiration (Longo et al, 2012).*
- Note new onset of abdominal distention or increased rigidity of abdomen. **EB:** *Abdominal distention or rigidity can be associated with paralytic or mechanical obstruction and an increased likelihood of vomiting and aspiration (Longo et al, 2012).*
- If client has a tracheostomy, ask for referral to speech pathologist for swallowing studies before attempting to feed. **EB:** *There is an increased risk for aspiration when tracheostomy tubes are in place, and inflating the cuff does not prevent aspiration (Rees, 2013).*
- Provide meticulous oral care including brushing of teeth at least two times per day. *Good oral care can prevent bacterial or fungal contamination of the mouth, which can be aspirated. EB: Research has shown that excellent dental care/oral care can be effective in preventing hospital-acquired (or extended care-acquired) pneumonia (Munro, 2014).*
- Sedation agents can reduce cough and gag reflexes as well as interfere with the client's ability to manage oropharyngeal secretions. **EB:** *Using the smallest effective level of sedation may help reduce risk of aspiration (Bell, 2011; Barr et al, 2013).*

Enteral Feedings

- Insert nasogastric feeding tube using the internal nares to distal-lower esophageal-sphincter distance, an updated version of the Hanson method. The ear-to-nose-to-xiphoid-process is often inaccurate. **CEB:** *A study demonstrated that the revised Hanson's method was more accurate in predicting the correct distance than the traditional method (Ellett et al, 2011).*
- Verification of gastric tube placement should initially be obtained by radiography. Other methods of assessing proper gastric tube placement include capnography, aspirate assessment, tube markings, and pH tests. *Auscultation should not be used to assess gastric tube placement (Bell, 2011; Amirlak et al, 2012; Williams et al, 2014).*
- Tape the feeding tube securely to the nose using a skin protectant under the tape. **EBN:** *A research study found that insertion of the feeding tube into the small intestine and keeping the HOB position elevated to at least 30 degrees reduced the incidence of aspiration and aspiration-related pneumonia drastically in critically ill clients (Metheny et al, 2010). Another study found that aspiration and pneumonia were reduced by feeding the clients in the mid-duodenum or farther in the small intestine (Metheny et al, 2011).*

- Check to make sure the initial nasogastric feeding tube placement was confirmed by x-ray, with the openings of the tube in the stomach, not the esophagus or lungs. This is especially important if a small-bore feeding tube is used, although larger tubes used for feedings or medication administration should be verified by radiography also. *Radiographic verification of placement remains the gold standard for determining safe placement of feeding tubes* (Guenter, 2010; Bell, 2011; Metheny et al, 2012a; Williams et al, 2014).
- After radiographic verification of correct placement of the tube or the intestines, mark the tube's exit site clearly with tape or a permanent marker (Simons & Abdallah, 2012).
- Measure and record the length of the tube that is outside of the body at defined intervals to help ensure correct placement. *Note the length of the tube outside of the body; it is possible for a tube to slide out and be in the esophagus, without obvious disruption of the tape* (Bankhead et al, 2009).
- Note the placement of the tube on any chest or abdominal radiographs that are obtained for the client. *Acutely ill clients receive frequent x-ray examinations. These are available for the nurse to determine continued correct placement of the nasogastric tube* (Bell, 2011; Simons & Abdallah, 2012). *When using electromagnetic feed tube placement, radiographic confirmation of tube position is preferred due to the variance of the ability of clinicians to place the tube* (Metheny & Meert, 2014).
- Check the pH of the aspirate. *If the pH reading is 4 or less, the tube is probably in the stomach. Recognize that the pH may not indicate correct placement if the client is receiving continuous tube feedings, is receiving a hydrogen ion blocker or proton pump inhibitor, has blood in the aspirate, or is receiving antacids* (Bell, 2011; Simons & Abdallah, 2012).
- Use a number of determinants for verification of correct placement before each feeding or every 4 hours if the client is on continuous feeding. Measure length of tube outside the body, and review recent x-ray results, check pH of aspirate if relevant, and characteristic appearance of aspirate. If findings do not ensure correct placement of the tube, obtain a radiograph to verify placement. Do not rely on the air insufflation method to assess correct tube placement. **CEB/EBN:** *The auscultatory air insufflation method is not reliable for differentiating between gastric or respiratory placement; the "whooshing" sound can be heard even if the tube is incorrectly placed in the lung* (Bell, 2011; Simons & Abdallah, 2012; Williams et al, 2014).
- Capnography (CO₂ sensor) may be used to assess proper tube placement (Gilbert & Burns, 2012; Williams et al, 2014).
- Follow unit policy regarding checking for gastric residual volume during continuous feedings or before feedings, and holding feedings if increased residual is present. **CEB/EBN:** *There is little evidence to support the use of measurement of gastric residual volume, and the practice may or may not be effective in preventing aspiration* (Makic et al, 2011). *It is still done at intervals* (Metheny et al, 2012b; Bell, 2011) *especially if there is a question of tube feeding intolerance. The practice of holding tube feedings if there is increased residual reduces the amount of calories given to the client. If the client has a small-bore feeding tube, it is difficult to check gastric residual volume and may be inaccurate. It is unclear if aspiration for residual volumes helps reduce the risk of aspiration* (Metheny et al, 2012b); *practice guidelines suggest continuing to feed the patient until the residual is greater than 500 mL* (Canadian Clinical Practice Guidelines, 2013; Elke et al, 2015).
- Follow unit protocol regarding returning or discarding gastric residual volume. At this time there is not a definitive research base to guide practice. **CEB/EBN:** *A study of the effectiveness of either returning gastric residual volumes to the client or discarding them resulted in inconclusive findings and more research is needed in the area* (Williams & Leslie, 2010).
- Do not use glucose testing to determine correct placement of enteral tube, and to identify aspirated enteral feeding. *Glucose was found in tracheal secretions of clients who were not receiving enteral feedings* (Guenter, 2010).
- Do not use blue dye to tint enteral feedings (Guenter, 2010). *The presence of blue and green skin and urine and serum discoloration from use of blue dye has been associated with the death of clients. The U.S. Food and Drug Administration (2009) has reported at least 12 deaths from the use of blue dye in enteral feedings.*
- During enteral feedings, position client with HOB elevated 30 to 45 degrees (Bell, 2011; Schallom et al, 2015). **CEB:** *A study of mechanically ventilated clients receiving tube feedings demonstrated that there was an increase of the presence of pepsin (from gastric contents) in pulmonary secretions if the client was in a flat position versus being positioned with head elevated* (Metheny & Franz, 2013). *Generally do not turn off the tube feeding when repositioning clients. Stopping the tube feeding during repositioning is counterproductive because the client receives less nutrition and the rate of emptying of the stomach is slow. If it is imperative*

to keep the HOB elevated, consider use of reverse Trendelenburg (head higher than feet) when repositioning (Metheny, 2011a).

- Take actions to prevent inadvertent misconnections with enteral feeding tubes into intravenous (IV) lines or other harmful connections. Safety actions that should be taken to prevent misconnections include:
 - Trace tubing back to origin. Recheck connections at time of client transfer and at change of shift.
 - Label all tubing.
 - Use oral syringes for medications through the enteral feeding; **do not use IV syringes.**
 - Teach nonprofessional personnel “Do Not Reconnect” if a line becomes dislodged; rather, find the nurse instead of taking the chance of plugging the tube into the wrong place. *Enteral feeding tube lines have been inadvertently plugged into IV peripheral catheters, peritoneal dialysis catheters, central lines, medical gas tubing, and tracheostomies, resulting in death in some cases (Guenter, 2010).*

Critical Care

- Recognize that critically ill clients are at an increased risk for aspiration because of severe illness and interventions that compromise the gag reflex. *Predisposing causes of aspiration include sedation, endotracheal intubation and mechanical ventilation, neurological disorders, altered level of consciousness, hemodynamic instability, and sepsis (Makic et al, 2011).*
- Recognize that intolerance to feeding as defined by increased gastric residual is more common early in the feeding process. **EB:** *A study found that feeding intolerance in critical care clients happened commonly in the first 5 days of feeding, and feeding intolerance was associated with increased length of both critical care and hospital length of stay (O'Connor et al, 2011).*
- *Maintain endotracheal cuff pressures at an appropriate level to prevent leakage of secretions around the cuff (Bell, 2011).*
- *Pepsin and amylase are biomarkers of microaspiration of gastric contents in tracheal aspirate. Amylase presence is a better biomarker of aspiration of oral contents in the tracheal aspirate. Both pepsin and amylase were present in tracheal aspirate of critically ill patients even with backrest elevation of 30 degrees. HOB elevation is inversely related to the presence of pepsin (Sole et al, 2014).*

Geriatric

- Carefully check older client's gag reflex and ability to swallow before feeding. *A slowed rate of swallowing is common in older adults (Rees, 2013).*
- Watch for signs of aspiration pneumonia in older adults with cerebrovascular accidents, even if there are no apparent signs of difficulty swallowing or of aspiration. *Bedside evaluation for swallow and aspiration can be inaccurate. EB: Silent aspiration can occur in the older population (Metheny, 2011b).*
- Recognize that older adults with aspiration pneumonia have fewer symptoms than younger people; repeat cases of pneumonia in older adults are generally associated with aspiration (Eisenstadt, 2010). *Aspiration pneumonia can be undiagnosed in older adults because of decreased symptoms; sometimes the only obvious symptom may be new onset of delirium (Metheny, 2011b).*
- Use central nervous system depressants cautiously; older clients may have an increased incidence of aspiration with altered levels of consciousness. *Older clients have altered metabolism, distribution, and excretion of drugs. Many medications can interfere with the swallowing reflex, including antipsychotic drugs, proton pump inhibitors, and angiotensin-converting enzyme inhibitors (van der Maarel-Wierink et al, 2011).*
- Keep an older, mostly bedridden client sitting upright for 45 minutes to 1 hour after meals.
- Recommend to families that enteral feedings may or may not be indicated for clients with advanced dementia. Instead, if possible use hand-feeding assistance, modified food consistency as needed, and feeding favorite foods for comfort (Sorrell, 2010). **EB/CEB:** *Research has demonstrated that tube feedings in this population do not prevent malnutrition or aspiration, improve survival, reduce infections, or result in other positive outcomes (Teno et al, 2010).*

Home Care

- The above interventions may be adapted for home care use.
- For clients at high risk for aspiration, obtain complete information from the discharging institution regarding institutional management.
- Assess the client and family for willingness and cognitive ability to learn and cope with swallowing, feeding, and related disorders.

- Assess caregiver understanding and reinforce teaching regarding positioning and assessment of the client for possible aspiration.
- Provide the client with emotional support in dealing with fears of aspiration. *Fear of choking can provoke extreme anxiety, which can interfere with the client's ability or willingness to adhere to the treatment plan.* Refer to care plan for **Anxiety**.
- Establish emergency and contingency plans for care of the client. *Clinical safety of the client between visits is a primary goal of home care nursing.*
- Have a speech and occupational therapist assess the client's swallowing ability and other physiological factors and recommend strategies for working with the client in the home (e.g., pureeing foods served to the client; providing adequate adaptive equipment for independence in eating). *Successful strategies allow the client to remain part of the family.*
- Obtain suction equipment for the home as necessary.
- Teach caregivers safe, effective use of suctioning devices. Inform the client and family that only individuals instructed in suctioning should perform the procedure.
- Institute case management of frail elderly to support continued independent living.

Client/Family Teaching and Discharge Planning

- Teach the client and family signs of aspiration and precautions to prevent aspiration.
- Teach the client and family how to safely administer tube feeding.
- Teach the family about proper client positioning to facilitate feeding and reduce risk of aspiration.
- Verify client family/caregiver knowledge about feeding, aspiration precautions, and signs of aspiration.

Risk for impaired Attachment

Mary Alice DeWys, RN, BS, CMI, and Margaret Elizabeth Padnos, RN, AB, BSN, MA

NANDA-I

Definition

Vulnerable to disruption of the interactive process between parent/significant other and child that fosters the development of a protective and nurturing reciprocal relationship

Risk Factors

Anxiety; child's illness prevents effective initiation of parental contact; disorganized infant behavior; inability of parent to meet personal needs; insufficient privacy; parental conflict resulting from disorganized infant behavior; parent-child separation; physical barrier (e.g., infant in isolette); prematurity; substance abuse

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Parent-Infant Attachment; Parenting Performance

Example NOC Outcomes with Indicators

Holds infant close, touches, strokes, pats infant, responds to infant cues, holds infant for feeding, vocalizes to infant. (Rate the outcome and indicators of appropriate parent and infant behaviors that demonstrate an enduring affectionate bond: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Parent(s)/Caregiver(s) Will (Specify Time Frame)

- Be willing to consider pumping breast milk (and storing appropriately) or breastfeeding, if feasible
- Demonstrate behaviors that indicate secure attachment to infant/child
- Provide a safe environment, free of physical hazards
- Provide nurturing environment sensitive to infant/child's need for nutrition/feeding, sleeping, comfort, and social play
- Read and respond contingently to infant/child's distress
- Support infant's self-regulation capabilities, intervening when needed
- Engage in mutually satisfying interactions that provide opportunities for attachment

- Give infant nurturing sensory experiences (e.g., holding, cuddling, stroking, rocking)
- Demonstrate an awareness of developmentally appropriate activities that are pleasurable, emotionally supportive, and growth fostering
- Avoid physical and emotional abuse and/or neglect as retribution for parent's perception of infant/child's misbehavior
- State appropriate community resources and support services

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anticipatory Guidance; Attachment Process; Attachment Promotion; Coping Enhancement; Developmental Care; Parent Education: Infant

Example NIC Activities—Anticipatory Guidance

Instruct about normal development and behavior, as appropriate; Provide a ready reference for the client (e.g., educational materials, pamphlets), as appropriate.

Nursing Interventions and Rationales

- Establish a trusting relationship with parent/caregiver. **EBN:** “Overall, the research indicates that health care professionals urgently need to address the concerns of parents ($N = 600$) and their emotional reactions, be positive with communication exchanges, encourage parents to seek help, enhance parents' capability to positively explore the sources of social support and fully mobilize all social forces to ease psychological pressure” (Kong et al, 2013).
- Support mothers of preterm infants in providing pumped breast milk to their babies until they are ready for oral feedings and transitioning from gavage to breast. **EBN:** A Turkish study found stimulation with breast milk odor effective in decreasing length of transition of preterm infants from gavage to oral feeding and associated with shorter length of hospital stay (Yildiz et al, 2011).
- Identify factors related to postpartum depression (PPD)/major depression and offer appropriate interventions/referrals. **EB:** An Australian study of nulliparous women ($N = 1507$) highlights the need to “integrate concern for physical health with initiatives to address psychological well-being” for extreme tiredness, lower back pain, breast problems, urinary incontinence, perineal pain, constipation, hemorrhoids, and cesarean wound pain (Woolhouse et al, 2014). **EBN:** Because a mother's unpreparedness for premature childbirth may predispose her to “multiple and continuous waves of emotional responses, which will consequently lead to decline in performance ... and mental irritation,” more attention should be given to support these mothers as the main caregivers of their infants (Valizadeh et al, 2014).
- Identify eating disorders/comorbid factors related to depression and offer appropriate interventions/referrals. **CEB:** Combined psychological stressors of new motherhood and body image concerns of pregnancy may predispose exacerbation of eating disorder symptoms and development of postpartum mood disorders, in which mothers can be nonresponsive, inconsistent, or rejecting of the infant (Astrachan-Fletcher et al, 2008). **EBN:** Even though they may have prioritized food before their children's need—or in the words of one participant ($N = 9$), “food comes before anything,” overall, mothers juggled the competing demands of their eating disorder with their children's needs” (Stitt & Reupert, 2014).
- Nurture parents so that they in turn can nurture their infant/child. **EBN:** The principles of family-centered care (FCC)—respect, honoring diversity, supporting parents' choice, tailoring practice to individual family needs—help families feel supported in helping achieve the best outcome for their child at all levels of care (Gephart & McGrath, 2012).
- Offer parents opportunities to verbalize their childhood fears associated with attachment. **CEB:** “Parental lack of resolution concerning loss or trauma has been proposed to result in atypical parenting behaviors, which may have a disorganizing effect on the parent-child relationship” (Bernier & Meins, 2008).
- Suggest journaling or scrapbooking as a way for parents of hospitalized infants to cope with stress and emotions. **EB:** Beyond the obvious value of providing lifetime family mementoes, taking digital photos and writing journal notes have been found (1) to give a sense of parental empowerment, (2) to reduce maternal psychological distress, (3) to facilitate parent-infant bonding, (4) to reaffirm mutual trust between parents and staff (Subhani & Kanwal, 2012).

- Offer parent-to-parent support to parents of infants in the neonatal intensive care unit (NICU). **EBN:** *In one neonatal unit, parent-support volunteers collaborated with staff to create an innovative educational and psychosocial support program specifically targeting teen parents in order to help them increase engagement with their hospitalized infants and their caregiving confidence (Walsh & Goser, 2013).*
- Encourage parents of hospitalized infants to “personalize the baby” by bringing in clothing, pictures of themselves, toys, and tapes of their voices. **CEB:** *These actions help parents claim the infant as their own and support families’ confidence/competence in caring for their infants at their own pace (Lawhon, 2002).*
- Encourage physical closeness using skin-to-skin experiences as appropriate. **EB:** *Because kangaroo mother care (KMC) provides proven health benefits to high-risk infants, involves parents in their care, and humanizes the NICU experience/environment, it is a commonly recognized model of care for very preterm infants as well as infants who “are not so preterm and not so tiny babies who are transferred from or admitted to the NICU (Davanzo et al, 2013).*
- Plan ways for parents to interact/assist with infant/child caregiving. **EB:** *The COPE program (Creating Opportunities for Family Empowerment), an audiotaped educational program, has been effective in (1) teaching parents how to engage with and care for their hospitalized infant and (2) reducing maternal stress (Gooding et al, 2011). “In the beginning, having parents lay hands on their infant is enough to develop a bond and connection”; in time, wiping their infant’s mouth and helping with diaper changes “facilitate the parents’ participation in care” (Zimmerman & Bauersachs, 2012).*
- Educate parents about the importance of the infant-caregiver relationship as a foundation for the development of the infant’s self-regulation capacities. **EB:** *Both contingent responsiveness and emotional-affective support model socialization practices and allow parents to support management of infant arousal states (Lynn et al, 2011).*
- Assist parents in developing new caregiving competencies and/or revising/extending old ones. **CEB:** *Five caregiving domains are identified: (1) being with infant, (2) knowing infant as a person, (3) giving care, (4) communicating/engaging with others regarding infant/parent needs, (5) problem-solving/decision-making/learning (Pridham et al, 1998).*
- Educate parents in reading/responding sensitively to their infant’s unique “body language” (behavior cues) that communicate approach (“I’m ready to play”), avoidance/stress (“I’m unhappy. I need a change.”), and self-calming (“I’m helping myself”). **CEBN:** *Mothers with lower competence and more technology-dependent children may perceive their children as more vulnerable and their cues as harder to read (Holditch-Davis et al, 2011).*
- Educate and support parents’ ability to relieve infant/child’s stress/distress. **CEBN:** *In facilitated tucking by parents (FTP), a parent holds the infant in a side-lying, fetal position and offers skin-to-skin contact with the hands during a stressful/painful situation (Axelin et al, 2010).* **EB:** *Controlled music stimulation appears safe and effective in ameliorating pain/stress in premature infants after undergoing heel-sticks (Tramo et al, 2011).*
- Guide parents in adapting their behaviors/activities with infant/child cues and changing needs. **EB:** *“For patterns of positive communication to lead to successful regulation of affect, the caregiver must be receptive to the infant’s cues, appropriately responsive, and motivated to foster further opportunities for interactions” (Lynn et al, 2011).*
- Attend to both parents and infant/child to strengthen high-quality interactions. **CEB:** *A mother’s behavioral and brain responses to her infant’s cues may be important predictors of infant development; in cases of maternal depression or substance abuse, an infant’s smiling face may fail to elicit positive caregiving (Strathearn et al, 2008).* **EB:** *“Positive facial expressions from one’s own infant may play a particularly important role in eliciting maternal responses and strengthening the mother-infant bond” (Strathearn & Kim, 2013).*
- Assist parents with providing pleasurable sensory learning experiences (i.e., sight, sound, movement, touch, and body awareness). **EB:** *A Finnish study found that, when combined with kangaroo care, music therapy helped parents of preterm infants (N = 61) feel more relaxed and able to focus on “being together with the infant” in a “calm space” in which they were able to exclude disturbing and stressful sounds, as well as stress and anxiety” (Teckenberg-Jansson et al, 2011).*
- Encourage physical closeness using skin-to-skin experiences as appropriate. **EB:** *When intermittent KMC is not deemed appropriate, parents must be taught alternative ways to minimize negative effects of separation from their baby (e.g., gentle containing touch, proprioceptive sense stimulation, face-to-face visual contact, talking, reading, singing soothing lullabies, and olfactory stimulation (Davanzo et al, 2013).*

- Encourage parents and caregivers to massage their infants and children. **CEB**: Preliminary studies suggest that infant massage combined with kinesthetic stimulation may have positive effects on preterm infants: greater weight gain, improved bone mineralization, earlier hospital discharge, and more optimal behavioral and motor responses compared to controls (Massaro et al, 2009). **EB**: A study of preterm and low-birth-weight infants who received massage reported the following results: greater alert and daytime activity in the first month of life; less awakening during sleep, and less crying in the second and third months; significantly greater weight gain at 2 and 3 months of age compared to infants who did not receive massage (Karbasi et al, 2014).
- Identify mothers who may need assistance in enhancing maternal role attainment (MRA). **CEBN**: “Mothers with more illness-related distress and less alert infants, and unmarried and less educated mothers may need interventions to enhance MRA” (Miles et al, 2011).
- Recognize that fathers, compared to mothers, may have different starting points in the attachment process in the NICU as nurses encourage parents to have early skin-to-skin contact. **CEBN**: One study showed that after giving birth prematurely, mothers felt powerless, experiencing the immediate postnatal period as surreal and strange. Fathers, however, experienced the birth as a shock but were ready to become immediately involved (Fegran et al, 2008). **CEB**: Specific experiences (e.g., receiving information consistently, speaking to a male health care provider may help fathers regain a sense of control to help them fulfill their various roles as protectors/partners/breadwinners (Arockiasamy et al, 2008). **EB**: A study conducted in an Irish NICU raises awareness of the need for health care professionals to consider the unique perspective of fathers regarding (1) “feeling like a second parent” because the primary focus is on the mother and infant and (2) viewing information sharing as a “double-edged sword” with both positive and negative effects (Hollywood & Hollywood, 2011).

Pediatric

- Recognize and support infant/child’s capacity for self-regulation and intervene when appropriate. **CEB**: Infants must learn to take in sensory information while simultaneously managing not to become overaroused and overwhelmed by stimuli (DeGangi & Breinbauer, 1997; Greenspan, 1992).
- Provide lyrical, soothing music in nursery and home that is age-appropriate (i.e., corrected, in the case of premature infants) and contingent with state/behavioral cues. **EBN**: “Before adopting an intervention such as music for use in the NICU, nurses should (1) consider the parents’ viewpoints about their preferences (e.g., recorded, classical, lullabies, mother’s humming/singing) and (2) offer guidance as needed regarding the individual infant’s response to musical stimuli” (Pölkki et al, 2012).
- Recognize and support infant/child’s attention capabilities. **CEB**: “The ability to take an interest in the sights, sounds, and sensations of the world” is a significant developmental milestone (Greenspan & Wieder, 1998).
- Encourage opportunities for mutually satisfying interactions between infant and parent. **CEB**: The process of attachment involves communication and synchronous and rhythmic patterns of interaction (Rossetti, 1999).
- Encourage opportunities for physical closeness. **CEB**: Despite overwhelming evidence provided by this comprehensive literature review regarding benefits of infant massage (e.g., increased weight gain and bone density), “preterm infant massage is only practiced in 38% of NICUs (Field et al, 2010). **EB**: A Finnish study proposes “that repeated combination of music therapy and kangaroo care may be more beneficial for preterm infants than KC alone” in terms of beneficial physiological outcomes (e.g., increased oxygen saturation) and parent reports of feeling calm and relaxed (Teckenberg-Jansson et al, 2011).

Multicultural

- Provide culturally sensitive parent support to non-English-speaking mothers and families. **CEBN**: In a study contrasting NICU norms in Christchurch, New Zealand, and Tokyo, Japan, areas of difference in parental support needs included (1) establishment of oral feeding, (2) nursing care-related decision-making, (3) parental information/involvement early in hospitalization, (4) visiting regulations, and (5) Western-based interventions (Ichijima, 2009). **EB**: Congruent parent-to-parent matching is an important way to help non-Anglophone mothers mobilize their strengths; cope with feelings of loss, guilt, helplessness, and anxiety; and increase access to services (Ardal et al, 2011).
- Discuss cultural norms with families to provide care that is appropriate for enhancing attachment with the infant/child. **EB**: Recognition of the NICU norms that may hinder parent-staff communication is important in nursing practice (Ichijima et al, 2011).

- Promote the attachment process in women who have abused substances by providing a culturally based, women-centered treatment environment. **CEB**: *Pregnant/postpartum Asian/Pacific Islander women identified provisions for the newborn, infant health care, parent education, and infant-mother bonding as conducive to their treatment (Morelli et al, 2001).*
- Promote attachment process/development of maternal sensitivity in incarcerated women. **EB**: *By creating a simple and uncomplicated plan for an incarcerated mother to pump and store her breast milk, “nurses have the opportunity to change the mothering experience” as they promote maternal-infant attachment and improve health for mother and infant (Allen & Baker, 2013).*
- Empower family members to draw on personal strengths in which multiple worldviews/values are recognized, incorporated, and negotiated. **CEBN**: *According to a Thai study of NICU parents, the need to be strong, to be there, and to care for infants emerged as main themes in parents’ stories (Sitanton, 2009).* **EBN**: *A study by Heidari et al (2012) found that “having a premature infant with anomalies is viewed as a family flaw,” carrying with it the “stigma of shame.”*
- Encourage positive involvement and relationship development between children and fathers. **EB**: *A study by Kadivar and Mozafarinia (2013) confirmed that using the HUG Your Baby DVD and family-friendly instructional program with NICU fathers increased their knowledge of infant behavior and is likely to boost their confidence, promote the parent-child relationship, and strengthen the family unit (Kadivar & Mozafarinia, 2013).*

Home Care

- The above interventions may be adapted for home care use.
- Assess quality of interaction between parent and infant/child. **CEB**: *In a study regarding effectiveness of home visiting by paraprofessionals/nurses, outcomes of nurse visitations in particular included more responsive mother-child interaction, less emotional vulnerability in response to fear stimuli among infants, greater infant emotional vitality in response to joy/anger stimuli, and less likelihood of language delays (Olds et al, 2002).*
- Use “interaction coaching” (i.e., teaching mother to let the infant lead) so that the mother will match her interaction style to the baby’s cues. **EBN**: *Although delivery of personalized interventions is labor intensive, and testing ways to provide targeted interventions in order to promote sensitive, responsive maternal-infant interactions is challenging, these are supported by current research (Mayberry & Horowitz, 2011).*
- ▲ Provide supportive care for infants and children whose parents have been deployed during wartime. **EB**: *Given the stressful task facing returning service members (i.e., reintegrating themselves into families “whose internal rhythms have changed and where children have taken on new roles”), the authors advocate for strengthening community support services and adopting public health education measures that reduce the stigma of seeking treatment for post-traumatic stress disorder (Lester & Flake, 2013).*
- Encourage custodial grandparents to utilize support groups available for caregivers of children. *A strengths-based support group for caregiving grandmothers recommended five interventions adaptable to nursing practice: (1) disseminate health information regarding chronic conditions (e.g., diabetes, heart disease, high cholesterol, arthritis, migraines, ocular hypertension); (2) expand practical information regarding social service, financial and legal resources; (3) explore spiritual and religious connections that could serve as sources of psychological well-being and sustenance; (4) provide socioemotional support to help manage mental health issues; (5) utilize youth “lock-ins” and outings to give needed breaks from childcare responsibilities (Collins, 2011).* **EB**: *The Family Child Care Network Impact Study found that relationship-based network supports delivered by specially trained staff were associated with higher quality caregiving by childcare providers (Bromer & Bibbs, 2011).*

Autonomic Dysreflexia *Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN*

NANDA-I

Definition

Life-threatening, uninhibited sympathetic response of the nervous system to a noxious stimulus after a spinal cord injury at T7 or above

Defining Characteristics

Blurred vision; bradycardia; chest pain; chilling; conjunctival congestion; diaphoresis (above the injury); headache (diffuse pain in different areas of the head and not confined to any nerve distribution area); Horner's syndrome; metallic taste in mouth; nasal congestion; pallor (below injury); paresthesia; paroxysmal hypertension; pilomotor reflex; red blotches on skin (above the injury); tachycardia

Related Factors

Bladder distention; bowel distention; insufficient caregiver knowledge of disease process; insufficient knowledge of disease process; skin irritation

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Neurological Status; Neurological Status: Autonomic; Vital Signs

Example NOC Outcome with Indicators

Neurological Status: Autonomic as evidenced by the following indicators: Systolic blood pressure/Diastolic blood pressure/Apical heart rate/Perspiration response pattern/Goose bumps response pattern/Pupil reactivity/Peripheral tissue perfusion. (Rate each indicator of **Neurological Status: Autonomic**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain normal vital signs
- Remain free of dysreflexia symptoms
- Explain symptoms, prevention, and treatment of dysreflexia

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Dysreflexia Management

Example NIC Activities—Dysreflexia Management

Identify and minimize stimuli that may precipitate dysreflexia; Monitor for signs and symptoms of autonomic dysreflexia

Nursing Interventions and Rationales

- Monitor the client for symptoms of dysreflexia, particularly those with high-level and more extensive spinal cord injuries. See Defining Characteristics. **EB**: *Autonomic dysreflexia (AD) occurs in up to 90% of clients with high level spinal cord injury (Cragg & Krassioukov, 2013). Because most clients are asymptomatic, it is important to recognize risk factors for AD, such as higher and more complete injuries and injuries related to trauma (Huang et al, 2011).*
- ▲ Collaborate with providers and caregivers to identify the cause of dysreflexia. AD is triggered by a stimulus from below the level of injury. The most common triggers are distention of the bladder, kidney stones,

kink in urinary catheter, urinary tract infection, fecal impaction, pressure ulcer, ingrown toenail, menstruation, hemorrhoids, invasive testing, and sexual intercourse (Cragg & Krassioukov, 2013; Wan & Krassioukov, 2014). **EB:** *Health care practitioners and caregivers should assess for conditions that place the client at risk for AD. Clients with upper thoracic and cervical injuries often have lower resting blood pressure, thus elevated blood pressure with AD may be less obvious, necessitating the importance of always assessing the condition (Jackson & Acland, 2011; Cragg & Krassioukov, 2013).*

- ▲ If symptoms of dysreflexia are present, place client in high Fowler's position, remove all support hoses or binders, loosen clothing, and immediately determine the noxious stimulus causing the response. If blood pressure cannot be decreased within 1 minute, notify the provider emergently (i.e., STAT). **EB:** *These steps promote venous pooling, decrease venous return, and decrease blood pressure. The client should be rapidly evaluated by both the health care provider and nurse to find the possible cause (Jackson & Acland, 2011; Furlan, 2013; Urden et al, 2013).* To determine the stimulus for dysreflexia:
 - First, assess bladder function. Check for distention, and if present catheterize the client using an anesthetic jelly as a lubricant. Do not use the Valsalva maneuver or Crede's method to empty the bladder. Ensure existing catheter patency. Also assess for signs of urinary tract infection. **EB:** *AD is commonly associated with bowel or bladder dysfunction in persons with a spinal cord injury (Furusawa et al, 2011; Cragg & Krassioukov, 2013).*
 - Second, assess bowel function. Numb the bowel area with a topical anesthetic as ordered and gently check for impaction. **EB:** *For clients who require manual removal of stool, pretreatment with lidocaine cream may decrease the flow of impulses from the bowel and lower blood pressure during removal (Urden et al, 2013; Faaborg et al, 2014).*
 - Third, assess the skin, looking for any points of pressure and ingrown toenails.
- ▲ Initiate antihypertensive therapy as soon as ordered and monitor for cardiac dysrhythmias. **EB:** *Due to the large amount of sympathetic discharge following AD, clients in hypertensive crisis are at risk for arrhythmias, myocardial infarction, and cerebral hemorrhage (Furlan, 2013; Wan & Krassioukov, 2014).*
- ▲ Be careful not to increase noxious sensory stimuli during assessment for cause of AD. If numbing agent is ordered, use it on anus and 1 inch of rectum before attempting to remove a fecal impaction. If necessary to replace an obstructed catheter, use an anesthetic jelly as ordered during the insertion. **EB:** *Increased noxious sensory stimuli can exacerbate the abnormal response and worsen the client's prognosis (Urden et al, 2013).*
- Monitor vital signs every 3 to 5 minutes during acute event; continue to monitor vital signs after event is resolved (e.g., symptoms resolve and vital signs return to baseline, usually up to 2 hours post event). **EB:** *It is possible for the client to develop rebound hypotension after the acute event because of the use of antihypertensive medications, or symptoms of dysreflexia may reoccur (Urden et al, 2013; Furlan, 2013).*
- Watch for complications of dysreflexia, including signs of cerebral hemorrhage, seizures, cardiac dysfunction, or intraocular hemorrhage. **EB:** *Extremely high blood pressure can cause intracranial hemorrhage, myocardial injury and dysfunction, and death (Wan & Krassioukov, 2014).*
- Accurately and completely record any incidences of dysreflexia; especially note the precipitating stimuli. *It is imperative to determine noxious stimuli that precipitated AD and whether the condition is persistent, requiring the client to take medications routinely or implement different interventions to prevent repeat incidences (Cragg & Krassioukov, 2013).*
- Use the following interventions to prevent dysreflexia:
 - Ensure that drainage from an indwelling catheter is good and that bladder is not distended. Assess the client frequently for signs and symptoms of urinary tract infection.
 - Ensure a regular pattern of defecation to prevent fecal impaction. **EB:** *AD is commonly associated with bowel dysfunction in persons with a spinal cord injury (Wan & Krassioukov, 2014). A recent study found that bowel management with transanal irrigation was less traumatic than bowel management by digital rectal evacuation (Faaborg et al, 2014).*
 - Frequently change position of client to relieve pressure and prevent formation of pressure ulcers.
- ▲ If ordered, apply an anesthetic agent to any wound below the level of injury before performing wound care. **EB:** *Stimuli that would cause pain in persons without spinal cord injury can lead to AD (Furlan 2013; Urden et al, 2013).*
- ▲ Because episodes can recur, notify all health care team members of the possibility of a dysreflexia episode. All health care personnel working with the client should be aware of the condition and how to treat it.
- ▲ For female clients with spinal cord injury, assess the client for AD during menstrual cycle. If the client becomes pregnant, collaborate with obstetrical health care practitioners to monitor for signs and

symptoms of dysreflexia. **EB:** *Autonomic dysreflexia may signal the onset of labor or be a sign of preterm labor. Women undergoing cesarean section should be carefully monitored intraoperatively and postoperatively (Walsh et al, 2010).*

Home Care

- The above interventions may be adapted for home care use.
- Provide the client and caregiver with written information on common causes of AD and initial treatment. An AD card is available from the *SCI-INFO-PAGES* online resource for clients with quadriplegia and paraplegia (<http://www.sci-info-pages.com/ad.html>) as well as from the *Christopher and Dana Reeve Foundation* (http://www.christopherreeve.org/site/c.mtKZKgMWKwG/b.7717499/k.D633/Autonomic_Dysreflexia_AD_Card__Send_to_a_Friend/apps/ka/ecard/choosecard.asp).
- Provide resources to the client with any known proclivity toward dysreflexia to wear a medical alert bracelet and carry a medical alert wallet card when not in a safe environment (i.e., not with someone who knows client has the condition and can respond appropriately).
- ▲ Establish an emergency plan: obtain provider orders for medications to be used in situations in which first aid does not work and plans to identify potential stimuli. **EB:** *Medication administered immediately can reverse early stage dysreflexia. Notify health care provider of emergency (Craig Hospital, 2013). If orders have not been obtained or client does not have emergency medications, contact emergency medical services.*
- When episode of dysreflexia is resolved, monitor blood pressure every 30 to 60 minutes for next 2 hours or admit to institution for observation. **EB:** *Autonomic dysreflexia can have a profound effect on vasculature, leading to chronic cardiovascular dysfunction (Furlan, 2013).*

Client/Family Teaching and Discharge Planning

- Teach recognition of the earliest symptoms of dysreflexia, the actions that should be taken when they occur, and the need to obtain help immediately. Give client a written card describing signs and symptoms of AD and initial actions. **CEB:** *Clients and caregivers at risk for not understanding the key elements of AD occurrence and management are clients with nontraumatic etiologies, those with T5 or lower injuries, those in the youngest age group at injury, and those who had a shorter duration of injury (Schottler et al, 2009). Clients have reported knowledge gaps regarding AD and having symptoms of AD but not recognizing the condition (McGillivray et al, 2009).*
- Teach steps to prevent dysreflexia episodes: care of bladder, bowel, and skin and prevention of other forms of noxious stimuli (e.g., not wearing clothing that is too tight, nail care). Discuss the potential impact of sexual intercourse and pregnancy on autonomic dysreflexia. **EB:** *Autonomic dysreflexia may be triggered by ejaculation and sperm retrieval for men (McGuire et al, 2011).*

Risk for Autonomic Dysreflexia

Betty J. Ackley, MSN, EdS, RN, and Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

NANDA-I

Definition

Vulnerable to life-threatening, uninhibited response of the sympathetic nervous system after spinal shock in an individual with spinal cord injury or lesion at T6 or above (has been demonstrated in clients with injuries at T7 and T8), which may compromise health

Risk Factors

Cardiopulmonary Stimuli

Deep vein thrombosis; pulmonary emboli

Gastrointestinal Stimuli

Bowel distention; constipation; difficult passage of feces; digital stimulation; enemas; esophageal reflux disease; fecal impaction; gallstones; gastric ulcer; gastrointestinal system pathology; hemorrhoids; suppositories

Musculoskeletal-Integumentary Stimuli

Cutaneous stimulations (e.g., pressure ulcer, ingrown toenail, dressings, burns, rash); fracture; heterotrophic bone; pressure over bony prominence; pressure over genitalia; range-of-motion exercises; spasm; sunburn; wound

Neurological Stimuli

Irritating stimuli below level of injury; painful stimuli below level of injury

Regulatory Stimuli

Extremes of environmental temperature; temperature fluctuations

Reproductive Stimuli

Ejaculation; labor and delivery period; menstruation; ovarian cyst; pregnancy; sexual intercourse

Situational Stimuli

Constrictive clothing (e.g., straps, stockings, shoes); pharmaceutical agent; positioning; substance withdrawal (e.g., narcotic, opiate); surgical procedure

Urological Stimuli

Bladder distention; bladder spasm; cystitis; detrusor sphincter dyssynergia; epididymitis; instrumentation; renal calculi; surgical procedure; urethritis; urinary catheterization; urinary tract infection

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan for **Autonomic Dysreflexia**.

List of Nursing Diagnoses by Letter: B

Risk for Bleeding	Disturbed Body Image	Insufficient Breast Milk
Ineffective Breastfeeding	Interrupted Breastfeeding	Readiness for enhanced Breastfeeding
Ineffective Breathing pattern		

Risk for Bleeding *June M. Como, EdD, RN, CNS*

B

NANDA-I

Definition

Vulnerable to a decrease in blood volume, which may compromise health

Risk Factors

Aneurysm; circumcision; disseminated intravascular coagulopathy; gastrointestinal condition (e.g., ulcer, polyps, varices); history of falls; impaired liver function (e.g., cirrhosis, hepatitis); inherent coagulopathy (e.g., thrombocytopenia); insufficient knowledge of bleeding precautions; postpartum complications (e.g., uterine atony, retained placenta); pregnancy complications (e.g., premature rupture of membranes, placenta previa/abruption, multiple gestation); trauma; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Blood Coagulation; Blood Loss Severity; Circulation Status; Fall Prevention Behavior; Gastrointestinal Function; Knowledge: Personal Safety, Maternal Status, Physical Injury Severity, Risk Control, Safe Home Environment, Vital Signs

Example NOC Outcome with Indicators

Blood Coagulation as evidenced by the following indicators: Clot formation, International normalized ratio (INR), Hemoglobin (HGB), Platelet Count, Bleeding, Bruising, Hematuria, Hematemesis. (Rate the outcome and indicators of **Blood Coagulation**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range.)

Client Outcomes

Client Will (Specify Time Frame)

- Discuss precautions to prevent bleeding complications
- Explain actions that should be taken if bleeding happens
- Maintain adherence to agreed upon anticoagulant medication and lab work regimens
- Monitor for signs and symptoms of bleeding
- Maintain a mean arterial pressure above 70 mm Hg, a heart rate between 60 and 100 bpm with a normal rhythm, and urine output greater than 0.5 mL/kg/hr
- Maintain warm, dry skin

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Admission Care; Bleeding Precautions; Bleeding Reduction; Blood Product Administration; Circumcision Care; Fluid Management; Health Screening; Hemorrhage Control; Neurologic Monitoring; Postpartum Care; Risk Identification; Teaching: Disease Process; Teaching: Prescribed Medication; Oxygen Therapy; Shock Prevention; Surveillance; Vital Signs Monitoring

Example NIC Activities—Bleeding Precautions

Monitor the client closely for hemorrhage; Monitor coagulation studies; Monitor orthostatic vital signs, including blood pressure; Instruct the client and/or family on signs of bleeding and appropriate actions in case bleeding occurs

Nursing Interventions and Rationales

- Perform admission risk assessment for falls and for signs of bleeding. Safety precautions should be implemented for all at risk clients. **EBN**: Upon client admission to any health care facility, nurses should assess for fall risk factors that could increase the risk of bleeding (Holmes, 2011).

- Monitor the client closely for hemorrhage, especially in those at increased risk for bleeding. Watch for any signs of bleeding, including bleeding of the gums, blood in sputum, emesis, urine or stool, bleeding from a wound, bleeding into the skin with petechiae, and purpura. **EB:** *Clients at increased risk for bleeding may include older individuals (>60 years of age), individuals with active gastroduodenal ulcer, intrapartum and postpartum women, previous bleeding episode, hypertension, labile INRs, low platelet count, active malignancy, renal or liver failure, intensive care unit stay, drug or alcohol use, coadministration of antiplatelets and nonsteroidal antiinflammatory drugs (NSAIDs), and antithrombotic and anticoagulant therapies (Hastings-Tolsma et al, 2013; Chen et al, 2011; Chua et al, 2011; Decousus et al, 2011). Individuals who take selective serotonin reuptake inhibitors (SSRIs) with or without a history of gastrointestinal bleeding may be at increased risk for bleeding especially if also taking NSAIDs or low-dose aspirin (Lanbos et al, 2011; Andrade et al, 2010). Use of aspirin and clopidogrel in the treatment of clients with image verified “small” subcortical strokes demonstrated higher rates of bleeding when compared with treatment with aspirin alone (Stiles, 2011).*
- If bleeding develops, apply pressure over the site or appropriate artery as needed. Apply pressure dressing if indicated. **EB:** *Nonpharmacological means, such as application of pressure, may reduce bleeding (Makris et al, 2013; Matteucci et al, 2011).*
- ▲ Collaborate on an appropriate bleeding management plan, including nonpharmacological and pharmacological measures to stop bleeding based on the antithrombotic used. **EB:** *Recommendations for bleeding risk prevention and management carefully weigh the risks and benefits of nonpharmacological and pharmacological interventions (Makris et al, 2013).*
- ▲ Monitor coagulation studies, including prothrombin time, INR, activated partial thromboplastin time (aPTT), fibrinogen, fibrin degradation/split products, and platelet counts as appropriate. **EB:** *New oral anticoagulants often have no requirement for routine coagulation studies; however, vigilance is still warranted in that risk for bleeding without benefit of reversal agents exists (Levy, 2014; Siegal & Crowther, 2013). INR is the preferred method to evaluate warfarin therapy, typically at least 16 hours after the last dose is administered. Dose adjustments will not result in a steady-state INR value for up to 3 weeks (ICSI, 2011). **CEB:** The aPTT is most commonly used to assess unfractionated heparin (UH) therapy but some clients may require additional testing to assess for heparin resistance (Russo, 2011). Replacement of UH with low-molecular-weight heparin and other new anticoagulants may be forthcoming but UH is still a drug of choice because of its ability to rapidly reverse effect with protamine sulfate (Lehman & Frank, 2009).*
- Assess vital signs at frequent intervals to assess for physiological evidence of bleeding, such as tachycardia, tachypnea, and hypotension. Symptoms may include dizziness, shortness of breath, and fatigue. **EB:** *Carefully assess for compensatory changes associated with bleeding, including increased heart rate and respiratory rate. Initially blood pressure may be stable, before beginning to decrease. Assess for orthostatic blood pressure changes (drop in systolic by >20 mm Hg and/or a drop in diastolic by >10 mm Hg in 3 minutes) by taking blood pressure with the client in lying, sitting, and standing positions (Matteucci et al, 2011; Urden et al, 2009). Prospective identification of clients at risk for massive transfusion is an imprecise science (Vandromme et al, 2011), although higher shock index (≥ 0.9) has been associated with increased bleeding risk (Olaussen et al, 2014).*
- ▲ Monitor all medications for potential to increase bleeding, including aspirin, NSAIDs, SSRIs, and complementary and alternative therapies such as coenzyme Q10 and ginger. **EB:** *Antiplatelet medications can increase the risk of bleeding in high-risk clients (ICSI, 2011). Ginger, when taken with medicines that slow clotting, may increase the chances for bruising and bleeding (Medline Plus, 2011). **CEB:** In a study of adults receiving warfarin, coenzyme Q10 and ginger appeared to increase the risk of bleeding (Shalansky et al, 2007).*

Consensus on Delivery of Inpatient Anticoagulant Therapy 2013

- ▲ **QSEN:** Systems-based process should be used for the management of inpatient anticoagulant therapy (Nutescu et al, 2013).
- ▲ **QSEN:** Multidisciplinary involvement that is accountable and provides leadership should be incorporated (Nutescu et al, 2013).
- ▲ **QSEN:** Seamless integration of anticoagulant system with all client resources including electronic health records (Nutescu et al, 2013; Villanueva et al, 2013).
- ▲ **QSEN:** Evidence-based standards, periodically reviewed, should be used to ensure appropriate use of anticoagulant therapies in all situations (Nutescu et al, 2013).

- ▲ QSEN: Competency based education for all multidisciplinary personnel engaged in anticoagulant management (Nutescu et al, 2013).
- ▲ QSEN: Ensure safe and effective use of therapies during care transitions and discharge through appropriate client education (Nutescu et al, 2013).
- ▲ QSEN: Ensure safe care transitions and maintenance of prescribed anticoagulants (Nutescu et al, 2013).
- ▲ QSEN: Measure quality indicators and assess client outcomes with a focus on quality improvement (Nutescu et al, 2013).

Safety Guidelines for Anticoagulant Administration: Joint Commission National Patient Safety Goals

Follow approved protocol for anticoagulant administration:

- Use prepackaged medications and prefilled or premixed parenteral therapy as ordered
- Check laboratory tests (i.e., INR) before administration
- Use programmable pumps when using parenteral administration
- Ensure appropriate education for client/family and all staff concerning anticoagulants used
- Notify dietary services when warfarin is prescribed (to reduce vitamin K in diet)
- Monitor for any symptoms of bleeding before administration. **EB:** *Standard defined protocols can decrease errors in administration (Joint Commission, 2011).*
- Anticoagulation therapy is complex. **EBN:** *Nurses have an integral role in medication management through the education of clients (Howland, 2012).* **EB:** *Medication reconciliation techniques and pre-discharge education employed by pharmacists in an emergency department setting demonstrated enhanced accuracy of preadmission medication listings, resulting in a reduction in readmission rates (Gardella et al, 2012).* **CEB:** *Risk of bleeding is reduced in clients who receive appropriate education in anticoagulant therapy use (Metlay et al, 2008).*
- ▲ Before administering anticoagulants, assess the clotting profile of the client. If the client is on warfarin, assess the INR. Hold the medication if the INR is outside of the recommended parameters and notify the health care provider or advanced practice nurse. **EB:** *Target INR for warfarin is between 2 and 3 for nonvalvular atrial fibrillation and between 2.5 and 3.5 for valvular atrial fibrillation. Risk for bleeding is increased when INR is >4 and risk for thromboembolism increases when INR is <1.7. A 2% to 4% risk for bleeding remains in individuals within therapeutic range of INR. Dose adjustments of 15% usually change the INR level by 1 (ICSI, 2011). A safety advisory was issued by the Australian regulatory authority for the anticoagulant dabigatran (Pradaxa) due to an increase in the number of bleeding-related adverse events (Hughes, 2011).*
- ▲ Recognize that vitamin K for vitamin K antagonists (e.g., warfarin, phenprocoumon, Synthrome, and phenindione) may be given orally or intravenously as ordered for INR levels greater than 5. In some circumstances, pro-hemostatic therapies may be warranted (tranexamic acid, desmopressin, fresh frozen plasma, cryoprecipitate, platelet transfusion, fibrinogen concentrate, prothrombin complex concentrate, activated prothrombin complex concentrate and/or recombinant factor VIIa) if serious or life-threatening bleeding occurs (Makris et al, 2013). **EB:** *With INR levels above 5, it is recommended to give vitamin K rather than withholding the warfarin; administration of vitamin K is by oral or intravenous route, because subcutaneous and intramuscular routes result in erratic absorption (ICSI, 2011).*
- ▲ Manage fluid resuscitation and volume expansion as ordered. **EB:** *A Cochrane systematic review including 86 trials and more than 5000 subjects suggests that there is no evidence that any one colloidal solution is safer or more effective than any other (Bunn & Trivedi, 2012). Prehospital administration of plasma may mitigate trauma-induced coagulopathy (Moore et al, 2014).* **CEB:** *Blood products (including human albumin), non-blood products or combinations can be used to restore circulating blood volume in individuals at risk for blood losses from trauma, burns, or surgery. Administration of albumin over normal sterile saline does not alter survival rates (Alderson et al, 2004).*
- ▲ Consider use of permissive hypotension and restrictive transfusion strategies when treating bleeding episodes. **EB:** *Hypotensive resuscitation (permissive hypotension), which maintains effective although low mean arterial pressures, may allow adequate perfusion without disruption of coagulation mechanisms, although additional research is warranted (Gourgiotis et al, 2013). A study of 921 subjects with upper gastrointestinal bleeding suggests that restrictive strategies (transfusing when hemoglobin level fell to below 7 g per deciliter) improved survival (P = .02) and resulted in fewer adverse events (P = .02) (Villanueva, 2013).*
- ▲ Consider discussing the coadministration of a proton-pump inhibitor alongside traditional NSAIDs, or with the use of a cyclo-oxygenase 2 inhibitor with the prescriber. **EB:** *Risk of NSAID-related bleeding may*

be reduced with the use of a proton-pump inhibitor or cyclo-oxygenase 2 inhibitor (van Soest et al, 2012; Chua et al, 2011; Rahme & Bernatsky, 2011; Wu et al, 2011).

- Ensure adequate nurse staffing to provide a high level of surveillance capability. **EBN/QSEN:** A key component in surveillance is monitoring; additional research is warranted in this area to identify new technologies and processes to optimize surveillance (Henneman et al, 2012). **CEB:** The size and mix of nurse staffing in hospitals has been demonstrated to have a direct impact on client outcomes. Lower levels of nurse staffing have been associated with higher rates of poor client outcomes, including those outcomes caused by gastrointestinal bleeding and “failure to rescue” (Needleman et al, 2002).

Pediatric

- ▲ Recognize that prophylactic vitamin K administration should be used in neonates for vitamin K deficiency bleeding (VKDB). **EB:** A dose of 0.5 to 1 mg vitamin K remains a standard administration for neonates to avoid VKDB and associated problems (Lippi & Franchini, 2011).
- ▲ Recognize warning signs of VKDB, including minimal bleeds, evidence of cholestasis (icteric sclera, dark urine, irritability), and failure to thrive. **EB:** Signs of classic VKDB may be mild and include delayed or difficulty feeding or bruising in 24 hours to 1 week, whereas late VKDB associated with breastfeeding may occur at 2 to 12 weeks (Lippi & Franchini, 2011).
- ▲ Use caution in administering NSAIDs in children. **CEB:** A study of children aged 2 months to 16 years found that although upper gastrointestinal bleeding is rare, one third of the cases seen were attributable to exposure to NSAIDs at doses used for analgesia or antipyretic purposes (Grimaldi-Bensouda et al, 2010). **EB:** A Cochrane review of 15 trials including about 1000 children found insufficient evidence to exclude an increase in bleeding risk after using NSAIDs, although the findings supported use of NSAIDs to reduce emesis (Lewis et al, 2013).
- ▲ Monitor children and adolescents for potential bleeding after trauma. **EB:** Trauma in children aged 1 through 12 years has been associated with early coagulopathy and subsequent bleeding (Christiaans et al, 2014). **CEB:** Children and adolescents who take SSRIs need to be closely monitored because the potential for bleeding exists across age groups (Andrade et al, 2010).
- ▲ Closely monitor children after cardiac surgery for excessive blood loss. **EB:** In a study of 182 children aged from neonate to older than 3 years, postoperative blood loss was found to be significantly associated with age ($P = .003$) and presence of cyanotic disease ($P = .01$) (Faraoni & Van der Linden, 2014).

Client/Family Teaching and Discharge Planning

- Teach client and family or significant others about any anticoagulant medications prescribed, including when to take, how often to have lab tests done, signs of bleeding to report, dietary restrictions needed, and precautions to be followed. Instruct the client to report any adverse side effects to his or her health care provider. Medication teaching includes the drug name, purpose, administration instructions (e.g., with or without food), necessary lab tests, and any side effects to be aware of. Provision of such information using clear communication principles and an understanding of the client’s health literacy level may facilitate appropriate adherence to the therapeutic regimen by enhancing knowledge base (Joint Commission, 2011; National Institutes of Health [NIH], 2011).
- Instruct the client and family on disease process and rationale for care. When clients and their family members have sufficient understanding of their disease process they can participate more fully in care and healthy behaviors. Knowledge empowers clients and family members, allowing them to be active participants in their care. **CEBN:** Use of written and verbal education enhances client retention of information needed when managing potent medications (Nurit et al, 2009).
- Provide client and family or significant others with both oral and written educational materials that meet the standards of client education and health literacy. **EB:** The use of clear communication, materials written at a fifth grade level, and the teach-back method enhance the client’s ability to understand important health-related information and improves self-care safety (NIH, 2011).

Disturbed Body Image *Gail B. Ladwig, MSN, RN, and Marsha McKenzie, MA Ed, BSN, RN*

B

NANDA-I

Definition

Confusion in mental picture of one's physical self

Defining Characteristics

Absence of body part; alteration in body function; alteration in body structure; alteration in view of one's body (e.g., appearance, structure, function); avoids looking at one's body; avoids touching one's body; behavior of acknowledging one's body; behavior of monitoring one's body; change in ability to estimate spatial relationship of body to environment; change in lifestyle; change in social involvement; depersonalization of body part by use of impersonal pronouns; depersonalization of loss by use of impersonal pronouns; emphasis on remaining strengths; extension of body boundary (e.g., includes external object); fear of reaction by others; focus on past appearance; focus on past function; focus on previous strength; heightened achievement; hiding of body part; negative feeling about body; nonverbal response to change in body (e.g., appearance, structure, function); nonverbal response to perceived change in body (e.g., appearance, structure, function); overexposure of body part; perceptions that reflect an altered view of one's body appearance; personalization of body part by name; personalization of loss by name; preoccupation with change; preoccupation with loss; refusal to acknowledge change; trauma to nonfunctioning body part

Related Factors (r/t)

Alteration in body function (due to, for example, anomaly, disease, medication, pregnancy, radiation, surgery, trauma); alteration in cognitive functioning; alteration in self perception; cultural incongruence; developmental transition; illness; impaired psychosocial functioning; injury; spiritual incongruence; surgical procedure; trauma; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Body Image; Self-Esteem; Acceptance Health Status: Coping, Identity

Example NOC Outcome with Indicators

Body Image as evidenced by the following indicators: Congruence between body reality, body ideal, and body presentation/ Satisfaction with body appearance/Adjustment to changes in physical appearance. (Rate the outcome and indicators of **Body Image**: 1 = never positive, 2 = rarely positive, 3 = sometimes positive, 4 = often positive, 5 = consistently positive [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate adaptation to changes in physical appearance or body function as evidenced by adjustment to lifestyle change
- Identify and change irrational beliefs and expectations regarding body size or function
- Recognize health-destructive behaviors and demonstrate willingness to adhere to treatments or methods that will promote health
- Verbalize congruence between body reality and body perception
- Describe, touch, or observe affected body part
- Demonstrate social involvement rather than avoidance and use adaptive coping and/or social skills
- Use cognitive strategies or other coping skills to improve perception of body image and enhance functioning
- Use strategies to enhance appearance (e.g., wig, clothing)

NIC (Nursing Interventions Classification)

B

Suggested NIC Interventions

Body Image Enhancement; Eating Disorder Management; Referral; Self-Awareness Enhancement; Self-Esteem Enhancement; Support Group Weight Gain Assistance

Example NIC Activities—Body Image Enhancement

Determine client's body image expectations based on developmental stage; Assist client to identify actions that will enhance appearance

Nursing Interventions and Rationales

- Incorporate psychosocial questions related to body image as part of nursing assessment to identify clients at risk for body image disturbance (e.g., body builders; cancer survivors; clients with eating disorders, burns, skin disorders, polycystic ovary disease; or those with stomas/ostomies/colostomies or other disfiguring conditions). **CEB:** *Assessment of psychosocial issues can help identify clients at risk for body image concerns as a result of a disfiguring condition (Borwell, 2009). Nurses, caring for clients during their hospital stay, are in the ideal position to assess how they are emotionally adapting to having a disfigurement (Bowers, 2008).*
- ▲ Discuss treatment options and outcomes for women diagnosed with breast cancer. Be prepared to explore options of lumpectomy vs. mastectomy and the potential for reconstructive surgery. Include cosmetic and appliance options available to mitigate effects of mastectomy and/or chemotherapy, such as wigs and customized mastectomy bras. **EB:** *Disturbance of body image has a relationship to the extent of the surgical procedure and the perceived ability to mitigate these body alterations (Rosenberg et al, 2013).*
- Discuss individual emphasis placed on body image before mastectomy. Be aware of increased psychosocial distress for women who maintain great emphasis on personal appearance. **EB:** *A study of 46 women undergoing mastectomy found higher rates of depression and psychological distress in women with a history of high body maintenance and appearance ideals (Arroyo & Lopez, 2011).*
- ▲ Assess for history of childhood maltreatment in clients suffering from body dissatisfaction, anorexia, or other eating disorders and make appropriate psychosocial referrals if indicated. **EB:** *The results from this study indicate specific forms of childhood maltreatment (emotional and sexual abuse) are significantly associated with body dissatisfaction, depressive symptoms, and eating disorders (Dunkley et al, 2010).*
- ▲ Assess for body dysmorphic disorder (BDD) (pathological preoccupation with muscularity and leanness; occurs more often in males than in females), and refer to psychiatry or other appropriate provider. **EB:** *BDD is a prevalent and disabling preoccupation with a slight or imagined defect in appearance. Results from the small number of available randomized controlled trials suggest that serotonin reuptake inhibitors and cognitive behavioral therapy (CBT) may be useful in treating clients with BDD (Ipser et al, 2009; Phillips, 2010).*
- ▲ Determine if body image impairment is actual or perceived and extent to which it affects the social actions and behaviors through the use of assessment tools such as Assessment of the Attitudinal Component of Body Image in Children or the Measures of Body Satisfaction and Related Concepts in Adolescents and Adults. **EB:** *Perceived defects or alterations in appearance do not necessarily reflect actual observed changes and psychosocial distress must be determined through individual assessment (Bolton et al, 2010).*
- Assess for lipodystrophy (an abnormal redistribution of adipose tissue) in clients receiving antiretroviral therapy for HIV/AIDS. This condition is common and can be a source of distress to clients. **EBN:** *Lipodystrophy is often an unavoidable side effect of antiretroviral therapy. Clients suffering from this syndrome are often ignored when expressing concerns about body changes. Nurses are uniquely qualified to assess these clients as well as provide education and psychosocial support (Gagnon & Holmes, 2011).*
- Discuss expectations for weight loss and anticipated body changes with clients planning to undergo bariatric surgery for morbid obesity. Assist the client in identifying realistic goals. **EB:** *Morbidly obese clients often set unrealistic goals for ideal body weight and appearance following bariatric surgery. Guidance is necessary to help them understand limitations of the surgery (Munoz et al, 2010).*

- ▲ Use cognitive-behavioral therapy (CBT) to assist the client to express his emotions and feelings. **EBN:** *This study of clients with bulimia used CBT and helped the clients to disentangle themselves regarding body image and weight (Huang & Hsieh, 2010).*
- Provide education and support for clients receiving treatments or medications that have the potential to alter body image. Discuss alternatives if available. **EBN:** *Men receiving androgen-deprivation therapy as a treatment for prostate cancer may be at greater risk for body image dissatisfaction (Harrington et al, 2009).*
- Take cues from clients regarding their readiness to look at a wound (ask if the client has seen the wound yet) and use clients' questions or comments as way to teach about wound care and healing. **CEB:** *Tailoring interventions to individual clients and reading their nonverbal cues likely contribute to their ability to heal emotionally from impact of wound on body image (Birdsall & Weinberg, 2001).*
- ▲ Encourage clients to participate in regular aerobic and/or nonaerobic exercise when feasible. **CEB:** *Participants of this study demonstrated higher levels of body satisfaction following the very first exercise session (Vocks et al, 2009).*
- ▲ Provide client with a list of appropriate community support groups (e.g., Reach to Recovery, Ostomy Association). **EB:** *This study of three different cancer groups (a group for women with metastatic cancer, a colorectal cancer support group, and a group for Chinese cancer clients) showed their perceived benefits were similar; the groups provided information, acceptance, and understanding (Bell et al, 2010).*

Pediatric

Many of the above interventions are appropriate for the pediatric client.

- ▲ Refer parents of children with eating disorders to a support group. **EB:** *Parents indicated that support groups assisted them in understanding eating disorder symptoms and treatment and in supporting their child struggling with an eating disorder. Additionally, the group was a source of emotional support. Results suggest that inclusion of a parent support group in the outpatient treatment of children and adolescents with eating disorders has important implications for parents (Pasold et al, 2010).*
- ▲ When caring for teenagers, be aware of the impact of acne vulgaris on quality of life. The impact was proportional to the severity of acne. Assess for symptoms of social withdrawal, limited eye contact, and expressions of low self-esteem. Educate teens on skin care and hygiene, and assist with referrals to a dermatologist when needed. **EB:** *Research performed by Tasoula et al (2012) showed that feelings of unworthiness attributable to negative appraisal by peers were present in half of subjects with acne in their study.*
- ▲ Refer families of children with severe facial burns for psychosocial support. **EB:** *Severe facial burn influences health-related quality of life in children. Additional psychosocial support is suggested to enhance recovery for clients with severe face burns and their families during the years following injury (Stubbs et al, 2011).*
- ▲ Assess family dynamics and refer parents of adolescents with anorexia or other eating disorders to professional family counseling if indicated. **EB:** *This study indicated that when adolescents' basic psychological needs are met, they are less likely to worry about the adequacy of body appearance and engage in unhealthy weight control behaviors. Parenting practices such as lack of emotional support or demanding conformity have negative impacts on adolescents suffering from eating disorders (Thøgersen-Ntoumani et al, 2010).*

Geriatric

- Focus on remaining abilities. Have client make a list of strengths. **CEB:** *Results from unstructured interviews with women aged 61 to 92 years regarding their perceptions and feelings about their aging bodies suggest that women exhibit the internalization of ageist beauty norms, even as they assert that health is more important to them than physical attractiveness and comment on the "naturalness" of the aging process (Hurd, 2000).*
- Encourage regular exercise for older adults. **EB:** *Research done by Mortensen et al (2012) supports the importance of physical activity to preserve functioning in older adults.*

Multicultural

- Assess for the influence of cultural beliefs, regional norms, and values on the client's body image. **EB:** *A study of young adults living in Hawaii and Australia demonstrated a tolerance for body sizes that are significantly larger than the body mass index size considered healthy (Knight et al, 2010).* **EBN:** *Each client*

should be assessed for body image based on the phenomenon of communication, time, space, social organization, environmental control, and biological variations (Giger & Davidhizar, 2008). **EB**: A study of Muslim women found that the strength of their religious faith was inversely related to body dissatisfaction (Mussap, 2009).

- Acknowledge that body image disturbances can affect all individuals regardless of culture, race, or ethnicity. **EB**: Results in this study suggest that gender and cultural differences in body image among adolescents are significant (Ceballos & Czyzewska, 2010). Body image disorders are becoming increasingly prevalent in developing non-Western countries such as China (Xu et al, 2010).

Home Care

- The above interventions may be adapted for home care use.
- Assess client's level of social support. Social support is one of the determinants of the client's recovery and emotional health. **CEB**: Females who perceived they have good social support were found to adapt better to changes in body image after stoma surgery (Brown & Randle, 2005).
- Assess family/caregiver level of acceptance of client's body changes. **CEB**: Family members' expressions and reactions were found to impact women's coping, and negative reactions in particular increased the women's level of anxiety (Brown & Randle, 2005).
- Encourage clients to discuss concerns related to sexuality and provide support or information as indicated. Many conditions that affect body image also affect sexuality. **CEB**: Brown & Randle (2005) found that clients (particularly females) with stomas often believe they are less sexually attractive after surgery, even though their sexual partner may not share that view. However, clients who underwent urostomy surgery often experienced a decrease in sexual functioning.
- Teach all aspects of care. Involve clients and caregivers in self-care as soon as possible. Do this in stages if clients still have difficulty looking at or touching changed body part. **EB**: Prostate cancer clients need interventions that assist them to manage the effects of their disease. Programs need to include spouses because they also are negatively affected by the disease and can influence client outcomes (Kershaw et al, 2008).

Client/Family Teaching and Discharge Planning

- Teach appropriate care of surgical site (e.g., mastectomy site, amputation site, ostomy site). **CEB**: Integration of a cosmetic program into the routine nursing care for oral cancer clients is highly recommended. This study confirmed that cosmetic rehabilitation had positive effects on the body image of oral cancer clients (Huang & Liu, 2008).
- Encourage significant others to offer support. **CEB**: Clients with heart failure in this study managed depressive symptoms that affect health-related quality of life by engaging in activities such as exercise and reading, and by using positive thinking, spirituality, and social support. Helping clients find enhanced social support is important (Dekker et al, 2009).
- ▲ Refer clients who are having difficulty with personal acceptance, personal and social body image disruption, sexual concerns, reduced self-care skills, and management of surgical complications to an interdisciplinary team or specialist (e.g., ostomy nurse) if available. **CEB**: There is sufficient research-based evidence to conclude that intestinal ostomy surgery exerts a clinically relevant impact on health-related quality of life and that nursing interventions can ameliorate this effect (Pittman et al, 2009).

Insufficient Breast Milk Kerstin West-Wilson, RNC, IBCLC, and David Wilson, MS, RNC

NANDA-I

Definition

Low production of maternal breast milk

Defining Characteristics

Infant

Constipation; frequent crying; frequently seeks to suckle at breast; prolonged breastfeeding time; suckling time at breast appears unsatisfactory; voids small amounts of concentrated urine; weight gain less than 500 g in a month

Mother

Absence of milk production with nipple stimulation; delay in milk production; expresses breast milk less than prescribed volume

Related Factors

Infant

Ineffective latching on to breast; ineffective sucking reflex; insufficient opportunity for suckling at the breast; insufficient suckling time at breast; rejection of breast

Mother

Alcohol consumption; insufficient fluid volume; malnutrition; pregnancy; smoking; treatment regimen

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Breastfeeding Establishment: Infant, Maternal; Breastfeeding Maintenance; Anxiety Self-control; Parent-Infant Attachment

Example NOC Outcome with Indicators

Breastfeeding Establishment: as evidenced by the following indicators: Proper alignment/latch on/areolar compression/suck reflex/Nursing minimum of 15 minutes per breast/Urinations and stools appropriate for age/Weight gain appropriated for age. (Rate the outcome and indicators of **Breastfeeding Establishment:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section 1].)

Client Outcomes**Client Will (Specify Time Frame)**

- State knowledge of indicators of adequate milk supply
- State and demonstrate measures to ensure adequate milk supply

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Lactation Counseling; Lactation Suppression; Kangaroo Care; Parent Education: Infant

Example NIC Activities—Lactation Counseling

Correct misconceptions, misinformation, and inaccuracies about breastfeeding; Provide educational material, as needed; Encourage attendance at breastfeeding classes and support groups for “perceived insufficient [milk supply]” (Gatti, 2008).

Nursing Interventions and Rationales

- Provide lactation support at all phases of lactation (Neifert & Bunick, 2013; Nielsen et al, 2011).
- Communicate routine advice to mothers without making them feel pressured or guilty and nurses should be aware of “how” they give routine instructions (Flaherman et al, 2012).
- Initiate skin-to-skin contact at birth and undisturbed contact for the first hour following birth; the mother should be encouraged to watch the baby, not the clock. *These behaviors are associated with an abundant milk supply (Noonan, 2011; Parker et al, 2013).*
- Encourage postpartum women to start breastfeeding based on infant need as early as possible and reduce formula use to increase breastfeeding frequency. Use nonnarcotic analgesics as early as possible. **EBN:** *These interventions are suggested to decrease early weaning in this study of women who had cesarean deliveries and perceived insufficient milk supply (Lin et al, 2011; Chantry, 2014; Gatti, 2008; Kent et al, 2013; Lou et al, 2014; Nielsen et al, 2011).*
- Provide suggestions for mothers on how to increase milk production and how to determine whether there is insufficient milk supply. **EBN:** *Teach mothers how to determine low intake of breast milk by checking baby’s wet diapers (fewer than 6 to 8) and monitoring the frequency and amount of baby’s bowel movements. Provide suggestions to women on how to increase milk production, such as improving latch-on, increasing frequency of feedings, offering both breasts during each breastfeeding session, and drinking enough fluids (Yen-Ju & McGrath, 2011; Gatti, 2008; Ndikom et al, 2014).*
- Instruct mothers that breastfeeding frequency, sucking times, and amounts are variable and normal. Assist mothers in optimal milk removal frequency. **EBN:** *Breastfeeding rates may be affected by a maternal perception of insufficient milk production and less than optimal milk removal frequency (Kent et al, 2012; Kent et al, 2013).*

- ▲ Consider the use of medication for mothers of preterm infants with insufficient expressed breast milk. **EBN:** *Breast milk remains the optimal form of enteral nutrition for term and preterm infants until up to 6 months postnatal age. In these studies there was modest improvement in expressing breast milk (EBM) values with the use of a galactagogue medication (Donovan & Buchanan, 2012).*
- ▲ Need to be more cautious with recommending galactagogues.
- ▲ Not in the scope of practice for IBLC lactation consultants to recommend galactagogues (*Academy of Breastfeeding Medicine Protocol Committee, 2011; Donovan & Buchanan, 2012*).

Pediatric

- Provide individualized follow-up with extra home visits or outpatient visits for teen mothers within the first few days after hospital discharge and encourage schools to be more compatible with breastfeeding. *Adolescent mothers in the United States are much less likely to imitate breastfeeding than older mothers. This study indicated that these interventions may be helpful for teens who desire to breastfeed (Tucker et al, 2011).*

Multicultural

- Provide information and support to mothers on benefits of breastfeeding at antenatal visits. **EB:** *A study of mothers of infants in Bhaktapur, Nepal, found that, although proper breastfeeding is the most cost-effective intervention for reducing childhood morbidity and mortality, adherence to breastfeeding recommendations in developing countries is not satisfactory. Although many mothers instituted breastfeeding within 1 hour of delivery, continuation for up to 6 months was not common. Very few mothers received any information on breastfeeding during the antenatal visit (Ulak et al, 2012; Neifert & Bunik, 2013; Sultana et al, 2013).*
- Refer to care plans Interrupted **Breastfeeding** and Readiness for enhanced **Breastfeeding** for additional interventions.

Ineffective Breastfeeding *Barbara J. Wheeler, RN, BN, MN, IBCLC*

B

NANDA-I

Definition

Difficulty providing milk to an infant or young child directly from the breasts, which may compromise nutritional status of the infant/child

Defining Characteristics

Inadequate infant stooling; infant arching at breast; infant crying at breast; infant crying within first hour after breastfeeding; infant fussing within 1 hour of breastfeeding; infant inability to latch on to maternal breast correctly; infant resisting latching on to breast; infant unresponsive to other comfort measures; insufficient infant weight gain; insufficient emptying of each breast per feeding; insufficient signs of oxytocin release; perceived inadequate milk supply; sore nipples persisting beyond first week; sustained infant weight loss; unsustained suckling at the breast

Related Factors (r/t)

Delayed lactogenesis II; inadequate milk supply; insufficient family support; insufficient opportunity for suckling at breast; insufficient parental knowledge regarding breastfeeding techniques; insufficient parental knowledge regarding importance of breastfeeding; interrupted breastfeeding; maternal ambivalence; maternal anxiety; maternal breast anomaly; maternal fatigue; maternal obesity; maternal pain; oropharyngeal defect; pacifier use; poor infant sucking reflex; prematurity; previous breast surgery; previous history of breastfeeding failure; short maternity leave; supplemental feedings with artificial nipple

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes and Example

Refer to care plan for Readiness for enhanced **Breastfeeding**.

Client Outcomes

Client Will (Specify Time Frame)

- Achieve effective breastfeeding (dyad)
- Verbalize/demonstrate techniques to manage breastfeeding problems (mother)
- Manifest signs of adequate intake at the breast (infant)
- Manifest positive self-esteem in relation to the infant feeding process (mother)
- Explain alternative method of infant feeding if unable to continue exclusive breastfeeding (mother)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions and Example

Refer to care plan Readiness for enhanced **Breastfeeding**.

Nursing Interventions and Rationales

- Identify women with risk factors for lower breastfeeding initiation and continuation rates (lack of information, inadequate family and social support) as well as factors contributing to ineffective breastfeeding as early as possible in the perinatal experience. **EBN**: *Nurses are well positioned to provide accurate information and support the development of breastfeeding skills, which facilitates breastfeeding confidence and success (Neifert & Bunik, 2013).*
- Provide time for clients to express expectations and concerns, and provide emotional support as needed. **EBN**: *Lactation consultants, nurses, and peers play a key role in the establishment and continuation of breastfeeding (Neifert & Bunik, 2013).*
- Encourage skin-to-skin holding, beginning immediately after delivery. **EB**: *Skin-to-skin holding is associated with improved milk supply, early initiation of breastfeeding, and improved breastfeeding duration (Moore et al, 2012).*

- Use valid and reliable tools to measure breastfeeding performance and to predict early discontinuance of breastfeeding whenever possible/feasible. **CEB:** *Ho and McGrath (2010) compared and contrasted the clinical usefulness and psychometric properties of seven self-report instruments and found that they each contribute to our understanding of breastfeeding in various ways. The Breastfeeding Self-Efficacy Scale has demonstrated an ability to predict breastfeeding success or failure, thus providing opportunity for focused education and support for mothers who need it (Dennis, 2003).*
- Promote comfort and relaxation to reduce pain and anxiety. **CEB:** *Discomfort and increased tension are factors associated with reduced let-down reflex and premature discontinuance of breastfeeding. Anxiety and fear are associated with decreased milk production (Mezzacappa & Katkin, 2002).*
- Avoid supplemental feedings. **EB:** *A correlation exists between hospital staff providing formula and/or water supplements and failure to succeed with exclusive breastfeeding (Kaikini & Hyrkas, 2014).*
- Teach mother to observe for infant behavioral cues and responses to breastfeeding. **EBN:** *Monitor and assess the mom and baby for several breastfeeding sessions. Teaching mother will build her confidence and knowledge base, which facilitates successful breastfeeding (Noonan, 2011).*
- ▲ Provide necessary equipment/instruction/assistance for milk expression as needed. **EBN:** *Expressing breast milk by hand may be more effective in the removal of milk, particularly in the immediate postpartum period, than the use of electric pumps (Flaherman et al, 2012).*
- ▲ Provide referrals and resources: lactation consultants, nurse and peer support programs, community organizations, and written and electronic sources of information. **EBN:** *Systematic reviews support the use of professionals with special skills in breastfeeding, peer support programs, and written and electronic information to promote continued breastfeeding (Neifert & Bunik, 2013).*
- See care plan for Readiness for enhanced **Breastfeeding.**

Multicultural

- Assess whether the client's cultural beliefs about breastfeeding are contributing to ineffective breastfeeding. **CEB:** *Some cultures may add semisolid food within the first month of life as a result of concerns that the infant is not getting enough to eat and the perception that "big is healthy" (Higgins, 2000). **EBN:** Some traditional cultures, including the Turkish, consider colostrum unsuitable to feed the newborn, thus formula may be required to prevent hypoglycemia and dehydration (Demirtas, 2012).*
- Assess the influence of family support on the decision to continue or discontinue breastfeeding. **EB:** *Family members' impressions and ideas about breastfeeding influence breastfeeding initiation and duration (Odom et al, 2014).*
- Provide traditional ethnic foods for breastfeeding mothers. **CEB:** *One barrier to breastfeeding is a lack of hospital foods that allow women to follow a traditional diet postpartum. After a staff training program on breastfeeding, and the creation of a Cambodian menu, initiation rates increased significantly more in Cambodians than in non-Cambodians. Postintervention, there was no significant difference between breastfeeding initiation rates among Cambodian women (66.7%) compared with non-Cambodians (68.9%) (Galvin et al, 2008).*
- See care plan for Readiness for enhanced **Breastfeeding.**

Home Care

- The above interventions may be adapted for home care use.
- Provide anticipatory guidance in relation to home management of breastfeeding. **EB:** *The two most common problems experienced by breastfeeding women are nipple and/or breast pain and low (or perceived low) milk supply; these problems may be preventable with anticipatory guidance (Amir, 2014). For mothers returning to the workforce, longer maternity leaves and regularly pumping milk during the workday are associated with longer breastfeeding duration (Neifert & Bunik, 2013).*
- ▲ Investigate availability of and refer to public health department, hospital home follow-up breastfeeding program, or other postdischarge support. **EBN:** *Postdischarge follow-up has been associated with improved breastfeeding duration (Mejdoubi et al, 2014).*
- See care plan for Risk for impaired **Attachment.**

Client/Family Teaching and Discharge Planning

- Instruct the client on maternal breastfeeding behaviors/techniques (preparation for, positioning, initiation of/promoting latch-on, burping, completion of session, and frequency of feeding). Consider use of a video. **EBN:** *Assess breastfeeding mothers to determine knowledge deficits and provide teaching.*

Assisting with breastfeeding and addressing the mother's concerns facilitate breastfeeding success (Neifert & Bunik, 2013).

- Teach the client self-care measures for the breastfeeding woman (e.g., breast care, management of breast/nipple discomfort, nutrition/fluid, rest/activity). **CEB:** *Painful nipples, mastitis, adequate hydration, and fatigue are some of the problems a breastfeeding woman may experience (Ladewig et al, 2010).*
- Provide information regarding infant cues and behaviors related to breastfeeding and appropriate maternal responses (e.g., cues that the infant is ready to feed, behaviors during feeding that contribute to effective breastfeeding, measures of infant feeding adequacy). *Improved knowledge base and ongoing support to learn psychomotor skills facilitates effective breastfeeding (Neifert & Bunik, 2013).*
- Provide education to partner/family/significant others as needed. **EBN/EB:** *Family members' impressions and ideas about breastfeeding influence breastfeeding initiation and duration (Odom et al, 2014).*

Interrupted Breastfeeding *Barbara J. Wheeler, RN, BN, MN, IBCLC*

NANDA-I

Definition

Break in the continuity of providing milk to an infant or young child directly from the breasts, which may compromise breastfeeding success and/or nutritional status of the infant/child.

Defining Characteristics

Nonexclusive breastfeeding

Related Factors (r/t)

Contraindications to breastfeeding (e.g., pharmaceutical agents); hospitalization of child; infant illness; maternal employment; maternal illness; maternal infant separation; need to abruptly wean infant; prematurity

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Breastfeeding Maintenance; Knowledge: Breastfeeding; Parent-Infant Attachment

Example NOC Outcome with Indicators

Breastfeeding Maintenance as evidenced by the following indicators: Infant's growth and development in normal range/Ability to safely collect and store breast milk/Awareness that breastfeeding can continue beyond infancy/Knowledge of benefits from continued breastfeeding. (Rate the outcome and indicators of **Breastfeeding Maintenance: Infant**: 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

Infant

- Receive mother's breast milk if not contraindicated by maternal conditions (e.g., certain drugs, infections) or infant conditions (e.g., galactosemia)

Maternal

- Maintain lactation
- Achieve effective breastfeeding or satisfaction with the breastfeeding experience
- Demonstrate effective methods of breast milk collection and storage

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Bottle Feeding; Emotional Support; Lactation Counseling

Example NIC Activities—Lactation Counseling

Instruct patient to contact lactation consultant to assist in determining status of milk supply (i.e., whether insufficiency is perceived or actual); Encourage employers to provide opportunities for and private facilities for lactating mothers to pump and store breast milk during the work day

Nursing Interventions and Rationales

- Discuss and provide support for mother's desire/intention to begin or resume breastfeeding. **EB**: *Mothers who perceived that care providers favored exclusive breastfeeding achieved significantly higher rates of exclusive breastfeeding at 1 and 3 months, as compared with those who perceived care providers were neutral about the method of infant feeding (Ramakrishnan et al, 2014).* **EBN**: *Breastfeeding rates are improved when hospitals have written breastfeeding policies and when staff has enhanced education regarding breastfeeding knowledge, attitudes, and skills (Li et al, 2014).*
- Clarify that interruption in breastfeeding is truly necessary. (Expert recommendation): *Mothers are sometimes inappropriately advised to discontinue breastfeeding (Sachs & AAP Committee on Drugs, 2013). When there is a question of possible contraindication to breastfeeding, a discussion of potential risks versus probable, known benefits of breastfeeding must be held with mother and family (Lawrence, 2013).*
- Provide anticipatory guidance to the mother/family regarding potential duration of the interruption when possible/feasible. Reassure mother/family that measures to sustain or restart lactation and promote parent-infant attachment can make it possible to resume breastfeeding when the condition/situation requiring interruption is resolved. **EB**: *Mothers who had never breastfed, and those who had stopped, were successful in establishing or reestablishing breastfeeding with the help of lactation support (Nyati et al, 2014).*
- Reassure the mother/family that the infant will benefit from any amount of breast milk provided. **EBN**: *One of the most common reasons mothers supplement or stop breastfeeding is their perception of the baby not getting milk and/or enough milk (Noonan, 2011).*

- Assess mother's concerns, and observe mother performing psychomotor skills (expression, storage, alternative feeding, skin to skin care, and/or breastfeeding) and assist as needed. **EBN:** *Individualized support and instruction improves likelihood of breastfeeding success (Demirtas, 2012).*
- Collaborate with mother/family/health care providers (as needed) to develop a plan for skin-to-skin contact. **EBN:** *Skin-to-skin contact between mothers and newborns results in improved rates of exclusive breastfeeding (Brown et al, 2014).*
- Collaborate with the mother/family/health care provider/employer (as needed) to develop a plan for expression/pumping of breast milk and/or infant feeding. **EB:** *Workplaces whose environments include supervisor or peer support, space (not in the bathroom) in which to pump, a fridge, rental pump, and on-site daycare were associated with improved duration of exclusive breastfeeding (Bai & Wunderlich, 2013).*
- Monitor for signs indicating infant's ability to breastfeed and interest in breastfeeding. **EBN:** *Teach the mother to recognize and respond to her baby's feeding cues and signs that her breasts are filling (Noonan, 2011).*
- ▲ Use supplementation only as medically indicated. **EBN:** *A correlation exists between hospital staff providing formula and/or water supplements and failure to succeed with breastfeeding (Kaikini & Hyrkas, 2014).*
- Provide anticipatory guidance for common problems associated with interrupted breastfeeding (e.g., incomplete emptying of milk glands, diminishing milk supply, infant difficulty with resuming breastfeeding, or infant refusal of alternative feeding method). **EBN:** *Emotional support, as well as information regarding how to prevent and respond to breastfeeding problems, contributes to promotion of exclusive breastfeeding (Neifert & Bunik, 2013).*
- ▲ Initiate follow-up and make appropriate referrals.
- Assist the client to accept and learn an alternative method of infant feeding if effective breastfeeding is not achieved. **CEB:** *If it is clear that breastfeeding cannot be achieved after the interruption and an alternative feeding method must be instituted, the mother needs support and education (Mozingo et al, 2000).*
- See care plans for Readiness for enhanced **Breastfeeding** and Ineffective **Breastfeeding**.

Multicultural

- Teach culturally appropriate techniques for maintaining lactation. **CEB:** *The Oketani method of breast massage is used by Japanese and other Asian women. Oketani breast massage improved quality of human milk by increasing total solids, lipids, casein concentration, and gross energy (Foda et al, 2004). Some traditional cultures, including the Turkish, consider colostrum unsuitable to feed the newborn, thus formula may be required to prevent hypoglycemia and dehydration (Demirtas, 2012).*
- See care plans for Readiness for enhanced **Breastfeeding** and Ineffective **Breastfeeding**.

Home Care

- The above interventions may be adapted for home care use.

Client/Family Teaching and Discharge Planning

- Teach mother effective methods to express breast milk. **EBN:** *Expressing breast milk by hand may be more effective in the removal of milk, particularly in the immediate postpartum period, than the use of electric pumps (Flaherman et al, 2012).*
- Teach mother/parents about skin-to-skin care. **EBN:** *Skin-to-skin care promotes attachment, facilitates improved milk production, and contributes to improved rate and duration of breastfeeding (Brown et al, 2014).*
- Instruct mother on safe breast milk handling techniques. **EB:** *Breastfeeding mothers can retain the high quality of breast milk and the health of their infant by using safe preparation guidelines and storage methods (CDC, 2014).*
- See care plans for Readiness for enhanced **Breastfeeding** and Ineffective **Breastfeeding**.

Readiness for enhanced Breastfeeding *Barbara J. Wheeler, RN, BN, MN, IBCLC*

NANDA-I

Definition

A pattern of providing milk to an infant or young child directly from the breasts, which may be strengthened

Defining Characteristics

Mother expresses desire to enhance ability to provide breast milk for child's nutritional needs; mother expresses desire to enhance ability to exclusively breastfeed

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Breastfeeding Establishment: Infant, Maternal; Breastfeeding Maintenance

Example NOC Outcome with Indicators

Breastfeeding Establishment: Infant as evidenced by the following indicators: Proper alignment and latch-on/Proper areolar grasp/Proper areolar compression/Correct suck and tongue placement/Audible swallow/Nursing a minimum of 5 to 10 minutes per breast/Minimum eight feedings per day/Urinations per day appropriate for age/Weight gain appropriate for age. (Rate the outcome and indicators of **Breastfeeding Establishment: Infant**: 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain effective breastfeeding without supplementation with formula
- Maintain normal growth patterns (infant)
- Verbalize satisfaction with breastfeeding process (mother)

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

NIC (Nursing Interventions Classification)

B

Suggested NIC Interventions

Lactation Counseling

Example NIC Activities—Lactation Counseling

Provide information about psychological and physiological benefits of breastfeeding; Provide mother the opportunity to breastfeed after birth, when possible

Nursing Interventions and Rationales

- Encourage expectant mothers to learn about breastfeeding before and during pregnancy. **EBN:** *Systematic reviews have identified that health education, particularly individualized education, significantly increases breastfeeding initiation rates (Neifert & Bunik, 2013).*
- Encourage and facilitate early skin-to-skin contact (position includes contact of the naked baby with the mother's bare chest). **EB:** *Skin-to-skin holding is associated with improved milk supply, early initiation of breastfeeding, and improved breastfeeding duration (Moore et al, 2012).*
- Encourage rooming-in and breastfeeding on demand. **EBN:** *Mothers who room-in with their infants have greater percentages of exclusive breastfeeding when released from the hospital (Neifert & Bunik, 2013).*
- Monitor the breastfeeding process and identify opportunities to enhance knowledge and experience regarding breastfeeding. **EB:** *While mothers and babies are in the hospital it is essential that hospital personnel support their effort to learn to breastfeed (CDC, 2011).*
- Give encouragement/positive feedback related to breastfeeding mother-infant interactions. **CEB:** *Positive feedback builds confidence. The Breastfeeding Self-Efficacy Scale, which measures maternal breastfeeding confidence, has demonstrated higher self-efficacy (confidence) is associated with longer duration of breastfeeding (Dennis, 2003).*
- Discuss prevention and treatment of common breastfeeding problems, such as nipple pain and/or trauma. **EB:** *Common problems experienced by breastfeeding women may be preventable with anticipatory guidance, or successfully managed with prompt assistance from a health care provider (Amir, 2014).*
- Teach mother to observe for infant behavioral cues and responses to breastfeeding. **EBN:** *Monitor and assess the mom and baby for several breastfeeding sessions. Teaching mother will build her confidence and knowledge base, which facilitates successful breastfeeding (Noonan, 2011).*
- Identify current support-person network and opportunities for continued breastfeeding support. **EB:** *Family members' impressions and ideas about breastfeeding influence breastfeeding initiation and duration (Odom et al, 2014).*
- Avoid supplemental bottle feedings and do not provide samples of formula on discharge. **EB:** *A correlation exists between hospital staff providing formula and/or water supplements and failure to succeed with exclusive breastfeeding (Kaikini & Hyrkas, 2014).*
- ▲ Provide follow-up contact; as available provide home visits and/or peer counseling. **EBN:** *Systematic reviews support the use of professionals with special skills in breastfeeding and peer support programs to promote continued breastfeeding (Neifert & Bunik, 2013).*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on current breastfeeding practices. **CEB:** *The Hispanic mother may believe stress and anger make bad milk, which makes a breastfeeding infant ill. Some Hispanic women neutralize the bowel when weaning from breast to bottle by feeding only anise tea for 24 hours (Gonzalez et al, 2008). **EBN:** Some traditional cultures, including the Turkish, consider colostrum unsuitable to feed the newborn, thus formula may be required to prevent hypoglycemia and dehydration (Demirtas, 2012).*

Home Care

- The above interventions may be adapted for home care use.

Client/Family Teaching and Discharge Planning

- Include the partner and other family members in education about breastfeeding. **EB:** *Family members' impressions and ideas about breastfeeding influence breastfeeding initiation and duration (Odom et al, 2014).*
- Teach the client the importance of maternal nutrition. **EB:** *Consumption or avoidance of specific foods or drinks is generally not necessary. Breastfeeding mothers should consume 450 to 500 calories more than nonpregnant, nonnursing women. Adequate intake of DHA is important with an average daily intake of 200 to 300 mg (the amount ingested with consumption of one to two portions of fish per week) recommended (AAP, 2012).*
- Teach mother about the infant's subtle hunger cues (e.g., rooting, sucking, mouthing, hand-to-mouth, hand-to-hand activity) and encourage her to breastfeed whenever signs are apparent. **EB:** *Evidence-based practice guidelines support the teaching/reinforcement of these skills as important to effective breastfeeding (Holmes et al, 2013).*
- Review guidelines for frequency (at least every 2 to 3 hours, or 8 to 12 feedings per 24 hours) and duration (until suckling and swallowing slow down and satiety is reached) of feeding times. **EB:** *In the first few days, frequent and regular stimulation of the breasts is important to establish an adequate milk supply; after breastfeeding is established, feeding lasts until the breasts are drained (Holmes et al, 2013).*
- Provide information about common infant behaviors related to breastfeeding, and appropriate maternal responses. **EBN:** *Improved knowledge base and ongoing support to learn psychomotor skills facilitates effective breastfeeding (Neifert & Bunik, 2013).*
- ▲ Provide referrals and resources: lactation consultants, nurse and peer support programs, community organizations, and written and electronic sources of information. **EBN:** *Systematic reviews support the use of professionals with special skills in breastfeeding, peer support programs, and written and electronic information to promote continued breastfeeding (Neifert & Bunik, 2013).*

Ineffective Breathing pattern *Debra Siela, PhD, RN, CCNS, ACNS-BC, CCRN-K, CNE, RRT*

NANDA-I

Definition

Inspiration and/or expiration that does not provide adequate ventilation

• = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Defining Characteristics

B

Abnormal breathing pattern (e.g., rate, rhythm, depth); altered chest excursion; bradypnea; decrease in expiratory pressure; decrease in inspiratory pressure; decrease in minute ventilation; decrease in vital capacity; dyspnea; increase in anterior-posterior chest diameter; nasal flaring; orthopnea; prolonged expiration phase; pursed-lip breathing; tachypnea; use of accessory muscles to breathe; use of three-point position

Related Factors (r/t)

Anxiety; body position that inhibits lung expansion; bony deformity; chest wall deformity; fatigue; chest wall deformity; fatigue; hyperventilation; hypoventilation syndrome; musculoskeletal impairment; neurological immaturity; neurological impairment (e.g., positive electroencephalogram, head trauma, seizure disorders); neuromuscular impairment; obesity; pain; respiratory muscle fatigue; spinal cord injury

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Respiratory Status: Airway Patency, Ventilation; Vital Signs

Example NOC Outcome with Indicators

Respiratory Status: Ventilation as evidenced by the following indicators: Respiratory rate/Moves sputum out of airway/Adventitious breath sounds not present/Shortness of breath not present/Auscultated breath sounds/Auscultated vocalization/Chest x-ray findings (Rate each indicator of **Respiratory Status: Ventilation**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate a breathing pattern that supports blood gas results within the client's normal parameters
- Report ability to breathe comfortably
- Demonstrate ability to perform pursed-lip breathing and controlled breathing
- Identify and avoid specific factors that exacerbate episodes of ineffective breathing patterns

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Airway Management; Respiratory Monitoring

Example NIC Activities—Airway Management

Encourage slow, deep breathing, turning, and coughing; Monitor respiratory and oxygenation status as appropriate

Nursing Interventions and Rationales

- Monitor respiratory rate, depth, and ease of respiration. *Normal respiratory rate is 10 to 20 breaths/min in the adult (Jarvis, 2015).* **EBN:** *When the respiratory rate exceeds 30 breaths/min, along with other physiological measures, a study demonstrated that a significant physiological alteration existed (Hagle, 2008).*
- Note pattern of respiration. If client is dyspneic, note what seems to cause the dyspnea, the way in which the client deals with the condition, and how the dyspnea resolves or gets worse. **EBN:** *Ask the patient if they are short of breath (Campbell, 2011). Use a tool such as the Respiratory Distress Observation Scale (RDOS) for assessing acutely ill or critically ill patients in respiratory distress who cannot self-report dyspnea (Campbell et al, 2010).*
- Note amount of anxiety associated with the dyspnea. *A normal respiratory pattern is regular in a healthy adult. To assess dyspnea, it is important to consider all of its dimensions, including antecedents, mediators, reactions, and outcomes.*
- Attempt to determine if client's dyspnea is physiological or psychological in cause. *The evaluation of a client with dyspnea continues to be dependent on a thorough history and physical examination. In the client*

with acute worsening of chronic breathlessness, the health care provider must be attuned to the possibility of a new pathophysiological derangement superimposed on a known disorder. Instruments or sections of instruments pertaining to dyspnea should be classified as addressing domains of sensory-perceptual experience, affective distress, or symptom/disease impact or burden (Parshall et al, 2012). **EB:** Maximal respiratory work is less unpleasant than moderately intense air hunger, and unpleasantness of dyspnea can vary independently from perceived intensity, consistent with pain. Separate dimensions should be measured (Banzett et al, 2008). A study found that when the cause was psychological (medically unexplained dyspnea), there was affective dyspnea, anxiety, and tingling in the extremities. Whereas, when the dyspnea was physiological, there was associated wheezing, cough, sputum, and palpitations (Han et al, 2008).

- The rapidity of which the onset of dyspnea is noted is also an indicator of the severity of the pathological condition (Croucher, 2014).

Psychological Dyspnea—Hyperventilation

- Monitor for symptoms of hyperventilation including rapid respiratory rate, sighing breaths, lightheadedness, numbness and tingling of hands and feet, palpitations, and sometimes chest pain (Bickley & Szilagyi, 2012).
- Assess cause of hyperventilation by asking client about current emotions and psychological state.
- Ask the client to breathe with you to slow down respiratory rate. *Maintain eye contact and give reassurance. By making the client aware of respirations and giving support, the client may gain control of the breathing rate.*
- ▲ Consider having the client breathe in and out of a paper bag as tolerated. *This simple treatment helps associated symptoms of hyperventilation including helping to retain carbon dioxide, which will decrease associated symptoms of hyperventilation (Bickley & Szilagyi, 2012).*
- ▲ If client has chronic problems with hyperventilation, numbness and tingling in extremities, dizziness, and other signs of panic attacks, refer for counseling.

