with intellectual disabilities. Results confirmed that the experiences of such clients follow the patterns of the general population but they feel more disenfranchised, which supports the need for open communication, information, and inclusion.

- Identify whether the client had been notified of the health status of the deceased and was able to be present during illness and death. **EB:** Dhiliwal and Muckaden (2015) studied clients (N = 690) using home care services for terminal cancer using the Edmonton Symptom Assessment Scale (ESAS) and found that 50.98% of clients were cared for at home, 28.85% of clients needed hospice referral, and 20.15% of clients needed short-term hospitalizations. Clients receiving home-based palliative care reported improved symptom control, health-related communication, and psychosocial support. **EBN:** Dosser and Kennedy (2014) used participatory action research in an acute care setting and found that improving nurses' communication skills and improving the environment for family caregivers by providing "safe space" away from the bedside of the dying client were nursing interventions that had a positive impact on families' grief experience.

G

Home Care

- Consider providing support via the Internet. **EB:** Varga and Paulus (2014) used discourse analysis to examine 107 initial Internet posts and found that there were three "non-normal" grief reactions: (1) unusual stories of loss, (2) describing uncontrollable emotional and physical states, and (3) engaging in "troubles telling," supporting the use of Internet support groups for complicated grief. **EB:** Jakoby (2014) studied the conversations of bereaved clients in an online survey and identified that clients sought out conversation partners to discuss grieving but they had difficulty in talking openly about grief and were concerned about being a burden to others.

Risk for complicated Grieving Gail B. Ladwig, MSN, RN, and Jane M. Kendall, RN, BS, CHT

NANDA-I

Definition

Vulnerable to a disorder that occurs after death of a significant other in which the experience of distress accompanying bereavement fails to follow normative expectations and manifests in functional impairment, which may compromise health

Risk Factors

Death of a significant other; insufficient social support; emotional disturbance

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan for Complicated **Grieving**.

Risk for disproportionate Growth Roberta Dobrzanski, MSN, RN

NANDA-I

Definition

Vulnerable to growth above the 97th percentile or below the 3rd percentile for age, crossing two percentile channels, which may compromise health

Risk Factors

Caregiver

Alteration in cognitive functioning; learning disability; mental health issue (e.g., depression, psychosis, personality disorder, substance abuse); presence of abuse (e.g., physical, psychological, sexual)

Environmental

Deprivation; economically disadvantaged; exposure to teratogen; exposure to violence; lead poisoning; natural disaster

Individual

Anorexia; chronic illness; infection; insatiable appetite; maladaptive feeding behavior by caregiver; maladaptive self-feeding behavior; malnutrition; prematurity; substance abuse

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Prenatal

Congenital disorder; exposure to teratogen; genetic disorder; inadequate maternal nutrition; maternal infection; multiple gestation; substance abuse

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Body Image; Child Development: 1 Month, 2 Months, 4 Months, 6 Months, 12 Months, 2 Years, 3 Years, 4 Years, 5 Years, Middle Childhood, Adolescence; Growth; Knowledge: Infant Care; Preconception Maternal Health; Pregnancy; Physical Maturation: Female, Male; Weight: Body Mass

Example NOC Outcome with Indicators

Growth as evidenced by the following indicators: Weight percentile for sex/Weight percentile for age/Weight percentile for height/Length/height percentile for age/Length/height percentile for sex. (Rate the outcome and indicators of **Growth**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes**Client/Parents/Primary Caregiver Will (Specify Time Frame)**

- State information related to possible teratogenic agents
- Identify components of healthy nutrition that will promote growth
- Maintain or improve weight to be within a healthy range for age and sex

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Eating Disorders Management; Weight Management; Nutrition Therapy; Nutrition Management; Teaching: Infant Nutrition, Toddler Nutrition

Example NIC Activities—Nutrition Therapy

Determine, in collaboration with dietician as appropriate, number of calories and type of nutrients needed to meet nutrition requirements; Ensure that diet includes foods high in fiber content to prevent constipation; Refer for diet teaching and planning, as needed

Nursing Interventions and Rationales**Preconception/Pregnancy**

- Counsel women who smoke to quit smoking prior to conception if possible and to avoid smoking and secondhand smoke while pregnant. **EB**: *Smoking during pregnancy has been linked to multiple complications for both mother and infant. The findings of this review also revealed that maternal exposure to environmental smoke is correlated with low birth weight in infants as well as numerous other adverse effects (Hawsawi et al, 2015).*
- Assess alcohol consumption of pregnant women and advise those who drink alcohol to discontinue all use of alcohol through the pregnancy. **EB**: *Current research suggests that alcohol intake of seven or more standard drinks (one standard drink = 13.6 grams of absolute alcohol) per week during pregnancy places the fetus at significant risk for the negative effects of ethanol. Effects of alcohol on the fetus are influenced not only by the amount of alcohol consumed, but also by the pattern of alcohol (binge drinking vs. daily consumption of alcohol) and the exposure threshold amounts of alcohol in the blood, as well as the timing of exposure during gestation (Stade et al, 2009).*
- Assess and limit exposure to all drugs (prescription, “recreational,” and over the counter) and give the mother information on known teratogenic agents. **EB**: *According to the National Research Council, 3% of all birth defects and developmental disabilities are caused by environmental exposures. No drug can be considered safe during pregnancy. It should be emphasized that any drug has the potential to cause a birth defect, so no listing of known teratogens is ever complete (CDC, 2014; Florida Birth Defects Registry, 2015).*

- All women of childbearing age who are capable of becoming pregnant should take 400 mcg of folic acid daily. **EB:** *Periconceptional use of folic acid reduces the incidence of neural tube defects. Up to 70% of neural tube defects could be prevented if all women who can become pregnant consumed 400 mcg of folic acid from at least 1 month before conception through the first trimester of pregnancy (CDC, 2014; Florida Birth Defects Registry, 2015).*
- ▲ Promote a team approach toward preconception and pregnancy glucose control for women with diabetes. **EB:** *Offspring of women with diabetes mellitus type 1 or type 2 have a twofold to fourfold increased risk of birth defects. Available data suggest that excellent preconception and first-trimester glucose control in the mother can greatly reduce, if not eliminate, this risk. Fetal morbidity may still be high in the second and third trimesters if gestational diabetes is not under good control. Programs with a team approach have been the most successful (CDC, 2014; Florida Birth Defects Registry, 2015).*
- ▲ Advise women with mental health disorders to seek appropriate counseling before pregnancy. **EB:** *Well-characterized risks are associated with valproate, carbamazepine, lamotrigine, and lithium (Nguyen et al, 2009).*

Pediatric

- Consider regular breast milk and protein-fortified breast milk for low-birth-weight infants in the neonatal intensive care unit. **CEB:** *Observational studies and meta-analyses of trials comparing feeding with formula milk versus donor breast milk suggest that feeding with breast milk has major nonnutrient advantages for preterm or low-birth-weight infants (Henderson et al, 2007). In an earlier study it was concluded that protein-enriched breast milk enables low-birth-weight infants requiring especially intensive care to attain growth at discharge comparable to that of healthier infants not given enriched milk (Funkquist et al, 2006).*
- Provide tube feedings per health care provider's orders when appropriate for clients with neuromuscular impairment. **EB:** *Malnutrition and gastrointestinal disorders are common in children with cerebral palsy. On the other hand, improved nutritional status seems to have a positive effect on motor function in these children (Bekem et al, 2008).*
- Provide for adequate nutrition and nutritional monitoring in clients with medical disorders requiring long-term medication and those with developmental delay. **EB:** *One study found a high prevalence of overweight children who had developmental delay. Many factors can contribute to overweight issues in this population, including sedentary lifestyle and medications with weight gain as a side effect (De et al, 2008). Drugs such as SSRIs (selective serotonin reuptake inhibitors), mood stabilizers, psychostimulants, and anti-psychotics can cause weight gain in adolescents. Other medications used to treat chronic conditions, such as stimulants, can cause poor weight gain (Jerrell, 2010).*
- Adequate intake of vitamin D is set at 400 IU/day by the National Academy of Sciences. Because adequate sunlight exposure is difficult to determine, a supplement of 400 IU/day is recommended for the following groups to prevent rickets and vitamin D deficiency in healthy infants and children:
 - All breastfed infants unless they are weaned to at least 500 mL/day of vitamin D–fortified formula or milk
 - All non-breastfed infants who are ingesting less than 500 mL/day of vitamin D–fortified formula or milk
 - Children and adolescents who do not receive regular sunlight exposure, do not ingest at least 500 mL/day of vitamin D–fortified milk, or do not take a daily multivitamin supplement containing at least 400 IU of vitamin D
- ▲ **EB:** *It is now recommended that all infants and children, including adolescents, have a minimum daily intake of 400 IU of vitamin D beginning soon after birth. New evidence supports a potential role for vitamin D in maintaining innate immunity and preventing diseases such as diabetes and cancer (Wagner & Greer, 2008).*
- Provide adequate nutrition to clients with active intestinal inflammation. **EB:** *Nutrition plays a role in inflammatory bowel disease (IBD), primarily in prevention and treatment of malnutrition and growth failure. Furthermore, in Crohn's disease, nutrition can induce remission, maintain remission, and prevent relapse. Malnutrition is common in IBD and the mechanisms involved include decreased food intake, malabsorption, increased nutrient loss, increased energy requirements, and drug-nutrient interactions (Shamir, 2009).*
- Encourage limiting “screen time” (television, video games, Internet, smartphones, and tablets) to less than 2 hours/day for children. **EB:** *High levels of sedentary behaviors, particularly television viewing, are associated with increased risk of overweight and obesity during youth (Hume et al, 2010). The relationship between*

weight status and time spent in sedentary activities is well documented among older children and adolescents. The formative school years may be an important period when these relationships emerge, providing an opportune time to intervene (Jones et al, 2010).

Multicultural

- Assess the influence of cultural beliefs, norms, values, and expectations on parents' perceptions of normal growth and development. **EBN:** One binational study found a Mexican cultural norm toward larger ideal body types for children and showed that the vestiges of this cultural norm persist in Mexican immigrant communities in the United States (Jones et al, 2010).
- Focus nutritional education on promoting good nutrition and physically active lifestyles for healthy child development as opposed to only for prevention or reduction of overweight. **EBN:** Programs to address overweight among children of Mexican descent in both the United States and Mexico may be more effective if they focus on alternative benefits of weight control strategies (Jones et al, 2010).
- Assess for the influence of acculturation. **EB:** One study found a marked relationship between acculturation, measured by generational status and language use at home, and failure to meet physical activity recommendations among adolescents aged 10 to 17 (Liu et al, 2009).
- Assess parents' understanding of appropriate nutrition for infants. **CEB:** Some cultures may add semisolid food within the first month of life because of concerns that the infant is not getting enough to eat and the perception that "big is healthy" (Higgins, 2000). Studies have found that the introduction of solids at less than 4 months is a risk factor for increased infant weight gain (Taveras et al, 2010).
- Assess the influence of family/parents on patterns of nutritional intake. **EBN:** In some studies, mothers' pressure on their children to eat has been associated with disinhibited eating and increased child energy intake and body weight (Taveras et al, 2010).
- Negotiate with clients regarding which aspects of healthy nutrition can be modified while still honoring cultural beliefs. **CEB:** Give and take with clients will lead to culturally congruent care (Leininger & McFarland, 2002). **EB:** Although black and Hispanic mothers were more likely to initiate breastfeeding, they were less likely to breastfeed their infants exclusively to 6 months of age and were more likely to introduce solid foods before 4 months of age (Taveras et al, 2010).
- Encourage parental efforts at increasing physical activity and decreasing dietary fat for their children. **EB:** Parental role modeling and parental social support are important elements to consider in designing programs to increase physical activity among underserved adolescents (Wright et al, 2010). Fluctuation of resources affects family food purchase and consumption, resulting in unstable eating patterns and unhealthy eating (Kaufman & Karpati, 2007).

Home Care

- The interventions previously described may be adapted for home care use.
- Assess parental perception of their child's weight. **EBN:** If parents do not recognize their child as at risk for overweight, or overweight, they cannot intervene to diminish the risk factors for pediatric obesity and its related complications (Doolen et al, 2009).
- Assess family meal planning and family participation in mealtime activities such as eating together at a scheduled time. **EB:** Lifestyle assessment is an opportunity to identify potential targets for prevention and increase families' self-awareness of current behaviors (Daniels et al, 2009).

Client/Family Teaching and Discharge Planning

- Educate families and children about providing healthy meals and healthy eating to improve learning ability. **EB:** Using standardized tests, results of one study suggest that a nutritional education program can improve academic performance measured by achievement of specific mathematics and English education standards (Shilts et al, 2009).

Deficient community Health

Gail B. Ladwig, MSN, RN, and Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Presence of one or more health problems or factors that deter wellness or increase the risk of health problems experienced by an aggregate

Defining Characteristics

Health problem experienced by aggregates or populations; program unavailable to eliminate health problems of an aggregate or population; program unavailable to enhance wellness of an aggregate or population; program unavailable to prevent health problems of an aggregate or population; program unavailable to reduce health problems of an aggregate or population; risk of hospitalization experienced by aggregates or population; risk of physiological states experienced by aggregates or populations; risk of psychological states experienced by aggregates or population

Related Factors

Inadequate consumer satisfaction with program; inadequate program budget; inadequate program evaluation plan; inadequate program outcome data; inadequate social support for program; insufficient access to healthcare provider; insufficient community experts; insufficient resources (e.g., financial, social, knowledge); program incompletely addresses health problem

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

List of Nursing Diagnoses by Letter: H

Deficient community Health	Risk-prone Health behavior	Ineffective Health management
Ineffective Family Health management	Readiness for Enhanced Health management	Ineffective Health maintenance
Impaired Home maintenance	Readiness for enhanced Hope	Hopelessness
Risk for compromised Human Dignity	Hyperthermia	Hypothermia
Risk for Hypothermia	Risk for Perioperative Hypothermia	

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Community Grief Response; Community Health Screening Effectiveness; Community Health Status Community Program Effectiveness; Community Resiliency; Community Risk Control: Obesity; Community Risk Control: Unhealthy Cultural Traditions

Example NOC Outcome with Indicators

Community Health Status as evidenced by the following indicators: Health status of infants/children/adolescents/adults/elders/minority populations/Prevalence of health promotion programs. (Rate the outcome and indicators of **Community Health Status**: 1 = poor, 2 = fair, 3 = good, 4 = very good, 5 = excellent, NA [see Section I].)

H

Client Outcomes

Community/Adolescents/Minority Clients Will (Specify Time Frame)

- Provide programs for healthy behaviors
- Demonstrate goal setting
- Describe and comply with healthy behaviors
- Describe and demonstrate compliance with HBV education and testing

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Community health development: Identify health concerns, strengths, and priorities with community partners; Assist community members in raising awareness of health problems and concerns

Nursing Interventions and Rationales

Refer to care plans: Readiness for Enhanced community **Coping**, Ineffective Community **Coping**, Ineffective **Health** maintenance, Impaired **Home** maintenance, Risk for other-directed **Violence**.

- Assess for the presence of demographic variables that predict community mortality. **EB**: *The following demographic variables were associated with increased community mortality: age 65 years or older, poverty, and a high concentration of construction and service workers (Chan et al, 2014).*
- Assess for needs related to the community's priority health concerns. **EB**: *Research results generated from the first study of the National Institutes of Health Sentinel Network identified the top five health concerns of respondents as hypertension, diabetes, cancer, weight, and heart problems (Cottler et al, 2013).*
- Encourage healthy nutrition and exercise among community members using the resources available to the community. **EB**: *Community-based health communication interventions must address the realities of the community including, literacy levels and existing networks of providers and consumers (Martinez et al, 2012). Community-belonging was strongly related to health behavior change in Canada and may be an important component of population health prevention strategies (Hystad & Carpiano, 2012).*
- Facilitate goal setting in the community for behavior change related to diet and exercise for overweight and obese adults. **EB**: *In this study goal setting shows promise as a community-based intervention to change behavior specific to diet and exercise (Pearson, 2012).*
- Utilize a community forum approach to increase community knowledge and awareness of community health issues. **EBN**: *A community forum was effective at disseminating education about domestic violence prevention and increasing awareness of domestic violence prevention programs (Gonzalez-Guarda et al, 2012).*

Pediatric

- ▲ Consider a community-based program for young people that encourages health-related behavior changes, increasing fruit and vegetable intake, and engaging in activity. **EB**: *This program for overweight and obese young people helped implement behavior and lifestyle changes that were associated with significant*

reductions in self-reported weight and body mass index Z-score (standard deviation), without compromising growth in height (Stubbs et al, 2012).

- ▲ Support religious affiliation and positive school climates for adolescents, particularly for lesbian, gay, and bisexual youths in the community. **EB:** *Although religious climate was also associated with health behaviors among heterosexual youths, it was more strongly associated with the health behaviors of lesbian, gay, and bisexual youths. Among LGB youths, a supportive religious climate was significantly associated with fewer alcohol abuse symptoms and fewer sexual partners (Hatzenbuehler et al, 2012).*

Geriatric

- ▲ Assess homeless older veterans in the community for post-traumatic stress disorder and/or suicidal behavior and make appropriate referrals. **EB:** *This study documented the increased prevalence of suicidal behavior in homeless older veterans (Schinka et al, 2012).*
- ▲ Provide community-dwelling older women with psychoeducation about aging skills and behaviors and cognitive function using group discussion. **EB:** *This new comprehensive educational group intervention reduces negative emotional reactions toward cognitive functioning. It can potentially contribute to the well-being of an important and large group of older adults (Hoogenhout et al, 2012).*

Multicultural

- Provide information and venues for testing about the pervasiveness and deadly consequence of hepatitis B virus (HBV) for Asians in the United States. **EB:** *Asians in San Francisco are disproportionately affected by chronic HBV infection and its fatal consequences. This information was most likely to drive clients to seek education and testing (Shiau et al, 2012).*
- Provide culturally and linguistically appropriate risk reduction programs to individuals living in rural and border regions of the country. **EBN:** *Culturally appropriate risk reduction programs will reduce sexual health disparities (Hernandez et al, 2014).*

Home Care and Client/Family Teaching and Discharge Planning

- The above interventions may be adapted for home care and client/family teaching.
- Provide support for establishment of a community garden. **EB:** *In this study, community garden participants consumed fruits and vegetables 5.7 times per day. Community gardeners met national recommendations to consume fruits and vegetables at least five times per day, compared with 37% of home gardeners and 24% of non-gardeners (Litt et al, 2011).*

Risk-prone Health behavior *Nicole Jones, MSN, FNP-BC*

NANDA-I

Definition

Impaired ability to modify lifestyle/behaviors in a manner that improves health status

Defining Characteristics

Failure to achieve optimal sense of control; failure to take action that prevents health problem; minimizes health status change; nonacceptance of health status change

Related Factors (r/t)

Economically disadvantaged; inadequate comprehension; insufficient social support; low self-efficacy; negative attitude toward health care; smoking; stressors; substance abuse

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Participation in Health Care Decisions; Psychosocial Adjustment: Life Change; Risk Detection

Example NOC Outcome with Indicators

Risk Detection as evidenced by the following indicators: Recognizes signs and symptoms that indicate risks/Identifies potential health risks/Participates in screening at recommended intervals/Obtains information about changes in health recommendations. (Rate the outcome and indicators of **Risk Detection**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- State acceptance of change in health status
- Request assistance in altering behaviors to adapt to change
- State personal goals for dealing with change in health status and means to prevent further health problems
- State experience of a period of grief that is proportional to the actual or perceived effect of the loss
- Report and/or demonstrate behavior changes mutually agreed upon with nurse as evidence of positive adaptation

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Self-Efficacy Enhancement

Example NIC Activities—Self-Efficacy Enhancement

Explore individual's perception of his/her capability to perform the desired behavior; Reinforce confidence in making behavior changes and taking action

Nursing Interventions and Rationales

- Assess the client's definitions of health and wellness and major barriers to health and wellness. **CEB**: *Each person has unique, individual perceptions of well-being and illness (Kiefer, 2008).*
- Use motivational interviewing to help the client identify and change unhealthy behaviors. **EBN**: *In these studies, motivational interviewing helped clients identify and examine their high-risk health behaviors (Wong & Cheng, 2013; Smedslund et al, 2011).*

- Encourage mindfulness and meditation to help the client cope with changes in health status. **EBN:** *Mindfulness and meditation can reduce stress, leading to increased quality of life and self-efficacy (Robins et al, 2014).*
- Allow the client adequate time to express feelings about the change in health status. **CEB:** *This is an important intervention for the client with a serious illness such as a malignant brain tumor (Khalili, 2007).*
- Use open-ended questions to allow the client free expression (e.g., “Tell me about your last hospitalization” or “How does this time compare?”). **CEB:** *Using open-ended questions generates more objective responses with less bias, leading to a more genuine qualitative understanding (Aleami & Harry, 2014).*
- Help the client work through the stages of grief that occur as part of a psychological adaptation to illness or life change. Assess for signs of nonacceptance to illness or change. **CEB:** *Clients who exhibit nonacceptance are at higher risk for stronger, delayed grief reactions. Identifying these clients and making appropriate referrals for counseling and support groups may prevent future adverse outcomes (Holland et al, 2013).*
- Assess the client for depression and refer to for counseling or medical follow-up, as appropriate. **CEB:** *Depression is often a response to and a comorbid condition of chronic disease. Depression is associated with poorer client outcomes and higher risk behavior (Di Benedetto et al, 2014).*
- Discuss the client’s current goals and assist in modification, if appropriate. Have the client list goals so that they can be referred to and steps can be taken to accomplish them. Support hope that the goals will be accomplished. **CEB:** *Clarification of the client/family goals and expectations will allow the nurse to clarify what is possible and to identify measures that can facilitate achievement of the goals (Northouse et al, 2002). “Hope theory” may facilitate recovery and clearer and more sustainable goals (Snyder et al, 2006).*
- ▲ Encourage participation in appropriate wellness programs associated with health changes. **EBN:** *Studies of clients with multiple sclerosis and chronic obstructive pulmonary disease found that wellness programs facilitating positive health choices and self-management demonstrated gains in functional status and decreased anxiety and depression (Hart et al, 2011; Simpson & Jones, 2013).*
- Provide assistance with activities as needed. **CEB:** *Clients’ feelings of personal control increased when assistance was available to help them do things they could not do by themselves; they felt insecure and experienced emotional discomfort when assistance was lacking (Lauck, 2009).*
- Give the client positive feedback for accomplishments, no matter how small. Support the client and family and promote their strengths and coping skills. **CEB:** *Support is necessary to help the client and family throughout the illness. Support leads to hopefulness and is associated with improved outcomes (Soundy et al, 2014).*
- Manipulate the environment to decrease stress; allow the client to display personal items that have meaning. **CEB:** *Appraisal uncertainty is a risk factor for a negative adaptation to health change (Dudley-Brown, 2002).*
- Maintain consistency and continuity in daily schedule. When possible, provide the same caregiver. **CEB:** *The predictability of interaction with the same nurses as a part of treatment facilitates trust, confidence, and positive adaptation (Richer & Ezer, 2002).*
- ▲ Promote use of positive spiritual influences, as appropriate. **EBN:** *Faith and spiritual-based resources may promote an atmosphere of forgiveness and stress personal resilience. These resources may also provide a sense of community and belonging and provide an additional support network (Brewer-Smith & Koenig, 2014).*
- ▲ Refer to community resources. Provide general and contact information for ease of use. **CEB:** *In this study in Canada, community-belonging was strongly related to health behavior change (Hystad & Carpiano, 2012).*

Pediatric

- Include social history in client assessment to help identify past abuse and traumatic experiences. **CEB:** *Studies show that clients who have experienced past abuse or trauma are at higher risk to engage in high-risk behaviors (Whetten et al, 2012).*
- Encourage visitation of children when family members are in intensive care. **CEB:** *Visitation of children should be supported to facilitate expression of feelings associated with major health changes in family members (Knutsson et al, 2008).*
- Encourage parents to process and express grief, uncertainty, and discouragement after learning about their child’s diagnosis, prognosis, and treatments. Provide parents with resources and tools to help further

their understanding of the illness. **CEB**: *Providing support has been shown to increase parental sense of empowerment and encourage patient advocacy (Mulligan et al, 2012).*

- ▲ Refer parents of critically ill children to an intervention program such as COPE, a theory-based intervention program. **CEBN**: *Research findings indicate that this program reduces short- and long-term stress, anxiety, and post-traumatic stress disorder symptoms often experienced by parents with critically ill children (Peek & Melnyk, 2010).*
- Use visualization and distraction with children undergoing procedures or treatment with unpleasant side effects. **EBN**: *This study found that visualization and distraction were the most effective coping strategies employed for children with chemotherapy-induced nausea and vomiting (Rodgers et al, 2012).*
- Discuss with parents and children possible adverse or unpleasant side effects associated with a treatment and assist with developing a plan to cope with these effects. **EBN**: *This study found that predetermined family interventions for developing coping strategies for cancer-related stressors was beneficial (Hildenbrand et al, 2011).*

Geriatric

- ▲ Assess for signs of depression resulting from illness-associated changes and make appropriate referrals. **CEB**: *Depression may be a consequence of aging. Assessments of the spouse's perception as well as of the client's factual situation may identify risk factors that are leading to a depressed state (Franzen-Dahlin, 2008).*
- Use open-ended questions in screening for depression in older adults (Magnil et al, 2011).
- Support activities that promote usefulness of older adults. **CEB**: *Older adults with persistently low perceived usefulness or feelings of uselessness may be a vulnerable group with increased risk for poor health outcomes in later life (Rozanova et al, 2012).*
- ▲ Encourage social support. **EBN**: *In this study, social support demonstrated a positive relation with perceived well-being in older adults (Kiefer, 2011).*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's ability to modify health behavior. **CEB**: *What the client considers normal and abnormal health behavior may be based on cultural perceptions (Leininger & McFarland, 2002; Richardson, 2004; Van Bruggen, 2008).*
- Assess the role of fatalism on the client's ability to modify health behavior. **CEB**: *Fatalistic perspectives, which involve the belief that you cannot control your own fate, may influence health behaviors in some cultures. CEB: Fatalism has been identified as a dominant belief among Latinos and is believed to act as a barrier to cancer prevention (Espinosa de los Monteros & Gallo, 2011). Some African American women experience a fatalistic attitude about breast cancer (McQueen et al, 2011).*
- Encourage spirituality as a source of support for coping. **CEB**: *Many African Americans and Latinos identify spirituality, religiousness, prayer, and church-based approaches as coping resources (Giger et al, 2008).*
- Negotiate with the client regarding the aspects of health behavior that will need to be modified. **CEB**: *Give-and-take with the client will lead to culturally congruent care (Leininger & McFarland, 2002).*
- Acknowledge client's identified gender and sexual orientation and refer client and family members to support networks that have experience with lesbian, gay, bisexual, or transgender (LGBT) issues, as appropriate. **EBN**: *Disclosure and support systems are associated with better self-help perception; creating safe and accepting environments for LGBT patients has been shown to improve overall care in this underserved population (Kamen et al, 2015).*

Home Care

- The above interventions may be adapted for home care use.
- Take the client's perspective into consideration and use a holistic approach in assessing and responding to client planning for the future. **EBN**: *Clients with newly diagnosed diabetes do not want to become their illness (Johansson et al, 2009).*
- Assist the client to adapt to his/her diagnosis and to live with their disease. **CEB**: *Despite being diagnosed with diabetes, clients still want to continue the same life and be the same persons as before, although they now carry a disease (Johansson et al, 2009).*
- Ensure that evaluations of the client's ability to perform activities of daily living are age appropriate and consider existing, as well as new, diagnoses. **CEB**: *This study used a geriatric-designed functional*

evaluation that took into account age-related decrease in flexibility and strength, identifying additional areas for potential loss of function (Adamo et al, 2015).

- ▲ Refer the client to a counselor or therapist for follow-up care. Initiate community referrals as needed (e.g., grief counseling, self-help groups). **CEB:** Families need assistance and support in coping with health change and caregiving (Honea et al, 2008).
- Refer to care plan for **Powerlessness**.

Client/Family Teaching and Discharge Planning

- Assess family/caregivers for coping and teaching/learning styles. **CEB:** The degree of optimism and pessimism influences the coping and health outcomes of caregivers of clients with Parkinson's disease (Lyons et al, 2004).
- Foster communication between the client/family and medical staff. **CEB:** Family members of individuals undergoing cardiopulmonary resuscitation expressed a need to be involved and present or informed at all times during the process (Wagner, 2004). **CEB:** Psychotherapeutic interventions should not only address the client's problems but also the support-giver's questions, needs, and psychosocial burdens (Frick et al, 2005).
- Educate and prepare families regarding the appearance of the client and the environment before initial exposure. **CEB:** Families indicated that knowing what to expect was helpful (Clukey, 2008).
- Help the client to enjoy a sense of "wellness." Provide support for progress and support enjoyment of the physical, emotional, spiritual, and social aspects of life. **EBN:** Nurses provide information and support to facilitate the individual in his/her progress toward achieving a sense of wellness and recognizing that healing will take time (White et al, 2012).
- Teach a client and his/her family relaxation techniques (controlled breathing, guided imagery) and help them practice. **EBN:** Guided imagery with relaxation may be an easy-to-use self-management intervention to improve the quality of life of older adults with osteoarthritis (Ha & Kim, 2013; Helgadottir & Wilson, 2014).
- Allow the client to proceed at own pace in learning; provide time for return demonstrations (e.g., self-injection of insulin). Tailor teaching and learning materials as appropriate for client and caregiver literacy level. **EBN:** Use clear and distinct language free of medical jargon and meaningless values. Be sensitive to education levels and cultural environments that may hinder effective communication (Protheroe & Rowlands, 2013).
- If long-term deficits are expected, inform the family as soon as possible. **CEB:** An honest assessment shared by the nurse of a particular situation is important to the family's sense of what is expected of them in adapting to a health care change (Weiss & Chen, 2002).
- Provide clients with information on how to access and evaluate available health information via the Internet. **CEB:** Client access to health information and personal health records is becoming increasingly important in today's health care society. MedlinePlus, NIH Senior Health, and ClinicalTrials.gov are designed to get medical information directly into the hands of clients (Koonce et al, 2007).

Ineffective Health management

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

Pattern of regulating and integrating into daily living a therapeutic regimen for the treatment of illness and its sequelae that is unsatisfactory for meeting specific health goals

Defining Characteristics

Difficulty with prescribed regimen; failure to include treatment regimen in daily living; failure to take action to reduce risk factors; ineffective choices in daily living for meeting health goals

Related Factors (r/t)

Complex treatment regimen; complexity of health care system; decisional conflict; economically disadvantaged; excessive demands; family conflict; family pattern of health care; inadequate number of cues to action; insufficient knowledge of therapeutic regimen; insufficient social support; perceived barrier; perceived benefit; perceived seriousness of condition; perceived susceptibility; powerlessness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Knowledge: Disease Process; Knowledge: Treatment Regimen; Participation in Health Care Decisions

Example NOC Outcome with Indicators

Knowledge: Treatment Regimen as evidenced by the following indicators: Extent of understanding of prescribed medication, activity, exercise, and specific disease process. (Rate the outcome and indicators of **Knowledge: Treatment Regimen**: 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see [Section 1](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Describe daily food and fluid intake that meets therapeutic goals
- Describe activity/exercise patterns that meet therapeutic goals
- Describe scheduling of medications that meets therapeutic goals
- Verbalize ability to manage therapeutic regimens
- Collaborate with health professionals to decide on a therapeutic regimen that is congruent with health goals and lifestyle

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Health System Guidance; Learning Facilitation; Learning Readiness Enhancement

Example NIC Activities—Learning Facilitation

Present the information in a stimulating manner; Encourage the client's active participation

Nursing Interventions and Rationales

NOTE: This diagnosis does not have the same meaning as the diagnosis **Noncompliance**. This diagnosis is made with the client, so if the client does not agree with the diagnosis, it should not be made. The emphasis

- = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

is on helping the client direct his or her own life and health, not on the client's compliance with the provider's instructions.

- Establish a collaborative partnership with the client for purposes of meeting health-related goals. **EBN:** *The concept of "knowing the patient" was studied through an integrative review and found to be a significant factor for clients but the barriers to "knowing the patient" are (1) time, (2) expedited client discharges, and (3) consistency of nursing assignments (Zolnierok, 2014).* **CEB:** *A study by Musich et al (2014) found that using a health care model based on the health care provider-client relationship decreased health care cost to the client by \$86.68/month.*
- Explore the client's perception of their illness experience and identify uncertainties and needs through open-ended questions. **EBN:** *Nurses understanding the client's meaning of pain as perceived by clients experiencing chronic pain contributed to the client's ability to self-manage and develop coping strategies (Roditi & Robinson, 2011).* **EBN:** *Having hope even when there is impending death is often misinterpreted by caregivers as denial; therefore, awareness of death, uncertainty, and hope can coexist (Borneman et al, 2014).*
- Assist the client to enhance self-efficacy or confidence in his or her own ability to manage the illness. **EBN:** *A study of women with advanced breast cancer supported self-management's positive relationship to developing self-care skills and feeling empowered (Schulman-Green et al, 2011).* **EBN:** *Clients who smoke have a higher risk for depression and lower self-efficacy (Mee, 2014).*
- Involve family members in knowledge development, planning for self-management, and shared decision-making. **EBN:** *Diabetic clients view family participation as support and motivation to care for themselves as supported by three reported themes in a qualitative study: (1) families needed to be recognized, (2) at times clients blamed family for nonadherence, and (3) family involvement made clients feel "cared for" (de Lima Santos & Marcon, 2014).* **EBN:** *Nurses found that by using an evidence-based structured communication algorithm with families of clients in the intensive care unit, there was increased participation in decision-making with health care providers (Huffines et al, 2013).*
- Review factors of the health belief model (HBM) (individual perceptions of seriousness and susceptibility, demographic and other modifying factors, and perceived benefits and barriers) with the client. **EBN:** *Studies using the HBM supports the view that individual perceptions along with a variety of modifying factors affect the likelihood of changing health behaviors (Pender et al, 2015).* **EBN:** *Using the HBM, specifically the concept of acceptance, to assess clients receiving vaccines found that age, perceived susceptibility, and perceived severity of the disease being immunized for, increases the odds of getting vaccines (Adams et al, 2014).*
- Use various formats to provide information about the therapeutic regimen, including group education, brochures, videotapes, written instructions, computer-based programs, and telephone contact. **CEB:** *Women's knowledge about health care screening for breast cancer in Nigeria was shown to be best disseminated by newspapers, TV/radio programs, libraries, and the Internet, which were accessible to women there (Ugwoke & Ezukwouke, 2014).* **EBN:** *Telephone calls and text messages supported significantly better control of symptoms and medication adherence for psychiatric clients (Bebe et al, 2014).*
- Help the client identify and modify barriers to effective self-management. **CEB:** *A qualitative study found that the words used for health promotion during the professional-client interaction affects the client's participation in health care (Moreira et al, 2013).* **EBN:** *A pre-test, post-test study with overweight African American women (N = 19) demonstrated that client activation and self-efficacy are essential for success in self-management (Onubogu et al, 2014).*
- Help the client self-manage his or her own health through education about strategies for changing habits such as overeating, sedentary lifestyle, and smoking. **CEB:** *A large-scale Chinese study involving 21 sites found that cessation to quit smoking was directly related to intent to quit and professional status, whereas risk factors for not quitting were related to smoking alone and reported addiction to nicotine (Yang et al, 2014).* **CEB:** *A study of 114 high school students demonstrated that peer-led interventions were effective at improving students' cigarette smoking knowledge, attitude, and behavior (Raji et al, 2014).*
- Develop a contract with the client to maintain motivation for changes in behavior. **CEB:** *A study that examined the impact of telephone reinforcement and a tailored maintenance contract on physical activity maintenance in older adults with osteoarthritis found that the contract group changed behavior more often than the telephone group (Desai et al, 2014).* **EBN:** *A descriptive study explored nurses' learning in the community settings and three major themes emerged: (1) power relationships are different in community settings, (2) clients have more autonomy and self-determination in decision-making, and (3) the development of a self-management plan (Merritt & Boogaerts, 2014).*

- Use focus groups to evaluate the implementation of self-management programs. **EBN:** *The use of focus groups to foster decision-making in mental health clients contributed to greater self-health management (Mahone et al, 2011).* **CEB:** *A qualitative study of members of the military with chronic low back pain found developing trusting relationships, establishing a need to be actively engaged in their rehabilitation, and finding workable rehabilitation solutions motivated clients to engage in needed rehabilitation (Harman et al, 2014).*
- Refer to the care plan ineffective Family **Health** management.

Geriatric

- Identify the reasons for behaviors that are not therapeutic and discuss alternatives. **EBN:** *Researchers found that implementing a programmed learning to encourage staff to help clients reminisce assisted dementia clients to “tell their story” (Cooney et al, 2013).* **CEB:** *Researchers followed older clients (65 and older) after discharge to home with structured telephone interviews about medication adherence; 69% were non-adherent at 3 months due to (1) the number of medications, (2) changes in medications, and (3) understanding the reason for medication (Pasina et al, 2014).*

Multicultural

- Assess the influence of cultural beliefs, norms, and values on the individual’s perceptions of the therapeutic regimen. **EBN:** *Identification of factors contributing to adherence of cardiac medication in the Asian population of Canada found clients relied on family members for support to be adherent with their medications (Ens et al, 2014).* **CEB:** *Infection prevention and control is affected by human behavior, which is influenced by cultural constructs, including (1) power, (2) uncertainty avoidance, and (3) masculinity (Borg, 2014).*
- Discuss all strategies with the client in the context of the client’s culture. **CEB:** *Adherence to antiretroviral therapy in Kenya was studied using cognitive interviewing with pediatric caregivers and HIV-infected adolescents by verbal probing and guided “thinking aloud”; comprehension problems were found as the reason for key missed doses and understanding side effects (Vreeman et al, 2014).* **CEB:** *Researchers interviewed clients of Arcadian descent on hemodialysis to learn about their intake of the Acadian diet and found that the diet held multiple meanings for different participants, which supports the individualization of care and discourages generalization based on assumptions of homogeneity of all clients within a cultural group (Raed Tarakji et al, 2014).*
- Provide health information that is consistent with the health literacy of clients. **EBN:** *Chinese clients, when surveyed, indicated that they prefer face to face communication and teaching (You et al, 2014).* **EBN:** *A study investigated economically and socially disadvantaged clients with type 2 diabetes with low health literacy and found that an educational program designed to be culturally sensitive and meet the needs of individuals with low health literacy improved short-term outcomes (Swaverly et al, 2014).*
- Assess for barriers that may interfere with client follow-up of treatment recommendations. **CEB:** *Patients discharged from specialty care are more likely to receive follow-up care if referred back to their familiar primary care provider (Tuot et al, 2014).* **EBN:** *Breastfeeding rates among black infants in the United States are 16% lower than among whites; a data analysis by ZIP code revealed that the largest differences were in hospitals that implemented breastfeeding practices, such as (1) early initiation of breastfeeding, (2) limited use of supplements, and (3) rooming-in, suggesting that there are racial disparities in access to maternity care practices that support breastfeeding (Lind et al, 2014).*
- Use electronic monitoring and dosing to improve management of medications. **EBN:** *The use of electronic dosing and monitoring devices, in conjunction with other measures of adherence, has contributed to successful client adherence to medication regimens (Cook et al, 2012).* **CEB:** *Post-discharge home-based, pharmacist-provided medication management services to clients after discharge assisted in resolving medication discrepancies (Pherson et al, 2014).*
- Validate the client’s feelings regarding the ability to manage his/her own care and the impact on lifestyle. **EBN:** *A descriptive correlational study identified self-care ability as being correlated with the concepts of health literacy and self efficacy (McCleary-Jones, 2011).* **CEB:** *Understanding youth’s and parents’ changing perceptions of illness during the course of a youth’s psychosis was studied and five themes that assisted the child’s self-determination and self-management included: 1) symptom recognition, 2) awareness of change, 3) negative appraisals, 4) positive appraisals, and 5) treatment self-management (Gearing et al, 2014).*

Home Care

- Prepare and instruct clients and family members in the use of a medication box. Set up an appropriate schedule for filling of the medication box, and post medication times and doses in an accessible area (e.g., attached by a magnet to the refrigerator). **EBN:** *Improved self-management of therapeutic regimen is increased through the use of cues and supports that help clients remember to take medications (Cook et al, 2012).* **CEB:** *Conklin et al (2014) found that post-discharge medication-related problems are largely due to poor health literacy.*
- Monitor self-management of the medical regimen. **EBN:** *Patient-centered care was analyzed by an extensive multidisciplinary literature review and three themes were identified as being fundamental: (1) client participation and involvement, (2) the relationship between the client and the health care professional, and (3) the context in which care is delivered (Kitson et al, 2013).* **CEB:** *Mohammed et al (2013) explored decision-making processes used in allocating occupational and physical therapy services for home care clients and found that funding was the primary determinant of home care treatment.*
- Refer to health care professionals for questions and self-care management. **CEB:** *Prehospital mobile telemedicine communication for stroke victims to receive plasminogen activators by emergency medical personnel was reliable and feasible (Wu et al, 2014).* **CEB:** *A study examined whether client satisfaction differed when clients were seen by a physician alone or by a physician and medical student and found that clients in rural and community-based outpatient settings were satisfied when a medical student was involved; therefore, medical students are a good interdisciplinary source in promoting client self-management (Law et al, 2014).*

Client/Family Teaching and Discharge Planning

- Identify the client and/or family's current knowledge and adjust teaching accordingly. Teach the client and family about all aspects of the therapeutic regimen, providing as much knowledge as the client and family will accept, in a culturally congruent manner. **CEB:** *The American Association of Diabetes Education found improved self-management when instruction and guidance were based on a collaborative relationship with health care providers that was based on individual monitored outcomes (Stetson et al, 2011).* **EBN:** *A qualitative study of significant others of dialysis clients found that significant others were involved in the decision-making and had a need to be informed and supported (DeRosenroll et al, 2013).*
- Teach ways to adjust activities of daily living (ADLs) for inclusion in therapeutic regimens. **EBN:** *Ha and Kim (2014) studied ADLs in clients with dementia and found that five leading factors (urinary and fecal incontinence, regularity of exercise, mental state scores, and stroke history) negatively affected clients when trying to perform ADLs.* **CEB:** *This study describes patterns of ADL functional disability in primary progressive aphasia (PPA) clients and found that ADL functionality varies between PPA subtypes and therapeutic strategies can be tailored to each client to promote improved ADL functioning (O'Connor et al, 2014).*
- Teach safety in taking medications. **CEB:** *This database study examines the primary practitioner's role in the prescription of drugs to home-dwelling older adults and found that the client's regular practitioner, not specialists, prescribe the major portion of nonaddictive and addictive medications and is key to coordination of prescriptions (Kann et al, 2014).* **EBN:** *Explored nurses' perspectives on preventing medication administration errors revealed three themes: (1) nurses' roles and responsibilities in medication safety, (2) nurses' ability to work safely, and (3) nurses' acceptance of safety practices placing nurses in a position to ensure safe medication management (Smeulders et al, 2014).*
- Teach the client to act as a self-advocate with health providers who prescribe therapeutic regimens. **EBN:** *A review of literature showed that nurses who advocate for clients and become partners in care need clarification to fully incorporate into the multiple roles that nurses already have (Wellard, 2014).* **CEB:** *A study analyzed data for children (N = 40,242) with special health care needs by a national survey to look at shared decision-making (SDM) in relation to sociodemographic/health characteristics and found that clients in medical homes had six times greater odds of perceived shared decision-making with providers (Smalley et al, 2014).*

Ineffective Family Health management *Roberta Dobrzanski, MSN, RN*

NANDA-I

Definition

A pattern of regulating and integrating, into family processes, a program for the treatment of illness and its sequelae that is unsatisfactory for meeting specific health goals

Defining Characteristics

Acceleration of illness symptoms of a family member; decrease in attention to illness; difficulty with prescribed regimen; failure to take action to reduce risk factors; inappropriate family activities for meeting health goals

Related Factors (r/t)

Complex treatment regimen; complexity of health care system; decisional conflict; economically disadvantaged; family conflict

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Family Health-Status; Knowledge: Treatment Regimen; Family Participation in Professional Care

Example NOC Outcome with Indicators

Knowledge: Treatment Regimen as evidenced by the following indicator: Understanding conveyed about prescribed medication, activity, exercise, and specific disease process. (Rate the outcome and indicators of **Knowledge: Treatment Regimen**: 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Make adjustments in usual activities (e.g., diet, activity, stress management) to incorporate therapeutic regimens of its members

- Reduce illness symptoms of family members
- Desire to manage therapeutic regimens of its members
- Describe a decrease in the difficulties of managing therapeutic regimens
- Describe actions to reduce risk factors

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Family Involvement Promotion; Family Mobilization; Teaching: Disease Process

Example NIC Activities—Family Involvement Promotion

Identify and respect coping mechanisms used by family members; Provide crucial information to family members about the patient in accordance with client's preference

H

Nursing Interventions and Rationales

- Base family interventions on knowledge of the family, family context, family dynamics, family structure, and family function. **EBN:** *Family research has established that families differ widely from one another, even within cultures (Wright & Leahey, 2013).*
- Use a family approach when helping an individual with a health problem that requires therapeutic management. **EBN:** *Family relationships can be a source of support for people with diabetes and may influence self-management behavior (Paddison, 2010).*
- Review with family members the congruence and incongruence of family behaviors and health-related goals. **EBN:** *To attain the motivation needed for changes in health habits, family members should understand the relation of daily habits to health-related goals (Wright & Leahey, 2013).*
- Acknowledge the challenge of integrating therapeutic regimens with family behaviors. **EBN:** *Therapeutic regimens require modifications of daily activities that have already been established based on family values and beliefs. Acknowledging the difficulty of changing family habits supports families through the process (Wright & Leahey, 2013).*
- Review the symptoms of specific illnesses and work with the family toward development of greater self-efficacy in relation to these symptoms. **EBN:** *Knowledge of symptoms improves the ability of family members to adjust behaviors to prevent and manage symptoms (Larsen, 2014).*
- Support family decisions to adjust therapeutic regimens as indicated. **EBN:** *Sometimes families do not have access to health care providers and should make independent decisions because of side effects or adverse effects of therapeutic regimens. Family members need to make informed decisions in their best interests (Wright & Leahey, 2009).*
- Advocate for the family in negotiating therapeutic regimens with health providers. **CEB:** *Illness regimens generally are neither arbitrary nor absolute; therefore, modifications can be discussed as needed to fit with the family lifestyle (Wright & Leahey, 2009).*
- Help the family mobilize social supports. **EBN:** *Increased social support helps families meet health-related goals (Pender et al, 2011).*
- Help family members modify perceptions as indicated. **EBN:** *Individual perceptions of the seriousness of, susceptibility to, and threat of illness may be distorted or inaccurate and may be modified with new information (Pender et al, 2011).*
- Use one or more theories of family dynamics to describe, explain, or predict family behaviors (e.g., theories of Bowen, Satir, and Minuchin). **EBN:** *Family systems may not be understood by the nurse without adequate knowledge of family theory (Wright & Leahey, 2013).*
- ▲ Collaborate with expert nurses or other consultants regarding strategies for working with families. **EBN:** *The family clinical nurse specialist uses components such as time allowance; level of staff's family theory knowledge; level of experience and comfort; institution policy; and interdisciplinary team commitment to positively influence the delivery of family-centered care (Parker, 2011).*
- Coaching methods can be used to help families improve their health. **EBN:** *Coaching is a beneficial tool for families of many children and teens with attention deficit hyperactivity disorder, executive functioning disorders (Sleeper-Triplett, 2008), and/or behavioral concerns. **CEB:** *Coaching processes were**

shown to improve family outcomes related to improved nutrition and physical activity (Heimendinger et al, 2007).

Pediatric

- Support kangaroo care for infants at risk at birth. Keep infants in an upright position in skin-to-skin contact until they no longer tolerate it. **CEB:** Kangaroo mother care has a positive impact on family and home environment. The results of this study also suggest, first, that both parents should be involved as direct caregivers in the kangaroo mother care procedure, and second, that this intervention should be directed more specifically at infants who are more at risk at birth (Tessier et al, 2009).

Geriatric

- Recommend that clients use the “Ask Me 3” program when communicating with their pharmacist (What is my main problem? What do I need to do? Why is it important for me to do this?). **CEB:** The Ask Me 3 program is a practical tool that created awareness and reinforced principles of clear health communication with pharmacists and community-dwelling well older adults who participated in this study (Miller et al, 2008).