Physiological Dyspnea

- ▲ Ensure that client in acute dyspneic state has received any ordered medications, oxygen, and any other treatment needed.
- Determine intensity, unpleasantness, or distress of dyspnea using a rating scale such as an intensity focused modified Borg scale or visual analogue scale (Parshall et al, 2012).
- Note client description of the quality of breathing discomfort, such as chest tightness, air hunger, inability to breathe deeply, urge to breathe, starved for air, feeling of suffocation (Parshall et al, 2012).
- Note use of accessory muscles, nasal flaring, retractions, irritability, confusion, or lethargy. *These symptoms signal increasing respiratory difficulty (Campbell, 2011).*
- Observe color of tongue, oral mucosa, and skin for signs of cyanosis. *In central cyanosis, both the skin and mucous membranes are affected due to seriously impaired pulmonary function from unventilated or underventilated alveoli. Peripheral cyanosis (skin only) usually indicates vasoconstriction or obstruction to blood flow (Loscalzo, 2013).*
- Auscultate breath sounds, noting decreased or absent sounds, crackles, or wheezes. *These abnormal lung sounds can indicate a respiratory pathology associated with an altered breathing pattern (Croucher, 2014).*
- Assess for hemodynamic stability for the client with acute dyspnea. *Rapid evaluation for impending respiratory failure is essential and includes fragmented speech, tripod positioning, diaphoresis, cyanosis, Pao₂ less than 50 mm Hg, Paco₂ greater than 70, and use of accessory muscles. Hypotension along with dyspnea indicates threat of cardiopulmonary collapse (Croucher, 2014).*
- ▲ Monitor oxygen saturation continuously using pulse oximetry. *Note blood gas results as available. An oxygen saturation of less than 90% (normal: 95% to 100%) or a partial pressure of oxygen of less than 80 mm Hg (normal: 80 to 100 mm Hg) indicates significant oxygenation problems.*
- Using touch on the shoulder, coach the client to slow respiratory rate, demonstrating slower respirations, making eye contact with the client, and communicating in a calm, supportive fashion. *The nurse's presence, reassurance, and help in controlling the client's breathing can be beneficial in decreasing anxiety. **EB:** Anxiety is an important indicator of severity of client's disease with chronic obstructive pulmonary disease (COPD) (Campbell et al, 2011).*
- Support the client in using pursed-lip and controlled breathing techniques. *Pursed-lip breathing may relieve dyspnea in advanced COPD (Parshall et al, 2012). Pursed-lip breathing results in increased use of intercostal muscles, decreased respiratory rate, increased tidal volume, and improved oxygen saturation levels*

(Faager et al, 2008). **EBN:** A systematic review found pursed-lip breathing effective in decreasing dyspnea (Carriero-Kohlman & Donesky-Cuenca, 2008).

- If the client is acutely dyspneic, consider having the client lean forward over a bedside table, resting elbows on the table if tolerated. *Leaning forward can help decrease dyspnea, possibly because gastric pressure allows better contraction of the diaphragm (Langer et al, 2009). This is called the tripod position and is used during times of distress, including when walking.*
- Position the client in an upright or semi-Fowler's position. *Most patients will have optimal vital capacity, oxygenation, and reduced dyspnea when upright with arms elevated on pillows or a bedside table (Campbell, 2011).* See Nursing Interventions and Rationales for Impaired Gas exchange for further information on positioning.
- ▲ Administer oxygen as ordered. *Oxygen administration has been shown to correct hypoxemia, which causes dyspnea (Wong & Elliott, 2009; Campbell, 2011). But, supplemental oxygen may not relieve all dyspnea (Parshall et al, 2012).*
- *Mechanical ventilation, invasive or noninvasive, is a reliable means of reducing dyspnea associated with respiratory failure (Campbell, 2011).*
- *Opioids may be used for both acute and terminal dyspnea, considering careful safe dosing for relief and side effect of constipation (Campbell, 2011; Parshall et al, 2012).*
- Increase client's activity to walking three times per day as tolerated. Assist the client to use oxygen during activity as needed. See Nursing Interventions and Rationales for **Activity** intolerance. Walking 20 minutes per day is recommended for those unable to be in a structured program (GOLD, 2015). *Supervised exercise has been shown to decrease dyspnea and increase tolerance to activity (GOLD, 2015).*
- Schedule rest periods before and after activity. *Respiratory clients with dyspnea are easily exhausted and need additional rest. Nurses coordinate all patient care and are integral to ensuring spacing of activity to minimize or prevent dyspnea (Campbell, 2011).*
- ▲ Evaluate the client's nutritional status. Refer to a dietitian if needed. Use nutritional supplements to increase nutritional level if needed. *Improved nutrition may help increase inspiratory muscle function and decrease dyspnea. **CEB:** A study found that almost half of a group of clients with COPD were malnourished, which can lead to an exacerbation of the disease (Odencrants et al, 2008).*
- Provide small, frequent feedings. *Small feedings are given to avoid compromising ventilatory effort and to conserve energy. Clients with dyspnea often do not eat sufficient amounts of food because their priority is breathing.*
- Offer a fan to move the air in the environment. **EBN:** A systematic review found that the movement of cool air on the face can be effective in relieving dyspnea in pulmonary clients (Carriero-Kohlman & Donesky-Cuenca, 2008). **EBP:** Handheld fans can significantly reduce dyspnea in clients with chronic breathlessness (Galbraith et al, 2010).
- Encourage the client to take deep breaths at prescribed intervals and do controlled coughing.
- Help the client with chronic respiratory disease to evaluate dyspnea experience to determine whether previous incidences of dyspnea were similar and to recognize that the client survived those incidences. Encourage the client to be self-reliant if possible, use problem-solving skills, and maximize use of social support. *The focus of attention on sensations of breathlessness has an impact on judgment used to determine the intensity of the sensation (Campbell et al, 2011).*
- See Ineffective **Airway** clearance if client has a problem with increased respiratory secretions.
- ▲ Refer the client with COPD for pulmonary rehabilitation. **EB:** A Cochrane study found pulmonary rehabilitation programs highly effective and safe for a client who has an exacerbation of COPD (Puhan et al, 2009). *Among the beneficial effects of pulmonary rehabilitation are a reduction in exertional dyspnea during exercise and improved exercise tolerance, as well as decreases in self-reported dyspnea with activity (Parshall et al, 2012). Appropriately resourced home-based exercise training has proven effective in reducing dyspnea and increasing exercise performance activity in the context of pulmonary rehabilitation (Spruit et al, 2013). Pulmonary rehabilitation benefits for COPD patients include reduction of the perceived intensity of breathlessness (GOLD, 2015).*

Geriatric

- Assess respiratory systems in older adults with the understanding that inspiratory muscles weaken, resulting in a slight barrel chest. Expiratory muscles work harder with use of accessory muscles (Martin-Plank, 2014).

- Encourage ambulation as tolerated. *Immobility is harmful to older adults because it decreases ventilation and increases stasis of secretions (Thomas, 2009).*
- Encourage older clients to sit upright or stand and to avoid lying down for prolonged periods during the day. *Thoracic aging results in decreased lung expansion; an erect position fosters maximal lung expansion (Thomas, 2009).*

Home Care

- The above interventions may be adapted for home care use.
- Work with the client to determine what strategies are most helpful during times of dyspnea. Educate and empower the client to self-manage the disease associated with impaired gas exchange. **EBN/EB:** *A study found that use of oxygen, self-use of medication, and breathing fresh air were most helpful in dealing with dyspnea (Thomas, 2009). Evidence-based reviews have found that self-management offers clients with COPD effective options for managing the illness, leading to more positive outcomes (Kaptein et al, 2008).*
- Assist the client and family with identifying other factors that precipitate or exacerbate episodes of ineffective breathing patterns (i.e., stress, allergens, stairs, activities that have high energy requirements). *Awareness of precipitating factors helps clients avoid them and decreases risk of ineffective breathing episodes (Campbell et al, 2011).*
- Assess client knowledge of and compliance with medication regimen. *Client/family may need repetition of instructions received at hospital discharge, and may require reiteration as fear of a recent crisis decreases. Fear interferes with the ability to assimilate new information.*
- ▲ Refer the client for telemonitoring with a pulmonologist as appropriate, with use of an electronic spirometer or an electronic peak flowmeter. **EB:** *A systematic review of home telemonitoring for conditions such as COPD, asthma, and lung transplantation found that use of telemonitoring resulted in early detection of deterioration of clients' respiratory status, and positive client receptiveness to the approach (Jaana et al, 2009).*
- Teach the client and family the importance of maintaining the therapeutic regimen and having as-needed drugs easily accessible at all times. *Appropriate and timely use of medications can decrease the risk of exacerbating ineffective breathing. The 2015 GOLD Report states that bronchodilator medications are central to management of dyspnea (GOLD, 2015).*
- Provide the client with emotional support in dealing with symptoms of respiratory difficulty. Provide family with support for care of a client with chronic or terminal illness. Refer to care plan for **Anxiety**. *Witnessing breathing difficulties and facing concerns of dealing with chronic or terminal illness can create fear in caregiver. Fear inhibits effective coping (Campbell et al, 2011).*
- When respiratory procedures (e.g., apneic monitoring for an infant) are being implemented, explain equipment and procedures to family members, and provide needed emotional support. *Family members assuming responsibility for respiratory monitoring often find this stressful. They may not have been able to assimilate fully any instructions provided by hospital staff (Martin-Plank et al, 2014).*
- When electrically based equipment for respiratory support is being implemented, evaluate home environment for electrical safety, such as proper grounding. Ensure that notification is sent to the local utility company, the emergency medical team, police and fire departments. *Notification is important to provide for priority service.*
- Refer to GOLD guidelines for management of home care and indications of hospital admission criteria.
- Support clients' efforts at self-care. Ensure they have all the information they need to participate in care.
- Identify an emergency plan including when to call your health care provider or 911. *Having a ready emergency plan reassures the client and promotes client safety.*
- ▲ Refer to occupational therapy for evaluation and teaching of energy conservation techniques (Langer et al, 2009).
- ▲ Refer to home health aide services as needed to support energy conservation. *Energy conservation decreases the risk of exacerbating ineffective breathing (Langer et al, 2009).*
- ▲ Institute case management of frail elderly to support continued independent living (Martin-Plank et al, 2014).

Client/Family Teaching and Discharge Planning

- Teach pursed-lip and controlled breathing techniques. **EB:** *Studies have demonstrated that pursed-lip breathing was effective in decreasing breathlessness and improving respiratory function (Faager et al, 2008). Pursed-lip breathing may relieve dyspnea in advanced COPD (Parshall et al, 2012).*
- Teach about dosage, actions, and side effects of medications. *Inhaled steroids and bronchodilators can have undesirable side effects, especially when taken in inappropriate doses.*
- Using a pre-recorded tape, teach client progressive muscle relaxation techniques. **EB:** *Relaxation therapy can help reduce dyspnea and anxiety (Langer et al, 2009). Benefits of pulmonary rehabilitation include reduction of anxiety and depression associated with COPD (GOLD, 2015).*
- Teach the client to identify and avoid specific factors that exacerbate ineffective breathing patterns, such as exposure to other sources of air pollution, especially smoking. If client smokes, refer to the smoking cessation section in the impaired **Gas** exchange care plan.

List of Nursing Diagnoses by Letter: C

Decreased Cardiac output	Risk for decreased Cardiac output	Risk for decreased Cardiac tissue perfusion
Risk for impaired Cardiovascular function	Caregiver Role Strain	Risk for Caregiver Role Strain
Risk for ineffective Cerebral tissue perfusion	Ineffective Childbearing process	Readiness for enhanced Childbearing process
Risk for ineffective Childbearing process	Impaired Comfort	Readiness for enhanced Comfort
Readiness for enhanced Communication	Impaired verbal Communication	Acute Confusion
Chronic Confusion	Risk for acute Confusion	Constipation
Chronic functional Constipation	Perceived Constipation	Risk for Constipation
Risk for chronic functional Constipation	Contamination	Risk for Contamination
Risk for adverse reaction to iodinated Contrast Media	Compromised family Coping	Defensive Coping
Ineffective community Coping	Ineffective Coping	Disabled family Coping
Readiness for enhanced Coping	Readiness for enhanced community Coping	Readiness for enhanced family Coping

Decreased Cardiac output *Ann Will Poteet, MS, RN, CNS*

NANDA-I

C

Definition

Inadequate blood pumped by the heart to meet the metabolic demands of the body

Defining Characteristics

Altered Heart Rate/Rhythm

Bradycardia, electrocardiogram change (e.g., arrhythmia, conduction abnormality, ischemia)

Altered Preload

Decreased central venous pressure (CVP); Decrease in pulmonary artery wedge pressure (PAWP); edema; fatigue; heart murmur; increase in CVP; increase in PAWP; jugular vein distention; weight gain

Altered Afterload

Abnormal skin color (e.g., pale, dusky, cyanosis); alteration in blood pressure; clammy skin; decrease in peripheral pulses; decrease in pulmonary vascular resistance (PVR); decrease in systemic vascular resistance (SVR); dyspnea; increase in PVR; increase in SVR; oliguria, prolonged capillary refill

Altered Contractility

Adventitious breath sounds; coughing; decreased cardiac index; decrease in ejection fraction; decrease in left ventricular stroke work index; decrease in stroke volume index; orthopnea; paroxysmal nocturnal dyspnea; presence of S3 heart sound; presence of S4 heart sound

Behavioral/Emotional

Anxiety; restlessness

Related Factors (r/t)

Alteration in heart rate; alteration in heart rhythm; altered afterload, altered contractility; altered preload; altered stroke volume

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cardiac Pump Effectiveness; Circulation Status; Tissue Perfusion: Abdominal Organs, Peripheral; Vital Signs

Example NOC Outcome with Indicators

Cardiac Pump Effectiveness as evidenced by the following indicators: Blood pressure/Heart rate/Cardiac index/Ejection fraction/Activity tolerance/Peripheral pulses/Neck vein distention not present/Heart rhythm/Heart sounds/Angina not present/Peripheral edema not present/Pulmonary edema not present. (Rate the outcome and indicators of **Cardiac Pump Effectiveness**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate adequate cardiac output as evidenced by blood pressure, pulse rate and rhythm within normal parameters for client; strong peripheral pulses; maintained level of mentation, lack of chest discomfort or dyspnea, and adequate urinary output; an ability to tolerate activity without symptoms of dyspnea, syncope, or chest pain
- Remain free of side effects from the medications used to achieve adequate cardiac output
- Explain actions and precautions to prevent primary or secondary cardiac disease

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cardiac Care; Cardiac Care: Acute

Example NIC Activities—Cardiac Care

Evaluate chest pain (e.g., intensity, location, radiation, duration, and precipitating and alleviating factors); Document cardiac dysrhythmias

Nursing Interventions and Rationales

- Recognize primary characteristics of decreased cardiac output as fatigue, dyspnea, edema, orthopnea, paroxysmal nocturnal dyspnea, and increased CVP. Recognize secondary characteristics of decreased cardiac output as weight gain, hepatomegaly, jugular venous distention, palpitations, lung crackles, oliguria, coughing, clammy skin, and skin color changes. **EBN:** *A nursing study to validate characteristics of the nursing diagnosis decreased cardiac output in a clinical environment identified and categorized related client characteristics that were present as primary or secondary (Martins et al, 2010).*
- Monitor and report presence and degree of symptoms including dyspnea at rest or with reduced exercise capacity, orthopnea, paroxysmal nocturnal dyspnea, nocturnal cough, distended abdomen, fatigue, or weakness. Monitor and report signs including jugular vein distention, S3 gallop, rales, positive hepatojugular reflux, ascites, laterally displaced or pronounced point of maximal impact, heart murmurs, narrow pulse pressure, cool extremities, tachycardia with pulsus alternans, and irregular heartbeat. **EB:** *These are symptoms and signs consistent with heart failure (HF) and decreased cardiac output (Yancy et al, 2013).* **EB:** *In a study of primary care clients, breathlessness during exercise, limitations in physical activity, and orthopnea were the three most significant symptoms most often associated with HF (Devroey & Van Casteren, 2011).*
- Monitor orthostatic blood pressures and daily weights. **EB:** *These interventions assess for fluid volume status (Yancy et al, 2013).*
- Recognize that decreased cardiac output can occur in a number of noncardiac disorders such as septic shock and hypovolemia. Expect variation in orders for differential diagnoses related to decreased cardiac output, because orders will be distinct to address the primary cause of the altered cardiac output.
- Obtain a thorough history. **EB:** *It is important to assess for cardiac and noncardiac disorders and/or behaviors that might accelerate the progression of HF symptoms, such as high sodium diet, excess fluid intake, or missed medication doses (Yancy et al, 2013).*
- ▲ Monitor pulse oximetry and administer oxygen as needed per health care provider's order. Supplemental oxygen increases oxygen availability to the myocardium and can relieve symptoms of hypoxemia. Resting hypoxia or oxygen desaturation may indicate fluid overload or concurrent pulmonary disease.
- Place client in semi-Fowler's or high Fowler's position with legs down or in a position of comfort. Elevating the head of the bed and legs in down position may decrease the work of breathing and may also decrease venous return and preload.
- During acute events, ensure client remains on short-term bed rest or maintains activity level that does not compromise cardiac output.
- Provide a restful environment by minimizing controllable stressors and unnecessary disturbances. Reducing stressors decreases cardiac workload and oxygen demand.
- ▲ Apply graduated compression stockings or intermittent sequential pneumatic compression (ISPC) leg sleeves as ordered. Ensure proper fit by measuring accurately. Remove stocking at least twice a day, then reapply. Assess the condition of the extremities frequently. Graduated compression stockings may be contraindicated in clients with peripheral arterial disease (Kahn et al, 2012). **EB:** *A study that assessed effects of ISPC on healthy adults found that there were significant increases in cardiac output, stroke volume, and ejection fraction due to increased preload and decreased afterload (Bickel et al, 2011); EB:* *A Cochrane review that assessed use of knee-length graduated compression stockings versus thigh-length graduated compression stockings found no difference in effectiveness. Type of stocking should be determined by patient preference, cost, and ease of use (Sajid et al, 2012).* **EB:** *Graduated compression stockings, alone or used in conjunction with other prevention modalities, help promote venous return and reduce the risk of deep vein thrombosis in hospitalized clients (Sachdeva et al, 2014).*

- ▲ Check blood pressure, pulse, and condition before administering cardiac medications such as angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, digoxin, and beta-blockers. Notify health care provider if heart rate or blood pressure is low before holding medications. It is important that the nurse evaluate how well the client is tolerating current medications before administering cardiac medications; do not hold medications without health care provider input. The health care provider may decide to have medications administered even though the blood pressure or pulse rate has lowered.
- Observe for and report chest pain or discomfort; note location, radiation, severity, quality, duration, and associated manifestations such as nausea, indigestion, or diaphoresis; also note precipitating and relieving factors. Chest pain/discomfort may indicate an inadequate blood supply to the heart, which can further compromise cardiac output. **EB:** *Clients with decreased cardiac output may present with myocardial ischemia. Those with myocardial ischemia may present with decreased cardiac output and HF (Amsterdam et al, 2014; Yancy et al, 2013).*
- ▲ If chest pain is present, refer to the interventions in risk for Decreased Cardiac tissue perfusion care plan.
- Recognize the effect of sleep disordered breathing in HF and that sleep disorders are common in patients with HF (Yancy et al, 2013). **EB:** *Central sleep apnea is recognized as an independent risk factor for worsening HF and reduced survival in patients with HF. The pathological effects of sleep apnea that contribute to worsening cardiac function include sympathetic nervous system stimulation, systemic inflammation, oxidative stress, and endothelial dysfunction (Costanzo et al, 2015).*
- Administer continuous positive airway pressure (CPAP) or supplemental oxygen at night as ordered for management of suspected or diagnosed sleep apnea. **EB:** *Both CPAP and nocturnal oxygen supplementation have been shown to reduce episodes of sleep apnea, reduce sympathetic nervous system stimulation, and improve cardiac function (Costanzo et al, 2015).*
- ▲ Closely monitor fluid intake, including intravenous lines. Maintain fluid restriction if ordered. In clients with decreased cardiac output, poorly functioning ventricles may not tolerate increased fluid volumes. **EB:** *Fluid restriction along with sodium restriction can enhance volume management with diuretics, and in some patients can improve outcomes (Yancy et al, 2013).*
- Monitor intake and output (I&O). If client is acutely ill, measure hourly urine output and note decreases in output. Decreased cardiac output results in decreased perfusion of the kidneys, with a resulting decrease in urine output. **EB:** *Clinical practice guidelines cite that monitoring I&Os is useful for monitoring effects of HF treatment, including diuretic therapy (Yancy et al, 2013).*
- ▲ Note results of initial diagnostic studies, including electrocardiography, echocardiography, and chest radiography. **EB:** *Clinical practice guidelines suggest that chest radiography, echocardiography, and electrocardiogram are recommended in the initial assessment of HF (Yancy et al, 2013).*
- ▲ Note results of further diagnostic imaging studies such as radionuclide imaging, stress echocardiography, cardiac catheterization, or magnetic resonance imaging (MRI). **EB:** *Clinical practice guidelines state that radionuclide and MRI are useful studies when assessing left ventricular ejection fraction and volume if echocardiography is not sufficient (Yancy et al, 2013).*
- ▲ Review laboratory data as needed including arterial blood gases, complete blood count, serum electrolytes (sodium, potassium, magnesium, calcium), blood urea nitrogen, creatinine, urinalysis, glucose, fasting lipid profile, liver function tests, thyroid stimulating hormone, B-type natriuretic peptide (BNP assay), or N-terminal pro-B-type natriuretic peptide (NTpro-BNP). Routine blood work can provide insight into the etiology of HF and extent of decompensation. **EB:** *Clinical practice guidelines recommend that BNP or NTpro-BNP assay should be measured in clients when the cause of HF is not known, and to determine prognosis or disease severity in chronic or acute decompensated HF (Yancy et al, 2013).*
- Gradually increase activity when the client's condition is stabilized by encouraging slower paced activities, or shorter periods of activity, with frequent rest periods following exercise prescription; observe for symptoms of intolerance. Take blood pressure and pulse before and after activity and note changes. Activity of the cardiac client should be closely monitored. See **Activity** intolerance.
- ▲ Serve small, frequent, sodium-restricted, low saturated fat meals. Sodium-restricted diets help decrease fluid volume excess. Low saturated fat diets help decrease atherosclerosis, which can cause coronary artery disease. Clients with cardiac disease tolerate smaller meals better because they require less cardiac output to digest (Hooper et al, 2012). **EB:** *Excess sodium can contribute to elevation of blood pressure, renal impairment, ventricular hypertrophy, diastolic dysfunction, and fibrosis of coronary arteries (Whelton et al, 2012).* **EB:** *A study that compared cardiac event-free survival between clients who ingested more or less than 3 g of dietary sodium daily found that those who were NYHA class III or IV clients benefited the most from dietary intake less than 3 g daily (Lennie et al, 2011);* **EBN:** *A study that compared HF symptoms with*

dietary sodium intake found that those with sodium intake greater than 3 g per day had more HF symptoms (Son et al, 2011).

- ▲ Monitor bowel function. Provide stool softeners as ordered. Caution client not to strain when defecating. Decreased activity, pain medication, and diuretics can cause constipation. **EBN:** Clients with HF have autonomic dysfunction, which places them at risk for reduced mean arterial blood pressure and reduced cerebral blood flow. Autonomic challenges, such as the Valsalva maneuver, can put the HF client at risk for hypoperfusion, ischemia, and stroke (Serber et al, 2014).
- Weigh the client at the same time daily (after voiding). Daily weight is a good indicator of fluid balance. Use the same scale if possible when weighing clients for consistency. Increased weight and severity of symptoms can signal decreased cardiac function with retention of fluids. **EB:** Clinical practice guidelines state that weighing at the same time daily is useful to assess effects of diuretic therapy (Yancy et al, 2013).
- ▲ Provide influenza and pneumococcal vaccines as needed before client discharge for those who have yet to receive those inoculations (Centers for Disease Control, 2015).
- Assess for presence of anxiety and refer for treatment if present. See **Nursing Interventions and Rationales** for **Anxiety** to facilitate reduction of anxiety in clients and family. **EB:** A study that assessed the relationship between anxiety and incidence of death, emergency department visits, or hospitalizations found that those with higher anxiety had significantly worse outcomes than those with lower anxiety (De Jong et al, 2011).
- ▲ Assess for presence of depression and refer for treatment if needed. **EB:** Depression is common in clients with HF, and it has been found that individuals with depressive symptoms have poorer quality of life, use health care services more frequently, have poorer self-care, and have worse clinical outcomes (Yancy et al, 2013). **EBN:** A study on combined depression and level of perceived social support found that depressive symptoms were an independent predictor of increased morbidity and mortality, and those with lower perceived social support had 2.1 times higher risk of events than nondepressed clients with high perceived social support (Chung et al, 2011).
- ▲ Refer to a cardiac rehabilitation program for education and monitored exercise. **EB:** Exercise training or regular physical activity is recommended for HF patients. Cardiac rehabilitation can improve quality of life and functional capacity, and decrease mortality (Arena et al, 2012; Smith et al, 2011; Yancy et al, 2013). A systematic review of outcomes of exercise based interventions in clients with systolic HF found that hospitalizations and those for systolic HF were reduced for clients in an exercise program and quality of life was improved (Taylor et al, 2014). In a study to assess effects of exercise in HF clients, exercise tolerance and left ventricular ejection fraction increased with exercise training (Alves et al, 2012).
- ▲ Refer to an HF program for education, evaluation, and guided support to increase activity and rebuild quality of life. Support for the HF client should be patient-centered, culturally sensitive, and include family and social support. **EB:** Multidisciplinary systems of care that are designed to support clients with HF can improve outcomes (Arena et al, 2012; Weintraub et al, 2010; Yancy et al, 2013). **CEB:** A study assessing the 6-month outcomes of a nurse practitioner-coordinated HF center found that readmissions, length of stay, and cost per case were all significantly reduced, while quality of life was significantly improved (Crowther et al, 2002).

Critically III

- ▲ Observe for symptoms of cardiogenic shock, including impaired mentation, hypotension, decreased peripheral pulses, cold clammy skin, signs of pulmonary congestion, and decreased organ function. If present, notify health care provider immediately. Cardiogenic shock is a state of circulatory failure from loss of cardiac function associated with inadequate organ perfusion and a high mortality rate. **EB:** Critical cardiogenic shock presents with severe hypotension, increasing inotropic and vasopressor support, organ hypoperfusion, and worsening acidosis and lactate levels (Yancy et al, 2013).
- ▲ If shock is present, monitor hemodynamic parameters for an increase in pulmonary wedge pressure, an increase in systemic vascular resistance, or a decrease in stroke volume, cardiac output, and cardiac index. **EB:** Hemodynamic monitoring with a pulmonary artery catheter can be beneficial in patients with respiratory distress, impaired systemic perfusion, and dependence on intravenous inotropic support, and when clinical assessment is inadequate or severe symptoms persist despite recommended therapies (Yancy et al, 2013).
- ▲ Titrate inotropic and vasoactive medications within defined parameters to maintain contractility, preload, and afterload per health care provider's order. By following parameters, the nurse ensures maintenance of a delicate balance of medications that stimulate the heart to increase contractility, while maintaining

adequate perfusion of the body. **EB:** *Clinical practice guidelines recommend that intravenous inotropic drugs might be reasonable for HF clients presenting with low blood pressure and low cardiac output to maintain systemic perfusion and preserve end-organ performance (Yancy et al, 2013; Weintraub et al, 2010).*

- ▲ Identify significant fluid overload and initiate intravenous diuretics as ordered. Monitor I&Os, daily weight, and vital signs, as well as signs and symptoms of congestion. Watch laboratory data, including serum electrolytes, creatinine, and urea nitrogen. **EB:** *Intravenous loop diuretics should be initiated in the HF client who presents with significant fluid overload as either intermittent boluses or continuous infusion to reduce morbidity (Yancy et al, 2013).*
- ▲ When using pulmonary arterial catheter technology, be sure to appropriately level and zero the equipment, use minimal tubing, maintain system patency, perform square wave testing, position the client appropriately, and consider correlation to respiratory and cardiac cycles when assessing waveforms and integrating data into client assessment. **EB:** *Clinical practice guidelines recommend that invasive hemodynamic monitoring can be useful in acute HF with persistent symptoms when therapy is refractory, fluid status is unclear, systolic pressures are low, renal function is worsening, vasoactive agents are required, or when considering advanced device therapy or transplantation (Yancy et al, 2013).*
- ▲ Observe for worsening signs and symptoms of decreased cardiac output when using positive pressure ventilation. **EB:** *Positive pressure ventilation and mechanical ventilation are associated with a decrease in preload and cardiac output (Lukacsovitis et al, 2012; Yucel et al, 2011).*
- ▲ Recognize that clients with cardiogenic pulmonary edema may have noninvasive positive pressure ventilation ordered. **EB:** *Clinical practice guidelines for HF state that continuous positive airway pressure improves daily functional capacity and quality of life for those with HF and obstructive sleep apnea and is reasonable for clients with refractory HF not responding to other medical therapies (Costanzo et al, 2015; Yancy et al, 2013).*
- ▲ Monitor client for signs and symptoms of fluid and electrolyte imbalance when clients are receiving ultrafiltration or continuous renal replacement therapy (CRRT). Clients with refractory HF may have ultrafiltration or CRRT ordered as a mechanical method to remove excess fluid volume. **EB:** *Clinical practice guidelines cite that ultrafiltration is reasonable for clients with obvious volume overload and congestion, and refractory congestion not responsive to medical therapy (Yancy et al, 2013).*
- Recognize that hypoperfusion from low cardiac output can lead to altered mental status and decreased cognition. **CEB:** *A study that assessed an association among cardiac index and neuropsychological ischemia found that decreased cardiac function, even with normal cardiac index, was associated with accelerated brain aging (Jefferson et al, 2010).*
- Recognize that clients with severe HF may undergo additional therapies, such as internal pacemaker or defibrillator placement, and/or placement of a ventricular assist device (VAD). **EB:** *The use of VADs is a reasonable treatment as a bridge to recovery, transplant, or decision making in selected HF clients with reduced ejection fraction and profound hemodynamic compromise (Yancy et al, 2013).*

Geriatric

- Recognize that older clients may demonstrate fatigue and depression as signs of HF and decreased cardiac output.
- ▲ If the client has heart disease causing activity intolerance, refer for cardiac rehabilitation. **EB:** *Cardiac rehabilitation can positively affect an individual's overall health outcome, especially in the older population, due to increased frailty and functional limitations (Arená et al, 2012).* **EBN:** *A study that assessed clients' acceptance of a cardiac rehabilitation program found knowledge and perceived quality of life had increased significantly, and anxiety and depression had been reduced at the end of the program and at 6-month follow-up (Muschalla et al, 2011).*
- ▲ Recognize that edema can present differently in the older population. **EB:** *In the older population, lower extremity edema is often related to peripheral causes, such as dependency, rather than cardiac causes (Yancy et al, 2013).*
- ▲ Recognize that blood pressure control is beneficial for older clients to reduce the risk of worsening HF. **EB:** *Hypertension treatment is particularly beneficial in the older population, and control of both systolic and diastolic hypertension has been shown to reduce the risk of incident HF (Yancy et al, 2013).*
- ▲ Recognize that renal function is not always accurately represented by serum creatinine in the older population due to less muscle mass (Yancy et al, 2013).
- ▲ Observe for side effects from cardiac medications. Older adults can have difficulty with metabolism and excretion of medications due to decreased function of the liver and kidneys; therefore, toxic side effects

are more common. **EB:** *Older adults are at increased risk for digoxin toxicity, especially at larger doses, due to lower body mass and impaired renal function (Yancy et al, 2013).*

- ▲ Older adults may require more frequent visits, closer monitoring of medication dose changes, and more gradual increases in medications, due to changes in the metabolism of medications and impaired renal function (Yancy et al, 2013).
- ▲ As older adults approach end of life, clinicians should help to facilitate a comprehensive plan of care that incorporates the patient and family's values, goals, and preferences (Allen et al, 2012).

Home Care

- Some of the above interventions may be adapted for home care use. Home care agencies may use specialized staff and methods to care for chronic HF clients. **CEB:** *A study assessing HF outcomes over a 10-year period between a multidisciplinary home care intervention and usual care found significantly improved survival and prolonged event-free survival and was both cost- and time-effective (Ingles et al, 2006).*
- Assess for fatigue and weakness frequently. Assess home environment for safety, as well as resources/obstacles to energy conservation.
- Help family adapt daily living patterns to establish life changes that will maintain improved cardiac functioning in the client. Take the client's perspective into consideration and use a holistic approach in assessing and responding to client planning for the future.
- Assist client to recognize and exercise power in using self-care management to adjust to health change. Refer to care plan for **Powerlessness**.
- ▲ Refer to medical social services, cardiac rehabilitation, telemonitoring and case management as necessary for assistance with home-care, access to resources, and counseling about the impact of severe or chronic cardiac diseases. **EB:** *Access to systems that promote care coordination is essential for successful care of the HF client. Good communication and documentation between services, health care providers, and transitions of care is essential to ensure improved outcomes in HF clients (Albert et al, 2015; Smith et al, 2011; Yancy et al, 2013).*
- ▲ As the client chooses, refer to palliative care for care, which can begin earlier in the care of the HF client. Palliative care can be used to increase comfort and quality of life in the HF client before end-of-life care (Buck & Zambroski, 2012). **EB:** *Palliative care should address quality of life, ongoing symptom control, preferences about end-of-life, psychosocial distress, and caregiver support (Yancy et al, 2013).*
- ▲ If the client's condition warrants, refer to hospice. **EB:** *The palliative care and HF teams are best suited to determine when end-of-life care is appropriate for the patient and family (Yancy et al, 2013).* **CEB:** *The multidisciplinary hospice team can reduce hospital readmission, increase functional capacity, and improve quality of life in end-stage HF (Coviello et al, 2002).*

Client/Family Teaching and Discharge Planning

- Begin discharge planning as soon as possible upon admission to the emergency department (ED) if appropriate with a case manager or social worker to assess home support systems and the need for community or home health services. **EB:** *Discharge planning should include adherence to the treatment plan, medication management, follow-up with health care providers and care coordination, dietary and physical activities, cardiac rehabilitation, and secondary prevention recommendations (Albert et al, 2015; Yancy et al, 2013).*
- Discharge education should be comprehensive, evidence based, culturally sensitive, and include both the client and family (Yancy et al, 2013).
- Teach client about any medications prescribed. Medication teaching includes the drug name, its purpose, administration instructions, such as taking it with or without food, and any side effects to be aware of. Instruct the client to report any adverse side effects to his/her health care provider.
- Teach the importance of performing and recording daily weights upon arising for the day, and to report weight gain. Ask if client has a scale at home; if not, assist in getting one. **EB:** *Clinical practice guidelines suggest that daily weight monitoring leads to early recognition of excess fluid retention, which, when reported, can be offset with additional medication to avoid hospitalization from heart failure decompensation (Yancy et al, 2013).*
- Teach the types and progression patterns of worsening heart failure symptoms, when to call a health care provider for help, and when to go to the hospital for urgent care (Yancy et al, 2013).
- Stress the importance of ceasing tobacco use. **EB:** *Tobacco use can cause or worsen decreased blood flow in the coronaries, as well as cause vasoconstriction, which can lead to atherosclerotic disease. Effects of*

nicotine include increasing pulse and blood pressure and constricting of blood vessels. Tobacco use is a primary factor in heart disease. (American Heart Association, 2014; Smith et al, 2011).

- ▲ Individuals should be screened for electronic cigarette use (e-cigarette). **EB:** While more studies are needed regarding the health effects of e-cigarette use, the American Heart Association recommends that all health care providers educate their patients regarding the long-term use of e-cigarettes given the known toxicities present in e-cigarettes, as well as the presence of nicotine in most types of e-cigarettes (Bhatnagar et al, 2014).
- Upon hospital discharge, educate clients about low sodium, low saturated fat diet, with consideration to client education, literacy, and health literacy level. **EB:** Excess sodium intake is directly related to elevated blood pressure (Whelton et al, 2012). A Cochrane review recommended that there be a permanent reduction in dietary saturated fats and replacement with unsaturated fats to reduce the risk of cardiovascular disease (Hooper et al, 2012).
- Instruct client and family on the importance of regular follow-up care with health care providers. **EB:** Post discharge support can significantly reduce hospital readmissions and improve health care outcomes, quality of life, and costs (Hernandez et al, 2010; Yancy et al, 2013).
- ▲ Teach stress reduction (e.g., imagery, controlled breathing, and muscle relaxation techniques). **CEB:** A study that assessed effects of relaxation or exercise in heart failure clients versus controls found that those who participated in regular relaxation therapy or exercise training reported greater improvements in psychological outcomes, with the relaxation group significantly improving depression and the exercise training group more improving fatigue (Yu et al, 2007).
- Discuss advance directives with the HF client, including resuscitation preferences. **EB:** Evidence suggests that advance directives can help to reduce overall health care costs, reduce in-hospital deaths, and increase hospice use (Yancy et al, 2013).
- Patients should be provided with education regarding the influenza vaccine and pneumococcal vaccine prior to discharge. **EB:** The influenza vaccine is recommended for all adults, and the pneumococcal vaccine is recommended for individuals greater than 65 years old and for individuals who are at high risk for cardiovascular disease (Centers for Disease Control, 2015).
- Teach the importance of physical activity as tolerated. **EB:** Exercise helps control blood pressure and weight, which are the most important controlled risk factors for cardiovascular disease. Individuals should engage in aerobic physical activity of moderate to vigorous intensity, three to four times per week (Eckel et al, 2013).

Risk for decreased Cardiac output

Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN, and Ann Will Poteet, MS, RN, CNS

NANDA-I

Definition

Vulnerable to inadequate blood pumped by the heart to meet metabolic demands of the body, which may compromise health

Risk Factors

Alteration in heart rate; alteration in heart rhythm; alteration in afterload; altered contractility; altered preload; altered stroke volume

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan for Decreased **Cardiac** output.

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Risk for decreased Cardiac tissue perfusion *Ann Will Poteet, MS, RN, CNS*

C

NANDA-I

Definition

Vulnerable to a decrease in cardiac (coronary) circulation, which may compromise health

Risk Factors

Cardiac tamponade; cardiovascular surgery; coronary artery spasm; diabetes mellitus; family history of cardiovascular disease; hyperlipidemia; hypertension; hypovolemia; hypoxemia; hypoxia; increase in C-reactive protein; insufficient knowledge about modifiable risk factors (e.g., smoking, sedentary lifestyle, obesity); pharmaceutical agent; substance abuse

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cardiac Pump Effectiveness; Circulation Status; Tissue Perfusion: Cardiac; Tissue Perfusion: Cellular; Vital Signs

Example NOC Outcome with Indicators

Tissue Perfusion: Cardiac as evidenced by the following indicators: Angina/Arrhythmia/Tachycardia/Bradycardia/Nausea/Vomiting/Profuse diaphoresis. (Rate the outcome and indicators of **Tissue Perfusion: Cardiac**: 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain vital signs within normal range
- Retain an asymptomatic cardiac rhythm (have absence of arrhythmias, tachycardia, or bradycardia)
- Be free from chest and radiated discomfort as well as associated symptoms related to acute coronary syndromes (ACSs)
- Deny nausea and be free of vomiting
- Have skin that is dry and of normal temperature

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cardiac Care; Cardiac Precautions; Embolus Precautions; Dysrhythmia Management; Vital Signs Monitoring; Shock Management: Cardiac

Example NIC Activity—Cardiac Precautions

Avoid causing intense emotional situations; Avoid overheating or chilling the client; Provide small frequent meals; Substitute artificial salt and limit sodium intake if appropriate; Promote effective techniques for reducing stress; Restrict smoking

Nursing Interventions and Rationales

- Be aware that the primary cause of ACS—unstable angina (UA), non-ST-elevation myocardial infarction (NSTEMI), and ST-elevation myocardial infarction (STEMI)—is an imbalance between myocardial oxygen consumption and demand that is associated with partially or fully occlusive thrombus development in coronary arteries (Amsterdam et al, 2014).
- Assess for symptoms of coronary hypoperfusion and possible ACS, including chest discomfort (pressure, tightness, crushing, squeezing, dullness, or achiness), with or without radiation (or originating) in the retrosternum, back, neck, jaw, shoulder, or arm discomfort or numbness; shortness of breath (SOB); associated diaphoresis; abdominal pain; dizziness, lightheadedness, loss of consciousness, or unexplained

fatigue; nausea or vomiting with chest discomfort, heartburn, or indigestion; associated anxiety. **EB:** *These symptoms are signs of decreased cardiac perfusion and ACS such as UA, NSTEMI, or STEMI, as well as other cardiovascular disorders such as aortic aneurysm, valve disorders, and pericarditis. A physical assessment will aid in assessment of the extent, location, and presence of, and complications resulting from a myocardial infarction (MI). It will promote rapid triage and treatment. It is also important to assess whether the client had a prior stroke, heart failure, or other cardiovascular disorder. It is important to note that certain psychiatric disorders (somatoform disorders, panic attack, anxiety disorders) can mimic ACS, but are typically noncardiac causes of chest pain (Amsterdam et al, 2014).*

- Consider atypical presentations of ACS for women, older adults, and individuals with diabetes mellitus, impaired renal function, and dementia. **EB/CEB:** *Women, older adults, and individuals with diabetes mellitus, impaired renal function, and dementia may present with atypical findings (Amsterdam et al, 2014; Mieres et al, 2014). A systematic review of differences showed that women had significantly less chest discomfort and were more likely to present with fatigue, neck pain, syncope, nausea, right arm pain, dizziness, and jaw pain (Coventry et al, 2011).*
- Review the client's medical, surgical, social, and familial history. **EB:** *A medical history must be concise and detailed to determine the possibility of ACSs and to help determine the possible cause of cardiac symptoms and pathology (Amsterdam et al, 2014).*
- Perform physical assessments for both CAD and noncoronary findings related to decreased coronary perfusion, including vital signs, pulse oximetry, equal blood pressure in both arms, heart rate, respiratory rate, and pulse oximetry. Check bilateral pulses for quality and regularity. Report tachycardia, bradycardia, hypotension or hypertension, pulsus alternans or pulsus paradoxus, tachypnea, or abnormal pulse oximetry reading. Assess cardiac rhythm for arrhythmias; skin and mucous membrane color, temperature, and dryness; and capillary refill. Assess neck veins for elevated central venous pressure, cyanosis, and pericardial or pleural friction rub. Examine client for cardiac S₄ gallop, new heart murmur, lung crackles, altered mentation, pain on abdominal palpation, decreased bowel sounds, or decreased urinary output. **EB:** *These indicators help assess for cardiac and noncardiac etiologies of symptoms and differential diagnoses (Amsterdam et al, 2014).*
- ▲ Administer supplemental oxygen as ordered and needed for clients presenting with ACS, respiratory distress, or other high-risk features of hypoxemia to maintain a PO₂ of at least 90%. **EB:** *American Heart Association guidelines for emergency cardiovascular care during ACS recommend administering oxygen for breathlessness, hypoxemia, signs of heart failure, or if signs of shock are present, and the need for oxygen should be guided by noninvasive monitoring of oxygen saturation. There is limited evidence to support or refute the use of high-flow or low-flow supplemental oxygen if a normal oxygen level (>90%) is present (Amsterdam et al, 2014; O'Connor et al, 2010). **EB:** A Cochrane review found there was limited evidence to support or refute the use of routine supplemental oxygen with ACS, recommending further studies (Cabello et al, 2013).*
- ▲ Use continuous pulse oximetry as ordered. **EB:** *Prevention and treatment of hypoxemia includes maintaining arterial oxygen saturation over 90% (Amsterdam et al, 2014).*
- ▲ Insert one or more large-bore intravenous catheters to keep the vein open. Routinely assess saline locks for patency. Clients who come to the hospital with possible decrease in coronary perfusion or ACS may have intravenous fluids and medications ordered routinely or emergently to maintain or restore adequate cardiac function and rhythm.
- ▲ Observe the cardiac monitor for hemodynamically significant arrhythmias, ST depressions or elevations, T-wave inversions and/or q-waves as signs of ischemia or injury. Report abnormal findings. **EB:** *Arrhythmias and electrocardiogram (ECG) changes indicate myocardial ischemia, injury, and/or infarction. Note that left ventricular hypertrophy, ventricular pacing, and bundle branch blocks can mask signs of ischemia or injury (Amsterdam et al, 2014).*
- Have emergency equipment and defibrillation capability nearby and be prepared to defibrillate immediately if ventricular tachycardia with clinical deterioration or ventricular fibrillation occurs. **EB:** *Life-threatening ventricular arrhythmias require defibrillation (Hazinski et al, 2010).*
- ▲ Perform a 12-lead ECG as ordered, to be interpreted within 10 minutes of emergency department arrival and during episodes of chest discomfort or angina equivalent. **EB:** *A 12-lead ECG should be performed within 10 minutes of emergency department arrival for all clients who are having chest discomfort. ECGs are used to identify the area of ischemia or injury, such as ST depressions or elevations, new left-bundle branch block, T-wave inversions, and/or q waves, and to guide treatment (Amsterdam et al, 2014).*

- ▲ Administer nonenteric coated aspirin as ordered, as soon as possible after presentation and for maintenance. **EB:** Aspirin has been shown to prevent platelet clumping, aggregation, and activation that leads to thrombus formation, which in coronary arteries leads to ACSs. Contraindications include active peptic ulcer disease, bleeding disorders, and aspirin allergy (Amsterdam et al, 2014; O’Gara et al, 2013).
- ▲ Administer nitroglycerin tablets sublingually as ordered, every 5 minutes until the chest pain is resolved while also monitoring the blood pressure for hypotension, for a maximum of three doses as ordered. Administer nitroglycerin paste or intravenous preparations as ordered. **EB:** Nitroglycerin causes coronary arterial and venous dilation, and at higher doses peripheral arterial dilation, thus reducing preload and afterload and decreasing myocardial oxygen demand while increasing oxygen delivery (Amsterdam et al, 2014).
- Do not administer nitroglycerin preparations to individuals with hypotension, or individuals who have received phosphodiesterase type 5 inhibitors, such as sildenafil, tadalafil, or vardenafil, in the last 24 hours (48 hours for long-acting preparations). **EB:** Synergistic effect causes marked exaggerated and prolonged vasodilation/hypotension (Amsterdam et al, 2014).
- ▲ Administer morphine intravenously as ordered every 5 to 30 minutes until pain is relieved while monitoring blood pressure when nitroglycerin alone does not relieve chest discomfort. **EB:** Morphine has potent analgesic and antianxiolytic effects and causes mild reductions in blood pressure and heart rate that reduce myocardial oxygen consumption. Hypotension and respiratory depression are the most serious complications of morphine use, and naloxone may be administered as ordered for morphine overdose (Amsterdam et al, 2014).
- ▲ Assess and report abnormal lab work results of cardiac enzymes, specifically troponin I or T, B-type natriuretic peptide, chemistries, hematology, coagulation studies, arterial blood gases, finger stick blood sugar, elevated C-reactive protein, or drug screen. **EB:** Abnormalities can identify the cause of the decreased perfusion and identify complications related to the decreased perfusion such as anemia, hypovolemia, coagulopathy, drug abuse, hyperglycemia, kidney (renal) failure, and heart failure. Markedly elevated cardiac enzymes are usually indicative of an MI, and the cardiac enzymes can also help determine short- and long-term prognosis (Amsterdam et al, 2014).
- Assess for individual risk factors for coronary artery disease, such as hypertension, dyslipidemia, cigarette smoking, diabetes mellitus, or family history of heart disease. Other risk factors including sedentary lifestyle, obesity, or cocaine or amphetamine use. Note age and gender as risk factors. **EB:** Certain conditions place clients at higher risk for decreased cardiac tissue perfusion (Amsterdam et al, 2014; Mieres et al, 2014).
- ▲ Administer additional heart medications as ordered, including beta blockers, calcium channel blockers, angiotensin-converting enzyme inhibitors, angiotensin II receptor blockers, aldosterone antagonists, antiplatelet agents, and anticoagulants. Always check blood pressure and pulse rate before administering these medications. If the blood pressure or pulse rate is low, contact the health care provider to establish whether the medication should be withheld. Also check platelet counts, renal function, and coagulation studies as ordered to assess proper effects of these agents. **EB:** These medications are useful to optimize cardiac and kidney function, including blood pressure, heart rate, myocardial oxygen demand, intravascular fluid volume, and cardiac rhythm (Amsterdam et al, 2014).
- ▲ Administer lipid-lowering therapy as ordered. **EB:** Use of statin drugs has been shown to reduce an individual’s risk of recurrent MI, stroke, and coronary heart disease mortality, especially with high-intensity statins that lower low-density lipoprotein cholesterol levels (Amsterdam et al, 2014, Stone et al, 2013). A systematic review of statin use in primary prevention of cardiovascular disease showed reductions in all-cause mortality, major vascular events, and revascularizations (Taylor et al, 2014).
- ▲ Prepare client with education, withholding of meals and/or medications, and intravenous access for early invasive therapy with cardiac catheterization, reperfusion therapy, and possible percutaneous coronary intervention in individuals with refractory angina or hemodynamic or electrical instability, and first medical contact to device time of less than 90 minutes if STEMI is suspected. **EB:** First medical contact to device time of less than 90 minutes was associated with improved client outcomes (Amsterdam et al, 2014; O’Gara et al, 2013).
- ▲ Prepare clients with education, withholding of meals and/or medications, and intravenous access for noninvasive cardiac diagnostic procedures such as 2D echocardiogram, exercise, or pharmacological stress test, and cardiac computed tomography scan as ordered. **EB:** Clients suspected of decreased coronary perfusion should receive these diagnostic procedures as appropriate to evaluate for coronary artery disease (Amsterdam et al, 2014; Fletcher et al, 2013; Mieres et al, 2014).

Geriatric

▲ Request a referral to a cardiac rehabilitation program. **EB:** *Cardiac rehabilitation programs are designed to limit the physiological and psychological effects of cardiac disease, reduce the risk for sudden cardiac death and reinfarction, control symptoms and stabilize or reverse the process of plaque formation, and enhance psychosocial and vocational status of clients (Amsterdam et al, 2014).*

- Consider atypical presentations of possible ACS in older adults. **CEB:** *Older adults may present with atypical signs and symptoms such as weakness, stroke, syncope, or change in mental status (Amsterdam et al, 2014).*
- ▲ Ask the prescriber about possible reduced dosage of medications for older clients, considering weight, creatinine clearance, and glomerular filtration rate. **EB:** *Older clients can have reduced pharmacokinetics and pharmacodynamics, including reduced muscle mass, reduced renal and hepatic function, and reduced volume of distribution that can alter drug dosing, efficacy, and safety, as well as some drug-drug interactions (Amsterdam et al, 2014; Stone et al, 2013).*
- Consider issues such as quality of life, palliative care, end-of-life care, and differences in sociocultural aspects for clients and families when supporting them in decisions regarding aggressiveness of care. Ask about living wills, as well as medical and durable power of attorney. **EB:** *Management decisions, including decisions regarding invasive treatment, should be client-centered and take into account client preferences and goals, comorbidities, cognitive and functional status, and life expectancy (Amsterdam et al, 2014).*

Client/Family Teaching and Discharge Planning

- ▲ Client and family education regarding a multidisciplinary plan of care should start early. Special attention to client and family education should occur during transitions of care. **EB:** *It is important to provide the client and family with a comprehensive plan of care and education materials that are evidence-based to assist with client compliance and to potentially reduce hospital readmissions related to ACS. The plan of care should take into consideration the client's psychosocial and socioeconomic status, access to care, risk for depression and/or social isolation, and health care disparities (Amsterdam et al, 2014).*
- Teach the client and family to call 911 for symptoms of new angina, existing angina unresponsive to rest and sublingual nitroglycerin tablets, or heart attack, or if an individual becomes unresponsive. **EB/CEB:** *Morbidity and mortality from MI can be reduced significantly when symptoms are recognized and emergency medical services activated, shortening time to definitive treatment (Hazinski et al, 2010).*
- Upon discharge, instruct clients about symptoms of ischemia, when to cease activity, when to use sublingual nitroglycerin, and when to call 911. **EB/CEB:** *Degree and extent of myocardial ischemia is related to duration of time with inadequate supply of oxygen-rich blood (Hazinski et al, 2010).*
- Teach client about any medications prescribed. Medication teaching includes the drug name, its purpose, administration instructions such as taking it with or without food, and any side effects to be aware of. Instruct the client to report any adverse side effects to the health care provider.
- Upon hospital discharge, educate clients and significant others about discharge medications, including nitroglycerin sublingual tablets or spray, with written, easy to understand, culturally sensitive information. **EB:** *Clients and significant others need to be prepared to act quickly and decisively to relieve ischemic discomfort (Amsterdam et al, 2014).*
- Provide client education related to risk factors for decreased cardiac tissue perfusion, such as hypertension, hypercholesterolemia, diabetes mellitus, tobacco use, advanced age, and gender (female). **EB:** *Those with two or more risk factors should have a 10-year risk screening for development of symptomatic coronary heart disease. Client education is a vital part of nursing care for the client. Start with the client's base level of understanding and use that as a foundation for further education. It is important to factor in cultural and/or religious beliefs in the education provided (Amsterdam et al, 2014; Eckel et al, 2013; Goff et al, 2013).*
- Instruct the client on antiplatelet and anticoagulation therapy, and about signs of bleeding, need for ongoing medication compliance, and international normalized ratio monitoring. **EB:** *Special attention and education should be provided to older individuals, because they are at greater risk for bleeding (Amsterdam et al, 2014).*
- After discharge, continue education and support for client blood pressure and diabetes control, weight management, and resumption of physical activity. **EB:** *Reducing risk factors acts as secondary prevention of coronary artery disease (Amsterdam et al, 2014; Eckel et al, 2013).*

- ▲ Clients should be provided with education regarding the influenza vaccine and pneumococcal vaccine before hospital discharge. **EB:** *The influenza vaccine is recommended for all adults, and the pneumococcal vaccine is recommended for individuals older than 65 years and for individuals who are at high risk for cardiovascular disease (Amsterdam et al, 2014; Centers for Disease Control, 2014).*
- ▲ Stress the importance of ceasing tobacco use. **EB:** *Tobacco use can cause or worsen decreased blood flow in the coronaries, as well as cause vasoconstriction, which can lead to atherosclerotic disease. Effects of nicotine include increasing pulse and blood pressure and constricting blood vessels. Tobacco use is a primary factor in heart disease (American Heart Association, 2014; Amsterdam et al, 2014).*
- ▲ Individuals should be screened for electronic cigarette use (e-cigarette). **EB:** *While more studies are needed regarding the health effects of e-cigarette use, the American Heart Association recommends that all health care providers educate their clients regarding the long-term use of e-cigarettes given the known toxicities present in e-cigarettes, as well as the presence of nicotine in most types of e-cigarettes (Bhatnagar et al, 2014).*
- ▲ Upon hospital discharge, educate clients about a low sodium, low saturated fat diet, with consideration to client education, literacy, and health literacy level. **EB:** *Reducing risk factors acts as secondary prevention of coronary artery disease (Amsterdam et al, 2014; Eckel et al, 2013).* A Cochrane review recommended that there be a permanent reduction in dietary saturated fats and replacement with unsaturated fats to reduce the risk of cardiovascular disease (Hopper et al, 2012).
- Teach the importance of physical activity. **EB:** *Exercise helps control blood pressure and weight, which are the most important controlled risk factors for cardiovascular disease. Individuals should engage in aerobic physical activity of moderate to vigorous intensity, three to four times per week (Amsterdam et al, 2014; Eckel et al, 2013).*

Risk for impaired Cardiovascular function

Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN, and Ann Will Poteet, MS, RN, CNS

C

NANDA-I

Definition

Vulnerable to internal or external causes that can damage one or more vital organs and the circulatory system itself

Risk Factors

Age older than 65 years; diabetes mellitus; dyslipidemia; family history of cardiovascular disease; history of cardiovascular disease; hypertension; insufficient knowledge of modifiable risk factors; obesity; pharmaceutical agent; sedentary lifestyle; smoking

NOC, NIC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan for Decreased **Cardiac** output, Risk for decreased **Cardiac** tissue perfusion, and **Sedentary** lifestyle.

Caregiver Role Strain

Paula Riess Sherwood, RN, PhD, CNRN, FAAN, and Barbara A. Given, PhD, RN, FAAN

NANDA-I

Definition

Difficulty in performing family/significant other caregiver role

Defining Characteristics

Caregiving Activities

Apprehension about future ability to provide care; apprehension about the future health of receiver; apprehension about possible institutionalization of care receiver; apprehension about well-being of care receiver if unable to provide care; difficulty completing required tasks; difficulty performing required tasks; dysfunctional change in caregiving activities; preoccupation with care routine

Caregiver Health Status: Physiological

Cardiovascular disease; diabetes mellitus; fatigue; gastrointestinal distress; headache; hypertension; rash; weight change

Caregiver Health Status: Emotional

Alteration in sleep pattern; anger; depression; emotional vacillation; frustration; impatience; ineffective coping strategies; insufficient time to meet personal needs; nervousness; somatization; stressors

Caregiver Health Status: Socioeconomic

Changes in leisure activities; low work productivity; refusal of career advancement; social isolation

Caregiver-Care Receiver Relationship

Difficulty watching care receiver with illness; grieving of changes with care recipient; uncertainty about changes in relationship with care receiver

Family Processes

Concerns about family members; family conflict

Related Factors (r/t)

Care Recipient Health Status

Alteration in cognitive functioning; chronic illness; codependency; dependency; illness severity; increase in care needs; problematic behavior; psychiatric disorder; substance abuse; unpredictability of illness trajectory; unstable health condition

Caregiver Health Status

Alteration in cognitive functioning; codependency; ineffective coping strategies; insufficient fulfillment of others' expectations insufficient fulfillment of self-expectations; physical conditions; substance abuse; unrealistic self-expectations

Caregiver-Care Receiver Relationship

Abusive relationship; care receiver's condition inhibits conversation; pattern of ineffective relationships; unrealistic care receiver expectations; violent relationship

Caregiving Activities

Around-the-clock care responsibilities; change in nature care of activities; complexity of care activities; duration of caregiving; excessive caregiving activities; recent discharge home with significant care needs; unpredictability of care situation

Family Processes

Pattern of family dysfunction; pattern of ineffective family coping

Resources

Caregiver not developmentally ready for caregiver role; difficulty accessing assistance; difficulty accessing community resources; difficulty accessing support; financial crisis (e.g., debt, insufficient finances); inexperience with caregiving; insufficient assistance; insufficient caregiver privacy; insufficient community resources (e.g., respite services, recreation, social support); insufficient emotional resilience; insufficient equipment for providing care; insufficient knowledge about community resources; insufficient physical environment for providing care; insufficient time; insufficient transportation

Socioeconomic

Alienation; competing role commitments; insufficient recreation; social isolation

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Caregiver Adaptation to Patient Institutionalization; Caregiver Emotional Health; Caregiver Home Care Readiness; Caregiver Lifestyle Disruption; Caregiver-Patient Relationship; Caregiver Performance: Direct Care; Caregiver Performance: Indirect Care; Caregiver Physical Health; Caregiver Role Support; Caregiver Role Endurance; Caregiver Stressors; Caregiver Well-Being

Example NOC Outcome with Indicators

Caregiver Emotional Health with plans for a positive future as evidenced by the following indicators: Satisfaction with life/Sense of control/Self-esteem/Perceived social connectedness/Perceived spiritual well-being. (Rate the outcome and indicators of **Caregiver Emotional Health**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section 1].)

Client Outcomes

Throughout the Care Situation, the Caregiver Will

- Feel supported by health care professionals, family, and friends; Report reduced or acceptable feelings of burden or distress; Take part in self-care activities to maintain own physical and psychological/emotional health; Identify resources available to help in giving care or to support the caregiver to give care; Verbalize mastery of the care situation; Feel confident and competent to provide care;
- Ask for help

Throughout the Care Situation, the Care Recipient Will

- Obtain quality and safe care

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Caregiver Support

Example NIC Activities—Caregiver Support

Determine caregiver's acceptance of role; Accept expressions of negative emotion

Nursing Interventions and Rationales

- Regularly monitor signs of depression, anxiety, burden, and deteriorating physical health in the caregiver throughout the care situation, especially if the relationship is poor, the care recipient has cognitive or neuropsychiatric symptoms, there is little social support available, the caregiver becomes enmeshed in the care situation, the caregiver is older, female, or has poor preexisting physical or emotional health. Refer to the care plan for **Hopelessness** when appropriate. **EBN:** *High levels of distress in caregivers are linked to multiple variables (van der Lee et al, 2014).* **EB:** *Caregiving may weaken the immune system and predispose the caregiver to illness, particularly cardiac illness and poor response to acquired infections (Fonareva & Oken, 2014; Lovell et al, 2012).*
- The impact of providing care on the caregiver's emotional health should be assessed at regular intervals using a reliable and valid instrument such as the Caregiver Strain Risk Index, which was validated with caregivers of clients with diagnosed Parkinson's disease. **EBN:** *Family caregivers face potential strain in caring for persons with Parkinson's disease because of the unpredictability of symptom presentation. The Caregiver Strain Risk Screen (CSRS) was developed and tested for initial validation. The 28-item CSRS demonstrated acceptable validity and reliability in measuring caregiver strain (Abendroth, 2015).* *Caregiver assessment should be done at regular intervals throughout the care trajectory (Adelman et al, 2014).*
- Identify potential caregiver resources such as mastery, social support, optimism, and positive aspects of care. **EB/EBN:** *Research has shown that caregivers can have simultaneous positive and negative responses to providing care. Positive responses may help buffer the negative effects of providing care on caregivers' emotional health and may also increase the effectiveness of interventions to reduce strain (Kruithof et al, 2011).*
- Screen for caregiver role strain at the onset of the care situation, at regular intervals throughout the care situation, and with changes in care recipient status and care transitions, including institutionalization. **EB/EBN:** *Care situations that last for several months or years can cause wear and tear that exhaust caregivers' coping mechanisms and available resources, and that may continue after the care recipient has been institutionalized (Paun & Farran, 2011).* *In addition, changes in the care recipient's health status necessitate new skills and monitoring from the caregiver and affect the caregiver's ability to continue to provide care (Given et al, 2011).* *Providing caregiver support throughout the care situation may decrease care recipient institutionalization (Matsuzawa et al, 2011).*
- Watch for caregivers who become enmeshed in the care situation. **EBN:** *Caregivers are at risk for becoming overinvolved or unable to disentangle themselves from the caregiver role, particularly in the absence of adequate social support (Hricik et al, 2011).*
- Arrange for intervals of respite care for the caregiver; encourage use if available. **EB:** *Respite care provides time away from the care situation and may help alleviate some caregiver distress (Maayan et al, 2014).*
- Regularly monitor social support for the caregiver and help the caregiver identify and use appropriate support systems for varying times in the care situation. **EBN:** *Lower levels of perceived support can cause caregivers to feel abandoned and increase their distress (Hwang et al, 2011).*
- Encourage the caregiver to grieve over changes in the care recipient's condition and give the caregiver permission to share angry feelings in a safe environment. Refer to nursing interventions for **Grieving**. **EB:** *Caregivers grieve the loss of personhood of their loved one, especially when dementia is involved (Kramer et al, 2011).*
- Help the caregiver find personal time to meet his or her needs, learn stress management techniques, schedule regular health screenings, and schedule regular respite time. **EB:** *Due to increased risk for poor physical health as a result of providing care, caregivers must feel empowered to maintain self-care activities (Merluzzi et al, 2011).* *Interventions to provide support for family caregivers have shown improvements in caregiver health (Basu et al, 2013).*

- Encourage the caregiver to talk about feelings, concerns, uncertainties, and fears. Support groups can be used to gain mutual and educational support. **EBN:** *Support groups can improve depressive symptoms and burden, particularly for female caregivers (Chien et al, 2011).* **EB:** *Social support groups can be effective over the Internet, using forums such as Facebook (Bender et al, 2011).*
- Observe for any evidence of caregiver or care recipient violence or abuse, particularly verbal abuse; if evidence is present, speak with the caregiver and care recipient separately. **EB/CEB:** *Caregiver violence is possible and screening should be done at regular intervals (Hoover & Polson, 2014).*
- ▲ Involve the family in care transitions; use a multidisciplinary team to provide medical and social services for instruction and planning specific to the care situation. **EBN:** *Family members need education specific to their situation beyond what is traditionally provided at discharge; this educational approach should be proactive and anticipate potential problems in the home (Loupis & Faux, 2013).*
- ▲ Encourage regular communication with the care recipient and with the health care team. **EB:** *There can be a large discrepancy between what the health care professional feels he or she has communicated and what the caregiver reports hearing (Molinuevo et al, 2011).*
- Help caregiver assess his or her financial resources (services reimbursed by insurance, available support through community and religious organizations) and the impact of providing care on his or her financial status. **EB/EBN:** *Better physical and mental health outcomes were common for caregivers and non-caregivers who reported having more resources (e.g., higher income, better preparedness for future financial need, higher satisfaction with transportation and housing, and no limitation of usual daily activities) (Ahn et al, 2012).*
- Help the caregiver identify competing occupational demands and potential benefits to maintaining work as a way of providing normalcy. Guide caregivers to seek ways to maintain employment through mechanisms such as job sharing or decreasing hours at work. **EB:** *Employed caregivers report that work can provide a sense of fulfillment, refuge, and satisfaction (Eldh & Carlsson, 2011).*
- Help the caregiver problem solve to meet the care recipient's needs. **EBN:** *Interventions that teach caregivers problem-solving skills have been shown to positively influence caregivers' psychosocial well-being (Cheng et al, 2014).*

Geriatric

- Monitor the caregiver for psychological distress and signs of depression, especially if caring for a mentally impaired older adult or if there was an unsatisfactory marital relationship before caregiving. **EBN:** *As the majority of family caregivers are spouses, degree of marital satisfaction is strongly linked with caregiver role strain (Green & King, 2011).*
- Assess the health of caregivers, particularly their control over chronic diseases, at regular intervals. **CEB:** *Caregivers with high levels of depressive symptoms have demonstrated poor health and increased health care utilization and cost (Zhu et al, 2014).*
- Assess the presence of and use of social support and encourage the use of secondary caregivers with older caregivers. **EBN:** *Social support has been shown to be an integral part of maintaining caregiver health (Quinn et al, 2014).*
- To improve the ability to provide safe care: provide skills training related to direct care, perform complex monitoring tasks, supervise and interpret client symptoms, assist with decision-making, assist with medication adherence, provide emotional support and comfort, and coordinate care. **CEB:** *Each task demands different skills and knowledge, and caregivers show a desire to master these skills (Moon & Adams, 2013).*
- Teach symptom management techniques (assessment, potential causes, aggravating factors, potential alleviating factors, reassessment), particularly for fatigue, constipation, anorexia, and pain. **EBN:** *Caregivers require training in care recipient monitoring symptom management and interpretation, and can benefit from a problem-solving approach (Sherwood et al, 2012).*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's ability to modify health behavior. **EBN:** *What the client considers normal and abnormal health behavior may be based on cultural perceptions (Giger, 2014).* **EBN:** *Each client should be assessed for ability to modify health behavior based on the phenomenon of communication, time, space, social organization, environmental control, and biological variations (Giger, 2014).*
- Despite the importance of cultural differences in perceptions of caregiver role strain, there are certain characteristics that are distressing to caregivers across multiple cultures. **EBN:** *Social support and care*

recipients' behavioral difference have been shown to be an important factor in caregiver distress across multiple cultures (Chiao & Schepp, 2012; Hwang et al, 2011; Zahid & Ohaeri, 2010).

- Persons with different cultural backgrounds may not perceive the provision of care with equal degrees of distress. **EB:** A group of caregivers in Belize did not report providing care as negative, although they did exhibit physical symptoms of distress (Vroman & Morency, 2011).
- Recognize that cultures often play a role in identifying who will be recognized as a family caregiver and form partnerships with those groups. **EB:** In a study of American Indians, people who attended and participated in Native events and endorsed traditional healing practices were more likely to be caregivers. The study also reported that gender played a role in identifying caregivers in some tribes, but not all (Goins et al, 2011).
- Encourage spirituality as a source of support for coping. **EBN:** Many African Americans and Latinos identify spirituality, religiousness, prayer, and church-based approaches as coping resources. Socioeconomic status, geographical location, and risks associated with health-seeking behavior all influence the likelihood that clients will seek health care and modify health behavior (Giger, 2014).
- Assess for the presence of conflicting values within the culture. **EBN:** Whereas sharing and caring is part of the Amish community, females with breast cancer were found to value privacy issues related to their body image and health status and to prefer this was shared in the closed community (Schwartz, 2008).
- Recognize that different cultures value and use caregiving resources in different ways. **CEB:** When Korean and Caucasian American caregivers were compared, there was more family support in Korean caregivers while Caucasian Americans were more likely to use formal support (Kong, 2007).

Home Care

- Assess the client and caregiver at every visit for quality of relationship, and for the quality of caring that exists. **EB:** Quality of the caregiver-care recipient relationship and the impact of the care situation on that relationship can be an important source of distress or support for the caregiver (van der Lee et al, 2014). Chronic illness, especially dementia, can represent a gradual and devastating loss of the marital relationship as it existed formerly.
- Assess preexisting strengths and weaknesses the caregiver brings to the situation, as well as current responses, depression, and fatigue levels. **EB/EBN:** Caregivers' personality type, mastery, self-efficacy, optimism, and social support have all been linked to the amount of distress the caregiver will perceive as a result of providing care (Adelman et al, 2014).
- ▲ Refer the client to home health aide services for assistance with activities of daily living and light house-keeping. Allow the caregiver to gain confidence in the respite provider. Home health aide services can provide physical relief and respite for the caregiver. **EB:** The need for caregiver respite has been linked with the number of hours per week spent providing care (Hughes et al, 2014).

Client/Family Teaching and Discharge Planning

- Identify client and caregiver factors that necessitate the use of formal home care services, that may affect provision of care, or that need to be addressed before the client can be safely discharged from home care. **EBN:** Although home care resources can be useful in decreasing caregiver distress, they are not used with regularity across client populations. Health care practitioners should assess for the need for support resources prior to discharge and at routine intervals throughout the care situation, tailoring community resources to individual caregiver needs (Greene et al, 2011). Interventions prior to discharge may include medication management, medication reconciliation, identification of medical red flags, identification of community-based resources, and specific caregiver concerns about home care (Hendrix et al, 2011).
- Collaborate with the caregiver and discuss the care needs of the client, disease processes, medications, and what to expect; use a variety of instructional techniques (e.g., explanations, demonstrations, visual aids) until the caregiver is able to express a degree of comfort with care delivery. **EB:** Knowledge and confidence are separate concepts. Self-assurance in caregiving will decrease the amount of distress the caregiver perceives as a result of providing care (Giovannetti et al, 2012; Ostwald et al, 2014) and may improve the quality of care provided.
- Assess family caregiving skill. The identification of caregiver difficulty with any of a core set of processes highlights areas for intervention. **CEB:** The ability to engage effectively and smoothly in nine processes has been identified as constituting family caregiving skill: monitoring client behavior, interpreting changes accurately, making decisions, taking action, making adjustment to care, accessing resources, providing hands-on care, working together with the ill person, and negotiating the health care system (Schumacher et al, 2000).

EB: Caregiver skills training has been shown to improve caregiver knowledge and skills and may be reimbursable within governmental health care plans (Gitlin et al, 2010).

- Discharge care should be individualized to specific caregiver needs and care situations, and enable them to be prepared. **EBN:** Interventions implemented by advanced practice nurses have been successful in preventing negative outcomes (Bradway et al, 2012; Stone, 2014).
- Assess the caregiver's need for information such as information on symptom management, disease progression, specific skills, and available support. **EBN:** Caregiver interventions should be individualized to meet specific caregiver needs (Greene et al, 2011; Hendrix et al, 2011). Multicomponent strategies to provide education, support, counseling, and linkage to community resources to ease transitions from the hospital to the home can improve caregiver health and coping (Ostwald et al, 2014).
- Teach the caregiver warning signs for burnout, depression, and anxiety. Help them identify a resource in case they begin to feel overwhelmed.
- Teach the caregiver methods for managing disruptive behavioral symptoms if present. Refer to the care plan for Chronic **Confusion**. **CEB:** Behavioral interventions that consist of nine to 12 sessions over several months have been shown to be as effective as pharmacological interventions to control behavioral problems in the care recipient (Brodaty & Arasaratnam, 2012).
- Teach the caregiver how to provide the care needed and put a plan in place for monitoring the care provided.
- Provide ongoing support and evaluation of care skills as the care situation and care demands change.
- Provide information regarding the care recipient's diagnosis, treatment regimen, and expected course of illness.
- ▲ Refer to counseling or support groups to assist in adjusting to the caregiver role and periodically evaluate not only the caregiver's emotional response to care but the safety of the care delivered to the care recipient.

Risk for Caregiver Role Strain *Jane M. Kendall, RN, BS, CHT*

NANDA-I

Definition

Vulnerable to difficulty in performing the family/significant other caregiver role, which may compromise health

Risk Factors

Alteration in cognitive functioning in care receiver; care receiver discharged home with significant needs; care receiver exhibits bizarre behavior; care receiver exhibits deviant behavior; caregiver health impairment; caregiver isolation; caregiver not developmentally ready for caregiver role; caregiver's competing role commitments; caregiving task complexity; codependency; congenital disorder; developmental delay; developmental delay of caregiver; excessive caregiving activities; exposure to violence; extended duration of caregiving required family isolation; female caregiver; illness severity of care receiver; inadequate physical environment for providing care; ineffective caregiver coping pattern; ineffective family adaptation; experience with caregiving; instability in care receiver's health; insufficient caregiver recreation; insufficient respite for caregiver;

partner as caregiver; pattern of family dysfunction prior to the caregiving situation; pattern of ineffective relationship between caregiver and care receiver; prematurity; presence of abuse (e.g., physical, psychological, sexual); psychological disorder in caregiver; psychological disorder in care receiver; stressors; substance abuse; unpredictability of illness trajectory

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching, Rationales, and References

Refer to care plan for **Caregiver Role Strain**.

Risk for ineffective Cerebral tissue perfusion *Laura Mcilvoy, PhD, RN, CCRN, CNRN*

NANDA-I

Definition

Vulnerable to a decrease in cerebral tissue circulation, which may compromise health

Risk Factors

Abnormal partial thromboplastin time; abnormal prothrombin time; akinetic left ventricular wall segment; aortic atherosclerosis; arterial dissection; atrial fibrillation; atrial myxoma; brain injury (e.g., cerebrovascular impairment, neurological illness, trauma, tumor); brain neoplasm; carotid stenosis; cerebral aneurysm; coagulopathy (e.g., sickle cell anemia); dilated cardiomyopathy; disseminated intravascular coagulopathy; embolism; hypercholesterolemia; hypertension; infective endocarditis; mechanical prosthetic valve; mitral stenosis; pharmaceutical agent; recent myocardial infarction; sick sinus syndrome; substance abuse; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Acute Confusion Level; Tissue Perfusion: Cerebral; Agitation Level; Neurological Status; Cognition; Seizure Control; Motor Strength

Example NOC Outcome with Indicators

Tissue Perfusion: Cerebral as evidenced by the following indicators: Headache/Restlessness/Listlessness/Agitation/Vomiting/Fever/Impaired Cognition/Decreased level of consciousness/Motor weakness/Dysphagia/Slurred speech. (Rate the outcome and indicators of **Tissue Perfusion: Cerebral**: 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State absence of headache
- Demonstrate appropriate orientation to person, place, time, and situation
- Demonstrate ability to follow simple commands
- Demonstrate equal bilateral motor strength
- Demonstrate adequate swallowing ability

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Medication Management; Neurologic Monitoring; Positioning: Neurologic; Cerebral Perfusion Promotion; Fall Prevention; Cognitive Stimulation; Environmental Management: Safety

Example NIC Activities—Neurological Monitoring

Monitor pupillary size, shape, symmetry, and reactivity; Monitor level of consciousness; Monitor level of orientation; Monitor trend of Glasgow Coma Scale; Monitor facial symmetry; Note complaint of headache

Nursing Interventions and Rationales

- To decrease risk of reduced cerebral perfusion related to stroke or transient ischemic attack:
 - Obtain a family history of hypertension and stroke to identify persons who may be at increased risk of stroke. **EB:** *A positive family history of stroke increases risk of stroke by approximately 30% (Goldstein et al, 2011).*
 - Monitor blood pressure (BP) regularly, because hypertension is a major risk factor for both ischemic and hemorrhagic stroke. **EB:** *Systolic BP should be treated to a goal of less than 140 mm Hg and diastolic BP to less than 90 mm Hg, while clients with diabetes or renal disease have a BP goal of less than 130/80 mm Hg (Goldstein et al, 2011).*
 - Teach hypertensive clients the importance of taking their health care provider-ordered antihypertensive agent to prevent stroke. **EB:** *Treatment of hypertension in adults with diabetes with an angiotensin converting enzyme inhibitor (ACEI) or an angiotensin receptor blockers (ARB) is useful (Goldstein et al, 2011).*
 - Stress smoking cessation at every encounter with clients, using multimodal techniques to aid in quitting, such as counseling, nicotine replacement, and oral smoking cessation medications. **EB:** *Epidemiological studies show a consistent and overwhelming relationship between smoking and both ischemic and hemorrhagic stroke (Goldstein et al, 2011).*
 - Teach clients who experience a transient ischemic attack (TIA) that they are at increased risk for a stroke. **EB:** *The 90-day risk for stroke after a TIA is as high as 17%, with the greatest risk occurring in the first week (Furie et al, 2011).*
 - Screen clients 65 years of age and older for atrial fibrillation with pulse assessment. **EB:** *Atrial fibrillation is associated with a fivefold increase in stroke. Systematic pulse assessment in primary care setting resulted in a 60% increase in the detection of atrial fibrillation (Goldstein et al, 2011).*
 - Call 911 or activate the rapid response team of a hospital immediately when clients display symptoms of stroke as determined by the Cincinnati Stroke Scale (F: facial drooping; A: arm drift on one side; S: speech slurred), being careful to note the time of symptom appearance. Additional symptoms of stroke include sudden numbness/weakness of face, arm or leg, especially on one side, sudden confusion, trouble speaking or understanding, sudden difficulty seeing with one or both eyes, sudden trouble walking, dizziness, loss of balance or coordination, or sudden severe headache (National Stroke Association, 2012). **EB:** *The Cincinnati Stroke Scale (derived from the NIH Stroke Scale) is used to identify clients having a stroke who may be candidates for thrombolytic therapy (Jauch et al, 2013). EMS activation results in faster health care provider assessment, computed tomography, and neurological evaluation, which facilitates administering thrombolytics to eligible stroke victims within the required 3-hour time period (Jauch et al, 2013).*
 - Use clinical practice guidelines for glycemic control and BP targets to guide the care of clients with diabetes who have had a stroke or TIA. **EB:** *The American Stroke Association recommends that evidence-based guidelines be used in the care of clients with diabetes. Good glycemic control has been associated with decreased incidence of strokes (Furie et al, 2011; Handelsman et al, 2011).*
 - Maintain head of bed less than 30 degrees in the acute phase (<72 hours of symptom onset) of ischemic stroke. **EB:** *Cortical cerebral blood flow is decreased when head of bed is elevated from 0 degrees to 30 degrees in clients with acute ischemic stroke (Favilla et al, 2014).*
 - Head of bed may be elevated to sitting position without detrimental effect to cerebral blood flow in clients with ischemic stroke or subarachnoid hemorrhagic at 72 hours after symptom onset. **EB:** *Head of bed elevation of 45 degrees and 70 degrees in the subacute phase of ischemic stroke resulted in minor changes in cerebral blood flow velocities (Aries et al, 2013). EB: Cerebral blood flow had no significant changes in head of bed elevations from 0 degree to 90 degrees in clients with subarachnoid hemorrhage at day 3, 7, and 10 (Kung et al, 2013).*
 - Administer oral nimodipine as prescribed by the healthcare provider after subarachnoid hemorrhagic strokes for 21 days. **EB:** *Nimodipine, a calcium channel blocker, has been shown by multiple randomized clinical trials to improve outcome by limiting delayed cerebral ischemia after subarachnoid hemorrhage strokes (Diringer et al, 2011).*
- ▲ To decrease risk of reduced cerebral perfusion pressure (CPP): Cerebral perfusion pressure = Mean arterial pressure – intracranial pressure (CPP = MAP – ICP): See care plan for Decreased **Intracranial** adaptive capacity.
 - Maintain euvoolemia. **CEB:** *Infusing intravenous fluids to sustain normal circulating volume helps maintain normal cerebral blood flow (Bullock et al, 2001).*

- ▲ To treat decreased CPP:
 - Clients with subarachnoid hemorrhagic stroke experiencing delayed cerebral ischemia, as evidenced by declining neurological exam, should undergo a trial of induced hypertension. **EB**: *Hypertension increased cerebral blood flow and produced neurological improvement in the majority of clients (Diringer et al, 2011)*.
 - Administer phenylephrine infusion to raise MAP per collaborative protocol. **EB**: *Phenylephrine was more effective than dopamine in raising MAP and more effective than norepinephrine in raising CPP in severely injured clients with traumatic brain injury (Sookplung et al, 2011)*.

Ineffective Childbearing process *Dianne Frances Hayward, RN, MSN, WHNP*

NANDA-I

Definition

Pregnancy and childbirth process and care of the newborn that does not match the environmental context, norms, and expectations

Definition

During Pregnancy

Inadequate prenatal care; inadequate prenatal lifestyle (e.g., elimination, exercise, nutrition personal hygiene, sleep); inadequate preparation of newborn care items; inadequate preparation of the home environment; ineffective management of unpleasant symptoms in pregnancy; insufficient access of support system; insufficient respect for unborn baby; unrealistic birth plan

During Labor and Delivery

Decrease in proactivity during labor and delivery; inadequate lifestyle for stage of labor (e.g., elimination, exercise, nutrition, personal hygiene, sleep); inappropriate response to onset of labor; insufficient access or support system; insufficient attachment behavior

After Birth

Inadequate baby care techniques; inadequate postpartum lifestyle (e.g., elimination, exercise, nutrition personal hygiene, sleep); inappropriate baby feeding techniques; inappropriate breast care; insufficient access of support system; insufficient attachment behavior; unsafe environment for infant

Related Factors

Domestic violence; inconsistent prenatal health visits; insufficient knowledge of childbearing process; inadequate maternal nutrition; insufficient parental role model; insufficient prenatal care; insufficient support system; low maternal confidence; maternal powerlessness; maternal psychological distress; substance abuse; unplanned pregnancy; unrealistic birth plan; unsafe environment; unwanted pregnancy

NOC Nursing Outcomes Classification

Suggested NOC Outcomes

Fetal Status: Antepartum, Intrapartum; Maternal Status: Antepartum, Intrapartum; Depression Level; Family Resiliency; Knowledge: Substance Use Control; Social Support; Spiritual Support

Example NOC Outcome with Indicators

Maternal Status: Antepartum as evidenced by the following indicators: Emotional attachment to fetus/Coping with discomforts of pregnancy/Mood lability/Has realistic birth plan/Has support system. (Rate each indicator of **Maternal Status: Antepartum**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

Antepartum

- Obtain early prenatal care in the first trimester and maintain regular visits
- Obtain knowledge level needed for appropriate care of oneself during pregnancy including good nutrition and psychological health
- Understand the risks of substance abuse and resources available
- Feel empowered to seek social and spiritual support for emotional well-being during pregnancy
- Use support systems for labor and emotional support
- Develop a realistic birth plan, taking into account any high-risk pregnancy issues
- Understand the labor and delivery process and comfort measures to manage labor pain

Postpartum

- Use a safe environment for self and infant
- Obtain knowledge to provide appropriate newborn care and postpartum care of self
- Obtain knowledge to develop appropriate bonding and parenting skills

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

High-Risk Pregnancy Care; Intrapartal Care

Example NIC Activities—High-Risk Pregnancy Care

Instruct patient on importance of receiving regular prenatal care and to follow plan of care by taking prescribed medications and following nutrition guidelines; Encourage identification of psychosocial/psychological issues and substance use and appropriate treatment and referrals as needed

Nursing Interventions and Rationales

- Encourage early prenatal care and regular prenatal visits. **EB/EBN**: Women who attended for less than four visits or started care late were at risk for a poorer outcome. Culture must also be assessed to provide appropriate prenatal care (Beeckman et al, 2013; Lewallen, 2011). **EBN**: A study compared outcomes of infants born to women who received Medicaid and prenatal care coordination (PNCC) services versus women who received Medicaid but did not receive PNCC. Women who received PNCC services resulted

in delivery of fewer low-birth-weight infants, fewer preterm infants, and fewer infants transferred to the neonatal intensive care unit. PNCC is an effective strategy for preventing adverse birth outcomes (Van Dijk et al, 2011).

- ▲ Identify any high-risk factors that may require additional surveillance, such as preterm labor, hypertensive disorders of pregnancy, diabetes, depression, other chronic medical conditions, presence of fetal anomalies, or other high-risk factors. **EB:** *Timely and accurate antenatal screening is believed to be an important factor in preventing preterm birth, screening for gestational diabetes, preeclampsia, intrauterine growth restriction, and depression, to mention a few. Finding and treating problems early improves outcome (Beeckman et al, 2013).*
- ▲ Assess and screen for signs and symptoms of depression during pregnancy and in the postpartum period including history of depression or postpartum depression, poor prenatal care, poor weight gain, hygiene issues, sleep problems, substance abuse, and preterm labor. If depression is present, refer for behavioral-cognitive counseling, and/or medication (postpartum period only). Both counseling and medication are considered relatively equal to help with depression. **EB/EBN:** *Screen pregnant women using a tool like the Patient Health Questionnaire (PHQ-9) for depression risk identification. When comprehensive screening is not included during antepartum care, there is less likelihood that significant information will be revealed. Subsequently, undiagnosed clinical depression in pregnancy may lead to serious perinatal complications such as inadequate maternal weight gain, preterm birth, and low infant birth weight (Breedlove & Fryzelka, 2011; Sidebottom et al, 2012; Rollans et al, 2013).*
- ▲ Observe for signs of alcohol use and counsel women to stop drinking during pregnancy. Give appropriate referral for treatment if needed. **EB:** *Alcohol is teratogenic, and prenatal exposure may result in growth impairment, facial abnormalities, central nervous system and/or intellectual impairment, and behavioral disorders. Evidence suggests women's past pregnancy, current drinking behavior, and attitude toward alcohol use in pregnancy were the strongest predictors of alcohol consumption in pregnancy (Barclay, 2011; Peadon et al, 2011).*
- ▲ Obtain a smoking history and counsel women to stop smoking for the safety of the baby. Give appropriate referral to smoking cessation program if needed. **CEB:** *Tobacco smoking in pregnancy remains one of the few preventable factors associated with pregnancy complications. Use the 5As (tobacco cessation interventions) to treat tobacco use and dependence in pregnant women. According to the USDHHS Clinical Practice Guidelines, health care professionals should at every contact (1) ask if a woman is a tobacco user, (2) advise her to quit, (3) assess her willingness to quit, (4) assist with the quit attempt (such as counseling, medication), and (5) arrange for follow-up (telephone support 1-800-QUIT-NOW). The evidence is compelling, even a minimal (less than 3 minute) intervention can make a difference in motivation to quit smoking (USDHHS, 2008).*
- ▲ Monitor for substance abuse with recreational drugs. Refer to drug treatment program as needed. Refer opiate-dependent women to methadone clinics to improve maternal and fetal pregnancy outcomes. **EBN:** *The drug addict is obsessed by the drug of choice because of a change in the pathophysiology of the brain. Treating addiction as a chronic disease instead of a moral weakness is more supportive to women who abuse drugs. It is important to involve a pregnant woman in a treatment program like a methadone clinic to help to stabilize the maternal-fetal dyad. Methadone prevents withdrawal symptoms and eliminates drug craving. Methadone blocks the euphoric effects of illegal self-administered narcotics. It also supports stable maternal opioid levels to protect the fetus from repeated occurrences of withdrawal and decreases the risk for sexually transmitted infections by decreasing drug-seeking behaviors such as prostitution. When a woman makes the decision to enroll in a methadone treatment program, she is taking a significant step toward recovery (Maguire, 2014).*
- ▲ Monitor for psychosocial issues including lack of social support system, loneliness, depression, lack of confidence, maternal powerlessness, domestic violence, and socioeconomic problems. **CEB:** *A study that compared psychosocial assessment versus routine care for pregnant women concluded that the health care providers who assessed psychosocial factors were more likely to identify psychosocial concerns, including family violence, and to rate the level of concern as high. In two trials, women identified they did not want to feel so alone, be judged, or be misunderstood, and they wanted to feel an increased sense of their own worth. Social support interventions can improve health. The use of doulas or labor coaches can provide assistance in addressing social-psychological issues and socioeconomic disparities (Austin et al, 2008; Gentry et al, 2010; Small et al, 2011).*
- ▲ Monitor for signs of domestic violence. Refer to a community program for abused women that provides safe shelter as needed. **EB:** *Women who were involved in intimate partner violence were more*

likely to experience negative outcomes such as preterm delivery and delivery of low-birth-weight infants (Shneyderman & Kiely, 2013). Women enduring domestic violence are often in denial. Pregnancy and immediately postpartum are highly vulnerable times for mothers and their infants to experience domestic violence. These women also need to be assessed regularly because they may not be ready to seek help at first. This may be the only time a pregnant victim of domestic violence comes in contact with a health care provider who can assess for the abuse and take action to resolve it (Menezes Cooper, 2013).

- Provide antenatal education to increase the woman's knowledge needed to make informed choices during pregnancy, labor, and delivery and to promote a healthy lifestyle. **EB:** Antenatal classes must be interesting enough to maintain attention, relevant to the attendees, and understandable. The parents should feel empowered that the decisions they make about maternity care and parenthood are made with up-to-date evidence-based information and fit into their lifestyle. O'Sullivan et al (2014) found that class sizes tended to be too large to include class participation. They also reported educators sometimes just focused on maternity care and not on parenthood, healthy lifestyle, and changing relationships. Although resources are available, the educators reported their facility had limited educational resources.
- Encourage expectant parents to prepare a realistic birth plan in order to prepare for the physical and emotional aspects of the birth process and to plan ahead for how they want various situations handled. **CEB:** The degree of satisfaction the mothers have with the birth of their baby is increased when they have made an individualized birth plan and the medical team and parents are able to follow it (Sato & Umemo, 2011).
- Encourage good nutritional intake during pregnancy to facilitate proper growth and development of the fetus. Women should consume an additional 300 calories per day during pregnancy, take a multi-micronutrient supplement containing at least 400 µg folic acid, and achieve a total weight gain of 25 to 30 lb. **EB:** A healthy, varied diet (e.g., ChooseMyPlate.gov) is of vital importance for optimal birth outcome, including taking a multivitamin with folic acid from before conception to at least the twelfth week of pregnancy, as well as a vitamin D supplement throughout pregnancy. Many women are not following the guidelines and there are concerns for these vulnerable groups (USDA, 2014; Williamson & Wyness, 2013). Inadequate levels of key nutrients during crucial periods of fetal development may lead to changes within fetal tissues, predisposing the infant to chronic illnesses and conditions in later life (Procter & Campbell, 2014).

Multicultural

- ▲ Provide for a translator if needed. **EB:** The health care industry must recognize that providing translators for language assistance is an important tool for improving quality of care, saving lives, and avoiding costly and dangerous medical errors. Although costly, the American health care industry needs to comply with federal and state laws as well as accreditation standards by being prepared to provide care in at least 100 different languages (Rivers & Rivers, 2013).
- ▲ Provide depression screening for clients of all ethnicities. **EB:** Race and ethnicity are important risk factors for antenatal depression. A study found that non-Hispanic white women, black women, and Asian/Pacific Islander women had an increased risk for antenatal depression. The prevalence of antenatal depression was 15.3% in black women, 6.9% in Latinas, and 3.6% in non-Hispanic white women (Gavin et al, 2011). **EB:** Screening Latina women for depression, 20.4% were positive for depressive symptoms and 36.7% reported psychosocial issues such as intimate partner violence and substance abuse while pregnant (Connelly et al, 2013). **CEB:** Women who are depressed are at risk for unhealthy behaviors such as using tobacco, alcohol, and or drugs. They either sleep too much or not enough, their hygiene suffers, and they are less likely to attend prenatal visits. Maternal levels of corticosteroids and catecholamine are increased, which directly affect the growth and development of the fetus. Maternal depression may also affect bonding (Bowen & Muhajarine, 2006).
- Perform a cultural assessment and provide obstetrical care that is culturally appropriate to ensure a safe and satisfying childbearing experience. **EBN:** Just because a woman is a part of a certain culture, it is not safe to assume she follows all the beliefs of that culture. Asking about what she needs and expects is vital. Nurses must acknowledge that the maternity health care system has a unique culture that may clash with the cultures of many of our clients. Women not accustomed to this culture of potential risk in prenatal care, childbirth, and neonatal care may be frightened, overwhelmed, or made to feel guilty if they are not willing to undergo some of the expected interventions (Lewallen, 2011).

Readiness for enhanced Childbearing process

Gail B. Ladwig, MSN, RN, and Dianne Frances Hayward, RN, MSN, WHNP

NANDA-I

Definition

A pattern of preparing for and maintaining a healthy pregnancy, childbirth process, and care of newborn for ensuring well-being that can be strengthened

Defining Characteristics

During Pregnancy

Expresses desire to enhance knowledge of childbearing process; expresses desire to enhance management of unpleasant pregnancy symptoms; expresses desire to enhance prenatal lifestyle (e.g., elimination, exercise, nutrition, personal hygiene, sleep); expresses desire to enhance preparation for newborn

During Labor and Delivery

Expresses desire to enhance lifestyle appropriate for stage of labor (e.g., elimination, exercise, nutrition, personal hygiene, sleep); expresses desire to enhance proactivity during labor and delivery

After Birth

Expresses desire to enhance attachment behavior; expresses desire to enhance baby care techniques; expresses desire to enhance baby feeding techniques; expresses desire to enhance breast care; expresses desire to enhance environmental safety for the baby; expresses desire to enhance postpartum lifestyle (e.g., elimination, exercise, nutrition, personal hygiene, sleep); expresses desire to enhance use of support system

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Knowledge: Pregnancy; Knowledge: Infant Care; Knowledge: Postpartum Maternal Health

Example NOC Outcome with Indicators

Knowledge: Pregnancy as evidenced by client conveying understanding of the following indicators: Importance of frequent prenatal care/Importance of prenatal education/Benefits of regular exercise/Healthy nutritional practices/Anatomic and physiological changes with pregnancy/Psychological changes associated with pregnancy/Birthing options/Effective labor techniques/Signs and symptoms of labor. (Rate the outcome and indicators of **Knowledge: Pregnancy**: 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)****During Pregnancy**

- State importance of frequent prenatal care/education
- State knowledge of anatomic, physiological, psychological changes with pregnancy
- Report appropriate lifestyle choices prenatal: Activity and exercise/healthy nutritional practices

During Labor and Delivery

- Report appropriate lifestyle choices during labor
- State knowledge of birthing options, signs and symptoms of labor, and effective labor techniques

After Birth

- Report appropriate lifestyle choices postpartum
- State normal physical sensations following delivery
- State knowledge of recommended nutrient intake, strategies to balance activity and rest, appropriate exercise, time frame for resumption of sexual activity, strategies to manage stress
- List strategies to bond with infant
- State knowledge of proper handling and positioning of infant/infant safety
- State knowledge of feeding technique and bathing of infant

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Prenatal Care; Intrapartal Care; Postpartal Care; Attachment Promotion; Infant Care: Newborn

Example NIC Activities—Prenatal Care

Encourage prenatal class attendance; Discuss nutritional needs and concerns (e.g., balanced diet, folic acid, food safety, and supplements); Discuss activity level with client (e.g., appropriate exercise, activities to avoid, and importance of rest); Discuss importance of participating in prenatal care throughout entire pregnancy while encouraging involvement of client's partner or other family member

Nursing Interventions and Rationales

Refer to care plans: Risk for impaired **Attachment**; Readiness for enhanced **Breastfeeding**; Readiness for enhanced family **Coping**; Readiness for enhanced **Family** processes; Risk for disproportionate **Growth**; Readiness for enhanced **Nutrition**; Readiness for enhanced **Parenting**; Ineffective **Role** performance.