Multicultural

- Acknowledge racial and ethnic differences at the onset of care. **CEB:** Acknowledgment of race and ethnicity issues enhances communication, establishes rapport, and promotes treatment outcomes (Giger & Davidhizar, 2008; Leininger & McFarland, 2006).
- Ensure that all strategies for working with the family are congruent with the culture of the family. **CEB:** Many nursing studies among people of a variety of cultures show that cultural variations exist in the management of therapeutic regimens, and these differences should be taken into account when working with families (Hanley, 2008; Leininger & McFarland, 2006).
- Use a family-centered approach when working with Latino, Asian, African American, and Native American clients. **CEB:** Latinos may perceive the family as a source of support, solver of problems, and source of pride. Asian Americans may regard the family as the primary decision-maker and influence on individual family members. Native American families may have extended structures and exert powerful influences over functioning (Hanley, 2008; Leininger & McFarland, 2006). Findings in this study suggest that incorporating family norms is critical when developing interventions to increase formal health service utilization among African Americans (Barksdale & Molock, 2009).
- Facilitate modeling and role playing for the family regarding healthy ways to communicate and interact. **CEB:** It is helpful for families and the client to practice communication skills in a safe environment before trying them in a real-life situation (Degazon, 2006; Wright & Leahey, 2013).
- Use the nursing intervention of cultural brokerage to help families deal with the health care system. **CEB:** In a study based on 24 in-depth interviews, four empirical mechanisms of cultural brokerage were identified: translating between health systems, bridging divergent images of medicine, establishing long-term relationships, and working with patients’ relational networks (Lo, 2010).

Client/Family Teaching and Discharge Planning

- Teach about all aspects of therapeutic regimens. Provide as much knowledge as family members will accept, adjust instruction to account for what the family already knows, and provide information in a culturally congruent manner.
- Teach ways to adjust family behaviors to include therapeutic regimens, such as safety in taking medications and teaching family members to act as self-advocates with health providers who prescribe therapeutic regimens.

Readiness for Enhanced Health management

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

A pattern of regulating and integrating into daily living a therapeutic regimen for treatment of illness and its sequelae, which can be strengthened

Defining Characteristics

Expresses desire to enhance choices of daily living for meeting goals; expresses desire to enhance management of illness; expresses desire to enhance management of prescribed regimens; expresses desire to enhance management of risk factors; expresses desire to enhance management of symptoms; expresses desire to enhance immunization/vaccination status

NOC

(Nursing Outcomes Classification)

Suggested NOC Outcomes

Health-Promoting Behavior; Health-Seeking Behavior; Knowledge: Health Behavior; Health Promotion; Health Resources; Illness Care; Medication; Prescribed Activity; Treatment Regimen

Example NOC Outcome with Indicators

Health-Promoting Behavior as evidenced by the following indicators: Monitors personal behavior for risks/Seeks balance activity and rest/Performs healthy behaviors routinely/Uses financial and social support resources to promote health. (Rate each indicator of **Health-Promoting Behavior**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Describe integration of therapeutic regimen into daily living
- Demonstrate continued commitment to integration of therapeutic regimen into daily living routines

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Anticipatory Guidance; Mutual Goal Setting; Client Contracting; Self-Modification Assistance; Self-Responsibility Facilitation; Support System Enhancement

Example NIC Activities—Mutual Goal Setting

Assist client and significant others to develop realistic expectations of themselves in performance of their roles; Clarify with the client the roles of the health care provider and the client, respectively

Nursing Interventions and Rationales

H

- Acknowledge the expertise that the client and family bring to health management. **EBN:** *The use of focus groups to acknowledge expertise and foster decision-making in mental health consumers contributed to greater health management (Mahone et al, 2011).* **CEB:** *This study investigated the influence of factors on the use of speech, the use of sign, spoken language multilingualism, and spoken language of caregivers of children with hearing loss and found that caregivers' decision-making regarding communication mode is influenced by factors that are not equally weighted and that relate to the child, family, community, and advice from others (Crowe et al, 2014).*
- Review factors that contribute to the likelihood of health promotion and health protection. Use Pender's Health Promotion Model and Becker's Health Belief Model to identify contributing factors (Pender et al, 2015). **EBN:** *Many studies using both the Health Promotion Model and the Health Belief Model (HBM) support the view that individual perceptions and a variety of modifying factors affect the likelihood of improving health behaviors (Pender et al, 2015).* **EBN:** *When using the HBM to examine weight management barriers in first-year college students, researchers found that students identified resources to assist them with weight management such as curriculum inclusion and methods to promote physical activity and nutrition (Das & Evans, 2014).*
- Further develop and reinforce contributing factors that might change with ongoing management of the therapeutic regimen (e.g., knowledge, self-efficacy, self-esteem, and perceived benefits). **EBN:** *The purpose of this study was to decrease sun exposure and skin cancer to clients at their workplace through an intervention that significantly improved perceived self-efficacy and increased use of sunscreen protection (Lee et al, 2014).* **CEB:** *When studying adolescents with food allergy-induced anaphylaxis self-care behaviors, it was identified that adherence was influenced by severity of reaction, barriers to adherence, illness identity, cyclical beliefs, and emotional responses (Jones et al, 2014).*
- Support all efforts to manage therapeutic regimens. **EBN:** *Ongoing support and assistance from health care providers is needed to identify and enhance factors that contribute to the likelihood of taking action for health promotion and health protection (Pender et al, 2015).* **EBN:** *The HBM was used to measure and predict the sleep behavior of employed college students (N = 188) and found that it explained 34% of the variance in sleep behavior and the significant elements were perceived severity, perceived barriers, cues to action, and self-efficacy (Knowlden & Sharma, 2014).*
- Review the client's strengths in the management of the therapeutic regimen. **CEB:** *Researchers studied conversations of hearing-impaired clients to assess knowledge and attitudes about hearing and hearing protection and use of hearing protection and found a significant relationship between use of hearing protection and the HBM (Saunders et al, 2014).* **CEB:** *A study examined older clients' reasons for help-seeking for hearing impairment and found the most important factors related to attitudinal beliefs (e.g., perceived benefits of hearing aids) and external cues to action (e.g., support from significant others) (Meyer et al, 2014).*
- Collaborate with the client to identify strategies to maintain strengths and develop additional strengths as indicated. **CEB:** *A study about chronic pain, identification of strengths regarding pain management, rather than direct elimination of the pain, helped empowered and enabled clients to manage their pain (Roditi & Robinson, 2011).* **CEB:** *Corcoran and Crowley (2014) studied Latina women's attitudes and perceptions regarding cervical cancer screening and found that the most important factors were culturally appropriate education and improving accessibility to health care.*

- Identify contributing factors that may need to be improved now or in the future. **EBN:** *Health promotion and protection are complex behaviors that are difficult to implement on a daily basis. Based on the complexity of achieving these behaviors and the perceived barriers to implementation (e.g., time, energy, money), usually one or more contributing factors would benefit from increased focus and attention (Pender et al, 2015).* **EBN:** *This study identified the health-seeking preferences of older Filipinos in the community, and results indicated that the most important element in terms of health-seeking behavior was the client's experience with the health care provider (de Guzman et al, 2014).*
- Provide knowledge as needed related to the pathophysiology of the disease or illness, prescribed activities, prescribed medications, and nutrition. **EBN:** *Knowledge is a factor that contributes significantly to the client's taking action for health promotion and protection. Remember, however, that knowledge is necessary but not sufficient to explain why people perform or do not perform actions for health promotion and protection (Pender et al, 2015).* **CEB:** *Researchers provided veteran clients with a 12-week "Pain Education School" program for chronic pain; quantitative findings suggest that veterans reported (1) learning "new and useful" information, (2) perceived the program as "easy to understand," (3) used the learned information, and (4) recommended the program to others (Watson et al, 2014).*
- Support positive health promotion and health protection behaviors. **EBN:** *Ongoing support may be needed to maintain these behaviors (Pender et al, 2015).* **EBN:** *Key predictors of "help-seeking behavior" in adolescents with mental illness were identified and include health beliefs, personality traits, and attitudes, but perceived benefits were a particularly strong indicator (O'Connor et al, 2014).*
- Help the client maintain existing support and seek additional supports as needed. **EBN:** *In numerous research studies, social support was shown to be a factor contributing to ongoing maintenance of positive health behaviors (Pender et al, 2015).* **EBN:** *A study used visual imagery depicting super heroes with college students to engage them in a health campaigns about sleep and found that providing health care messaging to college students about sleep health promotion may benefit from visual imaging (Mackert et al, 2014).*

Geriatric

- Facilitate the client and family to obtain health insurance and drug payment plans whenever needed and possible. **CEB:** *Adherence to medications and self-health regimens is facilitated by payers' knowledge and use of value-based insurance designs (Cohen et al, 2012).* **CEB:** *An investigation probed the continuation of clients' medication from primary care to hospital and back again to primary care and found that clients were using an average of 8.2 drugs before hospital admission. Of those, 0.9 were discontinued while the clients were in the hospital and an average of 1.7 new drugs were started for each client in the hospital and less than half of newly initiated drugs were continued after discharge (Larsen et al, 2014).*

Multicultural

- Assess client's cultural perspectives on health management. **EBN:** *The effect of an HBM-based nursing intervention was studied on health care outcomes in Chinese clients with chronic obstructive pulmonary disease (COPD). Clients had significantly increased scores of health belief and self-efficacy after receiving HBM-based nursing intervention compared with a control group (Wang et al, 2014).* **EBN:** *Researchers pilot tested a culturally specific curriculum for African American college students to increase awareness of cardiovascular disease (CVD). The program increased student understanding of family history and strategies to reduce their own risk of CVD (Holland et al, 2014).*
- Assess health literacy in clients of diverse backgrounds. **EBN:** *The high recurrence rate of chlamydial infection among African American urban women was studied using the HBM. Results of participant interviews suggested knowledge deficits about the seriousness of Chlamydia compared to other sexually transmitted infections (Craft-Blacksheare et al, 2014).* **EBN:** *A study evaluated commonly used printed health materials for readability and found 28% of the teaching material at a 9th grade or higher level and only 23% below a 5th grade level. Researchers then showed providers how to assess readability to improve client outcomes (Ryan et al, 2014).*
- Validate the client's feelings regarding the ability to manage his/her own care and the impact on current lifestyle. **CEB:** *A descriptive study correlated self-care ability with health literacy and self-efficacy (McCleary-Jones, 2011).* **EBN:** *There is a high incidence of anxiety and depression in COPD clients. This study educated nurses to screen for depression and anxiety and to offer motivational interviewing for self-management, which increased the clients' capability to manage their condition (Hardy et al, 2014).*

- Facilitate the client and family to obtain financial assistance in the form of health insurance and drug payment plans whenever needed and possible. **CEB:** *Adherence to medications and health regimens is facilitated by payers' knowledge and use of value-based insurance designs (Cohen et al, 2012).* **CEB:** *A retrospective analysis of insurance plan drug coverage data for three drug classes (statins, angiotensin II receptor blockers, and protein-tyrosine kinase inhibitors) demonstrated that there was substantially less drug reimbursement with low copays for Medicare plans than for commercial plans, employer plans, or union plans, and with pharmacy benefit management companies (Reignier, 2014).*
- Use electronic monitoring to improve medication adherence. **EBN:** *The use of electronic dosing and monitoring devices, in conjunction with other measures of adherence, has contributed to adherence to medication regimen (Cook et al, 2012).* **EBN:** *A study used a Meducation technology health literacy intervention to evaluate medication adherence for clients at risk for CVD for 6 months, at which time medication adherence improved 3.2% and there was a decrease in clients' average systolic blood pressure (0.5 mm Hg), diastolic blood pressure (1.5 mm Hg), and body weight (3.6 pounds) (Zullig et al, 2014).*
- Discuss with clients their beliefs about medication and treatment to enhance medication and treatment adherence. **CEB:** *A study used the HBM with mixed-race clients from a lower socioeconomic, nonurban environment to look at vaccine efficacy and personal constraints on vaccination behavior and found that vaccine efficacy and personal constraints do not significantly predict vaccination behavior and that convenience was the most important factor (Avery & Lariscy, 2014).* **EBN:** *This study focused on asthmatic clients and found they are generally nonadherent to medication therapy 30% to 70% of the time and need to engage in appropriate management strategies, which can be assisted by health care professionals who acknowledge and reflect the client's perspectives (Clayton, 2014).*

Community Teaching

- Review therapeutic regimens and their optimal integration with daily living routines. **EBN:** *Improved therapeutic regimen management is increased through the use of cues and supports that help clients remember to take medications (Cook et al, 2012).* **EBN:** *A case study reveals that a client living with HIV infection requires highly complex HIV care, including antiretroviral adherence therapies, cognitive behavioral therapy to alleviate depression, and motivational interviewing as essential components of complete HIV management (Paparello et al, 2014).*
- Teach disease processes and therapeutic regimens to clients and peer supporters for management of disease processes. **CEB:** *A study reviewed the role of peer supporters in helping individuals to maximize their medication adherence by promoting self-advocacy and negotiation skills (West, 2011).*
- ▲ **EBN:** *A qualitative study explored the lives of hemodialysis clients and their adherence to treatment and quality of life and found that clients' two most important motivators were (1) embracing the disease and dialysis and (2) using management to prevent disease progression (Guerra-Guerrero et al, 2014).*

Ineffective Health maintenance

Kathaleen C. Bloom, PhD, CNM, and Barbara J. Olinzock, MSN, EdD, RN

NANDA-I

Definition

Inability to identify, manage, and/or seek out help to maintain health

Defining Characteristics

Absence of adaptive behaviors to environmental changes; absence of interest in improving health behaviors; inability to take responsibility for meeting basic health practices; insufficient knowledge about basic health practices; insufficient social support; pattern of lack of health-seeking behavior

Related Factors (r/t)

Alteration in cognitive functioning; complicated grieving; decrease in fine motor skills; decrease in gross motor skills; impaired decision-making; ineffective communication skills; ineffective coping strategies; insufficient resources (e.g., financial, social knowledge); perceptual impairment; spiritual distress; unachieved developmental tasks.

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Health Beliefs: Perceived Resources; Health-Promoting Behavior; Health-Seeking Behavior

Example NOC Outcome with Indicators

Health-Seeking Behavior as evidenced by the following indicators: Completes health-related tasks/Performs self-screening/Obtains assistance from health professional. (Rate the outcome and indicators of **Health-Seeking Behavior**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

H**Client Outcomes****Client Will (Specify Time Frame)**

- Discuss fear of or blocks to implementing health regimen
- Follow mutually agreed on health care maintenance plan
- Meet goals for health care maintenance

NIC (Nursing Interventions Classification)**Suggested NIC Intervention**

Health Education; Health System Guidance; Support System Enhancement

Example NIC Activities—Health Education

Prioritize identified learner needs based on client preference, skills of nurse, resources available, and likelihood of successful goal attainment; Emphasize immediate or short-term positive health benefits to be received by positive lifestyle behaviors, rather than long-term benefits or negative effects of noncompliance

Nursing Interventions and Rationales

- Assess the client's feelings, values, and reasons for not following the prescribed plan of care. See Related Factors. **EBN**: *A systematic review of 80 studies determined that personal beliefs and values, decisional control preferences, and perception of the decision-making process affect treatment decision-making in older adults diagnosed with cancer (Tariman et al, 2012).*
- Assess for family patterns, economic issues, spiritual, and cultural patterns that influence compliance with a given medical regimen. **CEB**: *A qualitative study (N = 14) found that critical challenges to increasing physical activity among low-income African American women included financial constraints (Harley et al, 2014).*
- Involve the client in shared decision-making regarding health maintenance. **CEB**: *A meta-analysis of 32 clinical trials revealed that assessing client preferences and involving them in shared decision-making had higher adherence, higher satisfaction, and better clinical outcomes (Lindhiem et al, 2014).*
- Show genuine interest in client's individual needs. **EBN**: *A systematic review of 24 qualitative studies concluded that clients' perception of the health care professional's responsiveness, interest in their individual needs, and shared information positively influence self-care for heart failure (Currie et al, 2014).*
- Assist the client in finding methods to reduce stress. **EBN**: *In a survey of 1257 university students, those who had high levels of perceived stress also engaged in high-risk behaviors such as alcohol consumption, unhealthy diet, physical inactivity, and tobacco and drug use (Deasy et al, 2014).*
- Help the client determine how to manage complex medication schedules (e.g., HIV/AIDS regimens or polypharmacy). **EBN**: *In a pilot study with 20 older adults taking an average of 13.2 prescription medications, providing an illustrated daily medication schedule improved both self-efficacy and adherence (Martin et al, 2012).*
- Identify complementary healing modalities, such as herbal remedies, acupuncture, healing touch, yoga, or cultural shamans that the client uses in addition to or instead of the prescribed allopathic regimen

along with the client's perception of the complementary healing modalities. **CEB:** *Use of complementary healing modalities among clients with chronic disease is relatively high. In an exploratory study with 217 Mexican immigrants, a person's beliefs about complementary and alternative therapies may negatively influence medical adherence (Villagran et al, 2012).*

- ▲ Refer the client to appropriate medical and social services as needed, providing adequate information on details about the service, including scheduling. **EBN:** *A metasynthesis of 62 qualitative studies concluded that client participation in services such as cardiac rehabilitation is most strongly associated with perceptions of the nature, suitability, and scheduling, but not the benefits of the rehabilitation program (Clark et al, 2013).*
- Identify support groups related to the disease process. **EBN:** *Individuals who attend support groups demonstrate improved disease management and enhanced quality of life. A systematic review of 84 studies of group visits for chronic illness found client benefits to include greater satisfaction and improved clinical outcomes (Jones et al, 2014).*
- Use social media such as text messaging to remind clients of scheduled appointments. **CEB:** *A Cochrane review of eight randomized controlled trials concluded that text messaging reminders increase attendance at health care appointments similar to telephone reminders but better than no reminders or postal reminders (Gurol-Urganci et al, 2013). Additional relevant research: Farmer et al, 2014; McInnes et al, 2014.*
- Use telehealth interventions to facilitate self-care. **EBN:** *A systematic review of 14 studies supports telehealth as a positive factor in enabling self-care behaviors related to daily weighing, medication management, exercise adherence, fluid and alcohol restriction, salt restriction, and stress reduction in clients with heart failure (Radhakrishnan & Jacelon, 2012).*

Geriatric

- Assess the client's perception of health and health maintenance. **CEB:** *A study of 681 older clients with diabetes or metabolic syndrome found that they often underestimate their cardiovascular risk, with as many as 42% perceiving themselves to be in good or excellent health (Martell-Claros et al, 2013).*
- Assist client to identify both life- and health-related goals. **CEB:** *A study of 308 women demonstrated beginning evidence that when the health goals of older individuals are congruent with their life goals, they are more likely to participate in health-related activities (Saajanaho et al, 2014).*
- Provide information that supports informed decision-making. **CEB:** *In a modified grounded theory study (N = 59), participants endorsed the elements of informed decision-making, including discussion of the role of the client, the clinical issue, the alternatives, benefits/risks/uncertainties; assessment of client understanding and preference; soliciting input from trusted others, and discussion of the impact on clients' daily lives (Price et al, 2012).*
- Discuss realistic goal setting for changes in health maintenance with the client and support person. **EBN:** *An integrative review of 13 studies revealed that mutual goal-setting between the client and the health care provider improves overall health behaviors and outcomes for older adults with chronic conditions (Anuruang et al, 2014).*
- Educate the client about the symptoms of life-threatening illness, such as myocardial infarction (MI), and the need for timeliness in seeking care. **EBN:** *A qualitative study with 42 persons with an MI found that misinformation regarding the symptoms of MI is common; many believe sudden, intense chest pain is the only indication of MI, resulting in delay in seeking treatment (O'Donnell & Moser, 2012).*

Multicultural

- Assess influence of cultural beliefs, norms, and values on the client's ability to modify health behavior. **EBN:** *A descriptive qualitative study of 30 Thai Buddhist people revealed that understanding the cultural and religious traditions, influence of family and economics when choosing interventions to help them cope with their illness and empower them to control their disease is essential for effective care (Lundberg & Thrakul, 2012).*
- Assess the effect of fatalism on the client's ability to modify health behavior. **CEB:** *A population-based study of 2018 adults found that fatalistic beliefs about cancer may hamper screening and delay help-seeking for symptoms (Beeken et al, 2011).*
- Clarify culturally related health beliefs and practices. **EBN:** *Language, culture, and ethnicity influence the choice of a health care provider and participation in health management strategies. An exploratory*

descriptive study with 23 women found that health/illness beliefs affect both self-care and care seeking (Hjelm et al, 2012).

- Provide culturally appropriate education and health care services. **CEB:** In a randomized controlled trial involving 223 Hispanic women, a culturally tailored lifestyle behavior intervention was shown to significantly influence dietary habits, weight, and waist circumference (Koniak-Griffin et al, 2014). **CEB:** In a systematic review of 28 studies of culturally adapted strategies to improve diet and weight outcomes of African American women, strategies that reflected the group's values and beliefs and that drew from the group's experiences were the most successful (Kong et al, 2014).

Home Care

- The interventions described previously may be adapted for home care use.
- ▲ Provide nurse-led case management. **EBN:** A review of relevant research concluded that individualized, systematic, and guideline-based nurse case management promotes cardiovascular risk reduction in home-based, primary care, and community settings (Berra, 2011).
- Provide a health promotion focus for the client with disabilities, with the goals of reducing secondary conditions (e.g., obesity, hypertension, pressure sores), maintaining functional independence, providing opportunities for leisure and enjoyment, and enhancing overall quality of life. **CEB:** A retrospective analysis of data from a national survey comparing health of adults with and without physical or cognitive disabilities found that individuals living with physical disabilities or cognitive impairment receive fewer preventive services and have higher rates of chronic illness (Reichard et al, 2011). A systematic review of 11 studies found that community-based physical activity and educational programs provide fitness and psychosocial benefits for individuals with intellectual disabilities (Heller et al, 2011).
- Provide support and individual training for caregivers before the client is discharged from the hospital. **EBN:** Caregivers are very interested in receiving instruction and hands-on practice of procedures they would need to perform at home. In a study of hospital-to-home transition of older veterans, caregivers (N = 40) reported increased confidence in their ability to provide such care and to help their loved ones manage symptoms at home (Hendrix et al, 2011).
- Assist client to develop confidence in ability to manage the health condition. **CEB:** A clinical trial of self-management education targeted at self-efficacy (N = 57) improved physiological outcomes, enhanced coping techniques, and reduced health care use (Labrecque et al, 2011).

Client/Family Teaching and Discharge Planning

- Provide the family with credible sources where information can be obtained from social media. (Most libraries have Internet access with printing capabilities.) **CEB:** In an experimental study (N = 197), researchers concluded that websites containing credible and evidence-based medical information positively affected users' health information seeking. General, non-evidence-based sites were perceived positively by the user, independent of the site's credibility, and often negatively influencing opinions about health practices (Allam et al, 2014).
- ▲ Develop collaborative multidisciplinary partnerships. **CEB:** Multidisciplinary and multifactorial interventions are likely to be more effective in achieving desired outcomes. In a quality improvement study of readmission rates for 463 clients with pneumonia, the clients whose in-hospital and post-discharge diagnosis and care was managed by a multidisciplinary team consisting of health care providers, nurses, and social workers had significantly fewer all-cause readmissions and readmissions for pneumonia (Hussein et al, 2014).
- Tailor both the information provided and the method of delivery of information to the specific client and/or family. **CEB:** A systematic review of 27 studies related to medication adherence and diabetes outcomes was not able to identify a specific intervention, but emphasized the need to tailor interventions to optimize management and improve outcomes (Williams et al, 2014).
- Explain nonthreatening qualities before introducing more anxiety-producing information regarding possible side effects of the disease or medical regimen. **EBN:** In a laboratory study of anxiety and task interference (N = 157), anxiety was found to interfere with concentration and the ability to understand and remember (Lachman & Agrigoroaei, 2012).