Prenatal Care

- ▲ Ensure that pregnant clients have an adequate diet and take multi-micronutrient supplements containing at least 400 micrograms of folic acid during pregnancy. **EB:** *A healthy, varied diet (i.e., ChooseMyPlate.gov) is of vital importance for optimal birth outcome, and this includes taking a folic acid supplement from before conception to the 12th week of pregnancy, as well as a vitamin D supplement throughout pregnancy; many women are not following these guidelines and there are concerns for vulnerable groups (USDA, 2014; Williamson & Wyness, 2013).*
- Encourage pregnant clients to include enriched cereal grain products in their diets. **EB:** *Folate is a B vitamin that helps prevent neural tube defects, serious abnormalities of the brain and spinal cord. Fortified cereals are great sources of folic acid. (Mayo Clinic, 2014).* **CEB:** *The number of pregnancies affected by neural tube defects greatly decreased in the United States after the fortification of cereal grain products with folic acid was mandated (CDC, 2010).*
- Assess smoking status of pregnant clients and offer effective smoking-cessation interventions. **EB:** *Prenatal smoking prevalence remains high in the United States. It is one of the most significant modifiable risk factors for adverse infant outcomes (e.g., low birth weight, preterm birth [preterm], and sudden infant death syndrome). To reduce prenatal smoking prevalence, efforts should focus on delivering evidence-based cessation interventions (Tong et al, 2011; Batech et al, 2013; USDHHS Clinical Practice Guidelines, 2008).*
- Also see Risk for disturbed **Maternal–Fetal** dyad for USDHHS guidelines.
- ▲ Assess for signs of depression and make appropriate referral: inadequate weight gain, underutilization of prenatal care, increased substance use, and premature birth. Past personal or family history of depression, single, poor health functioning, and alcohol use. **EBN:** *Social and emotional health problems associated with depression in the perinatal period can lead to poor outcomes for women, their infants, and their families (Rollans et al, 2013).*
- Discuss breastfeeding with a pregnant client, including all the benefits both to the infant and the mother. **EB:** *Pregnant women need information about overcoming potential breastfeeding problems and the physiology of breastfeeding. Interventions designed to promote breastfeeding confidence need to be directed to primiparas and women with a lack of breastfeeding knowledge (Laanterä et al, 2012).*

Intrapartal Care

- Encourage psychosocial support during labor, especially by the father of the baby or the woman's mother if possible. **EB:** *When a husband provides continuous support during his wife's labor, his presence is considered effective in reducing her dissatisfaction with the childbirth process. According to Lacerda et al (2014), the ideal companion is someone with whom the client has a bond and is trusted. The father of the child ranked first, followed by the mother of the postpartum woman. **EBN:** The key to promoting a normal birth and reducing medical interventions is high-quality continuous support. This support increases a woman's perception of a positive birth experience, fosters a positive adaptation to motherhood, and reduces the risk for posttraumatic stress disorder and other postpartum mental health problems (Ross-Davie & Cheyne, 2014; Sapkota et al, 2013).*
- Consider using aromatherapy during labor. **EB:** *Aromatherapy has been used in childbirth to reduce anxiety and pain (Horowitz, 2011).*
- Provide massage and relaxation techniques during labor. **EB:** *There is some evidence to suggest that relaxation and massage may improve management of labor pain, with few adverse effects. These interventions relieved pain and improved satisfaction with pain and childbirth experience when compared with placebo or standard care. Relaxation was associated with fewer assisted vaginal births (Jones et al, 2012).*
- Offer the client in labor a clear liquid diet and water if allowed. **EB:** *There is insufficient evidence to make conclusions about the relationship between fasting times for clear liquids and the risk for emesis, reflux, or pulmonary aspiration during labor. Although there is some disagreement, the majority of experts agree that oral intake of clear liquids during labor does not lead to increased maternal complications (ACOG, 2013).*

Multicultural Prenatal

- Assess the client's beliefs and concerns about prenatal care. Provide culturally appropriate prenatal care for clients. **EBN:** *Most Samoan women attended their first antenatal appointment in their first trimester of pregnancy. Fewer attended antenatal care later in pregnancy (fifteenth week or after). Samoan women*

viewed pregnancy as wellness. Most participants did not relate to the content of mainstream antenatal classes because they were not culturally appropriate (Tanuvasa et al, 2013; Torres et al, 2012).

- ▲ Refer the client to a centering pregnancy group (8 to 10 women of similar gestational age receive group prenatal care after initial obstetrical visit) or group prenatal care. **EB:** Group prenatal care appears to have created a benefit to the women, not just with their birth experiences, but also with the psychological and social aspects of this life change (Risisky et al, 2013).

Intrapartal

- Assess client's beliefs and concerns about labor. Consider the client's culture when assisting in labor and delivery. **EBN:** A culturally appropriate OB/GYN service has input from the community, provides options, and respects choices (Simmonds et al, 2012). According to van Dijk et al (2013), most clients of these services desired the option of culturally appropriate care but typically did not receive it.

Postpartal

- Assess client's beliefs and concerns about the postpartum period. Provide culturally appropriate health and nutrition information and guidance on contemporary postpartum practices and take away common misconceptions about traditional dietary and health behaviors (e.g., fruit and vegetables should be restricted because of cold nature). Encourage a balanced diet and discourage unhealthy hygiene taboos. **EB:** Many cultures practice food taboos surrounding pregnancy with consequent depletion of vital nutrients, which can be detrimental to both the mother and fetus (Oni & Tukur, 2012). **EBN:** In some cultures, women refuse to bathe and wash their hair after childbirth and during the postpartum period. The influence of beliefs and taboos offers health risks for the postpartum woman and newborn. In contrast, beliefs and taboos that do not offer health risks should not be countered because they contribute to the well-being of postpartum women (Trettene & Mancini, 2012).

Home Care

Prenatal

- ▲ Involve pregnant drug users in drug treatment programs that include coordinated interventions in several areas: drug use, infectious diseases, mental health, personal and social welfare, and gynecological/obstetric care. **EBN:** The drug addict is obsessed by the drug of choice because of a change in the pathophysiology of the brain. Treating addiction as a chronic disease instead of a moral weakness will be more supportive to women who abuse drugs. It is important to involve a pregnant woman in a treatment program like a methadone clinic to help to stabilize the maternal-fetal dyad. Methadone prevents withdrawal symptoms and eliminates drug craving. Methadone blocks the euphoric effects of illegal self-administered narcotics. It also supports stable maternal opioid levels to protect the fetus from repeated occurrences of withdrawal and decreases the risk for STIs (sexually transmitted infections) by decreasing drug-seeking behaviors such as prostitution. When a woman makes the decision to enroll in a methadone treatment program, she is taking a significant step toward recovery (Maguire, 2014).

Postpartal

- Provide video conferencing to support new parents. **EBN:** Parents viewed videoconferencing as a possible chance to obtain extra support after returning home with their newborns (Lindberg, 2013).
- Consider reflexology for postpartum women to improve sleep quality. **EBN:** A systematic review and meta-analysis indicates that foot reflexology is a useful nursing intervention to relieve fatigue and to promote sleep (Lee et al, 2011).

Client/Family Teaching and Discharge Planning

Prenatal

- Provide dietary and lifestyle counseling as part of prenatal care to pregnant women. **EB:** A healthy pre-pregnancy weight, appropriate weight gain, physical activity during pregnancy, intake of a wide variety of foods, appropriate vitamin and mineral supplementation, avoidance of alcohol and other harmful substances, regular prenatal visits, and safe food handling are all components leading to a healthy pregnancy outcome. Pregnancy is a crucial period and maternal nutrition and lifestyle choices are major influences on mother and infant/child health. Healthy lifestyle changes are the key to the health of the next generation (Procter & Campbell, 2014).

- Provide the following information in parenting classes via DVD and Internet: support mechanisms, information and antenatal education, breastfeeding, practical baby care, and relationship changes. Include fathers in the parenting classes. **EB**: *Most fathers, expectant and experienced, felt there were not enough resources to support their education, spaces to support their involvement, or recognition of their experiences and feelings about pregnancy, labor, birth, and fathering. As the findings from the St. George and Fletcher (2011) study indicate, receiving encouragement and education that supports involved fathers is welcomed by many men. Although fathers' contribution to their children's well-being varies across cultures and roles, the effect of a father's positive involvement reaches far into the future of the child's social, emotional, and cognitive well-being.*
- Provide group prenatal care to families in the military. **EB**: *A 3-year randomized clinical trial was conducted to examine differences in perinatal health behaviors, perinatal and infant health outcomes, and family health outcomes for women receiving group prenatal care (GPC) when compared with those receiving individual prenatal care. Women in GPC were almost 6 times more likely to receive adequate prenatal care than women in individual prenatal care and were considerably more satisfied with their care (Kennedy et al, 2011).*

Postpartal

- Encourage physical activity in postpartum women, after being cleared by health care provider; provide telephone counseling, teach postpartum women that exercise may reduce anxiety and depression, encourage to download phone apps that help track exercise like Fitbit or Pedometer Master. **EBN**: *Exercise during the postpartum period is important for healthy weight loss and decreasing anxiety (Lewis et al, 2011).* **EB**: *Research on anxiety, depression, and exercise shows that the psychological and physical benefits of exercise can help reduce anxiety and improve mood (Mayo Clinic Staff, 2014).*
- ▲ Provide breastfeeding mothers contact information for a lactation consultant, phone numbers and website information for La Leche League (<http://www.lalecheleague.org>), and local breastfeeding support groups. **EB**: *Problems with breastfeeding are encountered in up to 80% of mother–infant dyads. In Western societies, the difficulties decrease the breastfeeding rate within the first months considerably. Dealing with the problems of breastfeeding efficiently requires a profound understanding of its physiology, as well as of its psychological, cultural, and social factors (Bergmann et al, 2014).*
- Teach mothers of young children principles of a healthy lifestyle: Substitute foods high in saturated fat with foods moderate in polyunsaturated fatty acids (PUFAs) such as avocados, tuna, walnuts, and olive oil. Include lean protein, fruits and vegetables, and complex carbohydrates. It is also important to increase physical activity. **EB**: *Parents are the most important influence on their child. Parents can do many things to help their children develop healthy eating habits for life. Offering a variety of foods helps children get the nutrients they need from every food group. They will also be more likely to try new foods and to like more foods (USDA, 2011). It is not recommended to feed children a low-fat diet but to make sure fats are good fats (PUFAs).* **EBN**: *Omega 3 PUFAs are required for very early brain development, and that need continues throughout life. These essential fatty acids are crucial in cell functioning. Humans are not able to synthesize omega 3 PUFAs; therefore, they must be included in the daily diet (Helvig & Decker, 2014).*

Risk for ineffective Childbearing process Jane M. Kendall, RN, BS, CHT

NANDA-I

Definition

Vulnerable to not matching environmental context, norms and expectations of pregnancy, childbirth process, and the care of the newborn

Risk Factors

Domestic violence; inconsistent prenatal health visits; insufficient cognitive readiness for parenting; insufficient knowledge of childbearing process; inadequate maternal nutrition; insufficient parental role model; insufficient prenatal care; insufficient support system; low maternal confidence; maternal powerlessness; maternal psychological distress; substance abuse; unplanned pregnancy; unrealistic birth plan; unwanted pregnancy

NOC, NIC, Client Outcomes, Nursing Interventions, Client/Family Teaching, Rationales, and References

Refer to care plan for Ineffective **Childbearing** process.

Impaired Comfort *Katharine Kolcaba, PhD, RN*

C

NANDA-I

Definition

Perceived lack of ease, relief, and transcendence in physical, psychospiritual, environmental, cultural and/or social dimensions

Defining Characteristics

Alteration in sleep pattern; anxiety; crying; discontent with situation; distressing symptoms; fear feeling cold; feeling hot; feeling of discomfort; feeling of hunger; inability to relax; irritability; itching; moaning; restlessness; sighing; uneasy in situation

Related Factors (r/t)

Illness-related symptoms; insufficient environmental control; insufficient privacy; insufficient resources (e.g., financial, social, knowledge); insufficient situational control; noxious environmental stimuli; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Client Satisfaction; Symptom Control; Comfort Status; Coping; Hope; Pain and/or Anxiety Management; Personal Well-Being; Spiritual Health

Example NOC Outcomes with Indicators

Comfort Status as evidenced by the following indicators: Physical and psychological well-being/Symptom control/Enhanced comfort. (Rate the outcome and indicators of **Comfort Status**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Provide evidence for improved comfort compared to baseline
- Identify strategies, with or without significant others, to improve and/or maintain acceptable comfort level
- Perform appropriate interventions, with or without significant others, as needed to improve and/or maintain acceptable comfort level
- Evaluate the effectiveness of strategies to maintain/and or reach an acceptable comfort level
- Maintain an acceptable level of comfort when possible

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Calming Techniques; Massage; Healing Touch; Still Point Induction; Heat/Cold Application; Hope Inspiration; Humor; Meditation Facilitation; Music Therapy; Pain Management; Presence; Progressive Muscle Relaxation; Spiritual Growth Facilitation; Distraction

Example NIC Activities—Hope Inspiration

Assist the client/significant others to identify areas of hope in life; Help expand spiritual self; Involve the client actively in own care

Nursing Interventions and Rationales

- Assess client's understanding of ranking his or her comfort level. **CEB:** *Performing accurate comfort measurements is essential for providing evidence about which strategies and interventions are effective (Kolcaba, 2003).*
- Ask about client's current level of comfort. This is the first step in helping clients achieve improved comfort. **CEB:** *It is important for nurses to address detractors from comfort (Kolcaba, 2003). Sources of assessment data to determine level of comfort can be subjective, objective, primary, or secondary (Kolcaba, 2014).*
- Comfort is a holistic state under which pain management is included. **CEB:** *Management of discomforts, however, can be better managed, and with fewer analgesics, by also addressing other comfort needs such as anxiety, insufficient information, social isolation, and financial difficulties (Kolcaba, 2003).* **CEB:** *One randomized study (N = 53) found that female breast cancer clients undergoing radiation therapy rated their overall comfort as being greater than the sum of the hypothesized components of comfort, which provided evidence for the theory of the holistic nature of comfort (Kolcaba, 2014).*
- Assist clients to understand how to rate their current state of holistic comfort, using the institution's preferred method of documentation. **CEB:** *Documentation of comfort pre-nursing and post-nursing interactions is essential to demonstrate efficacy of nursing activities (Kolcaba et al, 2014).*
- Enhance feelings of trust between the client and the health care provider. To attain the highest comfort level, clients must be able to trust their nurse. **CEB:** *This randomized design (N = 31) demonstrated the importance of promoting open relationships with clients, which helps to acknowledge their individuality. Knowing the client/significant others is essential in the provision of optimum palliative and terminal care (Kolcaba, 2014).*
- Manipulate the environment as necessary to improve comfort. **CEB:** *Addressing clients' environmental preferences or needs enhances holistic comfort (Kolcaba, 2003).* **CEB:** *In two experimental studies, the protocol included that all clients be asked about preferences for light, furnishings, body position, television settings, and so on (Dowd et al, 2007).*
- Encourage early mobilization and provide routine position changes. Range of motion and weight bearing decrease physical discomforts and disability associated with bed rest. **CEB:** *Before hand massage, positions of comfort were assured to maximize the effect of the intervention (Kolcaba et al in Kolcaba, 2000).*
- Provide simple massage. Massage has many therapeutic effects, including improved relaxation, circulation, and well-being. **EBN:** *Several quantitative studies support the efficacy of simple massage for enhancing holistic comfort (Townsend et al, 2014; Kolcaba et al in Kolcaba, 2000).*
- Provide healing touch, which is well-suited for clients who cannot tolerate more stimulating interventions. **CEB:** *Inform the client of options for control of discomfort such as meditation and guided imagery, and provide these interventions if appropriate (Dowd et al, 2007).*
- Use empathy as a response to a client's negative emotions. **EBN:** *An evaluation interaction analysis found that an accurate empathic response to a client's expressions of negative emotions can contribute to comfort (Eide et al, 2011).*
- Encourage clients to use relaxation techniques to reduce pain, anxiety, depression, and fatigue. **EBN:** *In a quantitative study with 22 participants, the effects of traditional massage and cranial still point induction were statistically significant in improving comfort and decreasing chronic pain (Townsend et al, 2014).*

Geriatric

- Use hand massage for older adults. Most older adults respond well to touch and the health care provider's presence. Lines of communication open naturally during hand massage. **CEB:** *In an experiment (N = 60), the effects of hand massage on comfort of nursing home residents was found to be significant immediately after the massage compared to residents who did not receive hand massage (Kolcaba et al in Kolcaba, 2014).*
- Discomfort from cold can be treated with warmed blankets. There are physiological dangers associated with hypothermia. **EBN:** *A study (N = 126) found significantly increased comfort and decreased anxiety in clients who used self-controlled warming gowns (Wagner et al, 2006, in Kolcaba, 2014).*
- Use complementary therapies such as doll therapy in clients with dementia to increase comfort and reduce stress. **EBN:** *In a review of the literature, doll therapy reduced panic, anxiety, and aggression while improving the dining experience and social interaction (Mitchell & O'Donnell, 2013).*
- Address any unmet physical, psychological, emotional, spiritual, and environmental needs when attempting to mediate the behavior of an older client with dementia. **EBN:** *A case study demonstrated that all*

possible causes for demented older clients' behavior must be considered to maximize comfort (Gallagher & Long, 2011).

- Provide simple massage. **CEB**: Simple massage addresses four contexts of holistic comfort (Kolcaba, 2003). **CEB**: A prospective study (N = 52) found that providing massage to nursing home residents with dementia was effective in controlling agitation (Holliday-Welsh et al, 2009).

Multicultural

- Identify and clarify cultural language used to describe pain and other discomforts. Expressions of pain and discomfort vary across cultures. **CEB**: Clients may interchange words meaning discomfort and pain, may not admit to having pain, may refer to minor discomforts as pain, or may not discuss nonpainful discomforts at all (Kolcaba, 2003).
- Assess skin for ashy or yellow-brown appearance. **CEB**: Black skin appears ashy and brown skin appears yellow-brown when clients have pallor sometimes associated with discomfort (Peters, 2007).
- Use soap sparingly if the skin is dry. Black skin tends to be dry, and soap exacerbates this condition.
- Encourage and allow clients to practice their own cultural beliefs and recognize the impact that different cultures have on a client's belief about health care, comforting measures, and decision-making. *Hindus believe in reincarnation, which gives them comfort during the dying process. Hindus also believe that physical suffering can lead to spiritual growth (Thrane, 2010).*
- Assess for cultural and religious beliefs when providing care. **EB**: In a hermeneutic phenomenological study in six medical-surgical wards in Iran (N = 22), it was found that family members play an important role in the comfort of the client. It was also found that caregivers should allow clients to follow religious and traditional principles to facilitate comfort despite physical constraints (Yousefi et al, 2009).

Client/Family Teaching and Discharge Planning

- Teach techniques to use when the client is uncomfortable, including relaxation techniques, guided imagery, hand massage, and music therapy. **CEB**: Interventions such as progressive muscle relaxation training, guided imagery, and music therapy can effectively decrease the perception of uncomfortable sensations, including pain (Kolcaba, 2003). **CEB**: Families want to learn how to provide comfort measures to their loved ones who are uncomfortable (Kolcaba et al, 2004, in Kolcaba, 2014).
- At end of life, the dying client is comforted by having a companion. **EBN**: A grounded theory study demonstrated the importance of teaching the family of a dying client how to accompany the client on his or her final journey, sharing stories, thoughts, doubts, feelings, and emotions (Martins & Basto, 2011).
- Instruct the client and family about prescribed medications and complementary therapies that improve comfort (Kolcaba, 2003).
- Teach the client to follow up with the health care provider if discomfort persists. There are many avenues for enhancing comfort (Kolcaba, 2003).
- Encourage clients to use the Internet as a means of providing education to complement medical care for those who may be homebound or unable to attend face-to-face education. **CEB**: In a randomized trial with intervention (N = 41), it was found that the Internet was an effective mode for delivering self-care education to older clients with chronic pain (Berman et al, 2009).

Mental Health

- Encourage clients to use guided imagery techniques. Guided imagery helps distract clients from stressful situations and facilitates relaxation. **CEB**: A quasi-experimental study (N = 60) found that clients who listened to a guided imagery compact disk once a day for 10 days had improved comfort and decreased depression, anxiety, and stress over time (Apustolo & Kolcaba, 2009, in Kolcaba, 2014).
- Provide psychospiritual support and a comforting environment to enhance comfort during emotional crises. **EBN**: A case study demonstrates the importance of reducing stimuli in the environment of clients with dementia (Gallagher & Long, 2011). **CEB**: In a cross-sectional descriptive study (N = 98), it was found that cancer clients had lower comfort levels relating to psychospiritual and environmental comfort than to physical and sociocultural comfort. Improvements in psychospiritual and environmental support will enhance overall comfort (Kim & Kwon, 2007).
- When nurses attend to the comfort of perioperative clients, the clients' sense of hope for a full recovery increases. **EBN**: In a quantitative study with 191 participants, direct and significant relationships were observed between comfort and hope (Seyedfatemi et al, 2014).

- Providing music and verbal relaxation therapy enhances holistic comfort by reducing anxiety. **EBN**: A literature review found that music and verbal relaxation therapy provided reduced chemotherapy-induced anxiety (Lin et al, 2011).
- Caregivers should not hesitate to use humor when caring for their clients. **CEB**: Analysis of two studies found that humor can be comforting and can contribute to a positive experience for both client and caregiver (Kinsman-Dean & Major, 2008).

Readiness for enhanced Comfort *Lina Daou Boudiab, MSN, RN*

NANDA-I

Definition

A pattern of ease, relief, and transcendence in physical, psychospiritual, environmental, and/or social dimensions that is sufficient for well-being and can be strengthened

Defining Characteristics

Expresses desire to enhance comfort; expresses desire to enhance feelings of contentment; expresses desire to enhance relaxation; expresses desire to enhance resolution of complaints

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Client Satisfaction: Caring; Symptom Control; Comfort Status; Coping; Hope; Motivation; Pain Control; Participation in Health Care Decisions; Spiritual Health

Example NOC Outcomes with Indicators

Comfort Status as evidenced by the following indicators: Physical well-being/Symptom control/Psychological well-being. (Rate the outcome and indicators of **Comfort Level**: 1 = not at all satisfied, 2 = somewhat satisfied, 3 = moderately satisfied, 4 = very satisfied, 5 = completely satisfied [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Assess current level of comfort as acceptable
- Express the need to achieve an enhanced level of comfort
- Identify strategies to enhance comfort
- Perform appropriate interventions as needed for increased comfort
- Evaluate the effectiveness of interventions at regular intervals
- Maintain an enhanced level of comfort when possible

NIC

Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Calming Technique; Cutaneous Stimulation; Environmental Management; Comfort; Heat/Cold Application; Hope Inspiration; Humor; Meditation Facilitation; Music Therapy; Pain Management; Presence; Simple Guided Imagery; Simple Massage; Simple Relaxation Therapy; Spiritual Growth Facilitation; Therapeutic Play; Therapeutic Touch; Touch; Distraction

Example NIC Activities—Spiritual Growth Facilitation

Assist the client with identifying barriers and attitudes that hinder growth or self-discovery; Assist the client to explore beliefs as related to healing of the body, mind, and spirit; Model healthy relating and reasoning skills

Nursing Interventions and Rationales

- Assess clients' comfort needs and current level of comfort in various contexts, as outlined in [Kolcaba's \(2003\)](#) Comfort theory and practice: physical, psychospiritual, sociocultural, and environmental. **CEB:** *Assessing comfort needs helps develop holistic, client-centered comfort interventions, while establishing a baseline helps evaluate their effectiveness by comparing comfort levels after each intervention to the previous baseline (Kolcaba, 2003).*
- Educate clients about the various contexts of comfort and help them understand that enhanced comfort is a desirable, positive, and achievable goal. **CEB:** *Human beings strive to have their basic comfort needs met, with comfort being more than just the absence of pain (Kolcaba, 2003). Having clients view comfort more holistically may be especially helpful when total relief and ease of symptoms may not be achievable, and the goal of health care becomes helping clients transcend their comfort needs (Kolcaba, 2003).*
- Enhance feelings of trust between the client and the health care provider in order to maintain an effective and therapeutic relationship. **CEB:** *To attain the highest comfort level, a client must be able to trust the nurse (Hupcey et al, 2000).* **EBN:** *Trust is an essential element in the nurse-client relationship that is fostered through caring attitudes, availability, respect, empathy, sensitivity to client needs, competence, and good communication (Dinç & Gastmans, 2013).*
- Maintain an open and effective communication with clients and keep them informed about their health, their plan of care, and their environment. **EBN:** *Evidence suggests that sharing of information genuinely and empathetically with adult oncology clients and encouraging them to ask questions strengthen the nurse-client relationship and empower clients to reach out to nurses for emotional support (Joanna Briggs Institute, 2011), and it enhances their psychospiritual comfort. EBN:* *Communicating to hospitalized cardiothoracic clients the source of sounds heard or expected to be heard around the unit, such as alarms, staff conversations, and rolling carts alleviated their anxiety and enhanced relaxation (Mackrill et al, 2013), hence promoting their environmental comfort.*
- Implement comfort rounds that regularly assess for clients' comfort needs. **EBN:** *Regular 1-hour or 2-hour rounds that address pain, positioning, personal needs, and environment were found to increase client satisfaction, decrease call light usage, and promote safety by decreasing fall rates (Ciccu-Moore et al, 2014; Chu, 2014).*
- Collaborate with other health care professionals, such as health care providers, pharmacists, social workers, chaplains, occupational and physical therapists, dietitians, among others, in planning interventions that address comfort needs in various contexts: physical, psychospiritual, sociocultural, and environmental.

- Educate clients about and encourage the use of various integrative therapies and modalities to provide options that enhance comfort, beyond the traditional plan of care. Institute of Medicine (IOM) AND PAIN—Examples of such modalities are listed below:
 - Therapeutic massage and touch therapy. **EBN:** *Massage and touch therapy have been found to promote comfort in clients with dementia by decreasing anxiety and agitation (Battaglini, 2014). There is evidence to support recommending massage to clients with subacute and chronic back pain, mechanical neck pain, and labor pain, as well as to decrease anxiety and blood pressure and to improve quality of life in clients with HIV/AIDS (D'Arcy, 2014). Furthermore, case studies on using the M-technique (M standing for manual), a structured light stroking technique, seemed to decrease agitation and pain in palliative care clients and promote their and their families' comfort (Roberts & Campbell, 2011).*
 - Guided imagery. **EBN:** *Guided imagery was also effective in improving chronic tension headaches and body pain, as well as promoting overall mental health and energy level (Read, 2013).*
 - Mindfulness and mindfulness-based interventions such as mindfulness-based stress reduction (MBSR), mantra repetition (silent repetition of a sacred word), mindfulness meditation, and mindful breathing and walking, among others. Since the original research by Kabat-Zinn, founder of MBSR, and colleagues established the effectiveness of mindfulness in helping clients manage chronic pain and improving body image and other symptoms, including anxiety and depression (Kabat-Zinn, Lipworth, & Burney, 1985), mindfulness-based interventions have been used to promote physical and psychospiritual comfort. **EB:** *A study of MBSR in cancer clients concluded that mindfulness promotes a sense of calmness, inner peace, and personal and spiritual growth (Labellea et al, 2014), while a small randomized controlled trial found MBSR to be effective in treating chronic insomnia (Gross et al, 2011). **EBN:** *Mantra repetition is found to decrease posttraumatic stress disorder (PTSD) symptoms and increase sense of well-being in veterans, when added to their traditional PTSD treatment plan (Bormann et al, 2014).**
 - Energy therapy or biofield therapy such as healing touch, therapeutic touch, and reiki. Biofield therapy seems to be promising in promoting comfort and relaxation, but more sound and systematic research is needed to build a strong body of evidence. **EBN/EB:** *Healing touch has been found effective as an adjunct therapy in relieving anxiety and depression (Harlow, 2013), as well as symptoms of PTSD when coupled with guided imagery in returning active military exposed to combat (Jain et al, 2012). **EBN:** *Biofield therapy strengthens the immune system, decreases stress, and allows the body to heal. It can be integrated in the care of cancer clients in various settings for relaxation and symptom management, as well as in those with musculoskeletal and joint pain, agitation and dementia, and other chronic conditions (Gonella et al, 2014).**
 - Acupuncture and auricular acupuncture. **EB:** *There is strong evidence that acupuncture is effective in alleviating nausea and vomiting, headache, and back and neck pain (Rathnayake, 2014). A study of acupuncture in women in later stages of pregnancy concluded that the modality decreased low back and pelvic pain and increased function (Pennick & Liddle, 2013), while another found that it improved pain and stiffness in clients with fibromyalgia (Deare et al, 2013). **EB:** *The National Acupuncture Detox Association five-point ear acupuncture protocol has been effective in reducing cravings and withdrawal symptoms associated with substance abuse. Growing research suggests it may be promising as well for pain relief, promotion of comfort and relaxation, and decrease in PTSD symptoms in veterans.**
 - Aromatherapy
 - Music
 - Other mind-body therapies. **EB:** *The most common therapies used were meditation, imagery, and yoga. Research demonstrating the connection between the mind and body has therefore increased interest in the potential use of these therapies (Wolsko et al, 2004). **EBN:** *Meditation has been shown to reduce anxiety, relieve pain, decrease depression, enhance mood and self-esteem, decrease stress, and generally improve clinical symptoms (Bonadonna, 2003). A review of clinical trials for meditation and massage used in end of life found that there was a significant relationship between meditation and pain reduction in the two studies that assessed pain (Lafferty et al, 2006).**
- Foster and instill hope in clients whenever possible. **EBN:** *A study of clients undergoing surgery in the preanesthesia stage found a strong correlation between hope and comfort (Seyedfatemi et al, 2014).* See the care plan for **Hopelessness**.
- Provide opportunities for and enhance spiritual care activities. The need for comfort and reassurance may be perceived as spiritual needs. To meet these needs, nurses engaged in interaction when they comforted and assured clients. Participants also identified absolution as a spiritual need, and there is evidence

that forgiveness may bring one feelings of joy, peace, and elation, and a sense of renewed self-worth (Narayananomy et al, 2004). Individuals who practiced spiritual meditation were found to have a greater increase in pain tolerance (Wachholtz & Pargament, 2008).

- ▲ Enhance social support and family involvement. **EBN:** *Methods to help terminally ill clients and their families transition from cure to comfort care included spending an increased amount of time with one's family, appointing one close friend to act as a contact person for other friends, and establishing an email listerv for updates of a client's status and care (Duggleby & Berry, 2005).* Promote participation in creative arts and activity programs. **CEBN:** *A creative arts program for caregivers of cancer clients was shown to decrease anxiety, and positive emotions were expressed (Walsh et al, 2004).* *The use of an individualized music protocol program by older women was shown to promote and maintain sleep (Johnson, 2003).*
- ▲ Encourage clients to use health information technology (HIT) as needed. Client services can now include management of medications, symptoms, emotional support, health education, and health information (Moody, 2005). **EBN:** *In this study, clients experienced significantly lower dimensions of pain and discomfort with nursing intervention via telephone (Franzen et al, 2009).*
- Evaluate the effectiveness of all interventions at regular intervals and adjust therapies as necessary. It is important for nurses to determine comfort and pain management goals because comfort goals will change with circumstances. Ask questions and ask them frequently, such as, "How is your comfort?" Establish guidelines for frequency of assessment and document responses, noting whether goals are being met (Kolcaba, 2003). **EB:** *A comprehensive palliative care project was conducted at 11 sites. The interdisciplinary review process built trust, endorsed creativity, and ultimately resulted in better meeting the needs of clients, families, and the community (London et al, 2005).* *Evaluation must be planned for, ongoing, and systematic. Evaluation demonstrates caring and responsibility on the part of the nurse (Wilkinson & VanLeuven, 2007).*

Geriatric

- Refer to above interventions for geriatric interventions.

Pediatric

- Assess and evaluate child's level of comfort at frequent intervals. Comfort needs should be individually assessed and planned for. With assessment of pain in children, it is best to use input from the parents or a primary care provider. Use only accepted scales for standardized pain assessment (Remke & Chrastek, 2007).
- Skin-to-skin contact (SSC) and selection of the most effective method improves the comfort of newborns during routine blood draws. **EB:** *Premature infants who received skin-to-skin contact demonstrated a decrease in pain reaction during heel lancing (Castral et al, 2008).*
- Adjust the environment as needed to enhance comfort. Environmental comfort measures include maintaining orderliness; quiet; minimizing furniture; special attention to temperature, light and sound, color, and landscape (Kolcaba & DeMarco, 2005).
- Encourage parental presence whenever possible. The same basic principles for managing pain in adults and children apply to neonates. In addition to other comfort measures, parental presence should be encouraged whenever possible (Pasero, 2004). **EBN:** *This study reported the effects of co-residence and caregiving on the parents of children dying with AIDS. Although parents who did more caregiving did experience anxiety, insomnia, and fatigue, the caregiving experiences for many parents gave them an opportunity to fulfill their perceived duty as parents before their child died. This in turn resulted in better physical and emotional health outcomes (Kespichayawattana & VanLandingham, 2003).*
- Promote use of alternative comforting strategies such as positioning, presence, massage, spiritual care, music therapy, art therapy, and story-telling to enhance comfort when needed. In addition to oral sucrose, other comfort measures should be used to alleviate pain such as swaddling, skin-to-skin contact with mother, nursing, rocking, and holding (Pasero, 2004). **EBN:** *Building on the belief that parents are the primary care providers and health care resource for families, the blended infant massage-parenting program is effective for both mother and infant (Porter & Porter, 2004).* **EBN:** *In this study, focus groups were conducted with Moroccan pediatric oncology nurses and health care providers to better understand how pain management was achieved in children with cancer. When no medication was available to relieve pain, other techniques were used to comfort clients. These included using cold therapy, being present, holding a child's hand, using distraction techniques, playing with the child, story-telling, and encouraging parental engagement activities (McCarthy et al, 2004).* **EB:** *In a study that examined the effects of music on pain in a pediatric burn unit during nursing procedures, the use of music during procedures reduced pain*

(Whitehead-Pleaux *et al*, 2007). **EBN**: A talk-and-touch intervention by the mothers of infants in the preanesthesia care unit found that 62% of the mothers thought that the intervention made a difference in the pain the infant experienced and 73% thought that talk and touch decreased their infant's distress (Rennick *et al*, 2011).

- Support the child's spirituality. **CEB**: Children are born with an intrinsic spiritual essence that can be enhanced. Spirituality promotes a sense of hope, comfort, and strength and creates a sense of being loved and nurtured by a higher power (Elkins & Cavendish, 2004).

Multicultural

- Identify cultural beliefs, values, lifestyles, practices, and problem-solving strategies when assessing clients. Cultural sensitivity must always be a component of pain assessment. The nurse must remember that pain expression will vary among clients and that variation must also be acknowledged within cultures (Andrews & Boyle, 2003). **EBN**: In a qualitative study that identified issues in pain management, cultural beliefs were cited as impediments or barriers to pain management; for example, some Moroccan health care providers thought illness-related pain was inevitable, that suffering was normal, and that it had to be endured, especially by boys (McCarthy *et al*, 2004). **EBN**: In a qualitative study, Muslim clients, particularly Shiites, expressed feeling more comfortable when they were allowed to practice their religious beliefs (Yousefi *et al*, 2009).
- Enhance cultural knowledge by actively seeking out information regarding different cultural and ethnic groups. Cultural knowledge is the process of actively seeking information about different cultural and ethnic groups such as their world views, health conditions, health practices, use of home remedies or self-medication, barriers to health care, and risk-taking or health-seeking behaviors (Institute of Medicine, 2002).
- ▲ Recognize the impact of culture on communication styles and techniques. Communication and culture are closely intertwined, and communication is the way culture is transmitted and preserved. It influences how feelings are expressed, decisions are made, and what verbal and nonverbal expressions are acceptable. By the age of 5, cultural patterns of communication can be identified in children (Giger & Davidhizar, 2004).
- Provide culturally competent care to clients from different cultural groups. Cultural competency requires health care providers act appropriately in the context of daily interactions with people who are different from themselves. Health care providers need to honor and respect the beliefs, interpersonal styles, attitudes, and behaviors of others. This level of cultural awareness requires health care providers to refrain from forming stereotypes and judgments based on one's own cultural framework (Institute of Medicine, 2002). **EBN**: The findings from a review of two studies of Japanese and American women suggest that although there were common ethical concerns between the two cultures, the cultural context of the underlying values may create very different meanings and result in different nursing practices (Wros *et al*, 2004).

Home Care

- The nursing interventions described for Readiness for enhanced **Comfort** may be used with clients in the home care setting. When needed, adaptations can be made to meet the needs of specific clients, families, and communities.
- ▲ Make appropriate referrals to other organizations or health care providers as needed to enhance comfort. Referrals should have merit, be practical, timely, individualized, coordinated, and mutually agreed upon by all involved (Hunt, 2005).
- ▲ Promote an interdisciplinary approach to home care. Members of the interdisciplinary team who provide specialized care to enhance comfort can include the health care provide, physical therapist, occupational therapist, nutritionist, music therapist, and social worker, among others (Stanhope & Lancaster, 2006).
- Evaluate regularly if enhanced comfort is attainable in the home care setting. Home health agencies monitor client outcomes closely. Evaluation is an ongoing process and is essential for the provision of quality care (Stanhope & Lancaster, 2006).
- Use music therapy at home. **EBN**: The use of music 30 minutes before peak agitation in clients with dementia demonstrated that their mean pain levels after listening to music were significantly lower than before the music intervention (Park, 2010).

Client/Family Teaching and Discharge Planning

- Teach client how to regularly assess levels of comfort.
- Instruct client that a variety of interventions may be needed at any given time to enhance comfort.
- Help clients understand that enhanced comfort is an achievable goal.

- Teach techniques to enhance comfort as needed.
- ▲ When needed, empower clients to seek out other health professionals as members of the interdisciplinary team to assist with comforting measures and techniques.
- Encourage self-care activities and continued self-evaluation of achieved comfort levels to ensure enhanced comfort is maintained.

Readiness for enhanced Communication

Stacey M. Carroll, PhD, ANP-BC, and Suzanne White, MSN, RN, PHCNS-BC

NANDA-I

Definition

A pattern of exchanging information and ideas with others that can be strengthened

Defining Characteristics

Expresses desire to enhance communication

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Communication; Communication: Expressive, Receptive

Example NOC Outcome with Indicators

Communication as evidenced by the following indicators: Use of spoken language/Use of written language/Acknowledgment of messages received/Exchanges messages accurately with others. (Rate the outcome and indicators of **Communication**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, mildly compromised, 5 = not compromised [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Express willingness to enhance communication
- Demonstrate ability to speak or write a language
- Form words, phrases, and language
- Express thoughts and feelings
- Use and interpret nonverbal cues appropriately
- Express satisfaction with ability to share information and ideas with others

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening; Communication Enhancement: Hearing Deficit; Communication Enhancement: Speech Deficit

Example NIC Activities—Communication Enhancement: Hearing Deficit

Listen attentively; Allow patient adequate time to process communication and respond; Verify what was said or written using patient's response before continuing

Nursing Interventions and Rationales

- Establish a therapeutic nurse-client relationship: provide appropriate education for the client, demonstrate caring by being present to the client. **CEB:** *Clients who were nonvocal and ventilated appreciated nursing care that was delivered in an individualized, caring manner (Carroll, 2007).*
- Assess the client's readiness to communicate, using an individualized approach, and avoid making assumptions regarding the client's preferred communication method. **EBN:** *Using varied communication approaches improved communication efficiency and client engagement (Radtko et al, 2011).* **EB:** *Increased numbers of communication methods decreased fear and anger in those who were mechanically ventilated (Khalaila et al, 2011).*
- Assess the client's literacy level so information can be tailored accordingly. *The Rapid Estimate of Adult Literacy in Medicine—Short Form (REALM-SF) provides a quick valid assessment (AHRQ, 2014).*
- Use these practical guidelines to assist in communication: Listen attentively and provide a comfortable environment for communicating; slow down and listen to the client's story; use augmentative and alternative communication methods (e.g., lip reading, communication boards, writing, body language, and computer/electronic communication devices) as appropriate; repeat instructions if necessary; limit the amount of information given; have the client "teach back" to confirm understanding; avoid asking, "Do you understand?"; be respectful, caring, and sensitive. **EB:** *Multiple augmentative and alternative communication methods, applied with an individualized and creative approach, aid in facilitating communication (Radtko et al, 2011).*
- ▲ Use interdisciplinary collaboration to ensure continuity of enhanced communication. **EB:** *Effective interdisciplinary collaboration and follow-up was recommended when working with clients with significant communication impairments after having a stroke (Jones et al, 2013).*
- ▲ Refer couples in maladjusted relationships for psychosocial intervention and social support to strengthen communication; consider nurse specialists. **EB:** *Being part of a strong dyad may serve as a buffering factor regarding posttraumatic stress related to a cancer diagnosis (Brosseau et al, 2011).*
- Consider using music to enhance communication between a client who is dying and his or her family. **CEB:** *In clients with communication difficulties, music therapy resulted in improvement in communication (Leow et al, 2010).*
- Encourage clients with aphasia to sing. **EB:** *Participation in a community choir led by a neurologic music therapist resulted in qualitatively identified improvement/changes in communication among clients with aphasia (Tamplin et al, 2013).*
- See care plan for Impaired verbal **Communication**.

Pediatric

- All individuals involved in the care and everyday life of children with learning difficulties need to have a collaborative approach to communication. **EBN:** *Collaboration in tasks requires the formation of personal relationships based on mutual trust and respect (Callery & Milnes, 2012).*
- See care plan for Impaired verbal **Communication**.

Geriatric

- ▲ Assess for hearing and vision impairments, and make appropriate referrals for hearing aids. **EB:** *Healthy People 2020 recommends early identification of people with hearing and vision loss (Healthy People 2020, 2014).*

- Use touch if culturally acceptable when communicating with older clients and their families. **EBN**: *Touch has a calming effect on a client who may be frightened due to difficulty with communication (Grossbach et al, 2011).*
- Consider singing during caregiving of clients with dementia. **EB**: *When professional caregivers sang to clients with dementia during care, enhanced communication and cooperation resulted (Hammar et al, 2011).*
- See care plan for Impaired verbal **Communication**.

Multicultural

- See care plan for Impaired verbal **Communication**.

Home Care

- The interventions described previously may be used in home care.
- See care plan for Impaired verbal **Communication**.

Client/Family Teaching and Discharge Planning

- See care plan for Impaired verbal **Communication**.

Impaired verbal Communication

Stacey M. Carroll, PhD, ANP-BC, and Suzanne White, MSN, RN, PHCNS-BC

NANDA-I

Definition

Decreased, delayed, or absent ability to receive, process, transmit, and/or use a system of symbols

Defining Characteristics

Absence of eye contact; difficulty comprehending communication; difficulty expressing thoughts verbally (e.g., aphasia, dysphasia, apraxia, dyslexia); difficulty forming sentences; difficulty forming words (e.g., aphonia, dyslalia, dysarthria); difficulty in selective attending; difficulty in use of body expressions; difficulty in use of facial expressions; difficulty maintaining communication; difficulty speaking; difficulty verbalizing; disoriented to person; disoriented to place; disoriented to time; does not speak; dyspnea; inability to speak; inability to speak language of caregiver; inability to use body expressions; inability to use facial expressions;

inappropriate verbalization; partial visual deficit; refusal to speak; slurred speech stuttering; total visual deficit

Related Factors (r/t)

Absence of significant other; alteration in development; alteration if perception; alteration in self concept; central nervous system impairment; cultural incongruence; emotional disturbance; environmental barrier; insufficient information; insufficient stimuli; low self-esteem; oropharyngeal defect; physical barrier (e.g., tracheostomy, intubation); physiological condition (e.g., brain tumor, decreased circulation to brain, weakened musculoskeletal system); psychotic disorder; treatment regimen; vulnerability

C

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Communication; Communication: Expressive, Receptive

Example NOC Outcome with Indicators

Communication as evidenced by the following indicators: Use of spoken and written language/Acknowledgment of messages received/Exchanges messages accurately with others. (Rate the outcome and indicators of **Communication**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Use effective communication techniques
- Use alternative methods of communication effectively
- Demonstrate congruency of verbal and nonverbal behavior
- Demonstrate understanding even if not able to speak
- Express desire for social interactions

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening; Communication Enhancement: Hearing Deficit; Communication Enhancement: Speech Deficit

Example NIC Activities—Communication Enhancement: Hearing Deficit

Listen attentively; Allow client adequate time to process communication and respond; Verify what was said or written using client's response before continuing

Nursing Interventions and Rationales

- Use a comprehensive nursing assessment to determine the language spoken, cultural considerations, literacy level, cognitive level, and use of glasses and/or hearing aids. **EBN**: *Language barriers, low literacy, and lack of understanding are barriers to effective communication (Taylor et al, 2013).*
- Determine client's own perception of communication difficulties and potential solutions when possible. *In clients with aphasia, nurses should avoid making assumptions regarding communication (Borthwick, 2012).* **EB**: *The Communication Confidence Rating Scale for Aphasia (CCRSA) was found to be an effective tool for assessment of the self-report of communication confidence among clients with aphasia (Babbitt et al, 2011).*
- Involve a familiar person when attempting to communicate with a client who has difficulty with communication, if accepted by the client. **EB**: *A competent communication partner—family member or not—reduced stress in the client by facilitating effective communication (Laasko et al, 2011).*
- Listen carefully. Validate verbal and nonverbal expressions particularly when dealing with pain and use appropriate scales for pain when appropriate. **EB/EBN**: *The critical care pain observation tool and the*

behavioral pain scale are valid and reliable options for use in clients who are nonverbal (Aust, 2013; Flynn Makic, 2013).

- Use appropriate scales to assess communication and behavior in clients who are nonvocal and mechanically ventilated. **EBN:** *Although further testing is needed, preliminary research shows that the revised Communication Interaction Behavior Instrument scale has good face validity and shows good interrater reliability for use with older adults who are ventilated and nonvocal (Nilsen et al, 2014).*
- Use therapeutic communication techniques: speak in a well-modulated voice, use simple communication, maintain eye contact at the client's level, get the client's attention before speaking, and show concern for the client. **EBN:** *Effective communication entails involving clients, being sensitive to client needs, and ensuring client understanding (O'Hagan et al, 2014).*
- Avoid ignoring the client with verbal impairment; be engaged and provide meaningful responses to client concerns. Place call light or bell within reach of client who cannot verbally call for help. *Safety is at risk when communication barriers are present (Giammarino et al, 2012).* **EBN:** *Ignoring clients was found to be a negative communication strategy (O'Hagan et al, 2014).*
- Use touch as appropriate. *Touch has a calming effect on a client who may be frightened due to difficulty with communication (Grossbach et al, 2011).*
- Use presence: spend time with the client, allow time for responses, and make the call light readily available. *Client-centered care involves respect, communication, and comfort (Bechtold & Fredericks, 2014).*
- Explain all health care procedures. **CEBN:** *Clients who were nonvocal and ventilated were attuned to everything occurring around them, and they appreciated explanations from the nurse (Carroll, 2007).*
- Be persistent in deciphering what the client is saying, and do not pretend to understand when the message is unclear. *In clients with aphasia, nurses should allow the client extra time to communicate and should not interrupt the client (Borthwick, 2012).* **CEBN:** *Persons who were nonvocal and ventilated appreciated persistence on the nurses' part with respect to being understood, and found it bothersome when others pretended to understand them (Carroll, 2007).*
- Use an individualized and creative multidisciplinary approach to augmentative and alternative communication (AAC) assistance and other interventions. *Ensure the choice of AAC is driven by clients' communication needs rather than by the device (Light & McNaughton, 2013).* **EB:** *A combination of high-technology (with voice output) and low-technology options improved communication efficiency (Radtke et al, 2011).* **EB:** *AAC improved communication among those with intellectual disabilities (Hagan & Thompson, 2014).*
- Use consistent nursing staff for those with communication impairments. **CEBN:** *Consistent nursing care increased client-nurse communication and decreased client powerlessness (Carroll, 2007).*
- ▲ Consult communication specialists from various disciplines as appropriate. Speech language pathologists, audiologists, and interpreters provide comprehensive communication assistance for those with impaired communication. *Lip reading therapists (LRTs) are proficient lip readers who determine what a nonvocal client is mouthing and then verbalize the client's words verbatim to others, in order to facilitate communication (Carroll, 2003; Grossbach et al, 2011).* **EB:** *Lip reading interpreters can assist in meeting nonvocal clients' communication needs (Meltzer et al, 2012).* **EB:** *Interprofessional communication was found to be important for client safety (Brock et al, 2013).*
- ▲ When the client is having difficulty communicating, assess and refer for audiology consultation for hearing loss. Suspect hearing loss when:
 - Client frequently complains that people mumble, claims that others' speech is not clear, or client hears only parts of conversations.
 - Client often asks people to repeat what they said.
 - Client's friends or relatives state that client doesn't seem to hear very well, or plays the television or radio too loudly.
 - Client does not laugh at jokes due to missing too much of the story.
 - Client needs to ask others about the details of a meeting that the client attended.
 - Client cannot hear the doorbell or the telephone.
 - Client finds it easier to understand others when facing them, especially in a noisy environment.
- People with hearing loss do not hear sounds clearly. The loss may range from hearing speech sounds faintly or in a distorted way to profound deafness (American Academy of Audiology, 2011).
- When communicating with a client with a hearing loss:
 - Obtain client's attention before speaking and face toward his or her unaffected side or better ear while allowing client to see speaker's face at a reasonably close distance; use gestures as appropriate to aid

in communication. *Correct positioning increases the client's awareness of the interaction and enhances the client's ability to communicate (Alexander Graham Bell Association for the Deaf and Hard of Hearing, 2011; Thiart & Saxby, 2011).* **EB:** Gestures are helpful communication tools both for those with hearing loss and those with normal hearing who are faced with environmental noises or other factors impeding hearing (Obermeier et al, 2012).

- Provide sufficient light and do not stand in front of window. *Light illuminates the speaker's face, making expressions and lip movements clearer; standing in front of a window causes glare, which impedes the client's ability to clearly see the speaker (Alexander Graham Bell Association for the Deaf and Hard of Hearing, 2011; Thiart & Saxby, 2011).*
- Remove masks if safe to do so, or use see-through masks. Information on see-through masks: www.amphl.org.
- Reduce background noise whenever possible. *Noise reduction facilitates understanding (Cleveland Clinic, 2012).*
- Do not raise voice or over-enunciate. *This practice distorts the voice and lips, inhibiting effective lip-reading (Cleveland Clinic, 2012).*
- Avoid making assumptions about the communication choice of those with hearing loss or voice impairments. **CEBN:** *After seeking client input, communication rounds or communication care plans can be completed (Happ et al, 2010).*
- Encourage physical activity among those with hearing loss. **EB:** *Lower levels of physical activity were found among those with moderate or greater hearing loss (Chen et al, 2014).* **EB:** *Hearing loss in older adults is associated with frailty (Kamil et al, 2014).*

Pediatric

- Observe behavioral communication cues in infants. **EB:** *Reissland et al (2012) studied mothers and infants (N = 50) and found that preverbal infants express pain by crying and with facial and body behaviors, which have to be interpreted by the caregiver.*
- Identify and define at least two new forms of socially acceptable communication alternatives that may be used by children with significant disabilities. **EB:** *Pasco and Tohill (2011) conducted a study of nonverbal children with autism spectrum disorder (N = 23) and found that the Picture Exchange Communication System (PECS) may provide valuable predictive information regarding social communication skills.* **EB:** *Brady et al (2013) investigated a model of language development for nonverbal school-aged children (N = 93) and found the importance of enriching social communication input across home and school environments, as well as assessments of and interventions aimed at improving comprehension, play, visual discrimination, and communication complexity.*
- Teach children with severe disabilities functional communication skills. **EB:** *Allen and Marshall (2011) conducted a study involving parent-child interaction therapy (PCIT) (N = 16) for school-aged children with specific language impairment and found that PCIT offered a single block of therapy where the parents' communication and interaction skills are developed to provide the child with an appropriate language-rich environment.*
- ▲ Refer children with primary speech and language delay/disorder for speech and language therapy interventions. **EB:** *Pasco and Tohill (2011) conducted a study of nonverbal children with autism spectrum disorder (N = 23) and found the assessment of the developmental level of potential PECS users may provide valuable predictive information for speech-and-language therapists and other professionals in relation to the likely degree of progress and in setting realistic and achievable targets.*

Geriatric

- Carefully assess all clients for hearing difficulty using an audiometer. Healthy People 2020 encourages early identification of people with hearing loss (Healthy People 2020, 2014).
- Avoid use of "elderspeak." **CEB:** *Using elderspeak, a speech style similar to baby talk that fails to communicate appropriate respect, increases resistiveness to care in clients with dementia (Williams et al, 2009).*
- Initiate communication with the client with dementia, and give client time to respond. The responsibility to use a creative approach and take the time to listen and understand clients who have dementia lies with the clinician (Jootun & McGhee, 2011).
- Encourage the client to wear hearing aids, if appropriate. **EB:** *Hearing aid usage is low among older adults with hearing loss, despite the benefits of hearing aids (Gopinath et al, 2011).*

- Facilitate communication through reminiscing with memory boxes that contain objects, photographs, and writings that have meaning for the client. Reminiscence stimulates memories, thus improving communication (Swann, 2013). **CEB:** *Collage creation as a means of reminiscence facilitated the conveying of information by older adults with dementia who had difficulty communicating verbally (Stallings, 2010).*
- Continue to find means to communicate even with those who are completely nonverbal. **EB:** *Spontaneous reciprocal interaction promoted family harmony among nonvocal clients with severe dementia (Walmsley & McCormack, 2014).*

Multicultural

- Nurses should become more sensitive to the meaning of a culture's nonverbal communication modes, such as eye contact, facial expression, touching, and body language. **EBN:** *Kozłowska and Doboszynska (2012) conducted a study among nurses (N = 95) and found that among nonverbal means of communication in everyday practice, those who participated most frequently used touch, facial expression, and visual contact in a conscious way when delivering care.*
- Assess for the influence of cultural beliefs, norms, and values on the client's communication process. **EBN:** *In a 2011 study by El-Amouri and O'Neill that aimed to identify cross-cultural communication needs of hospitals, findings suggested that recognition of the importance of cross-cultural communication skills and intercultural literacy in nurse education were of significant importance in providing culturally competent care.*
- Assess personal space needs, acceptable communication styles, acceptable body language, interpretation of eye contact, perception of touch, and use of paraverbal modes when communicating with the client. **EB:** *A 2011 study by Hasnain et al (N = 27) found that the majority (93.8%) of responding clients reported that their health care provider did not understand their religious or cultural needs.*
- Assess for how language barriers contribute to health disparities among ethnic and racial minorities. **EBN:** *Taylor et al (2013) found that language barriers were the main obstacle in eliciting an accurate medical history, explaining and gaining pain scores, communicating reasons for client transport delays, arranging appointments by telephone, explaining medication and side effects, or diagnosing and communicating problems (N = 34).*
- Although touch is generally beneficial, there may be times when it may not be advisable due to cultural considerations. **CEB/EBN:** *Touch is largely culturally defined and conveys various meanings depending on the client's culture (Leininger & McFarland, 2002; Lewis et al, 2011).*
- Modify and tailor the communication approach in keeping with the client's particular culture. A 2011 study by Fakhri-Movahedi et al conducted among eight Iranian nurses and nine clients suggested that socio-cultural-economic issues between nurses and clients influence nurse-client communication.
- Use reminiscence therapy as a language intervention. **EB:** *Issues of culture, language, and aging are challenging. Less engaged residents and clients who are nonverbal, immobile, or who have other occupational performance issues may become engaged in occupations of reminiscence that are rich in personal meaning and relevance (Hodges & Schmidt, 2009).*
- The Office of Minority Health of the U.S. Department of Health and Human Services standards on culturally and linguistically appropriate services (CLAS) in health care should be used as needed. **EB:** *The National Standards for Culturally and Linguistically Appropriate Services in Health and Health Care (The National CLAS Standards) aim to improve health care quality and advance health equity by establishing a framework for organizations to serve the nation's increasingly diverse communities (CLAS, 2014).*

Home Care

The interventions described previously may be adapted for home care use.

Client/Family Teaching and Discharge Planning

- ▲ Refer the client to a speech-language pathologist (SLP) or audiologist. Audiological assessment quantifies and qualifies hearing in terms of the degree of hearing loss, the type of hearing loss, and the configuration of the hearing loss. Once a particular hearing loss has been identified, a treatment and management plan can be put into place by an SLP (Baumgartner et al, 2008).
- ▲ Teach the client and family techniques to increase communication, including the use of communication devices and tactile touch. Incorporate multidisciplinary recommendations. The nurse plays a critical role in individualized communication assessment as clients transition from hospital to home (Cerantola & Happ, 2012). **EB:** *Recommendations by SLPs were omitted from discharge summaries at a high rate, placing*

clients at risk for lack of continuity of care (Kind et al, 2011). **EB:** Clients who are mechanically ventilated at home have a long struggle to find effective communication methods (Laasko et al, 2011).

Acute Confusion *Mila W. Grady, MSN, RN*

NANDA-I

Definition

Abrupt onset of reversible disturbances of consciousness, attention, cognition, and perception that develop over a short period of time

Defining Characteristics

Agitation; alteration in cognitive functioning; alteration in level of consciousness; alteration in psychomotor functioning; hallucinations; inability to initiate goal-directed behavior; inability to initiate purposeful behavior; insufficient follow-through with goal directed behavior; insufficient following-through with purposeful behavior; misperception; restlessness

Related Factors (r/t)

Age >60 years; alteration in sleep-wake cycle; delirium; dementia; substance abuse, polypharmacy

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cognition; Distorted Thought Self-Control; Information Processing

Example NOC Outcome with Indicators

Cognition as evidenced by the following indicators: Communication clear for age/Comprehension of the meaning of situations/Attentiveness/Concentration/Cognitive orientation. (Rate the outcome and indicators of **Cognition**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate restoration of cognitive status to baseline
- Be oriented to time, place, and person
- Demonstrate appropriate motor behavior
- Maintain functional capacity

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Delirium Management; Delusion Management

- = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Example NIC Activities—Delirium Management

Inform client of time, place, and person as needed; Provide information slowly and in small doses with frequent rest periods

C

Nursing Interventions and Rationales

- Recognize that delirium is characterized by an acute onset, a fluctuating course, inattention, and disordered thinking.
- Identify the three distinct types of delirium: hyperactive (easy to recognize), hypoactive (commonly missed), and mixed (the most commonly occurring). (Downing et al, 2013).
- Hyperactive: delirium characterized by restlessness, agitation, irritability, hypervigilance, hallucinations, and delusions; client may be combative or may attempt to remove tubes, lines
 - Hypoactive: delirium characterized by decreased motor activity, decreased vocalization, detachment, apathy, lethargy, somnolence, reduced awareness of surroundings, and confusion
 - Mixed: delirium characterized by the client fluctuating between periods of hyperactivity and agitation and hypoactivity and sedation. **EBN:** *Delirium is underrecognized by both medical and nursing staff, particularly the hypoactive form (Cerejeira & Mukaetova-Ladinska, 2011).*
- Obtain an accurate history and perform a mental status examination that includes the following assessment:
 - History from a reliable source that documents an acute and fluctuating change in cognitive function, attention, and behavior from baseline
 - Cognition as evidenced by level of consciousness; orientation to time, person, and place; thought process (thinking may be disorganized, distorted, fragmented, slow, or accelerated with delirium; conversation may be irrelevant or rambling); and content (perceptual disturbances such as visual, auditory or tactile delusions or hallucinations)
 - Level of attention (may be decreased or may fluctuate with delirium; may be unable to focus, shift, or sustain attention; may be easily distracted or may be hypervigilant)
 - Behavior characteristics and level of psychomotor behavior (activity may be increased or decreased and may include restlessness, finger tapping, picking at bedclothes, changing position frequently, spastic movements or tremors, or decreased psychomotor activity such as sluggishness, staring into space, remaining in the same position for prolonged periods)
 - Level of consciousness (may be easily aroused, lethargic, drowsy, difficult to arouse, unarousable, hyperalert, easily startled, overly sensitive to stimuli)
 - Mood and affect (may be paranoid or fearful with delirium; may have rapid mood swings)
 - Insight and judgment (may be impaired)
 - Memory (recent and immediate memory is impaired with delirium; unable to register new information)
 - Language (may have rapid, rambling, slurred, incoherent speech)
 - Altered sleep-wake cycle (insomnia, excessive daytime sleepiness)
 - **EB:** *Establishing the client's baseline mental status by obtaining an accurate history and performing a brief cognitive assessment observing for key diagnostic criteria are important in the diagnosis of delirium (Inouye et al, 2014).*
- Assess the client's behavior and cognition systematically and continually throughout the day and night; use a validated tool to assess presence of delirium, such as the Confusion Assessment Method (CAM) or Delirium Observation Screening Scale (DOS). **EB:** *The CAM is accurate, brief, and easy to use (Grover & Kate, 2012); the DOS was found to be a useful screening tool in a small study of verbally active palliative care clients (Detroyer et al, 2014).*
- Recognize that delirium may be superimposed on dementia; the nurse must be aware of the client's baseline cognitive function. **EB:** *Dementia increases the risk and severity of delirium (Voyer et al, 2011b); delirium superimposed on dementia was a strong predictor of decline in function and resultant institutionalization of older adults admitted to a rehabilitation facility (Morandi et al, 2014).*
- Identify predisposing factors that may precede the development of delirium: dementia, cognitive impairment, functional impairment, visual impairment, alcohol misuse, multiple comorbidities, severe illness, history of transient ischemic attack or stroke, depression, history of delirium, and advanced age (older than 70). **EB:** *Delirium is a multifactorial syndrome most commonly seen in the intensive care unit (ICU),*

palliative care, and postoperative settings; identification of risk factors is important for prevention (Inouye et al, 2014).

- Identify precipitating factors that may precede the development of delirium, especially for individuals with predisposing factors: use of restraints, indwelling bladder catheter, metabolic disturbances, polypharmacy, pain, infection, dehydration, blood loss, constipation, electrolyte imbalances, immobility, general anesthesia, hospital admission for fractures or hip surgery, anticholinergic medications, anxiety, sleep deprivation, lack of use of vision and/or hearing aids, and environmental factors. **EB:** *Prevention of delirium must be a high priority in light of frequency of occurrence, high treatment costs, longer hospital length of stay, higher rates of functional decline and resultant institutional care, and greater mortality; delirium may persist and lead to long-term cognitive decline (O'Mahoney et al, 2011).* **EB:** *Interventions to prevent or lessen the length and severity of delirium may be developed when early identification of delirium risk is instituted (van Boogaard et al, 2012).*
- ▲ Assess for and report possible physiological alterations (e.g., sepsis, hypoglycemia, hypoxia, hypotension, infection, changes in temperature, fluid and electrolyte imbalance, and use of medications with known cognitive and psychotropic side effects). **EB:** *Systemic disturbances, including immunologic, metabolic, neuroinflammatory, endocrinological, and neurological factors lead to alterations in neurotransmitter synthesis and availability, which leads to delirium (Maldonado, 2013).*
 - Treat the underlying risk factors or the causes of delirium in collaboration with the health care team: establish/maintain normal fluid and electrolyte balance, normal body temperature, normal oxygenation (if the client experiences low oxygen saturation, deliver supplemental oxygen), normal blood glucose levels, and normal blood pressure, and address malnutrition and anemia. **EB:** *Early recognition of risk factors may help to prevent the negative sequelae of delirium (Fineberg et al, 2013).*
- ▲ Conduct a medication review and eliminate unnecessary medications; potentially inappropriate medications for older adults at risk for delirium include anticholinergics, benzodiazepines, corticosteroids, H₂ receptor antagonists, sedative hypnotics, tricyclic antidepressants (American Geriatrics Society, 2012). **EB:** *A software based program that identified potential delirium-causing medications and triggered a medication review and monitoring plan by pharmacists led to a decreased incidence of delirium in long-term care (Clegg et al, 2014); polypharmacy is associated with delirium and a reduction of polypharmacy improves cognition (Van der Cammen et al, 2014).*
 - Communicate client status, cognition, and behavioral manifestations to all necessary health care providers.
 - Monitor for any trends occurring in these manifestations, including laboratory tests. **CEB:** *Careful monitoring is needed to identify the potential etiologic factors for delirium (Sendelbach & Guthrie, 2009).*
- Identify, evaluate and treat pain quickly and adequately (see care plans for Acute **Pain** or Chronic **Pain**). **EB:** *Untreated pain is a potential cause of delirium, as is excessive opioid administration (Clegg & Young, 2011).*
- Promote regulation of bowel and bladder function; use bladder scanning to identify retention; avoid prolonged insertion of urinary catheters and remove catheters as soon as possible. **EB:** *Stool impaction may cause urinary retention, which is associated with delirium (Boddaert et al, 2014).* **EB:** *Constipation may precipitate delirium (O'Mahoney et al, 2011); urinary catheterization is associated with delirium (Ahmed et al, 2014).*
- Ensure adequate nutritional and fluid intake. **EB:** *Malnutrition is significantly associated with delirium (Ahmed et al, 2014); attending to correct levels of B vitamins, antioxidants, glucose, water, and lipids may lead to resolution of delirium (Sanford & Flaherty, 2014).*
- Promote early mobilization and rehabilitation in a progressive manner. **EB:** *Avoiding immobility and promoting early mobilization postoperatively reduces delirium (Butler et al, 2013).* **EBN:** *Standardized early mobilization protocols promote functional status, prevent complications associated with functional decline, and contribute to greater well-being and/or decreased length of stay for medical-surgical inpatients (Pashikanti & Von Ah, 2012).*
- Promote continuity of care; avoid frequent changes in staff and surroundings. **EB:** *Changes may contribute to feelings of disorientation and confusion (O'Mahoney et al, 2011).*
- Plan care that allows for an appropriate sleep-wake cycle. Refer to the care plan for **Sleep** deprivation. **EB:** *Interventions to promote sleep were associated with a decreased incidence of delirium (Patel et al, 2014).*
- Facilitate appropriate sensory input by having clients use aids (e.g., glasses, hearing aids, dentures) as needed; check for impacted ear wax. **EB:** *Delirium can be addressed with nonpharmacologic interventions, such as decreasing sensory impairment (Javedan & Tulebaev, 2014) or avoiding sensory overload*

for clients with agitation. **EB:** Multicomponent interventions, such as encouraging use of vision and hearing aids, may assist in the prevention of delirium in individuals who are not cognitively impaired (Khan et al, 2012).

- Modulate sensory exposure; eliminate excessive noise, use appropriate lighting based on the time of day, and establish a calm environment. **EB:** Noise levels in the hospital, often from staff conversation and other avoidable sources, are higher than recommended and lead to significant sleep loss (Yoder et al, 2012).
- Provide cognitive stimulation through conversation about current events, viewpoints, relationships and encourage reminiscence or word games. **EBN:** Daily cognitive stimulation can prevent cognitive decline and promote cognitive recovery (Cheng et al, 2012).
- Provide reality orientation, including identifying self by name at each encounter with the client, calling the client by their preferred name, and the gentle use of orientation techniques; when reorientation is not effective, use distraction. **EB:** Efforts to reorient may agitate some clients; changing the subject may help calm the client (Flaherty & Little, 2011).
- Provide clocks and calendars, update dry erase white boards each shift, encourage family to visit regularly and to bring familiar objects from home, such as family photos or an afghan, and gently correct misperceptions. **EB:** Persons at risk for delirium should be provided clocks and calendars that are easily visible; family and friends may help with reorientation (O'Mahoney et al, 2011).
- Use gentle, caring communication; provide reassurance of safety; give simple explanations of procedures.
- Provide supportive nursing care, including meeting basic needs such as feeding, regular toileting, and ensuring adequate hydration; closely observe behaviors that provide clues to what might be distressing the client. Delirious clients are unable to care for themselves due to their confusion (Rubin et al, 2011). **EB:** Understanding and anticipating behaviors promotes client comfort and safety (Flaherty & Little, 2011).
- ▲ Recognize that delirium is frequently treated with antipsychotic medications or sedatives; if there is no other way to keep the client safe, administer these medications cautiously, as ordered, while monitoring for medication side effects. **EB:** Reducing unnecessary medications, pain, stress, sleep deprivation, inflammation and other neurological insults is crucial, because antipsychotics and sedatives may actually prolong the duration of delirium and worsen outcomes (Inouye et al, 2014).
 - For clients nearing the end of life, for whom delirium may be irreversible, focus on relief of symptoms by increasing supervision, reducing invasive lines and devices that restrict movement, keeping the bed in low position, and placing mats on the floor; support of family, caregivers, and the health care team is also of prime importance. **EB:** Nonpharmacologic means should always be used to ameliorate delirium and may be used in conjunction with medication; delirium is distressing to those caring for the client (Irwin et al, 2013).
 - Choose the appropriate medication and consider the type and reversibility of the delirium; titrate the medication to control the symptoms and minimize side effects. **EB:** Pharmacologic means can be rapid, safe, and effective using the lowest effective dose of the appropriate medication based on the type of delirium (Irwin et al, 2013).

Critical Care

- Recognize admission risk factors for delirium. **EB:** ICU clients are at increased risk for delirium due to greater use of sedatives, analgesics, severity of illness, age, infection, multiorgan failure, sleep deprivation, surgery, fracture, restraint use, immobility, tubes, catheters, hypovolemia, polypharmacy, malnutrition, electrolyte imbalance, and stroke (Mistraletti et al, 2012).
- Obtain an accurate history regarding cognitive impairment and mental health, including history of anxiety and depression, alcohol use, medication use, chronic pain, and use of benzodiazepines. **EBN:** An accurate history guides appropriate interventions to maximize neurocognitive status of older adults with complex illnesses in the ICU (Tate & Happ, 2011).
- Assess level of arousal using the Richmond Agitation Sedation Scale; clients receiving a score of –5 to –4 are comatose and unable to be assessed for delirium. **EB:** Establishing level of arousal before using the Confusion Assessment Method for the ICU (CAM-ICU) decreases the incidence of inappropriate “unable to assess” (UTA) ratings on the CAM-ICU; it was found that noncomatose clients were inappropriately determined to be UTA (Swan, 2014).
- Assess for pain every 2 to 3 hours or more frequently as needed with a standardized assessment tool, which includes either a numerical rating scale or one with behavioral indicators, such as the Behavioral Pain Scale (BPS) or Critical Care Pain Observation Tool (CPOT). **EB:** The self-report is the gold standard

for pain assessment (Barr & Pandharipande, 2013); the BPS and CPOT are the most valid and reliable tools to use for adult ICU clients (excluding brain injured) with intact motor function and observable behaviors, who are unable to self-report (Barr et al, 2013). **EBN:** Uncontrolled pain is common in the ICU and can contribute to delirium; routine assessment of pain may decrease duration of ventilation and ICU length of stay, and increase client satisfaction (Stites, 2013); clients are less likely to communicate symptoms such as pain when delirious (Tate et al, 2013).

- ▲ Incorporate the Awakening and Breathing Coordination, Delirium Monitoring and Management, and Early Mobility (ABCDE) ICU delirium and weakness prevention bundle in conjunction with the interdisciplinary team. **EB:** Interdisciplinary communication and daily rounds and staff education facilitate optimal ABCDE bundle implementation (Balas et al, 2013); bundle implementation leads to less delirium, reduced ventilator time, and more time out of bed (Balas et al, 2014).
 - Assess safety of and implement a spontaneous awakening trial (SAT) using an established protocol. **EB:** Daily interruption of sedation may be beneficial when it results in a reduced total dose of sedative administered; minimizing the depth and duration of sedation is beneficial for reducing delirium (Reade & Finfer, 2014).
 - Assess safety of and implement a spontaneous breathing trial (SBT). **EBN:** Implementing SAT/SBT protocols reduces the duration and use of mechanical ventilation, which may lead to decreased complications and does not increase self-extubation (Jones et al, 2014).
 - Assess sedation and agitation level using a valid and reliable tool; titrate sedation to target sedation level. **EB:** Sedatives and analgesics prescribed to improve client-ventilator dyssynchrony and treat anxiety and pain may precipitate delirium (Banerjee et al, 2011); for most clients being ventilated in the ICU, a score of 3-4 on the Riker or a score of -2-0 on the Richmond are appropriate targets (Reade & Finfer, 2014).
 - Screen for delirium using a reliable and valid monitoring tool once per shift or more often if delirium is present, and recognize that hypoactive delirium is the form most often present in the ICU; communicate and discuss results with the interdisciplinary team. **EB:** The CAM-ICU and the Intensive Care Delirium Screening Checklist are the most valid and reliable tools for adult ICU clients (Barr et al, 2013); staff education, discussion of delirium during bedside rounds, and documentation promote successful screening and treatment (Brummel et al, 2013). **EBN:** The hypoactive form of delirium is the most common form seen in the ICU and contributes to the under-recognition of delirium by clinicians (Tate et al, 2013).
 - Assess safety to begin mobilization; collaborate with physical therapy (PT), occupational therapy (OT), and respiratory therapy (RT) to implement an early mobility plan using a progressive approach. **EB:** Early mobilization of stable ICU clients may significantly reduce the length of delirium and length of stay and prevent other complications related to immobility (Hunter et al, 2014).
- Encourage visits from families and educate families about delirium if it occurs. **EB:** Delirium is distressing to clients and families; providing education can alleviate distress (Irwin et al, 2013). **EBN:** Families are most familiar with the client's baseline behavior, assist in the diagnosis of delirium, and by their presence, may help to prevent and ameliorate delirium (Keyser et al, 2012).
- Promote uninterrupted sleep by grouping cares at night to avoid sleep interruption, offering eye mask, soft music, and earplugs; optimizing room temperature; reducing noise and light after 10 PM; and avoiding excessive daytime napping. **EB:** Sleep deprivation and delirium in the ICU may be iatrogenic; engaging clients to keep them more awake during the day may ensure better outcomes (Weinhouse, 2014). **EBN:** Multifaceted approaches are required to promote sleep in the ICU in order to avoid the negative consequences of disrupted sleep (Kamdar et al, 2013).

Geriatric

- The interventions described previously are relevant to the geriatric client.
- Reorient high-risk clients frequently, answer questions, discuss concerns; use a white board, clock, watch, and calendar, and encourage family members to bring familiar objects from home such as family photos or afghan to assist with orientation. **EB:** Environmental factors may be modified to improve outcomes for clients with delirium (McCusker et al, 2013).
- Provide cognitive stimulation by discussing current events, reading the newspaper, promoting reminiscence, or using games. **EB:** Therapeutic activities can minimize cognitive decline (Zaubler et al, 2013).
- Promote use of glasses, assistive hearing devices, hearing aids, and dentures. **CEB:** Sensory impairment is a modifiable risk factor for delirium.

- Provide feeding assistance as needed. See care plan for Imbalanced **Nutrition**: less than body requirements.
- ▲ Determine whether the client is adequately nourished; watch for protein-calorie malnutrition. Consult with health care provider or dietitian as needed. **EB**: *Malnutrition is significantly associated with delirium (Ahmed et al, 2014); attending to correct levels of B vitamins, antioxidants, glucose, water, and lipids may lead to resolution of delirium (Sanford & Flaherty, 2014).*
- Promote adequate hydration; keep a glass of water within easy reach of the client and offer fluids frequently. **EB**: *Keeping a glass of water within reach abated dehydration and delirium in the long-term care population (McCusker et al, 2013).*
- Avoid use of restraints; remove all nonessential equipment such as telemetry, blood pressure cuffs, catheters, and intravenous lines as soon as possible. **EBN**: *In a study of long-term care residents with dementia, the use of physical restraints was the factor most associated with delirium; initiate alternative interventions (Voyer et al, 2011a).*
- Evaluate all medications for potential to cause or exacerbate delirium; potentially inappropriate medications for older adults at risk for delirium include tricyclic antidepressants, anticholinergics, antipsychotics, benzodiazepines, corticosteroids, H₂ receptor antagonists, and sedative hypnotics. **EB**: *To enhance client safety, medications used for older adults should be routinely assessed for inappropriateness (Morandi et al, 2011).*
- Assess pain frequently and treat pain with the lowest dose of regularly scheduled medication as well as with nonpharmacologic approaches; use client self-report or a validated behavioral pain scale to assess pain accurately. **EB**: *Uncontrolled pain can lead to delirium (Stites, 2013).*
- ▲ Assess risk for falls and implement fall prevention strategies. **EB**: *Geriatric syndromes are more common in older adults with delirium discharged to postacute care facilities; proactively addressing risk factors may improve outcomes (Anderson et al, 2012).*
- Recognize that delirium may be superimposed on dementia; determine client's baseline cognitive status. **EB**: *Dementia increases the risk and severity of delirium (Voyer et al, 2011b); delirium superimposed on dementia was a strong predictor of decline in function and resultant institutionalization of older adults admitted to a rehabilitation facility (Morandi et al, 2014).*
- ▲ Determine whether the client is nourished; watch for protein-calorie malnutrition. Consult with health care provider or dietitian as needed. **EB**: *Malnutrition is significantly associated with delirium (Ahmed et al, 2014); attending to correct levels of B vitamins, antioxidants, glucose, water, and lipids may lead to resolution of delirium (Sanford & Flaherty, 2014).*
- Explain hospital routines and procedures slowly and in simple terms; repeat information as necessary.
- Provide continuity of care when possible, avoid room changes, and encourage frequent visits from family members or significant others. **EB**: *Frequent changes may contribute to confusion (O'Mahoney et al, 2011).*
- Educate family members about delirium assessment and strategies to use to prevent and lessen delirium; use the Family Confusion Assessment Method (FAM-CAM) assessment tool to solicit accurate information from caregivers regarding the presence of delirium. **EBN**: *A small pilot study found that forming a trusting and respectful partnership with family caregivers in delirium prevention impacts family and nurse satisfaction (Rosenbloom & Fick, 2013); the FAM-CAM is a sensitive screening tool to assist in the early diagnosis of delirium in individuals with preexisting dementia (Steis et al, 2012).*
- If clients know that they are not thinking clearly, acknowledge the concern. Fear is frequently experienced by people with delirium. **EB**: *Confusion is frightening; the memory of the delirium can be distressing to clients and families (Partridge et al, 2013).*

Home Care

- The interventions described previously are relevant to home care use. Assess and monitor for acute changes in cognition and behavior. **EB**: *Delirium has an acute onset and fluctuating course, and is characterized by disordered thinking and a change in behavior (Downing et al, 2013).*
- Recognize that delirium is reversible but can become chronic if untreated in a multidisciplinary fashion; the client may be discharged from the hospital to home care in a state of undiagnosed delirium. **EB**: *Complete recovery may be possible with appropriate multidisciplinary care (Wakefield et al, 2014).*
- Avoid preconceptions about the source of acute confusion; assess each occurrence on the basis of available evidence.
- ▲ Institute case management of frail elderly clients to support continued independent living if possible once delirium has resolved.

Client/Family Teaching and Discharge Planning

- ▲ Teach the family to recognize signs of early confusion and seek medical help.
- Counsel the client and family regarding the management of delirium and its sequelae. Increased care requirements at discharge may be needed for clients who have experienced delirium; frailty and delirium can lead to functional decline and institutionalization (Quinlan et al, 2011).

Chronic Confusion Mila W. Grady, MSN, RN

NANDA-I

Definition

Irreversible, long-standing, and/or progressive deterioration of intellect and personality characterized by decreased ability to interpret environmental stimuli; decreased capacity for intellectual thought processes; manifested by disturbances of memory, orientation, and behavior

Defining Characteristics

Alteration in interpretation; alteration in personality; alteration in response to stimuli; alteration in short-term memory; impaired social functioning; chronic cognitive impairment; normal level of consciousness; organic brain disorder; progressive alteration in cognitive impairment

Related Factors (r/t)

Alzheimer's disease; cerebrovascular accident; Korsakoff's psychosis; multi-infarct dementia

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cognition; Cognitive Orientation; Distorted Thought Self-Control

Example NOC Outcome with Indicators

Cognition as evidenced by the following indicators: Cognitive orientation/Communicates clearly for age/Comprehends the meaning of situations/Attentiveness/Concentration. (Rate the outcome and indicators of **Cognition**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain content and free from harm
- Function at maximal cognitive level
- Participate in activities of daily living at the maximum of functional ability
- Have minimal episodes of agitation (agitation occurs in up to 70% of clients with dementia)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Dementia Management; Environmental Management; Surveillance: Safety

Example NIC Activities—Dementia Management

Use distraction rather than confrontation to manage behavior; Give one simple direction at a time

Nursing Interventions and Rationales

- Determine the client's cognitive level using a screening tool such as the Mini-Mental State Exam (MMSE), Mini-Cog (includes a three-item recall and clock drawing test), or Montreal Cognitive Assessment. *Culture and ethnicity (Struble & Sullivan, 2011), and language and education (Velayudhan et al, 2014) must be taken into account when interpreting the results of cognitive testing; an abnormal score necessitates further evaluation. For older adults with mild cognitive impairment, the Short Test of Mental Status and Montreal Cognitive Assessment are more sensitive diagnostic tools than the MMSE (Petersen, 2011).*
- ▲ In clients who are complaining of memory loss, assess for depression, alcohol use, medication use, problems with sleep, and nutrition status. *These factors may be implicated in memory loss (Struble & Sullivan, 2011).*
- ▲ Recognize that pharmacological treatment to slow the progression of Alzheimer's disease is most effective when used early in the course of the disease. *The U.S. Food and Drug Administration has approved five drugs that slow the progression of symptoms for approximately 6 to 12 months (Thies et al, 2011).*
- If the client is hospitalized, gather information about the client's preadmission cognitive functioning, daily routines and care, and decision-making capacity. Establishing continuity of care lessens risk for hospitalized clients. Informed consent may create a dilemma; decision-making capacity will vary depending on the degree of cognitive impairment (Weitzel et al, 2011). **EBN:** *Individuals with a history of cognitive dysfunction are at higher risk for acute confusion during acute illness (Voyer et al, 2011a).*
- Assess the client for signs of depression: anxiety, sadness, irritability, agitation, somatic complaints, tension, loss of concentration, insomnia, poor appetite, apathy, flat affect, and withdrawn behavior. **EB:**

Depression in dementia is common (Enache et al, 2011), and often unrecognized and undertreated. The Cornell Scale for Depression in Dementia and the Montgomery-Asberg Depression Rating Scale may be used for screening purposes in individuals who cannot be interviewed and may enhance recognition of depression in nursing home practice (Leontjevas et al, 2012).

- Assess the client for anxiety if he or she reports worry regarding physical or cognitive health; reports feelings of being anxious, short of breath, or dizzy; or exhibits behaviors such as restlessness, irritability, sensitivity to noise, motor tension, fatigue, or disturbed sleep. The Rating Anxiety in Dementia (RAID) scale may be used; this may require caregiver input. Recognize that anxiety is common in dementia, is often undiagnosed, and may significantly impact quality of life. **EB:** *The RAID scale is a reliable and valid tool for identifying and measuring anxiety in dementia (Snow et al, 2012).*
- ▲ Recognize that clients with Alzheimer's disease may experience neuropsychiatric symptoms such as apathy, anxiety and depression, delusions, disinhibition, euphoria, hallucinations, agitation, including verbal/vocal behavior, and aggression; nonpharmacological interventions for management should be attempted first. **EB:** *Neuropsychiatric symptoms are common in individuals with dementia living in nursing homes; agitation and apathy are the most prevalent symptoms (Selbaek et al, 2013). Nonpharmacological and individualized behavioral interventions should be the first approach to treatment; medications should be used selectively and sparingly (Borisovskaya et al, 2014).*
- Obtain information about the client's life history, interests, routines, needs, and preferences from the family or significant others; collaborate with family members to engage in reminiscence. **EBN:** *Understanding the individual's past and sharing memories enhances communication and client and staff satisfaction (Cooney et al, 2014).*
- Begin each interaction with the client by gaining and maintaining eye contact, identifying yourself, and calling the client by name. Approach the client with a caring, accepting, and empathetic attitude, and speak calmly and slowly. **EB:** *Specific communication skills training for caregivers improves the well-being and quality of life in individuals with dementia and increases positive interactions (Eggenberger et al, 2013).*
- To enhance communication, use a calm approach, avoid distractions, show interest, keep communication simple, give clear choices and one-step instructions, give the client time with word finding, use repetition and rephrasing, and use gestures, prompts, and cues or visual aids. Listen attentively to understand non-verbal messages, and engage in topics of interest to the client. **EB:** *These communication techniques assist in focusing attention, incorporate nonverbal means of communication, simplify memory demands, compensate for cognitive slowing, and assist with retrieval and comprehension (Smith et al, 2011).*
- Engage the client in scheduled activities that relate to past interests, experiences, and hobbies and are matched to current preferences and abilities. **CEB:** *Activities that were once meaningful to the client in terms of self-identity are more likely to result in engagement, even for those with severe cognitive impairment. Residents with current interests in art, music, and pets were more engaged in stimuli that reflected those current interests (Cohen-Mansfield et al, 2010).*
- Promote regular exercise. **EB:** *Exercise programs can improve the ability to perform activities of daily living (Forbes et al, 2013); a small study demonstrated that a specific walking program for individuals in the later stages of dementia can reduce functional and cognitive decline (Venturelli et al, 2011).*
- Provide opportunities for contact with nature or nature-based stimuli, such as facilitating time spent outdoors or indoor gardening. **EBN:** *Gardens and horticultural activities stimulate the senses, may improve well-being, and may reduce disruptive behavior in individuals with dementia (Gonzalez & Kirkevold, 2013).*
- Provide animal-assisted therapy to enhance the care environment. **EB:** *In a study of animal-assisted therapy with a group of clients with severe Alzheimer's disease, animal-assisted therapy was associated with a decrease in sadness and anxiety and an increase in motor activity and positive emotions (Mossello et al, 2011). **EBN:** Centrally located aquariums were found to decrease problematic behaviors in individuals residing in dementia specific units and improved staff satisfaction (Edwards et al, 2014).*
- Break down self-care tasks into simple steps, giving one direction at a time. For example, instead of saying, "Take a shower," say to the client, "Please follow me. Sit down on the bed. Take off your shoes. Now take off your socks." Use gestures when giving directions; allow for adequate time and model the desired action if needed or possible. **EB:** *Assistance in focusing attention, modeling behavior, and using prompts and cues maximizes communication with individuals with dementia (Smith et al, 2011).*
- Promote engagement in individual client routines and facilitate success by keeping frequently used items in a visible and consistent location. **EBN:** *Person-centered care environments facilitate the completion of activities of daily living in individuals with dementia and positively impact quality of life (Sjogren et al, 2013).*

- Use reminiscence and life review therapeutic interventions for clients in the early to middle stages of dementia; ask questions about the client's past activities and important events and experiences from the past while using photographs, videos, artifacts, music, newspaper clippings, or multimedia technology to stimulate memories. **EB:** *In a small preliminary study using YouTube videos, it was found that reminiscence and life review may improve well-being and social engagement (O'Rourke et al, 2011); reminiscence positively impacts quality of life in clients with dementia living in long-term care (O'Shea et al, 2014). Memories from childhood or young adulthood are generally intact in the early and middle stages of Alzheimer's (Smith et al, 2011).*
- Engage clients in the middle to late stages of dementia in creative expression through the use of Time Slips story-telling groups or through person-centered art activities. **EB:** *A small qualitative study demonstrated that Time Slips positively impacted creativity, quality of life, and behavior of clients with dementia and assisted staff to gain a better understanding of residents in the nursing home community (George & Houser, 2014). An exploratory study that used an intergenerational and person-centered arts activity program called Opening Minds through Art demonstrated an improvement in pleasure and engagement for participants using this program versus using a program with traditional arts activities such as scrapbooking and coloring (Sauer et al, 2014).*
- If the client is verbally agitated (repetitive verbalizations, complaints, moaning, muttering, threats, screaming), assess for and address unsatisfied basic needs or environmental factors that may be addressed and redirect the individual. **EB:** *Disruptive vocalizations may be an indication that the client with dementia has the need for comfort, attention, or more or less stimulation (Bédard et al, 2011); redirection may be an effective nonpharmacological means to reduce vocalizations (Yusupov & Galvin, 2014).*
- Assist clients in wayfinding, monitoring them so that they do not get lost in unfamiliar settings; place cues and familiar objects in the environment. **EB:** *Living in a familiar environment that provides opportunities for privacy as well as social contact is associated with better quality of life for individuals with dementia (Fleming et al, 2014).*
- For clients who wander, refer to the **Wandering** care plan.
- Promote sleep by promoting daytime activity, creating a restful sleep environment, decreasing waking, and promoting quiet. **EB:** *Sleep disorders are very common in those with dementia; individuals with Lewy body dementia experience disturbed sleep twice as often as those without Lewy Body dementia (Bliwise et al, 2011).* **CEB:** *Promoting a dark and quiet nighttime environment, providing a comfortable sleeping temperature for the client, encouraging physical activity, especially in the afternoon, maintaining a consistent schedule of meals and activities, maintaining a bright daytime environment, and facilitating outdoor activity are all methods of improving sleep (Neikrug & Ancoli-Israel, 2010).*
- Provide activities for the client, such as folding, sorting, or stacking activities, arranging flowers, or other hobbies or routines the individual enjoyed before the onset of dementia. **CEB:** *The purposeful use of activities tailored to an individual's abilities may allow the individual to maintain social roles and feelings of connectedness, express themselves in a positive way, enhance self-identity, reduce frustration, and prevent boredom, resulting in less agitation (Gitlin et al, 2009).* **EBN:** *A small pilot study demonstrated that volunteers may be trained to engage clients in meaningful individualized activities in order to enhance quality of life (Van der Ploeg et al, 2014).*
- Anticipate and assess for physical stressors such as fatigue, hunger, thirst, constipation, urinary symptoms, and pain. **EBN:** *Safe function is enhanced through the establishment of consistent routines and anticipation of basic needs (Lavoie-Vaughan, 2014).*
- ▲ If the client becomes increasingly confused and/or agitated, perform the following steps:
 - Assess the client for physiological causes, including acute hypoxia, pain, medication effects, malnutrition, and infections such as urinary tract infection, fatigue, electrolyte disturbances, and constipation. *Dementia increases the risk and severity of delirium, which may be precipitated by several factors (Voyer et al, 2011b).*
 - Assess for psychological causes, including changes in the environment, caregiver, or routine; demands to perform beyond capacity; or multiple competing stimuli, including discomfort. Encourage communication by addressing the client in a calm, gentle tone of voice and by using appropriate body language, facial expressions, and gestures. **EB:** *Agitated behaviors can be an expression of a need that is not being met; needs assessment is facilitated through methods to enhance communication so that needs may be expressed (Cohen-Mansfield et al, 2014).*
 - Use music as a nonpharmacological approach to managing agitation. Identify the client's music preferences; interview family members if necessary. **EB:** *Music therapy may lead to a short-term decrease in*

agitation in individuals with dementia (Vink et al, 2013). **EBN:** Using percussion instruments with familiar music was found to be a cost effective method for decreasing anxiety and improving psychological well-being (Sung et al, 2012); both active and passive musical interventions may improve quality of life (Vasionyte & Madison, 2013).

- In clients with agitated behaviors, rather than confronting the client, decrease stimuli in the environment or provide gentle stimulation through diversional activities such as quiet music, looking through a photo album with a staff member, or providing the client with textured items to handle. **EBN:** Soothing music at mealtimes may improve agitated behavior (Ho et al, 2011); clients with dementia are frequently overstimulated or understimulated, and activities that provide one-to-one attention from staff may decrease agitation (Maseda et al, 2014).
- If clients with dementia become more agitated, assess for pain. **EBN:** Pain assessment should include the use of a valid and reliable observer-rated tool such as the Pain Assessment in Advanced Dementia Scale (PAINAD); self-report, the gold standard of pain assessment, may be difficult as dementia advances (Lukas et al, 2013).
- ▲ Avoid using restraints if possible. **EB:** The use of trunk restraints is associated with higher fall risk for clients with dementia (Luo et al, 2011).
- ▲ Use as-needed or low-dose regular dosing of psychotropic or antianxiety drugs only as a last resort; start with the lowest possible dose. **EB:** Psychotropic medications can cause serious adverse effects such as sedation, cardiovascular symptoms, and falls; use nonpharmacological interventions to reduce their use (Richter et al, 2012).
- ▲ Avoid the use of anticholinergic medications such as diphenhydramine. Anticholinergic medications have a high side-effect profile that includes disorientation, urinary retention, and excessive drowsiness, especially in those with decreased cognition. **EB:** Older adults with dementia are especially sensitive to the side effects of anticholinergics; one study found that 23% of older adults with dementia use anticholinergic medications (Sura et al, 2013).
- For interventions on bathing, refer to the geriatric interventions in the care plan for Bathing **Self-Care** deficit.
- For care of early dementia clients with primarily symptoms of memory loss, see the care plan for Impaired **Memory**.
- For clients nearing the end of life, consider a hospice referral. **EB:** Family members of individuals with dementia reported higher perceptions of the quality of care and quality of dying experience with hospice care (Teno et al, 2011).
- For care of clients with self-care deficits, see the appropriate care plan (Feeding **Self-Care** deficit; Dressing **Self-Care** deficit; Toileting **Self-Care** deficit).

Geriatric

NOTE: All interventions are appropriate for geriatric clients.

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the family's or caregiver's understanding of chronic confusion or dementia; assist the family or caregiver in identifying barriers that would prevent the use of social services or other supportive services that could help reduce the impact of caregiving and refer to social services or other supportive services. **EB:** African Americans are at a higher risk for Alzheimer's disease; cultural diversity exists within the older age group of African Americans, influences perceptions of health and knowledge of Alzheimer's disease, and may lead to health disparity (Rovner et al, 2013). Individuals from minority ethnic groups are more cognitively impaired at the time of diagnosis and seek care later in the disease process; a variety of barriers exist for seeking care (Sayegh & Knight, 2013).
- Inform the client's family or caregiver of the meaning of and reasons for common behavior observed in clients with dementia. **EB:** An understanding of behavior enables the client's family or caregiver to provide the client with a safe environment. Disease expression may vary in different ethnorracial groups; Latinos were found in one study to have more depressive symptoms (Livney et al, 2011).

Home Care

NOTE: Keeping the client as independent as possible is important. Because community-based care is usually less structured than institutional care, in the home setting the goal of maintaining safety for the client takes on primary importance.

- The interventions described previously may be adapted for home care use.
- Provide information to the family and home care client regarding advance directives. *A variety of factors influence the initiation of advance care planning discussions (van der Steen et al, 2014); determining health care preferences and goals in the early stages of dementia is preferable for facilitating optimal end of life care.*
- Assess the client's memory and executive function deficits before assuming the inability to make any medical decisions; driving capacity and financial capacity should be assessed for clients with mild cognitive impairment. *Decisional capacities for informed consent include understanding and demonstrating comprehension of diagnosis and treatment-related information, appreciation of the significance of the information, reasoning regarding alternatives and consequences, and expressing a choice (Weitzel et al, 2011).*
- Assess the home for safety features and client needs for assistive devices. Refer to the interventions for Feeding **Self-Care** deficit, Dressing **Self-Care** deficit, and Bathing **Self-Care** deficit as needed.
- Promote cognitive stimulation and memory training exercises for individuals in the early stages of dementia. **EBN:** *Cognitive stimulation therapy may positively impact mood, quality of life, and cognitive function (Yamanaka et al, 2013).*
- Provide education and support to the family regarding effective communication, home safety, fall prevention, engagement in meaningful activities, ways to manage cognitive and behavioral changes, and comprehensive health care including screening for depression; be prepared to offer support and information to family members who live at a distance as well. **EB:** *The need for care, services, and support for individuals in the community with dementia and their caregivers is often unmet; evaluation and diagnosis of dementia, personal and home safety, physical and mental health care, advanced care planning, and legal issues are needs that should be addressed (Black et al, 2013).*
- Use familiar aspects of the environment (smells, music, foods, pictures) to cue the client, capitalizing on habit to remind the client of activities in which the client can participate. **CEB:** *While clients with dementia are probably unable to learn new activities because of deteriorated explicit memory, preserved implicit memory or habit may be useful in maximizing functional ability (Hong & Song, 2009).*
- Instruct the caregiver to provide a balanced activity schedule that does not stress the client or deprive him or her of stimulation; avoid sustained low- or high-stimulation activity. **CEB:** *Planned individualized structured activities can prevent agitation (Gitlin et al, 2009).*
- Encourage the caregiver to plan leisure activities that promote cognitive and physical stimulation. **EB:** *One study that tested the effects of engaging in both tai chi exercises and the game of mahjong found that these activities were beneficial in preserving cognitive function and delayed cognitive decline in some domains of cognitive function (Cheng et al, 2014).*
- ▲ If the client will require extensive supervision on an ongoing basis, evaluate the client for adult day health care programs. Refer the family to medical social services to assist with this process if necessary. *Day care programs provide safe, structured care for the client and respite for the family, provide care on a sliding scale fee basis, and provide stress relief and respite for the caregiver (Alzheimer's Association, 2014).* **EB:** *Adult day services use can decrease care-related stressors for the caregiver, which can positively impact the health of the caregiver (Zarit et al, 2013).*
- Encourage the family to include the client in family activities when possible. Reinforce the use of therapeutic communication guidelines (see **Client/Family Teaching and Discharge Planning**) and sensitivity to the number of people present. *These steps help the client maintain dignity and lead to familial socialization of the client.*
- Assess family caregivers for caregiver stress, loneliness, and depression. Refer to the care plan for **Caregiver Role Strain**.
- ▲ Refer the client to medical social services as necessary to evaluate financial resources and initiate benefits, and to facilitate access to health care providers and community-based organizations such as support groups and training programs for caregivers. **EB:** *Comprehensive and coordinated care has the potential to maximize function and independence and reduce caregiver stress while reducing overall costs (Reuben et al, 2013).*
- ▲ Institute case management for frail elderly clients to support continued independent living.

Client/Family Teaching and Discharge Planning

- In the client's early stages of dementia, provide the caregiver with information on illness processes, needed care, available services, role changes, and importance of advance directives discussion; facilitate family cohesion. **EB:** *Education provided to caregivers early in the disease trajectory may assist them to anticipate*

care needs and role changes and to facilitate involving the individual with dementia in care decisions (de Vugt & Verhey, 2013).