Impaired Home maintenance *Kathleen C. Bloom, PhD, CNM, and Barbara J. Olinzock, MSN, EdD, RN*

NANDA-I

Definition

Inability to independently maintain a safe, growth-promoting immediate environment

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Defining Characteristics

Difficulty maintaining a comfortable environment; excessive family responsibilities; financial crisis (e.g., debt, insufficient finances); insufficient clothing; insufficient cooking equipment; insufficient equipment for maintaining home; insufficient linen; pattern of disease caused by unhygienic conditions; pattern of infection caused by unhygienic conditions; request for assistance with home maintenance; unsanitary environment

Related Factors (r/t)

Alteration in cognitive functioning; condition impacting ability to maintain home (e.g., disease, illness injury); illness impacting ability to maintain home; injury impacting ability to maintain home; insufficient family organization; insufficient family planning; insufficient knowledge of home maintenance; insufficient knowledge of neighborhood resources; insufficient role model; insufficient support system

NOC (Nursing Outcomes Classification)

H

Suggested NOC Outcomes

Safe Home Environment; Self-Care: Activities of Daily Living (ADLs)

Example NOC Outcome with Indicators

Safe Home Environment as evidenced by the following indicators: Elimination of pests/Smoke detector maintenance/Accessibility of assistive devices/Elimination of tobacco smoke. (Rate the outcome and indicators of **Safe Home Environment**: 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain a healthy home environment
- Use community resources to assist with home care needs
- Maintain a safe home environment

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Home Maintenance Assistance

Example NIC Activities—Home Maintenance Assistance

Involve client/family in deciding home maintenance requirements; Provide information on how to make home environment safe and clean; Help family use social support network

Nursing Interventions and Rationales

- Assess the concerns of family members, especially the primary caregiver, about home care for a long time. **EBN**: A cross-sectional study of 515 caregiver/client dyads found that caregiver confidence in ability to contribute to their family member's self-care was a significant determinant of how much they were involved in self-care maintenance and management (Vellone et al, 2014).
- Provide home safety education and, safety equipment when possible. **CEB**: A Cochrane review of 98 studies (with meta-analysis of 54 studies) concluded that home safety interventions, especially those delivered in the home, were effective in reducing injury and in increasing uptake of home safety measures, including safe water temperature, functional smoke alarms, a fire escape plan, and storing hazardous items out of reach (Kendrick et al, 2012).
- ▲ Consider a predischarge home assessment referral to determine the need for accessibility and safety-related environmental changes. **CEB**: A randomized controlled trial (RCT) (N = 842 households; 1848 individual occupants) found significantly fewer falls and fall-related injuries in those households

that had specific low-cost home modifications such as alterations in steps inside and outside the house, grab rails and non-slip bath mats in bathrooms, outside lighting, and alterations in carpeting (Keall et al, 2014).

- Use an assessment tool to identify environmental safety hazards in the home. **EBN:** In a study of 130 persons receiving discharge teaching, those who received targeted education and practice using a mock-up of their home regarding home safety modifications had significantly fewer overall and in-home falls 1 year after discharge (Kamei et al, 2014).
- Establish an individualized plan of care for improved home maintenance with the client and family based on the client's needs and the caregiver's capabilities. **EBN:** In a study involving 116 households with 170 children with asthma, an in-home assessment followed by targeted changes in the home environment resulted in a decrease in all measures of asthma severity and health care utilization (Turcotte et al, 2014).
- Set up a system of relief for the main caregiver in the home and a plan for sharing of household duties and/or outside assistance. **EBN:** In a qualitative study, seven mothers providing care to children with complex health care needs verified that respite care provides decreased burden and improved quality of life for the caregiver and the family as a whole (Thomas & Price, 2012).
- ▲ Provide a multidisciplinary approach to target the home environment and the client's ability to function in the home. **EBN:** The Community Aging in Place: Advancing Better Living for Elders (CAPABLE), a program involving teams of nurses, occupational therapists, and handymen, targets the home environment and individual physical function (Pho et al, 2012; Szanton et al, 2014a). There is an ongoing RCT with 300 individuals testing the program's outcomes in terms of functional abilities, mobility, and environmental safety (Szanton et al, 2014b).
- Assess the quality of relationships among family members. **CEB:** In a cross-sectional study of fifth graders (N = 3218), unintentional injuries requiring medical attention were associated with parental marital discord (Schwebel et al, 2012).

Geriatric

- All of the previously mentioned interventions are applicable for the geriatric population.
- Assess injury prevention knowledge and practices of the client and caregivers and provide information as appropriate. **EBN:** A survey of 84 older adults showed that only 36% had a working smoke alarm, 22% had a working carbon monoxide alarm, and 36% had water that was hotter than recommended (Shields et al, 2013).
- Assess functional ability to manage safely after hospital discharge. **CEB:** A validation study of The Assessment of Motor and Process Skills and Cognitive Performance Test were found to reliably predict time to incident of harm post discharge (Douglas et al, 2013).
- Explore community resources to assist with home maintenance (e.g., senior centers, Department of Aging, hospital case managers, friends and relatives, the Internet, or church parish nurse). **CEB:** In a qualitative study with 43 older adults living at home, participants perceived they were both capable and willing to manage many home maintenance tasks. They reported using compensatory means, such as tools and technologies, to do home maintenance and repairs themselves as well as either hiring someone or having friends, neighbors, or family do the task (Kelly et al, 2014).
- Support "aging in place" by providing assistive technology devices: home modification, daily living aids, mobility aids, seating and positioning devices, and sensory aids. **CEB:** Assessment for risk and incorporation of compensatory strategies, home modification for access and safety, and exercises to promote balance and muscle strength in programs such as Advancing Better Living for Elders (ABLE) are cost-effective ways to delay functional decline and mortality in older adults (Jutkowitz et al, 2012).
- Focus on the interaction between the older client and the technology, assisting the client to be an active participant in choices of and uses for technology. **EBN:** A systematic review of 18 studies of communication technologies and assistive strategies concluded that when users of technologies are active in the technological process, assessed in interaction with technology in their everyday practices, the technology can be more efficiently used to meet the needs of the client (Rodeschini, 2011).
- See the care plans for Risk for **Injury** and Risk for **Falls**.

Multicultural

- Acknowledge the stresses unique to racial/ethnic communities. **CEB:** A systematic review of 57 studies revealed that cultural factors, including distrust of home visits, language barriers and lifestyle were barriers to home injury prevention interventions (Ingram et al, 2012).

Home Care

- The previously mentioned interventions incorporate these resources.
- See care plans **Contamination** and Risk for **Contamination**.

Client/Family Teaching and Discharge Planning

- Identify support groups within the community to assist families in the caregiver role. **CEB**: *Community-based participatory research using focus groups with 39 family caregivers found that caregivers are most in need of effective communication, emotional support, education, and advocacy (MacLeod et al, 2012).*
- Provide counseling and support for clients and for caregivers of clients. **CEB**: *A Cochrane review of 11 RCTs involving 1836 caregiver participants found evidence suggesting that interventions directly supporting the caregiver may help reduce psychological distress (Candy et al, 2011).*
- Focus teaching on environmental hazards identified in the nursing assessment. Areas may include, but are not limited to:
 - **Home Safety.** Identify the need for and use of common safety devices in the home. **EB**: *An RCT (N = 355) found that an intervention to reduce exposure to injury hazards (including installing smoke detectors, stair gates, and cabinet locks) in homes of young children led to a 70% reduction in injury (Phelan et al, 2011).*
 - **Food Safety.** Instruct client to avoid microbial food-borne illness by storing and cooking food at the proper temperature, regularly washing hands, food contact surfaces, and fruits and vegetables, and monitoring expiration dates. **EBN**: *A qualitative study of 10 households found that all took risks in terms of not following recommended practices with respect to best practices and that the logic behind food practices was often faulty (Dickinson et al, 2014).*
- Teach clients to assess their homes for potential environmental health hazards in the home, including risks related to structure, moisture/mold, fire, pets, electrical, ventilation, pests, and lifestyle. **CEB**: *The housing-based hazard index (HHI) is a measure of overall home hazards with good reliability and validity and the ability to discriminate between healthy and nonhealthy homes (N = 643) (Nriagu et al, 2012; Nriagu et al, 2011).*
- See care plans **Contamination**, Risk for **Contamination**, Risk for **Falls**, Risk for **Infection**, and Risk for **Injury**.

Readiness for enhanced Hope *Gail B. Ladwig, MSN, RN, and Marina Martinez-Kratz, MS, RN, CNE*

H

NANDA-I

Definition

A pattern of expectations and desires for mobilizing energy on one's own behalf, which can be strengthened

Defining Characteristics

Expresses desire to enhance ability to set achievable goals; expresses desire to enhance belief in possibilities; expresses desire to enhance congruency of expectations with goal; expresses desire to enhance connectedness with others; expresses desire to enhance hope; expresses desire to enhance problem solving to meet goal; expresses desire to enhance sense of meaning in life; expresses desire to enhance spirituality

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Hope; Quality of Life

Example NOC Outcome with Indicators

Hope as evidenced by the following indicators: Expresses expectation of a positive future/Expresses faith/Expresses meaning in life/Exhibits a zest for life/Sets goals. (Rate the outcome and indicators of **Hope**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Describe values, expectations, and meanings
- Set achievable goals that are consistent with values
- Design strategies to achieve goals
- Express belief in possibilities

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Emotional Support; Hope Inspiration; Presence; Support System Enhancement

Example NIC Activities—Hope Inspiration

Assist client and family to identify areas of hope in life; Demonstrate hope by recognizing the client's intrinsic worth; Encourage therapeutic relationships; Help the person expand spiritual self

Nursing Interventions and Rationales

- Develop an open and caring and empathetic relationship that enables the client to discuss hope. **EBN:** *Time nurses spend with clients can inspire hope (Montana & Kautz, 2011). In this study of clients in palliative care, hope was increased when empathy was used (Richardson et al, 2012).*
- Assist clients to identify sources of gratitude in their lives using a future oriented focus. **CEB:** *Research shows that clients with a regulatory focus of promotion were more likely to express gratitude, which inspired them to strengthen their relationships with helpful and responsive partners (Mathews & Shook, 2013).*
- Assist families to identify sources of gratitude in their lives. **CEB:** *Research showed that gratitude fostered all facets of post-traumatic growth, such as relationships, personal strengths, and awareness of meaningful possibilities (Ruini & Vescovelli, 2013).*
- Screen the client for hope using a valid and reliable instrument as indicated. **CEB:** *The HHI is a brief instrument with good psychometric properties that has been developed for clinical use. It has been designed to facilitate the examination of hope at various intervals so that changes in levels of hope can be identified (Van Gestel-Timmermans et al, 2010).*
- Focus on the positive aspects of hope, rather than the prevention of hopelessness. *Hope is essential to life and is therefore a fundamental human need. Without hope, despair and depression take hold with devastating effects (O'Hara, 2010).*
- Assist the client to expect positive outcomes and recognize the pathways to achieve the positive outcomes. **CEB:** *Research shows that these actions facilitate the development of hope as a strength (Proctor et al, 2011).*
- Assist clients in developing realistic goals for their recovery. **EBN:** *Realistic goals reflect realistic sense of hope versus false hope (Tutton et al, 2012).*
- Assist clients to set a goal, write down what steps are needed to achieve the goal, and visualize themselves reaching the goal. **CEB:** *Research found that structured goal setting session was sufficient to foster hope (Feldman & Dreher, 2011).*
- Teach individuals how to become aware of attention that is focused on unwanted aspects of life and how to redirect attention toward things that feel more wanted or desired by using a future directed approach. **CEB:** *Future directed therapy is effective at decreasing hopelessness and increases positive future expectations (Vilhauer et al, 2013).*
- Engage the client in a therapeutic relationship to enhance social connectedness and social support networks. **EBN:** *Nursing research found that relationship based interventions improve a client's sense of social connectedness and decrease hopelessness (McCay et al, 2011).*
- Provide emotional support and encourage hope. **CEB:** *This study illustrates how reestablishment of a hopeful attitude can strengthen a client even with end-stage pulmonary disease and passive suicidal ideation (Anbar & Murthy, 2010).*
- Help the client identify his or her desires and expectations. **EBN:** *This study indicates that nurses working with clients with serious conditions such as cancer listen carefully to the clients' metaphors and reflect on the implicit meaning of them, helping the clients to see the light on the horizon and helping them to realize that hope and hopelessness are two sides of the same coin (Hammer et al, 2009).*
- Use a family-oriented approach when discussing hope. **CEB:** *Adaptation is an issue for the whole family and is facilitated by being able to stay close to the client and receive supportive unambiguous information from the staff both during the intensive care unit stay and after discharge (Söderström et al, 2009).*
- Review internal and external resources to enhance hope. **EBN:** *In a concept analysis of hope, based on a review of 17 research studies of terminally ill clients, the 10 attributes of hope were identified as positive expectation, positive qualities, spirituality, goals, comfort, help/caring, interpersonal relationships, control, legacy, and life review (Johnson, 2007).*
- Identify spiritual beliefs and practices. **CEB:** *Hope is a spiritual need, as identified in a study of 683 individuals (Flannelly et al, 2006).* **CEB:** *Spirituality was identified as a factor in increasing hope in clients with mental illness (Schränk et al, 2012).*
- Assist the person to consider possible adaptations to changes. **EBN:** *A grounded theory study of 41 women looked at refocusing hope after having a diagnosis of fetal abnormality identified by ultrasound. It identified four phases they experienced as "assume normal," "shock," "gaining meaning," and "rebuilding." It showed that they maintained hope by attaching their hopes to reality and adapting to changes as needed (Lalor et al, 2009).*

Home Care

- The above interventions may be adapted for home care use.

Client/Family Teaching and Discharge Planning

- Assess client and family hope before teaching. **CEB**: *The degree and type of client and family hope may differ from each other, which may interfere with learning and use of knowledge for problem solving (Benzein & Berg, 2005).*
- Incorporate client and family goal setting within teaching content. **EBN**: *Realistic goal setting fosters and supports hope (Lalor et al, 2009).*
- Teach alternative coping strategies such as physical activity. **CEB**: *Clients with severe mental illness showed decreased hopelessness after participation in an adjunct exercise program (Sylvia et al, 2013).*
- Provide information to the client and family regarding all aspects of the client's health condition. **EBN**: *Accurate and complete information sharing empowers, which is more likely to support hope than the perceptions that might occur without accurate and complete information (Forbat et al, 2009; Lalor et al, 2009). The most important need identified in the Critical Care Family Needs Inventory was "hope," followed by the need for adequate and honest information (Linnarsson et al, 2010).*
- Offer emotional support, active listening, and coping assistance to client families. **EBN**: *Family hopelessness is addressed when nurses offer emotional support (Coco et al, 2013).*

Hopelessness *Gail B. Ladwig, MSN, RN, and Marina Martinez-Kratz, MS, RN, CNE*

NANDA-I

Definition

Subjective state in which an individual sees limited or no alternatives or personal choices available and is unable to mobilize energy on own behalf

Defining Characteristics

Alteration in sleep pattern; decrease in affect; decrease in appetite; decrease in initiative; decrease in response to stimuli; decrease in verbalization; despondent verbal cues (e.g., “I can’t,” sighing); inadequate involvement in care; passivity; poor eye contact; shrugging in response to speaker; turning away from speaker

H

Related Factors (r/t)

Chronic stress; deterioration in physiological condition; history of abandonment; loss of belief in spiritual power; loss of belief in transcendent values; prolonged activity restriction; social isolation

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Hope; Mood Equilibrium; Nutritional Status: Food and Fluid Intake; Quality of Life; Sleep

Example NOC Outcome with Indicators

Has a presence of **Hope** as evidenced by the following indicators: Expresses expectation of a positive future/Expresses faith/Expresses will to live. (Rate the outcome and indicators of **Hope**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize feelings
- Participate in care
- Make positive statements (e.g., “I can” or “I will try”)
- Set goals
- Make eye contact, focus on speaker
- Maintain appropriate appetite for age and physical health
- Sleep appropriate length of time for age and physical health
- Express concern for another
- Initiate activity

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Hope Inspiration

Example NIC Activities—Hope Inspiration

Assist client/family to identify areas of hope in life; Demonstrate hope by recognizing client’s intrinsic worth and viewing client’s illness as only one facet of the individual; Expand the client’s repertoire of coping mechanisms

Nursing Interventions and Rationales

- ▲ Assess for, monitor, and document the potential for suicide. (Refer the client for appropriate treatment if a potential for suicide is identified.) Refer to the care plan risk for **Suicide** for specific interventions. **CEB**: *In this study of men who had attempted suicide, hopelessness was identified as an important risk factor and thus it is important to be identified by nurses (Hinkkurinen et al, 2011).*

- ▲ Assess and monitor potential for depression. (Refer the client for appropriate treatment if depression is identified.) **CEB:** *Hopelessness is a potential predictor for depressive and suicidal symptoms (Wang et al, 2013).*
- ▲ Assess for hopelessness with the modified Beck Hopelessness Scale. **CEB:** *The modified Beck Hopelessness Scale is a valid and reliable tool to measure hopelessness (Fisher & Overholser, 2013).*
- Engage the client in a therapeutic relationship to enhance social connectedness and social support networks. **EBN:** *Nursing research found that relationship-based interventions improve a client's sense of social connectedness and decrease hopelessness (McCay et al, 2011).*
- Assess and monitor family caregivers for symptoms of hopelessness. **CEB:** *Caregivers of advanced cancer clients are at risk for experiencing hopelessness (Mystakidou et al, 2007a).* **EBN:** *Adult daughter caregivers experience hopelessness as part of compassion fatigue (Day et al, 2014).*
- Determine appropriate approaches based on the underlying condition or situation that is contributing to feelings of hopelessness. **CEB:** *Understanding the source of the hopelessness, such as negative life events, will indicate the approaches that may be most beneficial to the person (Toussaint et al, 2008).* **CEBN:** *Women with advanced breast cancer and their families and men with prostate cancer and their families benefit from specific strategies of intervention (Northouse et al, 2007).*
- Assess for pain and respond with appropriate measures for pain relief. **CEB:** *Pain that interferes with mood and enjoyment in life results in feelings of hopelessness for clients with advanced cancer (Mystakidou et al, 2007b).*
- Facilitate access to resources to support spiritual well-being. **EBN:** *Spiritual care that addresses three universal spiritual needs (meaning and purpose, love and relatedness, and forgiveness) is recommended as a valuable intervention to address hopelessness (Taylor, 2012).*
- Facilitate sources of the client's resilience. **CEB:** *Higher levels of resilience were associated with lower levels of hopelessness in children of HIV positive parents (Mo et al, 2014).*
- Assist the client to expect positive outcomes and recognize the pathways to achieve the positive outcomes. **CEB:** *Research shows that these actions facilitate the development of hope as a strength (Proctor et al, 2011).*
- Assist the client in looking at alternatives and setting long- and short-term goals that are important to him/her. **CEBN:** *When health professionals work with men with prostate cancer and their family caregivers, they should help them replace avoidant coping strategies with alternate strategies (Northouse et al, 2007).* *Setting goals is a future oriented action that promotes the development of hope and optimism (Duke et al, 2011).*
- Encourage clients to discuss hope, because discussion may be helpful in increasing hope. **CEBN:** *Entering into discussion of hope may be helpful in increasing hope (Cutcliff & Koehn, 2007).* **CEBN:** *Health-promoting conversations about hope and suffering with couples in palliative care has potential for improving hope (Benzein & Savemant, 2008).*
- Assist clients in developing realistic goals for their recovery. **EBN:** *Realistic goals reflect realistic sense of hope versus false hope (Tutton et al, 2012).*
- Assist clients to set a goal, write down what steps are needed to achieve the goal, and visualize themselves reaching the goal. **CEB:** *Research found that structured goal setting was sufficient to foster hope (Feldman & Dreher, 2011).*
- Provide accurate information. **CEBN:** *Accurate information allows the redefining and transforming of hope (Duggleby & Wright, 2005; Duggleby et al, 2009).*
- Encourage decision-making and problem solving. **EBN:** *Hopelessness may be an outgrowth of a perceived loss of control and/or self-efficacy. As changes occur, the nurse interacts with the client to evaluate their impact on life goals and assists in making adaptations that support hopefulness and decrease hopelessness (Kylma, 2005).* **CEB:** *Problem solving was associated with higher resilience and lower levels of hopelessness (Gooding et al, 2012).*
- Spend one-on-one time with the client. Use empathy; try to understand what the client is saying and communicate this understanding to the client to create a nonjudgmental trusting environment to develop therapeutic relationships with the client. **CEBN:** *The therapeutic relationship is an essential component of interventions to address hopelessness (Koehn & Cutcliff, 2007).*
- Teach alternative coping strategies such as physical activity. **CEB:** *Clients with severe mental illness showed decreased hopelessness after participation in an adjunct exercise program (Sylvia et al, 2013).*
- Use a future directed approach that teaches individuals how to become aware of attention that is focused on unwanted aspects of life and how to redirect attention toward things that feel more wanted or desired.

CEB: *Future directed therapy is effective at decreasing hopelessness and increases positive future expectations (Vilhauer et al, 2013).*

- Review the client's strengths and resources in conjunction with the client. **CEBN:** *Working with the client to identify positive experiences, resources, and personal strengths facilitates the development of hopefulness (Kylma, 2005).*
- Encourage the client to adopt active coping strategies. **CEB:** *Active coping strategies decreased hopelessness in both curative and palliative cancer patients (van Laarhoven et al, 2011).*
- Involve family and significant others in the plan of care. **EBN:** *Social support decreased hopelessness and anxiety in parents of children with cancer (Bayat et al, 2008).*
- Offer emotional support, active listening, and coping assistance to client families. **EBN:** *Family hopelessness is addressed when nurses offer emotional support (Coco et al, 2013).*
- For additional interventions, see the care plans for Readiness for enhanced **Hope**, **Spiritual** distress, Readiness for enhanced **Spiritual** well-being, and Disturbed **Sleep** pattern.

H

**Geriatric**

- Previous interventions may be adapted for geriatric clients.
- ▲ If depression is suspected, confer with the primary health care provider regarding referral for mental health services. **CEB:** *This study of older adults identified hopelessness as a major risk factor for suicide (Neufeld et al, 2010).*
- Take threats of self-harm or suicide seriously and intervene as needed. **CEB:** *This study of older adults identified hopelessness as a major risk factor for suicide (Neufeld et al, 2010). Older adults have the highest risk of death by suicide in the United States (Cukrowicz et al, 2011).*
- Use reminiscence and life-review therapies to identify past coping skills. Older people in residential facilities benefit from this therapy (Wang, 2004). **CEB:** *Life review produced a positive outcome when used with individuals with right hemisphere cerebrovascular accidents (Davis, 2004).*
- Encourage visits from children and family members. **CEBN:** *Social relationships foster hopefulness (Duggleby, 2001).*
- Consider videoconferencing for older adults in nursing homes with relatives as alternatives to “live visits.” *Once-a-week videoconferencing effectively improved the nursing home residents’ emotional and appraisal social support, depressive status, and loneliness (Tsai et al, 2010).*
- Position the client by a window, take the client outside, or encourage such activities as gardening (if ability allows). *Using nature can help older people expand their perspectives, connect with strength, and expand their coping strategies, while gaining a wider sense of acceptance and completion in life (Berger, 2009).*
- Provide esthetic forms of expression, such as dance, music, literature, and pictures. **EBN:** *Esthetic experiences are related to feelings of timelessness and spacelessness and serve as sources of gratification (Wikstrom, 2004).*
- Consider “biblio and telephone therapy” (BTT). **CEB:** *The results of this study of older adults demonstrated that the clients benefited from BTT and that depressive symptoms lessened (Brenes et al, 2010).*

**Multicultural**

- Assess for the influence of cultural beliefs, norms, and values on the client's feelings of hopelessness. **CEB:** *In some Latino cultures, talking about depression (depresión) may be taboo. Hopelessness (desanimo) may be understood differently by clients of various cultural backgrounds and may have a more normative and culturally specific, comfortable sound for clients (Marsiglia et al, 2011).*
- Assess the effect of fatalism on the client's expression of hopelessness. **EBN:** *Fatalistic perspectives, which involve the belief that one cannot control one's own fate, may influence health behaviors in some Asian, African American, and Latino populations (Marsiglia et al, 2011). This study of African Americans with multiple sclerosis identified fatalism, defined as a surrender of power to external forces in life leading to hopelessness, as being common among some African Americans (Holland et al, 2011).*
- ▲ Assess for depression and refer to appropriate services. **CEB:** *Hispanic women expressing hopelessness may also be at risk for depression (Marsiglia et al, 2011).*
- Encourage spirituality as a source of support for hopelessness. **CEBN:** *African Americans and Latinos may identify spirituality, religiousness, prayer, and church-based approaches as coping resources (Samuel-Hodge et al, 2000). CEBN: Spiritual beliefs, the role of prayer, and the role of family in caregiving were predominant aspects of the end-of-life experience in Mexican Americans. There is a need to focus on the role*

of religious institutions in Mexican American culture, where spirituality and religion are strong influences in the life experience (Johnston, 2007).

Home Care

- Previously mentioned interventions may be adapted for home care use.
- ▲ Assess for isolation within the family unit. Encourage the client to participate in family activities. If the client cannot participate, encourage him/her to be in the same area and watch family activities. Refer for telephone support. **CEBN:** *Hope is facilitated by meaningful interpersonal relationships (Koehn & Cutcliff, 2007).* **CEB:** *Clients show significant improvements in depression and positive affect during the 16 weeks of telephone-administered treatment (Mohr et al, 2005).*
- Reminisce with the client about his/her life. **CEBN:** *The process of remembering past activities helps find meaning and purpose in life and inspires hope (Duggleby & Wright, 2005).* **CEB:** *Older people in residential facilities benefit from life review (Chin, 2007).*
- Identify areas in which the client can have control. Allow the client to set achievable goals in these areas. Assist the client when necessary to negotiate desirable outcomes. **CEBN:** *Mobilization of resources to promote self-efficacy promotes hope (Kylma, 2005).*
- If illness precipitated the hopelessness, discuss knowledge of and previous experience with the disease. Help the client identify past coping strengths. **CEBN:** *Knowledge of the disease and previous positive coping experience with the illness provide hope for the future (Duggleby & Wright, 2005).*
- ▲ Provide plant or pet therapy if possible. **CEBN:** *Caring for pets or plants helps to find meaning and purpose and foster hope (Holtslander & Duggleby, 2009).*

Client/Family Teaching and Discharge Planning

- Provide information regarding the client's condition, treatment plan, and progress. **CEBN:** *Clear, direct communication of the potential of an intervention to overcome a threat along with honest discussion of negative aspects fosters hope for clients and their families (Duggleby & Wright, 2005; Holtslander et al, 2005).*
- Teach family caregivers skills to provide care in the home. **CEBN:** *Family caregivers find hope in giving skilled care to their family members (Duggleby et al, 2009).* **CEBN:** *A psychoeducational program preparing family caregivers for caring for a dying relative at home increased their feeling of caregiving competence and rewards (Hudson et al, 2008).*
- Provide positive reinforcement, praise, and acknowledgment of the challenges of caregiving to family members. **EBN:** *Positive comments and praise foster hope in family caregivers (Holtslander et al, 2005).*
- ▲ Refer the client to self-help groups, such as "I Can Cope" and "Make Today Count." **CEBN:** *Self-help and/or professionally led curriculum-based support programs for families are effective in reducing stress and facilitating coping and hope (Northouse et al, 2007).*
- ▲ Consider an Internet-based behavior change intervention when depression is identified by primary care provider in adolescents. **CEB:** *In this study, a primary care/Internet-based intervention model among adolescents demonstrated reductions in depressed mood over 6 months and may result in fewer depressive episodes (Hoek et al, 2011).*

Risk for compromised Human Dignity

Shari D. Froelich, DNP, MSN, MSBA, ANP, BC, ACHPN, PMHNP, BC, and Betty J. Ackley, MSN, EdS, RN

NANDA-I

Definition

Vulnerable for perceived loss of respect and honor, which may compromise health

Risk Factors

Cultural incongruence; dehumanizing treatment; disclosure of confidential information; exposure of the body; humiliation; insufficient comprehension of health information; intrusion by clinician; invasion of privacy; limited decision-making experience; loss of control over body function; stigmatization

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health Beliefs: Perceived Control; Decision-Making; Spiritual Control; Perceived Social Support

Example NOC Outcome with Indicators

Health Beliefs: Perceived Control as evidenced by the following indicators: Perceived responsibility for health decisions/Requested involvement in health decisions/Efforts at gathering information/Belief that own decisions control health outcomes/Willingness to designate surrogate decision maker. (Rate the outcome and indicators of **Health Beliefs: Perceived Control**: 1 = very weak, 2 = weak, 3 = moderate, 4 = strong, 5 = very strong [see [Section I](#)].)

Client-Based Outcome

Client/Caregiver Will (Specify Time Frame)

- Perceive that dignity is maintained throughout hospitalization/encounter
- Consistently call client by name of choice
- Maintain client's privacy

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Presence; Decision-Making Support; Spiritual Support; Hope Instillation

Example NIC Activities—Presence

Demonstrate accepting attitude; Listen to client's concerns

Nursing Interventions and Rationales

- Be authentically present when with the client, try to limit extraneous thoughts of self or others, and concentrate on the well-being of the client. **EBN**: *Human presence never leaves one unaffected. Expressed as compassion and caring, it is not only the words that are spoken or the eyes that notice, leading to action (Manookian et al, 2014).*
- Enter into and stay within the other's frame of reference. Connect with the inner life world of meaning and spirit of the other. Join in a mutual search for meaning and wholeness of being and becoming to potentiate comfort measures, pain control, a sense of well-being, wholeness, or even spiritual transcendence of suffering. **EBN**: *Human dignity is a central concept within nursing and the caring professions because it communicates the shared humanity. A shared humanity is evident anywhere where human beings interact, and because nurses are eager to actualize the healing relationship with clients, they have the opportunity to share their humanity (Manookian et al, 2014).*
- Determine the client's perspective about his/her health. Example questions include "Tell me about your health." "What is it like to be in your situation?" "Tell me how you perceive yourself in this situation."

“What meaning are you giving to this situation?” “Tell me about your health priorities.” “Tell me about the harmony you wish to reach.” **CEB:** *Such questions usually contribute to helping people find meaning to the crisis in their life (Watson, 2008).* **CEB:** *Confirm the person’s worthiness and sense of self. A genuine respect for the person as a unique human being, with an inherent desire or right to make choices according to his/her subjective needs, was found to be fundamental in advocating autonomy and integrity. Confirming the person’s worthiness and sense of self in this way was identified as crucial in dignity preservation. In order to preserve personal dignity and reduce the experienced loss of freedom, autonomy, and integrity, going for frequent walks was given high priority (Tranvag et al, 2013).*

- Determine the client’s preferences for when and how nursing care is needed and follow the client’s guidelines if possible. *The client’s autonomy must be recognized as part of dignified nursing care.* **CEB:** *A summary of older adults’ perceptions of the most important nurse caring behaviors is, Knowing what they are doing, Know when it’s necessary to call the medical provider, Treat me as an individual, Give my treatments and medications on time, Check my condition very closely, Give my pain medication on time, Know how to handle equipment, Keep my family informed of my progress, Don’t give up on me when I am difficult to get along with (Marini, 1999).*
- Include the client in all decision-making; if the client does not choose to be part of the decision or is no longer capable of making a decision, use the named surrogate decision maker. *The Patient Self-Determination Act, effective in 1991, requires that all individuals receiving medical care also receive written information about their right to accept or refuse medical or surgical treatment and their right to initiate advance directives (Dossey & Keegan, 2009).*
- Maintain client’s privacy at all times.
- Actively listen to what the client is saying both verbally and nonverbally. **CEB:** *We must quiet our “inner dialogue” so that we may hear more clearly, allow others to tell the whole story, listen without judgment or advice, and bear witness to the experience. Attentive silence is a communicative act in its own right, an act of compassion. It signifies respect, legitimizes what is said, and creates an atmosphere in which self-discovery can occur (Stanley, 2002).*
- Encourage the client to share thoughts about spirituality as desired. **CEB:** *The care of the soul remains the most powerful aspect of the art of caring in nursing. The caring occasion becomes “transpersonal” when “it allows for the presence of the spirit of both—then the event of the moment expands the limits of openness and has the ability to expand human capabilities” (Watson, 2008).*
- Use interventions to instill increased hope; see the care plan for Readiness for enhanced **Hope**. **CEB:** *When hope for a cure is no longer possible, help clients recognize that the relationships change between clients, families, and caregivers but do not end. Hope continues, but has a different focus (Erlen, 2003). Caring does not end but is rather transformed when intensive treatment ends.*
- For further interventions on spirituality, see the care plan for Readiness for enhanced **Spiritual** well-being.

Geriatric

- Always ask the client how he/she would like to be addressed. Avoid calling older clients “sweetie,” “honey,” “Gramps,” or other terms that can be demeaning unless this is acceptable in the client’s culture or requested by the client. *Appropriate forms of address must be used with older adults to maintain dignity.* **CEB:** *A respectful form of address has positive effects, whereas overfamiliarity tends to have a negative impact on self-respect, physical and mental health, and recovery from disease, particularly in older adults and those with dementia (Williams et al, 2008; Woolhead et al, 2006).*
- Treat the older client with the utmost respect, even if delirium or dementia is present with confusion. *Confused clients respond positively to caregivers who approach gently, with positive regard, and treat the confused client with respect and dignity.*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client’s way of communicating, and follow the client’s lead in communicating in matters of eye contact, amount of personal space, voice tones, and amount of touching. If in doubt, ask the client. *What the client considers normal and appropriate communication that maintains and facilitates dignity is based on cultural perceptions.* **CEB:** *Client dignity is promoted when staff provide privacy and use interactions that help clients feel comfortable, in control, and valued. Individual staff behavior has a major impact on whether threats to client dignity actually lead to its loss (Baillie, 2009).*

Home Care

- Most of the interventions described previously may be adapted for home care use.
- Recognize that the client with the caregiver has complete autonomy in the home. *The nurse's role is to provide the care needed and desired. The client and caregiver determine if the care offered is acceptable.*

Client/Family Teaching and Discharge Planning

- Teach family and caregivers the need for the dignity of the client to be maintained at all times. How an individual cognitively perceives and emotionally deals with the illness can depend on the person's family and social relationships and ultimately can affect the ability to heal. NOTE: Caring is integral to maintaining dignity. **CEB:** *According to Jean Watson (2008), a caring occasion is the moment (focal point in space and time) when the nurse and another person come together in such a way that an occasion for human caring is created. Both the one cared for and the one caring can be influenced by the caring moment through the choices and actions decided within the relationship, thereby influencing and becoming part of their own life history.*

Hyperthermia *Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN*

NANDA-I

Definition

Core body temperature above the normal diurnal range due to failure of thermoregulation

Defining Characteristics

Abnormal posturing; apnea; coma; convulsions; flushed skin; hypotension; infant does not maintain suck; irritability; lethargy; seizure; skin warm to touch; stupor; tachycardia; tachypnea; vasodilation

Related Factors (r/t)

Decreased sweat response; dehydration; high environmental temperature; illness; inappropriate clothing; increase in metabolic rate; ischemia; pharmaceutical agent; sepsis; trauma; vigorous activity

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Thermoregulation; Thermoregulation: Newborn

- = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Example NOC Outcome with Indicators

Thermoregulation as evidenced by the following indicators: Increased skin temperature/Decreased skin temperature/Skin color changes/Dehydration/Hyperthermia. (Rate the outcome and indicators of **Thermoregulation**: 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain core body temperature within adaptive levels (less than 104° F, 40° C)
- Remain free of complications of malignant hyperthermia
- Remain free of complication of neuroleptic malignant syndrome
- Remain free of dehydration
- Remain free from infection
- Verbalize signs and symptoms of heat stroke and actions to prevent heat stroke
- Verbalize personal risks for malignant hyperthermia and neuroleptic malignant syndrome to be reported during health history reviews to all health care professionals, including pharmacists

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Fever Treatment; Malignant Hyperthermia Precautions; Temperature Regulation

Example NIC Activities—Hyperthermia Treatment

Monitor core body temperature using appropriate device; Monitor for abnormalities in mental status

Nursing Interventions and Rationales

Temperature Measurement

- Recognize that hyperthermia is a rise in body temperature above 40° C (104° F) that is not regulated by the hypothalamus, resulting in an uncontrolled increase in body temperature exceeding the body's ability to lose heat, and is a medical emergency (Dinarello & Porat, 2012; Saltzberg, 2013).
- Measure and record a client's temperature every hour and more frequently as clinically indicated. Two modes of temperature monitoring may be indicated. Continuous temperature monitoring using an indwelling method of temperature measurement is usually indicated to monitor effectiveness of interventions in lowering the body temperature. **EBN/CEB**: *Hyperthermia is a life-threatening crisis that requires accurate temperature measurement. Core temperature is obtained by a pulmonary artery catheter or from the distal esophagus; near core temperature measurements include oral, bladder, rectal, and temporal artery, and peripheral measurements are obtained by skin surface measurements and in the axilla (Davie & Amoore, 2010; Barnason et al, 2012; Hooper et al, 2009). Research is limited on accuracy of temporal artery measurements outside normal ranges; axillary temperature is accurate in neonates but is not well supported in adults; tympanic membrane measurements and chemical dot thermometers are least accurate and should be avoided in caring for the acutely ill adult client (Calonder et al, 2010; Davie & Amoore, 2010; Hooper et al, 2009; Makic et al, 2011; Barnason et al, 2012; Kenney et al, 2014).*
- Use the same site and method (device) for temperature measurement for a given client so that temperature trends are assessed accurately; record site of temperature measurement. **EBN/CEB**: *There are differences in temperature depending on the site from which temperature measurement is obtained; however, differences between sites should not be greater than 0.3° C to 0.5° C (Bridges & Thomas, 2009; Davie & Amoore, 2010; Dinarello & Porat, 2012; Hooper et al, 2009; Makic et al, 2011; Kenney et al, 2014).*
- ▲ Work with the health care provider to help determine the cause of the temperature increase, hyperthermia, which will often help direct appropriate treatment. *It is important to treat the underlying cause of the temperature to preserve neurological function of the client as well as implement interventions to rapidly lower the core temperature (Saltzberg, 2013; Dinarello & Porat, 2012; Leon & Helwig, 2010; Bohman & Levine, 2014).*
- Refer to care plan for Ineffective **Thermoregulation** for interventions managing fever (pyrexia).

Heat Stroke

- Recognize that heat stroke may be separated into two categories: classic and exertional. *Classic heat stroke usually involves the very young and older client during environmental heat waves. Exertional heat stroke occurs in young adults performing strenuous exercise in hot climates (Leon & Helwig, 2010; Thomas & Crowhurst, 2013; Kerr et al, 2014).*
- Watch for risk factors for classic heat stroke, which include (Leon & Helwig, 2010):
 - Medications, especially diuretic agents, anticholinergic agents, anti-Parkinson medications
 - Alcoholism
 - Mental illness
- ▲ **EB:** *Physiological effects of aging lower onset of sweating and rate of sweating needed to help with dissipation of body heat. Medications can dehydrate the client as well as blunt physiological responses necessary to assist with heat dissipation, increasing the risk of heat stroke in older clients (Brege, 2009; Leon & Helwig, 2010).*
- Risk factors of exertional heat stroke include (Kerr et al, 2014):
 - Preexisting illness
 - Drug use (e.g., alcohol, amphetamines, ecstasy)
 - Wearing protective clothing (uniforms and athletic gear) that limits heat dissipation
- Recognize signs and symptoms of hyperthermia: core body temperature greater than 40°C (104°F), exercise associated muscle cramps, tachycardia, tachypnea, orthostatic dizziness, weakness, vomiting, headache, confusion, delirium, seizures, coma, acute kidney injury (rhabdomyolysis), hot dry skin (classic heat stroke) (Pryor et al, 2013; Brege, 2009; Dinarello & Porat, 2012; Leon & Helwig, 2010).
- Recognize that antipyretic agents are of little use in treatment of hyperthermia. **CEB:** *Because the cause of the hyperthermia does not involve the hypothalamus, antipyretic agents are ineffective and not indicated in treatment of clients with hyperthermia (Dinarello & Porat, 2012; Hamaya et al, 2015).*
- ▲ Assess fluid loss and facilitate oral intake or administer intravenous fluids as ordered to accomplish fluid replacement and support the cardiovascular system. *Increased metabolic rate, diuresis, and diaphoresis-associated exertional hyperthermia cause loss of body fluids (Brege, 2009; CDC, 2013).* Refer to the care plan for Deficient **Fluid** volume.
- Use external cooling measures carefully: loosen or remove excessive clothing, give a tepid water bath, provide cool liquids if the client is alert enough to swallow, fan the client's face. **EB/EBN:** *Hyperthermia must be treated aggressively to lower the body temperature. However, interventions to cool the client should not be so aggressive that the client shivers. Shivering increases heat production, oxygen consumption, and cardiorespiratory effort (Pryor et al, 2013; Brege, 2009; CDC, 2013; Pitoni et al, 2011).*
- Recognize that cooling with ice packs, cooled intravenous solution, or a hypothermia blanket may be required to lower the body temperature quickly (Dinarello & Porat, 2012; Leon & Helwig, 2010). When using a cooling blanket, choose a circulating water cooling device if available and set the temperature regulator to 0.5°C to 1°C (1°F to 2°F) below the client's current temperature to prevent shivering. **CEB:** *A review examining cooling methods found that skin surface cooling methods using ice and fans provided inconsistent cooling; hydrogel-coated water circulating pads placed on the chest and legs provided better targeted cooling than water circulating cooling blankets that can be placed over or under the client; and intravascular core cooling is an invasive technique that may be used to rapidly cool the body (Polderman & Herold, 2009).*
- ▲ Continually assess the client's neurological and other organ function, especially kidney function (i.e., signs of rhabdomyolysis), for signs of injury from hyperthermia. **EB/EBN:** *Hyperthermia can cause permanent neurological injury, acute kidney injury, electrolyte imbalances, and coagulation disorders. Continuous assessment of neurological and other organ function is essential because the client's body temperature is rapidly lowered (CDC, 2013; Hamaya et al, 2015; Pryor et al, 2013; Dinarello & Porat, 2012; Thomas & Crowhurst, 2013).*

Malignant Hyperthermia

- ▲ If the client has just received general anesthesia, especially sevoflurane, desflurane, enflurane, isoflurane, or succinylcholine, recognize that the hyperthermia may be caused by malignant hyperthermia and requires immediate treatment to prevent death. *Malignant hyperthermia is often a fatal disease and must be treated promptly. Emergent treatment includes rapid administration of the medication dantrolene, increasing oxygenation and assisting ventilation, initiating external cooling measures, and treating*

acid-base (e.g., metabolic acidosis) and electrolyte disorders (Seifert et al, 2014; Dinarello & Porat, 2012; Hopkins, 2011).

- Recognize that signs and symptoms of malignant hyperthermia typically occur suddenly after exposure to the anesthetic agent and include rapid rise in core body temperature, hypercarbia (increase in end tidal carbon dioxide), muscle rigidity, arrhythmias, tachycardia, tachypnea, rhabdomyolysis, and acute kidney injury, and elevated serum calcium and potassium, progressing to disseminated intravascular coagulation and cardiac arrest (Seifert et al, 2014; Stewart 2014; Hopkins, 2011).
- ▲ If the client has malignant hyperthermia, begin treatment as ordered, including cessation of the anesthetic agent and intravenous administration of dantrolene sodium, stat, along with antiarrhythmics, and continued support of the cardiovascular system. *Dantrolene helps decrease the increased muscle activity associated with malignant hyperthermia and can be life-saving (Dinarello & Porat, 2012).*
- Provide client and family education when malignant hyperthermia occurs, as it is an inherited muscle disorder. *Obtaining a thorough health history to include family history of adverse experiences with anesthesia is important in identifying clients at risk for malignant hyperthermia. Genetic testing may also be indicated (Malignant Hyperthermia Association of the United States, 2015).*

Neuroleptic Malignant Syndrome

- ▲ Recognize that neuroleptic malignant syndrome is a rare condition associated with clients who are taking typical and atypical antipsychotic agents (Takanobu K et al, 2015; Paden et al, 2013; Gillman, 2010; Trollor et al, 2009). **EB/EBN:** *The most common agents associated with the condition are dopamine-2 inhibiting agents (e.g., haloperidol, fluphenazine, chlorpromazine, quetiapine, risperidone, and olanzapine). Dopamine antagonist agents have also been found to trigger the syndrome as well (e.g., metoclopramide, promethazine, prochlorperazine) (Takanobu et al, 2015; Paden et al, 2013; Dinarello & Porat, 2012; Gillman, 2010; Trollor et al, 2009).*
- Watch for signs and symptoms that can range from mild to severe and include a sudden change in mental status, rapid rise in body temperature, muscle rigidity, tachycardia, tachypnea, elevated or labile blood pressure, diaphoresis, rhabdomyolysis, and acute kidney injury (Paden et al, 2013).
- ▲ Begin treatment when diagnosed, including cessation of the neuroleptic or dopamine antagonist agent; order administration of dantrolene and continued support of the cardiovascular, pulmonary, and renal systems (Dinarello & Porat, 2012).
- A client health history that reports extrapyramidal reaction to any medication should be further explored for risk of neuroleptic malignant syndrome, because this syndrome can occur at any time during a client's treatment with typical and atypical antipsychotic agents (Takanobu et al, 2015; Paden et al, 2013; Trollor et al, 2009).
- Recognize that clients receiving rapid dose escalation of antipsychotic agents (e.g., haloperidol) intramuscularly for acute treatment of delirium may be at increased risk for neuroleptic malignant syndrome (Takanobu et al, 2015; Paden et al, 2013).

Pediatric

- Assess risk factors of malignant hyperthermia as this has an increased prevalence in the pediatric population. *The administration of inhalation anesthesia and succinylcholine is common in this age group. Risk assessment includes a personal or family history of anesthesia-related complications or death (Malignant Hyperthermia Association of the United States, 2015).*
- ▲ Administer dantrolene, provide oxygen and assist with ventilation, monitor heart rate and rhythm, and treat electrolyte and acid-base disorders (i.e., metabolic acidosis) as ordered if malignant hyperthermia is present. *Dantrolene and airway management/support are necessary during emergent treatment of malignant hyperthermia (Dinarello & Porat, 2012; Seifert et al, 2014).*

Geriatric

- Help the client seek medical attention immediately if elevated core temperature is present. To diagnose the hyperthermia, assess for possible precipitating factors, including changes in medication, environmental changes, and recent medical interventions or infectious exposures. *Older adults are more susceptible to environmentally and medication-induced hyperthermia, due to the greater incidence of underlying chronic medical conditions that impair thermal regulation or prevent removal from a hot environment (Saltzberg, 2013).*
- In hot weather, encourage the client to wear lightweight cotton clothing (Sadler, 2011).