- Teach the family communication strategies, personal care techniques, mobility enhancement, prevention, recognition and management of anxiety and depression, strategies for handling challenging behaviors and legal and financial considerations. **EBN:** *Clients and caregivers reported overwhelming satisfaction with in-home care delivery provided by a nurse practitioner who addressed dementia care issues proactively (Fortinsky et al, 2014).*
- Discuss with the family what to expect as the dementia progresses.
- ▲ Counsel the family about resources available regarding end-of-life decisions and legal concerns. **CEB:** *Family members report distress regarding decision-making throughout the course of dementia, having insufficient information, lack of support in having these discussions with family members in the early stages of dementia, role conflict, maintaining the dignity of their family member, family conflict, supporting caregivers throughout the process and assisting them in advocacy is essential (Livingston et al, 2010).*
- ▲ Inform the family that as dementia progresses, hospice care may be available in the home or nursing home in the terminal stages to help the caregiver. **EB:** *Goals for care include appropriate management of delirium and pain, avoidance of polypharmacy, and promotion of quality of life, comfort, and family and caregiver support (Merel et al, 2014).*

Risk for acute Confusion *Betty J. Ackley, MSN, EdS, RN*

NANDA-I

Definition

Vulnerable to reversible disturbances of consciousness, attention, cognition, and perception that develop over a short period of time, which may compromise health

Risk Factors

Age \geq 60 years; alteration in cognitive functioning; alteration in sleep-wake cycle; dehydration; dementia; history of cerebral vascular accident; impaired metabolic functioning (e.g., azotemia, decreased hemoglobin, electrolyte imbalance, increase in blood urea nitrogen/creatinine); impaired mobility; inappropriate use of restraints; infection; male gender; malnutrition; pain; pharmaceutical agent; sensory deprivation; substance abuse; urinary retention

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching, Rationales, and References

Refer to care plan for Acute **Confusion**.

Constipation *Amanda Andrews, MA, Ed, BSc, DN, RN, HEA Fellow, and A.B. St. Aubyn, BSc (Hons), RGN, RM, RHV, DPS:N (CHS), MSc, PGCert (Education), HEA Fellow*

NANDA-I

Definition

Decrease in normal frequency of defecation accompanied by difficult or incomplete passage of stool and/or passage of excessively hard, dry stool

Defining Characteristics

Abdominal pain; abdominal tenderness with palpable muscle resistance; abdominal tenderness without palpable muscle resistance; anorexia; atypical presentations in older adults (e.g., change in mental status, urinary incontinence, unexplained falls, elevated body temperature); borborygmi; bright red blood with stool; change in bowel pattern; decrease in stool frequency; decrease in stool volume; distended abdomen; fatigue; hard, formed stool; headache; hyperactive bowel sounds; hypoactive bowel sounds; inability to defecate; increase in intra-abdominal pressure; indigestion; liquid stool; pain with defecation; palpable abdominal mass; palpable rectal mass; percussed abdominal dullness; rectal fullness; rectal pressure; severe flatus; soft, paste-like stool in rectum; straining with defecation; vomiting

Related Factors

Functional

Abdominal muscle weakness; average daily physical activity is less than recommended for gender and age; habitually ignores urge to defecate; inadequate toileting habits; irregular defecation habits; recent environmental change

Mechanical

Electrolyte imbalance; hemorrhoids; Hirschsprung's disease; neurological impairment (e.g., positive electroencephalogram, head trauma, seizure disorders); obesity; postsurgical bowel obstruction; pregnancy; prostate enlargement; rectal abscess; rectal anal fissures; rectal anal stricture; rectal prolapsed; rectal ulcer; rectocele; tumors

Pharmacological

Laxative abuse; pharmaceutical agent

Physiological

Decrease in gastrointestinal motility; dehydration; eating habit change (e.g., foods, eating times); inadequate dentition; inadequate oral hygiene; insufficient dietary habits; insufficient fiber intake; insufficient fluid intake

Psychological

Confusion; depression; emotional disturbance

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Bowel Elimination; Hydration

Example NOC Outcome with Indicators

Bowel Elimination as evidenced by the following indicators: Elimination pattern/Stool soft and formed/Passage of stool without aids/Ease of stool passage. (Rate each indicator of **Bowel Elimination**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

Maintain passage of soft, formed stool every 1 to 3 days without straining; State relief from discomfort of constipation; Identify measures that prevent or treat constipation

NIC (Nursing Interventions Classification)**Suggested NIC Intervention**

Constipation/Impaction Management

Example NIC Activities—Constipation/Impaction Management

Identify factors (e.g., medications, bed rest, and diet) that may cause or contribute to constipation/impaction; Institute a toileting schedule, as appropriate

Nursing Interventions and Rationales

- Introduce yourself to the client and any companions, and inform them of your role. Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the basis for building trust upon which to base the provision of care (Howatson-Jones et al, 2012).
- Gain consent to carry out care before proceeding further with the assessment. Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Avery, 2013).
- Wash hands using a recognized technique. **EB**: *Performing strict hand-hygiene regimens significantly reduces the incidence of infection with methicillin-resistant Staphylococcus aureus and Clostridium difficile (Health Protection Agency, 2013).*
- Assess usual pattern of defecation and establish the extent of the constipation problem. **EB**: *A detailed and accurate assessment of the patient enables the nurse to plan interventions, monitor outcomes, and evaluate care, ensuring no unnecessary treatment is rendered (Matthews, 2011).*
 - Bowel habits
 - Time of day
 - Amount and frequency of stool
 - Consistency of stool (using the Bristol Stool Scale)
 - Bleeding/passing mucus on defecation
 - History of bowel habits and/or laxative use

- Lifestyle assessment
 - Fiber content in diet
 - Daily fluid intake
 - Exercise patterns
 - Personal remedies for constipation
 - Recently stopped smoking
 - Alcohol consumption/recreational drug use
- Past medical history
 - Obstetrical/gynecological/urological history and surgeries
 - Diseases that affect bowel motility
 - Bleeding/passing mucous on defecation
 - Current medications
- Emotional influences
 - Anxiety and depression
 - Long-term defecation issues
 - Stress
- Assess usual pattern of defecation, including time of day, amount and frequency of stool, consistency of stool; history of bowel habits or laxative use; diet, including fiber and fluid intake; exercise patterns; personal remedies for constipation; obstetrical/gynecological history; surgeries; diseases that affect bowel motility; alterations in perianal sensation; present bowel regimen. Individual bowel habits vary and clients with constipation experience a variety of symptoms (Spinzi et al, 2009; Kyle 2011a).
- Consider emotional influences (e.g., depression and anxiety) on defecation. Emotions influence gastrointestinal function, possibly because control of both emotions and gastrointestinal function is located in the limbic system of the brain. Difficulties with defecation often begin in childhood (e.g., during toilet training), and constipation is also associated with sexual and physical abuse, depression, and anxiety (Whitehead et al, 2009). **EBN:** *In a study, clients with functional constipation were compared to normal controls; subjects with functional constipation had significantly higher anxiety and depression scores (Zhou et al, 2010).*
- Complete a physical examination (palpation for abdominal distention, percussion for dullness, and auscultation for bowel sounds). A physical examination provides positive and negative findings and may provide the diagnosis without the need for further testing. It may also reveal unsuspected findings or confirm normality (Rhoads & Murphy-Jensen, 2014).
- Encourage the client or family to keep a 7-day diary of bowel habits to include time of day, length of time spent on the toilet, consistency, amount and frequency of stool, and any straining (using the Bristol Stool Scale). **EB:** *Keeping a diary helps establish a patient's bowel pattern and may contribute to the patient's adherence to the proposed care plan (Andrews & Morgan, 2013).*
- Encourage the client or family to keep a 7-day diary of lifestyle issues in relation to bowel habits to include fluid consumption, fiber content in diet, usual bowel stimulus and exercise regimen. **EB:** *Enabling patients to present their condition in their own words ensures that they feel the health care professionals understand their concerns (Smith, 2012).*
- Use the Bristol Stool Scale to assess stool consistency. *The Bristol Stool Scale is widely used as a more objective measure to describe stool consistency (Tack et al, 2011).*
- ▲ Review the client's current medications. **EB:** *Many medications are associated with chronic constipation including opioids, anticholinergics, antidepressants, antihypertensives (e.g., clonidine, calcium channel blockers), antispasmodics, diuretics, anticonvulsants, and psychotropics (Eoff & Lembo, 2008; Spinzi et al, 2009). If clients are suffering from constipation and are taking constipating medications, consult with the health care provider about the possibilities of decreasing the medication dosages or finding an alternative medication that is less constipating (Gallagher et al, 2008; Kyle, 2011b).*
- Discuss with clients already taking opioids (temporarily or long term) that constipation is a common side effect. Advise them to contact their health care provider for a prescription of an appropriate laxative. *The thorough and comprehensive assessment of patients on opioids experiencing constipation will also allow for a bowel function approach for laxative prescribing rather than one based on the opioid dose alone (Andrews & Morgan, 2012).*
- ▲ Recognize that opioids cause constipation. If the client is receiving temporary opioids (e.g., for acute postoperative pain), request an order for routine stool softeners from the primary care provider, monitor bowel movements, and request a laxative for the client if constipation develops. If the client is receiving

around-the-clock opiates (e.g., for palliative care), request an order for Senokot-S and institute a bowel regimen. *Opioids cause constipation because they decrease propulsive movement in the colon and enhance sphincter tone, making it difficult to defecate. Senokot-S is recommended to prevent constipation when opioids are given around the clock (Kyle, 2007).* **EB:** *In a study of clients with hip fracture who received opioids following surgery, clients who received prophylactic laxatives were less likely to develop constipation than those who did not (Davies et al, 2008).*

- ▲ If the client is terminally ill and is receiving around-the-clock opioids for palliative care, speak with the prescribing health care provider about ordering methylnaltrexone, a drug that blocks opioid effects on the gastrointestinal tract without interfering with analgesia. *Methylnaltrexone is FDA approved for clients in palliative care when other laxatives are ineffective (Greenwood-Van Meerveld & Standifer, 2008). Methylnaltrexone does not replace, but is given in addition to, the usual laxative regimen (Kyle, 2009).* **EB:** *In a randomized control trial (RCT) of subjects with opioid-induced constipation, a significantly greater percentage of those who received methylnaltrexone had a bowel movement within 4 hours (without other laxatives) than those who received placebo (Thomas et al, 2008). In a randomized study of clients who took opioids for chronic, nonmalignant pain, those who received subcutaneous methylnaltrexone daily or every other day had significantly more bowel movements than subjects who received placebo (Michna et al, 2011).*
- If new onset of constipation, determine whether the client has recently stopped smoking. *Constipation is common, but usually transient, when people stop smoking (Wilcox et al, 2010).* **CEB:** *In a survey about perceived effects of various foods and beverages on constipation, cigarettes was the item that was most often perceived to have a laxative effect among smokers in all three groups (Müller-Lissner et al, 2005).*
- Palpate for abdominal distention, percuss for dullness, and auscultate bowel sounds. *In clients with constipation the abdomen is often distended and tender, and stool in the colon produces a dull percussion sound. Bowel sounds will be present.*
- ▲ Check for impaction; if present, perform digital removal of stool per the health care provider's order. An impaction is hard stool that is too large to move through the sphincter and must be removed manually. Clients with neurogenic bowel dysfunction (e.g., spinal cord injury) commonly require manual evacuation of stool (Coggrave & Norton, 2010).
- ▲ Advise a fiber intake of 18 to 25 g daily and suggest foodstuffs high in fiber (e.g., prune juice, leafy green vegetables, whole meal bread and pasta). *Fiber creates bulky feces and stretches the bowel wall to stimulate peristalsis, thus shortening bowel transit time (Kyle, 2012).*
- Add fiber gradually to the diet to decrease bloating and flatus. *Larger stools move through the colon faster than smaller stools, and dietary fiber makes stools bigger because it is undigested in the upper intestinal tract. Fiber fermentation by bacteria in the colon produces gas. The effectiveness of water-insoluble fibers (e.g., wheat bran) on bowel function is well supported by research, and there is growing evidence that water-soluble fibers (e.g., psyllium) also promote laxation (Vuksan et al, 2008).* **CEB:** *The Nurses' Health Study found that women with a median fiber intake of 20 g/day were less likely to experience constipation than those with a median intake of 7 g/day (Dukas et al, 2003). In a study of subjects receiving each of five treatments in a randomized design, the five treatments included (1) bran cereal, (2) bran with corn cereal, (3) bran with psyllium cereal, (4) a cereal blend of 70% glucomannan and 30% xanthan, and (5) the low-fiber control diet. All four cereals produced significantly greater bowel movement than the low-fiber control diet and all were well tolerated (Vuksan et al, 2008). Researchers found that rye bread shortened intestinal transit time, softened the feces, and eased defecation in women with constipation, and that yogurt lessened the bloating and flatulence resulting from rye bread (Hongisto et al, 2006).*
- Use a mixture of bran cereal, applesauce, and prune juice; begin administration in small amounts and gradually increase amount. Keep refrigerated. Always check with the primary care provider before initiating this intervention. It is important that the client also ingest sufficient fluids. **CEB:** *This bran mixture has been shown to be effective even with short-term use in older clients recovering from acute conditions; however, it has not been tested with an RCT (Joanna Briggs Institute, 2008).* *Note: Giving fiber without sufficient fluid may result in worsening of constipation. Additional dietary fiber and bulk-forming laxatives are inappropriate for those who have difficulty ingesting adequate fluids, such as clients in palliative care (Kyle, 2007).*
- Provide prune or prune juice daily. Each 100 g of prunes contains about 6 g of fiber, 15 g of sorbitol, and 184 mg of polyphenol; all have laxative effects (Attaluri et al, 2011). **CEB:** *In a study about the perceived effects of various foods and beverages on stool consistency, more than half of subjects surveyed reported that prunes had a softening effect on their stools (Müller-Lissner et al, 2005). In a randomized study, dried prunes*

produced significantly more complete spontaneous bowel movements per week than psyllium, and both treatments produced significantly more complete spontaneous bowel movements than at baseline (Attaluri et al, 2011).

- Advise a fluid intake of 1.5 to 2 L of fluid per day (ideally, 6 to 8 glasses of water), unless contraindicated by comorbidities, such as kidney or heart disease. *Water passes into the gut to promote the formation of a softer fecal mass and provides lubrication to prevent a blockage of the gut (Boyle, 2013).*
- ▲ If the client is uncomfortable or in pain due to constipation or has acute or chronic constipation that does not respond to increased fiber, fluid, activity, and appropriate toileting, refer the client to the primary care provider for an evaluation of bowel function and health status. *There can be multiple causes of constipation, such as endocrine disorders (e.g., hypothyroidism), depression, neurological conditions (e.g., multiple sclerosis and Parkinson's disease), anorectal disorders, and Hirschsprung's disease (Eoff & Lembo, 2008).*
- Encourage physical activity within the client's current ability to mobilize. Encourage turning and changing position in bed if immobile. For clients with reduced mobility, encourage knee to chest raises, waist twists, and stretching the arms away from the body. For fully mobile clients, encourage walking and swimming. *Physical activity can help stimulate peristaltic waves in the colon and encourage the transit of feces to the rectum (Rogers, 2013; Andersen et al, 2006).*
- Demonstrate the use of gentle external abdominal massage, using aroma therapy oils, following the direction of colon activity. *Abdominal massage encourages rectal loading by increasing intra-abdominal pressure and in some cases it may elicit rectal waves, which may stimulate the somato-autonomic reflex and enhance bowel sensation (McClurg et al, 2011).*
- Recommend clients establish a regular elimination routine. If required assist clients to the bathroom at the same time every day, being mindful of the need for privacy (closing of bathroom doors). *Establishing a routine allows for the use of the gastrocolic reflex, especially in the morning, which aids defecation (Rogers, 2013).*
- Provide privacy for defecation. If not contraindicated, help the client to the bathroom and close the door. *Bowel elimination is a private act in Western cultures, and a lack of privacy can hinder the defecation urge, thus contributing to constipation (Kyle, 2011a).*
- Help clients onto a bedside commode or toilet so they can either squat or lean forward while sitting. Recognize that it is difficult to impossible to defecate in the lying supine position. Sitting upright allows gravity to aid defecation. **CEB:** *A study of men found that flexing the hip to 90 degrees or more straightens the angle between the anus and the rectum and pulls the anal canal open, decreasing the resistance to the movement of feces from the rectum and the amount of pressure needed to empty the rectum. Hip flexion is greatest when squatting or when leaning forward while sitting (Tagart, 1966). In a study involving volunteers, defecation required significantly less time and was significantly easier when squatting than when sitting (Sikirov, 2003). In another study, researchers found a significant decrease in the ability of subjects to defecate both a water-filled balloon and a silicone device in the lying position versus the sitting position (Rao et al, 2006).*
- Educate the client how to adopt the best posture for defecation. Keep knees slightly higher than hips, keep feet flat on the floor and lean forward putting elbows onto knees. **EB:** *Adopting the correct position to open one's bowels allows the angle of the rectum and anal canal to straighten out. This facilitates an increase in abdominal pressure, which makes defecation more effective (Rogers, 2013).*
- Teach clients of the importance of responding promptly to the urge to defecate. **EB:** *The body's natural "call to stool" should be heeded in that it is a response to the stimulation of nerve endings in the rectum when a stool is present. Ignoring this urge will result in the rectum becoming desensitized to a stool in situ (Coggrave et al, 2014). CEB: *A study of male volunteers determined that the defecation urge can be delayed and that delaying defecation decreased bowel movement frequency, stool weight, and transit time (Klauser et al, 1990).**
- Consider the use of laxatives, suppositories, enemas, and bowel irrigation as required if other more natural interventions are not effective. *Laxative therapies can be used in conjunction with lifestyle changes (while waiting for the lifestyle changes to take effect or if the change is not sufficient in itself) (Marples, 2011).*
- Discourage the use of long-term laxatives and enemas and advise clients to gradually reduce their use if taken regularly. *Long-term use or overuse of laxatives can cause health problems (e.g., electrolyte imbalance) or hide symptoms that may be from a serious medical condition, such as cardiac arrhythmias (Aschenbrenner, 2014).*

Geriatric

- Assess older adults for the presence of factors that contribute to constipation, including dietary fiber and fluid intake (less than 1.5 L/day), physical activity, use of constipating medications, and diseases that are associated with constipation.
- Explain the importance of adequate fiber intake, fluid intake, activity, and established toileting routines to ensure soft, formed stool. **EB:** *Strong evidence exists for the efficacy of adequate hydration and dietary fiber in the prevention of constipation in older adults; moderate evidence exists for the effectiveness of increased activity for those restricted to bed rest (Joanna Briggs Institute, 2008).* In an RCT of older nursing home residents who were chronically ill and regularly used laxatives, those who received an additional 5.1 g of oat bran with their usual diets had significant reductions in laxative use when compared to those who did not (Sturtzel & Elmadfa, 2008). **CEB:** *A study involving institutionalized older men with chronic constipation demonstrated that, with use of a bran mixture, clients were able to discontinue use of oral laxatives (Howard et al, 2000).*
- Determine the client's perception of normal bowel elimination and laxative use; promote adherence to a regular schedule. **EB:** *In a survey in the United States, United Kingdom, Germany, France, Italy, Brazil, and South Korea, older subjects reported more constipation and used laxatives more often than younger subjects (Wald et al, 2008).*
- Explain why straining (Valsalva maneuver) should be avoided. *Excessive straining can cause syncope or cardiac dysrhythmias in susceptible people (Gallagher et al, 2008).*
- Respond quickly to the client's call for assistance with toileting.
- Offer food, fluids, activity, and toileting opportunities to older clients who are cognitively impaired. *Even cognitively impaired individuals who are unable to initiate a request for food, fluids, and so forth may respond when opportunities are offered (Gallagher et al, 2008).* **EB:** *In an RCT involving nursing home residents, subjects who received the treatment protocol (offering of food, fluid, activity, and toileting opportunities) had significantly more bowel movements than the control group. Both cognitively intact and cognitively impaired subjects benefited from the treatment (Schnelle et al, 2010).*
- Avoid regular use of enemas in older adults. *Enemas can cause fluid and electrolyte imbalances (Gallagher et al, 2008) and damage to the colonic mucosa (Schmelzer et al, 2004).* However, judicious enema use may help prevent impactions (Gallagher et al, 2008).
- ▲ Use opioids cautiously. Opioids cause constipation (Davies et al, 2008).
- Position the client on the toilet or commode and place a small footstool under the feet. Placing a small footstool helps the client assume a squatting posture to facilitate defecation.

Home Care

- The interventions described previously may be adapted for home care use.
- Take complaints seriously and evaluate claims of constipation in a matter-of-fact manner. Continued constipation can lead to bowel obstruction, a medical emergency. Use of a matter-of-fact manner will limit positive reinforcement of the behavior if actual constipation does not exist. Refer to the care plan for Perceived **Constipation**.
- Assess the self-care management activities the client is already using. **CEB:** *Many older adults seek solutions to constipation, with laxative use a frequent remedy that creates its own problems (Annells & Koch, 2002).*
- Offer the following treatment recommendations:
 - Acknowledge the client's life-long experience of bowel function; respect beliefs, attitudes, and preferences, and avoid patronizing responses.
 - Make available comprehensive, useful written information about constipation and possible solutions.
 - Make available empathetic and accessible professional care to provide treatment and advice; a multi-disciplinary approach (including health care provider, nurse, and pharmacist) should be used.
 - Institute a bowel management program.
 - Consider affordability when suggesting solutions to constipation; discuss cost-effective strategies.
 - Discuss a range of solutions to constipation and allow the client to choose the preferred options.
 - Have orders in place for a suppository and enema as the need may occur. As part of a bowel management program, suppositories or enemas may become necessary.
- Although the use of a bedside commode may be necessitated by the client's condition, allow the client to use the toilet in the bathroom when possible and provide assistance. *Bowel elimination is a private act, and a lack of privacy can contribute to constipation.*

- In older clients, routinely advise consumption of fluids, fruits, and vegetables as part of the diet, and ambulation if the client is able. Introduce a bowel management program at the first sign of constipation. Constipation is a major problem for terminally ill or hospice clients, who may need very high doses of opioids for pain management (Sykes, 2006).
- ▲ Refer for consideration of the use of polyethylene glycol 3350 (PEG-3350) for constipation. **CEB:** *In a study of PEG-3350 use for idiopathic constipation, researchers concluded that it appeared to be safe and efficacious when dietary and lifestyle changes were ineffective. Clients reported increased perceived bowel control, with reduced complaints of straining, stool hardness, bloating, and gas (Stoltz et al, 2001). There is good evidence to support the use of PEG for chronic constipation (Ramkumar & Rao, 2005).*
- Advise the client against attempting to remove impacted feces on his or her own. *Older or confused clients in particular may attempt to remove feces and cause rectal damage.*
- When using a bowel program, establish a pattern that is very regular and allows the client to be part of the family unit. Regularity of the program promotes psychological and/or physiological readiness to evacuate stool. Families of home care clients often cannot proceed with normal daily activities until bowel programs are complete.

Client/Family Teaching and Discharge Planning

- Instruct the client on normal bowel function and the need for adequate fluid and fiber intake, activity, and a defined toileting pattern in a bowel program.
- Encourage the client to heed defecation warning signs and develop a regular schedule of defecation by using a stimulus such as a warm drink or prune juice. *Most cases of constipation are mechanical and result from habitual neglect of impulses that signal the appropriate time for defecation.*
- Encourage the client to avoid long-term use of laxatives and enemas and to gradually withdraw from their use if they are used regularly. *Use of stimulant laxatives should be avoided; long-term use can result in dependence on laxative for defecation (Roerig et al, 2010).*
- If not contraindicated, teach the client how to do bent-leg sit-ups to increase abdominal tone; also encourage the client to contract the abdominal muscles frequently throughout the day. Help the client develop a daily exercise program to increase peristalsis.
- Provide client with comprehensive written information about constipation and its management. **EB:** *Providing patients with well-written, evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. In addition, patients are more likely to retain important information that will assist them in making informed decisions about their care (Coulter, 2011).*
- ▲ Collaborate with members of the interprofessional team to provide treatment and advice to clients and caregivers. Team working is a central process in health care organizations. It increases the capacity of teams to absorb and develop new knowledge, which will improve patient health and well-being (Ortega et al, 2013).
- Formalize all advice by providing a bowel management program reiterating the mechanism of normal bowel function and the need for adequate fluid and fiber intake, physical activity, and a defined toileting pattern in an agreed bowel program. **EB:** *The implementation of an organized bowel management program is effective and significantly reduces hospital admissions in patients with severe idiopathic constipation (Russell et al, 2013).*
- Document all care and advice given in a factual and comprehensive manner. *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (St. Aubyn & Andrews, 2012).*

NANDA-I

Definition

Inrequent or difficult evacuation of feces, which has been present for at least three of the prior 12 months

Defining Characteristics

Abdominal distention; adult: presence of ≥ 2 of the following symptoms on Rome III classification system; lumpy or hard stools in $\geq 25\%$ defecations; straining during $\geq 25\%$ of defecations; sensation of incomplete evacuation for $\geq 25\%$ of defecations; sensation of anorectal obstruction/blockage for $\geq 25\%$ of defecations; manual maneuvers to facilitate $\geq 25\%$ of defecations (digital manipulation, pelvic floor support); ≤ 3 evacuations per week.; child: ≤ 4 years; presence of ≥ 2 criteria on Roman III pediatric classification system for ≥ 1 month; ≤ 2 defecations per week; ≥ 1 episode of fecal incontinence per week; stool retentive posturing; painful or hard bowel movements; presence of large fecal mass in the rectum; large diameter stools that may obstruct the toilet; child: ≥ 4 years: presence of ≥ 2 criteria on Roman III pediatric classification system for ≥ 2 months; ≤ 2 defecations per week; ≥ 1 episode of fecal incontinence per week; stool retentive posturing; painful or hard bowel movements; presence of large fecal mass in the rectum; large diameter stools that may obstruct the toilet; fecal impaction; fecal incontinence (in children); leakage of stool with digital stimulation; pain with defecation; palpable abdominal mass; positive fecal occult blood test; prolonged straining; type 1 or 2 on Bristol Stool Chart; amyloidosis; anal fissure; anal stricture; autonomic neuropathy; cerebral vascular accident; chronic intestinal pseudo-obstruction; chronic renal insufficiency; colorectal cancer; dehydration; dementia; depression; dermatomyositis; diabetes mellitus; diet disproportionately high in protein and fat; extraintestinal mass; failure to thrive; habitually ignores urge to defecate; hemorrhoids; Hirschsprung's disease; hypercalcemia; hypothyroidism; impaired mobility; inflammatory bowel disease; insufficient dietary intake; insufficient fluid intake; ischemic stenosis; low caloric intake; low fiber diet; multiple sclerosis; myotonic dystrophy; panhypopituitarism; paraplegia; Parkinson's disease; pelvic floor dysfunction; perineal damage; pharmaceutical agent; polypharmacy; porphyria; postinflammatory stenosis; pregnancy; proctitis; scleroderma; sedentary lifestyle; slow solon transit time; spinal cord injury; surgical stenosis

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Example NOC Outcome with Indicators

Bowel Elimination as evidenced by the following indicators: Elimination pattern/Stool soft and formed/Passage of stool without aids/Ease of stool passage. (Rate each indicator of **Bowel Elimination**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain passage of soft, formed stool every 1 to 3 days without straining
- State relief from discomfort of constipation
- Identify measures that prevent or treat constipation

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Constipation/Impaction Management

Example NIC Activities—Constipation/Impaction Management

Identify factors (e.g., medications, bed rest, and diet) that may cause or contribute to constipation/impaction; Institute a toileting schedule, as appropriate

Nursing Interventions and Rationales

All Client Ages

- Introduce yourself to the client and anyone accompanying him or her and inform them of your role. Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the basis for building trust on which to base the provision of care (Howatson-Jones et al, 2012).
- Gain consent to carry out care before proceeding further with the assessment. Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Avery, 2013)
- Wash hands using a recognized technique. Strict hand-hygiene regimens significantly reduce the incidence of methicillin-resistant *Staphylococcus aureus* and *Clostridium difficile* (Health Protection Agency, 2013).
- Assess usual pattern of defecation and establish the extent of the constipation problem to include:
 - Bowel habits
 - Time of day
 - Amount and frequency of stool
 - Consistency of stool (using the Bristol Stool Scale)
 - Bleeding/passing mucus on defecation
 - History of bowel habits and/or laxative use
 - Assess children younger than 4 years using the Rome III pediatric classification (for at least 1 month)
 - Assess children older than age 4 years using the Rome III pediatric classification (for at least 2 months)
 - Assess adults using the Rome III classification. *Rome III criteria, devised in 2006, specify that clients must be symptomatic with at least two or more of the criteria that are relevant to their specific age range (Leung et al, 2011).*
 - Lifestyle assessment
 - Fiber content in diet
 - Daily fluid intake
 - Exercise patterns
 - Personal remedies for constipation
 - Recently stopped smoking
 - Alcohol consumption/recreational drug use
 - Personal habits related to defecation
 - Past medical history
 - Obstetrical/gynecological/urological history and surgeries
 - Existing anatomical anomalies (e.g., anal fissures, anal strictures and hemorrhoids)
 - Diseases that affect bowel motility (e.g., colorectal cancer, chronic intestinal pseudo-obstruction and Hirschsprung's disease)
 - Bleeding/passing mucus on defecation
 - Current medications
 - Established algorithms and guidelines recommend that secondary pathology and causes of constipation are identified and firstly excluded before moving on to assessment of diet and lifestyle issues (Tack et al, 2011)

- Emotional influences
 - Anxiety and depression
 - Long-term defecation issues
 - Stress
- **EB:** *A detailed and accurate assessment of the client enables the nurse to plan interventions, monitor outcomes, and evaluate care, ensuring no unnecessary treatment is carried out (Matthews, 2011).*
- Complete a physical assessment (palpation for abdominal distention, percussion for dullness, auscultation for bowel sounds, observation for anal fissures, anal strictures, and hemorrhoids). *A physical examination provides positive and negative findings and may provide the diagnosis without the need for further testing. It may also reveal unsuspected findings or confirm normality (Rhoads & Murphy-Jensen, 2014).*
- Encourage the client or family to keep a 7-day diary of bowel habits to include time of day, length of time spent on the toilet, consistency, amount and frequency of stool, and any straining (using the Bristol Stool Scale). *Keeping a diary helps establish a client's bowel pattern and may contribute to the client's adherence to the proposed care plan (Andrews & Morgan 2013).*
- Encourage the client or family to keep a 7-day diary of lifestyle issues in relation to bowel habits to include fluid consumption, fibre content in diet, usual bowel stimulus and exercise regime. *Enabling clients to present their condition in their own words ensures that they feel the health care professionals understand their concerns (Smith, 2012).*
- Actively encourage the use of reward/star charts with children when establishing regular bowel routines. *Research highlights that children respond better to positive enforcement when learning to manage constipation with regular toileting rather than confrontation about the problem (Afzal et al, 2011).*
- Discuss with clients already taking opioids (temporarily or long term) that constipation is a common side effect. Advise the client to contact their primary health care provider for a prescription of an appropriate laxative. *The thorough and comprehensive assessment of clients on opioids experiencing constipation will also allow for a bowel function approach for laxative prescribing rather than one based on the opioid dose alone (Andrews & Morgan, 2012).*
- Advise a fiber intake of 18 to 25 g of fiber daily and suggest foodstuffs to facilitate this diet (e.g., prune juice, leafy green vegetables, wholemeal bread and pasta). *Fiber creates bulky feces and stretches the bowel wall to stimulate peristalsis, thus shortening bowel transit time (Kyle, 2012).*
- Advise a fluid intake of 1.5 to 2 L of fluid per day (ideally, 6 to 8 glasses of water), unless this is contraindicated by comorbidities such as renal or heart disease. *Water passes into the gut to promote the formation of a softer fecal mass and provides lubrication to prevent a blockage of the gut (Boyle, 2013).*
- Encourage physical activity within the client's current ability to mobilize. Encourage turning and changing position in bed if immobile. For reduced mobility clients, encourage knee to chest raises, waist twists, and stretching the arms away from the body. For fully mobile clients, encourage walking and swimming. *Physical activity can help stimulate peristaltic waves in the colon and encourage the transit of feces to the rectum (Rogers, 2013).*
- Demonstrate the use of gentle external abdominal massage, using aroma therapy oils, following the direction of colon activity. **EB:** *Abdominal massage encourages rectal loading by increasing intraabdominal pressure and in some cases it may elicit rectal waves that may stimulate the somatoautonomic reflex and enhance bowel sensation (McClurg et al, 2011).*
- Recommend clients establish a regular elimination routine. If required, assist clients to the bathroom at the same time every day, being mindful of the need for privacy (closing of bathroom doors). *Establishing a routine allows for the use of the gastrocolic reflex, especially in the morning, which aids defecation (Rogers, 2013).*
- Educate the client how to adopt the best posture for defecation: keep knees slightly higher than hips, keep feet flat on the floor and lean forward, putting elbows onto knees. *Adopting the correct position to open one's bowels allows the angle of the rectum and anal canal to straighten. This facilitates an increase in abdominal pressure, which makes defecation more effective (Rogers, 2013).*
- Consider the teaching of biofeedback therapy to encourage a "new normal" bowel routine for clients to adopt. **EB:** *A meta-analysis random control trial concluded that the use of biofeedback therapy in chronic constipation was successful and warranted the time and effort involved in establishing a bowel routine (Enck et al, 2009).*
- Teach clients of the need to respond promptly to the defecation urge. **EB:** *The body's natural "call to stool" should be heeded because it is a response to the stimulation of nerve endings in the rectum when a stool is*

present. Ignoring this urge results in the rectum becoming desensitized to a stool in situ (Coggrave et al, 2014).

- Consider the use of laxatives, suppositories, enemas, and bowel irrigation as required when other more natural interventions are not effective. **EB:** Laxative therapies can be used in conjunction with lifestyle changes (while waiting for the lifestyle changes to take effect or if the change is not sufficient in itself) (Marples, 2011; Kyle, 2011). Bowel irrigation is thought to both stimulate colonic reflex and act as a mechanical bowel washout (Coggrave et al, 2014).
- Discourage the use of long-term laxatives and enemas, and advise clients to gradually reduce their use if taken regularly. Long-term use or overuse of laxatives can cause health problems (e.g., electrolyte imbalance) or hide symptoms of a serious medical condition, such as cardiac arrhythmias (Aschenbrenner, 2014).
- Provide client with comprehensive written information about constipation and its management. **EB:** Research shows that providing clients with well-written evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. In addition clients are more likely to retain important information that will assist them in making informed decisions about their care (Coulter, 2011).
- Provide written instructions for children about taking their medication and about how the bowel works. Written clear information provided to children with chronic functional constipation will help them understand and therefore recognize when they are at risk for constipation recurrence (NICE, 2010).
- Liaise with members of the interprofessional team as appropriate to provide treatment and advice to clients and caregivers. Team work is a central process in health care organizations. It increases the capacity of teams to absorb and develop new knowledge, which will improve clients' health and well-being (Ortega et al, 2013).
- Educate the client on the mechanism of normal bowel function and the need for adequate fluid and fiber intake, physical activity, and a defined toileting pattern in an agreed-upon bowel management program. The implementation of an organized bowel management program is effective and significantly reduces hospital admissions in clients with severe idiopathic constipation (Russell et al, 2013).
- Document all care and advice given in a factual and comprehensive manner. Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (St. Aubyn & Andrews, 2012).

Perceived Constipation

Amanda Andrews, MA, Ed, BSc, DN, RN, HEA Fellow,
and A.B. St. Aubyn, BSc (Hons), RGN, RM, RHV, DPS:N (CHS), MSc, PGCert (Education), HEA Fellow

NANDA-I

Definition

Self-diagnosis of constipation combined with abuse of laxatives, enemas, and/or suppositories to ensure a daily bowel movement

Defining Characteristics

Enema abuse; expects a daily bowel movement; expects a daily bowel movement at the same time every day; laxative abuse; suppository abuse

Related Factors

Cultural health beliefs; family health beliefs; impaired thought process

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Bowel Elimination; Health Beliefs; Health Beliefs: Perceived Threat

Example NOC Outcome with Indicators

Bowel Elimination as evidenced by the following indicators: Elimination pattern/Stool soft and formed/ Passage of stool without aids/Ease of stool passage. (Rate each indicator of **Bowel Elimination**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Regularly defecate soft, formed stool without use of aids
- Explain the need to decrease or eliminate the use of stimulant laxatives, suppositories, and enemas
- Identify alternatives to stimulant laxatives, enemas, and suppositories for ensuring defecation
- Explain that defecation does not have to occur every day

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

- Bowel Management; Medication Management

Example NIC Activities—Bowel Management

Note preexistent bowel problems, bowel routine, and use of laxatives; Initiate a bowel training program, as appropriate

Nursing Interventions and Rationales

- Introduce yourself to the client and any companions, and inform them of your role. *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the bases for building trust upon which to base the provision of care (Howatson-Jones et al, 2012).*

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

- Gain consent before proceeding further with the assessment. *Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Avery, 2013).*
- Wash hands using a recognized technique. **EB:** *Performing strict hand-hygiene regimens significantly reduces the incidence of infection with methicillin-resistant Staphylococcus aureus and Clostridium difficile (Health Protection Agency, 2013).*
- Assess usual pattern of defecation and establish the extent of the perceived constipation problem to include:
 - Bowel Habits
 - Time of day
 - Amount and frequency of stool
 - Consistency of stool (using the Bristol Stool Scale)
 - Bleeding/passing mucus on defecation
 - Patient history of bowel habits and/or laxative use
 - Family history of bowel habits and/or laxative use

EB: *A detailed and accurate assessment of the patient enables the nurse to plan interventions, monitor outcomes, and evaluate care, ensuring no unnecessary treatment is rendered (Matthews, 2011).*
 - Lifestyle Assessment
 - Fiber content in diet
 - Daily fluid intake
 - Exercise patterns
 - Personal remedies for constipation
 - Cultural remedies for constipation
 - Recently stopped smoking
 - Alcohol consumption/recreational drug use

EB: *Alcohol has a dehydrating effect on the body. One of the key causes of constipation is dehydration of stools. A lack of water in the bowel leads to hard fecal matter, which is difficult to pass (Derbyshire, 2011).*
 - Past Medical History
 - Obstetrical/gynecological/urological history and surgeries
 - Diseases that affect bowel motility
 - Bleeding/passing mucus on defecation
 - Current medications
 - Emotional Influences
 - Anxiety and depression/psychological disorders
 - History of eating disorders
 - History of physical/or sexual abuse
 - Long-term defecation issues
 - Stress

EB: *Clients' psychological reactions to the experience of constipation change over time. Anxiety and fear about the anticipated health-related consequences of constipation are often expressed. The absence of a bowel movement or the failure of constipation treatment can lead to anxiety and depression (Dhingra et al, 2012).* **EB:** *Stress can alter the mucosal immune function of the central nervous system. This causes afferent signals to the gut to be reduced, causing constipation (Drossman, 2011).*
- Encourage the client or family to keep a 7-day diary of bowel habits to include time of day, length of time spent on the toilet, consistency, amount and frequency of stool, and any straining (using the Bristol Stool Scale). **EB:** *Keeping a diary helps establish a patient's bowel pattern and may contribute to the patient's adherence to the proposed care plan (Andrews & Morgan, 2013).*
- Encourage the client or family to keep a 7-day diary of lifestyle issues in relation to bowel habits to include fluid consumption, fiber content in diet, usual bowel stimulus, and exercise regimen. **EB:** *Enabling patients to present their condition in their own words ensures that they feel the health care professionals understand their concerns (Smith, 2012).*
- Educate the client that it is not necessary to have a daily bowel movement. **EB:** *A healthy bowel function can vary from three stools each day to three stools each week. The criteria of choice for establishing a diagnosis of constipation are often the Rome III criteria. The criteria based definition calls for the presence of two or more of the symptom for at least 3 months for a definition of constipation (Leung et al, 2011).*
- Encourage the client to record use of laxatives, suppositories, or enemas, and suggest replacing them with an increase in fluid and fiber intake. **EB:** *Overtreatment with laxatives can result in iatrogenic diarrhea,*

which can lead to dehydration, delirium, and the false-positive labeling and unnecessary treatment of *C. difficile* carriers. This can result in increased morbidity and mortality, and a longer stay in hospital. By improving the assessment and treatment of constipation, patient outcomes should improve, resulting in significant hospital cost savings (Linton, 2014).

- Advise a fiber intake of 18 to 25 g daily and suggest foodstuffs high in fiber (e.g., prune juice, leafy green vegetables, whole meal bread and pasta). Fiber creates bulky feces and stretches the bowel wall to stimulate peristalsis, thus shortening bowel transit time (Kyle, 2012). For further information on use of fiber, please refer to the care plan for **Constipation**.
- Advise a fluid intake of 1.5 to 2 L of fluid per day (ideally, 6 to 8 glasses of water), unless contraindicated by comorbidities, such as kidney or heart disease. Water passes into the gut to promote the formation of a softer fecal mass and provides lubrication to prevent a blockage of the gut (Boyle, 2013).
- Obtain a referral to a dietitian for analysis of the client's diet and fluid intake to provide strategies to improve diet and nutrition.
- Encourage physical activity within the client's current ability to mobilize. Encourage turning and changing position in bed if immobile. For clients with reduced mobility, encourage knee to chest raises, waist twists, and stretching the arms away from the body. For fully mobile clients, encourage walking and swimming. Physical activity can help stimulate peristaltic waves in the colon and encourage the transit of feces to the rectum (Rogers, 2013).
- Demonstrate the use of gentle external abdominal massage, using aroma therapy oils, following the direction of colon activity. Abdominal massage encourages rectal loading by increasing intra-abdominal pressure and in some cases it may elicit rectal waves, which may stimulate the somato-autonomic reflex and enhance bowel sensation (McClurg et al, 2011).
- Recommend clients establish a regular elimination routine. If required assist clients to the bathroom at the same time every day, being mindful of the need for privacy (closing of bathroom doors). Establishing a routine allows for the use of the gastrocolic reflex, especially in the morning, which aids defecation (Rogers, 2013).
- Observe for the presence of an eating disorder, the use of laxatives to control or decrease weight; refer for counseling if needed. People with eating disorders suffer from constipation and other gastrointestinal symptoms, or use laxatives as part of inducing weight loss (Roerig et al, 2010). **CEB:** Laxative abuse is found in clients with both anorexia and bulimia nervosa and may be associated with worsening of the eating disorder as a form of self-harm (Tozzi et al, 2006).
- Observe family cultural patterns related to eating and bowel habits. Cultural patterns may control bowel habits.

Client/Family Teaching and Discharge Planning

- Provide education to the client on ways to adopt the best posture for defecation. Keep knees slightly higher than hips, keep feet flat on the floor and lean forward putting elbows onto knees. Adopting the correct position to open one's bowels allows the angle of the rectum and anal canal to straighten out. This facilitates an increase in abdominal pressure, which makes defecation more effective (Rogers, 2013).
- Teach clients of the importance of responding promptly to the urge to defecate. **EB:** The body's natural "call to stool" should be heeded in that it is a response to the stimulation of nerve endings in the rectum when a stool is present. Ignoring this urge will result in the rectum becoming desensitized to a stool in situ (Coggrave et al, 2014).
- Discourage the use of long-term laxatives and enemas and explain the potential harmful effects of the continual use of defecation aids such as laxatives and enemas. **EB:** "Lazy bowel syndrome" may occur if laxatives are used too frequently, causing the bowel to become dependent on laxatives to stimulate a bowel movement. Overuse of laxatives can also lead to poor absorption of vitamins and other nutrients, and to damage of the gastrointestinal tract (Mayo Foundation for Medical Education and Research, 2011).
- Advise clients to gradually reduce their use of laxatives, if taken regularly, which may take months to achieve. Long-term use or overuse of laxatives can cause health problems (e.g., electrolyte imbalance) or hide symptoms that may be from a serious medical condition, such as cardiac arrhythmias (Aschenbrenner, 2014).
- Provide client with comprehensive written information about constipation and its management. **EB:** Providing patients with well-written, evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. In addition, patients are more likely to retain important information that will assist them in making informed decisions about their care (Coulter, 2011).

- Collaborate with members of the interprofessional team to provide treatment and advice to clients and caregivers. *Team working is a central process in health care organizations. It increases the capacity of teams to absorb and develop new knowledge, which will improve patient health and well-being (Ortega et al, 2013).*
- Formalize all advice by providing a bowel management program reiterating the mechanism of normal bowel function and the need for adequate fluid and fiber intake, physical activity, and a defined toileting pattern in an agreed bowel program. **EB:** *The implementation of an organized bowel management program is effective and significantly reduces hospital admissions in patients with severe idiopathic constipation (Russell et al, 2013).*
- Document all care and advice given in a factual and comprehensive manner. *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (St. Aubyn & Andrews, 2012).*

Risk for Constipation Betty J. Ackley, MSN, EdS, RN

NANDA-I

Definition

Vulnerable to a decrease in normal frequency of defecation accompanied by difficult or incomplete passage of stool, which may compromise health

Risk Factors**Functional**

Abdominal weakness; average daily physical activity is less than recommended for gender and age; habitually ignores urge to defecate; inadequate toileting habits; irregular defecation habits; recent environmental change

Psychological

Confusion; depression; emotional disturbance

Physiological

Decrease in gastrointestinal motility; dehydration; eating habit change (e.g., foods, eating times); inadequate dentition; inadequate oral hygiene; insufficient dietary habits; insufficient fiber intake; insufficient fluid intake

Pharmacological

Iron salts; laxative abuse; pharmaceutical agent

Mechanical

Electrolyte imbalance; hemorrhoids; Hirschsprung's disease; neurological impairment (e.g., positive electroencephalogram, head trauma, seizure disorders); obesity; postsurgical obstruction; pregnancy; prostate enlargement; rectal abscess; rectal anal fissures; rectal anal stricture; rectal prolapse; rectal ulcer; rectocele; tumor

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching, Rationales, and References

Refer to care plans for **Constipation**.

Risk for chronic functional Constipation *Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN***NANDA-I****Definition**

Vulnerable to infrequent or difficult evacuation of feces, which has been present nearly 3 of the prior 12 months, which may compromise health

Risk Factors

Aluminum-containing antacids; antiepileptics; antihypertensives; anti-Parkinsonian agents (anticholinergic or dopaminergic); calcium-channel antagonists; chronic intestinal pseudo-obstruction; decreased food intake; dehydration; depression; diet proportionally high in protein and fat; diuretics; failure to thrive; habitual ignoring of urge to defecate; impaired mobility; low-fiber diet; insufficient fluid intake; inactive lifestyle; iron preparations; low caloric intake; nonsteroidal anti-inflammatories; opioids; polypharmacy; slow colon transit time; tricyclic antidepressants

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan for Chronic functional **Constipation**.

Contamination *Pauline McKinney Green, PhD, RN, CNE***NANDA-I****Definition**

Exposure to environmental contaminants in doses sufficient to cause adverse health effects

Defining Characteristics

Pesticides

Dermatological effects of pesticide exposure; gastrointestinal effects of pesticide exposure; neurological effects of pesticide exposure; pulmonary effects of pesticide exposure; renal effects of pesticide exposure

Chemicals

Dermatological effects of chemical exposure; gastrointestinal effects of chemical exposure; immunological effects of chemical exposure; neurological effects of chemical exposure; pulmonary effects of chemical exposure; renal effects of chemical exposure

Biologicals

Dermatological effects of exposure to biological; gastrointestinal effects of biological exposure; neurological effects of biological exposure; pulmonary effects of biological exposure; renal effects of biological exposure

Pollution

Neurological effects of pollution exposure; pulmonary effects of pollution exposure

Waste

Dermatological effects of waste exposure; gastrointestinal effects of waste exposure; hepatic effects of waste exposure; pulmonary effects of waste exposure

Radiation

Exposure to radioactive material; genetic effects of radiation exposure; immunological effects of radiation exposure; neurological effects of radiation exposure; oncological effects of radiation exposure

Related Factors (r/t)

External

Carpeted flooring; chemical contamination of food; chemical contamination of water; economically disadvantaged; exposure to areas with high contaminant level; exposure to atmospheric pollutants; exposure to bioterrorism; exposure to disaster (natural or man-made); exposure to radiation; flaking, peeling surface in presence of young children (e.g., paint, plaster); household hygiene practices; inadequate breakdown of contaminant; inadequate municipal services (e.g., trash removal, sewage treatment facilities); inadequate protective clothing; inappropriate use of protective clothing; ingestion of contaminated material (e.g., radioactive, food, water); personal hygiene practices; playing where environmental contaminants are used; unprotected exposure to chemical (e.g., arsenic); use of environmental contaminants in the home; use of noxious material in insufficiently ventilated area (e.g., lacquer, paint); use of noxious material without effective protection (e.g., lacquer, paint)

Internal

Age (e.g., children < 5 years, older adults); concomitant exposure; developmental characteristics of children; extremes of age; female gender; gestational age during exposure; inadequate nutrition; preexisting disease; pregnancy; previous exposure to contaminant; smoking

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Community Health Status; Family Physical Environment; Anxiety Level; Fear Level

Example NOC Outcome with Indicators

Community Health Status as evidenced by the following indicators: Evidence of health protection measures/Compliance with environmental health standards/Health status of population. (Rate the outcome and indicators of **Community Health Status**: 1 = poor, 2 = fair, 3 = good, 4 = very good, 5 = excellent [see [Section 1](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Have minimal health effects associated with contamination
- Cooperate with appropriate decontamination protocol
- Participate in appropriate isolation precautions

Community Will (Specify Time Frame)

- Use health surveillance data system to monitor for contamination incidents
- Use disaster plan to evacuate and triage affected members
- Have minimal health effects associated with contamination
- Employ measures to reduce household environmental risks

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Triage: Disaster; Infection Control; Anxiety Reduction; Crisis Intervention; Health Education

Example NIC Activities—Triage: Disaster

Initiate appropriate emergency measures, as indicated; Monitor for and treat life-threatening injuries or acute needs

Nursing Interventions and Rationales

- ▲ Help individuals cope with contamination incident by doing the following:
 - Use groups that have survived terrorist attacks as useful resource for victims
 - Provide accurate information on risks involved, preventive measures, use of antibiotics and vaccines
 - Assist to deal with feelings of fear, vulnerability, and grief
 - Encourage individuals to talk to others about their fears
 - Assist victims to think positively and to move toward the future
- ▲ *In a crisis situation, interventions aimed at supporting an individual's coping help the person deal with feelings of fear, helplessness, and loss of control that are normal reactions in a crisis situation.*
- Triage, stabilize, transport, and treat affected community members. **EB:** *Accurate triage and early treatment provide the best chance of survival to affected persons (Veenema, 2013).*
- Prioritize mental health care for highly vulnerable risk groups or those with special needs (deeply affected groups, women, older persons, children and adolescents, displaced persons—especially those living in shelters, persons with preexisting mental health disorders (including those living in institutions) (Pan American Health Organization, 2012).
- Collaborate with other agencies (local health department, emergency medical service [EMS], state and federal agencies). *Communication among agencies increases ability to handle crisis efficiently (CDC, 2014a; Veenema, 2013).*
- Use approved procedures for decontamination of persons, clothing, and equipment. *Victims may first require decontamination before entering health facility to receive care in order to prevent the spread of contamination (U.S. Army Medical Research Institute of Infectious Diseases, 2011).*
- Use appropriate isolation precautions: universal, airborne, droplet, and contact isolation. *Proper use of isolation precautions prevents cross-contamination by contaminating agents (U.S. Army Medical Research Institute of Infectious Diseases, 2011).* **EB:** *A study of health care workers' client interactions found transfer of multidrug-resistant bacteria to workers' gowns and gloves increased after client contact with environmental contamination and recommended improved compliance with contact precautions and aggressive environmental cleaning (Morgan et al, 2012).*
- Monitor individual for therapeutic effects, side effects, and compliance with post-exposure drug therapy. Drug therapy may extend over a long period of time and requires monitoring for compliance as well as for therapeutic and side effects (Veenema, 2013).
- Perform effective hand washing before and after handling medical charts, entering case notes, touching clients, and performing procedures, especially in intensive care unit environments. **EB:** *A prospective study to identify and compare the incidence of bacterial contamination of hospital charts found the plastic chart*

covers to be contaminated (63.5% for general wards and 83.2% for special units); chart covers can act as vectors and potential sources of infection (Chen et al, 2014).

- Prevent cross contamination by systematically disinfecting stethoscopes (diaphragm and tubing) after each use. **EB:** A study of the contamination level of health care providers' hands and stethoscopes found that the contamination level of the stethoscope is substantial after a single health care provider examination and is comparable to the contamination of parts of the health care provider's hand (Longtin et al, 2014).
- Complete proper hand washing after touching the client's privacy curtain and before touching the client. **EB:** A longitudinal study determined that privacy curtains are contaminated with potentially pathogenic bacteria within 1 week of use; following the correct order for hand washing prevents contact with contaminated surfaces of privacy curtains (Ohl et al, 2012).

Geriatric

- Help the client identify age-related factors that may affect response to contamination incidents.
- Advise older adults to follow public notices related to drinking water. *Contaminated water can harm the health of older persons and those with chronic conditions (CDC, 2014b).*
- Encourage older adults to receive influenza vaccination when it is available, beginning as early as late August and continuing through the end of February. *Flu vaccination protects against influenza and protects those in proximity who are more vulnerable to serious flu illness (CDC, 2013a).*
- Instruct older adults with special needs or chronic conditions to plan for emergencies and keep medications, prescriptions, and special devices on hand (Federal Emergency Management Agency, 2014).

Pediatric

- Provide environmental health hazard information. *Developing children are more vulnerable to environmental toxicants due to greater and longer exposure and particular susceptibility windows (Children's Environmental Health Network, 2013).*
- Reduce risks from exposure to environmental contaminants by identifying the ages and life stages of children. **EB:** *The World Health Organization recommends coordination of hazard and exposure assessment using children's ages and life stages to accommodate for children's physiology and developmental stage that contribute to opportunities for environmental exposure and contamination (Hubal et al, 2014).*
- Screen newly arrived immigrant and refugee children for elevated blood lead levels secondary to lead hazards in older housing. **EB:** *Resettlement in areas with older housing stock increases risk for lead poisoning (CDC, 2013b).*
- Be aware that the risk for lead exposure is much higher in many of the countries from which children are adopted than in the United States (CDC, 2014c).
- Use the latest reference level of 5 µg/dL to identify children and environments associated with lead-exposure hazards. **EB:** *CDC currently recommends using 5 µg/dL as the reference value in place of the previously recommended level of 10 µg/dL; reference values are updated every 4 years based on the most recent population-based blood lead surveys among children (CDC, 2012).*

Multicultural

- Ask about use of imported or culture-specific products that contain lead, such as greta and azarcon (Hispanic folk medicine for upset stomach and diarrhea), ghasard (Indian folk medicine tonic), and ba-baw-san (Chinese herbal remedy). *Immigrant children are at increased risk for contamination, particularly from lead, related to exposure to imported culture-specific products (CDC, 2013c).*
- Nurses need to consider the cultural and social factors that impact access to and understanding of the health care system, particularly for groups such as migrant workers who do not have consistent health care providers. **EB:** *Subtle cultural biases in how nurses approach care can affect outcomes (Holmes, 2011; Hubal et al, 2014).*

Home Care

- Assess current environmental stressors and identify community resources. *Accessing resources decreases stress and increases ability to cope.*
- Recognize that relocated and unemployed individuals/families are at risk for psychological distress. **EB:** *People who lose their social network are at a very high risk for post-event psychological distress and require appropriate care (Oyama et al, 2012).*

- Support policy and program initiatives that provide emergency mental health services following large-scale contamination events. **EB**: *A study of the utilization of mental health services following a major disaster found community mental health service use increased in the period following the event and that brief interventions were more effective than conventional multisession interventions (Boscarino et al, 2011).*
- Instruct community members concerned about lead in drinking water from plumbing pipes and fixtures to have the water tested by calling the EPA drinking water hotline at 800-426-4791.
- Educate community members to reduce exposure to lead by inquiring about lead-based paint before buying a home or renting an apartment built before 1978; Federal law requires disclosure of known information about lead-based paint (EPA, 2014).
- Instruct individuals and families that food contamination occurs through a variety of mechanisms and that food safety is associated with proper washing of hands and utensils, prompt refrigeration of food, and cooking foods at the correct temperature. **EB**: *Pathogens can be introduced into food from infected humans who handle food without thoroughly washing their hands, from food that touches surfaces or utensils contaminated by pathogens in raw food, and improper refrigeration or heating of food (CDC, 2013d).*

Client/Family Teaching and Discharge Planning

- Provide truthful information to the person or family affected.
- Discuss signs and symptoms of contamination.
- Explain decontamination protocols.
- Explain need for isolation procedures.
- *Well-managed efforts at communication of contamination information ensure that messages are correctly formulated, transmitted, and received and that they result in meaningful actions.*
- Emphasize the importance of pre- and post-exposure treatment of contamination. *Early treatment decreases associated complications related to contamination (ATSDR, 2014).*
- Provide parents with actionable information to reduce environmental contamination in the home. **EBN**: *A randomized educational intervention to reduce contamination in the home demonstrated significant reduction in biomarker levels and improved environmental health self-efficacy and precaution adoption (Butterfield et al, 2011).*

Risk for Contamination *Betty J. Ackley, MSN, EdS, RN*

NANDA-I

Definition

Vulnerable to exposure to environmental contaminants, which may compromise health

Risk Factors

External

Carpeted flooring; chemical contamination of food; chemical contamination of water; economically disadvantaged; exposure to areas with high contaminant level; exposure to atmospheric pollutants; exposure to bioterrorism; exposure to disaster (natural or man-made); exposure to radiation; flaking, peeling surface in presence of young children (e.g., paint, plaster); inadequate breakdown of contaminant; inadequate household hygiene practices; inadequate municipal services (e.g., trash removal, sewage treatment facilities); inadequate personal hygiene practices; inadequate protective clothing; inappropriate use of protective clothing; playing where environmental contaminants are used; unprotected exposure to chemical (e.g., arsenic); unprotected exposure to heavy metal (e.g., chromium, lead); use of environmental contaminant in the home; use of noxious material insufficiently ventilated area (e.g., lacquer, paint); use of noxious material without effective protection (e.g., lacquer, paint)

Internal

Concomitant exposure; developmental characteristics of children; extremes of age; female gender; gestational age during exposure; inadequate nutrition; preexisting disease; pregnancy; previous exposure to contaminant; smoking

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching, Rationales, and References

Refer to care plans for **Contamination**.

Risk for adverse reaction to iodinated Contrast Media

Paula D. Hopper, MSN, RN, CNE, and Betty J. Ackley, MSN, EdS, RN

NANDA-I

Definition

Vulnerable to noxious or unintended reaction associated with the use of iodinated contrast media that can occur within 7 days after contrast agent injection, which may compromise health

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Risk Factors

Anxiety; chronic illness; concurrent use of pharmaceutical agents (e.g., beta blockers, interleukin-2, metformin nephrotoxins); contrast media precipitates adverse event (e.g., iodine concentration, viscosity, ion toxicity); dehydration; extremes of age; fragile vein (e.g., chemotherapy/radiation in limb to be injected, indwelling line for more than 24 hours, axillary lymph node dissection in limb to be injected, distal intravenous [IV] access site); generalized debilitation; history of allergy; history of previous adverse effect from iodinated contrast media; unconsciousness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Perfusion: Renal; Kidney Function

Example NOC Outcome with Indicators

Kidney Function as evidenced by 24-hour intake and output balance/Blood urea nitrogen/Serum creatinine/Urine color/Serum electrolytes. (Rate the outcome and indicators of **Kidney Function**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain normal blood urea nitrogen and serum creatinine levels
- Maintain urine output of 0.5 mL/kg/hr
- Maintain serum electrolytes (K⁺, PO₄, Na⁺) within normal limits

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Fluid/Electrolyte Management; Laboratory Data Interpretation

Example NIC Activities—Fluid/Electrolyte Management

Monitor for serum electrolytes levels, as available; Weigh daily and monitor trends; Monitor vital signs, as appropriate

Nursing Interventions and Rationales

Recognize that iodinated contrast media can be harmful to clients in a number of ways, including onset of contrast-induced nephropathy, allergic reactions to the dye, and damage to veins and vascular access devices.

Contrast-Induced Nephropathy (CIN)

Protect clients from contrast media induced nephropathy by taking the following actions:

- ▲ Assess clients for low body mass index (BMI) or history of heart failure. Low BMI and heart failure are risk factors for CIN (Balemans et al, 2012).
- ▲ In nondiabetic clients with acute coronary syndrome, assess for presence of hyperglycemia on admission and report to health care provider. “[Index] admission high blood glucose in acute coronary syndrome patients not known to be diabetic is associated with increased incidence of contrast induced nephropathy after percutaneous coronary intervention” (Islam et al, 2013).
- Identify clients who have had multiple doses of iodinated contrast media in less than 24 hours and report to health care provider. *Repeat administration of contrast material may be a risk factor for CIN (American College of Radiology, 2013).*
- Notify the health care provider and the radiology staff if the client has preexisting renal disease. *Clients with preexisting impaired renal function are susceptible to develop acute contrast media-induced nephropathy (Schilcher et al, 2011; Wong et al, 2011).*
- ▲ Ensure that clients having diagnostic testing with contrast are well hydrated with isotonic IV fluids as ordered before and after the examination. **EB:** *Incidence of CIN is reduced by IV hydration with isotonic fluids (lactated Ringer’s or 0.9% normal saline) before and after IV contrast administration (American*

College of Radiology, 2013). Low incidence of CIN is associated with the use of hydration (Balemans et al, 2012).

- ▲ Verify that a baseline serum creatinine has been drawn from clients at risk for CIN. A *baseline value is important for comparison following the contrast injection (American College of Radiology, 2013).*
- Recognize that many clients with decreased renal function are not aware of their health status and that a questionnaire checklist administered before testing may not be satisfactory to determine which clients with impaired renal function should receive contrast media carefully or which are not candidates for testing utilizing contrast media. **EB:** *A study found that use of a preprocedure checklist was not effective in identifying all the clients with a history of chronic kidney disease to protect them from further kidney damage; instead, point-of-care creatinine testing was recommended (Kalisz et al, 2011).*
- Be vigilant for signs of CIN in clients who have cancer. *Clients with cancer are vulnerable to CIN, especially within 45 days of chemotherapy and in those with hypertension (Cicin et al, 2014).*
- Monitor the client carefully for symptoms of hypovolemia following use of contrast media, including measuring intake and output, obtaining blood pressure measurements, and assessing for new onset of postural hypotension with dizziness. *Hypovolemia can result following contrast media administration due to the increased osmolarity of the contrast media, resulting in postprocedure diuresis (O'Donovan, 2011).*
- ▲ Monitor for and report signs of acute kidney injury for 48 hours following iodinated contrast administration in clients at risk: absolute serum creatinine increase ≥ 0.3 mg/dL, percentage increase in serum creatinine $\geq 50\%$, or urine output reduced to ≤ 0.5 mL/kg/hr for at least 6 hours. *These are signs of acute kidney injury (American College of Radiology, 2013).*

Allergic Reaction to Contrast Media

- ▲ Discuss premedication with steroids or diphenhydramine with health care provider for clients who have had previous reactions to contrast media. *Premedication may reduce the incidence of allergic reaction in some clients (American College of Radiology, 2013).*
- ▲ Monitor carefully for symptoms of a reaction, which can be mild, moderate, or severe. Report all symptoms to primary care provider because symptoms can advance rapidly from mild to severe.
 - *Mild reactions:* Urticaria, pruritus, rhinorrhea, nausea, emesis, diaphoresis, coughing, dizziness
 - *Moderate reactions:* Persistent emesis, widespread urticaria, headache, edema of the face, laryngeal edema, mild dyspnea, palpitations, tachycardia/bradycardia, hypertension, abdominal cramps
 - *Severe reactions:* Severe bronchospasm, severe arrhythmias, severe hypotension, pulmonary edema, laryngeal edema, seizures, syncope, death (Wilson, 2011)
 - *Both allergic and allergic-like (anaphylactoid) reactions can occur. Life-threatening events usually occur within 20 minutes after injection (American College of Radiology, 2013).*

Vein Damage and Damage to Vascular Access Devices

- Recognize that only vascular access devices labeled “power injectable” can be used to administer power injected contrast media. These include a power port, a power PICC line, and a power central venous catheter (Radiology and Biomedical Imaging, 2014). *A regular vascular access device used for administration of contrast media can rupture from the high pressures used to administer the contrast media. EB:* *A retrospective study of the function of 204 power ports found that they are safe for use with power injections of contrast media (Goltz et al, 2012). The U.S. Food and Drug Administration has received more than 250 adverse event reports in which vascular access devices have ruptured when used with power injectors. The adverse events include rupture and device fragmentation (Earhart & McMahon, 2011).*
- Reduce the risk of vein and vascular access device damage with the following:
 - Maintain constant communication with the client during the injection. Discontinue the injection if the client reports pain or the sensation of swelling at the injection site. *These are signs of complications (American College of Radiology, 2013).*
 - Be vigilant in clients at increased risk of extravasation. *Clients at increased risk include those who cannot communicate such as infants, older adults, or those with altered consciousness; severely ill or debilitated clients; clients with abnormal circulation in the affected limb; clients receiving the injection via a peripheral IV line that has been in place for more than 24 hours or into a vein that has been punctured multiple times; clients with arterial insufficiency or compromised venous or lymphatic drainage in the affected extremity (American College of Radiology, 2013).*
 - Assess for venous backflow before injecting contrast. *If backflow is not obtained, the catheter may need adjustment (American College of Radiology, 2013).*

- Directly monitor and palpate the venipuncture site during the first 15 seconds of injection. *A critical step in preventing significant extravasation is direct monitoring of the venipuncture site (American College of Radiology, 2013).*
- After diagnostic testing using contrast media given intravenously, inspect the IV site used for administration for possible problems, such as extravasation or development of compartment syndrome with excessive amounts of contrast pushed into the tissues under pressure. *The incidence of serious complications associated with the media has increased since advent of use of power or pressure mechanical injectors. Although rare, compartment syndrome can result in infection, loss of use of the affected extremity, necrosis, skin sloughing, amputation, need for skin grafting, paralysis, and death (Wilson, 2011).*

Geriatric

- Screen the older client thoroughly before diagnostic testing utilizing contrast media. *Older adults are more likely to have preexisting renal failure along with other comorbidities and are more vulnerable to development of renal damage (O'Donovan, 2011).*

Compromised family Coping Katherina Nikzad-Terhune, PhD, LCSW

NANDA-I

Definition

A usually supportive primary person (family member, significant other, or close friend) provides insufficient, ineffective, or compromised support, comfort, assistance, or encouragement that may be needed by the client to manage or master adaptive tasks related to his or her health challenge

Defining Characteristics

Assistive behaviors by support person produce unsatisfactory results; client complaint about support person's response to health problems; client concern about support person's response to health problem; limitation in communication between support person and client; protective behavior by support person incongruent with client's abilities; protective behavior by support person incongruent with client's need for autonomy; support person reports inadequate understanding that interferes with effective behaviors; support person

reports insufficient knowledge that interferes with effective behaviors; support person reports preoccupation with own reaction to client's need; support person withdraws from client

Related Factors (r/t)

Coexisting situations affecting the support person; developmental crises experienced by support person; exhaustion of support person's capacity; family disorganization; family role change; insufficient information available to support person; insufficient reciprocal support; insufficient support given by client to support person; insufficient understanding of information by support person; misinformation obtained by support person; preoccupation by support person with concern outside of family; prolonged disease that exhausts capacity of support person; situational crisis faced by support person

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Caregiver Emotional Health; Caregiver-Client Relationship; Family Coping; Family Participation in Professional Care; Family Support During Treatment

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Confronts family problems/Manages family problems/Reports needs for family assistance. (Rate each indicator of **Family Coping**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)].)

Client Outcomes

Family/Significant Person Will (Specify Time Frame)

- Verbalize internal resources to help deal with the situation
- Verbalize knowledge and understanding of illness, disability, or disease
- Provide support and assistance as needed
- Identify need for and seek outside support

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Caregiver Support; Coping Enhancement; Family Involvement Promotion; Family Mobilization; Family Support; Mutual Goal Setting; Normalization Promotion; Sibling Support

Example NIC Activitis—Family Support

Appraise family's emotional reaction to client's condition; Promote trusting relationship with family

Nursing Interventions and Rationales

- Assess the strengths and deficiencies of the family system. **EBN**: *Thorough and comprehensive assessments offer valuable information regarding how problems evolve within the family context over time, and allow for anticipatory care and guidance to help family members acquire and maintain support and coping strategies (Wright & Leahey, 2012).*
- Establish rapport with families by providing accurate communication. **EBN**: *Enthusiasm or interest demonstrated by health care professionals helps establish stronger rapport and a therapeutic relationship with clients (Bahrami, 2011).*
- Assist family members to recognize the need for help and teach them how to ask for it.
- Encourage expression of positive thoughts and emotions to help reduce stress. **EB**: *A comprehensive survey of meta-analyses examining the efficacy of cognitive behavioral therapy (CBT) found it to be a strong evidence-based intervention to use with a variety of complex issues, including stress reduction (Hofmann et al, 2012).*
- Encourage family members to verbalize feelings. Spend time with them, sit down and make eye contact, and offer coffee and other nourishment.

- Incorporate family variables, including dyadic adjustment, into assessment protocols and intervention strategies. **EB:** *Pereira et al (2012) revealed a positive relationship among dyadic adjustment, psychological morbidity, and family coping in clients and their partners, in that better dyadic adjustment predicted family coping in the client.*
- Provide privacy during family visits. If possible, maintain flexible visiting hours to accommodate more frequent family visits. If possible, arrange staff assignments so the same staff members have contact with the family. Familiarize other staff members with the situation in the absence of the usual staff member. Providing privacy, maintaining flexible hours, and arranging consistent staff assignments reduces stress, enhances communication, and facilitates the building of trust.
- Provide education to clients regarding active coping strategies to use in situations involving chronic illnesses. **EBN:** *Active coping strategies, including planning, giving priority, reappraisal, waiting, and acceptance, were predictive of better quality of life and lower levels of depression and hopelessness in cancer clients (van Laarhoven et al, 2011).*
- Use evidence-based tools to assess for post-intensive care syndrome (e.g., anxiety, acute stress disorder, posttraumatic stress, depression, and complicated grief) in families who have experienced a critical illness. **EB:** *Prevention strategies for post-intensive care syndrome include adequate communication and involving families in decision-making processes, while treatment strategies include support groups and referrals for treatment (Davidson et al, 2012).*
- Refer the family with ill family members to appropriate resources for assistance as indicated (e.g., counseling, psychotherapy, financial assistance, or spiritual support).

Pediatric

- Provide screening for postpartum depression (PPD) during the prenatal period and during the 6-week postpartum check-up to identify symptoms of depression in mothers. **CEB:** *The Edinburgh Postnatal Depression Scale (EPDS) is the most widely used screening tool for detecting PPD and has been shown to be effective both prenatally and postnatally for detecting symptoms of depression in women (Cox et al, 1987).*
- ▲ Consider medication management and psychosocial interventions, including individual therapy, group therapy, support groups, and brief psychotherapy. **EB:** *These are effective treatment strategies for managing PPD (Miniati et al, 2014; Kleiman & Raskin, 2013).*
- ▲ Use preventive strategies, such as screening, psychoeducation, postpartum debriefing, and companionship in the delivery room (e.g., community volunteer). **EBN:** *These strategies play an important role in the prevention of and recovery from PPD (Dennis & Dowswell, 2013).*
- Provide educational and psychosocial interventions, such as coping skills training, in treatment for families and their adolescents who have diabetes. **EBN:** *Educational and support interventions help improve coping skills for parents of adolescents with diabetes (Konradsdottir & Svavarsdottir, 2011).*
- Provide readily available resources to support parents of children with autism and their families. **EBN:** *Study findings from Hall (2011) highlighted the association between the low adaptive functioning of the child with autism and increased parental stress, the need for additional family support, and the need for effective coping strategies.*
- Provide family-centered care during neonatal intensive care to encourage family members to play an active role in providing emotional, social, and developmental support. **EBN:** *When neonatal intensive care unit staff collaborate with parents, families become more involved in decision-making processes and care planning, and are empowered to impact the process of their infant's recovery (Gooding et al, 2011).*
- Provide evidence-based psychological therapies for parents with children with chronic conditions. **EB:** *Psychological therapies (e.g., cognitive behavioral therapy and problem-solving therapy) that included parents significantly improved child symptoms for painful conditions immediately after treatment (Eccleston et al, 2012).*
- Assist with fostering co-parenting alliances in fragile families. **EB:** *Providing preventive interventions to support the development of a positive co-parenting alliance between parents who have not made an enduring relationship commitment to one another can help benefit children and families (McHale et al, 2012).*
- Provide options for home-based interventions when severe childhood illnesses make it difficult for children and families to participate in interventions. **EBN:** *A home-based 12-week cognitive training program for child cancer survivors yielded significant increases in working memory and decreases in parent-rated attention problems following the intervention (Hardy et al, 2011).*

Geriatric

- ▲ Perform a holistic assessment of all needs of informal spousal caregivers. **EBN:** *Caregiver assessments should be systematic, should take into consideration the caregiver's perspective, and should include follow-up on care coordination and linkages to services (Levine, 2011). Refer caregivers of clients with Alzheimer's disease to a monthly psychoeducational support group (i.e., the Alzheimer's Association), and incorporate nonpharmacological support programs for caregivers. EB: Nonpharmacological interventions, such as skill training programs for stress management, in home support, individual or group psychotherapy, and respite programs, demonstrate efficacy in reducing caregiver stress and burden (Gallagher-Thompson et al, 2012).*
- ▲ Provide caregivers with options for Internet-based support strategies to enhance coping. **EB:** *Creating bonds between caregivers using online support programs produces beneficial psychological outcomes among caregivers, including improved coping (Namkoong et al, 2012).*
- Assist in finding transportation to enable family members to visit. **EB:** *If a family member is homebound and unable to visit, encourage alternative contact (e.g., telephone, cards and letters, email) to provide ongoing scheduled progress reports and to help reduce loneliness and isolation. Visually impaired older adults, who experience more limitations with driving, have a higher risk for loneliness (Alma et al, 2011).*
- Assist informal caregivers with reducing unmet needs by helping them obtain the information and education necessary for caring for an older adult with a chronic health condition. **EB:** *Evidence supports the use of a health information delivery system (e.g., providing information that is proactive, understandable, and individualized) specifically designed to meet the unique needs of informal caregivers of older adults with chronic health conditions (Washington et al, 2011).*

Multicultural

- Acknowledge racial/ethnic differences at the onset of care. **EBN:** *Accurate cultural knowledge assists in enhancing the ability of health care service providers to identify and understand cultural factors that influence diagnosis, treatment, and illness management, and create warm and trusting relationships with their clients (Higginbottom et al, 2011).*
- Assess for the influence of cultural beliefs, norms, and values on the individual/family/community's perceptions of coping. **EB:** *Cultural values are a valid predictor of coping when traits are taken into account (Bardi & Guerra, 2011).*
- Use valid and culturally competent assessment tools and procedures when working with families with different racial/ethnic backgrounds. **EBN:** *The cultural information in nursing models and assessments should encompass health beliefs and practices, communication styles, religious orientation, and the degree of acculturation amongst others (Higginbottom et al, 2011).*
- Provide culturally relevant interventions by understanding and using treatment strategies that are acceptable and effective for a particular culture. **EB:** *Interventions should be theoretical based and incorporate cultural beliefs within a contextual framework in order for prevention and risk reduction messages to reach targeted at risk populations (Wyatt et al, 2012).*
- Provide opportunities for families to discuss spirituality. **EBN:** *African American women with breast cancer use more positive religious coping and experience less distress and greater spiritual well-being (Gaston-Johansson et al, 2013).*
- Determine how the family's cultural context impacts their decisions in regard to managing and coping with a child's illness; recognize and validate the cultural context. **EBN:** *Nurses and other clinicians working with families must include cultural variables when assisting family members with ill children, and demonstrating competency and respect for one's cultural values helps ensure the good of the client as well as client autonomy (Leever, 2011).*

Home Care

- The interventions described previously may be adapted for home care use.
- Assess the reason behind the breakdown of family coping. *Knowledge of the reasons behind compromised coping will assist in identification of appropriate interventions. Refer to the care plan for Caregiver Role Strain.*
- During the time of compromised coping, increase visits to ensure the safety of the client, support of the family, and reassurance regarding expectations for prognosis as appropriate. **EBN:** *When providing care in the home setting, conforming to the norms and values of clients and their families is extremely important for building rapport and ensuring a sense of safety (Lindahl et al, 2011).*

- ▲ Assess the needs of the caregiver in the home, and intervene to meet needs as appropriate; explore all available resources that may be used to provide adequate home care (e.g., parish nursing as an effective adjunct, home health aide services to relieve the caregiver's fatigue).
- ▲ Encourage caregivers to attend to their own physical, mental, and spiritual health, and give more specific information about the client's needs and ways to meet them.
- ▲ Refer the family to medical social services for evaluation and supportive counseling. Serve as an advocate, mentor, and role model for caregiving; provide written information for the care needed by the client.
- ▲ A positive approach and caring by the nurse and concrete task definition and assignment reinforce positive coping strategies and allow caregivers to feel less guilty when tasks are delegated to multiple caregivers.
- ▲ When a terminal illness is the precipitating factor for ineffective coping, offer hospice services and support groups as possible resources. **EBN:** *Research suggests that clients and their families highly value hospice care services and report experiencing beneficial outcomes as a result of using hospice services, including effective pain management and avoiding death in the hospital setting (Candy et al, 2011).*
- Encourage the client and family to discuss changes in daily functioning and routines created by the client's illness, and validate discomfort resulting from changes. *Individuals who live together for a long period tend to become familiar with each other's patterns: for example, meals are expected at certain times or a spouse becomes accustomed to the client's sleep habits.*
- Support positive individual and family coping efforts. *Positive feedback reinforces desired behaviors and supports the family unit.*
- ▲ If compromised family coping interferes with the ability to support the client's treatment plan, refer for psychiatric home health care services for family counseling and/or Internet-based behavioral interventions. **EBN:** *Schubart et al (2011) identified two characteristics contributing to Internet interventions that engage users: (1) the intervention targets participants with serious health concerns, and (2) the intervention adapts to individual needs.*

Client/Family Teaching and Discharge Planning

- Assess for and address grief issues that arise in the process, including anticipatory grief. **EB:** *Research conducted by Garand et al (2012) revealed high levels of anticipatory grief in dementia caregivers, suggesting that this grief reaction may be highest at the earliest stages of Alzheimer's disease caregiving, or when family members begin to provide care assistance to their loved one with mild cognitive impairment.*
- ▲ Refer women with breast cancer and their family caregivers to support groups and other services that provide assistance with daily coping. Refer women with breast cancer and their family caregivers to support groups, including social network sites and online communities, to provide assistance with daily coping. **EB:** *Social network sites and online communities present a convenient way to exchange information and support for breast cancer survivors, including awareness, service promotion, client/caregiver support, and fundraising (Bender et al, 2011).*
- Promote individual and family relaxation and stress-reduction strategies. *The immune system weakens in response to stress; persistent relaxation may elicit positive effects on one's immune system (Kang et al, 2011).*
- ▲ Refer parents to support and education groups to provide opportunities for parents to access support, learn new parenting skills, and ultimately, optimize their relationships with their children after divorce. **EB:** *Through education, parents can be taught to improve the quality of their parenting, which has been linked to improvements in children's academic functioning and reductions in children's mental health and substance use problems (Sigal et al, 2011).*
- Provide Internet-based resources, including online social networking groups, to enhance social support, bonding, and coping for caregivers. **EB:** *Perceived bonding through social support yields positive effects on caregivers' problem-focused coping strategies (Namkoong et al, 2012).*

Defensive Coping Arlene T. Farren, RN, PhD, AOCN, CTN-A

NANDA-I

Definition

Repeated projection of falsely positive self-evaluation based on a self-protective pattern that defends against underlying perceived threats to positive self-regard

Defining Characteristics

Alteration in reality testing; denial of problems; denial of weaknesses; difficulty establishing relationships; difficulty maintaining relationships; grandiosity; hostile laughter; hypersensitivity to a discourtesy; hypersensitivity to criticism; insufficient follow through with treatment; insufficient participation in treatment; projection of blame; projection of responsibility; rationalization of failures; reality distortion; ridicule of others; superior attitude toward others

Related Factors

Conflict between self-perception and value system; fear of failure; fear of humiliation; fear of repercussions; insufficient confidence in others; insufficient resilience; insufficient self-confidence; insufficient support system; uncertainty unrealistic self-expectations

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Decision-Making; Impulse Self-Control; Information Processing

Example NOC Outcome with Indicators

Coping as evidenced by the following indicators: Identifies effective and ineffective coping patterns/Modifies lifestyle to reduce stress. (Rate the outcome and indicators of **Coping**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Acknowledge need for change in coping style
- Accept responsibility for own behavior
- Establish realistic goals with validation from caregivers
- Solicit caregiver validation in decision-making

NIC (Nursing Interventions Classification)

Suggested Nursing Interventions

Body Image Enhancement; Complex Relationship Building; Coping Enhancement; Patient Contracting; Resiliency Promotion; Self-Awareness Enhancement; Self-Esteem Enhancement; Socialization Enhancement; Surveillance

Example NIC Activities—Self-Awareness Enhancement

Encourage client to recognize and discuss thoughts and feelings; Assist client in identifying behaviors that are self-destructive

Nursing Interventions and Rationales

- Assess for possible symptoms associated with defensive coping: depressive symptoms, excessive self-focused attention, negativism and anxiety, hypertension, posttraumatic stress disorder (e.g., exposure to terrorism), unjust world beliefs. **EB**: *In a study of coping styles and anxiety in a small sample (N = 47) of persons with chronic low back pain, researchers found evidence of more defensiveness than in the general population. Researchers suggested that individuals with defensive high-anxious coping styles may be at risk for poorer psychological and physical outcomes and recommended assessment of these characteristics and further research to ensure appropriate treatments and improved outcomes (Lewis et al, 2012).* **EB**: *Defensive reactions were present in a sample of college women (N = 1679) who identified as having experience with childhood abuse or other traumas; researchers concluded that victims' defensive reactions to trauma may contribute to the unique effects of trauma (Bottoms et al, 2012).*
- ▲ Use cognitive behavioral interventions. **EBN**: *In a randomized control trial (N = 240), 120 in each group—experimental and control), a nurse-led cognitive behavioral intervention addressed inaccurate thinking and*

promoted more positive self-regard; the experimental group had improved quality of life, which included physical and psychological health, relief of symptom, and social functioning (Zhuang et al, 2013).

- Ask appropriate questions to assess whether denial (defensive coping) is being used in association with health problems including alcoholism, myocardial infarction (MI), or rheumatoid arthritis. **EBN:** In a qualitative study of 28 people after MI, researchers found that those who used negative coping, including denial and defensive coping, did not make the necessary changes toward physical and psychological health and experienced depression; researchers recommended follow-up care including psychoeducational interventions (Salminen-Tuomaala et al, 2012). **EBN:** In a case-based article, Wilson (2013) demonstrates a nurse-provided approach to Screening, Brief Intervention, and Referral to Treatment (SBIRT), an approach recommended by the Substance Abuse and Mental Health Services Administration (2015), in a client requiring a peripherally inserted central catheter for a man with liver disease due to alcoholism. **EB:** In a 5-year prospective study of adults with rheumatoid arthritis (N = 74), researchers found that defensive coping impacted responses to pain and overall health, leading to poorer outcomes (Goulia et al, 2015).
- Promote interventions with multisensory stimulation environments. **EB:** In a review of the literature regarding sharing multisensory body space with others for those with altered bodies, such as amputations or congenital limb absence, researchers concluded that sharing multisensory body space is pertinent and may close the gap between neurology and psychiatry in the treatment of persons with altered bodies (Brugger & Lenggenhager, 2014).
- Empower the client/caregiver's self-knowledge. **EB:** In a qualitative study of adults receiving highly active antiretroviral treatment for HIV and methadone maintenance, participants described tension between negative feelings such as denial and positive feelings of empowerment (Batchelder et al, 2013).

Geriatric

- ▲ Identify problems with alcohol in older adults with the appropriate tools and make suitable referrals. **EB:** Community-dwelling older adults (N = 370) completed the Drinking Motives Questionnaire (DMQ); findings indicated that the most frequent motivation for drinking was social, with enhancement and coping motives, respectively, as the top three motivations (Gilson et al, 2013). **CEB:** Tools such as the Alcohol Use Disorders Identification Test (AUDIT), Michigan Alcohol Screening Test-Geriatric Version (MAST-G), and the Alcohol-Related Problems Survey (ARPS) may have additional use in this population. Brief interventions have been shown to be effective in producing sustained abstinence or reducing levels of consumption, thereby decreasing hazardous and harmful drinking (Culbertson, 2006).
- Encourage exercise for positive coping. **EBN:** One research group identified that exercise is known to facilitate maintenance of functional abilities in older adults and tested an intervention to encourage older adults (N = 106) to engage in physical activity/exercise using peer mentors. The researchers found high participation and retention and improved fitness scores in all mentored groups (Dorgo et al, 2013). **EB:** Researchers performed a secondary analysis of data to examine the use of physical activity (PA) in mid and older adults during a smoking cessation attempt (N = 799), the researchers found that physical activity, primarily walking, was used by only a small percent of participants (11.6%); women were more likely to use PA as a coping strategy than men; the researchers recommend further study and approaches that encourage older adults to engage in PA for general health and quality of life (Treviño et al, 2014).
- Stimulate individual reminiscence therapy. **EBN:** Structured reminiscence is an evidence-based, independent nursing intervention that is used with individuals and groups and is used to increase emotional awareness and enhance social interactions in older adults (Stinson & Long, 2014).
- Stimulate group reminiscence therapy. **EBN:** Stinson's structured group reminiscence is a multisession evidence-based approach used with older adults (Stinson & Long, 2014). **EB:** A multimedia intergenerational reminiscence program was tested in a small (N = 26) group of community-dwelling older adults; qualitative data from stories and focus groups indicated the intervention showed promise as a group intergenerational intervention (Chonody & Wang, 2013).

Multicultural

- Acknowledge racial/ethnic differences at the onset of care. **EB:** In a qualitative study of white professionals working with racial minority immigrant clients, researchers found that while some professionals reported being comfortable discussing race and cultural differences, some expressed discomfort and difficulty, and others did not perceive race and culture to be a priority; the researchers recommended further attention to cultural competence training in clinical programs (Singer & Tummala-Narra, 2013).

- Assess an individual’s sociocultural backgrounds in teaching self-management and self-regulation. **EBN:** *A systematic review of qualitative evidence related to women’s coping with type 2 diabetes indicated that in multiple countries self-management is challenged by the complexities of regimens and women’s multiple-caregiving roles; researchers recommended recognition of the coping and emotional factors by health care providers; families, and friends, psychoeducation programs for clients and families, and enhanced support of family and friends (Li et al, 2014).* **EB:** *In a study of the Cellie Coping Kit for Sickle Cell Disease, researchers provided the intervention to 15 black/African American children aged 6 to 14 years and their health care providers; although the researchers reported strong acceptability, some sociocultural issues like living situation and health literacy did provide challenges to the use of the tool (Marsac et al, 2014).*
- Encourage the client to use spiritual coping mechanisms such as faith and prayer. **CEB/EBN:** *In a qualitative study of Thai Buddhist and Muslim women’s (N = 48) use of religion and spiritual practices related to self-management of type 2 diabetes, researchers found four themes that related to cultural or spiritual practices, including prayer, that helped them cope, despite poor glycemic control (Lundberg & Thrakul, 2013).* **EB:** *In a study of religion and coping with racial discrimination among African American (N = 2032) and Caribbean blacks (N = 857), researchers found that both groups were similar in their likelihood of using prayer for coping with discrimination (Hayward & Krause, 2015).*
- Encourage spirituality as a source of support for coping. **EBN:** *In a small (N = 17) pilot study of African American women with breast cancer, women reported high levels of spiritual and positive religious coping (sense of purpose in life) strategies such as prayer; researchers recommended that although the findings of the pilot are not generalizable, spirituality and religious coping need to be explored as core coping mechanisms for African American women with breast cancer (Gaston-Johansson et al, 2013).*

Home Care

- ▲ Refer the client for programs that teach coping skills. **EBN:** *In a small pilot study of an intervention with mothers and their children who were exposed to domestic violence, researchers found preliminary evidence that the intervention (a relationally based multi-method program) improved defensive avoidance (Kearney & Cushing, 2012).* **EB:** *Researchers examining bullying and the association with cultural/family factors, substance use, and depressive symptoms in ninth and tenth grade Hispanic youth (N = 1167) found the stress of acculturation was associated with substance use and depressive symptoms and the need for the development of coping skills in youth; recommendations included school-based programs to teach coping skills (Forster et al, 2013).*

Client/Family Teaching and Discharge Planning

- Teach coping skills to clients and caregivers. **EBN:** *Teaching and modeling problem-solving skills to mothers with children who were exposed to domestic violence improved defensive avoidance (Kearney & Cushing, 2012).* **EBN:** *In a trial of a culturally adapted cognitive behavioral therapy intervention to promote coping skills among Chinese Americans with type 2 diabetes, strategies and coping skills that addressed personal, family, and illness specific topics were included; researchers reported enhanced efficacy for self-management (Chesla et al, 2013).*
- Teach reflexive and expressive writing to address emotions. **EBN:** *Journaling was used in an intervention study to enhance civility among nursing students; researchers found coping improvements in self-controlling and positive reappraisal (Jenkins et al, 2013).* **EB:** *In a randomized trial of expressive writing in the third person, 44 undergraduates wrote about their deepest thoughts and feelings about a traumatic or very stressful life event; findings included less intrusive thinking in both groups but third-person writers had better outcomes in overall health than did the first-person writers; researchers recommend third-person expressive writing for those recovering from traumatic or highly stressful events (Andersson & Conley, 2013).*

Ineffective community Coping Roberta Dobrzanski, MSN, RN

NANDA-I

Definition

A pattern of community activities for adaptation and problem solving that is unsatisfactory for meeting the demands or needs of the community

Defining Characteristics

Community does not meet expectations of its members; deficient community participation; elevated community illness rate; excessive community conflict; excessive stress; high incidence of community problems (e.g., homicides, vandalism, terrorism, robbery, abuse, unemployment, poverty, militancy, mental illness); perceived community powerlessness; perceived community vulnerability

Related Factors

Exposure to disaster (natural or man-made); history of disaster (e.g., natural, man-made); inadequate resources for problem solving; insufficient community resources (e.g., respite, recreation, social support); nonexistent community systems

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Community Competence; Community Health Status; Community Violence Level

Example NOC Outcome with Indicators

Community Competence as evidenced by the following indicators: Participation rates in community activities/ Consideration of common and competing interests among groups when solving community problems/Representation of all segments of the community in problem solving/Effective use of conflict management strategies. (Rate the outcome and indicators of **Community Competence**: 1 = poor, 2 = fair, 3 = good, 4 = very good, 5 = excellent [see Section I].)

Community Outcomes**A Broad Range of Community Members Will (Specify Time Frame)**

- Participate in community actions to improve power resources
- Develop improved communication among community members
- Participate in problem solving
- Demonstrate cohesiveness in problem solving
- Develop new strategies for problem solving
- Express power to deal with change and manage problems

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Community Health Development; Program Development

Example NIC Activities—Community Health Development

Enhance community support networks; Identify and develop potential community leaders; Unify community members behind a common mission; Ensure that community members maintain control over decision-making

Nursing Interventions and Rationales

NOTE: The diagnosis of Ineffective Coping does not apply and should not be used when stress is being imposed by external sources or circumstance. If the community is a victim of circumstances, using the nursing diagnosis Ineffective Coping is equivalent to blaming the victim. See the care plan for Readiness for enhanced community Coping.

- ▲ Establish a collaborative partnership with the community (see the care plan for Readiness for enhanced community Coping for additional references). **EBN**: *Community activation to promote health encompasses organized efforts in increased community awareness, establishes a general consensus about health problems, coordinates partnerships to change environmentally based health issues, allocates resources across organizations, and promotes citizen participation in positive health outcomes (Pender et al, 2011).*
- Assist the community with team building. **EBN**: *Health partnerships across various community settings help optimize the health of the community, promote continuity of care, and synergistically use resources to achieve optimal efficiency and enhanced effectiveness (Pender et al, 2011).*
- Participate with community members in the identification of stressors and assessment of distress; for example, observe and participate in faith-based organizations that want to improve community stress management. **EBN**: *Health programs in faith-based organizations are increasingly forming partnerships with nursing for health promotion programs and make a significant difference in health outcomes (Anderson & McFarlane, 2011).*
- ▲ Identify the health services and information resources that are currently available in the community. **EBN**: *Gynecological cancer survivors in Queensland were studied to identify awareness of, utilization of, and factors associated with use of community support services. Seventy-two percent were aware of the primary cancer support organization, Cancer Council Queensland; 74% were aware of booklets; 66% were aware of helplines; 56% were aware of support groups, and 50% were aware of Internet resources. Less than half were aware of other services (Beesley et al, 2010).*

- ▲ Consult with community mediation services, for example, the National Association of Community Mediation. **EB:** *Community mediation services effectively resolve conflicts and encourage stakeholders to exert direct and indirect pressure within the community (Handley & Howell-Moroney, 2010).*
- Work with community members to increase awareness of ineffective coping behaviors (e.g., conflicts that prevent community members from working together, anger and hate that paralyze the community, health risk behaviors of adolescents). **EBN:** *Problem solving is essential for effective coping. Community members in partnership with health care providers can modify behaviors that interfere with problem solving (Anderson & McFarlane, 2011).*
- Provide support to the community and help community members identify and mobilize additional supports. **EBN:** *Often people need help mobilizing supports that are available (Pender et al, 2011).*
- Advocate for the community in multiple arenas (e.g., television, newspapers, and governmental agencies). **EBN:** *Advocacy is a specific form of caring that enhances power resources for community coping (Anderson & McFarlane, 2011).*
- Write grant proposals to help community members obtain funds for programs that reduce stress or improve coping. **EBN:** *The programs that are necessary may be expensive, and often funds may not be available without the assistance of public or privately funded grants (Anderson & McFarlane, 2011).*
- Work with members of the community to identify and develop coping strategies that promote a sense of power (e.g., obtaining sources for funding, collaborating with other communities). **EBN:** *A first step in power enhancement is for the community to identify and develop its own coping strategies (Anderson & McFarlane, 2011).*
- Protect children from exposure to community conflicts. **EB:** *McKelvey et al (2011) examined the extent to which community violence impacts 18-year-old adolescents' psychosocial outcomes and found that the effects of community violence differ based on gender and family conflict in the home during childhood, influencing adolescent depression, anxiety, risk taking, and antisocial behavior.*

Multicultural

- Acknowledge the stressors unique to racial/ethnic communities. **EBN:** *Understanding ethnic interpretations and cultural determinants that contribute to clients' stress assists the nurse in promoting health within a community (Anderson & McFarlane, 2011).*
- Identify community strengths with community members. **EB:** *Latino men from three urban housing communities in the southeastern United States identified Latino community strengths and general community strengths as factors that promote health and prevent risk (Rhodes et al, 2009).*
- Work with members of the community to prioritize and target health goals specific to the community. **EB:** *Such prioritization and targeting will increase feelings of control over and sense of ownership of programs (Anderson & McFarlane, 2011; Chinn, 2012).*
- Establish and sustain partnerships with key individuals within communities when developing and implementing programs. **EB:** *Health partnerships between collaborating parties are a crucial strategy to optimize the health of a community (Pender et al, 2011).*
- Use mentoring strategies for community members. **EB:** *In a study of child vaccination in Haiti, it was found that mother's use of traditional healer services was negatively associated with vaccination of their children, underscoring the potential of enlisting the support of traditional healers in promoting child health by mentoring and educating traditional healers in supporting vaccination efforts (Muula et al, 2009).*
- Use community church settings as a forum for advocacy, teaching, and program implementation. **EBN:** *Participant and pastor feedback supported the feasibility of ongoing faith-based screening and education programs as one way to reduce risk factors for diabetes, cardiovascular disease, and stroke in Southern rural African Americans (Frank & Grubbs, 2008).*

Community Teaching

- Teach strategies for stress management.
- Explain the relationship between enhancing power resources and coping.