- Provide education on the importance of drinking eight glasses of fluid per day (within their cardiac and renal reserves) regardless of whether they are thirsty. Assess for the need for and presence of fans or air conditioning, and also appropriate clothing. *Older adults are more susceptible to a hot environment than are younger adults because of a decreased sensitivity to heat, decreased sweat gland function, decreased thirst, and decreased mobility (Brege, 2009).*
- ▲ In hot weather, monitor the older client for signs of heat stroke: rising temperature, orthostatic blood pressure drop, weakness, restlessness, mental status changes, faintness, thirst, nausea, and vomiting. If signs are present, move the client to a cool place, have the client lie down, give sips of water, check orthostatic blood pressure, spray with lukewarm water, cool with a fan, and seek medical assistance immediately. *Older adults are predisposed to heat exhaustion and should be watched carefully for occurrence; if present, it should be treated promptly (Sadler, 2011; Brege, 2009).*
- During warm weather, help the client obtain a fan or an air conditioner to increase evaporation, as needed. Help the older client locate a cool environment to which they can go for safety in hot weather.
- Take the temperature of the older client in hot weather. *Older clients may not be able to tell that they are hot because of decreased sensation.*

Home Care

- Some of the interventions described previously may be adapted for home care use.
- Determine whether the client or family has a functioning thermometer, and know how to use it. Refer to the interventions above on taking a temperature.
- Help the client and caregivers prevent and monitor for heat stroke/hyperthermia during times of high outdoor temperatures. *Preventive measures include minimizing time spent outdoors, use of air conditioning or fans, increasing fluid intake, and taking frequent rest periods (Sadler, 2011; CDC, 2013).*
- To prevent heat-related injury in athletes, laborers, and military personnel, instruct them to acclimate gradually to the higher temperatures, increase fluid intake, wear vapor-permeable clothing, and take frequent rests (Kerr et al, 2014; CDC, 2013).
- In the event of temperature elevation above the adaptive range, institute measures to decrease temperature (e.g., get the client out of the sun and into a cool place, remove excess clothing, have the client drink fluids, spray the client with lukewarm water, and fan with cool air). Initiate emergency transport. *Hyperthermia is an acute and possibly life-threatening situation (Kerr et al, 2014; CDC, 2013).*

Client/Family Teaching and Discharge Planning

- ▲ Instruct to increase fluids to prevent heat-induced hyperthermia and dehydration in the presence of fever. Liberal fluid intake replaces fluid lost through perspiration and respiration (Pinto & Walsh, 2011; Sadler, 2011).
- Teach the client to stay in a cooler environment during periods of excessive outdoor heat or humidity. If the client does go out, instruct him/her to avoid vigorous physical activity; wear lightweight, loose-fitting clothing; and wear a hat to minimize sun exposure. *Such methods reduce exposure to high environmental temperatures, which can cause heat stroke and hyperthermia (Sadler, 2011; Kerr et al, 2014; CDC, 2013).*

Hypothermia *Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN*

NANDA-I

Definition

Core body temperature below normal diurnal range due to failure of thermoregulation

Defining Characteristics

Acrocyanosis; bradycardia; cyanotic nail beds; decrease in blood glucose level; decrease in ventilation; hypertension; hypoglycemia; hypoxia; increase in metabolic rate; increase in oxygen consumption; peripheral vasoconstriction; piloerection; shivering; skin cool to touch; slow capillary refill; tachycardia

Accidental Low Body Temperature in Children and Adults

Mild hypothermia, core temperature approaching 32°C to 35°C; moderate hypothermia, core temperature approaching 30°C to 32°C; severe hypothermia, core temperature < 30°C

Injured Adults and Children

Hypothermia, core temperature < 35°C; severe hypothermia, core temperature < 32°C

Neonates

Grade 1 hypothermia, core temperature 36°C to 36.5°C; grade 2 hypothermia, core temperature 35°C to 35.9°C; grade 3 hypothermia, core temperature 34°C to 34.9°C; grade 4 hypothermia, core temperature < 34°C; infant with insufficient energy to maintain sucking; infant with insufficient weight gain (<30 g/d); irritability; jaundice; metabolic acidosis; pallor; respiratory distress

Related Factors (r/t)

Alcohol consumption; damage to hypothalamus; decrease in metabolic rate; economically disadvantaged; extremes of age; extremes of weight; heat transfer (e.g., conduction, convection, evaporation, radiation); inactivity; insufficient caregiver knowledge of hypothermia prevention; insufficient clothing; insufficient supply of subcutaneous fat; low environmental temperature; malnutrition; pharmaceutical agent; radiation; trauma

Neonates

Delay in breastfeeding; early bathing of newborn; high-risk out-of-hospital birth; immature stratum corneum; increased body surface area to weight ratio; increase in oxygen demand; increase in pulmonary vascular resistance; ineffective vascular control; inefficient nonshivering thermogenesis; unplanned out-of-hospital birth

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Thermoregulation; Thermoregulation: Newborn

Example NOC Outcome with Indicators

Thermoregulation as evidenced by the following indicators: Increased skin temperature/Decreased skin temperature/Skin color changes/Dehydration/Hypothermia. (Rate the outcome and indicators of **Thermoregulation**: 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

- Maintain body temperature within normal range
- Identify risk factors of hypothermia
- State measures to prevent hypothermia
- Identify symptoms of hypothermia and actions to take when hypothermia is present
- If hypothermia is medically induced client/family will state goals for hypothermia treatment

NIC (Nursing Interventions Classification)**Suggested NIC Intervention**

Hypothermia Treatment; Temperature Regulation; Temperature Regulation: Intraoperative; Vital Signs Monitoring

Example NIC Activities—Temperature Regulation

Institute use of a continuous core temperature-monitoring device, as appropriate; Promote adequate fluid and nutritional intake

Nursing Interventions and Rationales**Temperature Measurement**

- Recognize hypothermia as a drop in core body temperature below 35°C (95°F) (Danzl et al, 2011; Turk, 2010).
- Measure the client's temperature at least hourly and with changes in client condition (e.g., chills, change in mental status); if more than mild hypothermia is present (temperature lower than 35°C [95°F]), use a continuous temperature-monitoring device. Two modes of temperature monitoring may be indicated. Continuous temperature monitoring using an indwelling method of temperature measurement is usually indicated to monitor effectiveness of treating body alterations in core body temperature. **EBN/CEB:** *Hypothermia can be a life-threatening crisis that requires accurate temperature measurement. Core temperature is obtained by a pulmonary artery catheter or from the distal esophagus; near core temperature measurements include oral, bladder, rectal, and temporal artery, and peripheral measurements are obtained*

by skin surface measurements and in the axilla (Barnason et al, 2012). Research is limited on accuracy of temporal artery measurements outside normal ranges; axillary temperature is accurate in neonates but is not well supported in adults; tympanic membrane measurements and chemical dot thermometers are least accurate and should be avoided in caring for the acutely ill adult client (Calonder et al, 2010; Hooper et al, 2009; Makic et al, 2011; Barnason et al, 2012).

- Use the same site and method (device) for temperature measurement for a given client so that temperature trends are assessed accurately and record site of temperature measurement. **EBN/CEB:** *There are differences in temperature depending on the site (esophageal, oral, bladder, rectal, axillary, or temporal artery); however, differences should not be greater than 0.3°C to 0.5°C (Barnason, 2012; Jefferies et al, 2011; Bridges & Thomas, 2009; Davie & Amoores, 2010; Hooper et al, 2009; Makic et al, 2011; Polderman & Herold, 2009).*
- Bladder temperature may be used as an indwelling urinary catheter and is often inserted in the management of hypothermia to monitor diuresis. **CEB:** *Bladder temperature probes have been shown to be accurate during states of increased diuresis, but measurements may be less accurate when urine volume is low (low rate of diuresis) (Polderman & Herold, 2009; Wollerich et al, 2012). Temperatures obtained by this method may lag, up to 20 minutes during targeted temperature hypothermia interventions (Polderman & Herold, 2009).*
- See the care plan for Ineffective **Thermoregulation** as appropriate.

Accidental Hypothermia

- Recognize that there are three types of accidental hypothermia (environmental causes):
 - Acute hypothermia, also called immersion hypothermia, often from sudden exposure to cold through immersion in cold water or snow
 - Exhaustion hypothermia, caused by exposure to cold in association with lack of food and exhaustion
 - Chronic hypothermia that occurs over days or weeks and primarily affects older adults (Guly, 2011; Petrone, 2014)
- Remove the client from the cause of the hypothermic episode (e.g., cold environment, cold or wet clothing) and bring into a warm environment. Cover the client with warm blankets and apply a covering to the head and neck to conserve body heat. *Layering of dry clothing, including wearing a hat, can be effective in warming a client with mild hypothermia; the goal is also to prevent any further heat loss (Petrone, 2014; Danzl et al, 2011).*
- Watch the client for signs of hypothermia: shivering, slurred speech, confusion, clumsy movements, fatigue, and dehydration. As hypothermia progresses, the skin becomes pale, muscles are tense, fatigue and weakness progress, breathing is decreased, and pulmonary congestion is present, compromising oxygenation; pulses are decreased and blood pressure and heart rate decrease, progressing to lethal arrhythmias (e.g., ventricular fibrillation) (Danzl et al, 2011; Petrone, 2014).
- ▲ Administer oxygen as ordered. *Oxygenation is hampered by the change in the oxyhemoglobin curve caused by hypothermia (Danzl et al, 2011).*
- Monitor the client's vital signs every hour and as appropriate. Note changes associated with hypothermia, such as initially increased pulse rate, respiratory rate, and blood pressure as well as diuresis with mild hypothermia, and then decreased pulse rate, respiratory rate, and blood pressure as well as oliguria with moderate to severe hypothermia. *With mild hypothermia, there is activation of the sympathetic nervous system, which can increase the values of vital signs. As hypothermia progresses, decreased circulating volume develops, which results in decreased cardiac output and depressed oxygen delivery. Hypoxia, metabolic acidosis, and intrinsic irritability of a cold myocardium result in dysrhythmias (Danzl et al, 2011; Turk, 2010; Petrone, 2014; Soreide, 2014).*
- ▲ Attach electrodes and a cardiac monitor. Watch for dysrhythmias. *With hypothermia, the client is prone to dysrhythmias because of the cold myocardium; dysrhythmias may include atrial fibrillation, ventricular fibrillation, or asystole (Danzl et al, 2011; Petrone, 2014).*
- ▲ Monitor for signs of coagulopathy (e.g., oozing of blood from any open areas or from intravascular catheter sites or mucous membranes). Also note results of clotting studies as available. *Coagulopathy is a common occurrence during hypothermia (Thorsen et al, 2011; Petrone, 2014; Soreide, 2014).*
- For mild hypothermia (core temperature of 32.2°C to 35°C [90°F to 95°F]), rewarm client passively:
 - Set room temperature to 21°C to 24°C (70°F to 75°F)
 - Keep the client dry; remove any damp or wet clothing

- Layer clothing and blankets and cover the client's head; use insulated metallic blankets
- Offer warm fluids; avoid alcohol or caffeine

For mild hypothermia, allow the client to rewarm at his/her own pace. Heat is regained through the body's ability to generate heat (Danzl et al, 2011; Petrone, 2014; Kelly et al, 2013). Passive rewarming is not encouraged for clients with temperatures lower than 32.2°C (90°F) because it is a slow process, requires sufficient glycogen stores to be used by the client's body, and may increase oxygen consumption, increasing the risk of adverse cardiac events (Danzl et al, 2011).

- ▲ For moderate hypothermia (core temperature 28°C to 32.1°C [82.4°F to 90°F]), use active external rewarming methods. The rewarming rate should not exceed 0.5°C to 1°C (1.8°F) per hour. Methods include the following (Danzl et al, 2011; Galvao et al, 2010):
 - Forced-air warming blankets
 - Circulation of water through external heat exchange pads
 - Radiant heat sources
- ▲ For severe hypothermia (core temperature below 28°C [82.4°F]), use active core rewarming techniques as ordered (Danzl et al, 2011; Petrone, 2014; Soreide, 2014):
 - Recognize that extracorporeal blood rewarming methods, such as coronary artery bypass, are most effective.
 - Use intravascular countercurrent in-line heat exchange to deliver warmed fluid or blood (Danzl et al, 2011).
 - Use heated and humidified oxygen through the ventilator as ordered.
 - Administer heated intravenous (IV) fluids at prescribed temperature.
 - Use heated irrigation of the gastrointestinal tract (nasogastric lavage) or bladder irrigations as ordered.
- Rewarm clients slowly, generally at a rate of 0.5°C to 1°C every hour. *Slow rewarming helps prevent a phenomenon called "afterdrop," wherein cold, hyperkalemic blood from the periphery returns to the heart, resulting in a biochemical injury, leading to dysrhythmias and severe hypotension (Danzl et al, 2011).*
- Check blood pressure frequently when rewarming; watch for hypotension. *As the body warms, formerly vasoconstricted vessels dilate, which results in hypotension (Kelly et al, 2013; Petrone, 2014).*
- ▲ Administer IV fluids, using a rapid infuser IV fluid warmer as ordered. *Fluids are often needed to maintain adequate fluid volume. If the client develops untreated fluid depletion, hypotension with decreased cardiac output and acute renal failure can result. A rapid infuser warmer is needed to keep IV fluids warmed sufficiently to be effective in raising the body temperature (Danzl et al, 2011).*
- Determine the factors leading to the hypothermic episode; see Related Factors. *It is important to assess risk factors and precipitating events to prevent another incident of hypothermia and to direct treatment (Guly, 2011).*
- ▲ Request a social service referral to help the client obtain the heat, shelter, and food needed to maintain body temperature. *A preventive approach that includes adequate food and fluid intake, shelter, heat, and clothing decreases the risk of hypothermia.*
- ▲ Encourage proper nutrition and hydration. *Request a referral to a dietitian to identify appropriate dietary needs. Insufficient calorie and fluid intake predisposes the client to hypothermia, especially in older adults (Danzl et al, 2011).*

Targeted Temperature Hypothermia

- Recognize that targeted temperature management, also called therapeutic hypothermia, is the active lowering of the client's body temperature, in a controlled manner, to preserve neurological function after an acute myocardial injury or cardiac arrest. **CEB:** *In the event the client is successfully resuscitated after an acute myocardial injury/arrest, recognize that medically induced targeted temperature management has been shown to provide neurological protection against ischemic neuronal injury after cardiac arrest (Scirica, 2013; Bravo & Kim, 2014; Kim et al, 2015).*
- Recognize that controlled cooling of clients should be considered for all unconscious survivors of out-of-hospital ventricular tachycardia arrest as well as clients experiencing in-hospital arrests (Neumer et al, 2011; Scirica, 2013; Kim et al, 2015). The optimal targeted temperature for therapy is between 34° and 36°C for up to 48 hours (Azmoon et al, 2011; Neumer et al, 2011; Scirica, 2013; Bravo & Kim, 2014). **CEB:** *The American Heart Association and the International Liaison Committee on Resuscitation have included therapeutic hypothermia as an intervention to be considered in the management of cardiac arrest patients to optimize neurological outcomes (Neumer et al, 2011; Scirica, 2013).*

- Monitor core or near core temperatures continuously using two methods of temperature monitoring. **CEB:** *To ensure that the targeted temperature is achieved and maintained closely within the prescribed temperature range, two methods of core or near core temperature monitoring are recommended (Polderman & Herold, 2009; Barnason et al, 2012).*
- Recognize that cooling may be achieved noninvasively, using fluid-filled cooling devices that are placed next to the client's skin, or invasively, infusing iced solution. **EB/EBN:** *Invasive cooling provides a more predictable cooling; however, current research has found air- or fluid-filled external devices to provide effective cooling as well. Less optimal methods of cooling include the use of fans, ice packs, or blankets, which do not provide temperature regulation feedback between the machine and client (Galvao et al, 2010; Morita et al, 2011).*
- Obtain vital signs hourly (or via continuous monitoring) to include continuous electrocardiogram monitoring. Observe for signs of hypotension, bradycardia, and arrhythmias. Mechanical ventilation is required to protect the client's airway and breathing during treatment. **CEB:** *Diuresis is more pronounced during the induction of hypothermia. Hypotension may be more prominent as the client is rewarmed because of vasodilatation, requiring close monitoring and interventions to support blood pressure. Bradycardia associated with hypothermia is often not responsive to atropine. If the client is overcooled (temperature drops below 32°C), the risk of arrhythmias will increase; ventricular fibrillation refractory to defibrillation may occur at temperatures below 30°C (Polderman & Herold, 2009).*
- ▲ Observe for shivering and administer sedation agents as prescribed. **CEB:** *Shivering significantly increases the body's metabolic rate and oxygen consumption (Polderman & Herold, 2009).*
- ▲ Closely inspect the skin before and throughout the cooling intervention to prevent skin breakdown associated with the treatment. Implement frequent turning and other pressure reduction interventions as indicated. *Lowering the body temperature causes vasoconstriction and can compromise perfusion to the skin, increasing the client's risk of skin breakdown (Polderman & Herold, 2009).*
- ▲ Monitor and treat serum electrolytes (e.g., potassium, magnesium, calcium, and phosphorus) and serum glucose closely during targeted hypothermia and during rewarming of the client. Electrolytes will fluctuate as the client is rewarmed. **EB/EBN:** *Diuresis, acid-base imbalances, and metabolic responses are responsible for fluctuations of electrolytes and glucose. As the client is rewarmed, electrolyte replacements, especially potassium replacements, should be closely monitored to prevent rebound hyperkalemia that may occur as the body temperature rises (Polderman & Herold, 2009; Turk, 2010; Petrone, 2014).*
- ▲ Observe for signs and symptoms of coagulopathy during targeted hypothermia treatment. Hemoconcentration may be noticed as fluids shift during treatment. **CEB:** *For every 1°C decline in temperature, the hematocrit may increase by approximately 2%, requiring monitoring but not treatment. Platelet counts decrease during hypothermic states, but research has not found a significant risk of bleeding during targeted hypothermia treatment (Polderman & Herold, 2009; Thorsen et al, 2011; Turk, 2010; Petrone, 2014).*
- Rewarming should occur in a controlled manner with a rise in body temperature of 0.5°C to 1°C per hour and targeted goal of normothermia, 37°C. **CEB:** *Aggressive rewarming may cause rebound hyperthermia, cerebral edema, seizures, hypotension, and ventricular fibrillation (Niklasch, 2010; Polderman & Herold, 2009; Bravo & Kim, 2014; Kim et al, 2015).*
- ▲ Neurological and cognitive function should be assessed during targeted temperature treatment and after rewarming. **CEB:** *The goal of targeted temperature treatment is neurological protection; close monitoring of neurological function after intervention and serial assessments are indicated (Nunnally et al, 2011; Polderman & Herold, 2009; Scirica, 2013).*

Pediatric

- Recognize that pediatric clients have a decreased ability to adapt to temperature extremes. Take the following actions to maintain body temperature in the infant/child:
 - Keep the head covered.
 - Use blankets to keep the client warm.
 - Keep the client covered during procedures, transport, and diagnostic testing.
 - Keep the room temperature at 22.2°C (72°F).

The combination of a relatively smaller body surface area, smaller body fluid volume, less well-developed temperature control mechanisms, and smaller amount of protective body fat limits the infant's and child's ability to maintain normal temperatures (Pio et al, 2010; Wyckoff, 2014).

- ▲ For the preterm or low-birth-weight newborn, use specially designed bags, skin-to-skin care, warmer mattresses, and radiant warmers to keep the infant warm. **EB/EBN:** *These methods can help keep*

the vulnerable newborn warm in the delivery room (McCall et al, 2010). Parents should be taught how to wrap neonates/infants to maintain body temperature (Bissinger & Annibale, 2010), yet there is a need for more studies in this area (McCall et al, 2010).

- ▲ Targeted hypothermia may be implemented in the treatment of neonates with hypoxic-ischemic encephalopathy. Passive cooling may be achieved by withholding external heat sources and requires frequent monitoring of the neonate's temperature to prevent severe hypothermia (Wyckoff, 2014; Sussman & Weiss, 2013).

Geriatric

- Normal aging often includes changes in touch-related sensations, making it harder to differentiate cool and cold. Decreased temperature sensitivity increases the risk of hypothermia in the older adult (Dugdale, 2012).
- Recognize that older adults can develop indoor hypothermia from air conditioning or ice baths. Clients present with vague complaints of mental and/or other skill deterioration (Heller, 2012).
- Assess neurological signs frequently, watching for confusion and decreased level of consciousness. **CEB:** Mechanisms to control body temperature decrease with age; coupled with a slower counterregulatory response, lower rate of metabolism, and less effective vascular response, this will make hypothermia less obvious. Early signs of hypothermia are subtle (Danzl et al, 2011).
- Recognize that older adults often wear socks and sweaters to protect themselves from feeling cold, even in warmer weather (Sadler, 2011).

Home Care

Hypothermia is not a symptom that appears in the normal course of home care. When it occurs, it is a clinical emergency, and the client/family should access emergency medical services immediately.

- Some of the interventions described earlier may be adapted for home care use.
- Before a medical crisis occurs, confirm that the client or family has a thermometer and can read it. Instruct as needed. Verify that the thermometer registers accurately.
- Instruct the client or family to take the temperature when the client displays cyanosis, pallor, or shivering.
- ▲ Monitor temperature every hour, as noted previously. If the temperature of the client begins dropping below the normal range, apply layers of clothing or blankets, or adjust environmental heat to the comfort level. Do not overheat. Contact a health care provider. *Passive rewarming is the only method of rewarming that is appropriate for home care under normal circumstances.*
- ▲ If temperature continues to drop, activate the emergency system and notify a health care provider. *Hypothermia is a clinically acute condition that cannot be managed safely in the home.*
- ▲ If the client is in hospice care or is terminally ill, follow advance directives, client wishes, and the health care provider's orders. Keep the client free of pain. *The goal of terminal care is to provide dignity and comfort during the dying process.*

Client/Family Teaching and Discharge Planning

- Teach the client and family signs of hypothermia and the method of taking the temperature (age appropriate).
- Teach the client methods to prevent hypothermia: wearing adequate clothing, including a hat and mittens; heating the environment to a minimum of 20°C (68°F); and ingesting adequate food and fluid. *Simple measures such as layering clothes, wearing a hat, and avoiding extremes in temperature prevent significant heat loss (Petrona, 2014).*
- ▲ Teach the client and family about medications such as sedatives, opioids, and anxiolytics that predispose the client to hypothermia (as appropriate). *If the client has had hypothermia in the past, using alternative medications is an option if there is no contraindication (Danzl et al, 2011).*

Risk for Hypothermia

Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

NANDA-I

Definition

Vulnerable to a failure of thermoregulation that may result in a core body temperature below the normal diurnal range, which may compromise health

Risk Factors

Alcohol consumption; damage to hypothalamus; economically disadvantaged; extremes of age; extremes of weight; heat transfer (e.g., conduction, convection, evaporation, radiation); inactivity; insufficient caregiver knowledge of hypothermia prevention; insufficient clothing; insufficient supply of subcutaneous fat; low environmental temperature; malnutrition; pharmaceutical agent; radiation; trauma

Children and Adults: Accidental

Mild hypothermia, core temperature approaching 35°C; moderate hypothermia, core temperature approaching 32°C; severe hypothermia, core temperature approaching 30°C

Neonates

Decrease in metabolic rate; delay in breastfeeding; early bathing of newborn; grade 1 hypothermia, core temperature approaching 36.5°C; grade 2 hypothermia, core temperature approaching 36°C; grade 3 hypothermia, core temperature approaching 35°C; grade 4 hypothermia, core temperature approaching 34°C; high-risk out-of-hospital birth; immature stratum corneum; increased body surface area to weight ratio; increase in oxygen demand; increase in pulmonary vascular resistance; ineffective vascular control; inefficient nonshivering thermogenesis; unplanned out-of-hospital birth

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan for **Hypothermia**.

H

Risk for Perioperative Hypothermia *Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN***NANDA-I****Definition**

Vulnerable to an inadvertent drop in core body temperature below 36°C (96.8°F) occurring 1 hour before to 24 hours after surgery, which may compromise health

Risk Factors

American Society of Anesthesiologist (ASA) Physical Status classification score > 1; cardiovascular complications; combined regional and general anesthesia; diabetic neuropathy; heat transfer (e.g., high volume of unwarmed infusion, unwarmed irrigation > 20 L); low body weight; low environmental temperature; low preoperative temperature (<36°C [96.8°F]); surgical procedure

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Thermoregulation

Example NOC Outcome with Indicators

Thermoregulation as evidenced by the following indicators: Increased skin temperature/Decreased skin temperature/Skin color changes/Dehydration/Hypothermia. (Rate the outcome and indicators of **Thermoregulation**: 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see [Section 1](#)].)