Ineffective Coping *Arlene T. Farren, RN, PhD, AOCN, CTN-A*

NANDA-I

Definition

Inability to form a valid appraisal of the stressors, inadequate choices of practiced responses, and/or inability to use available resources

Defining Characteristics

Alteration in concentration; alteration in sleep pattern; change in communication pattern; destructive behavior toward others; destructive behavior toward self; difficulty organizing information; fatigue; frequent illness; inability to ask for help; inability to attend to information; inability to deal with a situation; inability to meet basic needs; inability to meet role expectation; ineffective coping strategies; insufficient access of social support; insufficient goal directed behavior; insufficient problem resolution; insufficient problem-solving skills; risk taking behavior; substance abuse

Related Factors

Gender differences in coping strategies; high degree of threat; inability to conserve adaptive energies; inaccurate threat appraisal; Inadequate confidence in ability to deal with a situation; inadequate opportunity to prepare for stressor; inadequate resources; ineffective tension release strategies; insufficient sense of control; insufficient social support; maturational crisis; situational crisis; uncertainty

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Decision-Making; Impulse Self-Control; Information Processing

Example NOC Outcome with Indicators

Coping as evidenced by the following indicators: Identifies effective and ineffective coping patterns/Modifies lifestyle to reduce stress. (Rate the outcome and indicators of **Coping**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Use effective coping strategies
- Use behaviors to decrease stress
- Remain free of destructive behavior toward self or others
- Report decrease in physical symptoms of stress
- Report increase in psychological comfort
- Seek help from a health care professional as appropriate

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Decision-Making Support

Example NIC Activities—Coping Enhancement

Assist the client in developing an objective appraisal of the event; Explore with the client previous methods of dealing with life problems

Nursing Interventions and Rationales

- Observe for contributing factors of ineffective coping such as poor self-concept, grief, lack of problem-solving skills, lack of support, recent change in life situation, maturational or situational crises. **EBN:** *Factors predicting caregiver burden among caregivers of individuals with dementia (N = 302) included the number of hours of caregiving, lack of support, co-residence, spousal status, and use of coping strategies (Kim et al, 2012).* **EB:** *In a large sample (N = 758) of people living with HIV, the top three life stressors identified were taking on too many things at once, not having enough money for what is needed, and having a scary experience in childhood that one continues to think about (Gibson et al, 2011).*
- Use verbal and nonverbal therapeutic communication approaches including empathy, active listening, and confrontation to encourage the client and family to express emotions such as sadness, guilt, and anger (within appropriate limits); verbalize fears and concerns; and set goals. **EBN:** *Active, empathic listening and values clarifying communication techniques are strategies used by neonatal intensive care nurses (N = 25) engaged in a pilot study of a guided family-centered care intervention to support parents' coping strategies (Weis et al, 2014).* Likewise, positive health care provider communication techniques were also found to be important for coping with all the phases of the cancer experience (Molina et al, 2014). Collaborate with the client to identify strengths such as the ability to relate the facts and to recognize the source of stressors. **EBN:** *Northouse (2012) made recommendations such as identifying strengths in clients and family caregivers to help them cope with cancer based on a program of research.* **EB:** *Ruddick (2011) describes solution-focused communications as enhancing the identification of strengths and resources for coping.*
- Encourage the client to describe previous stressors and the coping mechanisms used. **EB:** *Researchers found that fatigue in mothers of children with an autism spectrum disorder due to problematic child behaviors was associated with ineffective coping and maternal stress (Seymour et al, 2013).* Be supportive of coping behaviors; allow the client time to relax. **CEBN:** *Solari-Twadell (2010) found a selection of nursing interventions used by parish nurses (N = 1161) to provide coping assistance to women including presence, touch, emotional support, and coping enhancement.*
- Provide opportunities for the client to discuss the meaning the situation might have for the client. **EBN:** *Qualitative researchers in the Netherlands found that adults recently admitted to a nursing home described the meaning of the situation in conflicting ways; some individuals expressed a sense of meaninglessness due to feelings of boredom, loneliness, or lack of hope for improvement, and others expressed a sense of meaning in their lives and their contributions to society, which contributed to their coping capacity and sense of dignity (Oosterveld-Vlug et al, 2014).* **EBN:** *Elmir (2014) interviewed 21 women who experienced postpartum hemorrhage and emergency hysterectomy and found that all the women found meaning in life that helped them cope with the situation and get on with their lives in the aftermath of the emergency situation.*
- Assist the client to set realistic goals and identify personal skills and knowledge. **EB:** *In a qualitative study, adults (N = 9) who were able to lose 10% of body weight and maintain the loss for a minimum of 12 months differed from those (N = 9) who were not successful at weight maintenance on factors such as realistic goal setting, self-monitoring, and other effective coping skills (McKee et al, 2013).*
- Provide information regarding care before care is given. **EBN:** *Family members of intensive care unit clients at risk for dying identified nursing actions such as providing information helped family members to cope (Adams et al, 2014).*
- Discuss changes with the client before making them. **EBN/QSEN:** *Knobf (2013) discusses the ways being prepared is essential to persons with cancer throughout the survivorship trajectory; it helps to deal with uncertainty, develop awareness of the illness and treatments, and provide client-centered, safe, quality cancer nursing care.* **EBN:** *When dealing with adults with cancer, the authors assert the importance of informing clients of treatment-related symptoms and toxicities to help clients prepare for the treatment course;*

furthermore, nurses should discuss additional coping strategies to help with managing treatment-related problems (Boucher et al, 2011).

- Provide mental and physical activities within the client's ability (e.g., reading, television, radio, crafts, outings, movies, dinners out, social gatherings, exercise, sports, games). **EB/CEBN:** In a pilot study of a nurse-based, in-home transitional care intervention for seriously mentally ill persons, researchers found that one of the factors of importance to community transition was involvement in daily activities (Rose et al, 2007).
- Discuss the client's and family's power to change a situation or the need to accept a situation. **CEBN:** Researchers conducted a controlled trial of a nursing intervention to facilitate older adults' (N = 89) access to community resources to assist them to remain at home. Researchers found the older adults accepted the intervention and had improved health empowerment, purposeful participation in goal attainment, and well-being (Shearer et al, 2010). **EBN:** Following a review of the literature, Knobf (2013) concluded that meeting clients/families' informational and support needs contribute to client empowerment and overall coping ability.
- Offer instruction regarding alternative coping strategies. **EBN:** A Recovery Education program used in inpatient behavioral health units include strategies of cognitive behavioral therapy, mindfulness meditation, and other coping strategies for persons with mental illness (Knutson et al, 2013). **EBN:** A variation of the COPE intervention, a theory-based intervention, was piloted for parents of children with cancer (COPE-PCC), with the small sample (N = 15) suggesting the intervention, which included education, information, and behavior-skill development, facilitated coping for both children and mothers (Peek & Melnyk, 2014).
- Encourage use of spiritual resources as desired. **EBN:** Researchers found that African American women living with HIV use spiritual practices to cope with HIV and ensuing depression, and recommend nurses include spiritual practices in assessments and plans of care (Peltzer et al, 2015). **EB:** In a small randomized control trial of a psychoeducational intervention (45 minute sessions once per week for 3 weeks) to promote problem-solving strategies in college-aged students (N = 25) who were found to be highly neurotic, the researchers found the participants had significant improvement in problem solving at 11 weeks after the intervention (Stillmaker & Kasser, 2013).
- Encourage use of social support resources. **EB:** Researchers found that in genderqueer individuals (N = 64) higher reported social support and the use of more facilitative coping was associated with less anxiety (Budge et al, 2014).
- ▲ Refer for additional or more intensive therapies as needed. **CEBN/EBN/QSEN:** More complex interventions are available to assist with coping, for example, a nurse-delivered intervention for depression in clients with cancer and for persons with mental health issues (Forchuk, 2009; Knutson et al, 2013).

Pediatric

- Monitor the client's risk of harming self or others and intervene appropriately. **QSEN:** See care plan for risk for **Suicide**. **CEB/QSEN:** Adolescents may use self-harming behaviors as a means of communication or of coping (Murray & Wright, 2006). **EB:** A research team in Italy studied differences in coping strategies of adolescents aged 12 to 20 (N = 1713) and found that adolescents who were in the self-harm group used less help-seeking behaviors and support and used more avoidance coping strategies than adolescents who do not self-harm (Guerreriro et al, 2015).
- Monitor adolescents for exposure to community violence. **EB:** In one study of Latino adolescents (N = 223) in ninth grade, researchers found negative psychological effects of exposure to community violence (Epstein-Ngo et al, 2013).
- Support adolescent and children's individual coping styles. **EBN:** Qualitative researchers found that children (N = 10, ages 7 to 12 years) hospitalized and receiving chemotherapy used coping strategies such as understanding the need for treatment, seeking relief from pain and treatment side effects, seeking pleasure in nourishment, engaging in entertaining/fun activities, staying hopeful for a cure, and support (Sposito et al, 2015). **CEBN:** In a study of coping of 4- to 6-year-olds who were hospitalized, researchers concluded that it was essential to support children's individual coping strategies with information, guidance, and participation in decisions (Salmela et al, 2010).
- Encourage social support, religion-based coping, and moderate aerobic exercise as appropriate. **EB:** Epstein-Ngo and colleagues (2013) identified the use of religion-based coping and seeking social support as the more frequent coping responses in Latino adolescents who were exposed to community violence. **CEB:** Exercise was found to decrease the likelihood of depressive feelings when used as a positive coping strategy for school-aged children with angry feelings (Goodwin, 2006).

Geriatric

- ▲ Assess and report possible physiological alterations (e.g., sepsis, hypoglycemia, hypotension, infection, changes in temperature, fluid and electrolyte imbalances, and use of medications with known cognitive and psychotropic side effects). **EBN/QSEN:** *Findings from a study on psychotropic medication use and physical and psychological outcomes in older adults in long-term care (N = 419) indicated that older adults receiving psychotropic medications have poorer physical and psychological outcomes and are less likely to engage in functional activities and experience poorer quality of life (Galik & Resnick, 2013).* **CEB:** *A reversible pathophysiological process may be causing symptoms (Rocchiccioli & Sanford, 2009).*
- Screen for elder neglect or other forms of elder mistreatment. **QSEN/EBN:** *The majority of participants in a study of 76 older adults indicated they would not disclose elder abuse to a doctor or nurse; the researchers concluded that screening of community-dwelling older adults for elder abuse is warranted (Ziminski Pickering & Rempusheski, 2014).*
- Encourage the client to make choices (as appropriate) and participate in planning care and scheduled activities. **EBN:** *In a small study (N = 20) of older adults with symptomatic myeloma, the majority of participants reported a preference for participation in treatment decisions; the researchers recommended oncology nurses and other health care providers respect the autonomy of clients and their role choices in treatment decision making (Tariman et al, 2014).*
- Target selected coping mechanisms for older persons based on client features, use, and preferences. **EBN:** *Older adults described coping processes that they perceived as part of successful aging; researchers found more evidence of gerotranscendence than spirituality and recommended interventions to enhance these factors to improve older adults' quality of life (Troutman-Jordan & Staples, 2014).* **EB:** *Researchers found that European American adults showed development to early old age toward coping mechanisms that were judged more adaptive; in late old age, the pattern was reversed, which suggests coping in late old age presents challenges (Diehl et al, 2014).*
- Increase and mobilize support available to older persons by encouraging a variety of mechanisms involving family, friends, peers, and health care providers. **CEBN:** *Researchers conducted a controlled trial of a nursing intervention to facilitate older adults' (N = 89) access to community resources to assist them to remain at home. Researchers found the older adults accepted the intervention and had improved health empowerment, purposeful participation in goal attainment, and well-being (Shearer et al, 2010).*
- Actively listen to complaints and concerns. **EBN:** *One of the most frequently used strategies by nurses in end-of-life care and communication was active and passive listening (Boyd et al, 2011).*
- Engage the client in reminiscence. **EBN:** *An evidence-based reminiscence protocol was developed for use with older persons; it is a 12-session structured protocol that includes themes such as firsts, positive memories, and favorite holidays. The developer recommends nurses and other health care workers be trained in the protocol and use it in a variety of settings to enhance/improve quality of life for older adults (Stinson & Long, 2014).*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's perceptions of effective coping. **EBN:** *The representation of "strength" influences African American women's conceptualization of depression and coping strategies (Porter & Pacquiao, 2011).*
- Assess the influence of fatalism and/or passivity on the client's coping behavior. **EBN:** *Deniz and Ayaz (2014) found that Turkish women (N = 322) with a newborn (aged 0 to 3 months) who had stress due to personal physical self-care, baby care, and social life were likely to adopt an emotion-oriented passive coping style characterized by acceptance of things as they are even though they wanted a different situation. Assess the influence of cultural conflicts that may affect coping abilities. **EBN:** *In one ethnographic study, the researcher concluded that in the United States, there are differences between nurses' cultures and those of Syrian Muslims and suggested that improved cultural knowledge can lessen cultural pain and conflicts (Wehbe-Alamah, 2011).**
- Assess for intergenerational family problems that can overwhelm coping abilities. **EB:** *Incarcerated (many for long-term sentences) older adults (N = 677) experienced trauma and stress related to lack of contact with and concerns about family; types of coping used were social, cognitive, and spiritual coping (Maschi et al, 2015). Encourage spirituality as a source of support for coping. **EB:** *Researchers examined coping strategies in three groups: Caucasian, Korean, and African American older women (N = 343) and found all three groups used religious/spiritual coping (Lee & Mason, 2013).**

- Negotiate with the client with regard to the aspects of coping behavior that will need to be modified. **QSEN/EB:** *Adolescents in Italy who self-harm used more avoidance coping strategies; researchers recommend enhancing the use of help-seeking behaviors (Guerrero et al, 2015).*
- Encourage moderate aerobic exercise or other forms of physical activity (as appropriate). **EBN/EB:** *Global researchers have found that exercise contributes to coping by people with a variety of conditions, such as women living with fibromyalgia in Spain (group-based exercise program) (Beltrán-Carrillo et al, 2013), adults in Germany trying to cope with chronic neck pain (90 minutes of lyengar yoga once per week for 9 weeks) (Cramer et al, 2013), middle age Europeans as a coping tool for smoking cessation (primarily walking) (Treviño et al, 2014), and in the U.S. for young adults in college experiencing depression (general exercise) (Aselton, 2012).*
- Identify which family members the client can count on for support. **EBN:** *In a study of Irish mothers who experienced the loss of child, participants used formal and self-support in addition to family support which was received from partners, other family members, and friends (Jennings & Nicholl, 2014).*
- Support the inner resources that clients use for coping. **EBN:** *Self-transcendence is an inner resource for coping and well-being; both self-transcendence and spiritual well-being have been found to be high in a sample of Older Order Amish (N = 134) (Sharpnack et al, 2011). EB: *Researchers conducting a large study of Finnish and Swedish older adults' (N = 6119) inner strength and self-rated health found that inner strength was important in changing the relationship between disease and self-rated health; they concluded that interventions to enhance inner strength may support coping with disease in older adults (Viglund et al, 2014).**
- Use an empowerment framework to redefine coping strategies. **EBN:** *Yang and colleagues (2015) engaged women (N = 68) who were marriage migrants from Asian countries married to Taiwanese men in a health empowerment program (3 hours for eight sessions) using participatory action research; the project resulted in building of social networks, enhanced self-worth, resilience, and improved health literacy. EB: *In a qualitative study of deaf people in the United States, researchers found that many participants self-identified as members of an ethno-linguistic minority. Both individual and community empowerment strategies were uncovered in the Internet weblog format, such as the value of using American Sign Language, use of humor, and advocating for social justice (Hamill & Stein, 2011).**

Home Care

- The interventions described previously may be adapted for home care use.
- ▲ **QSEN:** *Assess for suicidal tendencies. Refer for mental health care immediately if indicated.*
- ▲ **QSEN:** *Identify an emergency plan should the client become suicidal. Ineffective coping can occur in a crisis situation and can lead to suicidal ideation if the client sees no hope for a solution. A suicidal client is not safe in the home environment unless supported by professional help. Refer to the care plan for risk for **Suicide**.*
- Discuss preferred coping strategies of family caregivers. **EBN:** *One qualitative study of informal caregivers (N = 20) in a home palliative care program identified a variety of coping strategies; support of family and friends was the most cited (Epiphaniou et al, 2012).*
- Encourage the client to participate knowingly in their care. Refer to the care plan for **Powerlessness**. **EBN:** *Prenatal women (second and third trimester) (N = 21) who participated in a 6-week yoga program had enhanced feelings of power from participating in this 6-week program; participants shared journal entries that indicated through their involvement in the program they were feeling more relaxed, had more strength, and had a better mood (Reis & Alligood, 2014).*
- ▲ Refer the client and family to support groups. **EB:** *One mixed method study exploring the role of online and in-person support groups for breast cancer survivors (N = 73) found that 31% of respondents used the online support to assist with unmet needs, provide treatment and symptom management information, they joined online due to lack of access locally, or due to increased stress or uncertainty (Bender et al, 2013).*
- ▲ If monitoring medication use, contract with the client or solicit assistance from a responsible caregiver. **CEB:** *Older adults with arthritis identified taking medications as an assertive action coping strategy (Tak, 2006).*
- ▲ Institute case management for frail elderly clients to support continued independent living. **EB:** *In a study of one transitional care model for at-risk seniors that included follow-up phone calls and home care visits, hospital readmissions were significantly decreased (61%) and participant quality of life was improved; the researchers concluded that social support, health education, and follow-up are effective home care strategies for at-risk older adults (Watkins et al, 2012).*

Client/Family Teaching and Discharge Planning

- Teach the client to problem solve. Have the client define the problem and cause, and list the advantages and disadvantages of the options. **EB**: *Teaching problem-solving skills to clients using a structured approach (1 hour per week for six sessions) has been found to be helpful to those experiencing depression (Erdley et al, 2014). Provide the seriously ill client and his or her family with needed information regarding the condition and treatment.* **EBN**: *In a qualitative study of former ICU clients, participants shared that information and education for themselves and their families was an important need (Deacon, 2012).*
- Teach relaxation techniques. **EBN**: *Based on a review of the literature, the researchers found evidence of the positive effects of a variety of relaxation approaches for persons experiencing mental disorders (Shah et al, 2014).* **EB**: *A randomized control trial of persons with generalized anxiety disorder (N = 93) indicated that mindfulness meditation improved coping (Hoge et al, 2013).*
- Work closely with the client to develop appropriate educational tools that address individualized needs. **CEB**: *Researchers developed a purpose-based information assessment (PIA) tool to evaluate how effective the information met the clients' individual needs; findings included estimates supporting the validity, reliability, and sensitivity of the PIA. Researchers concluded that the PIA can be used to identify strengths and limitations in meeting an individual's information needs (Feldman-Stewart et al, 2007).*
- ▲ Teach the client about available community resources (e.g., therapists, ministers, counselors, self-help groups). **EBN**: *Researchers concluded from a review of the literature regarding couples surviving prostate cancer that in addition to meeting educational needs, nurses must assess for potential concerns and make recommendations and referrals to assist couples with finding appropriate resources for coping with issues related to their relationship (Galbraith et al, 2011).*

Disabled family Coping *Marsha McKenzie, MA Ed, BSN, RN*

NANDA-I

C

Definition

Behavior of primary person (family member, significant other, or close friend) that disables his or her capacities and/or the client's capacities to effectively address tasks essential to either person's adaptation to the health challenge

Defining Characteristics

Abandonment; aggression; agitation; carrying on usual routines without regard for client's needs; client's development of dependence; depression; desertion; disregarding client's needs; distortion of reality regarding client's health problem; family behaviors that are detrimental to well-being; hostility; impaired individualization; impaired restructuring of a meaningful life for self; intolerance; neglectful care of client in regard to basic human needs; neglectful care of client in regard to illness treatment; neglectful relationships with other family members; prolonged overconcern for client; psychosomaticism; rejection; taking on illness signs of client

Related Factors (r/t)

Arbitrary handling of family's resistance to treatment; dissonant coping styles for dealing with adaptive tasks by the significant person and client; dissonant coping styles among significant people; highly ambivalent family relationships; significant person with chronically unexpressed feelings (e.g., guilt, anxiety, hostility, despair)

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Caregiver Well-Being; Family Coping; Family Normalization; Neglect Recovery

Example NOC Outcome with Indicators

Family Normalization as evidenced by the following indicators: Adapts family routines to accommodate needs of affected member/Meets physical and psychosocial needs of family members/Provides activities appropriate to age and ability for affected family member/Uses community support groups. (Rate the outcome and indicators of **Family Normalization**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Significant Person Will (Specify Time Frame)

- Identify normal family routines that will need to be adapted
- Participate positively in the client's care within the limits of his or her abilities
- Identify responses that may be harmful
- Acknowledge and accept the need for assistance with circumstances
- Identify appropriate activities for affected family member

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Family Process Maintenance; Caregiver Support; Family Support; Family Therapy; Respite Care

Example NIC Activities—Family Process Maintenance

Determine typical family processes; Minimize family routine disruption by facilitating family routines and rituals such as private meals together or family discussions for communication and decision-making; Design schedules of home care activities that minimize disruption of family routine

Nursing Interventions and Rationales

- Families dealing with life-changing illnesses should be involved with the management process from the outset of treatment. Education and counseling should be provided early and repeatedly as learning and coping needs are reassessed. Caregivers should be invited to attend therapy sessions at an early stage. **EBN:** *These interventions are effective treatment for stroke victims and families to aid in coping (Gillespie & Campbell, 2011).*
- Assess coping strategies of both the patient and the spouse when managing women with breast cancer and men with prostate cancer. **EB:** *The findings of Kraemer et al (2011) suggest that active engagement by both the patient and the partner can have salutary effects on patient adjustment. A congruent coping strategy by patient and partner generally predicted better adaptation than did dissimilar coping. EB: A study conducted by Lambert et al (2012) concluded that coping with prostate cancer was more effective when both the patient and spouse were assisted with management of the illness.*
- ▲ Health care practitioners should be prepared to give specific information to families regarding the trajectory of a terminal illness. **EB:** *This study found that families felt the need to have more specific information and open communication regarding the anticipated course of a terminal illness, especially when young children are involved. Nurses and their colleagues have an important role to play in providing emotional support and in providing referrals to support services (Bugge et al, 2009).*
- Nurses caring for clients with terminal cancer should recognize the need to treat family caregivers as “pseudopatients.” **EBN:** *The burden and stress of caring for a loved one throughout a terminal illness will most likely cause caregivers to need clinical care themselves if inadequate support is not provided during the stressful stages of cancer care (Northfield & Nebauer, 2010).*
- Provide psychosocial intervention for parents dealing with a child who is suffering from a serious illness. Allow time for parents to express feelings. Recognize and validate parent’s feelings of anxiety, depression, and stress. **EBN:** *The diagnosis of childhood cancer has an impact on the entire family. Interventions focused on facilitating parental coping will have a positive impact on the entire family (Peek & Melnyk, 2010).*
- Assess social support of family members caring for survivors of traumatic brain injuries. Facilitate realistic expectations about caregiving. **CEB:** *Family members providing care following traumatic brain injuries often internalize the survivor’s impairments as a sign that they are not masterful caregivers (Hanks et al, 2007).*
- Assist families to identify physical and mental health effects of caregiving. **CEB:** *Evidence over the last two decades shows that caregiving is a major public health issue. Caregiving has features of a chronic stress experience with high levels of unpredictability and uncontrollability leading to secondary stress in multiple life domains (Schulz & Sherwood, 2008).*
- Assist family members to find professional assistance for primary stressors such as financial issues, insurance coverage, or communicating with professionals.
- Handle dysfunctional family dynamics in an open, transparent, and professional way. Remain neutral when dealing with family conflicts and avoid involvement in long-term prior conflicts. **EBN:** *Maintaining a neutral, professional position in managing clients and families in an end-of-life care setting is essential (Holst et al, 2009).*
- Respect and promote the spiritual needs of the client and family. **EBN:** *Spiritual well-being is associated with better mental health and positive coping skills of family caregivers (Yeh & Bull, 2009).*

Pediatric

- Siblings of sick children should be considered at risk for emotional disturbances until a full assessment of the family and social support circumstances proves otherwise. **CEB:** *Siblings of sick children frequently suffer from anxiety and depression. Socioeconomic status and parental stress are strong predictors of sibling outcomes (O’Brien et al, 2009).*
- Assist parents and children suffering from chronic illness to develop accommodative coping skills (adapting to stressors rather than attempting to change the stressors). **EB:** *Compas et al (2012) found considerable evidence across chronic childhood illnesses and medical conditions that suggests that secondary control coping, or accommodative coping, is related to better adjustment in children and adolescents.*
- Assess educational level of parents of ill children and construct parent teaching to address educational attainment. **EB:** *Gage-Bouchard et al (2013) found programs that address educational gaps and teach caregivers planning and active coping skills may be beneficial for parents with lower educational attainment, particularly men.*

- Assess parents of children with chronic illness for depression. **EB:** *Grey et al (2011) note that parental coping with the stress of diabetes is likely to play an important role in child and family adjustment to the disease.*
- Recognize predictors of anger in adolescents: anxiety, depression, exposure to violence, and trait anger. **EBN:** *A meta-analytic study of predictors of anger in adolescents found these traits can forecast moderate to substantial effects in relation to anger (Mahon et al, 2010).*

Geriatric

- Assess family members who are caring for clients in long-term care facilities for compassion fatigue: symptoms include the inability to disengage from the suffering of the loved one, a growing feeling of hopelessness or despair, sadness or grief, and inattention to personal care or outside responsibilities. Encourage family members to attend to their own physical, emotional, and social needs. Develop relationships of trust with family caregivers, providing them with a sense of confidence in the level of care their loved ones will be receiving in their absence. Promote therapeutic relationships with family members who are assisting with care, allowing for sharing of concerns and emotions. **EBN:** *This study explored the effects of compassion fatigue in family members caring for loved ones in long-term care facilities, suggesting implications for nursing staff (Perry, 2010).*
- Be aware of age-related deterioration in coping skills. **EB:** *Diehl et al (2014) found that the defense mechanisms of doubt, displacement, and regression increased after the age of 65 years. Linear age-related decreases were found for the coping mechanism of ego regression and the defense mechanisms of isolation and rationalization.*

Multicultural

- Health care professionals working with African American adolescents who are coping with parental cancer should be sensitive to the potential for post-traumatic growth. **EB:** *A qualitative study of African American youths found they are able to attain post-traumatic growth as early as age 11, following the experience of parental cancer. Previous studies of white adolescents found post-traumatic growth only in older adolescents. This study suggests the possibility of a cultural difference in coping abilities found among African American adolescents (Ma et al, 2010).*

Home Care

The interventions described previously may be adapted for home care use.

- Assess for strain in family caregivers. **EBN:** *Using a tool such as the Modified Caregiver Strain Index gives the nurse information about a caregiver's abilities. It also could identify a need to evaluate the care recipient's living situation (Onega, 2008).* **EB:** *Williams et al (2010) conducted a study of a significant number of caregivers of Alzheimer's patients at home and found that video-based coping skills training and telephone coaching resulted in improved mental and physical health outcomes as well as reduced medical care costs among caregivers.*

Client/Family Teaching and Discharge Planning

- Involve the client and family in the planning of care as often as possible; mutual goal setting is considered part of "client safety." Major changes in the fifth annual issuance of National Patient Safety Goals include home care, assisted living, and disease-specific care programs in 2009. An expectation is to "encourage patients' active involvement in their own care as a patient safety strategy" (The [Joint Commission, 2009](#)).
- Recognize that family decision-makers may need additional psychosocial support services. **EBN:** *Family members directly responsible for health care decisions are most at risk for psychological stress (Hickman et al, 2010).*
- Educate family members regarding stress management techniques including massage and alternative therapies. **EBN:** *Education, support, psychotherapy, and respite interventions have demonstrated the greatest effect in reducing caregiver strain and burden. A significant decline was observed in the depression and anxiety scores of caregivers in the treatment group receiving massage therapy (Honea et al, 2008).*

Readiness for enhanced Coping *Arlene T. Farren, RN, PhD, AOCN, CTN-A*

NANDA-I

Definition

A pattern of cognitive and behavioral efforts to manage demands related to well-being, which can be strengthened

Defining Characteristics

Awareness of possible environmental change; expresses desire to enhance knowledge of stress management strategies; expresses desire to enhance management of stressors; expresses desire to enhance social support; expresses desire to enhance use of emotion oriented strategies; expresses desire to enhanced use of problem oriented strategies; expresses desire to enhance use of spiritual resource

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Personal Well-Being; Social Interaction Skills; Quality of life

Example NOC Outcome with Indicators

Coping as evidenced by the following indicators: Identifies effective coping patterns/Uses effective coping strategies. (Rate the outcome and indicators of **Coping**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Acknowledge personal power
- State awareness of possible environmental changes that may contribute to decreased coping
- State that stressors are manageable
- Seek new effective coping strategies
- Seek social support for problems associated with coping
- Demonstrate ability to cope, using a broad range of coping strategies
- Use spiritual support of personal choice

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Health Education; Decision-Making Support

Example NIC Activities—Coping Enhancement

Assist client in developing an objective appraisal of the event; Explore with client previous methods of dealing with life problems

Nursing Interventions and Rationales

- Assess and support positive psychological strengths, that is, hope, optimism, self-efficacy, resiliency, and social support. **EBN:** Researchers found that army wives ($N = 102$) who experienced deployment separation from spouses, used support systems as an effective coping strategy (Blank et al, 2012). **EBN:** Based on a systematic review ($N = 57$ studies) covering the phases of the cancer experience, researchers found resilience and optimism are protective characteristics that contribute to coping and well-being (Molina et al, 2014).
- Be physically and emotionally present for the client while using a variety of therapeutic communication techniques. **EBN:** In a study exploring the experiences and needs of families ($N = 20$) in one intensive care unit, the researcher found that families need communication of information and prognosis in a manner that reflects caring, compassion, and attention to their supportive needs (Gutierrez, 2012). **EBN:** Adult primary care clients ($N = 251$) receiving early cancer care identified nurses' use of active listening, providing information, and being present for client-centered care as critical behaviors of oncology nurse navigators (Horner et al, 2013).
- Empower the client to set realistic goals and to engage in problem solving. **EBN:** In a randomized control trial testing the effectiveness of a 16 week Oncology Nurse Navigator (ONN) program compared to standard care to support clients with cancer ($N = 251$) during early treatment, researchers described the intervention, which included the use of using problem solving and motivational interviewing in the provision of psychosocial support (Horner et al, 2013). **EB:** The use of active problem solving contributed to coping effectiveness in a sample of 434 adults with rheumatoid arthritis (Englbrecht et al, 2012).
- Encourage expression of positive thoughts and emotions. **EBN:** In an intervention study of Turkish family caregivers of adults with mental illness, a family to family support intervention resulted in improvements in self-confidence and optimism in the experimental group ($N = 34$) following the intervention from baseline and at 3 months while there was no change in the control group ($N = 34$) at any measurement period (Bademli & Duman, 2014).
- Encourage the client to use spiritual coping mechanisms such as faith and prayer. **EBN:** In a qualitative study of the lived spiritual experiences of those receiving outpatient surgery, clients ($N = 7$) described their use of spiritual coping and that spiritual care at a time of vulnerability contributed to their well-being (Griffin, 2013). **EBN:** Use of spiritual coping such as praying has been associated with increased psychological well-being and decreased psychological distress in samples of Caucasian and African American early breast cancer survivors (Gaston-Johansson et al, 2013b; Schreiber, 2011).
- Encourage the client to visit favorite natural settings or to have access to a window or pictures and sounds of nature. **EBN:** Research demonstrates that a client's connection to nature can play a crucial role in his/her healing (Morrison, 2011). In a pilot study of an intervention using nature (garden walking) and art, researchers found markedly reduced self-reports of depression in a sample of older adults (McCaffrey et al, 2011).

- Help the client with serious and chronic conditions such as depression, cancer diagnosis, and chemotherapy treatment to maintain social support networks or assist in building new ones. **EBN:** *Women with advanced breast cancer (N = 35) receiving high-dose chemotherapy were treated with a comprehensive coping strategy program that included the use of social support and other coping enhancement skills; the treatment group had improved quality of life at 1 year posttreatment (Gaston-Johansson et al, 2013a).*
- ▲ Refer women facing diagnostic and curative breast cancer surgery for psychosocial support. **EBN:** *In a pilot randomized control trial, a psychoeducation intervention showed promise for increasing overall quality of life and lowering psychological symptom distress in women breast cancer survivors (N = 25) (Park et al, 2012).*
- ▲ Refer for cognitive-behavioral therapy (CBT) to enhance coping skills. **EBN:** *Gaston-Johansson et al (2013a) from the Johns Hopkins School of Nursing conducted an intervention study that included cognitive restructuring as part of a comprehensive coping strategies program and found that women with breast cancer in the intervention group (N = 38) had improved well-being and quality of life compared with the control group (N = 35) at 1 year postintervention. EB:* *Another intervention, called the No-Panic CBT Self-Help program, demonstrated that CBT was effective for a wide range of anxiety disorders (Hawkins, 2011).* Refer to the care plans for Readiness for enhanced **Communication** and Readiness for enhanced **Spiritual** well-being.

Pediatric

- Encourage children and adolescents to engage in diversional activities and exercise to promote self-esteem, enhance coping, and prevent behavioral and other physical and psychosocial problems. **EBN:** *Researchers examining physical activity in children attending school (N = 133) found that enjoyment and self-efficacy were important influences in promoting physical activity in children (Ling et al, 2015). EBN:* *In a qualitative study of hospitalized children (N = 10) receiving chemotherapy for cancer, researchers found that engaging children in entertaining activities and having fun were among positive coping strategies (Sposito et al, 2015).*
- Encourage families of children with chronic illness to try additional coping strategies. **EBN:** *Families of children with autism (N = 38) participated in a descriptive study examining severity of behaviors and coping strategies; the researchers concluded that early diagnosis and intervention for the children and their families including community social support was needed (Hall, 2012). EB:* *Continued support for parents is necessary when children complete therapy for cancer (Wakefield et al, 2011).*

Geriatric

- Encourage active, meaning-based coping strategies for older adults with chronic illness. **EBN:** *In a qualitative study of older adults living with HIV (N = 40) residing in an urban environment, researchers uncovered four themes: accessing support, helping one's self as well as others, and tapping into their own spirituality that address successful coping for the participants (DeGrazia & Scrandis, 2015).*
- Consider the use of Web-based and technological resources for older adults in the community. **EB:** *The results of a mixed method systematic review of 112 articles indicated that approximately 24% of the articles addressed Web-based packages and assistive information technology that assists older adults and their family caregivers with health information, resources for performing tasks safely, engaging in self-management, increasing coping strategies, and other types of support; studies indicated client satisfaction as an outcome (Vedel et al, 2013).*
- Refer the older client to self-help support groups that address health, psychosocial, and/or social support. **EB:** *In a mixed age sample with more than 50% of the participants older than age 50 years (range 19 to 83 years), Internet-based self-help groups for persons who experienced cancer (N = 350) have been associated with perceived increased coping as well as improved satisfaction with perceived health status (Seckin, 2013). EB:* *Greysen et al (2013) studied social isolation in older veterans and recommended the use of in-person and Internet-based self-help support groups.*
- ▲ Refer the client with Alzheimer's disease who is terminally ill to hospice. **EBN:** *Hospice care is encouraged for those with Alzheimer's disease; hospice admission increases as the hours of care and caregiver burden increase (Karikari-Martin et al, 2012).*

Multicultural

- Assess an individual's sociocultural backgrounds to identify factors that support coping. **EBN:** *In a qualitative study of native Hawaiian migrants to the mainland United States (N = 41), researchers identified*

themes including nurturing relationships with family and friends that contribute to the participants' perceptions of well-being (Lassetter et al, 2012). **EB**: In a study comparing coping strategies used by Caucasian, Korean, and African American older women (N = 343), researchers found there are differences in preferred coping strategies used by the three ethnic groups; the most common strategy used by all three groups was religious/spiritual belief systems (Lee & Mason, 2013).

- Encourage spirituality as a source of support for coping. **EBN**: Religion and spiritual practices were used by Buddhist and Muslim Thai women to cope with type 2 diabetes self-management (Lundberg & Thrakul, 2013).
- Facilitate positive ethnocultural identity to enhance coping. **EB**: Ojeda and Liang (2014) examined coping in Mexican American adolescent men (N = 93) and found that ethnocultural factors such as positive affirmation and view of one's ethnic identity, as well as culture bound characteristics such as caballerismo (positive Latino masculinity), was associated with more effective coping strategies, such as positive reframing, planning, and the use of humor. **EB**: In African American women who self-reported experience with trauma (N = 161), higher self-esteem and well-being were associated with more effective, active coping strategies (Stevens-Watkins et al, 2014).
- Foster intergenerational support. **EB**: A qualitative study explored the phenomena of racism, trauma, and coping in 19 adults of color and identified that intergenerational support contributed to coping in the participants (Lowe et al, 2012). Refer to the care plan for Ineffective Coping.

Home Care

- The interventions described previously may be adapted for home care use.
- Engage both clients and their caregivers as a dyad. **EBN**: In a review of a program of research about helping clients and family caregivers cope with cancer, Northouse (2012) relates lessons learned about caring for client and family caregiver dyad; recommendations include identifying strengths, three-way, open communication and alliances, and promoting active coping (vs. avoidant coping).
- Provide an Internet-based health coach to encourage self-management for clients with chronic conditions such as depression, impaired mobility, and chronic pain. **EBN**: Telephone health coaching, along with in-person individual educational sessions and group sessions, was included in a psychoeducation intervention randomized control trial pilot study in women survivors of breast cancer (N = 48); researchers concluded the intervention showed promise to increase overall quality of life and decrease psychological symptom distress (Park et al, 2012).
- Refer the client to mutual health support groups. **EBN**: A review of the literature regarding peer support suggests that peer support has the potential for positive outcomes in individuals in recovery (Repper & Carter, 2011).
- Refer prostate cancer clients and their spouses to family programs that include family-based interventions of communication, hope, coping, uncertainty, and symptom management. **EBN**: Researchers conducted a qualitative study of prostate cancer survivors and their spouses (N = 95) to determine the long-term quality of life effects of treatment at 36 months after treatment; the recommendations included offering counseling to couples following treatment to improve quality of life and assist with managing relationship intimacy (Harden et al, 2013).
- ▲ Refer combat veterans and service members directly involved in combat as well as those providing support to combatants, including nurses for mental health services. **EBN**: Veterans' transition to home life is deeply embedded in the context of relationships. Nurses can use Swanson's theory of caring to find guidance for ways to provide meaningful support to veterans (Wands, 2011).

Client/Family Teaching and Discharge Planning

- Teach the client about available community resources (e.g., therapists, ministers, counselors, self-help groups, family education groups). **EBN**: Navigators provide community resources on post-discharge follow-up to minimize gaps in care and promote independence in older adults; in this study, readmissions were decreased and participants reported improved quality of life (Watkins et al, 2012).
- Teach caregivers using a variety of interventions that contribute to coping. **EBN**: Researchers conducting a systematic review of 17 articles regarding couples-based intervention for coping with cancer recommended interventions that include skills training, psychoeducational interventions, and client/family support (Li & Loke, 2014).
- Teach expressive writing, journaling, and education about emotions. **EBN**: Journaling was one of the components of an intervention study aimed to promote civility among nursing students; there were

improvements in coping in the areas of self-controlling, seeking social support, and positive reappraisal after the intervention (Jenkins et al, 2013). **EB**: Researchers used a combination of expressive writing with elements of psychoeducation on emotion regulation with adolescents. It demonstrated that this may be an effective preventive tool to improve psychosocial adjustment by establishing functional emotion regulation strategies (Horn et al, 2011).

Readiness for enhanced community Coping *Roberta Dobrzanski, MSN, RN*

NANDA-I

Definition

A pattern of community activities for adaptation and problem solving for meeting the demands or needs of the community, which can be strengthened

Defining Characteristics

Expresses desire to enhance availability of community recreation programs; expresses desire to enhance availability of community relaxation programs; expresses desire to enhance communication among community members; expresses desire to enhance communication between aggregates and larger community; expresses desire to enhance community planning for predictable stressors; expresses desire to enhance community resources for managing stressors; expresses desire to enhance community responsibility for stress management; expresses desire to enhance problem solving for identified issue

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Community Competence; Community Health Status

Example NOC Outcome with Indicators

Community Health Status as evidenced by the following indicators: Prevalence of health promotion programs, health status of infants, children, adolescents, adults, elders, participation rates in community health programs. (Rate the outcome and indicators of **Community Health Status**: 1 = poor, 2 = fair, 3 = good, 4 = very good, 5 = excellent [see [Section 1](#)].)

Community Outcomes

Community Will (Specify Time Frame)

- Develop enhanced coping strategies
- Maintain effective coping strategies for management of stress

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Environmental Management: Community; Health Policy Monitoring: Program Development

Example NIC Activities—Program Development

Assist the group or community in identifying significant health needs or problems; Identify alternative approaches to address the need(s) or problem(s)

Nursing Interventions and Rationales

NOTE: Interventions depend on the specific aspects of community coping that can be enhanced (e.g., planning for stress management, communication, development of community power, community perceptions of stress, community coping strategies). *Nursing interventions are conducted in collaboration with key*

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

members of the community, community/public health nurses, and members of other disciplines (Anderson & McFarlane, 2011).

- Describe the roles of community/public health nurses in working with healthy communities. **EBN:** Nurses at general and specialists' levels (bachelor's and master's degrees) have significant roles in helping communities achieve optimum health, including coping with stress (Chinn, 2012).
- Help the community obtain funds for additional programs, or identify resources to assist in the funding of additional programs. **EBN:** Healthy communities may need additional funding sources to strengthen community resources (Anderson & McFarlane, 2011; Chinn, 2012).
- Encourage positive attitudes toward the community through the media and other sources. **EB:** Negative attitudes or stigmas create additional stress and deficits in social support (Anderson & McFarlane, 2011; Chinn, 2012).
- Help community members collaborate with one another for power enhancement and coping skills. **EBN:** Community members may not have sufficient skills to collaborate for enhanced coping. Health care providers can promote effective collaboration skills (Anderson & McFarlane, 2011; Chinn, 2012).
- Assist community members with cognitive skills and habits of mind for problem solving. Teach critical thinking and strategizing skills to help open lines of communication and facilitate participation. **EBN:** The cognitive skills and habits of mind of critical thinking support problem-solving ability (Rubinfeld & Scheffer, 2010).
- Demonstrate optimum use of power resources. **EBN:** Optimum use of power resources and working for community empowerment supports coping (Chinn, 2012).
- Reduce poverty whenever possible. **EB:** Poverty is a major determinant of poor health, and people living on low income consistently have higher rates of morbidity and mortality due to chronic and acute illness. Therefore, primary health care providers should consider and address income as a distinct risk to health, and researchers should explore these issues with a broader group of primary care providers and people who live in poverty (Bloch, Rozmovits, & Giambone, 2011).
- ▲ Collaborate with community members to improve educational levels within the community. **EB:** Patient safety, self-care behaviors, adherence to treatment plans, knowledge of one's medical condition, health care quality, and positive health outcomes are compromised by low health literacy. There is also compromised physical and mental health, as well as greater risk for hospitalization and increased mortality (Evangelista et al, 2010).

Multicultural

- Refer to care plan for Ineffective community Coping.

Client/Family Teaching and Discharge Planning

- Review coping skills, power for coping, and the use of power resources.

REFERENCES

- Refer to ineffective community Coping for additional references.

Readiness for enhanced family Coping Keith A. Anderson, MSW, PhD

NANDA-I

Definition

A pattern of management of adaptive tasks by primary person (family member, significant other, or close friend) involved with the client's health change, which can be strengthened

- = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Defining Characteristics

Expresses desire to acknowledge growth impact of crisis; expresses desire to choose experiences that optimize wellness; expresses desire to enhance connection with others who have experienced a similar situation; expresses desire to enhance enrichment of lifestyle; expresses desire to enhance health promotion

C

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Family Coping; Health-Seeking Behavior; Participation in Health Care Decisions

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Confronts and manages family problems/Cares for needs of all family members. (Rate the outcome and indicators of **Family Coping**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

State a plan indicating coping strengths, abilities, and resources as well as areas for growth and change; Perform tasks and engage resources needed for growth and change; Evaluate changes and continually reevaluate plan for continued growth

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Family Integration Promotion; Family Involvement Promotion; Family Support; Mutual Goal Setting

Example NIC Activities—Family Coping

Facilitate communication of concerns and feelings between clients and family or among family members; Provide resources that support and encourage adaptive family coping; Respect and support adaptive coping mechanisms used by family

Nursing Interventions and Rationales

- ▲ Assess the structure, resources, and coping abilities of families and use these assessments in selecting interventions and formulating care plans. **EB/EBN**: *It is critical to understand the resiliency and coping capabilities of families; the use of established assessment instruments (e.g., Family Assessment Device) can provide insight into family dynamics and the coping styles and resources of family systems (Mansfield et al, 2014; Knapp et al, 2013).*
- ▲ Acknowledge, assess, and support the spiritual needs and resources of families and clients. **EBN**: *Spirituality has been found to be an important, yet often overlooked, coping resource for families and clients during illness and recovery (O'Brien, 2014).*
- ▲ Establish rapport with families and empower their decision-making through effective, accurate, and empathic communication. **EBN**: *Effective engagement and communication between health care providers and clients' families can help establish rapport, provide timely and desired information to families, and empower families in their caregiving activities and decision-making capacities (Wittenberg-Lyles et al, 2012; Curtis et al, 2013).*
- ▲ Provide family members with educational and skill-building interventions to alleviate caregiving stress and to facilitate adherence to prescribed plans of care. **EBN**: *The provision of psychoeducational and supportive interventions may enable family members to gain a sense of control in the caregiving role and to become more comfortable in providing care and making informed decisions (Northouse et al, 2013; Ostlund & Persson, 2014).*
- ▲ Develop, provide, and encourage family members to use counseling services and interventions. **EB/EBN**: *Family-centered counseling interventions have been shown to be effective, particularly in situations regarding serious illness and difficult family decisions (Cheng et al, 2014; Hopkinson et al, 2012).*

- ▲ Identify and refer to support programs that discuss experiences and challenges similar to those faced by the family (e.g., cancer support groups). **EB**: *While there is wide diversity in the format of support programs, couple and family support approaches can be beneficial and enhance coping (Chambers et al, 2011; Shields et al, 2012).*
- ▲ Incorporate the use of emerging technologies to increase the reach of interventions to support family coping. **EB/EBN**: *Emerging computer and Internet-based supportive and educational interventions may hold promise in enhancing family members' well-being and informational needs (Hu et al, 2014; Northouse et al, 2014).*
- ▲ Refer to Compromised family **Coping** for additional interventions.

Pediatric

- ▲ Identify and assess the management styles of families and facilitate the use of more effective ways of coping with childhood illness. **EB**: *Understanding the dominant characteristics of each family's coping styles and resources and helping them to use more effective management styles can result in better family functioning and treatment outcomes (Barrera et al, 2014).*
- ▲ Provide educational and supportive interventions for families caring for children with illness and disability. **EB/EBN**: *Providing information, training parents in care management, and offering supportive programs can reduce stress levels in parents and lead to better outcomes for children (Marsac et al, 2012; Tomlinson et al, 2012).*

Geriatric

- ▲ Encourage family caregivers to participate in counseling and support groups. **EB/EBN**: *While a wide variety of programs exist, certain counseling and support group programs have been found to be effective in increasing family resourcefulness and lowering caregiver burden, anxiety, depression, and family conflict (Gonzalez et al, 2014; Nichols et al, 2011).*
- ▲ Provide educational and therapeutic interventions to family caregivers that focus on knowledge and skill building. **EB/EBN**: *Psychoeducational interventions that are accessible and tailored to individual needs can be highly valued and useful to family caregivers (Boots et al, 2014; Li et al, 2014).*

Multicultural

- ▲ Acknowledge and understand the importance of cultural influences in families and ensure that assessments and assessment tools account for such cultural differences. **EB/EBN**: *Family coping tends to vary across cultures and may impact the fit, reliability, and validity of existing family functioning and coping assessment tools (Higginbottom et al, 2011; Kuo, 2011).*
- ▲ Understand and incorporate cultural differences into interventions to enhance the impact of family interventions. **EBN**: *Tailoring interventions to the customs, beliefs, preferences, and strengths of specific groups may increase effectiveness (Davey et al, 2013; Gray et al, 2014; Dayer-Berenson, 2014).*

Readiness for enhanced Decision-Making Dawn Fairlie, ANP, FNP, GNP, DNS(c)

NANDA-I

Definition

A pattern of choosing a course of action for meeting short- and long-term health-related goals, which can be strengthened

Defining Characteristics

Expresses desire to enhance congruency of decisions with sociocultural goal; expresses desire to enhance congruency of decisions with sociocultural value; expresses desire to enhance congruency of decisions with goal; expresses desire to enhance congruency of decisions with values; expresses desire to enhance decision-making; expresses desire to enhance risk-benefit analysis of decisions; expresses desire to enhance understanding of choices for decision-making; expresses desire to enhance understanding of meaning of choices; expresses desire to enhance use of reliable evidence for decisions

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Participation in Health Care Decisions; Personal Autonomy

Example NOC Outcome with Indicators

Participation in Health Care Decisions as evidenced by the following indicators: Claims decision-making responsibility/Exhibits self-direction in decision-making/Seeks reputable information/Specifies health outcome preferences. (Rate the outcome and indicators of **Participation in Health Care Decisions**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

List of Nursing Diagnoses by Letter: D

Readiness for enhanced Decision-Making	Impaired emancipated Decision-Making	Readiness for enhanced emancipated Decision-Making
Risk for impaired emancipated Decision-Making	Decisional Conflict	Ineffective Denial
Impaired Dentition	Risk for delayed Development	Diarrhea
Risk for Disuse syndrome	Deficient Diversional activity	

Client Outcomes

Client Will (Specify Time Frame)

- Review treatment options with providers
- Ask questions about the benefits and risks of treatment options
- Communicate decisions about treatment options to providers in relation to personal preferences, values, and goals

NIC

(Nursing Interventions Classification)

Suggested NIC Interventions

Decision-Making Support; Mutual Goal Setting; Support System Enhancement; Values Clarification

Example NIC Activities—Decision-Making Support

Help client identify the advantages and disadvantages of each alternative; Facilitate collaborative decision-making; Help client explain decisions to others, as needed

Nursing Interventions and Rationales

- Support and encourage clients and their representatives to engage in health care decisions. **EB:** *Decisional conflict was assessed using the Decisional Conflict Scale among pregnant women considering antidepressant medication treatment. Although many pregnant women facing decisions regarding the use of antidepressant medication experience decisional conflict, their decisions were facilitated by interpersonal supports and emotional support reduced decisional conflict and facilitated the decision-making process (Walton et al, 2014).* **EBN:** *Decision aids are intended to help people participate in decisions that involve weighing the benefits and harms of treatment options, often with scientific uncertainty. Stacey et al (2014) concluded that there is high-quality evidence that decision aids improve clients' knowledge regarding options and reduce decisional conflict.*
- Respect personal preferences, values, needs, and rights. **EB:** *“Denial of this right of autonomy and self-determination may worsen the individual's physical and existential suffering” (Soriano & Lagman, 2012).*
- Determine the degree of participation desired by the client. **EB:** *“Ultimately, a patient must be able to understand the information given to him, evaluate the consequences of the options presented, deliberate on these options based on his values, communicate this choice, and maintain consistency over time” (Soriano & Lagman, 2012).*
- Provide information that is appropriate, relevant, and timely. **EB:** *Decisional conflict was assessed using the Decisional Conflict Scale among pregnant women considering antidepressant medication treatment. Although many pregnant women facing decisions regarding the use of antidepressant medication experience decisional conflict, their decisions were facilitated by interpersonal supports and emotional support reduced decisional conflict and facilitated the decision-making process (Walton et al, 2014).*
- Determine the health literacy of clients and their representatives before helping with decision-making. **EB:** *A randomized trial of a decision aid for coronary heart disease (CHD) adherence was conducted by Sheridan et al (2014), who reported that most participants found the decision aid easy to use and easy to understand. Participants reported improvement in personalization of information and that the decision aid helped them to decide what was important to them.*
- Tailor information to the specific needs of individual clients, according to principles of health literacy. **EB:** *Ko et al (2014) studied cultural and linguistic adaptation of a multimedia colorectal cancer screening Decision Aid for Spanish-Speaking Latinos. They concluded that new interventions that address the needs of diverse U.S. populations are needed to reduce health disparities. Additionally they noted the importance of adapting English-language health interventions to facilitate communication and decision-making.*
- Motivate clients to be as independent as possible in decision-making. **EB:** *According to Roberts (2014), national ethics and regulatory standards mandate that individuals must be offered as much choice in the decisional process whereby they make these decisions independently and true to their personal beliefs and values.*
- Identify the client's level of choice in decision-making. **EBN:** *A study conducted by Feenstra et al (2015) examined incorporating the child's perspective into his or her decision-making process. They found that*

treatment choices can successfully be made by parents together with their child and recommended interventions that successfully meet the needs of all those involved.

- Focus on the positive aspects of decision-making rather than the decisional conflicts. **EBN**: Numerous studies conducted during development of the health promotion model show that promotion differs from prevention and requires a positive rather than negative approach (Pender et al, 2011).
- Design educational interventions for decision support. **EBN**: A Cochrane review of decision aids (pamphlets, videos, or Web-based tools) concluded that use of decision aids fosters a positive effect on communication between clients and their health care provider and influenced the time required for the consultation. Additionally, there was an improvement with more detailed decision aids when compared to simpler decision aids, and both were better than usual care (Stacey et al, 2011).
- Acknowledge the complexity of everyday self-care decisions related to self-management of chronic illnesses. **EBN**: In a study of chronically ill community dwelling elders, Bonney (2014) found that this population prefers to learn about prognosis and end of life through conversations with their health care provider and supplementation from written materials. Decision aids can increase knowledge and more education leads to better decision-making.

Geriatric

- The above interventions may be adapted for geriatric use.
- Facilitate collaborative decision-making. **EBN**: A study of the shared decision-making process of persons with dementia identified a broad spectrum of the shared decision-making process. Results indicated that not all persons with dementia are excluded from participating in the decision-making process (Miller et al, 2014).

Multicultural

- Use existing decision aids for particular types of decisions or develop decision aids as indicated. **EBN**: Decision aids are intended to help people participate in decisions that involve weighing the benefits and harms of treatment options often with scientific uncertainty. Stacey et al (2014) concluded that there is high-quality evidence that decision aids improve clients' knowledge regarding options and reduce decisional conflict. **EB**: Ko et al (2014) studied cultural and linguistic adaptation of a multimedia colorectal cancer screening Decision Aid for Spanish-Speaking Latinos. They concluded that new interventions that address the needs of diverse U.S. populations are needed to reduce health disparities. Additionally they noted the importance of adapting English-language health interventions to facilitate communication and decision-making.

Home Care

- The above interventions may be adapted for home care use.
- Develop clinical practice guidelines that include shared decision-making. **EB**: According to Agoritsas et al (2015), clinical practice guidelines have for the most part been tailored to meet the educational needs of clinicians and seldom support shared decision-making. Furthermore, identifying decisions where shared decision-making is indicated is particularly important. Decision aids can be used with clinical practice guidelines. They recommend the generic production of decision aids from clinical practice guidelines.

D

Impaired emancipated Decision-Making

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

A process of choosing a health care decision that does not include personal knowledge and/or consideration of social norms, or does not occur in a flexible environment resulting in decisional dissatisfaction

Defining Characteristics

Delay in enacting chosen health care option; distress when listening to others' opinion; excessive concern about what others think is the best decision; excessive fear of what others think about a decision; feeling constrained in describing own opinion; inability to choose a health care option that best fits current lifestyle; limited verbalization about health care option in others' presence

Related Factors

Decrease in understanding of all available health care options; inability to adequately verbalize perceptions about health care options; inadequate time to discuss health care options; insufficient privacy to openly discuss health care options; limited decision-making experience; traditional hierarchical family; traditional hierarchical health care system

NOC

Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Self-Esteem; Coping; Health Promotion Behavior; Stress Level; Communication; Self-Care; Participation In Health Care Decisions; Health-Seeking Behavior; Knowledge: Treatment Options; Psychosocial Adjustment

Example NOC Outcome with Indicators

Participation in Health Care Decisions as evidenced by the following indicator: Claims decision making responsibility. (Rate the outcome and indicators of **Participation in Health Care Decisions**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize option outcomes freely before making a health care decision
- Freely verbalize own opinion with health care providers before making a health care decision
- Choose the health care option that fits his or her lifestyle within an appropriate amount of time that allows enactment of the choice
- Describe how the chosen option fits into his or her current lifestyle before or after the decision has been made
- Verbalizes appropriate concern about others' opinions before making the health care choice
- Remains stress-free when listening to others' opinions before making the health care choice
- Arrives at a decision in a timely manner

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Decision-Making Support

Example NIC Activities—Emancipated Decision-Making

Assist client in making an emancipated decision about health care options by discussing social norms with the client; Provide a flexible environment; Encourage the client to use personal knowledge

Nursing Interventions and Rationales

- Assess client's readiness to openly discussing the decision-making process. **EBN:** *A qualitative study in China demonstrated that older adults were open to discuss end-of-life care even though traditional and cultural barriers have long been present (Chan & Pang, 2011).*
- Use active listening in a nonjudgmental manner to provide the client with a flexible decision-making environment. **CEB:** *Listening and hearing clients' stories (N = 12), without labeling them, provides them with a voice which they need to negotiate the health care system (Van Den Tillaart et al, 2009).* **EBN:** *A correlational study demonstrates that active listening may be enhanced when nurses (N = 31) are aware of their own attitudes on a subject before they engage in a dialogue with a client (Boyd et al, 2011).*
- Use anticipatory guidance by proactively providing the client with information. **EB:** *Social workers found, through a qualitative, case-based study conducted by interviewing family members, that anticipatory guidance is needed before a decisional crisis occurs (Mamier & Winslow, 2014).* **EBN:** *Wittmann-Price et al (2011) found in a mixed method study that the majority of pregnant clients (N = 50) reported they had been provided with information prenatally, but not all clients felt they were given enough information at the time of delivery to make an informed choice.*
- Establish a purposeful provider-client relationship. **EB:** *A qualitative psychology study done by Cook and Loomis (2012) demonstrated that clients (N = 15) should remain as the center focus in the decision-making process in order to maintain control.* **EB:** *Clients (N = 17) who have fears about diagnosis and treatments were therapeutically treated by establishing a purposeful provider-client relationship in which "listening" was most valued by clients (Nunes et al, 2013).*
- ▲ Refer to counseling as needed. **EB:** *A qualitative psychology study indicated that a woman's perception of her childbirth experience was interwoven with her feelings of having been provided choices through education and consultation (Cook & Loomis, 2012).* **CEB:** *Wittmann-Price (2006) demonstrated in a quantitative correlational study that women's (N = 97) decision-making was empowered when they were provided resources and information to arrive at an emancipated choice.*
- Provide decision-making support. **EBN:** *Support may help guard against oppressive health care practices as demonstrated in a qualitative case study done by Treloar and Gunn (2012) that focused on why women choose to smoke.* **EBN:** *de Rosenroll et al (2013) found that significant others need their physical and emotional needs met to play a supportive role in decision-making for dialysis clients.*
- Provide a flexible environment by encouraging others to accept client's choice. **EBN:** *Tully and Ball (2013) interviewed 115 mothers about mode of delivery; participants differentiated health care issues from social issues surrounding childbirth, demonstrating that social issues play a role in the decisional process.* **CEB:** *Wittmann-Price and Bhattacharya (2008) quantitatively studied pain management decisions for clients in labor (N = 92) and found that a flexible environment was needed in order for the client to make a supported and emancipated decision.*
- Encourage the client to use personal knowledge as part of the decision-making process to increase decisional satisfaction. **EBN:** *Women can make health care decisions that are right for them if they can use personal knowledge to overcome oppressive social forces (Stepanuk et al, 2013).* **CEB:** *Using personal knowledge is the best indicator to making an emancipated decision and correlates strongly and positively with satisfaction with the decision (Wittmann-Price, 2006).*

Pediatric

- When able, involve client in health care decision-making when possible. **EBN:** *Mitchell (2014) studied disabled young adults (N = 10) and found that they viewed health care decisions as important, and each*

individual “framed” the decision differently, but all included consideration of independence. **EBN:** Kennedy (2014) did a systematic review about pediatric clients ages 4 to 18 years and found that interventional studies ($N = 5$) indicated communication and education assisted clients to actively participate in the decision-making process.

- Provide parental information in the decision-making process. **EBN:** Three focus groups of parents identified areas of needed information in order to make decisions regarding newborn care (Rothwell et al, 2013). **EBN:** Holland et al (2014) developed a decision support tool in a correlation study ($N = 197$) to determine clients who need discharge planning and referrals to assist in decisional processes.

Critical Care

- Enhance client decision-making in critical care setting. **EBN:** Bridges et al (2013) synthesized 16 studies and found that the conditions of critical care settings appear best suited to forming therapeutic relationships, while nurses working on acute nursing units more often report moral distress resulting from delivering unsatisfactory care due to lack of ability to build a nurse-client relationship.

Geriatric

- Include geriatric clients in the decisional process. **EBN:** Hardin (2012) describes older adults’ level of decision-making participation in critical care units and identified that nurses need to assess the clients’ preferred level of involvement with decisions before assuming that they prefer not to be involved. **EB:** Isaacs et al (2013) studied older adults ($N = 159$) requiring outpatient analgesic treatment for a chronic illness and found that being active participants in the pain management decision increased client satisfaction and decreased analgesic use.
- Include family in the decision-making process when needed. **EB:** Einterz et al (2012) developed and validated a decision tool to assist surrogate decision-makers for clients with dementia. **EBN:** Kryworuchko et al (2013) did a systematic review of the literature about end-of-life decision-making and found that using shared decision-making trended toward decreasing family member anxiety and decreasing intensive care unit length of stay.

Multicultural

- Consider cultural influences on decision-making. **EBN:** Mead et al (2013) did a systematic review of minority clients’ decision-making regarding cancer treatment and found that factors that mattered to clients were categorized into themes: being part of the decision-making process; including client, family, and important others; community, and provider factors. **EBN:** Duke (2013) qualitatively studied three diverse cultural groups living in the United States to discuss end-of-life decision-making and found that there were differences in preferences for treatments such as artificial nutrition.

Home Care

- Use open communication to assist clients to develop health care plans to which they can adhere. **EBN:** Cook and Loomis (2012) studied open communication between women and their caregivers and found that it enhanced clients’ knowledge and empowers them to implement the decision. **EBN:** Truglio-Londrigan (2013) interviewed 10 homecare nurses about their perception of shared decision-making and recorded four important themes: decision-making needs to begin at the level of the client, providing education for the decision-making process, including the “village” or the significant social piece in the process, and ultimately identifying whose decision it is.

Readiness for enhanced emancipated Decision-Making

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

A process of choosing a health care decision that includes personal knowledge and/or consideration of social norms, which can be strengthened

Defining Characteristics

Expresses desire to enhance ability to choose health care options that best fit current lifestyle; expresses desire to enhance ability to enact chosen health care option; expresses desire to enhance ability to understand all available health care options; expresses desire to enhance ability to verbalize own opinion without constraint; expresses desire to enhance comfort to verbalize health care options in the presence of others; expresses desire to enhance confidence in decision-making; expresses desire to enhance confidence to discuss health care options openly; expresses desire to enhance decision making; expresses desire to enhance privacy to discuss health care options

NOC

Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Self-Esteem; Coping; Health Promotion Behavior; Stress Level; Communication; Self-Care; Participation in Health Care Decisions; Health-Seeking Behavior; Knowledge: Treatment Options; Psychosocial Adjustment

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Example NOC Outcome with Indicators

Participation in Health Care Decisions as evidenced by the following indicator: Claims decision making responsibility. (Rate the outcome and indicators of **Participation in Health Care Decisions**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

D

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize option of outcomes freely before making a health care decision
- Freely verbalize own opinion with health care providers before making a health care decision
- Choose the health care option that best fits his or her lifestyle within an appropriate amount of time that allows enactment of the choice
- Describe how the chosen option fits into his or her current lifestyle before or after the decision has been made
- Verbalizes appropriate concern about others' opinions before making the health care choice
- Remains stress-free when listening to others' opinions before making the health care choice
- Arrives at a decision in a timely manner

NIC

Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Decision-Making Support

Example NIC Activities—Emancipated Decision-Making

Assist client in making an emancipated decision about health care options by discussing social norms with the client; Provide a flexible environment; Encourage the client to use personal knowledge

Nursing Interventions and Rationales

- Assess client's readiness to choose through active listening. **EB**: *Greenstein et al (2013) studied active listening skills of health care providers during handoff reports using a "HEAR" checklist and found that active listening is rare with interruptions, being present 98% of the time.* **CEB**: *Bryant (2009) reviewed literature about active listening and describes four themes present when a health care provider is actively listening to the client, including (1) being present, (2) being interested, (3) having time, and (4) being respectful.*
- Use anticipatory guidance by proactively providing the client with information. (Refer to Impaired emancipated **Decision-Making**.)
- Establish a purposeful provider-client relationship. **EB**: *Zeidler (2011) studied the services provided by the First Nation group for Aboriginal people and found that open dialogue leads to the development of services that are relevant and responsive to clients' needs and can be accomplished by professionals who engage in a respectful and mutually beneficial collaborative learning process.* **EBN**: *Woolley et al (2012) implemented relationship-based care on a medical-surgical unit and the unit had positive results, including an increase in client satisfaction, a reduction in falls, fewer hospital acquired pressure ulcers, and decreasing call light use.*
- ▲ Include interdisciplinary health care professionals as needed to increase knowledge of chosen option. **EB**: *Rainchuso (2013) discusses that the health care practices of oral hygiene in women and infants is predicated on misconceptions and lack of knowledge and evidence demonstrate no detrimental effects of pregnant women receiving routine and restorative care while pregnant.*
- Provide decision-making support. (Refer to Impaired emancipated **Decision-Making**.)
- Continue to provide a flexible environment for client to enact choice. **EBN**: *Smith and Kirkpatrick (2013) used solution-focused brief therapy in clients with chronic obstructive pulmonary disease to be more supportive of clients by adopting a "not knowing" position while the client is placed in the position of "expert."* **EBN**: *Webster (2013) used standardized examples to teach therapeutic communication to students; outcome data demonstrated such education increased students' ability to address clients' preferences, values, and beliefs.*

- Encourage the client to use personal knowledge as part of the decision-making process to increase decisional satisfaction. **EBN:** *Scaffidi et al (2014)* found that clients ($N = 45$) with increased personal knowledge about the risks and benefits of trial of labor after a cesarean delivery were found to be positively associated with deciding to have vaginal delivery instead of cesarean delivery.

Pediatric

- Understand interventions that parents prefer when in the decision-making process. **EBN:** *Rosales and Allen (2012)* describe “optimism bias” in parents who make decisions that are risk-taking for children and underscore the fact that this concept is not yet measurable.

Multicultural

- Use open communication to assist clients to develop health care plans to which they can adhere. **EBN:** *Vandewark (2014)* studied the correlations between knowledge and attitude and found them to be significantly related. **EBN:** *Kilanowski (2013)* studied Latino migrant farm workers ($N = 31$) and found that clients preferred comic book-style handouts, games, food replicas, text in English/Spanish, and digital video discs or digital versatile discs, but did not like black-and-white photos or cartoon-like illustrations, concluding that it is important to offer information in colored illustrations, in sizes that mothers may easily carry in purses, and with limited verbiage on a page.

Home Care

- Optimize self-care personal knowledge for home care. **EBN:** *Johansson (2013)* found that increasing dialysis clients' personal knowledge about home therapies increased their decision-making capacity. **EBN:** *Truglio-Londrigan (2013)* did a qualitative study involving homecare nurses ($N = 13$) and found that decisions in the home include assessing “where the client is” on issues of education and significant others, and based on this information the client decides who will be making decisions regarding their care.
- Refer to care plan Impaired emancipated **Decision-Making** for additional interventions for pediatric, critical care, geriatric, and multicultural care.

Risk for impaired emancipated Decision-Making

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

Vulnerable to the process of choosing a health care decision that does not include personal knowledge and/or considerations of social norms, or does not occur in a flexible environment, resulting in decisional satisfaction

Risk Factors

Inadequate time to discuss health care options; insufficient confidence to openly discuss health care options; insufficient information regarding health care options; insufficient privacy to openly discuss health care options; insufficient self-confidence in decision-making; limited decision-making experience; traditional hierarchical family; traditional hierarchical health care systems

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Self-Confidence; Coping; Health Promotion Behavior; Stress Level; Communication; Self-Care; Participation in Health Care Decisions; Health-Seeking Behavior; Knowledge; Treatment Options; Psychosocial Adjustment

Example NOC Outcome with Indicators

Participation in Health Care Decisions as evidenced by the following indicator: Claims decision making responsibility. (Rate the outcome and indicators of **Participation in Health Care Decisions**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize option outcomes freely before making a health care decision in a private setting with whom he or she feels comfortable
- Freely verbalize own opinion with health care providers before making a health care decision
- Discuss how options fit or hinder his or her lifestyle within an appropriate amount of time that allows enactment of the choice
- Discuss concerns about others' opinions before making the health care choice
- Decrease stress about others' opinions by placing options in perspective through informational resources
- Discuss the time frame in which the decision needs to be made

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Establish Rapport; Decision-Making Support

Example NIC Activities—Emancipated Decision-Making

Assist client to verbalize and discuss barriers that she or he perceives in making an emancipated decision about health care options; Acknowledge social norms about decision options; Provide a flexible environment that is safe and private for the discussions. Use empathy to understand the client's personal point of view about the options

Nursing Interventions and Rationales

- Assess client's vulnerability for an impaired decision-making process. **EBN: Goldberg & Shorten (2014)** studied the decision-making perceptions for clients during childbirth and their providers, and observe

• = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

providers being paternalistic and trying to influence the client's decision while nurses tried to suggest that it was the client's decision. **EBN:** Ebert et al (2014) quantitatively studied socially disadvantaged women and found that they wanted to engage in health care decisions but did not feel safe to engage due to inadequate information, perceived risks in not conforming, and the actions and reactions of nurses when they did seek choices which resulted in a silent compliance.

- Assess the client's experience with decision-making. **EB:** Chong et al (2013) interviewed interprofessional providers (N = 31) to learn about perceived barriers for using shared decision-making in mental health care and identified consumers' lack of competence to participate as a frequently cited barrier. **EBN:** Mayer et al (2014) used hermeneutic phenomenology to study women's decisions to seek help for signs of acute myocardial infarction and found that each client was informed by their unique social circumstances and past experiences.
- Recognize traditional hierarchical family and health care system. **EB:** Légaré and Witteman (2013) analyzed barriers to a shared decision-making process and recognize that more health care providers need training in the approach and to better engage the client. **EB:** Dierckx et al (2013) studied shared decision-making (SDM) between therapist perception and client preferred level of involvement in 237 consultations and found that SDM was not offered although clients preferred to provide their opinion about the treatment because physical therapists did not often recognize this factor and tended to apply a paternalistic approach.
- Provide privacy to discuss health care options. **EBN:** Jackson and McCulloch (2014) studied older rural women's decision to seek help for heart conditions and found women had difficulty identifying heart attack symptoms and were reluctant to access care because of concerns of maintaining their privacy. **EBN:** Peak et al (2012) explored the experiences of persons with HIV (N = 10) attending an assisted reproductive treatment program and found through interview that disclosure of HIV status and managing confidentiality were a significant challenge related to decision-making for infertility treatment.
- Allow the client time to choose. **EBN:** Cook et al (2014) used a mixed method approach to study the implementation of the nonreport option in Texas regarding sexual assault victims and found significant to reporting was confidentiality processes, storage and shipment of evidence, and the use of the nonreport option. **EB:** Pieterse et al (2013) performed a systematic literature review to identify process theories (N = 4) that guided decision-making practices and found that they encouraged clients to consider all options, discouraged clients from jumping to the first option, included client's values, compared options, and provided time to decide.
- ▲ Understand primary care providers' role in the decision-making process. **EB:** Uy et al (2014) used a mixed method study involving primary care practices (N = 4) and concluded that in order for clients to experience decisional support interventions that health care provider engagement and financial incentives were important. **EBN:** O'Sullivan and Rae (2014) studied psychiatric clients' perceptions of shared decision-making in relation to medication management and found clients wanted good quality information about medicines and alternative treatments from providers.
- Provide informational resources. **EBN:** Schroy et al (2014) used a cross-sectional survey with providers (N = 42) using a decision aid with clients for colon cancer screening adherence and the majority felt that the tool increased client knowledge, helped clients identify a preferred screening option, improved the quality of decision-making, and saved time. **EB:** Mathew et al (2014) studied client satisfaction with care and maximizing adherence with migraine treatment plans using a cross-sectional survey. The majority of participants (92%) preferred that the decision to prescribe a triptan be a joint decision and clients generally felt health care providers did a good job educating them.
- Provide encouragement so clients increase their confidence in the decision-making process. **EB:** Reeve et al (2013) did a systematic review of the literature (N = 21) to understand why clients do or do not decide on inappropriate medication use and identified the following barriers/enablers: disagreement/agreement with "appropriateness" of cessation, absence/presence of a "process" for cessation, negative/positive "influences" to cease medication, and "fear" of cessation and "dislike" of medications. **EB:** Joseph-Williams et al (2014) did a systematic review of the literature for shared decision-making barriers and found that themes related to clients' knowledge and the power imbalance in the doctor-client relationship and knowledge alone is insufficient and power is more difficult to attain.

Pediatric

- Understand the parent/guardian's vulnerability when making health care decisions for their children. **EB:** Crowe et al (2014) used a questionnaire to discover how parents chose a language mode for their child and found that factors such as family, community, and advice from others were significant.

- Understand adolescent decision-making processes. **EB**: DeBellis et al (2013) studied the decision-making process of adolescents in using cannabis and found that the participants (N = 23) demonstrated distinctly different activation patterns during risky decision-making and reward processing compared to nonusers (N = 18).
- Refer to care plan Impaired emancipated **Decision-Making** for additional interventions for critical care, geriatric, multicultural care, and home care.

Decisional Conflict Dawn Fairlie, ANP, FNP, GNP, DNS(c)

NANDA-I

Definition

Uncertainty about course of action to be taken when choice among competing actions involves risk, loss, or challenge to values and beliefs

Defining Characteristics

Delay in decision-making; distress while attempting a decision; physical sign of distress (e.g., increase in heart rate, restlessness); physical sign of tension; questioning of moral principle while attempting a decision; questioning of moral rule while attempting a decision; questioning of moral values while attempting a decision; questioning of personal beliefs while attempting a decision; questioning of personal values while

attempting a decision; recognizes undesired consequences of actions being considered; self-focused; uncertainty about choices; vacillating among choices

Related Factors (r/t)

Conflict with moral obligation; conflicting information sources; inexperience with decision-making; insufficient information; insufficient support system; interference in decision-making; moral principle supports mutually inconsistent actions; moral rule supports mutually inconsistent actions; moral value supports mutually inconsistent actions; perceived threat to value system; unclear personal beliefs unclear personal values

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Information Processing; Participation in Health Care Decisions; Personal Autonomy

Example NOC Outcome with Indicators

Decision-Making as evidenced by the following indicators: Identifies relevant information/Identifies alternatives/Identifies potential consequences of each alternative/Identifies needed resources to support each alternative. (Rate the outcome and indicators of **Decision-Making**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State the advantages and disadvantages of choices
- Share fears and concerns regarding choices and responses of others
- Seek resources and information necessary for making an informed choice
- Make an informed choice

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Decision-Making Support

Example NIC Activities—Decision-Making Support

Inform client of alternative views or solutions in a clear and supportive manner; Provide information requested by client

Nursing Interventions and Rationales

- Observe for factors causing or contributing to conflict (e.g., value conflicts, fear of outcome, poor problem-solving skills). **EBN**: *When studying clients with prostate cancer, Chien et al (2014) found that different treatments may cause conflicts in treatment decision-making and that decisional conflict improved over time. Additionally, education level, decision preferences, and psychosocial adjustment were associated with decisional conflict. They concluded that nurses must provide clients with adequate information and psychosocial intervention to reduce decisional conflict.*
- Provide emotional support. **EB**: *Knops et al (2013) evaluated associations between decisional conflict and emotions and found a decrease in decisional conflict leads to less decision postponing behavior and anxiety. EB*: *Decisional conflict was assessed using the Decisional Conflict Scale (DCS) among pregnant women considering antidepressant medication treatment. Although many pregnant women facing decisions regarding the use of antidepressant medication experience decisional conflict, their decisions were facilitated by interpersonal supports, and emotional support reduced decisional conflict and facilitated the decision-making process (Walton et al, 2014).*
- Use decision aids or computer-based decision aids to assist clients in making decisions. **EB**: *A Cochrane review of decision aids (pamphlets, videos, or Web-based tools) concluded that use of decision aids fosters a positive effect on communication with health care providers and influenced the time required for the*

consultation. Additionally, there was an improvement with more detailed decision aids when compared to simpler decision aids, and both were better than usual care (Stacey et al, 2011). **EB**: A randomized trial of a decision aid for CHD adherence was conducted by Sheridan et al (2014), who reported that most participants found the decision aid easy to use and easy to understand. Participants reported improvement in personalization of information and that the decision aid helped them to decide what was important to them.

- Initiate health teaching and referrals when needed. **EBN**: A prospective cross-sectional study of Australian women with early breast cancer reported that many women experienced post treatment distress requiring referral for psychological assessment and long term support (Budden et al, 2014). They concluded that individualized decision support interventions by nurses can help to identify women at risk and refer them to specialist services.
- Facilitate communication between the client and family members regarding the final decision; offer support to the person actually making the decision. **EBN**: A study of surrogate decision-makers' decisional conflict with end of life decision-making found that surrogates who had discussed end of life preferences with their loved one experienced less decisional conflict than those who had not discussed preferences (Fairlie, 2014).

Geriatric

- Carefully assess clients with dementia regarding ability to make decisions. **EBN**: A study of the shared decision-making process of persons with dementia identified a broad spectrum of the shared decision-making process. Results indicated that not all persons with dementia are excluded from participating in the decision-making process (Miller et al, 2014).
- Support previous wishes for clients with dementia. **EBN**: Educational level, commitment of nursing personnel and organizational culture influences participation in care by clients with dementia. Client participation was described as letting the clients make their own decisions, adjusting the choices, making decisions on behalf of the residents. Client participation was regarded as being grounded in the idea that being master of one's own life is essential to the dignity and self-esteem of all people (Helgesen et al, 2014).
- Discuss the purpose of advance directives such as a living will or medical power of attorney. **EB**: A Swedish study compared attitudes and knowledge about the implantable cardioverter defibrillator (ICD) to determine how well HF clients could participate in end-of-life decisions. Whether to deactivate an ICD at end-of-life was queried. Clients with an ICD were not prepared to engage in shared decision-making about their ICD and its use at the end-of-life (Strömberg et al, 2014). **EB**: A systematic review of advance care planning (ACP) interventions that included communication about end-of-life care increased the completion of advance directives was performed by Houben et al (2014). They found that communication about ACP improved concordance between preferences for care and delivered care and may improve other outcomes, such as quality of communication. Additionally, ACP interventions increase the completion of advance directives, occurrence of discussions about ACP, concordance between preferences for care and delivered care, and are likely to improve other outcomes for clients and their loved ones in different adult populations.

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's decision-making conflict. **EB**: A study of two hundred sixty-six parents of children with a life-threatening illness (Knapp et al, 2014) investigated how decisional conflict varies among racial and ethnic subgroups. Analyses suggest that minority parents report less effective decision-making and report less support in decision-making compared to white, non-Hispanic parents and concluded that significant differences exist by race, ethnicity, language. It is important to address these differences when creating clinical care plans, engaging in shared decision-making, and creating interventions to alleviate decisional conflict. **EB**: African American men with prostate cancer were encouraged to discuss screening alternatives with health care providers for informed decision-making (IDM). The intervention significantly promoted IDM among men who reported more education, being married, having financial resources, and younger age (Sultan et al, 2014).
- Provide support for client's decision-making. **EBN**: Decision aids are intended to help people participate in decisions that involve weighing the benefits and harms of treatment options often with scientific uncertainty. Stacey et al (2014) concluded that there is high-quality evidence that decision aids improve client's knowledge regarding options and reduce decisional conflict.
- Use cross-cultural decision aids when possible to enhance an informed decision-making process. **EB**: Ko et al (2014) studied cultural and linguistic adaptation of a multimedia colorectal cancer screening Decision Aid for Spanish-Speaking Latinos. They concluded that new interventions that address the needs of diverse

U.S. populations are needed to reduce health disparities. Additionally they noted the importance of adapting English-language health interventions to facilitate communication and decision-making.

Home Care

- The interventions described previously may be adapted for home care use.
- ▲ Before providing any home care, assess the client plan for advance directives (living will and power of attorney). If a plan exists, place a copy in the client file. If no plan exists, offer information on advance directives according to agency policy. Refer for assistance in completing advance directives as necessary. Do not witness a living will. *This is a legal requirement of the Consolidated Omnibus Budget Reconciliation Act (COBRA, 2009).*
- Assess the client and family for consensus (or lack thereof) regarding the issue in conflict. **EB:** *Miller et al (2014) reviewed empirical findings concerning the decision-making process of persons with dementia and their family caregivers and focused on the extent of involvement of persons with decision-making responsibility. They found that some families include persons with dementia in the decision-making, but cautioned that there is a broad view of what shared decision-making in dementia entails.*
- Refer to care plan for **Anxiety** as indicated.

Client/Family Teaching and Discharge Planning

- Instruct the client and family members to provide advance directives in the following areas:
 - Person to contact in an emergency
 - Preference (if any) to die at home or in the hospital
 - Desire to initiate advanced directives, such as a living will or medical power of attorney
 - Desire to donate an organ
 - Funeral arrangements (i.e., burial, cremation)
- ▲ **EBN:** *Shared decision makers experienced less decisional conflict when they had discussed the client's preferences with the client (Fairlie, 2014).*
- Inform the family of treatment options; encourage and defend self-determination. **EB:** *Weeks et al (2014) identified three phases of decision-making when clients with cancer consider complementary and alternative medicine (CAM) modalities. They noted that each phase involves different patterns of information-seeking and evaluation. They concluded that treatment choices are guided by beliefs, values, and other social and cultural norms and that clients frequently need help with discussing and prioritizing treatment decisions.*
- Recognize and allow the client to discuss the selection of complementary therapies available, such as spiritual support, relaxation, imagery, exercise, lifestyle changes, diet (e.g., macrobiotic, vegetarian), and nutritional supplementation. **EB:** *Weeks et al (2014) reported that clients with cancer frequently report anxiety and conflict surrounding CAM treatment. They found that decisions about CAM by clients with cancer is a complex, dynamic, nonlinear process and found increased levels of conflict and anxiety for clients who consider CAM as a part of their cancer care.*
- ▲ Provide the Physician Orders for Life-Sustaining Treatment (POLST) form for clients and families faced with end-of-life choices across the health care continuum. **CEB:** *The POLST form ensures that end-of-life choices can be implemented in all settings, from the home through the health care continuum. The POLST form was congruent with residents' existing advance directives for health care (Meyers et al, 2004).*

Ineffective Denial Julianne E. Doubet, BSN, RN, CEN, NREMT-P

NANDA-I

Definition

Conscious or unconscious attempt to disavow the knowledge or meaning of an event to reduce anxiety and/or fear, leading to the detriment of health

Defining Characteristics

Delays seeking health care; denies fear of death; denies fear of invalidism; displaces fear of impact of the condition; displaces source of symptoms; does not admit impact of disease on life; does not perceive relevance of danger; does not perceive relevance of symptoms; inappropriate affect; minimizes symptoms; refusal of health care; use of dismissive gestures when speaking of distressing event; use of dismissive comments when speaking of distressing event; use of treatment not advised by health care professional

Related Factors (r/t)

Anxiety; excessive stress; fear of death; fear of loss of autonomy; fear of separation; ineffective coping strategies; insufficient emotional support insufficient sense of control; perceived inadequacy in dealing with strong emotions; threat of unpleasant reality

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Acceptance: Health Status; Anxiety Self-Control; Health Beliefs: Perceived Threat; Symptom Control

Example NOC Outcome with Indicators

Anxiety Self-Control as evidenced by the following indicators: Eliminates precursors of anxiety/Monitors physical manifestations of anxiety/Controls anxiety response. (Rate the outcome and indicators of **Anxiety Self-Control**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Seek out appropriate health care attention when needed
- Use home remedies only when appropriate

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

- Display appropriate affect and verbalize fears
- Actively engage in treatment program related to identified “substance” of abuse
- Remain substance-free
- Demonstrate alternate adaptive coping mechanism

NIC (Nursing Interventions Classification)

D

Suggested NIC Intervention

Anxiety Reduction

Example NIC Activities—Anxiety Reduction

Use a calm, reassuring approach; Stay with the patient to promote safety and reduce fear

Nursing Interventions and Rationales

- Assess the client’s and family’s understanding of the illness, the treatments, and expected outcomes. **EBN:** *Effective communication between client and health care provider in relation to health promotion, disease prevention, and disease management is key to optimal health outcomes (Heinrich & Karner, 2011).* **EB:** *Communication difficulties in health care may arise when health care providers concentrate on the client’s diseases and its management, but fail to take into consideration the client’s lifestyle and feelings about health problems (Gaulden et al, 2012).*
- Allow client time for adjustment to his/her situation. **EBN:** *Thoughtful contemplation of life expectancy and end-of-life care are vital for clients to ensure their continued optimum quality of life (Walczak et al, 2014).*
- Aid the client in making choices regarding treatment and actively involve him or her in the decision-making process. **EBN:** *Current focus is on the person as the primary decision-maker in his/her health care and is apropos in relation to the key concept of quality of life, as defined by the person or community and expressed in the nursing theory of Human Becoming (Poirier, 2012).*
- Allow the client to express and use denial as a coping mechanism if appropriate to treatment. **EB:** *Sirri and Grandi (2012) suggest that those assessing a client who suffers illness denial, should bear in mind that denial may sometimes preclude patients from suffering overwhelming psychological and emotional distress as a result of a life-threatening or stigmatizing diagnosis.*
- Support the client’s spiritual coping measures. **EBN:** *According to Baldacchino et al (2013), spiritual, though not necessarily religious, coping, may enhance adjustment of clients to their chronic illnesses.*
- Develop a trusting, therapeutic relationship with the client/family. **EBN:** *According to Dinc and Gastmans (2013), in their study of the literature focusing on nurse-patient relationships, nurses’ professional expertise and interpersonal caring qualities were essential in developing trust; however, a combination of factors could hamper that trusting relationship.*
- Assist the client in using existing and additional sources of support. **EBN:** *Health care providers should recognize the individual’s needs, including emotional, psychosocial, sexual, and relational, of those who suffer from chronic illness and provide suitable information and support, especially for those who are isolated from the mainstream (Spring et al, 2011).*
- Refer to care plans for Defensive **Coping** and Dysfunctional **Family** processes.

Geriatric

- Allow the client to explain his/her concepts of their health care needs, then use reality-focused techniques whenever possible to provide feedback. **EB:** *Clients should be made conscious of the fact that primary medical treatment, even when associated with a positive prognosis, does not in and of itself predict how well clients will fare during their lifetime (Linden et al, 2014).*
- Encourage communication among family members. **EBN:** *This study testifies to the importance of the mutual influences of patient, family, and nurse during a critical illness and supports the inclusion of family in all facets of their loved one’s care (Cypress, 2011).*
- Recognize denial and be aware that grieving may prolong denial. **EBN:** *Nurses should understand the importance of reconciliation in the grief process and provide professional, empathetic care (Gustafsson et al, 2011).*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values involved in the client's understanding of and ability to acknowledge health status. **EB:** *Lee and Mason (2014) suggest that health care practitioners should develop programs that include ethnic- and gender-specific components, which, in turn, will aid older adults in coping with the stress caused by illness.*
- Discuss with the client those aspects of his/her health behavior/lifestyle that will remain unchanged by health status and those aspects of health behavior that need to be modified to improve health status. **EBN:** *"Culturally sensitive interventions are required to ensure people of culturally and linguistically diverse backgrounds have the appropriate skills to self-manage their complex medical conditions," Williams et al (2014).*
- Assess the role of fatalism in the client's ability to acknowledge health status. **EB:** *Some minorities, due to cultural factors (e.g., fatalism, medical mistrust), have negative attitudes toward health care interventions: targeting these cultural issues may help reduce undertreatment of minorities (Lin et al, 2014).*

Home Care

- Previously mentioned interventions may be adapted for home care utilization.
- Observe family interaction and roles. Refer the client/family for follow-up if prolonged denial is a risk. **EBN:** *A study by Benkel et al (2012) indicates that there is a connection between the loved one's understanding of a fatal disease and the caregiver's ability to cope.*
- Encourage communication between family members, particularly when dealing with the loss of a significant person. **EBN:** *Nurses should offer support and comfort to those who have lost a loved one and through empathetic communication: observe for nonverbal clues and the need for further interventions (Reid et al, 2011).*

Client/Family Teaching and Discharge Planning

- Instruct client and family to recognize the signs and symptoms of recurring illness and the appropriate responses to alteration in client's health status. **EBN:** *It has been found that patients and their families are commonly confused after hospital emergency department release about aftercare based on their discharge instructions; follow-up phone calls may be of some benefit to address educational needs (Zavala & Shaeffer, 2011).*
- Consider the client's belief in and use of complementary therapies in self-managing his/her disease. **EBN:** *No matter what other care is provided, nurses should support any program type that genuinely makes a difference for the client and his/her family (Madden, 2014).*
- Teach family members that denial may continue throughout the adjustment to treatment and they should not be confrontational. **EB:** *Losses come with progressing years and may dictate interpersonal and selfish readjustments to relationships, occupations, and avocations: the use of denial as a defense mechanism may play a significant role in these situations (Clemens, 2014).*
- ▲ Inform family of available community support resources. **EBN:** *The nurse will come in contact with family caregivers who are striving to keep their loved one at home, but find that physical, emotional, and monetary burdens necessitate an intervention to tap into targeted support (Schrauf, 2011).*

Impaired Dentition *Betty J. Ackley, MSN, EdS, RN*

NANDA-I

Definition

Disruption in tooth development/eruption patterns or structural integrity of individual teeth

Defining Characteristics

Abraded teeth; absence of teeth; dental caries; enamel discoloration; erosion of enamel; excessive oral calculus; excessive oral plaque; facial asymmetry; halitosis; incomplete tooth eruption for age; loose tooth; malocclusion; premature loss of primary teeth; root caries; tooth fracture; tooth misalignment; toothache

Related Factors (r/t)

Barriers to self-care, bruxism; chronic vomiting, difficulty accessing dental care; economically disadvantaged; excessive intake of fluoride; excessive use of abrasive oral cleaning agents; genetic predisposition; habitual use of staining substance (e.g., coffee, red wine, tea, tobacco); insufficient dietary habits; insufficient knowledge of dental health; insufficient oral hygiene; malnutrition; oral temperature sensitivity; pharmaceutical agent

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Oral Health

Example NOC Outcome with Indicators

Oral Health as evidenced by the following indicators: Cleanliness of teeth/Cleanliness of gums/Cleanliness of dentures/Tongue integrity/Gum integrity. (Rate the outcome and indicators of **Oral Health**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Have clean teeth, healthy pink gums
- Be free of halitosis
- Explain how to perform oral care
- Demonstrate ability to masticate foods without difficulty
- State free of pain in mouth

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Oral Health Maintenance; Oral Health Promotion; Oral Health Restoration

Example NIC Activities—Oral Health Maintenance

Establish a mouth care routine; Arrange for dental check-ups as needed

D

Nursing Interventions and Rationales

- ▲ Inspect oral cavity/teeth at least once daily and note any discoloration, presence of debris, amount of plaque buildup, presence of lesions such as white lesions or patches, edema, or bleeding, and intactness of teeth. Refer to a dentist or periodontist as appropriate. *Systematic inspection can identify impending problems. White lesions are often leukoplakia, which is a precursor to squamous cell carcinoma. If the lesion is cancerous, prompt treatment is needed (Engelke & Pravikoff, 2010).*
- If the client is free of bleeding disorders and is able to swallow, encourage the client to brush teeth with a soft toothbrush using fluoride-containing toothpaste at least two times per day. Do not use foam swabs or lemon glycerin swabs to clean the teeth. **EB:** *Oral bacteria cause caries and periodontal disease. Plaque is a biofilm of bacteria, which often becomes contaminated with antibiotic-resistant bacteria in the hospitalized client (Roberts & Mullany, 2010). CEB:* *The toothbrush is the most important tool for oral care; toothbrushing is the most effective method of reducing plaque and controlling periodontal disease; a nursing study demonstrated that foam swabs are not effective in removing plaque (Pearson & Hutton, 2002). Lemon glycerin swabs dry the oral mucosa and can erode the tooth enamel (Foss-Durant & McAfee, 1997; Meurman et al, 1996; Poland, 1987). Inspect the gingiva for signs of gingivitis. Normally the gums should be pink and firm; gingivitis is likely when the gums are red and loose. Bleeding from the gums is an indication of gingivitis, and the client should see a dentist (Bissett, 2011).*
- Encourage the client to floss the teeth at least once per day if free of a bleeding disorder, or if the client is unable, floss the teeth for the client. **EB:** *A Cochrane review found that there is some evidence that flossing in addition to toothbrushing reduces gingivitis compared to toothbrushing alone. Also, there is some evidence that flossing plus toothbrushing may be associated with a small reduction in plaque at 1 and 3 months (Sambunjak et al, 2011).*
- Use a rotation-oscillation power toothbrush for removal of dental plaque. **EB:** *Multiple studies have found a rotation-oscillation power toothbrush more effective than an ultrasonic toothbrush (Biesbrock et al, 2008; He et al, 2008; Williams et al, 2008). A systematic review found that the powered toothbrush was safe to use on both hard and soft dental tissues (Robinson, 2011).*
- Determine the client's mental status and manual dexterity; if the client is unable to care for self, nursing personnel must provide dental hygiene. The nursing diagnosis Bathing **Self-Care** deficit is then applicable.
- If the client is unable to brush own teeth, follow this procedure:
 1. Position the client sitting upright or on side.
 2. Use a soft bristle baby toothbrush.
 3. Use fluoride toothpaste and tap water or saline as a solution.
 4. Brush teeth in an up-and-down manner.
 5. Suction as needed.

Each client must receive oral care including toothbrushing two times every day to maintain healthy teeth and mouth, and to prevent complications associated with periodontitis (the advanced form of gum disease that can cause tooth loss), which is associated with health problems such as cardiovascular disease, stroke, and bacterial pneumonia (ADA, 2015).
- Monitor the client's nutritional and fluid status to determine if adequate. Recommend the client eat a balanced diet and limit between-meal snacks. *Poor nutrition predisposes clients to dental disease (ADA, 2015).*
- Recommend the client stop or at least decrease intake of soft drinks. *Sugar-containing soft drinks can cause cavities, and the low pH of the drink can cause erosion in teeth (ADA, 2015). EB:* *A study demonstrated a much higher incidence of caries in children who drank soft drinks, as well as increased intake of processed foods (Llena & Forner, 2008).*

- Instruct the client with halitosis to clean the tongue when performing oral hygiene. Brush tongue with a tongue scraper or toothbrush and follow with a mouth rinse. **EB:** *A Cochrane review found that tongue cleaning was effective for short-term control of halitosis (Van der Sleen et al, 2010).*
- Determine the client's usual method of oral care. Whenever possible, build on the client's existing knowledge base and current practices to develop an individualized plan of care.
- Tell the client to direct the toothbrush at a 45-degree angle toward the tooth surfaces, not horizontally (ADA, 2015).
- Use an antimicrobial mouthwash as ordered or tap water or saline only for a mouth rinse. Avoid the use of hydrogen peroxide, or alcohol-based mouthwashes. *Some antimicrobial mouthwashes have demonstrated effective action in decreasing bacterial counts in plaque and decreasing gingivitis (ADA, 2015).* **CEB:** *Hydrogen peroxide can cause mucosal damage and is extremely foul tasting to clients (Tombs & Gallucci, 1993).*
- ▲ Recommend client see a dentist at prescribed intervals, generally two times per year if teeth are in satisfactory condition. *It is important to see a dentist at regular intervals for preventive dental care (ADA, 2015).*
- ▲ If there are any signs of bleeding when the teeth are brushed, refer the client to a dentist or, if obvious signs of inflamed gums, a periodontist. Bleeding along with halitosis is associated with gingivitis. *Beginning gingivitis can often be reversed with good oral hygiene; with more advanced cases a periodontist may be needed to correct the condition.* If platelet numbers are decreased, or if the client is edentulous, use moistened Toothettes or a specially made very soft toothbrush for oral care. *A regular toothbrush can cause soft tissue injury and bleeding in clients with low numbers of platelets.*
- Recognize that good dental care/oral care can be effective in preventing hospital acquired (or extended care acquired) pneumonia. **CEB/EB:** *Many references have found that dental/oral care was effective in preventing new onset of pneumonia (Arpin, 2009; Ishikawa et al 2008; Sarin et al, 2008).*
- Provide scrupulous dental care to critically ill clients, including ventilated clients to prevent ventilator-associated pneumonia. **EB/EBN:** *Numerous studies have demonstrated decreased incidence of ventilator-associated pneumonia with good oral care (Fields, 2008; Panchabhai et al, 2009).*
- If teeth are nonfunctional for chewing, modification of oral intake (e.g., edentulous diet, soft diet) may be necessary. The nursing diagnosis imbalanced **Nutrition:** less than body requirements may apply.
- If the client is unable to swallow, keep suction nearby when providing oral care.
- See care plan for impaired **Oral Mucous Membrane.**

Pregnant Client

- Encourage the expectant mother to eat a healthy, balanced diet that is rich in calcium. The teeth usually start to form in the gums during the second trimester of pregnancy. *To encourage the development of good, strong teeth, expectant mothers should eat a healthy, balanced diet that is rich in calcium (ADA, 2015).*
- Advise the pregnant mother not to smoke. **CEB:** *Maternal smoking during pregnancy has been associated with increased caries in the teeth of the child (Lida et al, 2007).*
- Advise the expectant mother to practice good care of her teeth, to protect her child's teeth once born. *Dental caries in children are associated with high levels of Streptococcus mutans. This bacterium is commonly spread from the mother with infected teeth to the infant by tasting of food and sharing of utensils once the child is born (Kagihara et al, 2009).*

Infant Oral Hygiene

- Gently wipe baby's gums with a clean washcloth or sterile gauze at least once a day. *Wiping gums prevents bacterial buildup in the mouth.*
- Never allow the child to fall asleep with a bottle containing milk, formula, fruit juice, or sweetened liquids. If the child needs a comforter between regular feedings, at night, or during naps, fill a bottle with cool water or give the child a clean pacifier recommended by the dentist or health care provider. Never give child a pacifier dipped in any sweet liquid. Avoid filling child's bottle with liquids such as sugar water and soft drinks. *Decay occurs when sweetened liquids such as milk, formula, and fruit juice are given and are left clinging to an infant's teeth for long periods. Bacteria in the mouth use these sugars as food to produce acids that attack the teeth (ADA, 2015; Kagihara et al, 2009).*
- ▲ When multiple teeth appear, brush with small toothbrush with small (pea-size) amount of fluoride toothpaste. Recommend that child either use a fluoride gel or fluoride varnish. *Use of topical fluoride (mouth*

rinses, gels, or varnishes) in addition to toothpaste containing fluoride resulted in a modest reduction of cavity formation versus use of fluoride toothpaste only (Marinho et al, 2003).

- Advise parents to begin dental visits at 1 year of age. Caries and infection of the first set of teeth have been associated with problems of alignment of permanent teeth, difficulty chewing, problems speaking, sleeping, concentrating, and learning, as well as problems with self-esteem (Kagihara et al, 2009).

Older Children

- ▲ Encourage the family to talk with the dentist about dental sealants, which can help prevent cavities in permanent teeth. **EB:** A Cochrane review found that use of dental sealants on the molars of children was effective in preventing caries (Ahovuo-Saloranta et al, 2008).
- Teach to brush teeth twice a day. **EB:** Twice daily tooth brushing is a low-cost, effective strategy to reduce the risk of childhood caries (Huebner & Milgrom, 2015).
- Recommend the child use dental floss to help prevent gum disease. The dentist will give guidelines on when to start using floss.
- Recommend to parents that they not permit the child to smoke or chew tobacco, and stress the importance of setting a good example by not using tobacco products themselves.
- Recommend the child drink fluoridated water when possible. Fluoride in drinking water is one of several available fluoride resources. *The American Dental Association strongly endorses use of fluoridated water, based on scientific research that validates the effectiveness in preventing cavities (ADA, 2015).* **EB:** Community water fluoridation remains an effective public health strategy for delivering fluoride to prevent tooth decay and is the most feasible and cost-effective strategy for reaching entire communities (U.S. Department of Health & Human Services Federal Panel on Community Water Fluoridation, 2015).
- Recommend the child use toothpaste containing fluoride. **EB:** A Cochrane study demonstrated that use of fluoride toothpaste was effective in preventing caries in children and adolescents when compared to placebo (Walsh et al, 2010).

Geriatric

- Provide dentists with accurate medication history to avoid drug interactions and client harm. If the client is taking anticoagulants, the INR should be reviewed before providing dental care.
- Help clients brush own teeth, or provide dental care after breakfast and before bed every day. *If the client lacks dexterity in hands, consider use of a toothbrush by embedding the handle in foam tubing. Also consider use of a powered toothbrush because it has a larger handle (Bissett, 2011).*
- If the client has dementia or delirium and exhibits care-resistant behavior such as fighting, biting, or refusing care, use the following method:
 1. Ensure client is in a quiet environment such as own bathroom, sitting or standing at the sink to prime memory for appropriate actions.
 2. Approach the client at eye level within his/her range of vision.
 3. Approach with a smile, and begin conversation with a touch of the hand and gradually move up.
 4. Use mirror-mirror technique, standing behind the client, and brush and floss teeth.
 5. Use respectful adult speech, not elderspeak/sing song voice, calling “deary,” “honey,” or the like. *Elderspeak is a documented trigger for care-resistant behavior (Herman & Williams, 2009).*
 6. Promote self-care when client brushes own teeth if possible.
 7. Use distractors when needed, singing, talking, reminiscing, or use of a teddy bear.
- ▲ **EBN:** Use of specific techniques can decrease the fear-evoked response to nursing care, and increase the effectiveness of nurses providing oral care to clients (Jablonski et al, 2011).
- ▲ Ensure that dentures are removed and cleaned regularly, preferably after every meal and before bedtime. Soak dentures at night in cold water. Dentures left in the mouth at night impede circulation to the palate and predispose the client to oral lesions. **EB:** A Cochrane review found a lack of evidence about the effectiveness of the different denture cleaning methods considered including chemical and mechanical methods of cleaning (de Souza et al, 2009).
- ▲ Support other caregivers providing oral hygiene. Physical and cognitive impairment in older adults can interfere with the client’s ability to perform oral hygiene, and oral hygiene should be provided by a caregiver. If no caregiver is available, the client is prone to dental problems such as dental caries, tooth abscess, tooth fracture, and gingival and periodontal disease.

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's understanding of dental care. **EBN:** *What the client considers normal and abnormal dental care may be based on cultural perceptions (Giger & Davidhizar, 2008).*
- Assess for barriers to access to dental care, such as lack of insurance. *Children from racial minority groups may have significantly more difficulty in accessing dental care (Savage et al, 2004).* **CEB:** *African Americans and persons of lower socioeconomic status reported more new dental symptoms, were less likely to obtain dental care, and reported more tooth loss (Gilbert et al, 2003).*

Home Care

- Assess client patterns for daily and professional dental care and related patterns (e.g., smoking, nail biting). Assess for environmental influences on dental status (e.g., fluoride).
- Assess client facilities and financial resources for providing dental care. *Lack of appropriate facilities or financial resources is a barrier to positive dental care patterns. Provision for dental care may be missing from health care plans or unavailable to the uninsured.*
- Request dietary log from the client, adding column for type of food (i.e., soft, pureed, regular).
- Observe a typical meal to assess first-hand the impact of impaired dentition on nutrition. *Clients, especially older adults, are often hesitant to admit nutritional changes that may be embarrassing because of poor dentition.*
- Assist the client with accessing financial or other resources to support optimum dental and nutritional status.

Client/Family Teaching and Discharge Planning

- Teach how to inspect the oral cavity and monitor for problems with the teeth and gums.
- Teach how to implement a personal plan of dental hygiene, including appropriate brushing of teeth and tongue and use of dental floss. Utilize motivational interviewing to facilitate increased compliance in dental care. **EB:** *A study demonstrated improved dental hygiene with decreased amount of plaque when motivational interviewing was used as compared to a usual teaching session on dental care (Godard et al, 2011).* *A systematic review found motivational interviewing more effective in changing oral health than usual care (Watt, 2010).* See *Motivational Interviewing in Appendix C.*
- Advise the clients to change their toothbrush every 3 to 4 months, because after that toothbrushes are less effective in removing plaque and are a source of bacterial contamination of the mouth and teeth (ADA, 2015).
- Teach the client the value of having an optimal fluoride concentration in drinking water, and to brush teeth twice daily with toothpaste containing fluoride.
- Teach clients of all ages the need to decrease intake of sugary foods and to brush teeth regularly.
- Inform individuals who are considering tongue piercing of the potential complications such as chipping and cracking of teeth and possible trauma to the gingiva. If piercing is done, teach the client how to care for the wound and prevent complications. **EB:** *A study demonstrated that 74% of adolescents with tongue piercing had complications or alterations (Firoozmand et al, 2009).* *Another study demonstrated that gingival recession was associated with oral piercing (Slutzkey & Levin, 2008).*

Risk for delayed Development *Marsha McKenzie, MA Ed, BSN, RN*

NANDA-I

Definition

Vulnerable to delay of 25% or more in one or more of the areas of social or self-regulatory behavior, or in cognitive, language, gross, or fine motor skills, which may compromise health

Risk Factors

Prenatal

Economically disadvantaged; endocrine disorder; functional illiteracy; genetic disorder; infection; inadequate nutrition; insufficient prenatal care; late-term prenatal care; maternal age ≤15 years; maternal age ≥35 years; substance abuse; unplanned pregnancy; unwanted pregnancy

Individual

Behavior disorder (e.g., attention deficit, oppositional defiant); brain injury (e.g., abuse, accident hemorrhage, shaken baby syndrome); chronic illness; congenital disorder; failure to thrive; genetic disorder; hearing impairment; history of adoption; inadequate nutrition; involvement with the foster care system; lead poisoning; natural disaster; positive drug screen; prematurity; recurrent otitis media; seizure disorder; substance abuse; technology dependence (e.g., ventilator, augmentative communication); treatment regimen; visual impairment.

Environmental

Economically disadvantaged; exposure to violence

Caregiver

Learning disabilities; mental health issue (e.g., depression, psychosis, personality disorder, substance abuse); presence of abuse (e.g., physical, psychological, sexual)

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Abuse Recovery; Child Development: 1 Month, 2 Months, 4 Months, 6 Months, 12 Months, 2 Years, 3 Years, 4 Years, 5 Years, Middle Childhood, Adolescence; Development: Late Adulthood, Middle Adulthood, Young Adulthood; Knowledge: Parenting, Neglect Recovery

Example NOC Outcome with Indicators

Child Development as evidenced by the following indicators: Appropriate milestones of physical, cognitive, and psychosocial age-appropriate progression. (Rate the outcome and indicators of **Child Development**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes**Client/Parents/Primary Caregiver Will (Specify Time Frame)**

- Infant/Child/Adolescent will achieve expected milestones in all areas of development (physical, cognitive, and psychosocial)
- Parent/Caregiver will verbalize understanding of potential impediments to normal development and demonstrate actions or environmental/lifestyle changes necessary to provide appropriate care in a safe, nurturing environment

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Abuse Protection Support: Child; Caregiver Support; Developmental Enhancement: Child/Adolescent; Home Maintenance Assistance; Immunization/Vaccination Management; Infant Care; Kangaroo Care; Lactation Counseling; Learning Facilitation; Newborn Care; Newborn Monitoring; Nonnutritive Sucking; Normalization Promotion; Nutrition Management; Parent Education: Infant/Adolescent/Childbearing Family; Parenting Promotion; Referral; Risk Identification: Childbearing Family; Teaching: (Infant) Nutrition/Safety/Stimulation; (Toddler) Nutrition/Safety; Temperature Regulation (Infant); Therapeutic Play

Example NIC Activities—Parent Education: Childbearing Family

Instruct parent on normal physiological, emotional, and behavioral characteristics of child

Nursing Interventions and Rationales**Preconception/Pregnancy**

- Assess for alcohol/drug use during pregnancy. Expectant mothers should be instructed that no amount of alcohol consumption is safe during pregnancy. **EB**: *Fetal alcohol syndrome (FAS) is thought to be the most preventable cause of mental retardation in the United States (Ethen et al, 2009).*

- Be aware of state legislation requiring mandatory reporting of maternal prenatal drug use. Be aware that mandatory reporting may further hamper prenatal care in that drug addicted mothers may delay or defer care for fear of legal action. **EB:** *Wu et al (2013) notes that fear of reporting drug use to authorities can create a “flight from care” environment rather than promote improved prenatal care among drug addicted mothers.*
- Advise expectant mothers to stop smoking and assist with methods of smoking cessation. **EB:** *Smoking during pregnancy increases the risk for miscarriage, impaired fetal growth, low birth weight, and infant mortality (Greener, 2011).*
- Recommend that women of childbearing age take 400 mcg of folic acid daily in order to reduce the risk of neural tube defects. **EB:** *Taking 400 mcg of folic acid daily, at least 3 months before conception and continuing throughout pregnancy, can prevent as many as 70% of neural tube defects (Greener, 2011).*

Neonate/Infant

- Encourage mother/baby interactions when caring for premature infants. **EB:** *Premature infants have been found to be at risk for developmental delays. Positive mother-infant interactions are important for child development, particularly for premature infants (Nicolaou et al, 2009).*
- Assess infant iron status and encourage iron supplementation for deficient infants. **EB:** *A study by Angulo-Barroso et al (2011) suggests that fine motor development is delayed for infants with lower iron levels.*
- ▲ Support early advanced developmental screening tests for male infants who are born prematurely or are medically fragile at birth. **EBN:** *Male gender can be considered a significant biological risk factor for infants’ cognitive and motor development, especially for premature infants (Cho et al, 2010).*
- ▲ Encourage caution regarding use of glucocorticoids in premature and term infants. **EB:** *Vázquez et al (2012) note that administration of glucocorticoids in infancy has the potential of causing neurological developmental difficulties, including anxiety and depressive disorders later in life.*
- ▲ Be aware that socioeconomic factors are predictive of delayed infant development (physical and cognitive) and encourage continued screening along with follow-up care for these infants. Arrange appropriate social services referrals. **EBN:** *Lower socioeconomic status shows a strong correlation to growth percentile. Hill (2010) found that at 6 months of age, infants on Medicaid are 5.6 times more likely to be in the 10th percentile of weight, 15.2 times more likely to be in the 10th percentile of head circumference, and 9.8 times more likely to be in the 10th percentile of length than other infants.*
- ▲ Make arrangements for close follow-up monitoring of opioid-exposed infants. **EB:** *Infants born to mothers who abuse opioids are at a higher risk for developmental delays and physical abuse (Salo et al, 2010).*

Toddler/Preschooler/School-Age

- Provide support and education to parents of toddlers with developmental disabilities (i.e., Down syndrome, cerebral palsy). **EB:** *Parents should anticipate seeing moderate to significant delays in reaching developmental milestones such as walking and communication (Horovitz & Matson, 2011).*
- Encourage parents of toddlers to obtain age-appropriate developmental screenings to detect early problems. **EB:** *American Academy of Pediatrics guidelines for developmental screenings should be followed. Screening for autism spectrum disorders should be performed between ages 18 and 24 months (Macias & Lipkin, 2009).*
- Toddlers who are underweight should be offered solid foods first rather than juices. *Excessive juice and milk consumption may interfere with nutritional absorption.*
- Teach parents the importance of avoiding lead-based paints in the home as well as other sources of lead in the environment. **EB:** *Hou et al (2013) confirmed previous research indicating that when the blood lead level reaches about 50 mcg/L in the body of children, it can impair growth, memory, intelligence, and behavior, even when there is no obvious clinical manifestation.*
- ▲ Discuss advantages of early speech-language intervention with parents of toddlers having delayed development in communication. **EB:** *Early intervention makes a significant difference in the developmental course of communication for children with a variety of established conditions (Paul & Roth, 2011).*
- Educate parents on the importance of providing oral care for children with mild/moderate disabilities. Parents may need to assume the responsibility of toothbrushing for the child. **EB:** *This study showed children with mild/moderate developmental disabilities had nearly three times more decayed teeth on average than children with severe disabilities who received toothbrushing from parents (Liu et al, 2010).*

Multicultural

- Recognize cultural risks associated with higher infant mortality. **EB:** African American infants are two times more likely to die in the first year of life than Caucasian infants. Low birth weight is a significant determinant of the increased mortality (Dailey, 2009).

- Encourage mothers with postpartum depression to seek assistance and support as appropriate to ensure normal development of their children. **CEB:** In this study the overall incidence of developmental delay at 18 months in children of women displaying depression following pregnancy was 9% (Deave et al, 2008).
- Teach new mothers the importance of breastfeeding. **EB:** Prolonged and exclusive breastfeeding improves children's cognitive development (Kramer et al, 2008). **EB:** Jäger et al (2014) discovered an inverse association between breastfeeding duration and risk of diabetes.

Diarrhea Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN, and Betty J. Ackley, MSN, EdS, RN

NANDA-I

Definition

Passage of loose, unformed stools

Defining Characteristics

Abdominal pain; bowel urgency; cramping; hyperactive bowel sounds; loose liquid stools > 3 in 24 hours

Related Factors

Physiological

Gastrointestinal inflammation; gastrointestinal irritation; infection; malabsorption; parasite

Psychological

Anxiety; increase in stress level

Situational

Enteral feedings; exposure to contaminant; exposure to toxin; laxative abuse; substance abuse; travel; treatment regimen

D

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Bowel Elimination; Electrolyte and Acid-Base Balance; Fluid Balance; Hydration; Treatment Behavior: Illness or Injury

Example NOC Outcome with Indicators

Bowel Elimination as evidenced by the following indicators: Elimination pattern/Stool soft and formed/Bowel sounds/Liquid stool. (Rate each indicator of **Bowel Elimination**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

- Defecate formed, soft stool every 1 to 3 days
- Maintain the perirectal area free of irritation
- State relief from cramping and less or no diarrhea
- Explain cause of diarrhea and rationale for treatment
- Maintain good skin turgor and weight at usual level
- Have negative stool cultures

NIC (Nursing Interventions Classification)**Suggested NIC Intervention**

Diarrhea Management

Example NIC Activities—Diarrhea Management

Evaluate medication profile for gastrointestinal side effects; Suggest trial elimination of foods containing lactose

Nursing Interventions and Rationales

- Assess pattern of defecation or have the client keep a diary that includes the following: time of day defecation occurs; usual stimulus for defecation; consistency, amount, and frequency of stool; type of, amount of, and time food consumed; fluid intake; history of bowel habits and laxative use; diet; exercise patterns; obstetrical/gynecological, medical, and surgical histories; medications; alterations in perianal sensations; and present bowel regimen. *Assessment of defecation pattern and factors surrounding diarrhea episode to include changes in diet, medications, exercise, and health history will help direct interventions and treatment Willson et al, 2014).*
- Recommend use of standardized tool to consistently assess, quantify, and then treat diarrhea. **CEB/EB:** *Stool classification systems include the Hart and Dobb Diarrhea Scale, the Guenther and Sweed Stool Output Assessment Tool, the Bristol Stool Scale, Diarrhea Grading Scale (Hallquist & Fung, 2005; Kyle, 2007; Sabol & Carlson, 2007, Willson et al, 2014).*
- Inspect, auscultate, palpate, and percuss the abdomen, in that order. *Expect increased frequency of bowel sounds with diarrhea (Jarvis, 2012).*
- ▲ Use an evidence-based bowel management protocol which includes identifying and treating the cause of the diarrhea, obtaining a stool specimen if infectious etiology is suspected, evaluate current medications and osmolality of enteral feedings, assess and treat hydration status of client, review and stop ordered

and/or over-the-counter laxatives, provide good skin care and apply barrier creams to prevent skin irritation from diarrhea, and evaluate need for antidiarrheal agents and possible fecal containment device with provider. **EB:** *The possible cause of the diarrhea needs to be assessed and client hydration and skin protective interventions put into place rapidly to prevent secondary complications associated with the client's diarrhea episodes (Willson et al, 2014; Shahin & Lohrmann, 2015).*

- ▲ Identify cause of diarrhea if possible based on history (e.g., infection; gastrointestinal inflammation; medication effect; malnutrition or malabsorption; laxative abuse; osmotic enteral feedings, anxiety; stress). See Related Factors: *Identification of the underlying cause is important, because the treatment is determined based on the cause of diarrhea.*
- ▲ Testing for diarrhea may consist of laboratory work such as a complete blood count with differential and blood cultures if the client is febrile. Also obtain stool specimens as ordered, to either rule out or diagnose an infectious process (e.g., ova and parasites, *Clostridium difficile* infection, bacterial cultures for food poisoning). *Assessing for signs of systemic infection and inflammatory response as well as evaluation of the stool for infection are important first steps in identifying the cause of diarrhea (Abraham & Sellin, 2012; Dickinson & Surawicz, 2014).*
- ▲ Consider the possibility of *C. difficile* infection if the client has any of the following: watery diarrhea, low-grade fever, abdominal cramps, history of antibiotic therapy, history of gastrointestinal tract surgery, and if the client is taking medications that reduce gastric acid, including proton-pump inhibitors (PPIs). *Any antibiotic can cause C. difficile infection but clindamycin, cephalosporins, and fluoroquinolones pose the greatest risk, as do multiple antibiotics and longer duration of antibiotics (Surawicz et al, 2013).* **EB:** *C. difficile infections have become increasingly common because of the frequent use of broad-spectrum antibiotics, and now there is a hypervirulent form of C. difficile causing increased morbidity and mortality. Antibiotics and gastric acid reducing medications can change normal gut flora, increasing the risk for development of C. difficile infection, diarrhea, and colitis (Surawicz et al, 2013).*
- Use standard precautions when caring for clients with diarrhea to prevent spread of infectious diarrhea; use gloves and handwashing. *C. difficile* and viruses causing diarrhea have been shown to be highly contagious. *C. difficile* is difficult to eradicate because of spore formation (Surawicz et al, 2013; Martin et al, 2014). **CEB/EB:** *A review of client care related to C. difficile summarizes care to include contact isolation, soap and water handwashing (alcohol rubs are not effective), use of disposable equipment, and environmental room decontamination (Makic et al, 2011; Centers for Disease Control and Prevention, 2015; Martin et al, 2014). C. difficile can survive for at least 24 hours on inanimate surfaces, and spores can survive for months on objects such as toilets, sinks, and bed rails (Makic et al, 2011; CDC, 2015; Martin et al, 2014).*
- ▲ Antibiotic stewardship is an important aspect in prevention of *C. difficile* infections. *Antibiotics should be used judiciously (CDC, 2015; Martin et al, 2014; Surawicz et al, 2013).* If the client has diarrhea associated with antibiotic therapy, consult with the health care provider regarding the use of probiotics, such as yogurt with active cultures, to treat diarrhea, or probiotic dietary supplements; or preferably use probiotics to prevent diarrhea when first beginning antibiotic therapy. **EB:** *While conclusive evidence on the effectiveness of probiotic in treating and preventing C. difficile and diarrhea is lacking, evidence suggests that probiotics may be helpful for some clients. Probiotics may be used in an attempt to balance intestinal flora and restrict the colonization of C. difficile (Williams, 2010; Clauson & Crawford, 2015; Pattani et al, 2013).*
- ▲ If a probiotic is ordered, administer it with food. Recommend that it be taken through the antibiotic course and 10 to 14 days afterward. *Food tends to buffer the stomach acids, allowing more of the probiotic ingredients to pass through the stomach for absorption in the intestines. Beginning this therapy early helps prevent antibiotic-associated diarrhea (Clauson et al, 2015).*
- ▲ Recognize that *C. difficile* can commonly recur and that reculturing of stool is often required before initiating retreatment. **EB:** *High reinfection rates have been reported within the first 2 months of initial diagnosis. Repeat courses of antibiotics, usually metronidazole or vancomycin, are necessary to treat repeat C. difficile infections. New evidence is evolving to support fecal transplant for clients with severe recurrent C. difficile infections (Surawicz et al, 2013).*
- Have the client complete a diet diary for 7 days and monitor the intake of high fructose corn syrup and fructose sweeteners in relation to onset of diarrhea symptoms. If diarrhea is associated with fructose ingestion, intake should be limited or eliminated. **EB:** *High fructose corn syrup or fructose sweeteners from fruit juices can cause gastrointestinal symptoms of bloating, rumbling, flatulence, and diarrhea at amounts of 25 to 50 g. Malabsorption is demonstrated in clients after 25 g fructose, and most clients develop symptoms with 50 g fructose (Abraham & Sellin, 2012).*

- ▲ If the client has infectious diarrhea, consider avoiding use of medications that slow peristalsis. **CEB:** *If an infectious process is occurring, such as C. difficile infection or food poisoning, medication to slow peristalsis should generally not be given. The increase in gut motility helps eliminate the causative factor, and use of antidiarrheal medication could result in a toxic megacolon (Sunenshine & McDonald, 2006).*
- Assess for dehydration by observing skin turgor over sternum and inspecting for longitudinal furrows of the tongue. Watch for excessive thirst, fever, dizziness, lightheadedness, palpitations, excessive cramping, bloody stools, hypotension, and symptoms of shock. *Severe diarrhea can cause deficient fluid volume, electrolyte imbalance, extreme weakness, and a possible shock state (El-Sharkawy et al, 2014; Thorson et al, 2008).*
- Refer to care plans for Deficient **Fluid** volume and Risk for **Electrolyte** imbalance if appropriate.
- ▲ If the client has frequent or chronic diarrhea, consider suggesting use of dietary fiber after consultation with a nutritionist and/or provider. **EB:** *Use of a fiber supplement decreases the number of incontinent stools and improves stool consistency (Willson et al, 2014).*
- ▲ If diarrhea is chronic and there is evidence of malnutrition, consult with the provider for a dietary consult and possible nutrition supplementation to maintain nutrition while the gastrointestinal system heals (Change & Huang, 2013).
- Encourage the client to eat small, frequent meals, eating foods that are easy to digest at first (e.g., bananas, crackers, pretzels, rice, potatoes, clear soups, applesauce), but switch to a regular diet as soon as tolerated. Also recommend avoiding milk products, foods high in fiber, and caffeine (dark sodas, tea, coffee, chocolate). *The BRAT diet has been traditionally recommended but may be nutritionally incomplete (Shapiro et al, 2010; International Foundation for Functional Gastrointestinal Disorders, 2014).*
- Provide a readily available bathroom, commode, or bedpan.
- Thoroughly cleanse and dry the perianal and perineal skin daily and as needed using a cleanser capable of stool removal. Apply skin moisture barrier cream as needed. Refer to perirectal skin care in the care plan for bowel Incontinence.
- ▲ If the client has enteral tube feedings and diarrhea, consider infusion rate, position of feeding tube, tonicity of formula, possible formula contamination, and excessive intake of hyperosmolar medications, such as sorbitol commonly found in the liquid version of medications (Makic et al, 2011; Chang et al, 2013). Consider changing the formula to a lower osmolarity, lactose-free, or high-fiber feeding. *Determination of the cause of diarrhea should include an abdominal examination, fecal leukocytes, quantification of stool, stool culture for C. difficile (and/or toxin assay), serum electrolyte panel, and review of medications (Willson et al, 2014).*
- Avoid administering bolus enteral feedings into the small bowel. *The stomach has a larger capacity for large fluid volumes, whereas the small bowel can usually only tolerate up to 150 mL/hr (Chang et al, 2013; Sabol & Carlson, 2007).*
- ▲ Dilute liquid medications before administration through the enteral tube and flush the enteral feeding tube with sufficient water before and after medication administration. *Since many liquid medications contain sorbitol or are hyperosmotic, diluting the medication may help decrease occurrence of diarrhea (Chang et al, 2013; Sabol & Carlson, 2007; Thorson et al, 2008).*
- Teach clients with cancer the types of diarrhea they may encounter, emphasizing not only chemotherapy and radiation induced diarrhea, but also *C. difficile*, along with associated signs and symptoms, and treatments. **EB:** *Diarrhea in cancer patients is a common complication that causes dehydration, electrolyte imbalances, nutritional deficits, and hospitalization for treatment. Providing the client education focusing on early recognition of diarrhea necessitating early interventions is important in preventing adverse client outcomes (Andreyev et al, 2014).*
- ▲ For chemotherapy induced diarrhea (CID) and radiation induced diarrhea (RID), review rationale for pharmacological interventions, along with soluble fiber and probiotic supplements. Consult a registered dietitian to assist with recommendations to alleviate diarrhea, decrease dehydration, and maintain nutritional status. **EBN:** *Both CID and RID can occur as often as or more than 50% of the time, dependent on the chemotherapy regimen or combination with radiation (Andreyev et al, 2014; Sun & Yang, 2013).*
- ▲ Acute traveler's diarrhea is the most common illness affecting individuals traveling to, usually, low-income regions of the world. **EB:** *Improved hygiene and avoidance of foods for which preparation methods are unknown (e.g., street food) can mitigate the severity of gastric distress. Clients should be counseled about precautions they can take while traveling to reduce the severity of diarrhea, and a self-treatment antibiotic series may be prescribed by the health care provider for at risk clients (Steffen et al, 2015).*

Pediatric

- ▲ Assess for mild or moderate signs of dehydration with both acute and persistent diarrhea: mild (increased thirst and dry mouth or tongue); moderate (decreased urination; no wet diapers for 3+ hours; feeling of weakness/lightheadedness, irritability, or listlessness; few or no tears when crying) (Pye, 2011). Refer to primary care provider for treatment.
- ▲ Recommend that parents give the child oral rehydration fluids to drink in the amounts specified by the health care provider especially during the first 4 to 6 hours to replace lost fluid. Once the child is rehydrated, an orally administered maintenance solution should be used along with food. Continue even if child vomits. **EB:** *Treatment with oral rehydration fluids for children is generally as effective as intravenous fluids (Binder et al, 2014). Oral rehydration therapy (ORT) is an iso-osmolar, glucose-electrolyte solution that has been recognized for more than 40 years to be effective in treating children with dehydration due to acute infectious diarrhea (Binder et al, 2014). Vomiting is not a contraindication to ORT. Adequate ORT is absorbed by most clients during vomiting (Rehydration Project, 2014).*
- Recommend the mother resume breastfeeding as soon as possible.
- Recommend parents avoid giving the child flat soda, fruit juices, gelatin dessert, or instant fruit drink. *These fluids have a high osmolality from carbohydrate contents and can exacerbate diarrhea. In addition they have low sodium concentrations that can aggravate existing hyponatremia (Rehydration Project, 2014; Dekate et al, 2013).*
- Recommend parents give children foods with complex carbohydrates, such as potatoes, rice, bread, cereal, yogurt, fruits, and vegetables. Avoid fatty foods, foods high in simple sugars, and milk products.
- ▲ Recommend rotavirus vaccine within the child's vaccination schedule. **EB:** *Two vaccines, Rotarix and Rotateq, have undergone comprehensive studies with findings that they can significantly prevent severe rotavirus diarrhea and death due to dehydration in children (Gray, 2011; Glass et al, 2014).*

Geriatric

- ▲ Evaluate medications the client is taking. Recognize that many medications can result in diarrhea, including digitalis, propranolol, angiotensin-converting enzyme inhibitors, histamine-receptor antagonists, nonsteroidal anti-inflammatory drugs, anticholinergic agents, oral hypoglycemia agents, and antibiotics, among others. **EB:** *Numerous medications can cause diarrhea. Evaluate changes in the client's medications as a possible cause of the diarrhea (Willson et al, 2014).*
- ▲ Monitor the client closely to detect whether an impaction is causing diarrhea; remove impaction as ordered. Clients with fecal impaction commonly experience leakage of mucus or liquid stool from the rectum, rectal irritation, distention, and impaired anal sensation (Meiner, 2010).
- ▲ Seek medical attention if diarrhea is severe or persists for more than 24 hours, or if the client has history of dehydration or electrolyte disturbances, such as lassitude, weakness, or prostration. *Older adult clients can dehydrate rapidly; especially serious is development of hypokalemia with dysrhythmias. C. difficile is a common cause of diarrhea in older clients when they have been subjected to long-term antibiotic therapy (El-Sharkaway et al, 2013; Piacenti & Leuthner, 2013).*
- Provide emotional support for clients who are having trouble controlling unpredictable episodes of diarrhea. Diarrhea can be a great source of embarrassment to older clients and can lead to social isolation and a feeling of powerlessness.

Home Care

Previously mentioned interventions may be adapted for home care use to keep the client well hydrated.

- Assess the home for general sanitation and methods of food preparation. Reinforce principles of sanitation for food handling. *Poor sanitation or mishandling of food may cause bacterial infection or transmission of dangerous organisms from utensils to food.*
- Assess for methods of handling soiled laundry if the client is bed bound or has been incontinent. Instruct or reinforce universal precautions with family and bloodborne pathogen precautions with agency caregivers. *The Bloodborne Pathogen Regulations of the Occupational Safety and Health Administration (OSHA) identify legal guidelines for caregivers.*
- When assessing medication history, include over-the-counter (OTC) drugs, both general and those currently being used to treat the diarrhea. Instruct clients not to mix OTC medications when self-treating. *Mixing OTC medications can further irritate the gastrointestinal system, intensifying the diarrhea or causing nausea and vomiting.*

- Evaluate current medications for indication that specific interventions are warranted. *Blood levels of medications may increase during prolonged episodes of diarrhea, indicating the need for close monitoring of the client or direct intervention.*
- ▲ Evaluate the need for a home health aide or homemaker service referral. Caregiver may need support for maintaining client cleanliness to prevent skin breakdown.
- Evaluate the need for durable medical equipment in the home. The client may need a bedside commode, call bell, or raised toilet seat to facilitate prompt toileting.

Client/Family Teaching and Discharge Planning

- Encourage avoidance of coffee, spices, milk products, and foods that irritate or stimulate the gastrointestinal tract. A list of dietary items that may irritate the gastrointestinal track and trigger diarrhea is available at www.iffgd.org/site/gi-disorders/functional-gi-disorders/diarrhea/nutrition.
- Teach appropriate method of taking ordered antiarrheal medications; explain side effects.
- Explain how to prevent the spread of infectious diarrhea (e.g., careful handwashing, appropriate handling and storage of food, and thoroughly cleaning the bathroom and kitchen). **EB:** *Good hand hygiene has repeatedly been found to be the first step in preventing the spread of infectious diarrhea (Dickinson & Surawicz, 2014; Abraham & Sellin, 2012; CDC, 2015).*
- Help the client to determine stressors and set up an appropriate stress reduction plan, if stress is the cause of diarrhea.
- Teach signs and symptoms of dehydration and electrolyte imbalance.
- Teach perirectal skin care.
- ▲ Consider teaching clients about complementary therapies, such as probiotics, after consultation with primary care provider.

Risk for Disuse syndrome

Betty J. Ackley, MSN, EdS, RN, and Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

NANDA-I

Definition

Vulnerable to deterioration of body systems as the result of prescribed or unavoidable musculoskeletal inactivity, which may compromise health

Risk Factors

Alteration in level of consciousness; mechanical immobility; pain; paralysis; prescribed immobility

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Endurance; Immobility Consequences: Physiological; Mobility; Neurological Status: Consciousness; Pain Level

Example NOC Outcome with Indicators

Immobility Consequences: Physiological as evidenced by the following indicators: Pressure sores/Constipation/Compromised nutrition status/Urinary calculi/Compromised muscle strength. (Rate the outcome and indicators of **Immobility Consequences: Physiological**: 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain full range of motion in joints
- Maintain intact skin, good peripheral blood flow, and normal pulmonary function
- Maintain normal bowel and bladder function
- Express feelings about imposed immobility
- Explain methods to prevent complications of immobility

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Energy Management; Exercise Therapy: Joint Mobility; Muscle Control; Positioning

Example NIC Activities—Energy Management

Determine the client's significant other's perception of causes of fatigue; Use valid instruments to measure fatigue, as indicated

Nursing Interventions and Rationales

- When client's condition is stable, screen for mobility skills in the following order: (1) bed mobility; (2) supported and unsupported sitting; (3) transition movements such as sit to stand, sitting down, and

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

transfers; (4) standing and walking activities. Use a tool such as the Assessment Criteria and Care Plan for Safe Patient Handling and Movement (Sedlak et al, 2009) or the [Banner Mobility Assessment Tool for Nurses \(2014\)](#). **EB:** *In healthy adults, muscle strength declines by 1% per day of strict bed rest (De Jonghe et al, 2009)*. **EBN:** *A review of the literature found that mobilizing hospitalized adults assisted with physical, emotional, and social well-being (Kalisch et al, 2013)*.

- Assess the level of assistance needed by the client and express in terms of amount of effort expended by the person assisting the client. The range is as follows: total assist, meaning client performs 0% to 25% of task and, if client requires the help of more than one caregiver, it is referred to as a dependent transfer; maximum assist, meaning client gives 25% of effort while caregiver performs majority of the work; moderate assist, meaning client gives 50% of effort; minimal assist, meaning client gives 75% of effort; contact guard assist, meaning no physical assist is given but caregiver is physically touching client for steadying, guiding, or in case of loss of balance; stand by assist, meaning caregiver's hands are up and ready in case needed; supervision, meaning supervision of task is needed even if at a distance; modified independent, meaning client needs assistive device or extra time to accomplish task; independent, meaning client is able to complete task safely without instruction or assistance. **CEB:** *There are guidelines on how to determine the amount of care the client will need (Granger, 2011; Uniform Data System, 1997)*.
- ▲ Request a referral to a physical therapist as needed so that client's range of motion, muscle strength, balance, coordination, and endurance can be part of the initial evaluation.
- Incorporate bed exercises such as flexing and extending feet and quadriceps or use of Thera-Bands for upper extremities into nursing care to help maintain muscle strength and tone (Koenig et al, 2012).
- ▲ If not contraindicated by the client's condition, obtain a referral to physical therapy for use of tilt table to help determine the cause of syncope. *Use of the tilt table can help determine if the cause of syncope is autonomic or from another cause (Low & Engstrom, 2012)*.
- Perform range of motion exercises for all possible joints at least twice daily; perform passive or active range of motion exercises as appropriate. *If not used, muscles weaken and shorten from fibrosis of the muscle (Wagner et al, 2008; Wood et al, 2014)*. **EBN:** *Range of motion exercises are effective in maintaining joint mobility and muscle integrity (Gillis & MacDonald, 2008; Summers et al, 2009; Kalisch et al, 2013; Wood et al, 2014)*.
- Use specialized boots to prevent pressure ulcers on the heels and footdrop; remove boots twice daily to provide foot care. *Boots help keep the foot in normal anatomical alignment to prevent footdrop and prevent pressure ulcer formation on the heel*. **EB:** *A Cochrane review found that there is not a good evidence base to determine which boots or pressure redistribution system is most effective in preventing heel pressure ulcers (McGinnis & Stubbs, 2011)*. **CEBN:** *A study found that use of a wedge-shaped viscoelastic bed-sized support surface was more effective than use of a pillow to prevent heel ulcers (Heyneman et al, 2009)*.
- When positioning a client on the side, tilt client 30 degrees or less while lying on side. *Full (versus tilt) side-lying position places higher pressure on trochanter, predisposing to skin breakdown although more evidence is needed to fully determine the impact of full versus tilted positioning (van Rijswijk, 2009; National Pressure Ulcer Advisory Panel, 2014)*.
- Assess skin condition at least daily and more frequently if needed. Use a risk assessment tool such the Braden Scale or the Norton Scale to predict the risk of developing pressure ulcers. **EBN:** *Use of a risk assessment tool is possibly effective to predict the risk of developing a pressure ulcer (National Pressure Ulcer Advisory Panel, 2014)*. Refer to care plan for risk for Impaired **Skin** integrity.
- Discuss with staff and management a "safe handling" policy that may include a "no lift" policy. *Benefits of a safe handling policy include decreased injury to workers, increased safety and comfort for clients, decreased litigation related to injuries, and decreased lost work and wages due to injury, as well as decreased workers' compensation claims (Nelson et al, 2008; Boynton et al, 2014)*.
- Turn clients at high risk for pressure/shear/friction frequently. Turn clients at least every 2 to 4 hours on a pressure-reducing mattress/every 2 hours on standard foam mattress. *These are general guidelines for turning, but they do not have a good evidence base. Preferably base the turning schedule on close assessment of the client's condition and predisposing conditions (Krapfl & Gray, 2008; van Rijswijk, 2009; Makic et al, 2014; National Pressure Ulcer Advisory Panel, 2014)*.
- Provide the client with a pressure-relieving horizontal support surface. For further interventions on skin care, refer to the care plan for Impaired **Skin** integrity.
- Help the client out of bed as soon as able. *Early mobilization reduces risk of atelectasis, pneumonia, venous thromboembolism (VTE), and pulmonary embolism, and decreases orthostatic hypotension (Makic et al, 2014) as well as reducing risk of skeletal muscle atrophy, joint contractures, insulin resistance, microvascular*

dysfunction, systemic inflammation, and pressure ulcers (Brower, 2009). Bed rest is almost always harmful to clients; early mobilization is better than bed rest for most health conditions (Perme & Chandrashekar, 2009; Kalisch et al, 2013; Hoyer et al, 2014).

- When getting the client up after bed rest, do so slowly and watch for signs of postural (orthostatic) hypotension, tachycardia, nausea, diaphoresis, or syncope. Take the blood pressure with the client lying, sitting, and standing, waiting 2 minutes between each reading. *Consequences of bed rest are increased systemic vascular resistance, muscle atrophy, joint contracture, thromboembolic disease, and insulin resistance as well as microvascular dysfunction (Brower, 2009). Suggest waist-high elastic hosiery such as an elastic “belly binder” and/or bilateral lower extremity ace wraps over TED hose to facilitate venous return if hypotension is an issue (McPhee & Papadakis, 2009).*
- Obtain assistive devices such as braces, crutches, or canes to help the client reach and maintain as much mobility as possible. *Assistive devices can help increase mobility (Yoem et al, 2009; Boynton et al, 2014).*
- ▲ Apply graduated compression stockings as ordered. Ensure proper fit by measuring accurately. Remove the stockings at least twice a day, in the morning with the bath and in the evening to assess the condition of the extremity, then reapply. Knee length is preferred rather than thigh length. **CEBN/EB:** *Effectiveness of knee-high compression stockings is equal to thigh-high compression stockings, and knee-high stockings are more comfortable and fit better, adding to client compliance as stockings are most effective when worn continuously during the at-risk period; on during day and off at night (Hilleren-Listerud, 2009; McCaffrey & Blum, 2009). The American College of Chest Physicians (ACCP, 2012) recommends pharmacological or mechanical prophylaxis such as the use of graduated compression stockings to reduce the incidence of VTE in clients who have undergone high-risk orthopedic surgical procedures, clients older than 70 years of age, or clients who are at high risk for VTE for multiple reasons (Kahn et al, 2012). Please refer to the ACCP guidelines for use of mechanical prophylaxis for specific client situations.*
- Observe for signs of VTE, including pain, tenderness, and swelling in the calf and thigh. Also observe for new onset of breathlessness. *Clients commonly complain of a cramp in their lower calf that persists and becomes more painful with time. Symptoms of existing deep vein thrombosis are nonspecific and cannot be used alone to determine the presence of VTE. New onset of breathlessness is commonly associated with development of a pulmonary embolism (Goldhaber, 2012).*
- Have the client cough and deep breathe or use incentive spirometry every 2 hours while awake. *Bed rest compromises breathing because of decreased chest expansion, decreased cilia activity, pooling of mucus, and the effects of organ shift (such as the diaphragm and heart as well as pressure on the esophagus when in the supine position) and leads to partial or complete atelectasis usually of the left lower lobe (Brower, 2009).*
- Monitor respiratory functions, noting breath sounds and respiratory rate. Percuss for new onset of dullness in lungs.
- Note bowel function daily. Provide increased fluids, fiber, and natural laxatives such as prune juice as needed. *Constipation is common in immobilized clients because of decreased activity and fluid and food intake. Refer to care plan for Constipation.*
- Increase fluid intake to 2000 mL/day within the client’s cardiac and renal reserve. *Adequate fluids help prevent kidney stones and constipation, both of which are associated with bed rest.*
- Encourage intake of a balanced diet with adequate amounts of fiber and protein. *Consider recommending Practical Interventions to Achieve Therapeutic Lifestyle Changes (TLC), which includes monounsaturated and polyunsaturated fats, oils, margarines, beans, peas, lentils, soy, skinless poultry, lean fish, trimmed cuts of meat, fat-free and low-fat daily foods, omega-3 polyunsaturated fat sources, and whole grains, including soluble fiber sources such as oats, oat bran, and barley (Tucker, 2010).*

Critical Care

- ▲ Recognize that the client who has been in an intensive care environment may develop a neuromuscular dysfunction acquired in the absence of causative factors other than the underlying critical illness and its treatment, resulting in extreme weakness (Stevens et al, 2009). The client may need a workup to determine the cause before satisfactory ambulation can begin. *Critical care clients can develop disorders such as critical illness myopathy; polyneuropathy due to ischemia, pressure, prolonged recumbency, compartment syndrome, or hematomas; and the third critical care disorder, from prolonged pharmacologic neuromuscular blockade (Stevens et al, 2009).*
- ▲ Consider use of a continuous lateral rotation therapy bed. **EBN:** *Implementing kinetic therapy in the intensive care unit resulted in improved oxygenation and decreased length of stay for clients with pulmonary disorders (Swadener-Culpepper et al, 2008; Makic, 2014).*

- ▲ For the stable client in the intensive care unit, consider mobilizing the client in a four-phase method from dangling at the side of the bed to walking if there is sufficient knowledgeable staff available to protect the client from harm. *Even intensive care unit clients receiving mechanical ventilation can be mobilized safely if a multidisciplinary team is present to support, protect, and monitor the client for intolerance to activity (Perme & Chandrashekar, 2009; Boynton et al, 2014; Kalisch et al, 2013).* **CEB:** A study found that whole-body rehabilitation consisting of interruption of sedation and physical and occupational therapy in the early days of critical illness was safe and well tolerated, and resulted in better functional outcomes at discharge (Schweickert et al, 2009). **EBN:** Critical care clients are at high risk for complications related to immobility such as ventilator-associated pneumonia (VAP), atelectasis, and long-lasting functional limitations; therefore, once the client is hemodynamically stable, use progressive mobilization to dangle legs, sit in a chair, stand and bear weight, and walk. Use rotation therapy (kinetic and continuous lateral) to reduce risk of VAP for clients on mechanical ventilation (Rauen et al, 2008; Makic et al, 2014).

Geriatric

- Get the client out of bed as early possible and ambulate frequently after consultation with the health care provider. *Immobility is a risk factor for VTE; early ambulation can help prevent clot formation (American Association of Chest Physicians, 2012). Functional decline from hospital-associated deconditioning is common in older adults, and acute inpatient rehabilitation can be effective in preventing this condition (Kortebein, 2009; Wood et al, 2014).*
- Use the Exercise Assessment and Screening for You (EASY), which was developed to identify benefits of exercise and to assist older adults to select safe and effective exercises. This tool decreases barriers to exercise. **CEBN:** Use of self-efficacy-based interventions resulted in increased exercise (Resnick et al, 2008).
- ▲ Refer the client to physical therapy for resistance strength exercise training. **CEB:** Disuse, aging, loss of skeletal mass, and malnutrition, referred to as sarcopenia, should be assessed, and strategies to counter sarcopenia such as resistance training should be employed even in very old clients (Bautmans et al, 2009).
- Monitor for signs of depression: flat affect, poor appetite, insomnia, many somatic complaints. *Depression can commonly accompany decreased mobility and function in older adults and may be misinterpreted as not doing enough to help themselves (Rittenmeyer, 2010; Kalisch et al 2013).*
- Keep careful track of bowel function in older adults; do not allow the client to become constipated. *Older adults can easily develop impactions as a result of immobility. Refer to **Constipation** care plan.*

Home Care

- Some of the previous interventions may be adapted for home care use.
- ▲ Begin discharge planning as soon as possible with case manager or social worker to assess need for home support systems and community or home health services.
- ▲ Become oriented to all programs of care for the client before discharge from institutional care.
- ▲ Confirm the immediate availability of all necessary assistive devices for home.
- Perform complete physical assessment and recent history at initial home visit.
- ▲ Refer to physical and occupational therapies for immediate evaluations of the client's potential for independence and functioning in the home setting and for follow-up care.
- Allow the client to have as much input and control of the plan of care as possible. *Client perception of control increases self-esteem and motivation to follow medical plan of care.*
- Assess knowledge of all care with caregivers. Review as necessary. *Having the necessary knowledge and skills to perform care decreases caregiver role strain and supports safety of the client.*
- ▲ Support the family of the client in assumption of caregiver activities. Refer for home health aide services for assistance and respite as appropriate. Refer to medical social services as appropriate.
- ▲ Institute case management of frail elderly to support continued independent living, if possible in the home environment.

Client/Family Teaching and Discharge Planning

- Teach client/family how to perform range-of-motion exercises in bed if not contraindicated; this is referred to as a Home Exercise Program.
- Teach the family how to turn and position the client and provide all care necessary.

NOTE: Nursing diagnoses that are commonly relevant when the client is on bed rest include **Constipation**, risk for Impaired **Skin** integrity, Disturbed **Sleep** pattern, **Frail Elderly** syndrome, and **Powerlessness**.

Deficient Diversional activity *Mila W. Grady, MSN, RN*

NANDA-I

Definition

Decreased stimulation from (or interest or engagement in) recreational or leisure activities

Defining Characteristics

Boredom; current setting does not allow engagement in activity

Related Factors (r/t)

Insufficient diversional activity; extremes of age; prolonged hospitalization; prolonged institutionalization

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Leisure Participation; Play Participation; Social Involvement

Example NOC Outcome with Indicators

Leisure Participation as evidenced by the following indicators: Expresses satisfaction with leisure activities/Feels relaxed from leisure activities/Enjoys leisure activities. (Rate the outcome and indicators of **Leisure Participation**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)] ([Moorhead et al, 2013](#)).

Client Outcomes

Client Will (Specify Time Frame)

- Engage in personally satisfying diversional activities

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Recreation Therapy; Self-Responsibility Facilitation

Example NIC Activities—Recreation Therapy

Assist the client to identify meaningful recreational activities; Provide safe recreational equipment

Nursing Interventions and Rationales

- Observe for signs of deficient diversional activity: restlessness, unhappy facial expression, and statements of boredom and discontent. **EBN**: *In a study of residents living in long-term care in Turkey, 67% of the residents were diagnosed with deficient diversional activity* ([Güler et al, 2012](#)).
- Observe ability to engage in activities that require good vision and use of hands. *Diversional activities must be tailored to the client's capabilities.*
- Discuss activities with clients that are interesting and feasible in the present environment.
- Encourage the client to share feelings about situation of inactivity. *Work and hobbies provide structure and continuity to life; the client may feel a sense of loss.*
- Encourage the client to participate in any available social or recreational opportunities in the health care environment. **EB**: *Social engagement is associated with self-reported physical health in older adults* ([Cherry et al, 2013](#)).
- Encourage a mix of physical and mental activities if possible (e.g., crafts, crossword puzzles).
- Provide videos and/or DVDs of movies for recreation and distraction.
- Provide magazines and books of interest.

D

- Provide books on CD and CD player, and electronic versions of books for listening or reading as available.
- Set up a puzzle in a community space, or provide individual puzzles as desired.
- Provide access to a portable computer so that the client can access email and the Internet. Give client a list of interesting websites, including games and directions on how to perform Web searches if needed.
- Help client find a support group for the appropriate condition on the Internet if interested. **EBN:** *A study found that individuals dealing with low survival rate cancers desire online informational support (Buis & Whitten, 2011).*
- ▲ Arrange animal-assisted therapy if desired, with a dog, cat, or bird for the client to care for and interact with. **EB:** *Animal-assisted therapy has been associated with enhanced socialization, stress reduction, improvement in mood and well-being, a decrease in anxiety and loneliness, and the development of leisure and recreational skills (Muñoz Lasa et al, 2011).*
- Encourage the client to schedule visitors so that they are not all present at once or at inconvenient times. *A schedule prevents the client from becoming exhausted from frequent company.*
- If clients are able to write, help them keep journals or engage them in opportunities for creative writing in a group; if clients are unable to write, have them record thoughts on tape, or on videotape. **EB:** *A professional writer led creative writing workshop for a small group of older women in a nursing home; these workshops provided enjoyment, promoted the development of personal relationships within the community, and allowed staff to gain deeper insight into the lives of the residents (Wilson et al, 2011).*
- ▲ Request recreational or art therapist to assist with activities. **EB:** *Art therapy can assist individuals undergoing stroke rehabilitation to reduce anxiety and feelings of isolation (Ali et al, 2014).*
- ▲ Refer to occupational therapy. **EB:** *Occupational therapists are able to assist persons with compensatory strategies to assist with activities (Arbesman & Lieberman, 2011).*
- Provide a change in scenery; get the client out of the room as possible. *A lack of sensory stimulation has significant adverse effects on clients.*
- Help the client to experience nature through looking at a nature scene from a window, or walking through a garden if possible. **EB:** *Physical activity in the natural environment can promote emotional well-being (Pasanen et al, 2014).*
- Structure the environment as needed to promote optimal comfort and sensory diversity (e.g., have family bring in posters, banners, or photos; change lighting; change arrangement of furniture). **CEBN:** *For hospitalized clients needing close observation, consider the use of a S.A.F.E. unit that uses trained “diversional partners” rather than sitters; diversional activities were promoted through the use of TVs and VCRs on rolling carts, radios and CD players with music from various genres, movies, rocking chairs, a storage cabinet stocked with games and art supplies, stuffed animals, soft balls, and towels for folding (Nadler-Moodie et al, 2009).*
- Work with family or music therapist to provide music that is enjoyable to the client. **EB:** *Hospitalized patients who received an individualized music therapy session and who were provided with a CD for listening demonstrated marginally better quality of life pain scores after hospitalization and were more likely to recommend the hospital to others (Mandel et al, 2014).*
- Structure the client’s schedule around personal wishes for time of care, relaxation, and participation in fun activities. *Increased client control fosters increased client self-esteem.*
- Spend time with the client when possible, giving the client full attention and being present in the moment, or arrange for a friendly visitor.

**Pediatric**

- ▲ Request an order for a child life specialist or, if not available, a play therapist for children. *Child life therapists provide opportunities for self-expression and play for hospitalized children and may help to normalize the environment.*
- Promote a referral to a music therapist. **EBN:** *Music therapy may lead to a decrease in self-reported pain and anxiety in hospitalized children, and may lead to improved patient and family satisfaction (Colwell et al, 2013).*
- Consider art therapy for children living with chronic illness who have activity restrictions. **CEB:** *In a study of children with persistent asthma, those who engaged in art therapy demonstrated a reduction in anxiety and an improvement in emotional health (Beebe et al, 2010).*

- Provide opportunities for children to connect with family and friends through technology. **EBN:** *Children desire to feel connected to the world outside the hospital environment; technology can reduce isolation as well as support educational needs (Lambert et al, 2014).*
- Provide activities such as video projects and use of computer-based support groups for children, such as Starbright World, a computer network where teenagers interact virtually, sharing their experiences and escaping hospital routines (www.starbrightworld.org). **CEB:** *Starbright World was shown to significantly reduce loneliness and withdrawn behavior in chronically ill children (Battles & Wiener, 2002).*
- Provide animal-assisted therapy for hospitalized children. **CEBN:** *Animal-assisted therapy produces a number of therapeutic benefits for hospitalized children, including a reduction in pain (Braun et al, 2009).*
- Provide computer games and virtual reality experiences for children, which can be used as distraction techniques during venipuncture, wound care, or other procedures. **EBN:** *Actively engaging children in serious gaming resulted in lower observed behavioral pain scores and distress for children undergoing wound dressing changes (Nilsson et al, 2013).*

Geriatric

- Assess the interests of older adults and the types of activities that they enjoy; encourage creative expression such as storytelling, drama, dance, art, writing, or music. **EB:** *Art therapy was shown to be effective in reducing anxiety and negative emotions, and improving self-esteem in a group of Korean American older adults (Kim, 2013); participating in music-making with others may improve quality of life, well-being, and physical and mental health in older adults (Creech et al, 2013).*
- If the client is able, arrange for him or her to attend group senior citizen activities. **EB:** *Social connectedness may assist with older adults' perception that they are aging well (Hodge et al, 2013).*
- Promote activity for older adults through the use of exergames (video games combined with exercise). **EB:** *A pilot study demonstrated that Wii interactive videogaming is feasible for use with older adults with mild cognitive impairment; participants enjoyed physical, mental, and social stimulation from the intervention (Hughes et al, 2014).*
- Encourage involvement in dance. **EB:** *Active participation in dance may enhance healthy aging (Noice et al, 2013).*
- Encourage involvement in gardening. **EB:** *Gardening promotes relief from stress (Van Den Berg & Custers, 2011).*
- Encourage clients to use their ability to help others by volunteering. **EB:** *Volunteering is associated with better self-reported health, fewer functional limitations, reduced depressive symptoms, and lower mortality (Anderson et al, 2014).*
- Provide an environment that promotes activity (e.g., one that has adequate lighting for crafts, large-print books, and adequate acoustics).
- Balance effortful activities with restful activities. **EB:** *Older adults had higher happiness scores when they were able to combine effortful activities that were physical, social, or cognitive with activities that were restful (Oerlemans et al, 2011).*
- Provide tai chi as an activity. **EB:** *In a study of heart failure clients, it was found that participation in tai chi exercises may lead to an improvement in mood, exercise self-efficacy, and quality of life (Yeh et al, 2011).*
- Provide opportunities for storytelling and life review. **EBN:** *Reflection on one's life assists individuals to discover meaning and purpose; a pilot study demonstrated a significant reduction in depressive symptoms after the creation of life story books (Chan et al, 2014).*
- ▲ Use reminiscence therapy in conjunction with the expression of emotions. Refer to a reminiscence group if available. **EBN:** *Participation in a structured reminiscence group led to improved self-esteem and life satisfaction and a decrease in depressive symptoms in a group of institutionalized older veterans (Wu, 2011).*
- Arrange for intergenerational volunteering for individuals with mild to moderate dementia. **EB:** *In a study of older adults living in an assisted living facility with mild to moderate dementia who visited inner city students, it was found that engagement in singing, reading, writing, and reminiscence led to a decrease in stress and an increase in quality of life (George & Singer, 2011).*
- Use the Eden Alternative for older adults; bring in appropriate plants for the older client to care for and animals such as birds, fish, dogs, and cats as appropriate for the client and children to visit. See rationales for animal-assisted therapy above. *The Eden Alternative offers a more natural human habitat where the quality of life is improved by reducing loneliness, boredom, and helplessness (Baumann, 2008).*

- For clients who love gardening but who may have difficulty being outside, bring in seeds, soil, and pots for indoor gardening experiences. Use seeds such as sunflower, pumpkin, and zinnia that grow rapidly. **EB:** *Gardening may foster socialization, fitness, flexibility, cognitive ability, health, and quality of life (Wang & Macmillan, 2013).*
- For clients with depressive symptoms, facilitate regular music listening. **EB:** *Listening to pleasant music was found to enhance auditory and verbal memory, focused attention, and mood in patients in the early phase of recovery after stroke (Särkämö & Soto, 2012).*
- For hospitalized clients with cognitive impairment, engage the assistance of volunteers to provide diversional activities. **EBN:** *A small pilot study demonstrated that patients, caregivers, staff, and volunteers were satisfied with a volunteer program that engaged hospitalized patients in a variety of activities during hospitalization (Shee et al, 2014).*
- For clients in assisted-living facilities, provide leisure educational programs and pleasant dining experiences. **EB:** *Opportunities for social engagement lead to psychological benefits for older adults in assisted living (Jang et al, 2014).*
- For clients who are interested in reading and writing, promote book or writing groups or journaling, creative or expressive writing. **EB:** *Participation in reading and writing activities positively influenced quality of life in a group of older adults (Sampaio & Ito, 2013).*
- Prescribe activities to engage passive dementia clients based on their former interests and hobbies. **EB:** *Residents of long-term care facilities who have dementia spend the majority of their time engaged in no activity at all, and inactivity has been linked to agitated behavior; stimuli such as looking at and sorting pictures, arranging flowers, folding towels, making puzzles, planting seeds, screwing nuts and bolts together, and listening to and singing along with favorite music led to positive affect and a decrease in agitated behavior (van der Ploeg et al, 2013).*
- Initiate opportunities for creative expression such as a TimeSlips storytelling group or Memories in the Making project to foster meaningful activities for clients with dementia. **EB:** *A creative storytelling program for clients with dementia, TimeSlips, resulted in increased creativity, quality of life, and involvement in meaningful activity and positively altered resident behavior while allowing staff to develop a deeper understanding of residents (George & Houser, 2014).*

Home Care

- Many of the previously listed interventions may be administered in the home setting.
- Explore with the client previous interests; consider related activities that are within the client's capabilities.
- ▲ Assess the client for depression. Refer for mental health services as indicated. **EB:** *Lack of interest in previously enjoyed activities is part of the syndrome of depression (American Psychiatric Association, 2013).*
- Assess the family's ability to respond to the client's psychosocial needs for stimulation. Assist as able.
- ▲ Refer to occupational therapy. **EB:** *Clients with low vision who received adequate training in the use of low vision devices tailored to individual goals were able to improve independence at home (Liu et al, 2013).*
- Introduce (or continue) friendly volunteer visitors if the client is willing and able to have the company. If transportation is an issue or if the client does not want visitors in the home, consider alternatives (e.g., telephone contacts, computer messaging).
- For clients who are interested and capable, suggest involvement in a community gardening experience. **EB:** *Community gardens were identified as a source of individual and community well-being (Okvat & Zautra, 2011).*
- If the client is approaching the end of life, and is interested, assist in making a videotape, audiotape, or memory book for family members with treasured stories, memoirs, pictures, and video clips. **CEB:** *Leaving a legacy entails passing on the essence of one's self; passing on values and beliefs is important to older adults (Hunter, 2007-2008).*

Client/Family Teaching and Discharge Planning

- Work with the client and family on learning diversional activities in which the client is interested (e.g., knitting, hooking rugs, writing memoirs).
- If the client is in isolation, give the client complete information on why isolation is needed and how it should be accomplished, especially guidelines for visitors; provide diversional activities and encourage visitation. **EBN:** *Children in isolation feel lonely and bored; access to play, social connections, and education may assist (Austin et al, 2013).*

E

Risk for Electrolyte imbalance *Susan M. Dirkes, RN, MS, CCRN*

NANDA-I

Definition

Vulnerable to changes in serum electrolyte levels, which may compromise health

Risk Factors

Compromised regulatory mechanism; diarrhea; endocrine regulatory dysfunction; fluid imbalance (e.g., glucose intolerance, increase in IGF-1, androgen, DHEA, and cortisol); excessive fluid volume; insufficient fluid volume; renal dysfunction; treatment regimen; vomiting

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Electrolyte and Acid-Base Balance; Fluid Balance; Hydration; Nutritional Status: Biochemical Measures; Nutritional Status: Food and Fluid Intake; Nutritional Status: Nutrient Intake; Kidney Function

Example NOC Outcome with Indicators

Electrolyte and Acid-Base Balance as evidenced by the following indicators: Apical heart rate/Apical heart rhythm/Serum potassium/Serum sodium/Serum calcium, serum magnesium, serum phosphorus. (Rate the outcome and indicators of **Electrolyte and Acid-Base Balance**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain a normal sinus heart rhythm with a regular rate
- Have a decrease in edema
- Maintain an absence of muscle cramping
- Maintain normal serum potassium, sodium, calcium, and phosphorus
- Maintain normal serum pH

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Electrolyte Monitoring; Electrolyte Management: Hypokalemia, Hyperkalemia, Hypocalcemia, Hypercalcemia, Hyponatremia, Hyponatremia, Hypophosphatemia, and Hyperphosphatemia; Electrolyte Management: Hyponatremia; Fluid/Electrolyte Management; Laboratory Data Interpretation

Example NIC Activities—Electrolyte Monitoring

Identify possible causes of electrolyte imbalances; Monitor the serum level of electrolytes

List of Nursing Diagnoses by Letter: E

Risk for Electrolyte imbalance

Labile Emotional Control

Risk for dry Eye

Nursing Interventions and Rationales

- ▲ Monitor vital signs at least three times a day, or more frequently as needed. Notify health care provider of significant deviation from baseline. *Electrolyte imbalance can lead to clinical manifestations such as respiratory failure, arrhythmias, edema, muscle weakness, and altered mental status (Wagner & Hardin-Pierce, 2014).*
- ▲ Monitor cardiac rate and rhythm. Report changes to provider. *Hypokalemia and hyperkalemia can result in electrocardiogram (ECG) changes that can lead to cardiac arrest, and ventricular dysrhythmias. Magnesium and calcium imbalances also can cause cardiac arrhythmias. Low serum magnesium (≤ 2 mEq/L) is associated with hypokalemia and ECG changes, and high phosphate may indicate kidney injury (Wagner & Hardin-Pierce, 2014).*
- Monitor intake and output and daily weights using a consistent scale. *Weight gain is a sensitive and consistent sign of fluid volume excess (Wagner & Hardin-Pierce, 2014).*
- Monitor for abdominal distention and discomfort. *A focused assessment should be done on any patient presenting with hepatic, gastrointestinal or pancreatic dysfunction (Wagner & Hardin-Pierce, 2014).*
- Monitor the client's respiratory status and muscle strength. *Phosphorus is an essential element in cell structure, metabolism, and maintenance of acid-base processes. Consequences of hypophosphatemia include cardiac and respiratory failure (Wagner & Hardin-Pierce, 2014).*
- Assess cardiac status and neurological alterations. **EB:** *Hypophosphatemia can cause myocardial dysfunction, hematological dysfunction, respiratory depression, and neurological changes (Claire-DelGrando & Bouchard, 2012).*
- *Causes of neurological changes are not well documented. Hyperphosphatemia is associated with hypocalcemia (since it is inversely related to calcium), causing tetany, muscle spasms, and cardiac arrhythmias (Wagner & Hardin-Pierce, 2014).*
- ▲ Review laboratory data as ordered and report deviations to provider. *Laboratory studies may include serum electrolytes: potassium, chloride, sodium, bicarbonate, magnesium, phosphate, calcium; serum pH; comprehensive metabolic panel; and arterial blood gases.*
- Review the client's medical and surgical history for possible causes of altered electrolytes. *Periods of excess fluid loss can lead to dehydration and resulting loss of electrolytes; fluid can be lost through gastrointestinal illness, renal failure, hyperthermia, blood loss, and perspiration due to strenuous exercise (Wagner & Hardin-Pierce, 2014; Chlibkova et al, 2014). Additional causes of electrolyte imbalances include burns, trauma, sepsis, diabetic ketoacidosis, extensive surgeries, and changes in acid-base balance (Yee, 2010).*
- ▲ Complete pain assessment. Assess and document the onset, intensity, character, location, duration, aggravating factors, and relieving factors. Notify the provider for any increase in pain or discomfort or if comfort measures are not effective. *Symptoms of electrolyte imbalance and dehydration can include muscle cramps, paresthesias, abdominal cramps, skin manifestations, cardiac arrhythmias, and tetany (Wagner & Hardin-Pierce, 2014).*
- ▲ Monitor the effects of ordered medications such as diuretics and heart medications. *Medications can have adverse effects on kidney function and electrolyte balance, particularly contrast agents, chemotherapeutic agents, amphotericin B, aminoglycosides, phosphate ingestion, loop diuretics, and vitamin D (Calazza et al, 2014; Wagner & Hardin-Pierce 2014).*
- ▲ Administer parenteral fluids as ordered and monitor their effects. *Rapid resuscitation with fluids can cause adverse effects such as electrolyte imbalance, increased bleeding, and coagulopathies (Wang et al, 2014). Administration of fluids should be done in order to impact the plasma electrolytes and pH as well as hemodynamic improvement (Vassalos & Rooney, 2013).*

Geriatric

- Monitor electrolyte levels carefully, including sodium levels and potassium levels, with both increased and decreased levels possible. **EB:** *Older adults are prone to electrolyte abnormalities because of failure of regulatory mechanisms associated with heart and kidney disease, a decrease in the ability to reabsorb sodium, and a loss of diluting capacity in the kidneys (Bolognino et al, 2014). Many older clients receive selective serotonin reuptake inhibitors for treatment of depression, which can result in hyponatremia (Rudge & Kim, 2014).*

Client/Family Teaching and Discharge Planning

- Teach client/family the signs of low potassium and the risk factors. *Signs and symptoms of low potassium include muscle weakness, nausea, vomiting, constipation, and irregular pulse (Wagner & Hardin-Pierce, 2014).*

- Teach client/family the signs of high potassium and the risk factors. *Signs and symptoms of high potassium include restlessness, muscle weakness, slow heart rate, diarrhea, and cramping (Wagner & Hardin-Pierce, 2014).*
- Teach client/family the signs of low sodium and the risk factors. *Early signs of low sodium include nausea, muscle cramps, disorientation, and mental status changes (Wagner & Hardin-Pierce, 2014).*
- Teach client/family the signs of high sodium and the risk factors. *Signs of high sodium include thirst, dry mucous membranes, rapid heartbeat, low blood pressure, and mental status changes; symptoms can progress to confusion, delirium, and seizures (Wagner & Hardin-Pierce, 2014).*
- Teach client/family the importance of hydration during exercise. Dehydration occurs when the amount of water leaving the body is greater than the amount consumed. *The body can lose large amounts of fluid when it tries to cool itself by sweating (Jequier & Constant, 2010).*
- Teach client/family the warning signs of dehydration. Early signs of dehydration include thirst and decreased urine output. As dehydration increases, symptoms may include dry mouth, muscle cramps, nausea and vomiting, lightheadedness, and orthostatic hypotension. *Severe dehydration can cause confusion, weakness, coma, and organ failure (Wagner & Hardin-Pierce, 2014).*
- Teach client about any medications prescribed. Medication teaching includes the drug name, its purpose, administration instructions such as taking it with or without food, and any side effects to be aware of. **EB:** *Diuretic use remains a primary cause of low serum potassium levels (Arampatzis et al, 2013).*
- ▲ Instruct the client to report any adverse medication side effects to his/her health care provider. **EB:** *Assessing and instructing clients about medications and focusing on important details can help prevent client medication errors (Buckley et al, 2010).*

Labile Emotional Control *Wolter Paans, MSc, PhD, RN*

NANDA-I

Definition

Uncontrollable outbursts of exaggerated and involuntary emotional expression

Defining Characteristics

Absence of eye contact; difficulty in use of facial expressions; embarrassment regarding emotional expression; excessive crying without feeling sadness; excessive laughing without feeling happiness; expression of emotion incongruent with triggering factor; involuntary crying; involuntary laughing; tearfulness;

uncontrollable crying; uncontrollable laughing; withdrawal from occupational situation; withdrawal from social situation

Related Factors

Alteration in self-esteem; brain injury; emotional disturbance; fatigue; functional impairment; insufficient knowledge about symptom control; insufficient knowledge of disease; insufficient muscle strength; mood disorder; musculoskeletal impairment; pharmaceutical agent; physical disability; psychiatric disorder; social distress; stressors; substance abuse

E

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Knowledge: Disease Process; Impulse; Self-Control; Self-Esteem; Quality of Life; Personal Well-Being; Stress Level

Example NOC Outcomes with Indicators

Knowledge: Disease Process as evidenced by the following indicator: Specific disease process. (Rate the outcome and indicators of **Knowledge: Disease Process**: 1 = no knowledge, 2 = limited knowledge, 3= moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Improve coping strategies
- Improved knowledge about disease process, signs and symptoms, triggers, symptom control
- Employ mechanisms to control impulses and ask for help when feeling impulses
- Improve feelings of dignity
- Enhance and improve response to social and environmental stimuli

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Teaching: Disease Process; Enhance Self-Esteem; Improved Quality of Life; Improved Well-Being

Example NIC Activities—Labile Emotional Control

Coping Enhancement: Assist the patient to solve problems in a constructive manner; Instruct the patient on the use of relaxation techniques, as needed; Assist the patient to identify positive strategies to deal with limitations and manage needed lifestyle or role changes

Nursing Interventions and Rationales

- Provide progressive relaxation exercise techniques. **EB:** “Our present study with a randomized controlled group design clearly demonstrates that after two sessions, a single bout of PMR reduces anxiety and psychological stress, and improves subjective well-being” (Georgiev et al, 2012). **EB:** Systematic review demonstrates specific physical therapy interventions, including aerobic and muscle strength exercises, progressive muscle relaxation, and yoga, resulted in beneficial outcomes for psychiatric symptoms, psychosocial distress, anxiety, health-related quality of life, and aerobic and muscular fitness (Vancampfort et al, 2011).
- Offer instruction regarding alternative coping strategies such as mindfulness and breath awareness. **EB:** Increased breath awareness (a fundamental component of mindfulness meditation) has been shown to reduce autonomic and psychological arousal, and this increased capacity to remain calm can help individuals to respond more adaptively to internal and external stressors (Compare et al, 2014). **EB:** Studies have demonstrated the effects of mindfulness and yoga on well-being, somatic effects of stress, immune system, and physical symptoms and chronic conditions (Lazaridou et al, 2013).

- Use the Pathological Laughter and Crying Scale (PLACS) to identify pathological laughing and crying or related disorders (e.g., IEED, PBA). **EB/EBN**: PLACS is an interviewer-administered instrument that has been validated in clients with acute stroke. It has shown excellent interrater and test-retest reliability (Ahmed & Simmons, 2013).
- Consider using cognitive-behavioral therapy. **CEB/EB**: Cognitive-behavioral therapy has been shown to be moderately effective when compared to usual care and to relaxation, counseling, and education/support, although these effects have not been maintained over time (Malouff et al, 2008; Price et al, 2008).
- Provide, if possible, music therapy. **EB**: The use of music therapy can improve mental well-being, social functioning, quality of life, anxiety, pain, mood, relaxation, and comfort in persons with several disorders/diseases such as cancer, schizophrenia, mood disorders, and autism (Kamioka et al, 2014). Music therapy as an addition to standard care helps people with schizophrenia to improve their global state, mental state (including negative symptoms), and social functioning if a sufficient number of music therapy sessions are provided (Mössler et al, 2011).

Multicultural, Home Care

- The above interventions may be adapted for multicultural and home care.

Client/Family Teaching and Discharge Planning

- Inform client and family about the emotional lability and talk with them about how to cope with the situation. **EBN**: Stroke services should aim to produce easy-to-read literature that explains emotional lability, and offer clients and families reassurance and simple suggestions about how to cope with the condition (Gillespie et al, 2011).
- Use verbal and nonverbal therapeutic communication approaches including empathy, active listening, and confrontation to encourage the client and family to express emotions such as sadness, guilt, and anger (within appropriate limits); verbalize fears and concerns; and set goals. **EB**: Solution focused communication with clients helps focus on goals and helps find solutions (Ruddick, 2011).
- Provide psychoeducation for stress-related variables to client and family. **EB**: Psychoeducation was conducted in seven studies, six of which had positive outcomes on depression, anxiety, or knowledge levels (Bte Iskhandar Shah et al, 2013). **EB**: Learning about stress and extending techniques to cope with stress seems to contribute positively to mental health (Van Daele et al, 2012).

Risk for dry Eye *Paula D. Hopper, MSN, RN, CNE, and Betty J. Ackley, MSN, EdS, RN*

NANDA-I

Definition

Vulnerable to eye discomfort or damage to the cornea and conjunctiva due to reduced quantity or quality of tears to moisten the eye, which may compromise health

Risk Factors

Aging; autoimmune diseases (e.g., rheumatoid arthritis, diabetes mellitus, thyroid disease); contact lens wearer; environmental factor (e.g., air conditioning, excessive wind, sunlight exposure, air pollution, low humidity); female gender; history of allergy; hormonal change; lifestyle choice (e.g., smoking, caffeine use, prolonged reading); mechanical ventilation neurological lesions with sensory or motor reflex loss (e.g., lagophthalmos, lack of spontaneous blink reflex); ocular surface damage; treatment regimen; vitamin A deficiency

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes (Visual)

Dry Eye Severity; Sensory Function: Vision; Vision Compensation Behavior

Example NOC Outcome with Indicators

Dry Eye Severity as evidenced by the following indicators: Decreased tear production/Redness of conjunctiva/burning eye sensation/Itchy eye sensation/Eye pain/Excessive watering/Blurred vision. (Rate each indicator of **Dry Eye Severity**: 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- State eyes are comfortable with no itching, burning, or dryness
- Have corneal surface that is intact and without injury
- Demonstrate self-administration of eye drops if ordered
- State vision is clear

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Communication Enhancement: Visual Deficit; Environmental Management

Example NIC Activities—Communication Enhancement: Visual Deficit

Identify yourself when you enter the client's space; Provide adequate room lighting

Nursing Interventions and Rationales

- ▲ Assess for symptoms of dry eyes, such as “irritation, tearing, burning, stinging, dry or foreign body sensation, mild itching, photophobia, blurry vision, contact lens intolerance, redness, mucus discharge, increased frequency of blinking, eye fatigue, diurnal fluctuation, symptoms that worsen later in the day” ([American Academy of Ophthalmology \[AAO\], 2013](#)).
- ▲ If symptoms are present, refer client to an ophthalmologist for diagnosis and treatment. **EB**: *Clients with dry eye who are evaluated by non-ophthalmologist health care providers should be referred promptly to the ophthalmologist if moderate or severe pain, lack of response to therapy, corneal infiltration or ulceration, or vision loss occurs (AAO, 2013).*
- ▲ Administer ordered eye drops. *As the severity of the dry eye increases, aqueous enhancement of the eye using topical agents is appropriate. Emulsions, gels, and ointments can be used (AAO, 2013).*

- Consider use of eyeglass side shields or moisture chambers. **EB:** *Eyeglass side shields can protect the eyes from drafts. Moisture chambers are a type of eyeglasses that are frequently worn by motorcyclists and mountain climbers and can be purchased at stores or online (AAO, 2013).*
- ▲ Watch for symptoms of blepharitis including crusting and irritation at the base of the lashes and adjacent redness of the eyelid, which may accompany dry eye; refer for treatment as needed. **EB:** *Contributing ocular factors such as blepharitis should be treated. Particularly effective treatments for evaporative tear deficiency include eyelid therapy for conditions such as blepharitis (AAO, 2013).*
- ▲ Discuss use of caffeine with client's health care provider. **EB:** *Arita et al (2012) found that use of caffeine capsules increased tear volume.*

Geriatric

- Recognize that symptoms of dry eye are more common in menopausal women and geriatric clients. *Hormonal changes after menopause can disrupt tear production. It is estimated that one in three individuals older than 65 years experiences dry eyes (National Health Service [NHS], 2014).*

Critical Care

- ▲ Provide regular cleaning of the eyes, lubricating eye drops and ointments, and consultation with an ophthalmologist if infection is suspected in clients in the intensive care unit (ICU). *ICU staff may miss ocular complications while caring for life-threatening conditions; ocular complications can seriously impair vision and quality of life. EB: "As ICU patients are more susceptible to develop dry eye, keratopathy, and ocular infections, they should be consulted by an ophthalmologist for early diagnosis of ocular surface disorders" (Saritas et al, 2013).*
- Avoid using adhesive tape to keep eyes closed in sedated patients. **EBN:** *In an audit of eye dryness and corneal abrasions of patients in four ICUs in Iran, patients receiving adhesive tape as an eye care method were twice as likely to develop corneal abrasion (Masouudi et al, 2014).*

Client/Family Teaching and Discharge Planning

- Teach client conditions that can exacerbate dry eye symptoms. *Exacerbating conditions include wind, air travel, decreased humidity, air conditioning or heating, and prolonged activities that reduce blink rate such as reading and computer use (AAO, 2013).*
- Teach client good eye hygiene:
 - Apply warm compresses for 10-minute intervals using a clean cloth and water that has been boiled and cooled (or sterile water).
 - Gently massage around eyelids.
 - Gently clean eyelids to remove excess oil, crusts, and bacteria. Use a few drops of baby shampoo in water that has been boiled and cooled, or in sterile water.
 - *Good hygiene can help improve dry eyes, especially dry eye associated with blepharitis (NHS, 2014).*
- Teach clients methods to decrease problems with dry eye including the following:
 - Avoid drafty (e.g., ceiling fans) and low-humidity environments.
 - Avoid smoking and exposure to second-hand smoke.
- ▲ Discuss avoidance of offending medications with health care provider.
- Drink plenty of water to keep well hydrated. **EB:** *For patients with a clinical diagnosis of mild dry eye, potentially exacerbating exogenous factors such as antihistamine or diuretic use, cigarette smoking, and exposure to second-hand smoke, and environmental factors such as air drafts and low-humidity environments should be addressed (AAO, 2013). Symptoms of dry eye may be exacerbated by the use of medications such as diuretics, antihistamines, anticholinergics, antidepressants, and systemic retinoids (AAO, 2013). Self-care includes drinking plenty of water to stay hydrated (American Optometric Association, 2014).*
- Teach client to lower the computer screen to below eye level and to blink more frequently. *Measures such as lowering the computer screen to below eye level to decrease lid aperture, scheduling regular breaks, and increasing blink frequency may decrease the discomfort associated with computer and reading activities (AAO, 2013).*
- ▲ Teach client to consult with the health care provider regarding use of omega-3 supplements to decrease dry eye. **EB:** *Omega-3 fatty acid products without ethyl esters may be beneficial in the treatment of dry eye, although they may increase the risk of prostate cancer (AAO, 2013).*

- Teach client using eye drops how to self-administer eye drops.
- Warn clients with dry eyes that driving at night can be dangerous. *Clients with dry eyes have light sensitivity and decreased refraction.*

Risk for Falls *Sherry A. Greenberg, PhD, RN, GNP-BC*

F

NANDA-I

Definition

Vulnerable to increased susceptibility to falling, which may cause physical harm and compromise health

Risk Factors

Adults

Age ≥ 65 years; history of falls; living alone; lower limb prosthesis; use of assistive device (e.g., walker, cane, wheelchair)

Children

Absence of stairway gate; absence of window guard; age ≤ 2 years; inadequate supervision; insufficient automobile restraints; male gender when < 1 year of age

Cognitive

Alteration in cognitive functioning

Environment

Cluttered environment; exposure to unsafe weather-related condition (e.g., wet floors, ice); insufficient lighting; insufficient antislip material in bathroom; unfamiliar setting; use of restraints; use of throw rugs

Pharmaceutical Agents

Alcohol consumption; pharmaceutical agent

Physiological

Acute illness; alteration in blood glucose level; anemia; arthritis; condition affecting the foot; decrease in lower extremity strength; diarrhea; difficulty with gait; faintness when extending neck; faintness when turning neck; hearing impairment; impaired balance; impaired mobility; incontinence; neoplasm; neuropathy; orthostatic hypotension; postoperative recovery period; proprioceptive deficit; sleeplessness; urinary urgency; vascular disease; visual impairment

NOC

(Nursing Outcomes Classification)

Suggested NOC Outcomes

Fall Prevention Behavior; Knowledge: Child Physical Safety

- = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

List of Nursing Diagnoses by Letter: F

Risk for Falls	Dysfunctional Family processes	Interrupted Family processes
Readiness for enhanced Family processes	Fatigue	Fear
Ineffective infant Feeding pattern	Readiness for enhanced Fluid balance	Deficient Fluid volume
Excess Fluid volume	Risk for Deficient Fluid volume	Risk for imbalanced Fluid volume
Frail Elderly syndrome	Risk for Frail Elderly syndrome	

Example NOC Outcome with Indicators

Fall Prevention Behavior as evidenced by the following indicators: Uses assistive devices correctly/Eliminates clutter, spills, glare from floors/Uses safe transfer procedures. (Rate each indicator of **Fall Prevention Behavior**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of falls
- Change environment to minimize the incidence of falls
- Explain methods to prevent injury

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Dementia Management; Fall Prevention; Post-Fall Assessment; Surveillance: Safety

Example NIC Activities—Fall Prevention

Assist unsteady individual with ambulation; Monitor gait, balance, and fatigue level with ambulation

Nursing Interventions and Rationales

- Safety Guidelines. Complete a fall-risk assessment for older adults in acute care using a valid and reliable tool such as the Hendrich II Model. Recognize that risk factors for falling include recent history of falls, fear of falling, confusion, depression, altered elimination patterns, cardiovascular/respiratory disease impairing perfusion or oxygenation, postural hypotension, dizziness or vertigo, primary cancer diagnosis, and altered mobility (Gray-Miceli, 2008). *The Hendrich II Fall Risk Model is quick to administer and provides a determination of risk for falling based on gender, mental and emotional status, symptoms of dizziness, and known categories of medications increasing risk (Hendrich, 2006). This tool screens for primary prevention of falls and is integral in a post-fall assessment for the secondary prevention of falls (Gray-Miceli, 2007).*
- Screen all clients for balance and mobility skills (supine to sit, sitting supported and unsupported, sit to stand, standing, walking and turning around, transferring, stooping to floor and recovering, and sitting down). Use tools such as the Balance Scale by Tinetti or the Get Up and Go Scale. *It is helpful to determine the client's functional abilities and then plan for ways to improve problem areas or determine methods to ensure safety (Gray-Miceli, 2008).*
- Recognize that when people attend to another task while walking, such as carrying a cup of water, clothing, or supplies, they are more likely to fall. **CEB:** *Those who slow down when given a carrying task are at a higher risk for subsequent falls (Lundin-Olsson et al, 1998).*
- Carefully assist a mostly immobile client up. Be sure to lock the bed and wheelchair and have sufficient personnel to protect the client from falls. When rising from a lying position, have the client change positions slowly, dangle legs, and stand next to the bed before walking to prevent orthostatic hypotension. *Encourage client engagement in a monitored exercise program that will strengthen core and lower extremities to reduce fall risk (Grabiner, 2013; Hirase et al, 2014).*
- Use a “high-risk fall” armband/bracelet and fall risk room sign to alert staff for increased vigilance and mobility assistance. *These steps alert the nursing staff of the increased risk of falls (Goodwin et al, 2014; McCarter-Bayer et al, 2005).*
- ▲ Evaluate the client's medications to determine whether medications increase the risk of falling; consult with health care provider regarding the client's need for medication if appropriate. *Polypharmacy, or taking more than four medications, has been associated with increased falls. Medications such as benzodiazepines, as well as antipsychotic and antidepressant medications given to promote sleep, actually increase the rate of falls (Capezuti et al, 1999; Goodwin et al, 2014). EB: Short-to-intermediate-acting benzodiazepine and tricyclic antidepressants may produce ataxia, impaired psychomotor function, syncope, and additional falls (Fick et al, 2003; Molony, 2008).*

- Orient the client to environment. Place the call light within reach and show how to call for assistance; answer call light promptly.
- Use one-fourth to one-half-length side rails only, and maintain bed in a low position. Ensure that wheels are locked on bed and commode. Keep dim light in room at night. *Use of full side rails can result in the client climbing over the rails, leading with the head, and sustaining a head injury. Side rails with widely spaced vertical bars and side rails not situated flush with the mattress have been associated with asphyxiation deaths because of rail and in bed entrapment and should not be used (Capezuti, 2004; Goodwin et al, 2014).*
- Routinely assist the client with toileting on his or her own schedule. Take the client to bathroom on awakening and before bedtime (McCarter-Bayer et al, 2005; Goodwin et al, 2014). Keep the path to the bathroom clear, label the bathroom, and leave the door open.
- ▲ Avoid use of restraints if possible. Obtain health care provider's order if restraints are deemed necessary, and use the least restrictive device. *The use of restraints has been associated with serious injuries including rhabdomyolysis, brachial plexus injury, neuropathy, and dysrhythmias, as well as strangulation, asphyxiation, traumatic brain injuries, and all the consequences of immobility (Evans & Cotter, 2008).* **CEB/EB:** *A study demonstrated that there was no increase in falls or injuries in a group of clients who were not restrained versus a similar group that was restrained in a nursing home (Capezuti et al, 1999). A study in two acute care hospitals demonstrated that when restraints were not used, there was no increase in client falls, injuries, or therapy disruptions (Mion et al, 2001).*
- In place of restraints, use the following:
 - Well-staffed and educated nursing personnel with frequent client contact with careful consideration during shift changes
 - Nursing units designed to care for clients with cognitive or functional impairments
 - Nonskid footwear, sneakers preferable
 - Adequate lighting, night-light in bathroom
 - Frequent toileting
 - Frequently assess need for invasive devices, tubes, intravenous (IV) access
 - Hide tubes with bandages to prevent pulling of tubes
 - Consider alternative IV placement site to prevent pulling out IV line
 - Alarm systems with ankle, above-the-knee, or wrist sensors
 - Bed or wheelchair alarms
 - Wedge cushions on chairs to prevent slipping
 - Increased observation of the client
 - Locked doors to unit
 - Low or very low height beds
 - Border-defining pillow/mattress to remind the client to stay in bed
- *These alternatives to restraints can be helpful to prevent falls (McCarter-Bayer et al, 2005; Cotter & Evans, 2007; Grabiner 2013).*
- If the client has an acute change in mental status (delirium), recognize that the cause is usually physiological and is a medical emergency. Consider possible causes for delirium. Consult with the health care provider immediately. See interventions for Acute **Confusion**.
- If the client has chronic confusion due to dementia, implement individualized strategies to enhance communication. *Assessment of specific receptive and expressive language abilities is needed in order to understand the client's communication difficulties and facilitate communication.* See interventions for Chronic **Confusion**.
- Ask family to stay with the client to assist with activities of daily living and prevent the client from accidentally falling or pulling out tubes.
- ▲ If the client is unsteady on his/her feet, have two nursing staff members alongside when walking the client. Use facility approved mobility devices to assist with client ambulation (e.g., gait belts, walkers). Consider referral to physical therapy for gait training and strengthening. *The client can walk independently, but the nurse can rapidly ensure safety if the client becomes weak or unsteady. Interdisciplinary care is most comprehensive and beneficial to the client (Grabiner 2013).*
- Place a fall-prone client in a room that is near the nurses' station. *Such placement allows more frequent observation of the client.*
- Help clients sit in a stable chair with arm rests. Avoid use of wheelchairs except for transportation as needed. **CEB:** *Clients are likely to fall when left in a wheelchair because they may stand up without locking*

the wheels or removing the footrests. Wheelchairs do not increase mobility; people just sit in them the majority of the time (Simmons et al, 1995).

- Avoid use of wheelchairs as much as possible because they can serve as a restraint device. Most people in wheelchairs do not move. *Wheelchairs unfortunately serve as a restraint device.* **CEB:** A study has shown that only 4% of residents in wheelchairs were observed to propel them independently and only 45% could propel them, even with cues and prompts. Another study showed that no residents could unlock wheelchairs without help, the wheelchairs were not fitted to residents, and residents were not trained in propulsion (Simmons et al, 1995).
- ▲ Refer to physical therapy or other programs for exercise programs that target strength, balance, flexibility, or endurance. **EB:** Programs with at least two of these components have been shown to decrease the rate of falling and number of people falling, (Gillespie et al, 2009).

F

Geriatric

- Assess ability to move using the Hendrich II Fall Risk Model, which includes the Get Up and Go test. Ask the client to rise from a sitting position, walk 10 feet, turn, and return to the chair to sit. *Performance on this screening exam demonstrates the client's mobility and ability to leave the house safely. If the client completes the test in less than 20 seconds, he/she usually can live independently. If completing the test takes longer than 30 seconds, the client is more likely to be dependent on others and more likely to sustain a fall* (Gray-Miceli, 2007; Goodwin et al, 2014).
- Complete a fall risk assessment for older adults in acute care using a valid and reliable tool such as the Hendrich II Fall Risk Model. *It is quick to administer and provides a determination of risk for falling based on gender, mental and emotional status, symptoms of dizziness, and known categories of medications increasing risk* (Hendrich et al, 2003). *This tool screens for primary prevention of falls and is integral in a post-fall assessment for the secondary prevention of falls* (Gray-Miceli, 2007; Goodwin et al, 2014).
- ▲ If new onset of falling, assess for lab abnormalities, and signs and symptoms of infection and dehydration, and check blood pressure and pulse rate with client in supine, sitting, and standing positions for hypotension and orthostatic hypotension. If the client has borderline high blood pressure, the risk of falling due to administration of antihypertensives may outweigh the benefits of the antihypertensive medication. Discuss with the health care provider on a client-to-client basis. *If orthostatic hypotension is present and there is minimal change in the heart rate, most likely the baroreceptors are not working to maintain blood pressure on arising. This is common in older adults and may be caused by hypovolemia resulting from the excessive use of diuretics, vasodilators, or other types of drugs; dehydration; or prolonged bed rest as well as cardiovascular disease, neurological disease, or the adverse effects of another medication* (NINDS, 2011). *Insertion of a pacemaker can reduce falls in people with frequent falls associated with carotid sinus hypersensitivity, a condition that may cause changes in heart rate and blood pressure* (Gillespie et al, 2009).
- Complete a fear of falling assessment for older adults. This includes measuring fear of falling, or the level of concern about falling, and falls self-efficacy, the degree of confidence a person has in performing common activities of daily living without falling. Fear of falling may be measured by a single-item question asking about the presence of fear of falling or rating severity of fear of falling on a 1-4 Likert scale as is commonly done in studies. Falls self-efficacy may be measured using a valid and reliable tool such as the Falls Efficacy Scale-International (Yardley et al, 2005; Greenberg, 2011).
- Encourage the client to wear glasses and use walking aids when ambulating.
- If the client experiences dizziness because of orthostatic hypotension when getting up, teach methods to decrease dizziness, such as rising slowly, remaining seated several minutes before standing, flexing feet upward several times while sitting, sitting down immediately if feeling dizzy, and trying to have someone present when standing. **CEB/EB:** *Always have the client dangle at the bedside before standing to evaluate for postural hypotension. Watch the client closely for dizziness during increased activity. Postural hypotension can be detected in up to 30% of older clients. These methods can help prevent falls as well as maintain adequate fluid intake* (Tinetti, 2003; Goodwin et al, 2014).
- ▲ If the client is experiencing syncope, determine symptoms that occur before syncope, and note medications that the client is taking. Refer for medical care. The circumstances surrounding syncope often suggest the cause. *Use of many medications, including diuretics, antihypertensives, digoxin, beta-blockers, and calcium channel blockers can cause syncope. Use of the tilt table can be diagnostic in incidences of syncope* (Fick & Mion, 2007; Goodwin et al, 2014).

- ▲ Observe client for signs of anemia, and refer to health care provider for testing if appropriate.
- Evaluate client for chronic alcohol intake, as well as mental health and neurological function.
- ▲ Refer to physical therapy for strength training, using free weights or machines, and suggest participation in exercise programs. *Exercise can prevent falls in older people. Greater relative effects are seen in programs that include exercises that challenge balance, use a higher dose of exercise, and do not include a walking program. Service providers can use these findings to design and implement exercise programs for falls prevention (Sherrington et al, 2008; Grabiner, 2013; Hirase et al, 2014).*
- ▲ If an older woman has symptoms of urge incontinence, refer to a urologist or nurse specialist in incontinence for evaluation and ensure the path to the bathroom is well lit and free of obstructions. **CEB:** *Urge urinary incontinence was associated with an increased incidence of falls and non-spine, nontraumatic fractures in older women (Brown et al, 2000).*
- ▲ New evidence-based guidelines for preventing falls in older adults were published by the American Geriatrics Society (AGS) and British Geriatrics Society (BGS) collaboratively and specify recommendations for all clinical settings. The new recommendations include screening and assessment, as well as interventions. Examples of interventions include (1) exercise for balance and for gait and strength training, such as tai chi or physical therapy; (2) environmental adaptation to reduce fall risk factors in the home and in daily activities; (3) cataract surgery when indicated; (4) medication reduction with particular attention to medications that affect the brain such as sleeping medications and antidepressants; (5) assessment and treatment of postural hypotension; (6) identification and appropriate treatment of foot problems; (7) vitamin D supplementation for those with vitamin D (**American Geriatrics Society, 2011a,b**).