Client Outcomes**Client Will (Specify Time Frame)**

- Maintain body temperature within normal range
- Identify risk factors of hypothermia
- State measures to prevent hypothermia
- Identify symptoms of hypothermia and actions to take when hypothermia is present
- Client will be free of surgical site infection

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Hypothermia Treatment; Temperature Regulation; Temperature Regulation: Intraoperative; Vital Signs Monitoring

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Example NIC Activities—Temperature Regulation

Institute use of a continuous core temperature-monitoring device, as appropriate; Promote adequate fluid and nutritional intake

Nursing Interventions and Rationales

Temperature Measurement

- Recognize perioperative hypothermia as a drop in core body temperature below 36°C (96.8°F) (Campbell et al, 2015; CDC, 2015).
- Measure the client's temperature frequently, and with changes in client condition (e.g., chills, change in mental status); if more than mild hypothermia is present (temperature lower than 36°C [96.85°F]), use a continuous temperature-monitoring device. Two modes of temperature monitoring may be indicated. Continuous temperature monitoring using an indwelling method of temperature measurement is usually indicated to monitor effectiveness of treating body alterations in core body temperature. **CEB/EBN/CEB:** *Hypothermia can be a life-threatening crisis that requires accurate temperature measurement. Core temperature is obtained by a pulmonary artery catheter or from the distal esophagus; near core temperature measurements include oral, bladder, rectal, and temporal artery, and peripheral measurements are obtained by skin surface measurements and in the axilla (Barnason et al, 2012). Research is limited on accuracy of temporal artery measurements outside normal ranges; axillary temperature is accurate in neonates but is not well supported in adults; tympanic membrane measurements and chemical dot thermometers are least accurate and should be avoided in caring for the acutely ill adult client (Winslow et al, 2012; Calonder et al, 2010; Hooper et al, 2009; Makic et al, 2011; Barnason et al, 2012).*
- Use the same site and method (device) for temperature measurement for a given client so that temperature trends are assessed accurately, and record site of temperature measurement. **EBN/CEB:** *There are differences in temperature depending on the site (esophageal, oral, bladder, rectal, axillary, or temporal artery); however, differences should not be greater than 0.3°C to 0.5°C (Barnason et al, 2012; Jefferies et al, 2011; Bridges & Thomas, 2009; Davie & Amooore, 2010; Hooper et al, 2009; Makic et al, 2011).*
- Bladder temperature may be used as an indwelling urinary catheter and is often inserted in the management of hypothermia to monitor diuresis. **CEB:** *Bladder temperature probes have been shown to be accurate during states of increased diuresis, but measurements may be less accurate when urine volume is low (low rate of diuresis). Temperatures obtained by this method may lag, up to 20 minutes during targeted temperature hypothermia interventions (Wollerich et al, 2012).*

Unintentional Perioperative Hypothermia

- Keep the client warm throughout the perioperative period (preoperative, intraoperatively, and postoperatively) to prevent unintentional perioperative hypothermia. **CEB:** *Initiating warming interventions preoperatively has been found to assist with normothermia and client comfort (Burns et al, 2009; Horosz & Malec-Milewska, 2014).*
- Factors that increase the risk of perioperative hypothermia include anesthetic agents, ambient room air temperature, intravenous (IV) fluid infusion, and cavity solution irrigation, blood product administration, duration and type of surgical procedure, anemia, extremes of ages, neurologic disorders, cachexia; preexisting conditions (e.g., peripheral vascular disease, endocrine disease, pregnancy, burns, open wounds) (Billeter et al, 2014; ASPAN, 2015).
- Closely monitoring and preventing unintentional perioperative hypothermia is necessary to prevent adverse patient outcomes. **CEB:** *Adverse outcomes include client discomfort, shivering, cardiac events (e.g., arrhythmias), increased catecholamine release, impaired coagulation, altered drug metabolism, impaired wound healing, and impaired immune function (ASPAN, 2015; Kuchena et al, 2014; Horosz & Malec-Milewska, 2014; Winslow et al, 2012).*
- Several interventions should be implemented to prevent unintentional perioperative hypothermia:
 - Use warming and booties perioperatively
 - Use warming blankets over and under the client perioperatively
 - Use warming blankets under the client on the operating table
 - Adjust environmental room controls to prevent cool ambient room temperature in the perioperative and operative rooms
 - Use warmed forced-air blankets preoperatively, during surgery, and in the postanesthesia care unit

- Use warmed IV fluids and irrigation solutions
- Designate responsibility and accountability for thermoregulation
- ▲ **EB:** *Maintaining the client's temperature during the surgical procedure has been found to be essential in preventing surgical complications, especially surgical site infections. Maintaining normothermia also enhances client comfort (ASPAN, 2015; IHI, 2012a; CDC, 2015). One study found that clients who experienced unintentional perioperative hypothermia during elective operations experienced a four-fold increase in mortality and stroke (Billeter et al, 2014).*
- Using warmed IV fluids and irrigation solutions during the operative period may assist with reducing the client's risk of unintentional perioperative hypothermia. **CEB:** *Researchers found that warmed IV fluids and irrigation solutions kept the core temperature of study participants warmer than those in clients receiving room temperature fluids (Campbell et al, 2015).*
- Active warming interventions include the use of warm blankets and forced air warming devices. **EBN:** *Blankets used for warming client's quickly lose heat. To prevent rapid heat loss from blankets, warming cabinets should be set at 200°F, and reapply blankets frequently (Kelly et al, 2013).* **CEB:** *Actively warming clients with forced air warming offers a clinically important reduction in time to achieve normothermia in postoperative clients (Warttig et al, 2014).*
- Watch the client for signs of hypothermia: shivering, slurred speech, confusion, clumsy movements, fatigue, dehydration. As hypothermia progresses, the skin becomes pale, muscles are tense, fatigue and weakness progress, breathing is decreased, and pulmonary congestion is present, compromising oxygenation; pulses are decreased and blood pressure and heart rate decrease, progressing to lethal arrhythmias (e.g., ventricular fibrillation) (Danzl, 2012; Petrone, 2014).
- ▲ Administer oxygen as ordered. *Oxygenation is hampered by the change in the oxyhemoglobin curve caused by hypothermia (Danzl, 2012).*
- ▲ Attach electrodes and a cardiac monitor. Watch for dysrhythmias. *With hypothermia, the client is prone to dysrhythmias because of the cold myocardium; dysrhythmias may include atrial fibrillation, ventricular fibrillation, or asystole (Danzl, 2012; Petrone, 2014).*
- ▲ Monitor for signs of coagulopathy (e.g., oozing of blood from any open areas or from intravascular catheter sites or mucous membranes). Also note results of clotting studies as available. *Coagulopathy is a common occurrence during hypothermia (ASPAN, 2015; Petrone, 2014; Soreide, 2014).*
- ▲ Monitor for signs of surgical site infection (e.g., increased incisional pain, drainage, poor healing, poor incision approximation). *Unintentional perioperative hypothermia has been associated with increased risk of surgical site infections (CDC, 2015; IHI, 2012a; ASPAN, 2015).*
- See care plan for Ineffective **Thermoregulation** and **Hypothermia** as appropriate.

Pediatric

- Interventions implemented in the care of adult clients are similar when providing care to pediatric clients to prevent hypothermia. **CEB:** *Keep the head covered, use warm blankets or force warm air to keep the client warm; maintain normal ambient room temperature in the perioperative units, and use warmed IV fluids (IHI, 2012b).*

Home Care

- ▲ Hypothermia is not a symptom that appears in the normal course of postoperative home care. If the client continues to complain of chills or feeling cold after discharge home from a surgical procedure, provide the client with warm blankets and if the client is allowed to drink provide warm fluids by mouth.
- ▲ Monitor temperature every hour, as noted previously. If the temperature of the client begins dropping below the normal range, apply layers of clothing or blankets, or adjust environmental heat to the comfort level. Do not overheat. Contact a health care provider. *Passive rewarming is the only method of rewarming that is appropriate for home care under normal circumstances.*
- ▲ If temperature continues to drop, activate the emergency system and notify a health care provider. *Hypothermia is a clinically acute condition that cannot be managed safely in the home.*

Client/Family Teaching and Discharge Planning

- Teach the client/family signs of hypothermia and the method of taking the temperature (age-appropriate).

- ▲ Teach the client and family about medications such as sedatives, opioids, and anxiolytics that predispose the client to hypothermia (as appropriate). *If the client has had hypothermia in the past, using alternative medications is an option if there is no contraindication (Danzl, 2012).*

Disturbed personal Identity

Gail B. Ladwig, MSN, RN; revised by Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

Inability to maintain an integrated and complete perception of self

Defining Characteristics

Alteration in body image; confusion about cultural values; confusion about goals; confusion about ideological values; delusional description of self; feeling of emptiness; feeling of strangeness; fluctuating feelings about self; gender confusion; inability to distinguish between internal and external stimuli; inconsistent behavior; ineffective coping strategies; ineffective relationships; ineffective role performance

List of Nursing Diagnoses by Letter: I

Disturbed personal Identity	Risk for disturbed personal Identity	Ineffective Impulse control
Bowel Incontinence	Functional urinary Incontinence	Overflow urinary Incontinence
Reflex urinary Incontinence	Risk for Urge Urinary Incontinence	Stress Urinary Incontinence
Urge urinary Incontinence	Disorganized Infant behavior	Readiness for enhanced organized Infant behavior
Risk for disorganized Infant behavior	Risk for Infection	Risk for Injury
Risk for corneal Injury	Risk for urinary tract Injury	Insomnia
Decreased Intracranial adaptive capacity		

Related Factors

Alteration in social role; cult indoctrination; cultural incongruence; developmental transition; discrimination; dissociative identity disorder; dysfunctional family processes; exposure to toxic chemical; low self-esteem; manic states; organic brain disorder; perceived prejudice; pharmaceutical agent; psychiatric disorder; situational crisis; stages of growth

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Anxiety Self-Control; Abuse Recovery (Emotional, physical, sexual); Body Image; Decision-Making; Distorted Thought Self-Control; Identity; Mutilation; Suicide/Self-Restraint

Example NOC Outcome with Indicators

Identity as evidenced by the following indicators: Verbalizes affirmations of personal identity/Exhibits congruent verbal and nonverbal behavior about self/Differentiates self from environment and other human beings. (Rate the outcome and indicators of **Identity**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate new purposes for life
- Show interests in surroundings
- Perform self-care and self-control activities appropriate for age
- Acknowledge personal strengths
- Engage in interpersonal relationships

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Decision-Making Support; Mutual Goal Setting; Self-Awareness Enhancement; Self-Esteem Enhancement; Sexual Counseling; Substance Use Prevention

Example NIC Activities—Self-Esteem Enhancement

Monitor client's statements of self-worth; Encourage client to identify strengths

Nursing Interventions and Rationales

- Assess and support family strengths of commitment, appreciation, and affection toward each other, positive communication, time together, a sense of spiritual well-being, and the ability to cope with stress and crisis. **EB**: *Mayberry et al (2015) studied family behaviors, depression, stress, and adherence for clients (N = 192) with type 2 diabetes and found that obstructive family behaviors were associated with depressive symptoms and nonadherence to treatments.* **EBN**: *An investigation of the effects of a Family-to-Family Support (FFS) program on the coping strategies and mental health status of caregivers (N = 46) of schizophrenia clients was conducted by Bademli and Duman (2014), who found that the FFS program has a positive impact on caregivers' self-confidence, optimism, and ability to reach out to social supports, thereby increasing their coping strategies.*
- ▲ Assess for suicidal ideation and make appropriate referral for clients dealing with diversity, mental, or chronic somatic illness. **EB**: *Finley et al (2015) studied the association of post-traumatic stress disorder, traumatic brain injury, and chronic pain with suicide-related behavior among veteran clients (N = 211,652) and found these conditions significantly increased suicide ideation risk and/or attempts.* **EB**: *Researchers studied the correlation of adolescent clients' (N = 75,344) gender, sexual orientation, and risk of bullying to suicide ideation and concluded that white and Hispanic gay and bisexual males, white lesbian and bisexual females, and Hispanic bisexual females were at increased risk for being bullied and the sexual minority groups had increased reports of suicide ideation (Mueller et al, 2015).*

- ▲ Assess clients with mood disorders and make appropriate referrals for treatment. **EB:** *DeLas Cuevas et al (2014)* studied clients (N = 160) with depression and their adherence to antidepressant therapy and found that sociodemographic variables did not affect adherence but adherence was related to a positive attitude toward his/her treatment. **EB:** A large, national study found that 50% of clients with eating disorders also suffered from mood or anxiety disorders, but reported to health care professionals fewer symptoms than clients who suffered from mood or anxiety disorders without eating disorders (*Meng & D'Arcy, 2015*).
- ▲ Assess and make appropriate referrals for clients with physical or mental disabilities. **EB:** *Bogart (2014)* studied “disability identity” and its relationship to depression and anxiety in clients (N = 106) with multiple sclerosis and found through an Internet survey that “disability identity” predicted lower depression and anxiety. **EB:** An investigation explored self-identity in clients (N = 15) with mental health issues using in-depth interview sessions, which revealed three main themes about employment: (1) they did not like protective work settings, (2) relationships with others in the workplace are important, and (3) they experienced a change in self-identity and were not defined by their mental health problems but as a person who had worth and abilities (*Baum & Neuberger, 2014*).
- ▲ Assess clients for substance abuse and make appropriate referral. **EB:** *Beckwith et al (2015)* studied the social identity of addicted clients who were in a therapeutic community (TC) and found that clients who identified with the TC social group and less with the “outside” user group had a more successful recovery. **EB:** A study examined the efficacy of social identity targeting to increase anti-cigarette smoking beliefs among clients (N = 251). *Morgan and Sussman (2014)* used an online survey to categorize clients’ social identity. Using specific anti-smoking ads, they found that social identity targeting increased the effectiveness of smoking cessation.
- Use empathetic communication and encourage the client and family to verbalize fears, express emotions, and set goals. **EBN:** *Buus et al (2014)* studied the experiences of two groups of parents of children who had attempted suicide and through thematic analysis the parents communicated that their experience was a double trauma that included the suicide attempts and the psychosocial impact on the family’s well-being. **EBN:** Nurse researchers studied psychiatric clients (N = 20) who were in an acute-care facility using qualitative interviews and four themes were prominent: (1) being alone in the world, (2) staff exert power and control, (3) resentment towards staff, and (4) time for meditation (*Ezeobebe et al, 2014*).
- Be present for clients physically or by telephone. **EBN:** A study used telephone communication by nurses to clients with post-traumatic stress disorder (N = 14) and found qualitative telephone interviews worked well to collect information on sensitive topics and promoted healthy post-traumatic adaptation (*Mealer & Jones, 2014*).
- ▲ **EB:** *Muller et al (2015)* studied telephone communication’s effect on the development of the therapeutic relationship for clients in self-directed therapy and found that the therapists were able to establish over the phone therapeutic relationships that were client-centered.
- Empower the client to set realistic goals and engage in problem solving. **EB:** *Fisher and Freshwater (2014)* studied two types of research methodologies, post-structuralist and narrative, and found that the narrative approach offers greater emancipatory scope to help clients with mental health problems restore their lives and enhance their self-identity. **EB:** Researchers examined the relationships among heart failure (HF) symptoms, social support, social problem solving, depressive symptoms, and self-care behaviors in clients (N = 201) and found that HF symptoms and social support predicted depression and self-care (*Graven et al, 2015*).
- Encourage expression of positive thoughts and emotions. **EB:** Researchers surveyed participants (N = 265) about sexual identity compared to activism and collective self-esteem and found a significantly lower collective self-esteem for participants who identified themselves as bisexual, and activism was most likely among those who identified as queer (*Gray & Desmarais, 2014*). **EB:** A researcher conducted interviews with psychiatric clients (N = 30) about how their diagnosis effected them. The study used and found that metaphors assisted clients to reclaim their identity (*Probst, 2015*).
- Encourage the client to use coping mechanisms. **EBN:** *da Silva et al (2015)* completed a phenomenological study to understand the “musical identity” of palliative care clients (N = 7) and their relatives (N = 5) and found that “musical identity” was related to the client’s spirituality and history. Nurses should consider musical identity to empower clients in palliative care. **EB:** *Nguyen-Rodriquez et al (2015)* investigated the relationship of stress, depressive symptoms, sleep problems, and coping strategies in clients (N = 1676) by survey and discovered a positive relationship between depressive symptoms and sleep problems arising from use of angry coping strategies.
- Help clients with serious and chronic conditions to maintain social support networks or assist in building new ones. **EB:** *Read et al (2015)* surveyed clients (N = 28) with cerebral palsy about identity and

seeking support when needed. Results revealed that the majority of clients did seek support and identified that their personal and their social self was an important part of their total sense of self. **EBN:** *Rossmann et al (2015)* studied maternal role development in first-time neonatal intensive care moms ($N = 23$) and found through interviews that peer support was the most helpful agent in developing their maternal identity.

- ▲ Refer women facing diagnostic and curative breast cancer surgery for psychosocial support. **EBN:** *Budden et al (2014)* did a cross-sectional study with women ($N = 104$) to compare decision satisfaction with breast cancer treatment to psychological distress. Women who were living alone, worked as professionals, and were not involved in decision-making were less satisfied. Additionally, 26% were distressed, 18.3% had anxiety, 19.2% had sleeping problems, and 27.9% experienced depression. **EB:** Researchers evaluated the quality of life (QOL) and social support of clients with breast cancer and their significant others and found that the significant others' QOL was negatively affected. They recommend that significant others need more support that should be tailored to family needs (*Salonen et al, 2014*).
- Refer for cognitive behavioral therapy (CBT). **EB:** *Roscoe et al (2015)* evaluated cognitive behavioral therapy for insomnia (CBT-I) in clients with cancer ($N = 96$) and found that CBT-I resulted in significant improvements in sleep time and quality. **EB:** Researchers developed planned structured sessions of group CBT for detoxification for alcohol dependence and tested it at detoxification centers. Clients perceived that the intervention did indeed prepare them for detoxification (*Croxford et al, 2015*).
- ▲ Refer clients with borderline personality disorder (BPD) and dual-diagnosed BPD and substance-dependent female clients for dialectical behavior therapy (DBT) and psychoanalytical-orientated day-hospital therapy. **EB:** *Feenstra et al (2014)* investigated identity integration as a core component of personality disorders in adolescents in both normal ($N = 406$) and clinical populations ($N = 285$). Most adolescents receiving inpatient psychotherapy gradually changed toward more healthy levels of identity integration. **EB:** *Chen et al (2015)* did a pilot study on the use of DBT for adult anorexia nervosa (AN) and addressed over self-control successfully in clients ($N = 15$). The pilot study indicated that DBT is a positive intervention for AN and should be researched on a larger scale.
- ▲ Refer to the care plans for Readiness for enhanced **Communication** and Readiness for enhanced **Spiritual** well-being.

Pediatric

- Encourage adolescents to promote positive self-esteem, to enhance coping, and to prevent behavioral and psychological problems. **EB:** *Ikizler and Szymanski (2014)* studied the development of sexual minority identity in clients ($N = 12$) from a minority racial/ethnic group and identified themes that needed to be addressed: intersectionality, race/ethnicity, sexual identity development, discrimination, stigma, oppression, and invisibility. **EBN:** Peer support for children/adolescents in families affected by mental illness was studied using an exploratory approach. Clients made connections with others in the program, developed personal strengths, and learned how to contribute to others' well-being (*Foster et al, 2014*).
- Evaluate and refer children and adolescents for eating disorder prevention programs to include medical care, nutritional intervention, and mental health treatment and care coordination. **EB:** Researchers used a data base to identify 158,679 children aged 12 to 24 years to investigate whether parental mental illnesses are a risk factor for children's eating disorders. They found that it is a significant risk factor for female children in developing eating disorders (*Bould et al, 2015*). **EB:** *Mayes et al (2014)* researched 90 children aged 7 to 18 years with bulimia nervosa or AN for suicide ideation and found that it was more prevalent in clients with bulimia nervosa (43%) than clients with AN (20%), indicating a need for specialized nursing interventions for children with different eating disorders.
- Provide children with low self-esteem with appropriate support. **EB:** *Kemmerly and Compton (2014)* researched the self-identities of hearing deficit students ($N = 4$) and their caregivers/parents ($N = 6$) to understand the students' self-advocacy development. Interviews demonstrated that identity is affected by interactions with others, setting/context, and life experiences. **EB:** *Lingam et al (2014)* interviewed children ($N = 11$) with developmental coordination disorder using an art-based method and found that identity was described by the theme of "We're all different," but subthemes included attitude of the day to day lives and strategies used to overcome difficulties in school and at home.
- Use computer-mediated support groups to enhance identity formation. **EB:** *Hou et al (2015)* studied how children represent their identity online in a multicultural social environment. Qualitative results showed that children expose their complete identities online to learn about personal, ethnic, and gender identities of others and ignored cultural identity, which led to positive attitudes about others. **EB:** *Carey et al (2014)* developed

a clinical trial to examine stuttering adolescents' (N = 14) responsiveness to the Webcam-delivered Camperdown Program. After 25 sessions, 50% of the clients successfully reduced stuttering.

Geriatric

- Evaluate the effectiveness of nursing interventions used to promote positive self-identity in older adults. **EB:** *Bohlmeijer et al (2014)* studied processes that affect later life identity by narrative methods and developed a scale that was validated in two studies on middle-aged (N = 319) and older adults (N = 174). The scale was judged reliable to measure effectiveness of interventions aimed at positive identity development, such as life review and narrative therapy. **EB:** Researchers studied older clients' (N = 30) perceptions of age-friendly communities using photographs and found three factors that impact the perceptions of clients: (1) community history and identity, (2) aging in urban, rural, and remote communities, and (3) environmental conditions (*Novek & Menac, 2014*).
- Consider the use of telephone/interview/group/computer support for caregivers of family members with dementia. **EB:** *Lopez et al (2015)* interviewed dementia clients' caregivers (N = 108) about optimism, anger, and physical health and found that anger was negatively associated with optimism and vitality, and optimism was positively associated with vitality. The findings suggest that low optimism may be a key in understanding anger and reduced vitality. **EB:** *Ho et al (2015)* developed a Web-based learning project for dementia family caregivers (N = 279) and evaluated the demographic background and stressfulness of an online dementia educational program. More than 80% of clients showed interest in learning from a computer program, making it a viable teaching tool for caregivers.
- Encourage clients to discuss "life history." Life history-based interventions and self-esteem and life-satisfaction questionnaires may be used to reinforce personal identity and foster hope. **EB:** *Gammonley et al (2015)* used older clients' oral history interviews to successfully educate staff members in an assisted-living setting about personhood and identity. **EB:** Researchers developed a life story book (LSB) for clients with dementia (N = 23) and found that the development of the LSB provided positive relationships for the clients and their family members (*Subramaniam et al, 2014*).
- ▲ Refer the older client to self-help support groups. **EBN:** *Baldacchino et al (2014)* interviewed older clients (N = 137) about spirituality and discovered that interviews revealed three important themes for the clients: (1) self-empowerment through connectedness with God, self, others, and nature, (2) belongingness to the residence, and (3) the finding of meaning and purpose in life or afterlife, indicating that spiritual coping in self-awareness exercises and support groups is important.
- ▲ Refer the client with Alzheimer's disease who is terminally ill to hospice. **EBN:** *Brooke and Kirk (2014)* performed a literature review about end-of-life care needs for dementia clients and their families and found a lack of advance care planning.

Multicultural

- Assess an individual's sociocultural background in teaching self-management and self-regulation as a means of supporting hope and coping. **EB:** *Dommelen et al (2015)* studied multiple social identities and described an in-group identity as having being included in a group and this predicted participants' attitudes toward out-groups or others. **EB:** *Osborne et al (2015)* completed a large scale study (N = 6349) whose results supported that income and deprivation were negatively correlated with self-esteem, but group-based relative deprivation was positively correlated with ethnic identity.
- Decrease discrimination to promote positive ethnic identity. **EBN:** *Hall et al (2015)* assessed minority college students' self-reported stress, ethnic identity, and skin complexion as predictors of racial discrimination and found that skin complexion and ethnic identity had a positive relationship with racial discrimination; therefore, understanding racial discrimination may allow for the development of nondiscriminatory interventions. **EB:** Researchers investigated whether the prevalence of psychotic experiences is higher among ethnic minority youth (N = 1545) by self-report questionnaires and found a significantly increased risk for psychotic experiences in ethnic minority children (*Adriaanse et al, 2015*).
- Refer to care plan for Ineffective Coping.

Home Care

- The interventions described previously may be adapted for home care use.
- Provide an Internet-based health coach to encourage self-management for clients with chronic conditions such as depression, impaired mobility, and chronic pain. Use computer-mediated support groups to enhance identify formation.