Home Care

- Some of the above interventions may be adapted for home care use.
- Implement evidence-based fall prevention practices in community settings and home health care programs for older adults (**Fortinsky et al, 2008**).
- If the client was identified as a fall risk in the hospital, recognize that there is a high incidence of falls after discharge, and use all measures possible to reduce the incidence of falls. **CEBN:** *The rate of falls is substantially increased in the geriatric client who has been recently hospitalized, especially during the first month after discharge (Mahoney et al, 2000).*
- ▲ If delirium is present, assess for cause of delirium and/or falls with the use of an interprofessional team. Consult with the health care provider immediately. Assess and monitor for acute changes in cognition and behavior. *An acute and fluctuating change in cognition and behavior is the classic presentation of delirium. Delirium is reversible and should be considered a medical emergency. Delirium can become chronic if untreated, and clients may be discharged from hospitals to home care in states of undiagnosed delirium. **EB:** Falls may be a precipitating event or an indication of frailty consistent with acute confusion (Goodwin et al, 2014).*
- Assess home environment for threats to safety including clutter, slippery floors, scatter rugs, and other potential hazards. Additionally, assess external environment (e.g., uneven pavement, unlevelled stairs/steps). *Clients suffering from impaired mobility, impaired visual acuity, and neurological dysfunction, including dementia and other cognitive functional deficits, are all at risk for injury from common hazards. These recommendations were shown to be effective to reduce falls (Tinetti, 2003; Goodwin et al, 2014).*
- ▲ Institute a home-based, nurse-delivered exercise program to reduce falls or refer to physical therapy services for client and family education of safe transfers and ambulation and for strengthening exercises for the client (**Grabiner, 2013**).
- ▲ Instruct the client and family or caregivers on how to correct identified hazards for those with visual impairment. Refer to physical and occupational therapy services for assistance if needed. **EB:** *Interventions to improve home safety were shown to be effective in people at high risk, such as those with severe visual impairment (Gillespie et al, 2009).*
- ▲ Use a multifactorial assessment along with interventions targeted to the identified risk factors. Key components of the interventions include evaluating need for all medications, balance, gait and strength training, use of strategies to deal with postural hypotension if present, home safety evaluation with needed modifications, and any needed cardiovascular treatment. **EB:** *As people age, they may fall more often for multiple reasons including problems with balance, poor vision, and dementia. Fear of falling can result in self-restricted activity levels (Gillespie et al, 2009).*

- Encourage the client to eat a balanced diet, with particular inclusion of vitamin D and calcium. *Vitamin D deficiency and hypocalcemia are common in older adults, contributing to falls, musculoskeletal complaints, and functional and mobility deficits. Results show that vitamin D and calcium were superior to calcium supplementation alone in regard to fall prevention, musculoskeletal function, and bone metabolism, especially in recurrent falls and in frail older women with vitamin D deficiency. Older adults with unexplained falls, pain, and gait imbalance may have osteomalacia due to vitamin D deficiency (Dharmarajan, 2005).*
- If the client lives alone or spends a lot of time alone, teach the client what to do if he/she falls and cannot get up, and make sure he/she has a personal emergency response system or a mobile phone that is available from the floor (Tinetti, 2003). If the client is at risk for falls, use a gait belt and additional persons when ambulating. *Gait belts decrease the risk of falls during ambulation.*
- Ensure appropriate nonglare lighting in the home. Ask the client to install indoor strip or “runway” type of lighting to baseboards to help clients balance. Install motion-sensitive lighting that turns on automatically when the client gets out of bed to go to the bathroom.
- Have the client wear supportive, low-heeled shoes with good traction when ambulating. Avoid use of slip-on footwear. Wear appropriate footwear in inclement weather. *Supportive shoes provide the client with better balance and protect the client from instability on uneven surfaces. Antislip shoe devices worn in icy conditions have been shown to reduce falls (Gillespie et al, 2009).*
- Provide a signaling device for clients who wander or are at risk for falls. *Orienting a vulnerable client to a safety net relieves anxiety of the client and caregiver and allows for rapid response to a crisis situation.*
- Provide medical identification bracelet for clients at risk for injury from dementia, diabetes, seizures, or other medical disorders.
- Suggest a tai chi class designed for older adults and selected clients who have sufficient balance to participate. **EB:** *Participation in once per week tai chi classes for 16 weeks can prevent falls in relatively healthy community-dwelling older people (Voukelatos et al, 2007).*

Client/Family Teaching and Discharge Planning

- Safety Guidelines. Teach the client and the family about the fall reduction measures that are being used to prevent falls (The Joint Commission, 2009).
- Teach the client how to safely ambulate at home, including using safety measures such as hand rails in bathroom and avoiding carrying things or performing other tasks while walking.
- Teach the client the importance of maintaining a regular exercise program. If the client is afraid of falling while walking outside, suggest he/she walk the length of a local mall. *Exercise can prevent falls in older people. Greater relative effects are seen in programs that include exercises that challenge balance and use a higher dose of exercise than just walking programs (Sherrington et al, 2008; Hirase et al, 2014; Grabiner, 2013).*

Dysfunctional Family processes

Gail B. Ladwig, MSN, RN, and Deborah Yvonne Fields, RN, BSN, MA, LICDC, CCMC

NANDA-I

Definition

Psychosocial, spiritual, and physiological functions of the family unit are chronically disorganized, which leads to conflict, denial of problems, resistance to change, ineffective problem solving, and a series of self-perpetuating crises

Defining Characteristics

Behavioral

Agitation; alteration in concentration; blaming; broken promises; chaos; complicated grieving; conflict avoidance; contradictory communication pattern; controlling communication pattern; criticizing; decrease in physical contact; denial of problems; dependency; difficulty having fun; difficulty with intimate relationships; difficulty with life cycle transitions; disturbances in academic performance in children; enabling substance use pattern; escalating conflict; failure to accomplish developmental tasks; harsh self-judgment; immaturity; inability to accept a wide range of feelings; inability to accept help; inability to adapt to change; inability to deal constructively with traumatic experiences; inability to express wide range of feelings; inability to meet the emotional needs of its members; inability to meet the security needs of its members; inability to meet the spiritual needs of its members; inability to receive help appropriately; inappropriate anger expression; ineffective communication skills; insufficient knowledge about substance abuse; insufficient problem solving skills; lying; manipulation; nicotine addiction; orientation favors tension relief rather than goal attainment; paradoxical communication pattern; power struggles; rationalization; refusal to get help; seeking of affirmation; seeking of approval; self-blame; social isolation; special occasions centered on substance use; stress-related physical illnesses; substance abuse; unreliable behavior; verbal abuse of children; verbal abuse of parent; verbal abuse of partner

Feelings

Abandonment; anger; anxiety; confuses love and pity; confusion; depression; dissatisfaction; distress; embarrassment; emotional isolation; failure; fear; feeling different from others; feeling misunderstood; feeling unloved; frustration; guilt; hopelessness; hostility; hurt; insecurity; lack of identity; lingering resentment; loneliness; loss; mistrust; moodiness; powerlessness; rejection; reports feeling misunderstood; repressed emotions; responsibility for substance abuser's behavior; suppressed rage; shame; tension; unhappiness; vulnerability; worthlessness

Roles and Relationships

Change in role function; chronic family problems; closed communication systems; conflict between partners; deterioration in family relationships; diminished ability of family members to relate to each other for mutual growth and maturation; disrupted family rituals; disrupted family roles; disturbance in family dynamics; economically disadvantaged; family denial; inconsistent parenting; ineffective communication with partner; insufficient cohesiveness; insufficient family respect for autonomy of its members; insufficient family respect for individuality of its members; insufficient relationship skills; intimacy dysfunction; neglect of obligation to family member; pattern of rejection; perceived insufficient parental support; triangulating family relationships

Related Factors (r/t)

Addictive personality; biological factors; family history of resistance to treatment; family history of substance abuse; genetic predisposition to substance abuse; ineffective coping skills; insufficient problem-solving skills; substance abuse

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Family Coping; Family Functioning; Family Health Status; Substance Addiction Consequences

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Confronts/manages family problems/Involves family members in decision-making. (Rate the outcome and indicators of **Family Coping**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section 1].)

Client Outcomes

Family/Client Will (Specify Time Frame)

- State one way that alcoholism has affected the health of the family
- Identify three healthy coping behaviors that family members can employ to facilitate a shift toward improved family functioning

- Identify one Al-Anon meeting from Al-Anon meeting schedule that family members express a desire to attend
- Attend different types of meetings (lead, big book, discussion, beginner's meeting) to find a good match and commit to attending that group regularly

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Family Process Maintenance; Substance Use Treatment

Example Activities—Family Process Maintenance

Identify effects of role changes on family process; Assist family members to use existing support mechanisms

F

Nursing Interventions and Rationales

- Refer to care plans for Ineffective **Denial** and Defensive **Coping** for additional interventions.
- ▲ Behavioral screening and intervention (BSI) should be integrated into all health care settings. Different terminology has evolved for screening, intervention, and referral for various behavioral issues. The five As—ask, advise, assess, assist, and arrange—apply to tobacco use. SBIRT (screening, brief intervention, and referral to treatment) pertains to alcohol and drug use. **EB:** *The U.S. Preventive Services Task Force recommends universal screening and intervention for tobacco use, excessive drinking, and depression. These services improve health outcomes, decrease health care costs, enhance public safety, and generate substantial return on investment (Brown, 2011).*
- Screen clients for at-risk drinking during routine primary care visits and before surgery using the Alcohol Use Disorders Identification Test (AUDIT). **EB:** *Complications following total joint arthroplasty were significantly related to alcohol misuse in this group of male patients treated at a VHA facility. The AUDIT-C has three simple questions that can be incorporated into a preoperative evaluation and can alert the treatment team to patients with increased postoperative risk (Harris et al, 2011).*
- Stress early treatment and brief intervention to resolve the problem. **CEBN:** *This study demonstrated cost-effectiveness of the early treatment model (project TrEAT; Trial for Early Alcohol Treatment) (Mundt, 2006).*
- Provide brief education and individual counsel as a routine part of primary care. **EB:** *Brief interventions may be effective in helping patients engage in nonharmful drinking. The objective of the current study tested the implementation of a telephone-based brief intervention (telephone care management; TCM) with heavy drinkers in primary care. The addition of TCM to primary care provider standard care (screening and brief advice) was compared with standard care alone. Both groups significantly decreased their drinking over time, with 40% of participants no longer engaging in heavy drinking at follow-up. Both groups decreased the number of drinking days and the average number of drinks per day over the follow-up period. Participants reported a decrease in alcohol use frequency and alcohol-related problems (Helstrom et al, 2014).*
- Refer for family therapy. Family therapy is generally advisable to restore healthy family dynamics and to provide the appropriate environment and support for full recovery (*Psychology Today, 2012*).
- ▲ Refer for possible use of medications to control alcohol dependence. **EB:** *The Food and Drug Administration has approved three medications for treating alcohol dependence. Naltrexone can help people reduce heavy drinking. Acamprosate makes it easier to maintain abstinence. Disulfiram blocks the breakdown (metabolism) of alcohol by the body, causing unpleasant symptoms such as nausea and flushing of the skin. Those unpleasant effects can help some people avoid drinking while taking disulfiram. It is important to remember that not all people will respond to medications, but for a subset of individuals, they can be an important tool in overcoming alcohol dependence (NIH, 2014).*

Pediatric

- ▲ Encourage early intervention, when parental depression, childhood exposure to conflict and violence and childhood experience with abuse and neglect co-exist with parental substance abuse, their children are more likely to engage in increased teacher-rated unfavorable student behavioral problems. **EB:** *Early intervention with COSA (children of substance abusers) is necessary to reach children while they are more receptive to treatment (Conners-Burrow et al, 2012).*

- Encourage parent communication about alcohol use with adolescents. **EB:** *Abar et al (2011) identified parent-adolescent communication as important in delaying the onset and escalation of alcohol use.*
- ▲ Consider the Community Reinforcement Approach (CRA) that encourages clients to become progressively involved in alternative non-substance-related pleasant social activities and to work on enhancing the enjoyment they receive within the “community” of their family and job. **EB:** *CRA, originally developed for individuals with alcohol use disorders, has been successfully employed to treat a variety of substance use disorders for more than 35 years. Based on operant conditioning, CRA helps adolescents rearrange their lifestyles so that healthy, drug-free living becomes rewarding and thereby competes with alcohol and drug use (Meyers et al, 2010).*
- ▲ Educate family members about available educational and support programs and encourage no/limited alcohol use in the home. **EBN:** *Both individual and multiperson interventions exert an influential role in family-based therapy for treatment of adolescent drug abuse (Hoque et al, 2006).*
- Encourage adolescents to attend a 12-step program. **EB:** *Mundt et al (2012) demonstrated that adolescents who attend 12-step groups following alcohol and other drug (AOD) treatment are more likely to remain abstinent and to avoid relapse.*
- Provide a school-based drug-prevention program to junior high students. **EB:** *Students who received the drug-prevention program during junior high school were less likely to have violations and points on their driving records (Warner et al, 2007).*

Geriatric

- Include assessment of possible alcohol abuse when assessing older family members. **EB:** *Alcohol abuse and dependence in older people are important problems that frequently remain undetected by health services (Beullens & Aertgeerts, 2004). The majority of older alcoholics are married, have low education levels, and do not belong to high social classes (Shahpesandy et al, 2006).*

Multicultural

- Acknowledge racial/ethnic differences at the onset of care. **EBN:** *Acknowledgment of race/ethnicity issues will enhance communication, establish rapport, and promote treatment outcomes (Giger & Davidhizar, 2008).*
- Use a family-centered approach when working with Latino, Asian American, African American, and Native American clients. **EBN:** *American Indian families may be extended structures that could exert powerful influences over functioning (Kopera-Frye, 2009). Family therapy is important in addressing the needs of Hispanic families with adolescent substance abusers (Kopera-Frye, 2009).*
- Some less-aculturated Latino families may be unwilling to discuss family issues with health care providers until they perceive a close personal relationship with the provider. **EBN:** *Some Latino families may believe that personal problems should be kept private and may not respond to the health care provider until there is an established personal relationship (Kopera-Frye, 2009).*
- Work with families in a way that incorporates cultural elements. **CEB:** *Activities such as tundra walks and time with older adults supported in treatment were used successfully for substance abuse treatment with Yup'ik and Cup'ik Eskimos (Mills, 2003).*

Home Care

NOTE: In the community setting, alcoholism as cause of dysfunctional family processes must be considered in two categories: (1) when the client suffers personally from the illness, and (2) when a significant other suffers from the illness, that is, the client is not the active alcoholic but may depend on the alcoholic for caregiving. The following considerations apply to both situations with appropriate adaptation for the circumstances.

- The previous interventions may be adapted for home care use.
- Work with family members to support a sense of valued fit on their part; include them in treatment planning and identify the importance of their roles in the client's care. At the same time, encourage their pursuit of positive outside activities that enhance their sense of belonging. **CEBN:** *Sense of belonging (valued fit) has been identified as a buffer to depression among both depressed and nondepressed individuals with a family history of alcoholism. A buffering effect was not found for individuals with a family history of drug abuse (Sargent et al, 2002).*

- Educate client and family regarding the interactions of alcohol use with medications and the therapeutic regimen. *Increased awareness of drug interactions decreases the chance of relapse due to over-the-counter and other medications (Weisberg & Hawes, 2005).*
- Alcoholism is a family disease. *If everyone participates in recovery, everyone can be healed (Buddy, 2007).*
- ▲ Refer for psychiatric home health care services for client reassurance and implementation of therapeutic regimen. **CEB:** *Twelve studies (five randomized controlled trials, one quasi-experimental study, and six uncontrolled cohort studies) found that home and community-based treatment of psychiatric symptoms of socially isolated older adults with mental illness was associated with improved or maintained psychiatric status. All randomized controlled trials reported improved depressive symptoms, and one reported improved overall psychiatric symptoms (Van Citters & Bartells, 2004).*
- ▲ Consider use of a smartphone-based intervention for alcohol use disorders. *Participants in a pilot study indicated the smartphone provided numerous features for addressing ongoing drinking, craving, connection with supportive others, managing life problems, high-risk location alerting, and activity scheduling. These intervention modules were helpful in highlighting alcohol use patterns. Tools related to managing alcohol craving, monitoring consumption, and identifying triggers to drink were rated by participants as particularly helpful. Participants also demonstrated significant reductions in hazardous alcohol use while using the system (Dulin et al, 2014).*

Client/Family Teaching and Discharge Planning

- Suggest the client complete a confidential Internet self-screening test for identification of problems and suggestions for treatment if a problem with alcohol is suspected. Many tools are available. *The website www.AlcoholScreening.org helps individuals assess their own alcohol consumption patterns to determine if their drinking is likely harming their health or increasing their risk for future harm. Through education and referral, the site urges those whose drinking is harmful or hazardous to take positive action and informs all adults who consume alcohol about guidelines and caveats for lower risk drinking (Boston University School of Public Health, 2005).*
- Provide education for family. **EB:** *Family education facilitates understanding of the disease and its causes, effects, and treatment (U.S. Department of Health and Human Services, 2005).*
- Facilitate participation in mutual help groups (MHGs). **EB:** *Mutual help groups appear to mobilize the same change processes such as coping, motivation, and self-efficacy that are mobilized by many different types of professionally led groups (Kelly et al, 2009; Moos, 2008).*

Interrupted Family processes

Vanessa Flannery, MSN, PHCNS-BC, CNE

NANDA-I

Definition

Change in family relationships and/or functioning

Defining Characteristics

Alteration in availability for affective responsiveness; alteration in family conflict resolution; alteration in family satisfaction; alteration in intimacy; alteration in participation for problem solving; assigned tasks change; change in communication pattern; change in somatization; change in stress reduction behavior; changes in expressions of conflict with community resources; changes in expressions of isolation from community resources; changes in participation for decision-making; changes in relationship pattern; decrease in available emotional support; decrease in mutual support; ineffective task completion; power alliance change; ritual change

Related Factors (r/t)

Alteration in family finances; change in family social status; changes in interaction with community; developmental crisis; developmental transition; power shift among family members; shift in family roles; shift in health status of a family member; situational crisis; situational transition

NOC

(Nursing Outcomes Classification)

Suggested NOC Outcomes

Family Coping; Family Functioning; Family Normalization; Psychosocial Adjustment: Life Change, Role Performance

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Confronts/manages family problems/Involves family members in decision-making. (Rate the outcome and indicators of **Family Coping**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Client Will (Specify Time Frame)

- Express feelings (family)
- Identify ways to cope effectively and use appropriate support systems (family)

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

- Treat impaired family member as normally as possible to avoid overdependence (family)
- Meet physical, psychosocial, and spiritual needs of members or seek appropriate assistance (family)
- Demonstrate knowledge of illness or injury, treatment modalities, and prognosis (family)
- Participate in the development of the plan of care to the best of ability (significant person)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Family Integrity Promotion; Family Process Maintenance; Normalization Promotion

Example NIC Activities—Family Integrity Promotion

Collaborate with family in problem solving and decision-making; Counsel family members on additional effective coping skills for their own use

Nursing Interventions and Rationales

- Motivate family members to speak openly about illnesses, keeping in mind the importance of ethnic origin. **EBN:** *Recognizing ethnic origin to caregivers' open communication can improve the quality of life to allow family members to derive solutions and face challenges (Bachner et al, 2014).*
- Recognize informal roles in medical decision-making by family members. **EBN:** *Informal roles emerge in critical situations to help fill the gaps in how family members respond to the challenge of end-of-life decision-making (Quinn et al, 2012).*
- Acknowledge the range of emotions and feelings that may be experienced when the health status of a family member changes. **EBN:** *Nurses can better support caregivers regarding their perception of family support and expressive family functioning (Svavarsdottir & Sigurdardottir, 2013).*
- Encourage family members to list their personal strengths and available resources. **EBN:** *Families provide the main support network and family strengths are closely associated with the family use of resources (Coym, 2013).*
- Establish relationships among clients, their families, and health care professionals. **EBN:** *A systems approach to disease management incorporates the family as part of the care team and may improve outcomes for the individual (LaFrance, 2011).*
- Encourage family to visit the client; adjust visiting hours to accommodate family's schedule. **EBN:** *Incorporating visiting family members in the plan of care is complex and requires balancing the visitor's needs for information and access to a loved one with the nurse's need to safely manage the care of a critically ill individual (Alves, 2013).*
- Allow and encourage family members to assist in the client's treatment. **EBN:** *Support for family members is an essential part of quality end-of-life care for residents, and health care facilities should embrace the opportunity to demonstrate the value of family participation in care (Oliver et al, 2014).*
- Support family members during emotional and conflict situations in the clinical setting. **EBN:** *A key element of successful interpersonal relationships is the use of constructive conflict management, such as problem solving, compromise, affection, humor and apology (Baptist et al, 2012).*
- Refer to the care plan **Readiness for enhanced Family processes** for additional interventions.

Pediatric

- Carefully assess potential for reunifying children placed in foster care with their birth parents. **EB:** *Reunifying children placed in foster care with their birth parents is a primary goal of the child welfare system (Lewis, 2011).*
- Provide parents with both general information and professional support by family-centered early childhood intervention services to their families. **EBN:** *Providing families with general information (such as making information available in various forms and arranging for a guest speaker) in addition to specialized information about their children is most important to empower parents (Fordham et al, 2012).*
- Encourage and support parents/family to assist in client's care. **EBN:** *Parents need to be able to negotiate with health staff what this participation will involve and negotiate new roles for themselves in sharing care of their sick child (Kelly & Kelly, 2013).*

- ▲ Refer parents and other primary caregivers to a mindfulness-based stress reduction (MBSR) program. **EBN:** *Community-based MBSR programs can be an effective intervention to reduce stress and improve psychological well-being for parents and caregivers of children, especially those with developmental disabilities (Bazzano, 2013).*

Geriatric

- Encourage family members to be involved in the care of relatives who are in residential care settings. **EBN:** *Family involvement in residential long-term care is important especially when preparing for end-of-life care (Oliver et al, 2014).*
- Support group problem solving among family caregivers and include the older member. **EBN:** *Health personnel must be aware that family caregiving undergoes a transition, shifting both how and when family members mobilize to meet the needs of the older adult (Wongsawang et al, 2013).*
- ▲ Refer family for counseling with a psychotherapist who is knowledgeable about gerontology.
- Refer to care plan for **readiness for Enhanced Family processes** for additional interventions.

Multicultural

- Refer to the care plan **readiness for Enhanced Family processes** for additional interventions.

Home Care

- The nursing interventions described in the care plan for Compromised family **Coping** should be used in the home environment with adaptations as necessary.
- Encourage family members to find meaning in a serious illness. **EBN:** *Letting go before the death of a loved one involves a shift in thinking in which there is acknowledgment of impending loss without impeding its natural progression (Molzahn et al, 2012).*

Client/Family Teaching and Discharge Planning

- Refer to **Client/Family Teaching and Discharge Planning** in Compromised family **Coping** and Readiness for enhanced family **Coping** for suggestions that may be used with minor adaptations.

Readiness for enhanced Family processes *Kimberly Silvey, MSN, RN*

NANDA-I

Definition

A pattern of family functioning to support the well-being of family members, which can be strengthened

Defining Characteristics

Expresses desire to enhance balance between autonomy and cohesiveness; expresses desire to enhance communication pattern; expresses desire to enhance energy level of family to support activities of daily living; expresses desire to enhance family adaptation to change; expresses desire to enhance family dynamics; expresses desire to enhance family resilience; expresses desire to enhance growth of family members; expresses desire to enhance interdependence with community; expresses desire to enhance maintenance of boundaries between family members; expresses desire to enhance respect for family members; expresses desire to enhance safety of family members.

F

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Family Coping; Health-Promoting Behavior; Health-Seeking Behavior; Parent-Infant Attachment; Parenting Performance

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Confronts/manages family problems/Obtains family assistance. (Rate the outcome and indicators of **Family Coping**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Client Will (Specify Time Frame)

- Identify ways to cope effectively and use appropriate support systems (family)
- Meet physical, psychosocial, and spiritual needs of members or seek appropriate assistance (family)
- Demonstrate knowledge of potential environmental, lifestyle, and genetic risks to health and use appropriate measures to decrease possibility of risk (family)
- Focus on wellness, disease prevention, and maintenance (family and individual)
- Seek balance among exercise, work, leisure, rest, and nutrition (family and individual)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Decision-Making Support; Family Integrity Promotion; Family Involvement Promotion; Family Mobilization; Family Process Maintenance; Parent Education: Adolescent; Childrearing Family; Risk Identification; Role Enhancement

Example NIC Activities—Risk Identification

Determine availability and quality of resources (e.g., psychological, financial, education level, family and other social, and community)

Nursing Interventions and Rationales

- Assess the family's stress level and coping abilities during the initial nursing assessment. **EB**: *Assessing parental stress level will help the nurse to plan interventions to better care for the child and their parents (Burke et al, 2014).*

- Consider the use of family-centered theory as the conceptual foundation to help guide interventions. **EB:** *The concept of family-centered care stresses the importance of the family in children's well-being (Kuo et al, 2012).*
- Use family-centered care and role modeling for holistic care of families. **EB:** *A holistic approach to care enhances the family's well-being and respects the family's beliefs (Purow et al, 2011).*
- Discuss with family members and identify the perceptions of the health care experience. **EBN:** *Nurses and parents may perceive the care the child receives differently and it is important to help identify the differences to better care for the child and family (Stuart & Melling, 2014).*
- Support family needs, strengths, and resourcefulness through family interviews. **EBN:** *Family interviews can give the nurse an understanding of the family's understanding and expectations (Alsem et al, 2014).*
- Spend time with family members; allow them to verbalize their feelings. **EB:** *Listening to what the family is saying can help the nurse understand how they are feeling (SmithBattle et al, 2013).*
- Encourage family members to find meaning in a serious illness. **EBN:** *Just because parents have hope for their child does not mean they do not understand their child's prognosis (O'Brien, 2014).*
- Provide family-centered care to explore and use all available resources appropriate for the situation (e.g., counseling, social services, self-help groups, pastoral care). **EB:** *Family-centered care includes multiple members of the health care team (Hodgetts et al, 2013).*
- Consider focus groups to provide insight to family perceptions of illness and/or disease prevention. **EBN:** *Focus groups provide insight into the perception of care that is received by the client (Pozzar et al, 2014).*

Pediatric

- Provide a parenting class series based on individual and couple changes in meaning and identity, roles, and relationships and interaction during the transition to parenthood. Address mother and father roles, infant communication abilities, and patterns of the first 3 months of life in a mutually enjoyable, possibility focused manner. **EB:** *Parenting classes can improve parenting and coping skills to enhance quality of life (Okamoto et al, 2013).*
- Encourage families with adolescents to have family meals. *Eating family meals may enhance the health and well-being of adolescents. Public education on the benefits of family mealtime is recommended (Fruh et al, 2012). Family meals help strengthen a family and provide structure for better development (Utter et al, 2013).*
- ▲ Consider the use of adventure therapy for adolescents with cancer. **EBN:** *Adventure therapy is considered a strategy to promote health and in this study cancer survival (Wynn et al, 2012).*

Geriatric

- Carefully listen to residents and family members in the long-term care facility. **EBN:** *Nurses can improve life and dignity for residents by listening to residents and family members (van der Cingel, 2011).*
- Support caregivers' awareness of the positive effects of their contribution to the well-being of parents. **EBN:** *Children caring for their elderly parents can have a positive impact on the child and the parent (Lin et al, 2013).*
- Teach family members about the impact of developmental events (e.g., retirement, death, change in health status, and household composition). **EBN:** *Knowledge helps the family to better cope with health care and the care of the client (Nigolian & Miller, 2011).*
- Encourage social networks; social integration; social engagement and internet social networking with friends, children, and relatives of older adults. **EB:** *Social networking enables older adults to be more engaged (Cornejo et al, 2013).*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the family's perceptions of normal functioning. **EBN:** *Cultural beliefs will have a considerable impact on a client's functioning (Mutair et al, 2014).*
- Identify and acknowledge the stresses unique to racial/ethnic families. **EBN:** *Understanding a client's unique racial/ethnic background may help the nurse identify stressors that the client and the family may be experiencing (Balaam et al, 2013).*
- Assess and support spiritual needs of families. **EB:** *Assessing and supporting the spiritual needs of the client and the family can enhance the understanding of the family's perception of care and the care that was actually received (Chrash et al, 2011; Bernstein et al, 2013).*

- With the client's consent, facilitate a group meeting for family members to discuss how the family is functioning. **EBN**: *A family meeting opens communication and lets each family member know it is okay to talk about what is happening (Sharma & Dy, 2011).*
- Facilitate modeling and role playing for the client and family regarding healthy ways to start a discussion about the client's prognosis. **EBN**: *It is helpful to practice communication skills in a safe environment before trying them in a real-life situation (Fisher et al, 2012).*
- Encourage family mealtimes. **EB**: *Encouraging family mealtimes enhances the communication between the family and health and well-being (Fruh et al, 2012).*

Home Care

- The previous nursing interventions should be used in the home environment with adaptations as necessary.
- ▲ Encourage virtual support groups to family caregivers. **EB**: *Use of online support groups gives the caregiver a forum for giving and receiving guidance and support (Diefenbeck et al, 2014).* Encourage caregivers of older clients with chronic obstructive pulmonary disease (COPD) receiving long-term oxygen therapy to seek additional services such as social services, respite care, and additional home health visits. **EBN**: *Positive support should be given to the caregivers of clients with COPD (Janssen et al, 2012).*

Client/Family Teaching and Discharge Planning

- Refer to **Client/Family Teaching and Discharge Planning** for readiness for enhanced family **Coping** for suggestions that may be used with minor adaptations.

Fatigue

Victoria K. Marshall, RN, BSN, Paula Riess Sherwood, PhD, RN, CNRN, FAAN, and Barbara A. Given, PhD, RN, FAAN

F

NANDA-I

Definition

An overwhelming, sustained sense of exhaustion and decreased capacity for physical and mental work at the usual level

Defining Characteristics

Alteration in concentration; alteration in libido; disinterest in surroundings; drowsiness; guilt about difficulty maintaining responsibilities; impaired ability to maintain usual physical activity; impaired ability to maintain usual routines; increase in physical symptoms; increase in rest requirement; ineffective role performance; insufficient energy; introspection; lethargy; listlessness; nonrestorative sleep pattern (due to caregiver responsibilities, parenting practices, sleep partner); tiredness

Related Factors (r/t)

Anxiety; depression; environmental barrier (e.g., ambient noise, daylight/darkness exposure, ambient temperature/humidity, unfamiliar setting); increase in physical exertion; malnutrition; negative life event; nonstimulating lifestyle; occupational demands (e.g., shift work, high level of activity, stress); physical deconditioning; physiological condition (e.g., anemia, pregnancy disease); sleep deprivation; stressors

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Concentration; Endurance; Energy Conservation/Restoration; Nutritional Status; Energy; Vitality

Example NOC Outcome with Indicators

Endurance as evidenced by the following indicators: Performance of usual routine/Activity/Energy restored after rest/Blood oxygen level with activity/Muscle endurance. (Rate the outcome and indicators of **Endurance**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section 1].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify potential etiology of fatigue
- Identify potential factors that aggravate and relieve fatigue
- Describe ways to assess and track patterns of fatigue over set periods of time (e.g., a few days, a week, a month)
- Describe ways in which fatigue affects the ability to accomplish goals and activities of daily living (ADLs)
- Verbalize increased energy and improved vitality
- Explain energy conservation plan to offset fatigue
- Explain energy restoration plan to offset fatigue

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Energy management, including both conservation and restoration; conservation interventions are targeted at preserving an individual's energy, whereas restorative interventions are intended to reestablish vitality

• = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Example NIC Activities—Energy Management

Assess client's physiological and psychological status for deficits resulting in fatigue within the context of age, development, and stage of disease or illness; Determine client/significant other's perception of causes of client's fatigue

Nursing Interventions and Rationales

- Assess severity of fatigue on a scale of 0 to 10 (average fatigue, worst and best levels); assess frequency of fatigue (number of days per week and time of day), activities and symptoms associated with increased fatigue (e.g., pain), ability to perform ADLs and instrumental ADLs, interference with social and role function, times of increased energy, ability to concentrate, mood, usual pattern of physical activity, and typical sleep cycles. Consider use of an instrument such as the Profile of Mood State Short Form Fatigue Subscale, the Multidimensional Assessment of Fatigue, the Lee Fatigue Scale, the Multidimensional Fatigue Inventory, the HIV-Related Fatigue Scale, or the Brief Fatigue Inventory, Short Form Vitality Subscale, Piper Fatigue Scale, Chalder Fatigue Scale, or Nottingham of Chronic Illness Therapy Fatigue Scale. **EBN/CEB:** *These assessments have all been shown to have good internal reliability. The Fatigue Severity Scale, Fatigue Impact Scale, and Brief Fatigue Inventory are relatively short with good psychometric properties, making them clinically useful. These measures, along with the Multidimensional Assessment of Fatigue, have shown the ability to detect changes in fatigue over time (Whitehead, 2009). The European Organization for Research and Treatment of Cancer Quality of Life Core Questionnaire (EORTC QLQ-FA 13) (Weis et al, 2013) was proven reliable. Varying populations may respond differently to instruments. The Fatigue Scale for Motor and Cognitive functions and the Unidimensional Fatigue Impact Scale demonstrate good applicability in clients with multiple sclerosis; the Functional Assessment of Chronic Illness Therapy Fatigue subscale and the Fatigue Severity Scale demonstrate good applicability in clients with Parkinson's disease, and the Profile of Mood States Fatigue subscale demonstrates good applicability in clients who have had a stroke (Elbers et al, 2012).*
- Evaluate adequacy of nutrition and sleep hygiene (napping throughout the day, inability to fall asleep or stay asleep). Encourage the client to get adequate rest, limit naps (particularly in the late afternoon or evening), use a routine sleep/wake schedule, plan and prioritize for daily activities as tolerated, allow exposure to sunlight during daytime hours by going outside or opening shades and curtains in the home, use relaxation techniques before bedtime such as meditation, music therapy, or guided imagery (Kwekkeboom et al, 2010), avoid caffeine in the late afternoon or evening, and eat a well-balanced diet that includes fresh fruits, vegetables, and lean meats. Refer to Imbalanced **Nutrition:** less than body requirements or **Insomnia** if appropriate. **EBN:** *Dysfunction in sleep (too much, too little, or too many interruptions) can aggravate fatigue (Denlinger et al, 2014; Johansson et al, 2010). Inadequate nutrition can also contribute to fatigue, particularly if anemia is present (Bower et al, 2014).*
- Evaluate fluid status and assess for dehydration. Encourage at least eight glasses of water a day. Avoid caffeine, which can cause further dehydration. **EB:** *Dehydration has been shown to cause fatigue (Ganio et al, 2011; Pross et al, 2013). Some populations such as young children, older adults, and those with other medical conditions are more susceptible to dehydration (Ganio et al, 2011).*
- ▲ Collaborate with the primary care provider to identify physiological and/or psychological causes of fatigue that could be treated, such as anemia, pain, electrolyte imbalance (e.g., altered potassium levels), thyroid disorders, arthritis, depression, sleep disturbances (insomnia/sleep deprivation), acute or chronic infection, medication use or side effects, alcohol use/abuse, metabolic disorders (diabetes), or a preexisting comorbidity or disease (multiple sclerosis, cancer or cancer treatment, respiratory disease, fibromyalgia, cardiac disease, renal disease or renal replacement therapy, Parkinson's disease) (Berger et al, 2012; Connolly et al, 2013). **EB/EBN:** *If an etiology for fatigue can be determined, the condition should be treated according to the underlying cause. Anemia is highly correlated with fatigue, particularly in clients with cancer (Kleinman et al, 2012). Fatigue is also related to psychological distress, nausea/vomiting (Oh & Seo, 2011), medication side effects, and nutritional deficit (due to change in taste or cancer affecting swallowing or the digestive tract) in clients with cancer (Berger et al, 2012). Fatigue also negatively impacts a client's quality of life (Connolly et al, 2013; Borneman, 2013).*
- ▲ Work with the primary care provider to determine if the client has chronic fatigue syndrome, paying attention to risk factors in particular populations. *Chronic fatigue syndrome is unexplained fatigue lasting 6 months or longer that is not associated with a diagnosed physical or psychological condition (White et al, 2011; Stahl et al, 2014).* **EB:** *Studies also suggest there is a genetic component to chronic fatigue syndrome*

(Pihur et al, 2011). Cognitive behavioral therapy has been shown to be effective in improving symptoms of chronic fatigue syndrome (White et al, 2011; Stahl et al, 2014).

- Encourage the client to express feelings, attribution of cause and behaviors about fatigue, including potential causes of fatigue, and possible interventions to alleviate fatigue. Such interventions could include setting small, easily achieved short-term goals and developing energy management techniques; use active listening techniques to help identify sources of hope. Assess client's level of motivation and willingness to adopt new behaviors that can improve symptoms of fatigue (Connolly et al, 2013). **EBN/EB:** Cognitive behavioral therapy has been shown to be effective in reducing fatigue (Berger et al, 2012; Hofmann et al, 2012). Education, counseling, and expressive therapy have also been shown to be effective for managing fatigue (Berger et al, 2012). In addition, cognitive behavioral therapy in combination with hypnosis may improve fatigue in breast cancer clients undergoing radiotherapy (Montgomery et al, 2014).
- Encourage the client to keep a journal of activities that contribute to symptoms of fatigue, patterns of symptoms across days/weeks/months, and feelings, including how fatigue affects the client's normal daily activities and roles. **EBN:** Clients who feel as if they have control over their fatigue and its impact on their lives have lower levels of fatigue (Primdahl et al, 2011).
- Help the client identify sources of support and essential and nonessential tasks to determine which tasks can be delegated to whom. Give the client permission to limit social and role demands if needed (e.g., switch to part-time employment, hire cleaning service). **EBN:** Psychoeducational interventions that include fatigue education, self-care (Payne et al, 2012), coping techniques, and activity management have been shown to be effective in reducing cancer-related fatigue (Goedendorp et al, 2009). Emotional support has been linked to decreased level of physical symptoms, including fatigue, for heart failure clients (Heo et al, 2014).
- ▲ Collaborate with the primary care provider regarding the appropriateness of referrals to physical therapy for carefully monitored aerobic exercise program and possible physical aids, such as a walker or cane if client has a disability requiring such support. Occupational therapy may also be indicated (Connolly et al, 2013). **EBN:** Meta-analyses have shown that exercise, particularly aerobic exercise, can reduce cancer-related fatigue (McMillan & Newhouse, 2011; Berger et al, 2012; Payne et al, 2012).
- Encourage the client to try complementary and alternative therapy such as guided imagery, massage therapy, mindfulness, and acupressure. **EB:** Meta-analyses have suggested that guided imagery may be beneficial, although the studies have not been well developed enough to support analysis (Bernardy et al, 2011; Duijts et al, 2011). Mindfulness-cognitive behavioral therapy has exhibited improved outcomes for those experiencing chronic fatigue (Rimes & Wingrove, 2013). Mindfulness-based stress reduction has also revealed lower fatigue levels for cancer survivors (Johns et al, 2014).
- ▲ Refer the client to diagnosis-appropriate support groups such as the National Chronic Fatigue Syndrome Association, Multiple Sclerosis Association, or cancer fatigue websites such as the Oncology Nurses Association (<http://www.ons.org>) or the National Comprehensive Cancer Network. **EB:** Persons with chronic fatigue syndrome have reported needing support to reduce the impact of their disease on their life and regain control (Carvalho Leite et al, 2011).
- ▲ For a person with cardiac disease, recognize that fatigue is common after a myocardial infarction, CHF, or chronic cardiac insufficiency. Refer to cardiac rehabilitation for carefully prescribed and monitored exercise program. **EBN:** Fatigue is a common finding following cardiovascular insult (Johansson et al, 2010), CHF, and chronic obstructive pulmonary disease (Theander et al, 2014; Sharafkhaneh et al, 2013).
- If fatigue is associated with cancer or cancer-related treatment, assess for other symptoms that may enhance fatigue (e.g., pain, insomnia, anemia, emotional distress, electrolyte imbalance [nausea, vomiting, diarrhea], or depression). **EBN:** Clients with cancer who reported both pain and fatigue reported three times as many other symptoms as clients who reported neither pain nor fatigue; fatigue was linked to the presence of pain, multiple comorbid conditions, and site of cancer (National Comprehensive Cancer Network, 2014). Cancer treatment can increase fatigue and those who have cancer are more likely to experience fatigue than those without cancer (Goedendorp et al, 2013).
- Fatigue associated with rheumatoid arthritis can impact a client's quality of life and coping. Group cognitive behavior therapy (CBT) has been shown to be effective in improving fatigue self-management, coping, and fatigue severity. CBT involves using self-management skills such as problem-solving and goal setting to improve self-efficacy while achieving a sense of balance, priority planning, and pacing of activities (Hewlett et al, 2011).
- ▲ Collaborate with primary care provider to identify attentional fatigue, which may manifest itself as the inability to direct attention necessary to perform usual activities. Attentional fatigue is associated with

sleep disturbances, depressive symptoms, anxiety, psychosocial stressors and can lead to irrational decision-making, inability to plan goals, inability to control emotions or social interactions (Merriman et al, 2013). **EBN:** A meta-analysis reported that persons with chronic fatigue syndrome had deficits in the areas of attention, memory, and reaction time (Cockshell & Mathias, 2010).

- ▲ Collaborate with primary care providers to identify potential pharmacological treatment for fatigue. **EB/EBN:** Pharmacological therapy has been shown to be effective in reducing fatigue, particularly cancer-related fatigue (Minton et al, 2011), although meta-analysis demonstrated small effects in some client populations (Chauffier et al, 2011). Psychostimulants, erythropoiesis-stimulating agents (ESAs) for cancer related fatigue, cytokine blockers, and nutritional supplements have all been shown to improve symptoms of fatigue (Giacalone et al, 2013).

Geriatric

- Evaluate fatigue in geriatric clients routinely, particularly in clients with limited physical function and lower levels of social support. Chronic conditions related to age can contribute to fatigue in the geriatric client, such as cancer, anemia, multiple medication usage and side effects, depression, insomnia (Naeim et al, 2014), nutritional deficiencies, electrolyte imbalance, and comorbidities involving multiple organ dysfunction (Giacalone et al, 2013). **EBN:** Older adults report fatigue that limits functional and social ability and can aggravate comorbid conditions (Yu et al, 2010). Low levels of physical activity have been linked to fatigue in older adults (Avlund, 2013). In persons 80 years old and older, functional capacity, affect, and social support all predicted fatigue (Cho et al, 2012). Fatigue can be as high as 70% in the older cancer population (NCCN, 2014).
- Review medications to determine possible side effects or interaction effects that could cause fatigue. **EB:** The aging process changes the way an individual absorbs, metabolizes, and eliminates medications, leaving the geriatric client susceptible to medication side effects and medication interactions that can cause fatigue, especially when multiple medications are prescribed (Rich & Nienaber, 2014).
- Review comorbid conditions that may contribute to fatigue, such as congestive heart failure, pulmonary disease, cardiac disease, arthritis, obesity, anemia, depression, insomnia, and cancer. **EB:** Fatigue is one of the most common and debilitating symptoms experienced by clients living with chronic conditions and is also commonly experienced in the general U.S. population. (Lai et al, 2014).
- Identify recent losses; monitor for depression or loneliness as a possible contributing factor to fatigue. **EB:** There is a strong correlation between depression and fatigue (Mänty et al, 2014; Oh & Seo, 2011).
- Review other symptoms the client may be experiencing. Fatigue is often associated with other symptom clusters such as depression and sleep disturbances (Mänty et al, 2014; NCCN, 2014).
- ▲ Review medications for side effects. Certain medications (e.g., diuretics with associated loss of potassium, antihypertensives, antihistamines, pain medications [Rich & Nienaber, 2014], anticonvulsants [Siniscalchi et al, 2013], chemotherapeutic agents [Koornstra et al, 2014], psychiatric medications [Koornstra et al, 2014], and corticosteroids [Koornstra et al, 2014]) may cause fatigue, particularly in older adults.

Home Care

The above interventions may be adapted for home care use.

- Assess the client's history and current patterns of fatigue as they relate to the home environment and environmental and behavioral triggers of increased fatigue. **CEB:** Fatigue may be more pronounced in specific settings for physical, environmental (e.g., stairs required to reach bathroom, patterns of movement around home, cleaning activities that require high energy), or psychological (e.g., rooms associated with loss of loved ones) reasons (Wahl et al, 2009) or family responsibilities such as child care (Hazes et al, 2010).
- ▲ Encourage planned exercise regimens or physical activities such as walking or light aerobic exercises. This activity can be organized in the home or in a setting such as senior centers or wellness facilities. **EB:** Continued physical activity after cancer treatment has been associated with better quality of life, including improved functioning in both physical and social realms (Fong et al, 2012).
- ▲ Refer to occupational and/or physical therapy if substantial intervention is needed to assist the client in adapting to home and daily patterns. **CEB:** Interventions in older adults led by occupational and physical therapists have been associated with less difficulty in ADLs and instrumental ADLs, which may lead to lower levels of fatigue (Murphy & Niemiec, 2014). Occupational and physical therapy rehabilitation have also been shown to decrease fatigue in cancer survivors (Silver & Gilchrist, 2011). Home-based exercise in stage IV lung and colorectal clients has shown improvement in levels of fatigue (Cheville et al, 2013).

- For clients receiving chemotherapy, intervene to:
 - Relieve symptom distress (anxiety, nausea and vomiting, diarrhea, lack of appetite, emotional distress, difficulty sleeping)
 - Encourage as much physical activity as possible with a specific regimen
 - Support a positive attitude for the future and reduce uncertainty by being sure clients know expectations and treatment expectations
 - Support adequate recovery time between treatments

The above factors have been identified as associated with fatigue, particularly during early stages of chemotherapy (NCCN, 2014).

- Teach the client and family the importance of and methods for setting priorities for activities, especially those with high energy demand (e.g., home or family events). Instruct in realistic expectations and behavioral pacing. **EBN:** *Prioritization of activities can be effective in restoring energy (Goedendorp et al, 2009).*
- Assess effect of fatigue on the client's relatedness; recognize that the client's fatigue affects the whole family. Initiate the following interventions:
 - Avoid dismissing reports of fatigue; validate the client's experience and foster hope for eventual treatment, if not resolution, of the fatigue.
 - Identify with the client ways in which he or she continues to be a valued part of his or her social environment.
 - Identify with the client ways in which he or she continues to participate in equitable exchange with others.
 - Encourage the client to maintain regular family routines (e.g., meals, sleep patterns) as much as possible.
 - Initiate cognitive restructuring to refute the client's guilt-producing and negative thought patterns.
 - Assess and intervene with family's and friends' contributions to guilt-inducing self-talk.
 - Work with the client to inoculate against the negative thinking of others.
 - Explore family life and demands to identify accommodations.
 - Support the client's efforts at limit setting on the demands of others.
 - Assist the client to move toward a state of parallelism by working to identify and relieve sources of physical or emotional discomfort. Degree of involvement, limited by fatigue, need not be changed.
- ▲ Refer for family therapy in the event the client's fatigue interferes with normal family functioning. **EBN:** *The client's fatigue can have a major impact on family members, which is dependent upon the number of familial roles the client holds (Oktay et al, 2011).*

Client/Family Teaching and Discharge Planning

- Help client to reframe cognitively; share information about fatigue and how to live with it, including need for positive self-talk. **EBN:** *Cognitive behavioral approaches to managing fatigue enhance the client's sense of control over fatigue (White et al, 2011; Hewlett et al, 2011) as well as contributing factors such as depression and insomnia.*
- Teach strategies for energy conservation (e.g., sitting instead of standing during showering, storing items at waist level). **EB:** *Energy conservation strategies can decrease the amount of energy used (Payne et al, 2012; Goedendorp et al, 2009).*
- Teach the client to carry a pocket calendar, make lists of required activities, and post reminders around the house. **EB:** *Fatigue is often associated with memory loss and loss of ability to pay attention (Cockshell & Mathias, 2010).* Attentional fatigue is associated with sleep disturbances, depressive symptoms, anxiety, and psychosocial stressors and can lead to irrational decision-making, inability to plan goals, inability to control emotions or social interactions (Merriman et al, 2013).
- Teach the importance of following a healthy lifestyle with adequate nutrition, fluids, and rest; pain relief; insomnia correction; and appropriate exercise to decrease fatigue (i.e., energy restoration).
- See **Hopelessness** care plan if appropriate.

Fear Ruth McCaffrey, DNP, ARNP, FNP-BC, GNP-BC, FAAN

NANDA-I

Definition

Response to perceived threat that is consciously recognized as a danger

Defining Characteristics

Apprehensiveness; decrease in self-assurance; excitedness; feeling of dread; feeling of fear; feeling of pain; feeling of terror; feeling of alarm; increase in blood pressure; increase in tension; jitteriness; muscle tension; nausea; pallor; pupil dilation; vomiting

Cognitive

Decrease in learning ability; decrease in problem-solving ability; decrease in productivity; identifies object of fear; stimulus believed to be a threat

Behaviors

Attack behaviors; avoidance behaviors; focus narrowed to the source of fear; impulsiveness; increase in alertness

Physiological

Anorexia; change in physiological response (e.g., blood pressure, heart rate, respiratory rate, oxygen saturation, and end-tidal CO₂); diarrhea; dry mouth; dyspnea; fatigue; increase in perspiration; increase in respiratory rate

Related Factors (r/t)

Innate releasing mechanism to external stimuli (e.g., neurotransmitters); innate response to stimuli (e.g., sudden noise, height); language barrier; learned response; phobic stimulus; sensory deficit (e.g., visual, hearing); separation from support system; unfamiliar setting

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Fear Self-Control

Example NOC Outcome with Indicators

Fear Self-Control as evidenced by the following indicators: Eliminates precursors of fear/Seeks information to reduce fear/ Plans coping strategies for fearful situations. (Rate the outcome and indicators of **Fear Self-Control**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize known fears
- State accurate information about the situation
- Identify, verbalize, and demonstrate those coping behaviors that reduce own fear
- Report and demonstrate reduced fear

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anxiety Reduction; Coping Enhancement; Security Enhancement

Example NIC Activities—Anxiety Reduction

Use a calm, reassuring approach; Stay with the client to promote safety and reduce fear

Nursing Interventions and Rationales

- Assess source of fear with the client. **EB**: *The capacity to experience fear is adaptive, enabling rapid and energetic response to imminent threat or danger (George et al, 2011).* **EB**: *Fear can cause the inability to manage chronic diseases. The model of chronic pain describes how individuals experiencing acute pain may become trapped into a vicious cycle of chronic disability, suffering, and fear (Crombez et al, 2012). Many clients with chronic diseases such as multiple sclerosis or those with mobility issues have a fear of falling (Topuz et al, 2014).*
- Assess for a history of anxiety. **EB**: *Participants in a study of older adults who had anxiety were found to have a higher level of fear of pain (Lumley et al, 2011). Fear of pain independently predicts limitations in function and further exacerbation of pain (LeMay et al, 2011).* **EB**: *Clients experiencing post-traumatic stress disorder often fear uncertainty, which can exacerbate symptoms (Boswell et al, 2013).*
- Have the client draw the object of his or her fear. **EBN**: *In a study of older adults with a fear of falling, a community-based art program helped them overcome fears and anxiety (Beauvais & Beauvais, 2014).*
- Discuss the situation with the client and help distinguish between real and imagined threats to well-being. **EB**: *Fear activation occurs before conscious cognitive analysis of the stimulus can occur (George et al, 2011). There is a need to address psychological aspects of fear, catastrophizing, and emotional distress in the management of clients with pain (Westman et al, 2011).*
- Encourage the client to explore underlying feelings that may be contributing to the fear. *Exploring underlying feelings may help the client confront unresolved conflicts and develop coping abilities (Eva et al, 2011).*
- Stay with clients when they express fear; provide verbal and nonverbal (touch and hug with permission and if culturally acceptable) reassurances of safety if safety is within control. **EBN**: *One study in which nurses stayed with ventilated clients to provide support and reassurance reduced anxiety levels in these*

clients. Clients' ability to interact with the environment served as a basis for identification and management of anxiety or agitation. Health care providers' attributions about anxiety or agitation, and "knowing the patient," contributed to their assessment of client response (Tate et al, 2013).

- Explore coping skills previously used by the client to deal with fear; reinforce these skills and explore other outlets. Provide backrubs and massage for clients to decrease anxiety. **EB:** A study of 87 children who received massage prior to a painful treatment had lower levels of fear and anxiety than those who did not receive massage (Celebiogiu et al, 2014). In a group of older adults those who received massage had less pain after hip or knee surgery (Buyukyilmaz & Turkinaz, 2014).
- ▲ Refer for cognitive behavior therapy. **EB:** Therapeutic touch and harp music reduced fear and anxiety in a group of postoperative clients (Lincoln et al, 2014).
- ▲ Animal-assisted therapy can be incorporated into the care of clients in hospice situations.
- Encourage clients to express their fears in narrative form. Refer to care plans for **Anxiety and Death Anxiety**.

Pediatric

- Explore coping skills previously used by the client to deal with fear. **EB:** Children whose mothers were fearful and depressed had increased levels of fearfulness from infancy through the toddler stage (Gartstein et al, 2010).
- Teach parents to use cognitive behavioral strategies such as positive coping statements ("I am a brave girl [boy]. I can take care of myself in the dark") and rewards of bravery tokens for appropriate behavior.
- **EB:** Screen for depression in clients who report social or school fears (Chung et al, 2010). **EB:** Early onset of depression in young people is associated with a poor prognosis. All children with school fears or phobias should be screened for depression early to avoid poor outcomes and lingering depressive symptoms (Chung et al, 2010).
- Teach relaxation techniques to children to induce calmness. **EB:** Using relaxation and distraction techniques will calm children's fears during procedures and in times of stress (Koller & Goldman, 2012).

Geriatric

- Establish a trusting relationship so that all fears can be identified. Monitor for dementia and use appropriate interventions. **EB:** Fear is an early symptom of dementia and may be associated with decreased cognitive and reasoning ability. New onset fear in an older adult should be an indication for cognitive assessment and monitoring (Sigstrom et al, 2011).
- Provide a protective and safe environment, use consistent caregivers, and maintain the accustomed environmental structure. **EBN:** Providing an environment that included safety equipment and balance training reduced the fear of falling among older adults (Gusi et al, 2011).
- Observe for untoward changes if antianxiety drugs are taken. Advancing age renders clients more sensitive to both the clinical and toxic effects of many agents (Baldwin et al, 2011).
- Assess for fear of falls in hospitalized clients with hip fractures to determine risk of poor health outcomes. **EBN:** Fear of falling can increase risk of depression and isolation, and further decrease physical performance in older clients (Park et al, 2014).
- Encourage exercises to improve physical skills and levels of mobility to decrease fear of falling. *Improving physical skills and levels of mobility counteracts excessive fear during activity performance (Perry et al, 2013).*
- Assist the client in identifying and reducing risk factors for falls, including environmental hazards in and out of the home, the importance of good nutrition and activity, proper footwear, and how to stand up after a fall. **EB:** Clients receiving education focused on identifying and reducing risk factors for falls were found to have a significant reduction in their fear of falling (Park et al, 2014).

Multicultural

- Assess for the presence of culture-bound anxiety and fear states. **EBN:** Allowing clients to define their cultural beliefs, how their cultural beliefs impact their ideas about health and well-being, and how their culture identifies and deals with suffering is a way in which nurses can better understand culture-bound anxiety and fear (Kagawa-Singer, 2011).
- Assess for the influence of cultural beliefs, norms, and values on the client's perspective of a stressful situation. **EBN:** Having insight into clients' illness beliefs about the cause and experience of fear may assist in alleviating pain and create motivation to change detrimental and dysfunctional illness beliefs (Buitenhuis & de Jong 2011).

- Identify what triggers fear response. **EBN**: Consider all of the aspects of cultural belief including religious or spiritual beliefs when attempting to identify what triggers any fear response (Salman & Zoucha, 2011). **EB**: Culture plays a role in how people perceive themselves in fearful situations. Fear, fatalism, and current and historical relationships influence how people perceive themselves (Somayaji & Cloyes, 2014).
- Identify how the client expresses fear. **EBN**: Fear is culturally sensitive; therefore, nurses must attentively and actively listen to all clients to determine what expresses fear to that individual (Salman & Zoucha, 2011).
- Validate the client's feelings regarding fear. **EBN**: The most valid predictor of fear is younger clients with cancer. There is also a strong correlation between level of physical symptoms and fear (Crist & Grunfeld, 2012).
- Assess for fears of racism in culturally diverse clients.

Home Care

- The previous interventions may be adapted for home care use.
- Assess to differentiate the presence of fear versus anxiety. **EB**: Study findings suggest that fear and anxiety are largely distinct emotions and that psychological disorders of trait fear and trait anxiety warrant classification in separate higher-order categories (Sylvers et al, 2011). Addressing fear avoidance beliefs, catastrophizing, and emotional distress can reduce fear (Westman et al, 2011).
- Refer to care plan for **Anxiety**.
- During initial assessment, determine whether current or previous episodes of fear relate to the home environment (e.g., perception of danger in the home or neighborhood or of relationships that have a history in the home). **EB**: Fear of falling can negatively affect the ability of older adults to function and complete physical activities in the home (Hornyak et al, 2010).
- Identify with the client what steps may be taken to make the home a “safe” place to be. **EB**: Identifying a given area as a safe place reduces fear and anxiety when the client is in that area. Compared with whites, both blacks and Hispanics were less likely to own a variety of safety devices at baseline, but Hispanics were more likely than blacks to redeem vouchers (Pressley et al, 2010).
- ▲ Encourage the client to seek or continue appropriate counseling to reduce fear associated with stress or resolve alterations in irrational thought processes. *Correcting mistaken beliefs reduces anxiety. Creating a fear appeal that helps the client see that the fear is out of proportion to the situation can reduce fear in some clients (Sandkuhler & Lee, 2013).*
- ▲ Encourage the client to have a trusted companion, family member, or caregiver present in the home for periods when fear is most prominent. Pending other medical diagnoses, a referral to homemaker or home health aide services may meet this need. *Creating periods when fear and anxiety can be reduced allows the client periods of rest and supports positive coping. A healing environment responds to the needs of all the people within a critical care unit—those who receive or give care and those who support clients and staff. Critical care units should be designed to focus on healing the body, the mind, and the senses (Bauzin & Cardon, 2011).*
- ▲ Offer to sit quietly with a terminally ill client as needed by the client or family, or provide hospice volunteers to do the same. **EB**: Skill in communicating and being with dying clients and their families is an important aspect of health care (Curtis et al, 2013).

Client/Family Teaching and Discharge Planning

- Teach the client the difference between warranted and excessive fear. *Different interventions are indicated for rational and irrational fears. Creating a fear appeal that helps the client see that the fear is out of proportion to the situation can reduce fear in some clients (Sandkuhler & Lee, 2013).*
- Teach clients to use guided imagery when they are fearful; have them use all senses to visualize a place that is “comfortable and safe” for them. *Imagery makes use of subjective symbolism, bypassing the rational mind and making the areas “safe” that the client may otherwise be reluctant to face (Milad et al, 2014).*
- Teach use of appropriate community resources in emergency situations (e.g., hotlines, emergency departments, law enforcement, judicial systems). *Serious emergencies need immediate assistance to ensure the client’s safety. Social media has a profound impact on society and affects many aspects of human life. Its applications in combating crises are unanticipated results of social media inventors and many lessons could be learned from its applications in combating real crises (Chen et al, 2014).*
- Encourage use of appropriate community resources in nonemergency situations (e.g., family, friends, neighbors, self-help and support groups, volunteer agencies, churches, recreation clubs and centers,

seniors, youths, others with similar interests). *Social support and coping strategies were able to modify fears and anxiety in young women with eating disorders (Wonderlich-Tierney & Vander Val, 2010).*

- If fear is associated with bioterrorism, provide accurate information and ensure that health care personnel have appropriate training and preparation. *Clear, consistent, accessible, reliable, and redundant information (received from trusted sources) will diminish public uncertainty about the cause of symptoms that might otherwise prompt persons to seek unnecessary treatment. Training for providers is essential. EB: Using a diverse group of experts and providing a transparent and open line of communication can reduce fear in communities and the nation regarding bioterrorism (Siegrist & Zingg, 2014).*

Ineffective infant Feeding pattern *Vanessa Flannery, MSN, PHCNS-BC, CNE*

NANDA-I

F

Definition

Impaired ability of an infant to suck or coordinate the suck/swallow response, resulting in inadequate oral nutrition for metabolic needs

Defining Characteristics

Inability to coordinate sucking, swallowing, and breathing; inability to initiate an effective suck; inability to sustain an effective suck

Related Factors (r/t)

Neurological delay; neurological impairment (e.g., positive electroencephalogram, head trauma, seizure disorders); oral hypersensitivity; oropharyngeal defect; prematurity; prolonged nil per os (NPO) status

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Breastfeeding Establishment: Infant, Maternal; Breastfeeding: Maintenance; Hydration; Nutritional Status: Food and Fluid Intake

Example NOC Outcome with Indicators

Breastfeeding Establishment: Infant as evidenced by the following indicators: Proper alignment and latch-on/Correct suck and tongue placement/Urinations per day appropriate for age/Weight gain appropriate for age. (Rate the outcome and indicators of **Breastfeeding Establishment: Infant**: 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see [Section I](#)].)

Client Outcomes

Infant Will (Specify Time Frame)

- Consume adequate calories that will result in appropriate weight gain and optimal growth and development
- Have opportunities for skin-to-skin (kangaroo care) experiences
- Have opportunities for “trophic” (i.e., small volume of breast milk/formula) enteral feedings prior to full oral feedings
- Progress to stable, neurobehavioral organization (i.e., motor, state, self-regulation, attention-interaction)
- Demonstrate presence of mature oral reflexes that are necessary for safe feeding
- Progress to safe, self-regulated oral feedings
- Coordinate the suck-swallow-breathe sequence while nippleing
- Display clear behavioral cues related to hunger and satiety
- Display approach/engagement cues, with minimal avoidance/disengagement cues
- Have opportunities to pace own feeding, taking breaks as needed
- Display evidence of being in the “quiet-alert” state while nippleing
- Progress to and engage in mutually positive parent/caregiver-infant/child interactions during feedings

Parent/Family Will (Specify Time Frame)

- Recognize necessity of adequate calories for appropriate weight gain and optimal growth and development
- Learn to read and respond contingently to infant's behavioral cues (e.g., hunger, satiety, approach/engagement, stress/avoidance/disengagement)
- Learn strategies that promote organized infant behavior
- Learn appropriate positioning and handling techniques
- Learn effective ways to relieve stress behaviors during nipping
- Learn ways to help infant coordinate suck-swallow-breathe sequence (i.e., external pacing techniques)
- Engage in mutually positive interactions with infant during feeding
- Recognize ways to facilitate effective feedings: feed in quiet-alert state; keep length of feeding appropriate; burp; prepare/structure environment; recognize signs of sensory overload; encourage self-regulation; respect need for breaks and breathing pauses; avoid pulling and twisting nipple during pauses; allow infant to resume sucking when ready; provide oral support (cheek and/or jaw) as needed; use appropriate nipple hole size and flow rate

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Bottle Feeding; Breastfeeding Assistance; Fluid Monitoring; Kangaroo Care; Lactation Counseling; Teaching; Infant Safety

Example NIC Activities—Lactation Counseling

Provide information about psychological and physiological benefits of breastfeeding; Refer to a lactation consultant

Nursing Interventions and Rationales

- Refer to care plans for Disorganized **Infant** behavior, Risk for disorganized **Infant** behavior, Ineffective and Interrupted **Breastfeeding**, and Insufficient **Breast Milk** and assess as needed.
- Interventions follow a sequential pattern of implementation that can be adapted as appropriate.
- Assess coordination of infant's suck, swallow, and gag reflex. **EBN:** *During this first hour when the infant starts seeking the breast, the rooting reflex becomes successively more mature and distinct (Svensson et al, 2013).*
- ▲ Provide developmentally supportive neonatal intensive care for preterm infants. **EBN:** *To decrease barriers for mothers to optimize breast milk feedings during the infants' first weeks of life (Purdy et al, 2012).*
- Provide opportunities for kangaroo (i.e., skin-to-skin) care. **EBN:** *Use of kangaroo care increases the interval of breastfeeding and reduces the risk of mortality, infection/sepsis, hypothermia, and length of hospital stay (Gregson & Blacker, 2011).*
- ▲ Before the infant is ready for oral feedings, implement gavage feedings (or other alternative) as ordered, using breast milk whenever possible. **EBN:** *Gavage feeding is the method used to feed preterm infants or infants with inadequate suck/swallow during feeding (Pineda, 2011).*
- Provide a naturalistic environment for tube feedings (nasoro-gastric, gavage, or other) that approximates a pleasurable oral feeding experience: hold infant in semi-upright/flexed position; offer nonnutritive sucking; pace feedings; allow for semi-demand feedings contingent with infant cues; offer rest breaks; burp, as appropriate. **EBN:** *Nonnutritive sucking during gavage feeding is comforting for the infant and significantly supports breastfeeding ability (Garpiel, 2012).*
- Foster direct breastfeeding as early as possible and enable the first oral feed to be at the breast in the neonatal intensive care unit (NICU). **EBN:** *Research demonstrates a link between direct breastfeeding behaviors in the NICU and success with provision of milk at discharge (Pineda, 2011).*
- Allow parents to feed the infant when possible. **EBN:** *Parents who feed effectively early on develop positive feeding relationships with their infants and promote infant feeding self-regulation and normative growth patterns (Horodyski et al, 2011).*
- Position infant in semi-upright position, with head, shoulders, and hips in straight line facing the mother with the infant's nose level with the mother's nipple. **EBN:** *Good positioning of the baby during breastfeeding is crucial to encourage oxytocin and prolactin release (Hughes, 2011).*

- Feed infant in the quiet-alert state. **EBN:** *Preterm infants who are in awake states at the beginning of nipple feedings are more successful at ingesting their feeding volumes (McCain et al, 2012).*
- Determine the appropriate shape, size, and hole of nipple to provide flow rate for preterm infants. **EBN:** *The coordination of rhythmic sucking, swallowing, and breathing patterns during feeding is disorganized in preterm infants with bronchopulmonary dysplasia (McCain et al, 2012).*
- Implement pacing for infants having difficulty coordinating breathing with sucking and swallowing. **EBN:** *Paced feedings decrease risk of fatigue and oxygen desaturation of the infant (McCain et al, 2012).*
- Provide infants with jaw and/or cheek support, as needed. **EBN:** *Breastfeeding difficulties can be avoided if good attachment and positioning are achieved at the first and early feeds (Goyal et al, 2011).*
- Allow the stable newborn to breastfeed within the first half hour after birth. **EBN:** *Mothers of infants who were breastfed within 1 to 2 hours were almost three times more likely to experience breastfeeding problems in the postpartum period than those mothers who breastfed within 30 minutes of birth (Demirtas, 2012).*
- Allow appropriate time for nipple feeding to ensure infant's safety, limiting to 15 to 20 minutes for bottle feeding. **EBN:** *Bottle feeding mothers need to develop responsive behavior to their infants' hunger and satiety cues (Horodyski et al, 2011).*
- Monitor length of breastfeeding so that it does not exceed 30 minutes. Breast milk transfer may last from as little as 5 to 20 minutes during breastfeeding depending on variations in milk supply during a 24-hour day (Flaherman et al, 2012).
- Encourage transitioning from scheduled to semi-demand feedings, contingent with infant behavior cues. *Flexible feeding schedules allow infants to feed during awake and alert periods in response to infant's readiness and tolerance of nipple feedings (McCain et al, 2012).*
- ▲ Refer to a multidisciplinary team (e.g., neonatal/pediatric nutritionist, physical or occupational therapist, speech pathologist, lactation specialist) as needed. **EB:** *Follow-up visits with lactation consultants, nurses, and health care providers are beneficial for breastfeeding mothers (Henry & Britz, 2011).*

Home Care

- The above appropriate interventions may be adapted for home care use.
- ▲ Infants with risk factors and clinical indicators of feeding problems present before hospital discharge should be referred to appropriate community early-intervention service providers (e.g., community health nurses, early learning programs (individualized per states), occupational therapy, speech pathologists, feeding specialists) to facilitate adequate weight gain for optimal growth and development. **EBN:** *Late preterm infants are susceptible to multiple complications including feeding and sucking problems (Henry & Britz, 2011).*

Client/Family Teaching and Discharge Planning

- Provide anticipatory guidance for infant's expected feeding course. *Providing written information and education on breastfeeding with culturally sensitive awareness helps guide parents after early discharge (Wiener & Wiener, 2011).*
- Teach various effective feeding methods and strategies to parents. **EBN:** *Mothers need to be given evidence-based information and support before discharge, giving mothers a sense of security and providing understanding care (Demirtas, 2014).*
- Teach parents how to read, interpret, and respond contingently to infant cues. **EBN:** *Parents' ability to recognize and react quickly and consistently to their infant's state or cues leads to parental confidence in providing care, promotes parent-child relationship, and strengthens the family unit (Kadivar & Maryam Mozafarinia, 2013).*
- Help parents identify support systems before hospital discharge. *Nurses need to assess the support system of the family and collaborate with other health care team members to meet the mother's needs for successful breastfeeding (Feldman-Winter, 2013).*
- Provide anticipatory guidance for the infant's discharge. *Providing written information and education on breastfeeding with culturally sensitive awareness helps guide parents after early discharge (Wiener & Wiener, 2011).*

Readiness for enhanced Fluid balance *Susan M. Dirkes, RN, MS, CCRN*

NANDA-I

Definition

A pattern of equilibrium between the fluid volume and chemical composition of body fluids, which can be strengthened

Defining Characteristics

Expresses desire to enhance fluid balance

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Fluid Balance; Electrolyte and Acid-Base Balance; Hydration

Example NOC Outcome with Indicators

Maintains **Fluid Balance** as evidenced by the following indicators: BP/Peripheral pulses palpable/Skin turgor/Moist mucous membranes/Serum electrolytes/Hematocrit/Peripheral edema/Neck vein distention/Body weight stable/24-hour intake and output balanced/Urine specific gravity/Adventitious breath sounds. (Rate each indicator of **Fluid Balance**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see [Section 1](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain light yellow urine output of at least 0.5 mL/kg/hr
- Maintain elastic skin turgor, moist tongue, and mucous membranes
- Explain measures that can be taken to improve fluid intake

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Fluid Management; Fluid Monitoring

- = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Example NIC Activities—Fluid Management

Monitor hydration status as appropriate; Monitor food/fluid ingested and calculate daily caloric intake, as appropriate

Nursing Interventions and Rationales

- Discuss normal fluid requirements. A guideline is 1 to 1.5 mL of fluid per each calorie needed, so an average intake would be between 2000 and 3000 mL/day, or at least 8 cups of fluid. The adequate intake recommendation is 3 L for the 19- to 30-year-old male and 2.2 L for the 19- to 30-year-old female. **EB:** The previous general health recommendation of intake of eight 8-oz glasses of water per day is currently found to have no scientific basis but is used as a recommendation (McCartney, 2011).
- Recommend the client choose mainly water to meet fluid needs, although fruit juices and milk are also useful for hydration. The intake of beverages containing caffeine or alcohol is no longer thought to cause dehydration. **EB:** While caffeinated drinks and alcohol can cause mild diuresis, intake of these beverages is not associated with dehydration (Hobson & Maughan, 2010).
- Recommend the client choose and prepare foods with less salt, aiming for a maximum of 1500 mg per day, less than a teaspoon. The Centers for Disease Control and Prevention (2012) recommends that all salt-sensitive Americans, including everyone 40 years or older, should decrease daily sodium intake. **EB:** A study found that decreased sodium intake helped lower blood pressure, as well as increased flexibility in blood vessels, improving the health of the blood vessels (CDC, 2012).
- Recommend the client avoid intake of soft drinks with sugar; instead, encourage the client to drink water. **EB:** Consumption of sweetened beverages is associated with an increased risk of stroke (Larsson et al, 2014).
- Recommend the client note the color of urine at intervals when voiding. Normal urine is straw-colored or amber. **EB:** Dark-colored urine with an increased specific gravity may reflect increased urine concentration and fluid deficit (Perrier et al, 2013). Observing urine color is an effective and simple method of monitoring for possible dehydration (Jequier & Constant, 2010).
- Recommend client monitor weight at intervals for alterations. **EB:** Decreases in weight may be caused by inadequate fluid intake (Hooper et al, 2014).

Geriatric

- Encourage older clients to develop a pattern of drinking water regularly. **EB:** Thirst sensation diminishes with aging. Some geriatric clients limit fluid intake because of fear of incontinence, inability to drink on their own, due to poor availability and accessibility of fluids, altered sensorium/cognition, or decreased thirst as a part of the aging process. Mild levels of dehydration in older adults can produce disruptions in mood and cognitive functioning (Hooper et al, 2014). Also, older adults experience less hunger (Gregersen et al, 2011).
- Ensure that when food intake is reduced or limited, it is compensated with an increase in water/fluid intake. **EB:** Food contains water, thus any reduction in food intake also involves a reduction in water intake (Popkin et al, 2010).
- Incorporate regular hydration into daily routines, such as providing an extra glass of fluid with medication or during social activities. **EB:** Consider using a beverage cart to routinely offer beverages to clients in extended care facilities (Hooper et al, 2014).

Deficient Fluid volume *Susan M. Dirkes, RN, MS, CCRN*

NANDA-I

Definition

Decreased intravascular, interstitial, and/or intracellular fluid. This refers to dehydration, water loss alone without change in sodium level

Defining Characteristics

Alteration in mental status; alteration in skin turgor; decrease in blood pressure; decrease in pulse pressure; decrease in pulse volume; decrease in tongue turgor; decrease in urine output; decreased venous filling; dry mucous membranes; dry skin; increase in body temperature; increase in heart rate; increase in hematocrit; increase in urine concentration; sudden weight loss; thirst; weakness

Related Factors

Active fluid volume loss; compromised regulatory mechanisms

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Fluid Balance; Hydration; Nutritional Status: Food and Fluid Intake

Example NOC Outcome with Indicators

Fluid Balance as evidenced by the following indicators: Elastic skin turgor/Moist mucous membranes/Orthostatic hypotension not present/24-hour intake and output balance/Urine specific gravity. (Rate each indicator of **Fluid Balance**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain urine output of 0.5 mL/kg/hour or at least more than 1300 mL/day
- Maintain normal blood pressure, heart rate, and body temperature
- Maintain elastic skin turgor; moist tongue and mucous membranes; and orientation to person, place, and time
- Explain measures that can be taken to treat or prevent fluid volume loss
- Describe symptoms that indicate the need to consult with health care provider

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Fluid Management; Hypovolemia Management; Shock Management: Volume

Example NIC Activities—Fluid Management

Monitor hydration status (e.g., moist mucous membranes, adequacy of pulses, and orthostatic blood pressure) as appropriate; Administer intravenous (IV) therapy, as prescribed

Nursing Interventions and Rationales

- Watch for early signs of hypovolemia, including thirst, restlessness, headaches, and inability to concentrate. *Thirst is often the first sign of dehydration (Wagner & Hardin-Pierce, 2014). CEB: A study of healthy women showed heart rate was increased by fluid restriction along with increased urine specific gravity, darker urine color, and increased thirst. They also experienced decreased alertness and increased sleepiness, fatigue, and confusion (Pross et al, 2013).*

- Recognize symptoms of cyanosis, cold clammy skin, weak thready pulse, confusion, and oliguria as late signs of hypovolemia. *These symptoms occur after the body has compensated for fluid loss by moving fluid from the interstitial space into the vascular compartment (Wagner & Hardin-Pierce, 2014).*
- Monitor pulse, respiration, and blood pressure of clients with deficient fluid volume every 15 minutes to 1 hour for the unstable client and every 4 hours for the stable client. *Vital sign changes seen with fluid volume deficit include tachycardia, tachypnea, decreased pulse pressure first, then hypotension, decreased pulse volume, and increased or decreased body temperature (Wagner & Hardin-Pierce, 2014).* **CEB:** *A systematic review demonstrated that hypotension and tachycardia, and occasionally fever, are clinical signs of dehydration (Jequier & Constant, 2010).*
- Check orthostatic blood pressures with the client lying, sitting, and standing. *A decrease in systolic blood pressure of 20 mm Hg or a decrease in diastolic blood pressure of 10 mm Hg within 3 minutes of standing when compared with blood pressure from the sitting position is considered orthostatic hypotension. This can occur with dehydration or cardiovascular disorders (Lanier et al, 2011).*
- Note skin turgor over bony prominences such as the hand or shin.
- Monitor for the existence of factors causing deficient fluid volume (e.g., hypovolemia from vomiting, diarrhea, difficulty maintaining oral intake, fever, uncontrolled type 2 diabetes, diuretic therapy). *Early identification of risk factors and early intervention can decrease the occurrence and severity of complications from deficient fluid volume and acute kidney injury (Ftough & Lewington, 2014).*
- Observe for dry tongue and mucous membranes, and longitudinal tongue furrows. *These are symptoms of decreased body fluids (Wagner & Hardin-Pierce, 2014).*
- Recognize that checking capillary refill may not be helpful in identifying fluid volume deficit. Capillary refill can be normal in clients with sepsis because increased body temperature dilates peripheral blood vessels and capillary return may be immediate (Wagner & Hardin-Pierce, 2014). **EBN:** *A recent study indicated capillary refill showed good specificity to detect dehydration but had poor sensitivity (Shimizu et al, 2012).*
- Weigh client daily and watch for sudden decreases, especially in the presence of decreasing urine output or active fluid loss. *Body weight changes of 1 kg (2.2 lb) represent a fluid loss of 1 L (Wagner & Hardin-Pierce, 2014).*
- Monitor total fluid intake and output every 4 hours (or every hour for the unstable client or the client who has urine output equal to or less than 0.5 mL/kg/hr). Recognize that urine output is an accurate indicator of fluid balance. **EB:** *The incidence of kidney injury increased significantly from 24% to 52% when adding the urine output as criteria, as defined by the Acute Kidney Injury Network classification system, to the measurement of serum creatinine-based criteria alone (Macedo et al, 2011).*
- A urine output of less than 0.5 mL/kg/hr is indicative of acute kidney injury (Prowle et al, 2011). *The RIFLE criteria define oliguria as urine output less than 0.5 mL/kg/hr for each of 6 or more consecutive hours, which is thought to confer “risk” of kidney injury; when urine output less than 0.5 mL/kg/hr and persists for 12 or more consecutive hours, the kidneys are considered to be “in injury” (Ratanarat et al, 2013).*
- Note the color of urine, urine osmolality, and specific gravity. *Normal urine is straw-colored or amber. Dark-colored urine with a specific gravity greater than 1.030 and a high urine osmolality reflects fluid volume deficit (Wagner & Hardin-Pierce, 2014; Perrier et al, 2013).*
- Provide fresh water and oral fluids preferred by the client (distribute over 24 hours [e.g., 1200 mL on days, 800 mL on evenings, and 200 mL on nights]); provide prescribed diet; offer snacks (e.g., frequent drinks, fresh fruits, fruit juice); instruct significant other to assist the client with feedings as appropriate. *Distributing the intake over the entire 24-hour period and providing snacks, specifically those with creatine and carnitine, and beverages including caffeine may improve muscular ability, endurance, and alertness (Cherniack, 2012).*
- ▲ Provide oral replacement therapy as ordered and tolerated with a hypotonic glucose-electrolyte solution when the client has acute diarrhea or nausea/vomiting. Provide small, frequent quantities of slightly chilled solutions. *Maintenance of oral intake stabilizes the ability of the intestines to absorb nutrients and promote gastric emptying (Popkin et al, 2010); glucose-electrolyte solutions increase net fluid absorption while correcting deficient fluid volume. Use diluted carbohydrate-electrolyte solutions such as sports replacement drinks, and ginger ale (Deshpande et al, 2013).* **EB:** *Many studies have shown that diluted oral replacement fluids resulted in reductions in stool output, decreased vomiting, and less need for IV hydration (Suh et al, 2010).*
- ▲ Administer antidiarrheals and antiemetics as ordered and appropriate. *The goal is to stop the loss that results from vomiting or diarrhea. Refer to care plan for **Diarrhea or Nausea**.*

- ▲ Hydrate the client with ordered isotonic IV solutions if prescribed. *For clients with mild to moderate fluid deficit, crystalloids such as 0.9 saline or lactated Ringer's should be used for fluid volume replacement (Peng & Kellum, 2013).*
- Assist with ambulation if the client has postural hypotension. Hypovolemia causes orthostatic hypotension, which can result in syncope when the client goes from a sitting to standing position (Wagner & Hardin-Pierce, 2014).

Critically Ill

- ▲ Monitor central venous pressure (CVP), pulmonary artery pressure, or stroke volume for decreasing trends for more accurate fluid volume status. *Hemodynamic pressures such as CVP and pulmonary artery pressures have been demonstrated to be less to predict fluid volume responsiveness, whereas changes in stroke volume measured by a number of noninvasive methods including passive leg lift may more accurately predict fluid volume responsiveness of a client (Marik et al, 2011).*
- ▲ Monitor serum and urine osmolality blood urea nitrogen (BUN)/creatinine ratio, and hematocrit for elevations. *These are all measures of concentration and will be elevated with decreased intravascular volume (Wagner & Hardin-Pierce, 2014).*
- ▲ Insert an indwelling urinary catheter if ordered and measure urine output hourly. Notify health care provider if urine output is less than 0.5 mL/kg/hr. *A decrease in urine output is seen with poorly perfused kidneys and a drop in the glomerular filtration rate in the client with normal kidney function, and action, if taken early, can prevent further deterioration (Zheng et al, 2014).*
- ▲ When ordered, initiate a fluid challenge of crystalloids (e.g., 0.9% normal saline or lactated Ringer's) for replacement of intravascular volume; monitor the client's response to prescribed fluid therapy and fluid challenge, especially noting vital signs, urine output, blood lactate concentrations, and lung sounds. *A fluid challenge can help the client with deficient fluid volume regain intravascular volume quickly, but the client must be carefully observed to ensure that he or she does not go into fluid volume overload in that excess fluid volume can lead to organ edema and increased mortality (Peng & Kellum, 2013; Wang et al, 2014).*
- Position the client flat with legs elevated when hypotensive, if not contraindicated. *This position enhances venous return, thus contributing to the maintenance of cardiac output with an increased blood pressure (Singh et al, 2011).*
- ▲ Monitor trends in serum lactic acid levels and base deficit obtained from blood gases as ordered. *A trend of increasing lactic acid levels and increasing base deficit can help identify hypoperfusion, which results in decreased survival and increased incidence of organ dysfunction (Richards & Wilcox, 2014).*
- ▲ Consult provider if signs and symptoms of deficient fluid volume persist or worsen. *Prolonged deficient fluid volume increases the risk for development of complications, including decrease in cognitive function, weakness, tachycardia, hemodynamic instability, and kidney injury (Popkin et al, 2010).*

Pediatric

- Monitor the child for signs of deficient fluid volume, including sunken eyes, decreased tears, dry mucous membranes, poor skin turgor, and decreased urine output (Graves, 2013). **EB:** *These assessment factors are more significant in identifying dehydration, but a combination of physical examination findings is a much better predictor than individual signs (Falszewska et al, 2014).*
- ▲ Reinforce the health care provider recommendation for the parents to give the child oral rehydration fluids to drink in the amounts specified, especially during the first 4 to 6 hours to replace fluid losses. Consider using diluted oral rehydration fluids. Once the child is rehydrated, an orally administered maintenance solution should be used along with food. **EB:** *A study demonstrated that treatment with oral rehydration fluids for children was generally as effective as IV fluids, and IV fluids did not shorten the duration of gastroenteritis and are more likely to cause adverse effects than oral rehydration therapy (Ciccarelli et al, 2013).* **EB:** *Many studies have shown that diluted oral replacement fluids and some drugs resulted in reductions in stool output, decreased vomiting, and less need for IV hydration (Ciccarelli et al, 2013).*
- Recommend that the mother resume breastfeeding as soon as possible.
- Recommend that parents not give the child decarbonated soda, fruit juices, gelatin dessert, or instant fruit drink mix. Instead give the child oral rehydration fluids ordered and, when tolerated, food. *Anti-emetic, antidiarrheal agents, and probiotics have been shown to reduce the duration and severity of infectious diarrhea (Ciccarelli et al, 2013).*

- Once the child has been rehydrated, begin feeding regular food, but avoid milk products (*Guandalini et al, 2014*). When a child has diarrhea, dietary modification includes avoiding dairy products, because viral or bacterial infections can cause a transient lactase deficiency (*Bolen, 2012*).

Geriatric

- Monitor older clients for deficient fluid volume carefully, noting new onset of headache, weakness, dizziness, and postural hypotension. **EB:** Older adults have a decrease in thirst and drink less compared to younger persons (*Hooper et al, 2013*).
- Implement fall precautions for clients experiencing weakness, dizziness, and/or postural hypotension.
- Evaluate the risk for dehydration using the Dehydration Risk Appraisal Checklist. **CEB:** A study demonstrated that the checklist has potential to predict the onset of dehydration in nursing home clients (*Mentes & Wang, 2011*).
- Check skin turgor of older clients on the forehead and axilla; check for dry mucous membranes and sunken eyes. Older people commonly have decreased skin turgor from normal age-related loss of elasticity; therefore checking skin turgor on the arm is not reflective of fluid volume. The presence of longitudinal furrows or dry mucous membrane, tachycardia, and orthostatic hypotension are good indication of dehydration in older adults (*Hooper et al, 2013*).
- Encourage fluid intake by offering fluids regularly to cognitively impaired clients. **CEB:** A study in women demonstrated that fluid restriction resulted in impaired alertness, increased sleepiness, fatigue, and confusion (*Pross et al, 2013*).
- Incorporate regular hydration into daily routines (e.g., extra glass of fluid with medication or social activities) (*Hooper et al, 2013*).
- Because they have low water reserves, older adults should be encouraged to drink regularly even when not thirsty. Frequent and varied beverage offerings should be made available by hydration assistants to routinely offer increased beverages to clients in extended care. **EB:** Strategies to improve fluid intake include making healthy drinks and water easily available and accessible at all times and reminding and encouraging older adults to consume these fluids. Older people should not be encouraged to consume large amounts of fluids at once but rather small amounts throughout the day (*Hooper et al, 2013*).
- Flag the food tray of clients with chronic dehydration to indicate if the client is identified as having chronic dehydration and indicate that they should finish 75% to 100% of their food and fluids. Offering beverages in brightly colored cups may improve fluid intake. Older clients often have a combination of both malnutrition and fluid deficit, and may not have good taste sensation (*Hooper et al, 2013*).
- Recognize that lower blood pressures and a higher BUN/creatinine ratio can be significant signs of dehydration in older adults. Structural changes of the kidney include alterations of renal blood flow of up to 50% from age 20 to 80. As people age, the kidney undergoes age-related changes, which translate in an inexorable and progressive decline in renal function.
- In the United States, renal dysfunction has a 15% prevalence in persons older than 70 years (*Bolignano et al, 2014*).
- Note the color of urine and compare against a urine color chart to monitor adequate fluid intake. **CEB:** A research study on older veterans demonstrated that urine color correlated significantly with urine osmolality, serum sodium, and BUN/creatinine ratio (*Jequier & Constant, 2010*).
- Monitor older clients for excess fluid volume during the treatment of deficient fluid volume: auscultate lung sounds, assess for edema, and note vital signs. The older client has a decreased ability to adapt to rapid increases in intravascular volume and can quickly develop fluid overload.

Home Care

- Teach family members how to monitor output in the home (e.g., use of commode “hat” in the toilet, urinal, or bedpan, or use of catheter and closed drainage system). Instruct them to monitor both intake and output. Use common terms such as “cups” or “glasses of water a day” when providing education.
- When weighing the client, use same scale each day. Be sure scale is on a flat, not cushioned, surface. Do not weigh the client with scale placed on any type of rug.
- Teach family about complications of deficient fluid volume and when to call the health care provider.
- Teach the family the signs of hypovolemia, especially in older adults, and how to monitor for dizziness or unsteady gait.
- If the client is receiving IV fluids, there must be a responsible caregiver in the home. Teach caregiver about administration of fluids, complications of IV administration (e.g., fluid volume overload, speed of

medication reactions), and when to call for assistance. Assist caregiver with administration for as long as necessary to maintain client safety. *Administration of IV fluids in the home is a high-technology procedure and requires sufficient professional support to ensure safety of the client.*

- Identify an emergency plan, including when to call 911. *Some complications of deficient fluid volume cannot be reversed in the home and are life-threatening. Clients progressing toward hypovolemic shock will need emergency care.*
- Deficient fluid volume may be a symptom of impending death in terminally ill clients. In palliative care situations, treatment of deficient fluid volume should be determined based on client/family goals. Information and support should be provided to assist the client/family in this decision. Support the family/client in a palliative care situation to decide if it is appropriate to intervene for deficient fluid volume or to allow the client to die without fluids. *Deficient fluid volume may be a symptom of impending death in terminally ill clients. There is no defined gold standard for hydrating dying clients, and hydration and nutrition are considered basic acts for care of a dying client (Ong et al, 2012).*

F

Client/Family Teaching and Discharge Planning

- Instruct the client to avoid rapid position changes, especially from supine to sitting or standing.
- Teach the client and family about appropriate diet and fluid intake.
- Teach the client and family how to measure and record intake and output accurately.
- Teach the client and family about measures instituted to treat hypovolemia and to prevent or treat fluid volume loss.
- Instruct the client and family about signs of deficient fluid volume that indicate they should contact health care provider.

Excess Fluid volume *Susan M. Dirkes, RN, MS, CCRN*

NANDA-I

Definition

Increased isotonic fluid retention

Defining Characteristics

Adventitious breath sounds; alteration in blood pressure; alteration in mental status; alteration in pulmonary artery pressure (PAP); alteration in respiratory pattern; alteration in urine specific gravity; anasarca; anxiety; azotemia; decrease in hematocrit; decrease in hemoglobin; dyspnea; edema; electrolyte imbalance; hepatomegaly; increased central venous pressure (CVP); intake exceeds output; jugular vein distention; oliguria; orthopnea; paroxysmal nocturnal dyspnea; pleural effusion; positive hepatojugular reflex; pulmonary congestion; restlessness; presence of S3 heart sound; weight gain over short period of time

Related Factors

Compromised regulatory mechanism; excessive fluid intake; excessive sodium intake

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Electrolyte and Acid-Base Balance; Fluid Balance; Fluid Overload Severity; Hydration

Example NOC Outcome with Indicators

Fluid Balance as evidenced by the following indicators: Peripheral edema/Neck vein distention/Adventitious breath sounds/Body weight increase. (Rate each indicator of **Fluid Balance**: 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of edema, effusion, anasarca
- Maintain body weight appropriate for the client
- Maintain clear lung sounds; no evidence of dyspnea or orthopnea
- Remain free of jugular vein distention, positive hepatojugular reflex, and S3 heart sound
- Maintain normal CVP, PAP, cardiac output, and vital signs
- Maintain urine output of 0.5 mL/kg/hr or more with normal urine osmolality and specific gravity
- Explain actions that are needed to treat or prevent excess fluid volume including fluid and dietary restrictions, and medications
- Describe symptoms that indicate the need to consult with health care provider

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Fluid Management; Fluid Monitoring

Example NIC Activities—Fluid Monitoring

Monitor weight; Monitor intake and output

F

Nursing Interventions and Rationales

- Monitor location and extent of edema using the 1+ to 4+ scale to quantify edema; also measure the legs using a millimeter tape in the same area at the same time each day. Note differences in measurement between extremities. **EBN:** *Causes of peripheral edema in clients with heart failure are related to medications, compensatory changes that influence hydrostatic pressure, and fluid retention, among other things (Cooper, 2011).*
- Monitor daily weight for sudden increases; use same scale and type of clothing at same time each day, preferably before breakfast. *Body weight changes reflect changes in body fluid volume. EB: Body weight is commonly used to monitor for fluid overload (Wagner & Hardin-Pierce, 2014).*
- Monitor intake and output; note trends reflecting decreasing urine output in relation to fluid intake. **EB:** *Accurately measuring intake and output is important for the client with fluid volume overload (Macedo et al, 2011). The volume of all fluids should be measured. If the family is measuring, instruct them on common conversions between household measurements and metric.*
- Monitor vital signs; note decreasing blood pressure, tachycardia, and tachypnea. Monitor for S3 heart sounds. If signs of heart failure are present, see the care plan for Decreased **Cardiac** output. *Heart failure results in dyspnea, edema, orthopnea, and elevated CVP. The secondary characteristics are weight gain, hepatomegaly, jugular vein distention, palpitations, crackles, oliguria, coughing, clammy skin, and skin color changes (Wagner & Hardin-Pierce, 2014).*
- Auscultate lung sounds for crackles, monitor respiration effort, and determine the presence and severity of orthopnea. *Acute pulmonary edema may be due either to increased permeability of the alveolar capillary barrier, in the case of acute lung injury, or to increased pulmonary microvascular hydrostatic pressure, in the case of cardiogenic pulmonary edema (Wagner & Hardin-Pierce, 2014).*
- Monitor serum and urine osmolality, serum sodium, blood urea nitrogen (BUN)/creatinine ratio, and hematocrit for abnormalities. **EB:** *In a client with fluid overload, an increase in urine volume and dilution will usually be observed (Macedo et al, 2011). BUN and creatinine are monitored currently, but they lack sensitivity, and an overall assessment of client fluid status is critical before fluid is administered (Shiff & Lang, 2012).*
- With head of bed elevated 30 to 45 degrees, monitor jugular veins for distention with the client in the upright position; assess for positive hepatojugular reflex. *Increased intravascular volume results in jugular vein distention, edema, crackles, and S3 heart sound (Peacock & Soto, 2010).*
- Monitor the client's behavior for restlessness, anxiety, or confusion; use safety precautions if symptoms are present. *When excess fluid volume compromises cardiac output, the client may experience cerebral tissue hypoxia and demonstrate restlessness and anxiety. When the excess fluid volume results in hyponatremia, there is a shift of water into the cells, resulting in symptoms ranging from nausea, malaise, and abdominal cramping to confusion, seizure, and coma (Ronco et al, 2012).*
- ▲ Monitor for the development of conditions that increase the client's risk for excess fluid volume, including heart failure, kidney failure, and liver failure, all of which result in decreased glomerular filtration rate and fluid retention. **EB:** *Other causes are increased intake of oral or intravenous (IV) fluids in excess of the client's cardiac and renal reserve levels, and increased levels of antidiuretic hormone (Ronco et al, 2012). Many clients with fluid overload have acute kidney injury, and fluid balance is an important indicator of outcomes. Studies show increased morbidity and mortality in clients with fluid overload (Ricci & Ronco, 2013).*
- ▲ Provide a restricted-sodium diet as appropriate if ordered. *Restricting the sodium in the diet will favor the renal excretion of excess fluid. Take care to avoid hyponatremia, which can cause serious complications including nausea, seizures, coma, and death (Kornusky & Pravikoff, 2011; Rudge & Kimm, 2014).*

- ▲ Monitor serum albumin level and provide protein intake as appropriate. *When plasma proteins, especially albumin, no longer sustain sufficient colloid osmotic pressure to counterbalance hydrostatic pressure, edema develops (Wagner & Hardin-Pierce, 2014).*
- ▲ Administer prescribed diuretics as appropriate; ensure adequate blood pressure before administration. If diuretic is administered intravenously, note and record the blood pressure and urine output following the dose. **EB:** *Clinical practice guidelines on heart failure state that monitoring input and output is useful for monitoring effects of diuretic therapy (Wagner & Hardin-Pierce, 2014).*
- Monitor for side effects of diuretic therapy: orthostatic hypotension (especially if the client is also receiving angiotensin-converting enzyme [ACE] inhibitors), hypovolemia, and electrolyte imbalances (hypokalemia and hyponatremia). *Observe for hyperkalemia in clients receiving a potassium-sparing diuretic and in those on beta-blockers and ACE inhibitors (Wagner & Hardin-Pierce, 2014; Rudge & Kimm, 2014).*
- ▲ Implement fluid restriction as ordered, especially when serum sodium is low; include all routes of intake. Schedule limited intake of fluids around the clock, and include the type of fluids preferred by the client. *Fluid restriction may decrease intravascular volume and myocardial workload. Overzealous fluid restriction should not be used because hypovolemia can worsen heart failure. Client involvement in planning will enhance participation in the necessary fluid restriction.*
- Maintain the rate of all IV infusions, carefully using an IV pump. *This is done to prevent inadvertent exacerbation of excess fluid volume.*
- Turn clients with dependent edema at least every 2 hours. *Severe edema predisposes clients to skin breakdown and pressure ulcers (Cooper, 2011).*
- ▲ Provide ordered care for edematous extremities including compression, elevation, and muscle exercises. **EB:** *Treatments for clients with peripheral edema include the use of sequential compression devices, elevation of the extremities above heart level, and exercises that affect the calf muscle pump (i.e., pedal push exercises) and layered compression wraps (Cooper, 2011).*
- Promote a positive body image and good self-esteem. *Visible edema may alter the client's body image. Refer to the care plan for Disturbed **Body Image**.*
- ▲ Consult with the health care provider if signs and symptoms of excess fluid volume persist or worsen. *Pulmonary edema requires prompt treatment such as preload reducers, afterload reducers, and morphine to relieve anxiety (Mayo Foundation for Medical Education and Research, 2014).*

Critically III

- Insert an indwelling urinary catheter if ordered and measure urine output hourly. Notify health care provider if output is less than 0.5 mL/kg/hr. *Urine output of less than 0.5 mL/kg/hr for 6 or more hours is defined as oliguria (Prowle et al, 2011).*
- ▲ Monitor CVP, mean arterial pressure, PAP, and cardiac output/index; note and report trends of increasing or decreasing pressures over time. *Alterations in these parameters may indicate the client is going into shock. Hemodynamic criteria for cardiogenic shock are sustained hypotension (systolic blood pressure less than 90 mm Hg for at least 30 minutes) and a reduced cardiac index (less than 2.2 L/min/m²) in the presence of elevated pulmonary capillary occlusion pressure (greater than 15 mm Hg), pulmonary congestion, dyspnea, and hypoxemia (Wagner & Hardin-Pierce, 2014).*
- ▲ Monitor the effects of infusion of diuretic drips. Perform continuous renal replacement therapy (CRRT) as ordered if the client is critically ill and hemodynamically unstable and excessive fluid must be removed. **EBN:** *CRRT is indicated for hypervolemia, metabolic acidosis, and hyperkalemia (Dirkes, 2014).*

Geriatric

- Recognize that the presence of fluid volume excess is particularly serious in older adults. **EB:** *The kidney undergoes age-related changes that include structural and functional changes, which may increase the incidence of acute kidney injury (Bolignano et al, 2014).*
- Monitor electrolyte levels carefully, including sodium levels and potassium levels, with both increased and decreased levels possible. *Older adults are prone to electrolyte abnormalities due to aging, decreased muscle mass, and decreased total body water (Hooper et al, 2013), plus the large number of medications that are taken that can affect electrolyte levels. Many older clients receive selective serotonin reuptake inhibitors for treatment of depression, which can result in hyponatremia (Mannesse et al, 2013).* Refer to the care plan for risk for **Electrolyte** imbalance.

Home Care

- Assess client and family knowledge of disease process causing excess fluid volume.
- ▲ Teach about disease process and complications of excess fluid volume, including when to contact the health care provider.
- Assess client and family knowledge and compliance with medical regimen, including medications, diet, rest, and exercise. Assist family with integrating restrictions into daily living. *Assistance with integration of cultural values, especially those related to foods, with medical regimen promotes compliance and decreased risk of complications.*
- ▲ Teach and reinforce knowledge of medications. Instruct the client not to use over-the-counter (OTC) medications (e.g., diet medications) without first consulting the provider.
- ▲ Instruct the client to make the primary health care provider aware of medications ordered by other health care providers.
- Identify emergency plan for rapidly developing or critical levels of excess fluid volume when diuresing is not safe at home. *Excess fluid volume can be life threatening.*
- ▲ Teach about signs and symptoms of both excess and deficient fluid volume, such as darker urine and when to call the health care provider. *Urine color may be a simple indicator of hydration (Perrier et al, 2013).*

Client/Family Teaching and Discharge Planning

- Describe signs and symptoms of excess fluid volume and actions to take if they occur.
- ▲ Teach client on diuretics to weigh self daily in the morning and to notify the health care provider if there is a 2.2 pound (1 kg) or more weight gain (Wagner & Hardin-Pierce, 2014). **EB:** *Clinical practice guidelines on heart failure suggest that daily weight monitoring leads to early recognition of excess fluid retention, which, when reported, can be offset with additional medication to avoid hospitalization due to heart failure decompensation (Wagner & Hardin-Pierce, 2014).*
- ▲ Teach the importance of fluid and sodium restrictions. Help the client and family devise a schedule for intake of fluids throughout the entire day. Refer to a dietitian concerning implementation of a low-sodium diet.
- Teach clients how to measure and document intake and output with common household measurements, such as cups.
- ▲ Teach how to take diuretics correctly: take one dose in the morning and second dose (if taken) no later than 4 PM. Adjust potassium intake as appropriate for potassium-losing or potassium-sparing diuretics. Note the appearance of side effects such as weakness, muscle cramps, hypertension, palpitations, or irregular heartbeat (Wagner & Hardin-Pierce, 2014).
- For the client undergoing hemodialysis, teach client the required restrictions in dietary electrolytes, protein, and fluid. Spend time with the client to detect any factors that may interfere with the client's compliance with the fluid restriction or restrictive diet. **EBN:** *Recent research has shown an association between albumin level (an important marker of nutritional status and possible inflammation) and psychosocial factors. Also, lower levels of family support were associated with higher risk of nonadherence to medical care (Untas et al, 2011).*

Risk for Deficient Fluid volume

Betty J. Ackley, MSN, EdS, RN, and Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

NANDA-I

Definition

Vulnerable to experiencing decreased intravascular, interstitial, and/or intracellular fluid volumes, which may compromise health

Risk Factors

Active fluid volume loss; barrier to accessing fluid; compromised regulatory mechanism; deviations affecting fluid absorption; deviations affecting fluid intake; excessive fluid loss through normal route; extremes of age; extremes of weight; factors influencing fluid needs; fluid loss through abnormal route; insufficient knowledge about fluid needs; pharmaceutical agent

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching, Rationales, and References

Refer to care plan for [Deficient Fluid volume](#).

Risk for imbalanced Fluid volume

Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN, and Betty J. Ackley, MSN, EdS, RN

NANDA-I

Definition

Vulnerable to a decrease, increase, or rapid shift from one to the other of intravascular, interstitial, and/or intracellular fluid, which may compromise health; this refers to body fluid loss, gain, or both

Risk Factors

Apheresis; ascites; burns; intestinal obstruction; pancreatitis; sepsis; trauma; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Fluid Balance; Electrolyte and Acid-Base Balance; Hydration

Example NOC Outcome with Indicators

Maintains **Fluid Balance** as evidenced by the following indicators: BP/Peripheral pulses palpable/Skin turgor/Moist mucous membranes/Serum electrolytes/Hematocrit/Body weight stable/24-hour intake and output balanced/Urine specific gravity. (Rate each indicator of **Fluid Balance**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see [Section I](#)].)

Client Outcomes

- Lung sounds clear, respiratory rate 12 to 20 and free of dyspnea
- Urine output greater than 0.5 mL/kg/hr
- Blood pressure, pulse rate, temperature, and oxygen saturation within expected range
- Laboratory values within expected range, that is, normal serum sodium, hematocrit, and osmolarity
- Extremities and dependent areas free of edema
- Mental orientation appropriate based on previous condition

NIC (Nursing Interventions Classification)

F

Suggested NIC Interventions

Autotransfusion; Bleeding Precautions; Bleeding Reduction: Wound; Electrolyte Management; Fluid Management; Fluid Monitoring; Hemodynamic Regulation; Hypovolemia Management; Hypovolemia Management; Intravenous Therapy; Invasive Hemodynamic Monitoring; Shock Management: Volume; Vital Signs Monitoring

Example NIC Activities—Fluid Management

Maintain accurate intake and output record; Monitor vital signs

Nursing Interventions and Rationales

Surgical Clients

- Monitor the fluid balance. If there are symptoms of hypovolemia, refer to the interventions in the care plan for Deficient **Fluid** volume. If there are symptoms of hypervolemia, refer to the interventions in the care plan for Excess **Fluid** volume.

Preoperative

- Collect a thorough history and perform a preoperative assessment to identify clients with increased risk for hemorrhage or hypovolemia, that is, clients with recent traumatic injury, abnormal bleeding or altered clotting times, complicated kidney or liver disease, diabetes, cardiovascular disease, major organ transplant, history of aspirin and/or NSAID use, anticoagulant therapy, or history of hemophilia, von Willebrand's disease, or disseminated intravascular coagulation. Assess the client's use of over-the-counter agents to include herbal products. **CEB:** *Assessment of the client's use of herbal products is important as some herbs act as anticoagulants and could cause increased blood loss, and some herbs have diuretic or laxative effects (Young et al, 2009; Flanagan, 2001).*
- Recognize that NPO at midnight may or may not be appropriate for each surgical client. Guidelines from the **American Society of Anesthesiologists (ASA) in 2011** recommend the following: healthy clients having elective surgery should be allowed to have clear liquids up to 2 hours before surgery. *Research has shown the value of allowing healthy clients to consume clear liquids up to 2 hours before surgery; practice is not consistent (Crenshaw, 2011). Many clients are unnecessarily dehydrated from lack of fluid for an extended period, which can complicate postoperative recovery. It is important to provide clear communication to the client that only clear liquids can be safely consumed up to 2 hours before surgery (Allison & George, 2014).*
- Determine length of time the client has been without normal intake, been NPO, or experienced fluid loss (e.g., vomiting, diarrhea, bleeding). *The length of time and severity of the above factors, along with the presence of a fluid deficit, allow the health care provider to determine a general estimate of preoperative fluid loss, which can affect intraoperative fluid management. However, laboratory testing of hemoglobin, hematocrit, blood urea nitrogen (BUN), and creatinine should be used to corroborate the assessment (Allison & George, 2014).*
- Assess and document the client's mental status. *A baseline assessment is important so that changes in mental status during the postoperative period can be easily identified.*
- Recognize that there is conflicting evidence regarding liberal intraoperative fluid management versus restrictive fluid management. Fluid administration during surgery is more restrictive to prevent pulmonary complications associated with excessive fluid administration (Assaad et al, 2013). **CEB:** *Using a restrictive approach to intraoperative fluid management resulted in less postoperative pulmonary*

complications, fewer wound healing complications, and decreased length of time for bowel function to resume, than the use of a more liberal fluid regimen (Young et al, 2009). Studies involving clients having bowel resections showed that those clients who had restricted fluids developed hemodynamic instability, and it was concluded that a liberal approach might have improved both cardiopulmonary and renal function in these clients (Bamboato & Bordeianou, 2009). To reduce fluid administration volume, colloids rather than crystalloid fluids may be administered during surgery (Cortes et al, 2015).

- Recognize that an individualized fluid management plan would be developed incorporating client specific assessment parameters (e.g., existing comorbid diseases, age) and type of surgical procedure (Allison & George, 2014). **EB:** Perioperative hemodynamic and fluid management that is goal directed improved both short- and long-term outcomes and can easily be achieved (Cannesson, 2011; Cecconi et al, 2015).
- Recognize the effects of general anesthetics, inhalational agents, and of regional anesthesia on perfusion in the body and decreasing the blood pressure. **CEB:** None of these types of anesthesia alone affect circulating blood volume, but anesthetics can cause a drop in blood pressure that is often treated with a fluid bolus, which is especially important in critically ill clients who have poor cardiopulmonary reserves (Bamboato & Bordeianou, 2009).
- Monitor for signs of intraoperative hypovolemia: dry skin, dry mucous membranes, tachycardia, decreased urinary output, decreased central venous pressure, hypotension, increased pulse, and/or deep rapid respirations.
- Monitor for signs of intraoperative hypervolemia: dyspnea, coarse crackles, increased pulse and respirations, decreased oxygenation, and decreased urinary output, all of which could progress to pulmonary edema.
- In the critically ill surgical client a pulmonary artery catheter or other minimally invasive cardiac output monitoring device may be used to determine fluid balance and guide fluid and vasoactive intravenous (IV) drip administration. **EB:** Monitoring devices that directly (pulmonary artery catheter) or indirectly (minimally or noninvasively) assess the client's cardiac output and fluid volume status may be used to "optimize" cardiac function by allowing better fluid regimens. Fluids must be individually titrated based on each client's changes in monitored variables (Cannesson, 2011; Zang et al, 2011; Cecconi et al, 2015).
- Monitor the client for hyponatremia, that is, headache, anorexia, nausea and vomiting, diarrhea, tachycardia, general malaise, muscle cramps, weakness, lethargy, change in mental status, disorientation, seizures, and death. Many pathologies can predispose the client to hyponatremia, including adrenal insufficiency, brain tumor, cirrhosis, hypothyroidism, lung cancer, meningitis, renal disease, tuberculosis, use of complementary therapies, and head trauma (Allison & George, 2014).
- Monitor clients undergoing laparoscopic or hysteroscopic procedures for the development of hyponatremia, hypervolemia, and pulmonary edema when an irrigation fluid is used. **CEB:** Use of local or spinal anesthesia for these operations can cause the client to develop symptoms of hyponatremia and hypervolemia sooner than with other anesthetics (Young et al, 2009).
- Monitor clients undergoing transurethral resection of the prostate (TURP) procedures for development of hyponatremia, and hypervolemia with symptoms of TURP syndrome: headache, visual changes, agitation, lethargy, vomiting, muscle twitching, bradycardia, diminished pupillary reflexes, hypertension, and respiratory distress. Considerable fluid absorption occurs during TURP procedures and gynecological procedures, which can result in hyponatremia and/or hypervolemia (Young et al, 2009).
- Measure the irrigation fluid used during urological and gynecological procedures accurately for volume deficit, that is, amount of irrigation used minus amount of irrigation recovered via suction. Absorption of large amounts of fluid can cause complications for the client (Young et al, 2009).
- Monitor intraoperative intake and output including blood loss, urine output, and third-space losses, to provide an estimate of fluid volume. **EBN:** Weighing used sponges can provide an estimate of blood loss (Blanchard & Burlingam, 2012). **CEB:** Weighing fluid used and returned provides a more accurate measurement of fluid deficit than measuring the fluids (Young et al, 2009).
- Observe the surgical client for hyperkalemia, that is, dysrhythmias, heart block, asystole, abdominal distention, and weakness. Hyperkalemia can occur intraoperatively due to massive blood transfusions, tissue breakdown from surgery, shifting of potassium from the cells into the extracellular fluid, decreased potassium excretion due to renal failure or hypovolemia, crush injuries, or burns (Rothrock, 2010).
- Maintain the client's core temperature at normal levels, using warming devices as needed. Fluids administered during surgery can increase risk of hypothermia. **CEB:** Research has shown that perioperative hypothermia can adversely affect the cardiopulmonary system (Young et al, 2009).

Postoperative

- Continue to support restrictive fluid management postoperatively. **CEB:** *Using restrictive fluid management postoperatively has been found to result in earlier gastric emptying and shorter length of time before passage of flatus and the first postoperative bowel movement than in those receiving standard fluid management (Bamboot & Bordeianou, 2009; Young et al, 2009).*
- Assess the client for development of tissue edema. **CEB:** *Clients developing tissue edema have been shown to develop poor wound healing, compromised pulmonary function, and delay in return of bowel function (Bamboot & Bordeianou, 2009; Young et al, 2009).*
- Recognize that IV fluid replacement decisions incorporate multiple assessment parameters: hourly urine output, blood pressure, heart rate, respiratory rate, lung sounds, output from drains, and changes in laboratory results (e.g., hemoglobin/hematocrit, serum electrolytes).

Geriatric

- Check skin turgor of older client on the forehead, subclavian area, or inner thigh; also look for the presence of longitudinal furrows on the tongue and dry mucous membranes. *Older people commonly have decreased skin turgor from normal age-related loss of elasticity; checking skin turgor on the arm is not reflective of fluid volume (El-Sharkawy et al, 2014).*
- Closely monitor urine output, concentration of urine, and serum BUN/creatinine results. **EB:** *Reduced renal perfusion and altered renal function as a normal or abnormal change in physiologic aging can compromise the client's fluid volume status (El-Sharkawy et al, 2014).*
- Monitor older clients for excess fluid volume during the treatment of deficient fluid volume: auscultate lung sounds, assess for edema, and trend vital signs.
- Assess the older client's cognitive status. **EB:** *Cognitive impairment is a risk factor associated with dehydration, especially in the older adult (El-Sharkawy et al, 2014).*

Pediatric

- Assess the pediatric client's weight, length of NPO status, underlying illness, and the surgical procedure to be performed.
- Recognize that newborns require very little fluid replacement when undergoing major surgical procedures during the first few days of life.
- Monitor pediatric surgical clients closely for signs of fluid loss.
- Administer fluids preoperatively until NPO status must be initiated so that fluid deficit is decreased.
- Perform an assessment for signs of fluid responsiveness in the pediatric client. **EB:** *A systematic review found that respiratory variation was the only assessment parameter to most reliably predict a pediatric client's responsiveness for fluid administration (Gan et al, 2013).* **CEB:** *Oral rehydration therapy, when possible, is the treatment of choice for children with mild to moderate dehydration (Barclay, 2009).*

Frail Elderly syndrome *Noelle L. Fields, PhD, LCSW*

NANDA-I

Definition

Dynamic state of unstable equilibrium that affects the older individual experiencing deterioration in one or more domain of health (physical, functional, psychological, or social) and leads to increased susceptibility to adverse health effects, particularly disability

Risk Factors

Activity intolerance; bathing self-care deficit; decreased cardiac output; dressing self-care deficit; fatigue; feeding self-care deficit; hopelessness; imbalanced nutrition: less than body requirements; impaired memory; impaired physical mobility; impaired walking; social isolation; toileting self-care deficit

Related Factors

Alteration in cognitive functioning; chronic illness; history of falls; living alone; malnutrition; prolonged hospitalization; psychiatric disorder; sarcopenia; sarcopenic obesity; sedentary lifestyle

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Physical Aging; Psychosocial Adjustment: Life Change; Client Satisfaction: Functional Assistance

Example NOC Outcomes with Indicators

Client Satisfaction: Functional Assistance as evidenced by the following indicators: Included in planning for optimal mobility and self-care/Encouraged to be as active as possible/Assistance with physical activity/Allowed to choose food for meals. (Rate the outcome and indicators of **Client Satisfaction: Functional Assistance**: 1 = not at all satisfied, 2 = somewhat satisfied, 3 = moderately satisfied, 4 = very satisfied, 5 = completely satisfied [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain living as independently as possible in the home or care setting of his or her choice
- Maintain safety when engaging in activities of daily living and ambulation
- Increase exercise and/or daily physical activity in order to build muscle strength
- Maintain a healthy weight

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Physical Exercise; Strength Training; Balance Training

Example NIC Activities—Frail Elderly Syndrome

Promote physical activities that build strength and improve balance and endurance

Nursing Interventions and Rationales

- Assess frailty with a tool such as the Edmonton Frail Scale. **EB**: *The Edmonton Frail Scale is a tool designed to identify frail older adults in clinical settings and requires less than 5 minutes to administer (Clegg & Young, 2011).*

• = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

- Recognize that balance and gait impairment are features of frailty and are risk factors for falls. **EB:** *Cadore et al (2013) did a systematic review of the literature and found that exercise interventions composed of strength, endurance, and balance training improve the rate of falls in frail older adults.*
- Monitor physical frailty indicators such as slow gait speed and low physical activity. **EB:** *Vermeulen et al (2011) did a systematic review and found that monitoring physical frailty indicators might be useful to identify older adults who could benefit from interventions aimed at preventing disability.*
- Assess falls using a falls risk assessment tool such as the Hendrich II Fall Risk Model. **EBN:** *Ivziku et al (2011) studied 179 older adult patients in a hospital setting and found that this falls risk assessment tool had predictive properties for patients at risk for fall in acute care settings.*
- Evaluate the client's medications to determine whether medications increase the risk of frailty; if appropriate, consult with the client's health care provider regarding the client's medications. **EB:** *Polypharmacy, or taking five or more medications, has been associated with frailty in older adults (Gnjidic et al, 2012).*
- ▲ Refer to a dietitian for an individualized therapeutic diet. **EB:** *Dietary supplements such as protein are needed to promote muscle mass gain during exercise training in frail older adults (Tieland et al, 2012).* **EB:** *Malafarina et al (2013) did a systematic review of the literature about nutritional supplements in older adults and found that nutritional supplements are effective in the treatment of muscle mass loss, particularly in conjunction with physical exercise.*
- Refer to care plan for Readiness for enhanced **Nutrition** for additional interventions.
- Monitor weight loss. **EB:** *Weight loss is considered a main component of frailty syndrome (Morley et al, 2013).* **CEB:** *Milne et al (2009) did a systematic literature review and found that when given to older adults, nutritional supplements containing protein and energy result in weight gain.*
- Encourage clients to engage in active lifestyles. **CEB:** *Peterson et al (2009) studied 2964 older adults for 5 years and found that sedentary older individuals had a greater likelihood of developing frailty than individuals who were engaged in exercise.*
- Provide an exercise-training program. **EB:** *Physical exercise training leads to improved cognitive functioning as well as psychological well-being in older adults who are frail (Langlois et al, 2013).* **EB:** *Theou et al (2011) did a systematic review and found that structured exercise programs performed three times per week for 30 to 35 minutes per session had a positive impact on frail older adults.*
- Promote the benefits of home-based exercise to older clients who are frail. **EB:** *Clegg et al (2014) conducted a study of 49 frail older adults and found evidence that the deterioration in mobility may be reduced through a 12-week home-based exercise intervention.* **EB:** *Clegg et al (2012) did a systematic review of the literature and found evidence that home-based exercise interventions may improve disability in older adults with moderate frailty.*
- Use a multidisciplinary and person-centered approach for supporting frail older adults. **EBN:** *The focus of caring for frail older adults should not only be on medical problems but also on providing supportive services to help individuals maintain their independence and manage their lives despite frailty (Ebrahim et al, 2014).*
- Develop a trusting and responsive relationship with frail clients. **EBN:** *Bindels et al (2013) qualitatively interviewed nurses (N = 23) and found that building a trusting relationship, along with competence, responsiveness, and attentiveness were important for providing frail older adults with good care.*

Multicultural, Home Care, Client/Family Teaching

- The above interventions may be adapted for multicultural, home care, and client family teaching.

Risk for Frail Elderly syndrome *Noelle L. Fields, PhD, LCSW*

NANDA-I

Definition

Vulnerable to a dynamic state of unstable equilibrium that affects the older individual experiencing deterioration in one or more domains of health (physical, functional, or social) and leads to increased susceptibility to adverse health effects, in particular disability

Defining Characteristics

Activity intolerance; age >70 years; alteration in cognitive functioning; altered clotting process (e.g., factor VII, D-dimers); anorexia; anxiety; average daily physical activity is less than recommended for gender and age; chronic illness; constricted life space; decrease in energy; decrease in muscle strength; decrease in serum 25-hydroxyvitamin D concentration; depression; economically disadvantaged; endocrine regulatory dysfunction (e.g., glucose intolerance, increase in IGF-1, androgen, DHEA, and cortisol); ethnicity other than Caucasian; exhaustion; fear of falling; female gender; history of falls; immobility; impaired balance; impaired mobility; insufficient social support; living alone; low educational level; malnutrition; muscle weakness; obesity; prolonged hospitalization; sadness; sarcopenia; sarcopenic obesity; sedentary lifestyle; sensory deficit (e.g., visual, hearing); social isolation; social vulnerability (e.g., disempowerment, decreased life control); suppressed inflammatory response (e.g., IL-6, CRP); unintentional loss of 25% of body weight over 1 year; unintentional weight loss >10 pounds (>4.5 kg) in 1 year; walking 15 feet requires more than 6 seconds (4 m > 5 seconds)

NIC, NOC, Client Outcomes, Nursing Interventions, Rationales, and References

Refer to care plan for [Frail Elderly syndrome](#).

List of Nursing Diagnoses by Letter: G

Impaired Gas exchange	Dysfunctional Gastrointestinal motility	Risk for dysfunctional Gastrointestinal motility
Risk for ineffective Gastrointestinal perfusion	Risk for unstable blood Glucose level	Grieving
Complicated Grieving	Risk for complicated Grieving	Risk for disproportionate Growth

Impaired Gas exchange *Debra Siela, PhD, RN, CCNS, ACNS-BC, CCRN-K, CNE, RRT*

NANDA-I

Definition

Excess or deficit in oxygenation and/or carbon dioxide elimination at the alveolar-capillary membrane

Defining Characteristics

Abnormal arterial blood gases; abnormal arterial pH; abnormal breathing pattern (e.g., rate, rhythm, depth); abnormal skin color (e.g., pale, dusky, cyanosis); confusion; cyanosis; decrease in carbon dioxide (CO₂) levels; diaphoresis; dyspnea; headache upon awakening; hypercapnia; hypoxemia; hypoxia; irritability; nasal flaring; restlessness, somnolence; tachycardia; visual disturbances

Related Factors (r/t)

Alveolar-capillary membrane changes; ventilation-perfusion imbalance

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Respiratory Status: Gas Exchange, Ventilation

Example NOC Outcome with Indicators

Achieves appropriate **Respiratory Status: Gas Exchange** as evidenced by the following indicators: Cognitive status/Partial pressure of oxygen/Partial pressure of carbon dioxide/Arterial pH/Oxygen saturation. (Rate each indicator of **Respiratory Status**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate improved ventilation and adequate oxygenation as evidenced by blood gas levels within normal parameters for that client
- Maintain clear lung fields and remain free of signs of respiratory distress
- Verbalize understanding of oxygen supplementation and other therapeutic interventions

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Acid-Base Management; Airway Management

Example NIC Activities—Acid-Base Management

Monitor for symptoms of respiratory failure (e.g., low PaO₂ and elevated PaCO₂ levels and respiratory muscle fatigue); Monitor determinants of tissue oxygen delivery (e.g., PaO₂, SaO₂, and hemoglobin levels, and cardiac output) if available

Nursing Interventions and Rationales

- Monitor respiratory rate, depth, and ease of respiration. Watch for use of accessory muscles and nasal flaring. *Normal respiratory rate is 14 to 16 breaths/minute in the adult (Bickley & Szilagyi, 2012). EBN: A study demonstrated that when the respiratory rate exceeds 30 breaths/minute, along with other physiological measures, a significant cardiovascular or respiratory alteration exists (Hagle, 2008).*
- Auscultate breath sounds every 1 to 2 hours. The presence of crackles and wheezes may alert the nurse to airway obstruction, which may lead to or exacerbate existing hypoxia. *In severe exacerbations of chronic obstructive pulmonary disease (COPD), lung sounds may be diminished or distant with air trapping (Bickley & Szilagyi, 2012).*

- Monitor the client's behavior and mental status for the onset of restlessness, agitation, confusion, and (in the late stages) extreme lethargy. *Changes in behavior and mental status can be early signs of impaired gas exchange. In the late stages the client becomes lethargic and somnolent (Burns, 2011).*
- ▲ Monitor oxygen saturation continuously using pulse oximetry. Note blood gas results as available. *An oxygen saturation of less than 88% (normal: 95% to 100%) or a partial pressure of oxygen of less than 55 mm Hg (normal: 80 to 100 mm Hg) indicates significant oxygenation problems. Pulse oximetry is useful for tracking and/or adjusting supplemental oxygen therapy for clients with COPD (GOLD, 2015).*
- Observe for cyanosis of the skin; especially note color of the tongue and oral mucous membranes. *In central cyanosis both the skin and mucous membranes are affected due to seriously impaired pulmonary function from unventilated or underventilated alveoli. Peripheral cyanosis (skin only) usually indicates vasoconstriction or obstruction to blood flow (Loscalzo, 2013).*
- Central cyanosis of the tongue and oral mucosa is indicative of serious hypoxia and is a medical emergency. *Peripheral cyanosis in the extremities may be due to activation of the central nervous system or exposure to cold and may or may not be serious (Bickley & Szilagyi, 2012).*
- Position the client in a semirecumbent position with the head of the bed at a 30- to 45-degree angle to decrease the aspiration of gastric, oral, and nasal secretions (Grap, 2009; Siela, 2010; Vollman & Sole, 2011). Historically, evidence shows that mechanically ventilated clients have a decreased incidence of aspiration pneumonia if the client is placed in a 30- to 45-degree semirecumbent position as opposed to a supine position.
- If the client has unilateral lung disease, position with head of bed at 30 to 45 degrees with “good lung down” for about 1 hour at a time (Burns, 2011).
- ▲ If the client is acutely dyspneic, consider having the client lean forward over a bedside table, resting elbows on the table if tolerated. *Leaning forward can help decrease dyspnea, possibly because gastric pressure allows better contraction of the diaphragm (Langer et al, 2009). This is called the tripod position and is used during times of distress, including when walking, leaning forward on the walker.*
- Help the client deep breathe and perform controlled coughing. Have the client inhale deeply, hold the breath for several seconds, and cough two or three times with the mouth open while tightening the upper abdominal muscles as tolerated. *Controlled coughing uses the diaphragmatic muscles, which makes the cough more forceful and effective. If the client has excessive fluid in the respiratory system, see the interventions for Ineffective Airway clearance.*
- ▲ Monitor the effects of sedation and analgesics on the client's respiratory pattern; use judiciously. *Both analgesics and medications that cause sedation can depress respiration at times. However, these medications can be very helpful for decreasing the sympathetic nervous system discharge that accompanies hypoxia (Spruit et al, 2013).*
- Schedule nursing care to provide rest and minimize fatigue. *The hypoxic client has limited reserves; inappropriate activity can increase hypoxia (Spruit et al, 2013).*
- ▲ Administer humidified oxygen through an appropriate device (e.g., nasal cannula or Venturi mask per the health care provider's order); aim for an oxygen (O₂) saturation level of 90% or above. Watch for onset of hypoventilation as evidenced by increased somnolence. *There is a fine line between ideal and excessive oxygen therapy; increasing somnolence is caused by retention of CO₂ leading to CO₂ narcosis (Wong & Elliott, 2009). Promote oxygen therapy during a COPD exacerbation. Supplemental oxygen should be titrated to improve the client's hypoxemia with a target of 88% to 92% (GOLD, 2015).*
- Once oxygen is started, arterial blood gases should be checked 30 to 60 minutes later to ensure satisfactory oxygenation without carbon dioxide retention or acidosis (GOLD, 2015). **EBN:** *Use of high-flow nasal cannula oxygen therapy may improve gas exchange and oxygenation in acute respiratory therapy (Roca et al, 2010; Parke et al, 2011; Sztrymf et al, 2012; Lenglet et al, 2012; Rittayamai et al, 2014).*
- Assess nutritional status including serum albumin level and body mass index (BMI). *Weight loss in a client with COPD has a negative effect on the course of the disease; it can result in loss of muscle mass in the respiratory muscles, including the diaphragm, which can lead to respiratory failure (Odencrants et al, 2008; GOLD, 2015).*
- ▲ Assist the client to eat small meals frequently and use dietary supplements as necessary. Engage dietary in evaluating and creating an optimal nutrition plan. For some clients, drinking 30 mL of a supplement every hour while awake can be helpful.
- If the client is severely debilitated from chronic respiratory disease, consider the use of a wheeled walker to help in ambulation.
- ▲ Watch for signs of psychological distress including anxiety, agitation, and insomnia.

- ▲ Refer the COPD client to a pulmonary rehabilitation program. *Pulmonary rehabilitation is now considered a standard of care for the client with COPD (Spruit et al, 2013; GOLD, 2015; Nici et al, 2009).*

Critical Care

- ▲ Assess and monitor oxygen indices such as the PF ratio ($FI_{O_2}:pO_2$), venous oxygen saturation/oxygen consumption (SVO_2 or $ScVO_2$) (Headley & Guiliano, 2011; Burns, 2011).
- ▲ Turn the client every 2 hours. Monitor mixed venous oxygen saturation closely after turning. If it drops below 10% or fails to return to baseline promptly, turn the client back into the supine position and evaluate oxygen status. If the client does not tolerate turning, consider use of a kinetic bed that rotates the client from side to side in a turn of at least 40 degrees (Vollman et al, 2011).
- ▲ If the client has acute respiratory distress syndrome with difficulty maintaining oxygenation, consider positioning the client prone with the upper thorax and pelvis supported. Monitor oxygen saturation and turn the client back to supine position if desaturation occurs. **EBN/EB:** *Oxygenation levels have been shown to improve in the prone position, probably due to decreased shunting and better perfusion of the lungs (Gattinoni et al, 2013; Vollman & Powers, 2011). Prone ventilation significantly reduced mortality in clients with severe acute hypoxemic respiratory failure, but not in clients with less severe hypoxemia (Sud et al, 2010; Gattinoni et al, 2013).* NOTE: If the client becomes ventilator dependent, see the care plan for Impaired spontaneous **Ventilation**.
- ▲ High levels of positive end-expiratory pressures likely improve oxygenation and gas exchange (Meade et al, 2008; Suzumura et al, 2014).

Geriatric

- ▲ Use central nervous system depressants and other sedating agents carefully to avoid decreasing respiration rate.
- ▲ Maintain low-flow oxygen therapy for clients with impaired gas exchange and hypoxemia (GOLD 2015; Burns, 2011).

Home Care

- Work with the client to determine what strategies are most helpful during times of dyspnea. Educate and empower the client to self-manage the disease associated with impaired gas exchange. **EBN/EB:** *A study found that use of oxygen, self-use of medication, and getting some fresh air were most helpful in dealing with dyspnea (Thomas, 2009). Evidence-based reviews have found that self-management offers COPD clients effective options for managing the illness, leading to more positive outcomes (Kaptein et al, 2008; Spruit et al, 2013).*
- Collaborate with health care providers regarding long-term oxygen administration for chronic respiratory failure clients with severe resting hypoxemia. Administer long-term oxygen therapy greater than 15 hours daily for pO_2 less than 55 or SaO_2 at or below 88% (GOLD, 2015).
- Assess the home environment for irritants that impair gas exchange. Help the client adjust the home environment as necessary (e.g., install an air filter to decrease the level of dust).
- ▲ Refer the client to occupational therapy as necessary to assist the client in adapting to the home and environment and in energy conservation (GOLD, 2015).
- Assist the client with identifying and avoiding situations that exacerbate impairment of gas exchange (e.g., stress-related situations, exposure to pollution of any kind, proximity to noxious gas fumes such as chlorine bleach). *Irritants in the environment decrease the client's effectiveness in accessing oxygen during breathing.*
- Refer to GOLD guidelines for management of home care and indications of hospital admission criteria (GOLD, 2015).
- Instruct the client to keep the home temperature above 68° F (20° C) and to avoid cold weather. *Cold air temperatures cause constriction of the blood vessels, which impairs the client's ability to absorb oxygen (Brickley et al, 2012).*
- Instruct the client to limit exposure to persons with respiratory infections. *Viruses, bacteria, and environmental pollutants are the main causes of exacerbations of COPD (Barnett, 2008).*
- Instruct the family in the complications of the disease and the importance of maintaining the medical regimen, including when to call a health care provider.
- ▲ Refer the client for home health aide services as necessary for assistance with activities of daily living. *Clients with decreased oxygenation have decreased energy to carry out personal and role-related activities.*

- When respiratory procedures are being implemented, explain equipment and procedures to family members, and provide needed emotional support. *Family members assuming responsibility for respiratory monitoring often find this stressful (Langer et al, 2009).*
- When electrically based equipment for respiratory support is being implemented, evaluate home environment for electrical safety, proper grounding, and so on. Ensure that notification is sent to the local utility company, the emergency medical team, and police and fire departments. *Notification is important to provide for priority service.*
- ▲ Assess family role changes and coping ability. Refer the client to medical social services as appropriate for assistance in adjusting to chronic illness. *Inability to maintain the level of social involvement experienced before illness leads to frustration and anger in the client and may create a threat to the family unit (Langer et al, 2009).*
- Support the family of the client with chronic illness. *Severely compromised respiratory functioning causes fear and anxiety in clients and their families. Reassurance from the nurse can be helpful (Rose et al, 2014).*

Client/Family Teaching and Discharge Planning

- Teach the client how to perform pursed-lip breathing and inspiratory muscle training, and how to use the tripod position. Have the client watch the pulse oximeter to note improvement in oxygenation with these breathing techniques. **CEB:** *Studies demonstrated that pursed-lip breathing was effective in decreasing breathlessness and improving respiratory function (Faager et al, 2008). A systematic review found that inspiratory muscle training was effective in increasing endurance of the client and decreasing dyspnea (Langer et al, 2009).*
- Teach the client energy conservation techniques and the importance of alternating rest periods with activity. See nursing interventions for **Fatigue**.
- ▲ Teach the importance of not smoking. Refer to smoking cessation programs, and encourage clients who relapse to keep trying to quit. Ensure that clients receive appropriate medications to support smoking cessation from the primary health care provider. **EB:** *A systematic review of research demonstrated that the combination of medications and an intensive, prolonged counseling program supporting smoking cessation were effective in promoting long-term abstinence from smoking (Fiore et al, 2008). A Cochrane review found that use of the medication varenicline (Chantix) increased the rate of smoking withdrawal two to three times more than smoking withdrawal without use of medications (Cahill et al, 2008; GOLD, 2015).*
- ▲ Instruct the family regarding home oxygen therapy if ordered (e.g., delivery system, liter flow, safety precautions). *Long-term oxygen therapy can improve survival, exercise ability, sleep, and ability to think in hypoxemic clients. Client education improves compliance with prescribed use of oxygen (GOLD, 2015).*
- ▲ Teach the client the need to receive a yearly influenza vaccine. *Receiving a yearly influenza vaccine is helpful to prevent exacerbations of COPD (Black & McDonald, 2009).*
- Teach the client relaxation techniques to help reduce stress responses and panic attacks resulting from dyspnea. **EB:** *Relaxation therapy can help reduce dyspnea and anxiety (Langer et al, 2009).*
- Teach the client to use music, along with a rest period, to decrease dyspnea and anxiety (Loscalzo, 2013).

Dysfunctional Gastrointestinal motility

Betty J. Ackley, MSN, EdS, RN, and Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

NANDA-I

Definition

Increased, decreased, ineffective, or lack of peristaltic activity within the gastrointestinal system

Defining Characteristics

Abdominal cramping; abdominal distention; abdominal pain; absence of flatus; acceleration of gastric emptying; bile-colored gastric residual; change in bowel sounds; diarrhea; difficulty with defecation; hard, formed stool; increase in gastric residual; nausea; regurgitation; vomiting

Related Factors (r/t)

Aging; anxiety; enteral feedings; food intolerance; immobility; ingestion of contaminated material (e.g., radioactive, food, water); malnutrition; prematurity; sedentary lifestyle; treatment regimen

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Gastrointestinal Function; Electrolyte and Acid-Base Balance; Fluid Balance; Hydration; Nausea and Vomiting Control; Treatment Behavior: Illness or Injury

Example NOC Outcome with Indicators

Gastrointestinal Function as evidenced by the following indicators: Bowel sounds/Stool soft and formed/Appetite present without evidence of reflux, nausea, or vomiting/Reported normal abdominal comfort. (Rate the outcome and indicators of **Gastrointestinal Function**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see [Section 1](#)].)

Client Outcomes**Client Will (Specify Time Frame)**

- Be free of abdominal distention and pain
- Have normal bowel sounds
- Pass flatus rectally at intervals
- Defecate formed, soft stool every day to every third day
- State has an appetite
- Be able to eat food without nausea and vomiting

NIC (Nursing Interventions Classification)**Suggested NIC Intervention**

Gastric Motility Management

Example NIC Activities—Gastric Motility Management

Evaluate use of prokinetics for delayed gastric motility; Suggest change in dietary habits to either increase or decrease gastric motility, depending on the presenting complaint

Nursing Interventions and Rationales

- Monitor for abdominal distention, and presence of abdominal pain, weight loss, nausea, vomiting, obstipation, or diarrhea. *The acute onset of abdominal distention in conjunction with symptoms of cramping pain, weight loss, nausea, vomiting, obstipation, or diarrhea warrants further evaluation for disorders that cause intestinal obstruction (Camilleri, 2012).*
- Inspect, auscultate for bowel sounds noting characteristics and frequency; palpate and percuss the abdomen. *Hypoactive bowel sounds are found with decreased motility as with peritonitis from paralytic ileus or from late bowel obstruction. Hyperactive bowel sounds are associated with increased motility (Jarvis, 2012).*
- Review history noting any anorexia or nausea/vomiting. Other symptoms may include relation of symptoms to meals, especially if aggravated by food, satiety, postprandial fullness/bloating, and weight loss or weight loss with severe gastroparesis. *These are signs of abnormal gastric motility (Bouras et al, 2013).*
- Monitor for fluid deficits by checking skin turgor and moisture of tongue, daily weights, input and output, and electrolyte values. Refer to care plan deficient **Fluid** volume if relevant.
- ▲ Monitor for nutritional deficits by keeping close track of food intake. Review laboratory studies that affirm nutritional deficits, such as decreased albumin and serum protein levels, liver profile, glucose, and an electrolyte panel. Refer to care plan for imbalanced **Nutrition**: less than body requirements or Risk for **Electrolyte** imbalance as appropriate.

Slowed Gastric Motility

- Monitor the client for signs and symptoms of decreased gastric motility, which may include nausea after meals, vomiting, feeling full quickly while eating, abdominal bloating and abdominal pain (Bouras et al, 2013).

- ▲ Monitor daily laboratory studies and point of care testing blood glucose levels ensuring ordered glucose levels are performed and evaluated. *Elevated blood glucose levels can cause delayed gastric emptying; therefore, it is important to normalize blood glucose levels (Powers, 2012).*
- Obtain a thorough gastrointestinal history if the client has diabetes, because he/she is at high risk for gastroparesis and gastric reflux. *Gastroparesis with delayed emptying of the stomach is a well-known complication of diabetes (Olausson et al, 2014).*
- ▲ If client has nausea and vomiting, provide an antiemetic and intravenous fluids as ordered. Refer to the care plans for **Nausea**.
- ▲ Evaluate medications that the client is taking. Recognize that vasopressors, opioids, or anticholinergic medications can cause gastric slowing (Aderinto-Adike & Quigley, 2014).
- ▲ Review laboratory and other diagnostic tools, including complete blood count, amylase, and thyroid-stimulating hormone level, glucose with other metabolic studies, upper endoscopy, and gastric-emptying scintigraphy. *The diagnosis of diabetic gastroparesis is made when other causes are excluded and postprandial gastric stasis is confirmed by gastric emptying scintigraphy, which is considered the gold standard for diagnosing gastroparesis (Lacy, 2012).*
- ▲ Obtain a nutritional consult, considering a small particle size diet or diets lower or higher in liquids or solids, depending on gastric motility. **EB:** *A randomized controlled trial found that diets with smaller particle size reduced the symptoms of gastroparesis in diabetic clients (Olausson et al, 2014).*
- ▲ If client is unable to eat or retain food, consult with the registered dietitian and health care provider, considering further nutritional support in the form of enteral or parenteral feedings for the client with gastroparesis. *Some clients require supplementation with either enteral or parenteral nutrition for survival.*
- ▲ If client is receiving gastric enteral nutrition, see the care plan Risk for **Aspiration**.
- ▲ Administer medications that increase gastrointestinal motility as ordered (Chang et al, 2011).

Postoperative Ileus

- Observe for complications of delayed intestinal motility. Symptoms include vague abdominal pain and distention, nausea, vomiting, anorexia, sometimes bloating, and tympany to percussion. Clients may or may not pass flatus and some stool (Cagir, 2013).
- ▲ Recommend chewing gum for the abdominal surgery client who is experiencing an ileus, is not at risk for aspiration, and has normal dentition. **EB:** *Gum chewing may decrease postoperative ileus because it acts as a sham feeding, potentially stimulating gastric and bowel motility. A meta-analysis of research found that using chewing gum reduces the time of postoperative ileus (Shan et al, 2013).*
- Help the client out of bed to walk at least two times per day. Assist client to sit in a rocking chair to rock back and forth. *Exercise may increase gastrointestinal motility.*
- ▲ If postoperative ileus is associated with opioid pain medication, ensure opioids are decreased or ideally discontinued. Use nonsteroidal anti-inflammatory drugs for pain as feasible and if not contraindicated (Cagir, 2013).
- ▲ Note serum electrolyte levels, especially potassium and magnesium. *A low potassium level decreases the function of intestinal smooth muscle and can result in an ileus. A low magnesium level makes the body refractory to potassium replacement (Mount et al, 2012; Cagir, 2013).*

Increased Gastrointestinal Motility

- ▲ Observe for complications of gastric surgeries such as dumping syndrome. *This syndrome is the effect of changes in size and function of the stomach, with rapid dumping of hyperosmolar food into the intestines (Bosnic, 2014).*
- Watch for nausea, vomiting, bloating, cramping, diarrhea, dizziness, and fatigue. *These are common signs and symptoms of early rapid gastric emptying (Bosnic, 2014).*
- Monitor for low blood sugar, weakness, sweating, and dizziness 1 to 3 hours after eating as this is when late rapid gastric emptying may occur. Late rapid gastric emptying is associated with low blood sugar (Bosnic, 2014).
- ▲ Order a nutritional consult to discuss diet changes. The diet may vary depending on the kind of surgery causing dumping syndrome. *Encourage small meals that are low in carbohydrates and fats. Space fluids around meal times (Bosnic, 2014).*
- ▲ Give intravenous fluids as ordered for the client complaining of diarrhea with weakness and dizziness. Monitor electrolyte panel. *Severe diarrhea can cause deficient fluid volume with extreme weakness.*

- Offer bathroom, commode, or bedpan assistance, depending on frequency, amount of diarrhea, and condition of client.
- Monitor rectal area for decreased skin integrity, apply barrier creams as needed to protect and treat skin.
- Refer to the care plans for the nursing diagnoses of Deficient **Fluid** volume, **Nausea**, Impaired **Skin** integrity, and **Diarrhea** as relevant.

Pediatric

- Assess infants and children with suspected delayed gastric emptying for fullness and vomiting. *Babies and children with delayed gastric emptying take longer to get hungry again and throw up undigested or partially digested food several hours after feeding* (Waseem et al, 2012; Ambartsumyan & Rodriguez, 2014).
- ▲ Observe for nutritional and fluid deficits with assessment of skin turgor, mucous membranes, fontanelles, furrows of the tongue, electrolyte panel, fluid status, input and output, and daily weights (Saliakellis & Fotoulaki, 2013).
- ▲ Recommend gentle massage for preterm infants as appropriate. **EB:** *With massage, there was increased vagal activity. This was then associated with increased gastric motility and greater weight gain* (Field et al, 2011).

Geriatric

- Closely monitor diet and medication use/side effects as they affect the gastrointestinal system. Watch for constipation. *Many gastrointestinal functions are slowed in older adults* (Grassi et al, 2011).
- ▲ Watch for symptoms of dysphagia, gastroesophageal reflux disease, dyspepsia, irritable bowel syndrome, maldigestion, and reduced absorption of nutrients. *These are common gastrointestinal disorders in older adults* (Grassi et al, 2011).

Client/Family Teaching and Discharge Planning

- Teach the client and caregivers about medications, reinforcing side effects as they relate to gastrointestinal function.
- Teach client and caregivers to report signs and symptoms that may indicate further complications including increased abdominal girth, projectile vomiting, and unrelieved acute cramping pain (bowel obstruction).
- Review signs and symptoms of dehydration with client and caregivers.

Risk for dysfunctional Gastrointestinal motility

Betty J. Ackley, MSN, EdS, RN, and Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

NANDA-I

Definition

Vulnerable to a decrease in normal frequency of defecation accompanied by difficult or incomplete passage of stool, which may compromise health

Risk Factors

G

Aging, anxiety; change in water source; decrease in gastrointestinal circulation; diabetes mellitus; eating habit change (e.g., foods, eating times); food intolerance; gastroesophageal reflux disease; immobility; infection; pharmaceutical agent; prematurity; sedentary lifestyle; stressors; unsanitary food preparation

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan for Dysfunctional Gastrointestinal motility.

Risk for ineffective Gastrointestinal perfusion

Betty J. Ackley MSN, EdS, RN, and Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

NANDA-I

Definition

Vulnerable to decrease in gastrointestinal circulation, which may compromise health

Risk Factors

Abdominal aortic aneurysm; abdominal compartment syndrome; abnormal partial thromboplastin time (PTT); abnormal prothrombin time (PT); acute gastrointestinal hemorrhage; age >60 years; anemia; cerebral vascular accident; coagulopathy (e.g., sickle cell anemia); decrease in left ventricular performance; diabetes mellitus; disseminated intravascular coagulopathy; female gender; gastroesophageal varices; gastrointestinal condition (e.g., ulcer, ischemic colitis, ischemic pancreatitis); myocardial infarction; renal disease (e.g., polycystic kidney, renal artery stenosis, failure); smoking; trauma; treatment regimen; vascular disease

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Perfusion: Abdominal Organs; Gastrointestinal Function; Tissue Perfusion: Cellular; Circulation Status; Knowledge: Treatment Regimen

Example NOC Outcome with Indicators

Tissue Perfusion: Abdominal Organs as evidenced by the following indicators: Diastolic, systolic, and mean arterial blood pressure within normal limits/Bowel sounds active/Urine output within normal limits for age/Electrolyte and acid-base balance within normal limits. (Rate the outcome and indicators of **Tissue Perfusion: Abdominal Organs**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain blood pressure within normal limits
- Remain free from abdominal distention

- Tolerate feedings without nausea, vomiting, or abdominal discomfort
- Pass stools of normal color, consistency, frequency, and amount
- Describe prescribed diet regimen
- Describe prescribed medication regimen including medication actions and possible side effects
- Verbalize understanding of treatment regimen including monitoring for signs and symptoms that may indicate problems with gastrointestinal tissue perfusion, the importance of diet and exercise to gastrointestinal health

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Vital Signs Monitoring; Surveillance; Electrolyte Monitoring; Laboratory Data Interpretation

Example NIC Activities—Surveillance

Monitor gastrointestinal function; Monitor vital signs

Nursing Interventions and Rationales

Critical Care

- ▲ Complete a pain assessment. Assess and document the onset, intensity, character, location, duration, aggravating factors, and relieving factors. Determine whether the pain is exacerbated by eating. Notify the provider for any significant increase in pain. *A significant symptom of mesenteric ischemia is pain that is disproportionate to the physical examination findings. It is an emergent condition and positive outcomes are only possible with treatment in the early stages, preferable within 12 hours (Dang & Su, 2014; Hauser, 2011).*
- Perform a physical abdominal examination including inspection, auscultation, percussion, and palpation. Complete the assessment in the described order. *Initially with decreased perfusion there may be increased bowel sounds, and then absence of bowel sounds (Hauser, 2011).*
- Monitor vital signs frequently as needed, watching for hypotension and tachycardia. *Hemodynamic instability with ischemia or infarction of the gastrointestinal blood supply is a serious situation and can result in death of the client, especially older clients (Dang & Su, 2014; Hauser, 2011).*
- Monitor frequency, consistency, color, and amount of stools. *Clients presenting with sudden cramping, left lower abdominal pain, a strong urge to pass stool, and bright red or maroon blood mixed with the stool should be evaluated for colon ischemia. Obvious bleeding from the gastrointestinal tract is an ominous sign and often suggests bowel infarction (Dang & Su, 2014; Hauser, 2011).*
- Assess for abdominal distention. Measure abdominal girth and compare to client's accustomed waist or belt size. *Ischemia of the gastrointestinal system can result in decreased motility and a paralytic ileus with abdominal distention (Dang & Su, 2014).*
- Review the client's medical and surgical history. Certain conditions place clients at higher risk for ineffective tissue perfusion (see risk factors above). In addition to medical or surgical conditions, lifestyle choices such as smoking or cocaine and amphetamine use affect tissue perfusion (Hauser, 2011). *Gastrointestinal complications following cardiac surgery are rare, but substantially increase morbidity and mortality. Risk factors include age, intraoperative hypoperfusion, and need for high-dose vasopressors (Dang & Su, 2014).*
- Recognize that any client who has been in a shock state has decreased gastrointestinal perfusion due to compensatory mechanisms, and watch for symptoms as identified. *In shock, the blood flow is preferentially shunted away from the gut to the brain and heart to preserve life. Ischemia bowel necrosis is part of the multiple organ dysfunction syndrome that follows a shock state, especially septic shock (Munford, 2012).* See care plan for Risk for **Shock**.
- ▲ Monitor intake and output to evaluate fluid and electrolyte balance, and review laboratory data as ordered.
- ▲ Prepare client for diagnostic or surgical procedures. Diagnostic studies may include abdominal x-ray study to rapidly rule out intestinal obstruction, computed tomography, angiography, and abdominal ultrasound. Surgical procedures include exploratory laparotomy, thrombectomy, surgical revascularization, and/or stent placement (Dang & Su, 2014).

Pediatric

- Monitor vital signs frequently. Notify health care provider if there is significant deviation from baseline or findings are significantly abnormal. **EBN**: *Splanchnic hypoperfusion leads to mucosal ischemia and gastrointestinal dysfunction. Temperature instability, bradycardia, and apnea can be early symptoms of necrotizing enterocolitis in the newborn (Gregory et al, 2011).*
- Monitor oxygen saturation and provide oxygen therapy as ordered. Take steps to prevent hypovolemia and hypotensive episodes. *Untreated acute compartment syndrome leading to elevated intraabdominal pressure can result in multiple organ failure and death (Newcombe, 2012).*
- Monitor tolerance of enteral feedings. Measure gastric residual and note color and consistency. *The premature infant's gastrointestinal system is less able to absorb nutrients. The unabsorbed nutrients can lead to proliferation of enteral bacteria, which can produce intestinal gas, which leads to distention, increased pressure in the lumen of the intestine, and decreased circulation (Gregory et al, 2011).*

Geriatric

- ▲ Monitor for gastrointestinal side effects from medications, especially nonsteroidal antiinflammatory drugs (NSAIDs). *NSAIDs cause local tissue hypoxia due to vasoconstriction, resulting in gastric and duodenal ulcers, perforation, and possibly hemorrhage, especially in older adults (Wehling, 2014).*
- ▲ Recognize that decreased gastrointestinal perfusion, either acute or chronic, is much more common in older adults. *Risk factors for ischemia of the bowel are primarily older age and increased atherosclerosis (Dang & Su, 2014).*
- ▲ Be aware that gastrointestinal bleeding that is difficult to control in older adults may be associated with decreased gastrointestinal perfusion (Hauser, 2011).

Risk for unstable blood Glucose level Paula D. Hopper, MSN, RN, CNE

NANDA-I

Definition

Vulnerable to variation in blood glucose/sugar levels from the normal range, which may compromise health

Risk Factors

Alteration in mental status; average daily physical activity is less than recommended for gender and age; compromised physical health status; delay in cognitive development; does not accept diagnosis; excessive stress; excessive weight gain; excessive weight loss; inadequate blood glucose monitoring; ineffective medication management; insufficient diabetes management; insufficient dietary intake; insufficient knowledge of disease management; nonadherence to diabetes management plan; pregnancy; rapid growth period

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Compliance Behavior: Prescribed Diet; Compliance Behavior: Prescribed Medication; Coping; Endurance; Knowledge: Diabetes Management; Knowledge: Treatment Regimen; Nutritional Status; Personal Health Status; Self-Management: Diabetes; Weight Maintenance Behavior

Example NOC Outcome with Indicators

Blood Glucose Level as evidenced by the following indicators: Blood glucose/Glycosylated hemoglobin/Fructosamine/Urine glucose/Urine ketones. (Rate the outcome and indicators of **Blood Glucose Level**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

G

Client Outcomes**Client Will (Specify Time Frame)**

- Maintain A_{1C} less than 7% (normal level 4% to 6%) (American Diabetes Association [ADA], 2014)
- Maintain outpatient preprandial blood glucose in adults between 70 and 130 mg/dL (ADA, 2014a); consult primary care provider for client-specific goals
- Maintain preprandial blood glucose for preschoolers (0 to 6 years) between 100 and 180 mg/dL; school age (6 to 12 years) between 90 and 180 mg/dL; adolescents and young adults (13 to 19 years) between 90 and 130 mg/dL (ADA, 2014a)
- Maintain outpatient peak postprandial (1 to 2 hours after beginning of meal) glucose below 180 mg/dL (ADA, 2014a)
- Maintain preprandial blood glucose for gestational diabetes ≤95 mg/dL, 1-hour pc level at or below 140 mg/dL, and 2-hour pc level at or below 120 mg/dL (ADA, 2014a)
- Maintain premeal, bedtime, and overnight blood glucose for a pregnant mother with preexisting type 1 or 2 diabetes at 60 to 99 mg/dL, peak postprandial glucose at 100 to 129 mg/dL, and A_{1C} <6% (ADA, 2014a)
- Maintain blood glucose in critically ill hospitalized clients between 140 and 180 mg/dL (ADA, 2014a)
- Maintain premeal blood glucose values in non-critically ill hospitalized clients below 140 mg/dL and random blood glucose values below 180 mg/dL (ADA, 2014a)
- Collaborate with health care provider to individualize goal glucose levels, based on duration of diabetes, age and life expectancy, comorbid conditions, hypoglycemia unawareness, and individual client considerations (ADA, 2014a)
- Demonstrate how to accurately test blood glucose
- Identify self-care actions to take to maintain target glucose levels
- Identify self-care actions to take if blood glucose level is too low or too high
- Demonstrate correct administration of prescribed medications
- Demonstrate knowledge of appropriate diet and carbohydrate intake

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Hypoglycemia Management; Hyperglycemia Management

Example NIC Activities—Hypoglycemia Management

Monitor blood glucose levels, as indicated; Provide simple carbohydrate, as indicated

Nursing Interventions and Rationales

▲ Obtain blood glucose before meals and snacks. Obtain blood glucose every 4 to 6 hours in the client not receiving nutrition. **EB**: Self monitoring of blood glucose (SMBG) is useful in adjusting premeal insulin doses (ADA, 2014a). **EB**: Evidence supports a correlation between SMBG frequency and lower A_{1C} (ADA, 2014a).

- ▲ Evaluate blood glucose levels in hospitalized clients before administering oral hypoglycemic agents or insulin. Adjust timing of medication appropriately with meal times. *Inappropriately timed insulin can result in hypoglycemia (ADA, 2014a).*
- ▲ Recognize that SMBG may not be beneficial in clients who have had type 2 diabetes for more than 1 year and who are not taking insulin. **EB:** *A systematic review of 12 research studies concluded that SMBG in clients with type 2 diabetes for more than 1 year did not significantly affect glycemic control, quality of life, well-being, or client satisfaction (Malanda, 2012).*
- ▲ Monitor blood glucose every 30 minutes to 2 hours for clients on continuous insulin drips. **EB:** *More frequent blood glucose testing ranging from every 30 minutes to every 2 hours is required for clients on intravenous insulin infusions (ADA, 2014a).*
- Consider continuous glucose monitoring (CGM) in clients with type 1 diabetes on intensive insulin regimens. **EB:** *“When used properly, continuous glucose monitoring (CGM) in conjunction with intensive insulin regimens is a useful tool to lower A_{1C} in selected adults (aged ≥25 years) with type 1 diabetes” (ADA, 2014a).* **EB:** *In a study of children and adults with type 1 diabetes, CGM was associated with reduced time spent in hypoglycemia and a concomitant decrease in A_{1C} (Battelino et al, 2011).*
- ▲ Evaluate A_{1C} level for glucose control over previous 2 to 3 months. **EB:** *Two primary techniques are available to assess the effectiveness of the management plan on glycemic control: client SMBG or interstitial glucose and A_{1C} (ADA, 2014a).*
- Consider monitoring 1 to 2 hours after meals in individuals who have premeal glucose values within target but have A_{1C} values above target. **EB:** *“It is clear that postprandial hyperglycemia, like preprandial hyperglycemia, contributes to elevated A_{1C} levels” (ADA, 2014a).*
- Monitor for signs and symptoms of hypoglycemia, such as shakiness, dizziness, sweating, hunger, headache, pallor, behavior changes, confusion, or seizures. **EB:** *“Mild hypoglycemia may be inconvenient or frightening to patients with diabetes. Severe hypoglycemia can cause acute harm to the person with diabetes or others, especially if it causes falls, motor vehicle accidents, or other injury” (ADA, 2014a).*
- ▲ Be alert for hypoglycemia in clients receiving 0.6 unit/kg insulin or more daily, and in clients receiving NPH insulin. **EB:** *“Higher weight-based insulin doses are associated with greater odds of hypoglycemia independent of insulin type ... 0.6 unit/kg seems to be a threshold below which the odds of hypoglycemia are relatively low ... patients who received NPH trended toward greater odds of hypoglycemia compared with those given other insulins” (Rubin et al, 2011).*
- ▲ If client is experiencing signs and symptoms of hypoglycemia, test glucose; if result is below 70 mg/dL, administer 15 to 20 g glucose. Pure glucose is the preferred treatment, but any form of carbohydrate that contains glucose will suffice (½ cup fruit juice or regular [not diet] soda, 1 cup milk, 1 small piece of fruit, or 3 to 4 glucose tablets). Avoid treating with foods that contain fat. Repeat test in 15 minutes and repeat treatment if indicated. Once blood glucose returns to normal, the individual should consume a meal or snack to prevent recurrence of hypoglycemia. **EB:** *Treatment of hypoglycemia (plasma glucose <70 mg/dL) requires ingestion of glucose- or carbohydrate-containing foods. The acute glycemic response correlates better with the glucose content than with the carbohydrate content of the food. Although pure glucose is the preferred treatment, any form of carbohydrate that contains glucose will raise blood glucose. Added fat may retard and then prolong the acute glycemic response” (ADA, 2014a).*
- ▲ If the client is unable to swallow, parenteral glucagon may be given by a trained family member or by medical personnel. In unresponsive clients, intravenous glucose should be given. **EB:** *Intravenous dextrose or injected glucagon are alternatives to oral carbohydrate in hypoglycemic clients who cannot take oral glucose (AACE, 2014).*
- ▲ Clients who do not experience symptoms of hypoglycemia should raise their glucose targets to avoid hypoglycemia for several weeks. **EB:** *If the client has hypoglycemic unawareness and hypoglycemia-associated autonomic failure, several weeks of hypoglycemia avoidance may reduce the risk or prevent the recurrence of severe hypoglycemia (AACE, 2014).* **EB:** *Insulin-treated clients with hypoglycemia unawareness or an episode of severe hypoglycemia should be advised to raise their glycemic targets to strictly avoid further hypoglycemia for at least several weeks, to partially reverse hypoglycemia unawareness and reduce risk of future episodes (ADA, 2014a).*
- ▲ In clients with type 2 diabetes who become hypoglycemic and have been treated with an alpha-glucosidase inhibitor (e.g., acarbose [Precose] or miglitol [Glyset]) in addition to insulin or an insulin release stimulator, oral glucose rather than more complex carbohydrates must be given. **EB:** *Alpha-glucosidase inhibitors inhibit the breakdown and absorption of complex carbohydrates and disaccharides (AACE, 2014).*

- Monitor for signs and symptoms of hyperglycemia, such as increased thirst or urination, or high blood or urine glucose levels. **EB:** *“Improved glycemetic control is associated with significantly decreased rates of microvascular (retinopathy and nephropathy) and neuropathic complications” (ADA, 2014a).*
- ▲ Ensure an acutely ill client is receiving adequate fluids and nutrition. Adjustment in oral hypoglycemic or insulin therapy may be required. **EB:** *“The stress of illness, trauma, and/or surgery frequently aggravates glycemetic control and may precipitate diabetic ketoacidosis (DKA) or nonketotic hyperosmolar state, life-threatening conditions that require immediate medical care to prevent complications and death” (ADA, 2014a).*
- ▲ Test urine or blood for ketones in ketosis-prone clients during acute illness, trauma, surgery, or stress. *“If accompanied by ketosis, vomiting, or alteration in level of consciousness, marked hyperglycemia requires temporary adjustment of the treatment regimen and immediate interaction with the diabetes care team” (ADA, 2014a).*
- ▲ Prime intravenous (IV) tubing with 20 mL of diluted insulin solution before initiating insulin drip. **CEB:** *Glucose adsorbs to some IV tubing; priming with 20 mL is enough to minimize this effect (Goldberg et al, 2006; Zahid et al, 2008).*
- ▲ Evaluate client’s medication regimen for medications that can alter blood glucose. *Catecholamines, some antipsychotic and antidepressant agents, thiazide diuretics, glucocorticoids, and niacin, among others, can cause hyperglycemia. Alcohol, aspirin, and beta-blockers are among agents that can cause hypoglycemia (National Prescribing Service [NPS], 2011).*
- ▲ Refer client to dietitian for carbohydrate counting instruction. **EB:** *“Monitoring carbohydrate intake, whether by carbohydrate counting or experience-based estimation, remains a key strategy in achieving glycemetic control” (ADA, 2014a).*
- ▲ Refer overweight clients to dietitian for weight loss counseling. **EB:** *“Modest weight loss may provide clinical benefits (improved glycemia, blood pressure, and/or lipids) in some individuals with diabetes, especially those early in the disease process” (ADA, 2014a).*
- For interventions regarding foot care, refer to the care plan Ineffective peripheral **Tissue Perfusion**.

Geriatric

- Watch for age-related cognitive changes that can impair self-management of diabetes. **EBN:** *“In older people taking insulin, around one quarter of those aged over 75 years had evidence of cognitive impairment, which significantly reduced their ability to understand the actions required in the event of low blood glucose” (Phillips & Phillips, 2011).*
- Monitor for vision and dexterity impairments that may affect the older client’s ability to accurately measure insulin doses. **EB:** *Medication therapy can present a challenge due to possible visual and dexterity impairments (Pfützner et al, 2011).*
- ▲ Consider relaxing glucose targets for older adults with advanced diabetes complications, life-limiting comorbid illness, or substantial cognitive or functional impairment. **EB:** *“These patients are less likely to benefit from reducing the risk of microvascular complications and more likely to suffer serious adverse effects from hypoglycemia” (ADA, 2014a).* **EB:** *“A large cohort study suggested that among older adults with type 2 diabetes, a history of severe hypoglycemia was associated with greater risk of dementia” (ADA, 2014a).*
- Teach older clients the importance of verifying symptoms with a glucometer reading. **EB:** *A study of older adults found that they were unable to identify whether symptoms indicated high or low blood glucose. Common symptoms included sensations such as tingling or numbness, lightheadedness, dizziness, lack of energy, and blurred vision (Kirk et al, 2011).*

Pediatric

- Be aware that young children (<7 years) may not be aware of symptoms of hypoglycemia. **EB:** *“For young children (<7 years old), glycemetic goals may need to be modified because most children at that age have a form of ‘hypoglycemic unawareness,’ including immaturity of and a relative inability to recognize and respond to hypoglycemic symptoms. This places them at greater risk for severe hypoglycemia” (ADA, 2014a).*
- Teach children and adolescents (and their parents) with type 1 diabetes or on intensive insulin regimens (MDI or insulin pump therapy) to perform SMBG before meals and snacks, occasionally postprandially, at bedtime, before exercise, when they suspect low blood glucose, after treating low blood glucose until they are normoglycemic, and before critical tasks such as driving. **EB:** *A database study of almost 27,000*

children and adolescents with type 1 diabetes showed that ... increased daily frequency of SMBG was significantly associated with lower A_{1C} (-0.2% per additional test per day, leveling off at five tests per day) and with fewer acute complications (ADA, 2014a). **EB:** An “observational study shows a strong association between more frequent SMBG in the range of 0-5 per day and better metabolic control in adolescents above 12 yr of age” (Ziegler et al, 2011).

- Teach self-efficacy measures to adolescents with type 1 diabetes who are involved in family conflict. **CEB:** The effect of family conflict on frequency of SMBG is reduced when adolescents are taught self-efficacy (Sander et al, 2010).

Home Care

- ▲ Teach family and others having close contact with the person with diabetes how to use an emergency glucagon kit (if prescribed). Severe hypoglycemia in which client is unable to take oral glucose should be treated with glucagon (ADA, 2014a).

Multicultural

- Provide culturally appropriate diabetes health education. **EB:** Ten of 11 studies reviewed showed that structured intervention tailored to ethnic minority groups by integrating elements of culture, language, religion, and health literacy skills produced a positive impact on a range of outcomes (Zeh et al, 2012).
- Involve Hispanic community workers (promotoras) when working with Hispanic clients with diabetes. **CEB:** Improved A_{1C} level was associated with promotora advocacy and participation in promotora-led support groups (Ingram et al, 2007).
- Provide culturally adapted diabetes self-management education for African American clients with diabetes. **EB:** A systematic review of 32 research articles found that culturally appropriate education reduced HbA_{1c} in African American clients by 0.8% (Ricci-Cabello et al, 2013).
- Encourage involvement of African American client's family and friends in diabetes education activities. **CEB:** “Support from family, peers, and health care providers positively influenced adherence behaviors by providing cues to action, direct assistance, reinforcement, and knowledge” (Chlebowy et al, 2010).

Client/Family Teaching and Discharge Planning

- Provide “survival skills” education or review for hospitalized clients, including information about (1) identification of the health care provider who will provide diabetes care after discharge, (2) diagnosis of diabetes, SMBG, and explanation of home blood glucose goals, (3) information on consistent eating patterns, (4) when and how to take medications including insulin administration, (5) proper use and disposal of needles and syringes if applicable, (6) definition, recognition, treatment, and prevention of hyperglycemia and hypoglycemia, and (7) sick-day management. **EB:** “For the hospitalized patient, diabetes ‘survival skills’ education is generally a feasible approach to provide sufficient information and training to enable safe care at home” (ADA, 2014a).
- Evaluate clients’ monitoring technique initially and at regular intervals. Accuracy of SMBG is instrument- and user-dependent (ADA, 2014a).
- Teach client how to match prandial insulin dose to carbohydrate intake, premeal blood glucose, and anticipated activity. **EB:** “Results of SMBG can be useful in preventing hypoglycemia and adjusting medications (particularly prandial insulin doses), medical nutrition therapy (MNT), and physical activity” (ADA, 2014a).
- ▲ Refer client for Blood Glucose Awareness Training (BGAT) or Web-based training available at <http://www.BGAThome.com> for instruction in detection, anticipation, avoidance, and treatment of extremes in blood glucose levels. **CEB:** BGAT has been shown to significantly reduce both hypoglycemia and hyperglycemia (Cox et al, 2006), and BGAThome resulted in significant clinical improvements (Cox et al, 2008).
- Teach client to maintain a blood glucose log. A results log can help clients track their response to treatment. Many logs are available online (ADA, 2014b).
- Provide group-based training programs for instruction. **EB:** “Comprehensive group diabetes education programs including nutrition therapy or individualized education sessions have reported A_{1C} decreases of 0.3% to 1% for type 1 diabetes and 0.5% to 2% for type 2 diabetes” (ADA, 2014a).
- Teach client the importance of at least 150 minutes/week of moderate-intensity aerobic physical activity (50% to 70% of maximum heart rate), spread over at least 3 days per week. **EB:** “Regular exercise has been shown to improve blood glucose control, reduce cardiovascular risk factors, contribute to weight loss, and improve well-being (ADA, 2014a).

- Discuss recommending resistance training with client's provider. **EB**: *Clinical trials have provided strong evidence for the A_{1c}-lowering value of resistance training in older adults with type 2 diabetes and for an additive benefit of combined aerobic and resistance exercise in adults with type 2 diabetes (ADA, 2014a).*
- Teach client with type 1 diabetes to avoid vigorous activity if ketones are present in urine or blood. Exercise can worsen hyperglycemia and ketosis in people deprived of insulin for 12 to 48 hours (ADA, 2014a).
- Teach clients who are treated with insulin or insulin-stimulating oral agents to eat added carbohydrates before exercise if glucose levels are below 100 mg/dL. Physical activity can cause hypoglycemia if medication dose or carbohydrate consumption is not altered (ADA, 2014a).
- ▲ Teach clients on multiple-dose insulin or insulin pump therapy to perform SMBG before critical tasks such as driving. **EB**: *"Patients should understand ... that hypoglycemia may increase the risk of harm to self or other such as with driving" (ADA, 2014a).*
- ▲ Teach clients to use alcohol with caution. **EB**: *Alcohol consumption may place people with diabetes at increased risk for delayed hypoglycemia, especially if taking insulin or insulin secretagogues (ADA, 2014a).*

Grieving

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

A normal complex process that includes emotional, physical, spiritual, social, and intellectual responses and behaviors by which individuals, families, and communities incorporate an actual, anticipated, or perceived loss into their daily lives

Defining Characteristics

Alteration in activity level; alteration in dream pattern; alteration in immune functioning; alteration in neuroendocrine functioning; alteration in sleep pattern; anger; blaming; despair; detachment; disorganization; finding meaning in a loss; guilt about feeling relieved; maintaining a connection to the deceased; pain; panic behavior; personal growth; psychological distress; suffering

Related Factors (r/t)

Anticipatory loss of significant object (e.g., possession, job status); anticipatory loss of significant other; death of significant other; loss of significant object (e.g., possession, job, status, home, body part)

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Grief Resolution; Dignified Life Closure; Hope; Psychosocial Adjustment: Life Change

Example NOC Outcome with Indicators

Grief Resolution as evidenced by the following indicators: Resolves feelings about the loss/Verbalizes reality and acceptance of loss/Maintains living environment/Seeks social support. (Rate the outcome and indicators of **Grief Resolution**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)].)

Client/Family Outcomes

Client/Family Will (Specify Time Frame)

- Discuss meaning of the loss to his/her life and the functioning of the family
- Identify ways to support family members and articulate methods of support he/she requires from family and friends
- Accept assistance in meeting the needs of the family from friends/extended family

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Grief Work Facilitation; Dying Care; Emotional Support: Perinatal Death; Hope Instillation; Support System Enhancement; Family Support; Family Integrity Promotion

Example NIC Activities—Grief Work Facilitation

Identify the loss; Encourage expression of feelings about the loss; Assist to identify personal coping strategies; Identify sources of community support

Nursing Interventions and Rationales

Anticipatory Grieving Interventions

- Grieving of a critically ill or dying client and clients' family/relatives for the losses experienced during the deteriorating illness, and the future that will be filled with loss. **EB:** *Boer et al (2014) validated the use of the Acceptance of Disease and Impairments Questionnaire scale with clients (N = 145) with chronic obstructive pulmonary disease to identify the four stages of grieving that clients go through: denial, resistance, sorrow, and acceptance.*
- Develop a trusting relationship both with the client and with the family by using presence and therapeutic communication techniques. **EB:** *Hobgood et al (2013) studied emergency medical services personnel's (N = 30) preparation for notifying family about deaths using a program called GRIEVING and found an increase in confidence and competency, but communication was not significantly changed, warranting further research in this population of health care providers.* **EBC:** *Janze and Henriksson (2014) qualitatively explored family experiences when providing care to a terminally ill partner. Two themes resulted: (1) living in uncertainty and (2) preparing for caregiving in the awareness of death. Both issues can be addressed by therapeutic nursing communication.*
- Keep the family apprised of the client's ongoing condition as much as possible. Consult with the family for decision-making as appropriate. **EBC:** *McLeod-Sordjan (2014) found that 40% of older clients require decision-making and communication in the final days of life. Part of that communication should be about death preparedness with a health care provider regarding how the client would like their end of life to unfold and developing a plan.*
- Keep the family informed of client's needs for physical care and support in symptom control, and inform them about health care options at the end of life, including palliative care, hospice care, and home care. **EB:** *In a multicultural qualitative study, Angelo and Wilson (2014) explored participants' (N = 6) experiences in caring for a dying family member. Important themes were food preparation, spirituality, and family gathering.*
- Discuss preferred place of death (PPD) with client. **EB:** *Kulkarni et al (2014) studied the PPD by questionnaire and found that most people preferred to die at home where they would be more comfortable; therefore, clients should be asked about their PPD.* **EBC:** *Evans et al (2014) studied whether clients changed their PPD and found that the majority of clients (N = 204) in palliative care were able to identify a PPD and only 15% changed their PPD as the time of death approached.*
- Ask family members if they are receiving sufficient sleep. If a family member desires to be in the room for sleep, provide a reclining chair or portable bed if possible, and bedding to keep the family member comfortable. If needed, find housing for family member from out of town with support of case manager or social worker. **EB:** *Estevens et al (2014) qualitatively studied primary caregiver's perspective when caring for a terminally ill client and found that caregivers wanted to be in that role and also preferred the death to take place at home.* **EBC:** *Dosser and Kennedy (2014) completed a participatory action research study to determine family support at the end of life in a hospital setting and identified two things that would assist them: (1) improving nurses' communication skills and (2) improving the environment for family caregivers.*
- Ask family member about having adequate resources to care for themselves and the critically ill family member. **EBC:** *Cowan (2014) explored the experiences of Sikh (English) clients (N = 6) when caring for a dying client at home and found five themes: (1) being placed in the caring role, (2) emotional effects on the caregiver, (3) impact on family, (4) influence of health care services, and (5) religious influence. Additionally, clients felt a lack of support from health care professionals and did not always know about available services.*
- Listen to the family member's story. **EB:** *Gillies et al (2014) developed a reliable 30-category codebook with negative and positive themes from analysis of adults (N = 162) who were grieving to help professionals provide support to families who were losing a loved one.*
- Encourage family members to show their caring feelings and talk to the client. **EBC:** *Devery et al (2014) completed a systematic review of the literature (N = 8) about death bed phenomena (DBP), which is when a dying client recalls a significant dream or sees a dead relative and the experience is deeply meaningful. The research demonstrated that DBP brings comfort, peace, and reassurance; therefore, the significance of DBP should be recognized and health professionals and families should encourage clients to discuss them.*

- Recognize and respect different feelings and wishes from both the family members and the client. **EB:** *Researchers investigated whether homebound end-of-life clients (N = 77) had anticipatory medications prescribed for comfort and found only 54% had anticipatory medications prescribed and only 15% had prescriptions for recommended anticipatory medications, noting more attention by health professionals needs to be paid to making sure families have the proper medications to care for their loved one (Finucane et al, 2014).*
- If necessary, refer a family member for counseling or to a minister/priest to help him/her cope with the existential questions and current overwhelming reality. **EBN:** *Ramezani et al (2014) completed a concept analysis of spiritual care (N = 158) and found the attributes include healing presence, therapeutic use of self, intuitive sense, exploration of the spiritual perspective, client-centeredness, and creating a spiritually nurturing environment. Establishing a definition of spiritual care was done to increase nursing knowledge about holistic client care.*
- Recognize that one family member may be in a state of caregiver role strain from a long caregiving situation. **EBN:** *Yang et al (2014) investigated the role strain of family caregivers (N = 197) of clients with dementia using a cross-sectional correlational survey and found that having resources, predictability, and being prepared moderated the effects of role strain.*
- Promote the family roles as appropriate. **EBN:** *Al-Gamal (2013) used a cross-sectional descriptive correlational design to understand parents (N = 204) caring for a child with cerebral palsy (CP) and found that parents had high levels of anticipatory grief and lower quality of life compared with other parents who did not have a child with special needs child.*
- Promote mutual goal setting where decisions are made together that affect the family. **EBN:** *McLeod (2014) studied end-of-life decision-making related to intensive care unit (ICU) clients and families and explored ICU nurses' (N = 6) experiences in withdrawing treatment. The researcher concluded that treatment withdrawal creates significant professional and personal dilemmas that call for open discussion and collaborative decision-making with other health care professionals as well as family members.*

Grieving Interventions When Death of a Loved One Occurs

- Use the following activities when interacting with the bereaved person:
 - Be present and attentive, use active empathetic listening. **EBN:** *Researchers qualitatively explored the beliefs of recently bereaved clients (N = 46) about death to better understand bereavement care and found three themes: (1) death was described in terms of religious, dualist, eco-spiritualist, materialist, and death-as-transition; (2) life after death such as resurrection, reuniting, and reincarnation; and (3) relationship with the deceased person continuing after death due to a sense of presence (Draper et al, 2014).*
 - Validate the client's feelings of grief and feeling hurt, stressful, anxious, out of control, and further symptoms of grieving. **EBN:** *Ly Thuy et al (2014) sampled 251 palliative nurses who identified that they need to feel more competent in pain management, psychological and spiritual care, and communication while working with terminally ill oncology clients in order to better handle their clients' feelings and needs.*
 - Provide time and space for the person to tell their story of loss. **EBN:** *Braband et al (2014) conducted a qualitative study to evaluate the use of the Memory Book intervention for grief and loss recovery and found that it helped children to work through loss and grief when they are assisted in preserving and telling their story. Memory books may be a helpful nursing interaction for older clients also.*
 - Offer condolences: "I am sorry that you lost your husband." **EB:** *Collins (2014) explored by longitudinal method (18 months) the experiences of older widowed women (N = 26) and found the following themes: (1) family friction, (2) dependence, (3) additional losses, (4) overcommitment, (5) passivity, and (5) feeling different from other women.*
 - Explain that feelings will oscillate as the person does grief work, from coping to accept the loss to coping to build a new life without the loved one. **EB:** *Funk et al (2013) studied health care workers' (N = 11) grief management related to end-of-life care and reported personnel challenges due to witnessing death and experiencing loss; personnel often felt helplessness and frustration. To overcome negative feelings, participants often used "consoling refrains," such as, "Such is life," "They are better off," "They had a full life," "I did my best," and "I experience rewards."*
 - Intentionally schedule meetings with family members to provide support during grieving. **EBN:** *Lee and King (2014) found that caregivers of hemodialysis clients experience psychological stress, including death anxiety, unresolved grieving, and burnout, and found in their quantitative study that educational classes decreased participants' level of death anxiety and emotional exhaustion.*

- Refer to mental health providers as needed. **EB:** *Breen and O'Connor (2013) found inequalities in service delivery for cancer clients and their families (N = 11) living in rural areas. Lack of grief referral availability was categorized as (1) inequity of services, (2) strain being the “Jack of all trades” role, (3) lack of education, and (4) challenges in delivering post-bereavement services.*
- Help the client use a method to give voice to his unique story of loss. Methods include keeping a personal journal to record feelings and insights, retelling of the loss narrative to a caring person, music therapy techniques with a trained therapist or listening to music that has significance to the relationship, use of the “virtual dream,” a dreamlike short story written by the grieving person to tell the narrative of the loss.
- Discuss coping methods with the grieving person. Common coping techniques include exercise, telling the story of grief to a caring person, journaling, pets, and developing a legacy for the deceased. **EB:** *Parikh and Servaty-Seib (2013) studied college students’ (N = 23) beliefs about supporting a grieving friend using open-ended questions and found that students listened supportively to a friend in need and found a quiet place to do so.*
- Encourage the family to create a quiet and comfortable healing environment, and follow comforting grief rituals such as prayer, interacting with nature, or lighting votive candles. **EB:** *A study looked at how parents (N = 155) make meaning out of the loss of a child and found that many clients use spiritual and religious meanings and the cultivation of empathy for the suffering of others (Lichtenthal et al, 2013).*
- Refer the family members for spiritual counseling if desired. **EBN:** *Hatamipour et al (2015) qualitatively studied spiritual needs of cancer clients (N = 18) in Iran and identified four themes (connection, peace, meaning and purpose, and transcendence) that were integrated with verbalization about social support, normal behavior, inner peace, seeking forgiveness, hope, acceptance of reality, seeking meaning, ending well, change of life meaning, strengthening spiritual belief, communication with God, and prayer.*
- Help the family determine the best way and place to find social support. Encourage family members to continue to use supports as needed for years. **EBN:** *A qualitative study using a grounded theory method described how nurses (N = 22) engaged with families who had a member in palliative care and found that different families had different expectations, and the best intervention was to provide engaged and consistent care (Namasivavam et al, 2014).*
- Identify available community resources, including bereavement groups at local hospitals and hospice centers. Volunteers who provide bereavement support can also be effective. **EBN:** *Jennings and Nicholl (2014) investigated the bereavement support of mothers following the death of their child with a qualitative descriptive design study and found that the mothers used a combination of informal and formal bereavement support.*
- Refer to complicated **Grieving** if grieving fails to follow normative (or cultural) expectations and manifests in functional impairment.

Pediatric/Parent

- Treat the child/parents with respect, give him/her opportunity to talk about concerns and answer questions honestly. **EB:** *Quinn-Lee (2014) studied social workers’ experience (N = 22) with grieving children by a qualitative online method and found four main themes: (1) barriers prevent helping grieving students, (2) grief is defined differently by children, (3) social workers are not always prepared to deal with grief, and (4) students may need referrals to outside resources. **EB:** Researchers retrospectively looked at the time between extubation and documented cardiorespiratory in neonates (N = 117) who died in a neonatal intensive care unit in order to provide parents with a realistic time frame to assist with grieving (Saha & Kent, 2014).*
- Listen to the child’s expression of grief. **EBN:** *A qualitative study with parents (N = 8) demonstrated that reactions to young children’s grief was a balance between shielding including, informing/frightening, and creating a new life/cherishing the old (Bugge et al, 2014).*
- Help parents recognize that the grieving child does not have to be “fixed”; instead they need support going through an experience of grieving just as adults do. **EB:** *Researchers performed a mixed-methods investigation to study the impact of maternal death on families and children; findings demonstrated that maternal death has different effects on boy and girl children, and actually increases the risks for girl children to get married and pregnant early and to drop out of school in South Africa. Similar studies are needed in other populations (Yamin et al, 2015).*

- Consider the use of art for children in hospice care who are dying or dealing with the death of a parent, sibling, or other family member. **EB:** *Researchers tested a new intervention (MEND), which includes dialogue and art therapy to address the needs of families (N = 22) with a child with a chronic illnesses. Results demonstrated that the MEND program had positive effects across many psychosocial measures (Distelberg et al, 2014).*
- ▲ Refer grieving children and parents to a program to help facilitate grieving if desired, especially if the death was traumatic. **EB:** *A qualitative study of Israeli parents (N = 16) whose children were killed in terror attacks revealed, through interviews, four themes: (1) inclusiveness is helpful, (2) the “family of the bereaved” is most important in the healing process, (3) nongovernmental services are preferred, and (4) engaging in the heritage of the Jewish people helped (Possick et al, 2014).*
- Help the adolescent determine sources of support and how to use them effectively. **EB:** *A study looked at parental death in South African adolescents (N = 381) and its impact on functioning, comparing double, single, and non-orphans and examined bereavement, depression, behavior problems, and violence. Results showed double orphans had increased depression and poorer psychosocial functioning, and were more likely to be abused than single orphans or non-orphans (Sherr et al, 2014).*
- Encourage grieving parents to take good care of their own health. **EB:** *Aho et al (2013) investigated the experiences of peer supporters (N = 16) of bereavement interventions for grieving parents to analyze the program that included a support package for grieving parents, peer supporters’ contact, and health care personnel’s contact with parents and found that parents were willing to receive peer support and peer supporters were a good resource to encourage parents to care for themselves during the time of grieving.*
- ▲ Encourage grieving parents to seek mental health services as needed. The death of a child is regarded as among the most traumatic, incomprehensible, and devastating of losses, with the potential to precipitate a crisis of meaning for the bereaved parent. **EBN:** *Brännström (2014) did literature review (N = 55) about women who experienced a sudden infant death and found three themes: (1) women bear guilt and accountability, (2) social ordering portrays women as principal caregiver, and (3) women are marginalized socially in family policies. The researchers encourage further studies to recognize infant nursing practices, gender equality, and safe parenthood in child health research and nursing practices.*
- Recognize that men and women often grieve differently, and explain this to parents if it becomes an issue. **EBN:** *Steen (2015) studied multicultural perinatal bereavement interventions (N = 59) by using a cross-sectional method and found differences in interventions by nurses/midwives in different countries regarding knowledge, communication skills, and management of personal feelings, indicating that consistent bereavement information is needed.*
- Recognize that mothers who have a miscarriage/stillbirth grieve and experience sorrow because of loss of the child. **EBN:** *Tseng et al (2014) completed a qualitative descriptive study about women (N = 21) after stillbirth in which clients described a three-stage emotional journey of recovery: (1) suffering from silent grief, (2) searching for a way out, and (3) achieving peace of mind.*

Geriatric

- Monitor an older adult who has been treated for bereavement-related depression for relapse or recurrence. **EB:** *Holland et al (2013) studied older clients (N = 169) who lost their spouses to identify what grief experiences predict “intensified grieving” and found that early experiences of nonacceptance significantly predict more intense grief experiences later, suggesting that health professionals working with older clients should pay close attention to nonacceptance.*
- Provide support for the family when the loss is associated with dementia of the family member. **EBN:** *Graneheim et al (2014) completed a meta-ethnographic study that included 180 descriptions of caregivers’ experiences of relinquishing the care of a family member with dementia to a nursing home. The experiences were described as a three-stage grieving process: (1) being responsible for the decision, (2) living with the decision, and (3) adjusting to a role and changed relationship.*
- Determine the social supports of older adults. **EBN:** *Bellamy et al (2014) interviewed older clients on the telephone about their experiences and sources of bereavement support following the death of a spouse and found that family and friends, as well as community organizations, played a fundamental supporting role for older bereaved adults.*

Multicultural

- See interventions and rationales in care plans for complicated **Grieving** and chronic **Sorrow**.

Home Care

- The interventions previously described may be adapted for home care use.
- Assessment of activities of daily living (ADLs) and instrumental ADLs is essential as part of comprehensive care after a home care client has suffered the loss of a loved one. **EBN:** *Joo and Huber (2014) studied client-centered care provided in the community by conducting an integrative review (N = 6) and found that community-based case management significantly reduced hospital access outcomes, especially readmissions, and increased cost effectiveness, client clinical outcomes, and satisfaction.*
- Actively listen as the client grieves for his or her own death or for real or perceived loss. Normalize the client's expressions of grief for self. Demonstrate a caring and hopeful approach. **EB:** *Risk (2013) presented a case study of a client suffering from Parkinson's disease and used narrative theory to help the client develop new coping strategies and a new sense of identity as a spiritual, contingent self as the disease eroded the client's physical self and former life.*
- ▲ Refer the client to social services as necessary for losses not related to death. Support is helpful to grief work for all types of losses. Social workers can help the client plan for financial changes as a result of job losses and help with community referrals as appropriate. **EB:** *Chen et al (2015) conducted a longitudinal study of community-living older residents and used disability, chronic disease, depression, and social service usage data and found changes in levels of disability during the aging process were identified and also found that hypertension and depression were predictors of increased disability among clients and the use of social services such as personal care, homemaker-household, and physical therapy were significantly related to increases in disability.*
- ▲ Refer the bereaved to hospice bereavement programs or an Internet self-help group. Relief of the suffering of clients and families (physical, emotional, and spiritual) is the goal of hospice care. **EB:** *Hwang et al (2013) compared hospice care and usual care for older clients with terminal hepatocellular carcinoma (N = 729) in a nationwide survey in Taiwan and found that clients in hospice care were treated with better pain control and with less aggressive procedures and medical expenses than clients in hospital care.*

Complicated Grieving

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CHSE, ANEF, FAAN, and Betty J. Ackley, MSN, EdS, RN

NANDA-I

Definition

A disorder that occurs after the death of a significant other in which the experience of distress accompanying bereavement fails to follow normative expectations and manifests in functional impairment

Defining Characteristics

Anger; anxiety; avoidance of grieving; decrease in functioning in life roles; depression; disbelief; distress about the deceased person; excessive stress; experiencing symptoms the deceased experienced; fatigue; feeling dazed; feeling of detachment from others; feeling of shock; feeling stunned; feelings of emptiness; insufficient sense of well-being; longing for the deceased person; low levels of intimacy; mistrust; non-acceptance of a death; persistent painful memories; preoccupation with thoughts about a deceased person; rumination; searching for a deceased person; self-blame; separation distress; traumatic distress; yearning for deceased person

Related Factors (r/t)

Death of a significant other; emotional disturbance; insufficient social support (Adapted from the work of NANDA-I)

G

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Anxiety Level; Coping; Depression; Grief Resolution; Mood Equilibrium; Personal Well-Being; Psychosocial Adjustment; Life Change; Sleep

Example NOC Outcome with Indicators

See care plan for **Grieving**.

Client Outcomes

Client Will (Specify Time Frame)

- Express appropriate feelings of guilt, fear, anger, or sadness
- Identify somatic distress associated with grief (e.g., anxiety, changes in appetite, insomnia, nightmares, loss of libido, decreased energy, altered activity levels)
- Seek support in dealing with grief-associated issues
- Identify personal strengths and effective coping strategies
- Function at a normal developmental level and begin to successfully and increasingly perform activities of daily living

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Grief Work Facilitation; Grief Work Facilitation: Perinatal Death; Guilt Work Facilitation; Hope Installation

Example NIC Activities—Grief Work Facilitation

See care plan for **Grieving**.

Nursing Interventions and Rationales

- Assess for signs of complicated grieving that include symptoms that persist at least 6 months after the death and are experienced at least daily or to a disabling degree. Symptoms include feeling emotionally numb, stunned, shocked, and that life is meaningless; dysfunctional thoughts and maladaptive behaviors; experiencing mistrust and estrangement from others; anger and bitterness over the loss; identity confusion; avoidance of the reality of the loss, or excessive proximity seeking to try to feel closer to the deceased, sometimes focused on wishes to die or suicidal statements and behavior; or difficulty moving on with life. *Symptoms must be associated with functional impairment (Maercker et al, 2013; Shear et al, 2013). EB: Jordan and Litz (2014) describe the difference between normal bereavement reactions and prolonged grief disorder (PGD), which many times coexists with depression in the clients studied, and they suggest*

medication should be one treatment considered for PGD. **EB:** *McKinnon and Chonody (2014)* qualitatively interviewed survivors ($N = 14$) of loved ones who committed suicide, and their responses ranged from compassionate to coldness; therefore, the researchers concluded that survivors require support for their unique grief, yet they are inconsistently offered care and provided with information regarding available services.

- ▲ Determine the client's state of grieving. Use a tool such as the Prolonged Grief Disorder (PGD) scale (*Jordan & Litz, 2014*), the Grief Support in Health Care Scale (*Anderson et al, 2010*), the Hogan Grief Reaction Checklist (*Hogan et al, 2004*), and the Beck Depression Inventory. **EBN:** *Al-Gamal and Long (2014)* modified the MM-CGI Childhood Cancer to evaluate parents' anticipatory grief with children with cerebral palsy (CP) and used a cross-sectional, descriptive, correlational design to validate the subscales accurately measure the dimensions of anticipatory grief with good internal consistency reliability and construct validity.
- ▲ Determine whether the client is experiencing depression, suicidal tendencies, or other emotional disorders. Refer the client for counseling or therapy as appropriate. **EB:** *Burke et al (2014)* interviewed five families and revealed an association between complicated grief and complicated spiritual grief defined as a spiritual crisis following loss. The researchers found the clients expressed three major themes during the interviews, including (1) resentment for and doubt of God, (2) dissatisfaction with spiritual support, and (3) changes in spiritual beliefs and behaviors. **EB:** *Gillies et al (2014)* developed a 30-category coding system for positive and negative feelings experienced by clients ($N = 162$) who suffered the loss of a loved one; statistical analysis supports the coding system as reliable, comprehensive, and useful in studies about grief therapy.
- Educate the client and his or her support systems that grief resolution is not a sequential process and that the positive outcome of grief resolution is the integration of the deceased into the ongoing life of the griever. **EB:** *Bentley and O'Connor (2015)* interviewed bereaved family members ($N = 22$) to examine the most appropriate time to interview them about the death of their family member with motor neuron disease (MND) and/or cancer and found that 86% felt comfortable being interviewed within 5 months; of those, 43% reported they could be interviewed within weeks after the death.
- ▲ Assess caregivers, particularly younger caregivers, for pessimistic thinking and additional stressful life events. Refer for appropriate support. **EB:** *Avelin et al (2014)* interviewed adolescents ($N = 13$) who experienced the stillbirth of a half-sibling and found the main theme to be sadness, but the clients expressed feelings of not being totally included in family grief process, implying that half-siblings of the deceased infant need to be fully included in the grieving process. **EBN:** *Cinzia et al (2014)* performed a literature review ($N = 14$) to study the experiences and needs of adolescents who lose a parent to a chronic illness and identified four themes: (1) response to the loss, (2) the teenagers' life after the death, (3) coping strategies, and (4) the factors influencing the grieving process. These elements should be addressed by health professionals, parents, teachers, and therapists when counseling adolescents who lose a parent.
- See the interventions and rationales in the care plans for **Grieving and Chronic Sorrow**.

Pediatric/Parent

- ▲ Refer grieving children and parents to a program to help facilitate grieving if desired, especially if the death was traumatic. **EB:** *Thienprayoon et al (2015)* studied the bereavement services in U.S. pediatric hospitals by an online survey to chaplains ($N = 70$) and found that 47.8% of respondents felt resources are not adequate and need to include increased staff, financial resources, and consistency in services. **EBN:** *Howes (2015)* conducted a literature review ($N = 8$) about the provision of end-of-life care in pediatric intensive care units because the care delivered to a child and family surrounding death can have a lasting effect on the grieving process. Howes identified many challenges facing children, parents, and staff related to family views, staff views, decision-making, medicolegal issues, and resources, indicating the need for further research to inform clinical protocols.
- Encourage grieving parents to take part in activities that are supportive, such as faith based activities. **EB:** A qualitative study of Israeli parents ($N = 16$) whose children were killed in terror attacks revealed, through interviews, four themes: (1) inclusiveness is helpful, (2) the "family of the bereaved" is most important in the healing process, (3) nongovernmental services are preferred, and (4) engaging in the heritage of the Jewish people helped (*Possick et al, 2014*). These elements inform the development and delivery of psychosocial services.
- Encourage grieving parents to seek mental health services as needed. **EBN:** *Steen (2015)* surveyed U.S. ($N = 44$) and Spanish ($N = 15$) nurses about the interventions used in cases of perinatal death and found that interventions (accompanying, listening, offering keepsakes, baptism discussion, and funeral planning) were significantly different between the two groups, which demonstrates a need to promote an international

nursing standard of perinatal bereavement care. **EBN**: A grounded theory study examined black adolescents' ($N = 8$) experience with perinatal loss, and the results revealed stages that clients went through to ultimately "enduring to gain new perspective." First the clients felt "denying and hesitating" about the pregnancy, then "getting ready for this whole new life," followed by shock of "suffering through the loss," "all that pain for nothing," and "mixed emotions going everywhere." Researchers identified that clients "over time" reached out for support, which has implications for continuing nursing care (Fenstermacher, 2014).

- Help the adolescent determine sources of support and how to use them effectively. If client is an adolescent exposed to a peer's suicide, watch for symptoms of traumatic grief as well as post-traumatic stress disorder, which include numbness, preoccupation with the deceased, functional impairment, and poor adjustment to the loss. **EB**: Quinn-Lee (2014) interviewed 59 school social workers about their experiences with student grieving in an exploratory study using constant comparison and identified four important themes: (1) barriers to helping grieving students, (2) variations on how grief is defined, (3) social workers' preparation for dealing with grief, and (4) referrals of grieving students to outside resources. **EB**: Currier et al (2015) studied bereaved young adults ($N = 195$) and measured their attachment-related insecurities (anxiety and avoidance), their continuing bond (CB) to the deceased, and their complicated grief (CG) manifestations and found that CBs were less predictive of CG symptoms in clients with high anxiety and low avoidance, and more predictive for clients whose attachment styles were highly avoidant and minimally anxious.

Geriatric

- Assess for deterioration in bereaved older adults' self-care. **EBN**: Bellamy et al (2014) conducted telephone interviews with older clients ($N = 28$) about experiences with bereavement support following the death of a spouse or family member and found that family and friends and community-based organizations play an important supportive role, and they did not see the need for formal bereavement support services because they had life experiences and developed coping mechanisms. This study suggests that community and family supports need to be assessed for older bereaved clients. **EBN**: Gray (2014) studied clients entering the final phase of their lives and noted many older clients have well-established habits and rituals and found that they often struggle to balance addictive behaviors and a disciplined lifestyle in their quest to find a balance between meaningful fulfillment and the need to find pleasure in living the final years.
- Those who have lived with older adults with dementia and experienced significant feelings of loss before the loved one's death may be at risk for more intense feelings of grief after the death of the client with dementia. **EBN**: Lindauer and Harvath (2014) analyzed the concept of pre-death grief in families who were caring for a client with dementia ($N = 49$) and found it was associated with depression, burden, and caregiver coping. **EBN**: A qualitative study interviewed caregivers ($N = 6$) of clients with dementia about their counseling experiences and caregivers identified three themes: (1) feeling connected, (2) being understood, and (3) wanting to share information. All participants thought that counseling created "safe space" to disclose and share concerns (Elvish et al, 2014).
- Monitor the older client for complicated grieving manifesting in physical and mental health problems. **EBN**: McLeod-Sordjan (2014) analyzed death preparedness related to communication and end-of-life shared decisions and found that 40% of geriatric clients noted it involved a transition from denial to communication with a health care provider and that the client has to become aware and implement a plan. **EB**: Stahl and Schulz (2013) completed a systematic review ($N = 32$) to analyze the relationship between late-life spousal bereavement and changes in routine health and found that geriatric clients are at risk for poor nutrition, weight loss, impaired sleep, and increased alcohol consumption, which all have clinical implications for nursing interventions.

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's grief and mourning practices. **EB**: Neimeyer and Young-Eisendrath (2015) developed a bereavement intervention for Buddhist clients ($N = 41$) to deal with their belief of impermanence, which assists clients to reflect on the natural conditions of impermanence and provides a compassionate environment. **EBN**: Lee et al (2014) studied prolonged grief manifestations among clients ($N = 22$) who reported near-death experiences (NDEs) using an online survey and found that NDEs are associated with grief, meaning-making, and religion.
- Encourage discussion of the grief process. **EB**: Young et al (2014) conducted interviews about bereavement among people with profound and multiple learning disabilities (PMLDs) and their caregivers and used the information to develop a bereavement learning resource pack specifically for people with PMLD and their caregivers. **EB**: McRitchie et al (2014) qualitatively studied the bereavement experiences of clients ($N = 13$)