- ▲ Refer the client to mutual health support groups. Participating in mutual health support groups led to enhanced coping by improving psychological and social functioning. **EB:** *Gillard et al (2015) developed and researched an open access community support group for clients (N = 38) with personality disorders, and interviews found the model as a useful therapeutic, community-based peer support group and self-referral increased feelings of empowerment and engagement for clients.*
- ▲ Refer cancer clients and their spouses to family programs that include family-based interventions for communication, hope, coping, uncertainty, and symptom management. **EBN:** *Sautier et al (2014) studied predictors of participation in client support groups using clients (N = 1281) and assessed support group participation and satisfaction, psychosocial distress (anxiety, fear of cancer recurrence, depression), social support, coping, quality of life, pain, and treatment-related characteristics. The results revealed that unemployment, increased number of treatments, and a high emotion-oriented coping style significantly predicted self-help group participation. EB:* *Researchers compared the effectiveness of conventional Internet and Internet support groups that had a social networking component and found that, in support groups for women (N = 184) with breast cancer that had a social component, clients used more supportive behaviors (emotional, informational, and companionate support), posted more messages that were other-focused and fewer that were self-focused, and expressed less negative emotion (Lepore et al, 2014).*
- Refer combat veterans and service members directly involved in combat, as well as those providing support to combatants, including nurses, for mental health services. **EB:** *Hoglund and Schwartz (2014) investigated the mental health of deployed and nondeployed veterans compared with civilians (N = 41,903) and found that women had more adverse mental health issues than men among civilians, deployed veterans, and nondeployed veterans, and deployed men had more adverse mental health issues than men among civilians and nondeployed veterans. EB:* *This study investigated the relationship of housing, mental health, and service use in a sample of homeless clients with mental illness of veterans (N = 99) and non-veterans (N = 297) and found no significant difference (Bourque et al, 2014).*

Client/Family Teaching and Discharge Planning

- Teach the client about available community resources (e.g., therapists, ministers, counselors, self-help groups, family education groups). **EB:** *Researchers tracked usage of community-based exercise programs with the proximity of the program to clients' (N = 417) homes and found no differences in awareness or utilization of the community resource (Dondzila et al, 2014). EBN:* *Hanajin et al (2014) found methods to actively support public health and community nurses by providing services to individuals, families, and communities that are based on the best available research evidence.*
- Teach coping skills to family caregivers of cancer clients. **EBN:** *Gulliford et al (2015) studied a group-based parenting program to teach communication and coping skills to parents (N=14) of preschoolers. The program demonstrated significant changes in the use of productive coping and a reduction in nonproductive coping strategies. EB:* *Researchers studied personal beliefs and their relationship with learned resourcefulness and adaptive functioning in adults with depression. Results showed that clients (N = 187) with depression when being taught need to have their personal beliefs considered to affect learning resourcefulness and adaptive (Lai et al, 2014).*
- Teach caregivers the COPE intervention (creativity, optimism, planning, expert information) to assist with symptom management. **EBN:** *Mazurek et al (2014) performed a pre- and post-test pilot study to assess the usability of the COPE (Creating Opportunities for Personal Empowerment) program with adolescents (N = 16) who were depressed or anxious and found that the group COPE intervention was a positive teen experience.*

Risk for disturbed personal Identity *Gail B. Ladwig, MSN, RN*

NANDA-I

Definition

Vulnerable to the inability to maintain an integrated and complete perception of self, which may compromise health

Risk Factors

Alteration in social role; cult indoctrination; cultural incongruence; developmental transition; discrimination; dissociative identity disorder; dysfunctional family processes; exposure to toxic chemical; low self-esteem; manic states; organic brain disorder; perceived prejudice; pharmaceutical agent; psychiatric disorder; situational crisis; stages of growth

NOC, NIC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan for Disturbed personal Identity.

Ineffective Impulse control *Marina Martinez-Kratz, MS, RN, CNE*

NANDA-I

Definition

A pattern of performing rapid, unplanned reactions to internal or external stimuli without regard for the negative consequences of these reactions to the impulsive individual or to others

Defining Characteristics

Acting without thinking; asking personal questions despite the discomfort of others; gambling addiction; inability to save money or regulate finances; inappropriate sharing of personal details; irritability; overly familiar with strangers; sensation seeking; sexual promiscuity; temper outbursts; violent behavior

Related Factors

Alteration in cognitive functioning; alteration in development; hopelessness; mood disorder; organic brain disorder; personality disorder; smoking; substance abuse

NOC (Nursing Outcomes Classification)**Suggested NOC Outcome**

Impulse Self-Control

Example NOC Outcome with Indicators

Impulse Self-Control as evidenced by the following indicators: Identifies harmful impulsive behaviors/Identifies feelings that lead to impulsive actions/Avoids high-risk situations/Controls impulses/Maintains self-control without supervision. (Rate the outcome and indicators of **Impulse Self-Control**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = continually demonstrated [see Section I].)

I Client Outcomes**Client Will (Specify Time Frame)**

- Be free from harm
- Cooperate with behavioral modification plan
- Verbalize adaptive ways to cope with stress by means other than impulsive behaviors
- Delay gratification and use adaptive coping strategies in response to stress
- Verbalize understanding that behavior is unacceptable
- Accept responsibility for own behavior

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Impulse Control Training

Example NIC Activities—Impulse Control Training

Use a behavior modification plan, as appropriate, to reinforce the problem-solving strategy that is being taught; Teach client to cue himself/herself to “stop and think” before acting impulsively

Nursing Interventions and Rationales

- Refer to mental health treatment for cognitive behavioral therapy (CBT). **EB**: CBT has been beneficial in treating substance use disorders and impulse control disorders (Dempsey et al, 2011; Okai et al, 2013).
- Assess the circumstances that led the client to seek help for their impulse control disorder. **EB**: Clients may seek help because they continue to struggle with the desire to engage in the behavior because of the impact of their mounting social, occupational, financial, or legal problems (Grant et al, 2013).
- Implement motivational interviewing for clients with impulse control disorders. *Motivational interviewing includes treatment components that involve providing feedback to the client concerning current impulsive behaviors and the likely longer term effects associated with such behavior (Farmer & Golden, 2009).*
- Teach client mindfulness meditation techniques. Mindfulness meditation includes observing experiences in the present moment, describing those experiences without judgments or evaluations, and participating fully in one's current context. *Mindfulness meditation is used to assist the individual to develop an attentional focus on the present that is useful in controlling impulsive behavior (Farmer & Golden, 2009).*
- Refer to self-help groups such as Gambler's Anonymous or Overeaters Anonymous as needed. *Methods of psychological and psychosocial management related to specific symptoms are effective strategies for care of impulse control disorders (Dell'Osso et al, 2008; Gallagher, 2010; Greener, 2011).*
- Remove positive reinforcements associated with excessive behavior. *Altering reactivity to immediate environmental cues or circumstances is a contingency management approach effective for impulse control disorders (Farmer & Golden, 2009).*
- Assist the client to recognize patterns and cues of impulsive behavior. *The first step in gaining insight into behaviors is to recognize the causes so long-term therapeutic strategies for stimulus and impulse control can be developed (Dell'Osso et al, 2008).*

- Teach clients to use urge surfing techniques when impulses are triggered. A core skill associated with urge surfing is the ability to observe within oneself the rise and fall of urges and to “surf” or stay with these urges without acting on them. *Urge surfing is a behavioral skill used to facilitate tolerance of urgent action impulses without acting on them (Farmer & Golden, 2009).*
- Implement cue elimination procedures as a stimulus control technique. *Cue elimination is a stimulus control technique in which cues that signal the availability of rewards for problematic behavior are removed (Farmer & Golden, 2009).*
- Implement strategies to engage a high level construal mind-set by asking “why” abstaining from the targeted behavior will benefit the client. **EB:** *Questions of “why” are effective in priming a high-level construal mind-set, which then is effective at reducing the targeted behavior (Chiou et al, 2013).*

Pediatric

- Assess children who have been exposed to violence in their environment for impulsive behavior. **EB:** *Research indicates that children exposed to higher levels of violence show an increase in impulsive behavior (Sharkey et al, 2012).*
- Implement in situ training to address impulsive behavior followed by role-play, differential reinforcement, corrective feedback, and rehearsal in young children and adolescents. *In situ training provides children and adolescents with self-management skills that enable them to exhibit on-task and socially appropriate behavior (Farmer & Golden, 2009).*
- Refer to mental health treatment for CBT. *CBT has been beneficial in treating impulse control disorders in pediatric populations (Keeley et al, 2007).*

Geriatric

- Assess for impulsive symptoms and maintain increased surveillance of the client whenever use of dopamine agonists has been initiated. *Dopamine agonist therapy is related to the development of impulse control disorders in clients with Parkinson’s disease (Greener, 2011; Ambermoon et al, 2011).*
- Implement fall risk screening and precautions for geriatric clients with inattention and impulse control symptoms. *Research demonstrates that older adults with inattention and impulsivity are at highest risk for falls (Harrison et al, 2010).*
- Monitor caregivers for evidence of caregiver burden. *Recent research shows that significantly greater burden was seen in caregivers of Parkinson’s disease clients with impulse control disorders (Leroi et al, 2012).*

Client/Family Teaching and Discharge Planning

- Provide families with information about services such as addiction or marriage counseling. *Methods of psychological and psychosocial management related to specific symptoms is an effective strategy for care (Gallagher, 2010).*
- Families should be encouraged to employ practical measures to manage behavior such as limiting access to credit cards and restricting Internet access gambling and casino websites and other addictive social media. *Methods of psychological and psychosocial management related to specific symptoms are an effective strategy for care (Gallagher, 2010).*

Bowel Incontinence *Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN*

NANDA-I

Definition

Change in normal bowel elimination habits characterized by involuntary passage of stool

Defining Characteristics

Bowel urgency; Constant passage of soft stool; Does not recognize urge to defecate; Fecal odor; Fecal staining of bedding; Fecal staining of clothing; Inability to delay defecation; Inability to expel formed stool despite recognition of rectal fullness; Inability to recognize rectal fullness; Inattentive to urge to defecate; Reddened perianal skin

Related Factors

Increase in abdominal pressure; Abnormal increase in intestinal pressure; Alteration in cognitive functioning; Chronic diarrhea; Colorectal lesion; Deficient dietary habits; Difficulty with toileting self-care; Dysfunctional rectal sphincter; Environmental factor (e.g., inaccessible bathroom); Generalized decline in muscle tone; Immobility; Impaction; Impaired reservoir capacity; Incomplete emptying of bowel; Laxative abuse; Lower motor nerve damage; Pharmaceutical agent; Rectal sphincter abnormality; Stressors; Upper motor nerve damage

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Bowel Continence; Bowel Elimination

Example NOC Outcome with Indicators

Bowel Continence as evidenced by the following indicators: Maintains predictable pattern of stool evacuation/Maintains control of stool passage/Evacuates stool at least every 3 days. (Rate the outcome and indicators of **Bowel Continence**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Have regular, complete evacuation of fecal contents from the rectal vault (pattern may vary from every day to every 3 days)
- Have regulation of stool consistency (soft, formed stools)
- Reduce or eliminate frequency of incontinent episodes
- Exhibit intact skin in the perianal/perineal area
- Demonstrate the ability to isolate, contract, and relax pelvic muscles (when incontinence related to sphincter incompetence or high-tone pelvic floor dysfunction)
- Increase pelvic muscle strength (when incontinence related to sphincter incompetence)
- Identify triggers that precipitate change in bowel continence

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Bowel Incontinence Care; Bowel Incontinence Care: Encopresis; Bowel Training

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Example NIC Interventions—Bowel Incontinence Care

Determine physical or psychological cause of fecal incontinence; Instruct client/family to record fecal output, as appropriate

Nursing Interventions and Rationales

- In a private setting, directly question client about the presence of fecal incontinence. If the client reports altered bowel elimination patterns, problems with bowel control, or “uncontrollable diarrhea,” complete a focused nursing history including previous and present bowel elimination routines, dietary history, frequency and volume of uncontrolled stool loss, and aggravating and alleviating factors. **CEB/EB:** *Unless questioned directly, clients are often hesitant to report the presence of fecal incontinence (Fisher et al, 2008). The nursing history determines the patterns of stool elimination, to characterize involuntary stool loss and the likely etiology of the incontinence (Willson et al, 2014).*
- Recognize that risk factors for fecal incontinence include older individuals, female sex, impaired mobility, cognitive impairment, and structural or functional impairment of bowel function (Aitola et al, 2010; Langemo et al, 2011; Willson et al, 2014). *Although fecal incontinence is more common in women, it is also a problem for men and should not be overlooked when obtaining a health history (Aitola et al, 2010). Physiologic changes of the female pelvis occur with aging, increasing the risk of elimination problems, both constipation and incontinence (Mannella et al, 2013).* **CEBN:** *Double incontinence, defined as urinary and fecal incontinence, was found in 10.3% of 1869 community-dwelling women aged 45 to 85 years in a large cross-sectional study; thus, if a client is suffering from one form of incontinence, ask the client if he/she suffers from double incontinence as well (Slieker-ten Hove et al, 2010).*
- Recognize that additional risk factors for bowel incontinence in hospitalized clients include antibiotic therapy, medications, enteral feeding, immobility, inability to communicate elimination needs, acute disease processes and procedures (e.g., cancer, abdominal surgery), sedation, and mechanical ventilation (Hurnauth, 2011; Makic et al, 2011; Chang & Huang, 2013).
- ▲ Conduct a health history assessment that includes a review of current bowel patterns/habits to include constipation and use of laxatives; pelvic floor injury with childbirth; acute trauma to organs, muscles, or nerves involved in defecation; gastrointestinal inflammatory disorders; functional disability; and medications (Nurko & Scott, 2011; Kaiser et al, 2014).
- ▲ Closely inspect the perineal skin and skin folds for evidence of skin breakdown in clients with incontinence. **EBN:** *An expert consensus statement defined moisture-associated skin damage as inflammation and erosion of the skin caused by prolonged exposure to various sources of moisture (Black et al, 2011). Incontinence-associated dermatitis (IAD) is a form of skin irritation that develops from chronic exposure to urine or liquid stool (Black et al, 2011). A recent meta-analysis found a strong association between IAD and a client developing a pressure ulcer (Beeckman et al, 2014).*
- ▲ Use a validated tool that focuses on bowel elimination patterns to help provide a more clear understanding of the client’s individual challenges with fecal incontinence (Gillibrand, 2012; Langemo et al, 2011).
- ▲ Complete a focused physical assessment, including inspection of perineal skin, pelvic muscle strength assessment, digital examination of the rectum for presence of impaction and anal sphincter strength, and evaluation of functional status (mobility, dexterity, visual acuity).
- Complete an assessment of cognitive function; explore for a history of dementia, delirium, or acute confusion (Bliss et al, 2011; Drennan et al, 2014). **EBN:** *A study found that critically ill clients who were less cognitively aware were more likely to develop incontinence-associated dermatitis than clients who were more cognitively aware (Bliss et al, 2011).*
- Document patterns of stool elimination and incontinent episodes through a bowel record, including frequency of bowel movements, stool consistency, frequency and severity of incontinent episodes, precipitating factors, and dietary and fluid intake. *Documented patterns of elimination are used to narrow the likely etiology of stool incontinence and serve as a baseline to evaluate treatment efficacy (Nurko & Scott, 2011; Willson et al, 2014).*
- Assess stool consistency and its influence on risk for stool loss. *Several classification systems for stool exist and may assist the nurse and client to differentiate among normal soft, formed stool, hardened stools associated with constipation, and liquid stools associated with diarrhea.* **CEB:** *A study of stool consistency found good reliability when evaluated by nurses and clients. Word-only descriptors yielded equivocal consistency when assessed by subjects, as did tools that combined words with illustrations of various stool consistencies*

(Bliss et al, 2011). Less well-formed (loose or liquid) stool is associated with an increased severity and frequency of fecal incontinence episodes and potential for compromised skin integrity (Bharucha et al, 2008; Black et al, 2011; Langemo et al, 2011; Willson et al, 2014; Beeckman et al, 2014).

- Identify conditions contributing to or causing fecal incontinence. Fecal incontinence is frequently multifactorial. Accurate assessment of the probable etiology of fecal incontinence is necessary to select a treatment plan likely to control or eliminate the condition (Willson et al, 2014; Unger et al, 2014).
- Improve access to toileting:
 - Identify usual toileting patterns and plan opportunities for toileting accordingly.
 - Provide assistance with toileting for clients with limited access or impaired functional status (mobility, dexterity, access).
 - Institute a prompted toileting program for persons with impaired cognitive status.
 - Provide adequate privacy for toileting.
 - Respond promptly to requests for assistance with toileting.
- ▲ **CEB/EB:** Acute or transient fecal incontinence frequently occurs in the acute care or long-term care facility because of inadequate access to toileting facilities, insufficient assistance with toileting, or inadequate privacy when attempting to toilet (Bliss et al, 2000; Gillibrand, 2012; Park & Kim, 2014).
- Review the client's nutritional history and evaluate methods to normalize stool consistency with dietary adjustments (e.g., avoiding high-fat content foods) and use of fiber (Nurko & Scott, 2011; Willson et al, 2014; International Foundation for Functional Gastrointestinal Disorders [IFFGD], 2014). **EB:** Diet modifications have been found to be helpful in the management of fecal incontinence, including restrictions of some foods, adding fiber to the diet, and establishing consistent eating patterns (National Institute for Diabetes and Digestive and Kidney Diseases, 2013; Willson et al, 2014).
- Encourage the client to keep a nutrition log to track foods that irritate the bowel (Nurko & Scott, 2011).
- For hospitalized clients with tube feeding-associated fecal incontinence, involve the nutrition specialist to evaluate the formula composition, osmolality, and fiber content.
- For the client with intermittent episodes of fecal incontinence related to acute changes in stool consistency, begin a bowel reeducation program consisting of:
 - Cleansing the bowel of impacted stool if indicated
 - Normalizing stool consistency by adequate intake of fluids (30 mL/kg of body weight/day) and dietary or supplemental fiber
 - Establishing a regular routine of fecal elimination based on established patterns of bowel elimination (patterns established before onset of incontinence)

Education on bowel patterns and strategies to establish normal defecation patterns and stool consistency to reduce or eliminate the risk of recurring fecal incontinence have been found to be beneficial in controlling fecal incontinence associated with changes in stool consistency (NHS, 2015; IFFGD, 2014).

- ▲ Implement a scheduled stimulation defecation program for persons with neurological conditions causing fecal incontinence:
 - Cleanse the bowel of impacted fecal material before beginning the program.
 - Implement strategies to normalize stool consistency, including adequate intake of fluid and fiber and avoidance of foods associated with diarrhea.
 - Determine a regular schedule for bowel elimination (typically every day or every other day) based on prior patterns of bowel elimination.
 - Provide a stimulus before assisting the client to a position on the toilet; digital stimulation, a stimulating suppository, "mini-enema," or pulsed evacuation enema may be used for stimulation.

The scheduled, stimulated program relies on consistency of stool and a mechanical or chemical stimulus to produce a bolus contraction of the rectum with evacuation of fecal material (Penn, 2011).

- ▲ Begin a reeducation or pelvic floor muscle exercise program for the person with sphincter incompetence or high-tone pelvic floor muscle dysfunction of the pelvic muscles, or refer persons with fecal incontinence related to sphincter dysfunction to a nurse specialist or other therapist with clinical expertise in these techniques of care. **EB:** While evidence of overall effectiveness of pelvic floor muscle exercise programs is inconclusive as a treatment strategy for fecal incontinence, the programs are not harmful (Mannella et al, 2013; Unger et al, 2014).
- ▲ Consider a sacral nerve stimulation program in clients with urgency to defecate and fecal incontinence related to weakened sphincter muscles or sphincter defect. **EB:** Sacral nerve stimulation has been found to significantly reduce incontinence for some clients (Kaiser et al, 2014; Van Koughnett & Wexner, 2013).

- Institute a structured skin care regimen that incorporates three essential steps: cleanse, moisturize, and protect:
 - Select a cleanser with a pH range comparable to that of normal skin (usually labeled “pH balanced”).
 - Moisturize with an emollient to replace lipids removed with cleansing and protect with a skin. Products containing petrolatum, dimethicone, or zinc oxide base or a no-sting skin barrier should be used.
 - Routine incontinence care should include daily perineal skin cleansing and following each episode of incontinence.
 - When feasible, select a product that combines two or all three of these processes into a single step. Ensure that products are available at the bedside when caring for a client with total incontinence in an inpatient facility.
- ▲ Use of absorptive pads or adult containment briefs that are applied next to the client’s skin increases the risk of incontinence-associated dermatitis. Absorbent underpads that wick moisture away from skin may be used with immobile clients. **EBN:** *A structured skin care regimen based on a three-step process (cleanse, moisturize, and protect) is effective for the prevention of incontinence-associated dermatitis (Black et al, 2011; Langemo et al, 2011; Makic et al, 2011; Willson et al, 2014).*
- ▲ Consult the provider if a fungal infection is suspected. An antifungal cream or powder beneath a protective ointment may be indicated (Black et al, 2011; Langemo et al, 2011; Makic et al, 2011; Willson et al, 2014).
- Assist the client to select and apply a containment device for occasional episodes of fecal incontinence. A fecal containment device will prevent soiling of clothing and reduce odors in the client with uncontrolled stool loss. **CEBN:** *A study of community persons with fecal incontinence who used an absorptive dressing to contain mucus and stool leakage after surgery revealed that the device was preferred over traditional pads in 92% (Bliss et al, 2011).*
- In the client with frequent episodes of fecal incontinence and limited mobility, monitor the sacrum and perineal area for pressure ulcerations. **CEB/EBN:** *Limited mobility, particularly when combined with fecal incontinence and increased moisture, increases the risk of pressure ulceration. Routine cleansing, pressure reduction techniques, and management of fecal and urinary incontinence reduce this risk (Johanson et al, 1997; Junkin & Selekof, 2007; Schnelle et al, 1997; Willson et al, 2014; Beeckman et al, 2014).*
- With acutely ill clients, anticipate and evaluate the cause of acute diarrhea. Anticipate diarrhea associated with treatment or specific interventions (e.g., medications, initiation of tube feedings). *Interventions to manage acute diarrhea include use of absorbent pads and skin protectant moisturizers or fecal collector/pouch (Makic et al, 2011; Langemo et al, 2011; Willson et al, 2014).*
- ▲ Consult a provider about insertion of a bowel management system in the critically ill client when conservative measures have failed and fecal incontinence is excessive and/or produces perianal skin injury or incontinence-associated dermatitis. *Indwelling bowel management systems (BMSs), also called fecal management systems (FMS), are commercially available and designed to direct, collect, and contain liquid stool in immobile clients. BMS devices are approved by the Food and Drug Administration for up to 29 days for management of liquid stool (Langemo et al, 2011; Makic et al, 2011). CEB/EBN: Devices other than BMSs should not be used for indwelling bowel/feces diversion (Beeckman et al, 2009; Wishin et al, 2008; Pittman et al, 2012; Munhall & Jindal, 2013; Willson et al, 2014; Whitely et al, 2014).*

Geriatric

- Evaluate all older clients for established or acute fecal incontinence when the older client enters the acute or long-term care facility and intervene as indicated. **EB:** *Fecal incontinence often coexists with urinary incontinence, necessitating evidence-based interventions to prevent skin breakdown and/or pressure ulcer development in the older client (Willson et al, 2014; Shahin & Lohrmann, 2015; National Pressure Ulcer Advisory Panel, 2014).*
- Determine the client’s cognitive level using a screening tool such as the Mini-Mental State Exam (MMSE), the CAM, or Mini-Cog. **CEB/EB:** *Use of a standard evaluation tool such as the MMSE can help determine the client’s abilities and assist in planning appropriate nursing interventions. Acute or established dementias increase the risk of fecal incontinence among older adults (Borson et al, 2006; Braes et al, 2012).*
 - Teach nursing colleagues, nonprofessional care providers, family, and clients the importance of providing toileting opportunities and adequate privacy for the client in an acute or long-term care facility.

Home Care

- The preceding interventions may be adapted for home care use.
- Assess and teach a bowel management program to support continence. Address timing, diet, fluids, and actions taken independently to deal with bowel incontinence. *Identifying factors that change level of incontinence may guide interventions. If client has been taking over-the-counter medications or home remedies, it is important to consider their influence.*
- Instruct caregiver to provide clothing that is nonrestrictive, can be manipulated easily for toileting, and can be changed with ease. *Avoidance of complicated maneuvers increases the chance of success in toileting programs and decreases the client's risk for embarrassing incontinent episodes.*
- Evaluate self-care strategies of community-dwelling older adults, strengthen adaptive behaviors, and counsel older adults about altering strategies that compromise general health.
- Assist the family in arranging care in a way that allows the client to participate in family or favorite activities without embarrassment. *Careful planning can both help the client retain dignity and maintain integrity of family patterns.*
- ▲ If the client is limited to bed (or bed and chair), provide a commode or bedpan that can be easily accessed. Involve occupational and physical therapy services as indicated to promote safe transfers.
- ▲ If the client is frequently incontinent, refer for home health aide services to assist with hygiene and skin care.
- ▲ Refer the family to support services to assist with in-home management of fecal incontinence as indicated.

NOTE: Refer to nursing diagnoses **Diarrhea** and **Constipation** for detailed management of these related conditions.

Functional urinary Incontinence *Amanda Andrews, MA, Ed, BSc, DN, RN, HEA Fellow*

NANDA-I

Definition

Inability of usually continent person to reach toilet in time to avoid unintentional loss of urine

Defining Characteristics

Completely empties bladder; early morning urinary incontinence; sensation of need to void; time between sensation of urge and ability to reach toilet is too short; voiding prior to reaching toilet

Related Factors (r/t)

Alteration in cognitive functioning; alteration in environmental factor; impaired vision; neuromuscular impairment; psychological disorder; weakened supporting pelvic structure

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Urinary Continence; Urinary Elimination

Example NOC Outcome with Indicators

Urinary Continence as evidenced by the following indicators: Recognizes urge to void/Responds to urge in timely manner/Voids in appropriate receptacle/Underclothing remains dry during day/Underclothing or bedding remains dry during night. (Rate the outcome and indicators of **Urinary Continence**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Eliminate or reduce incontinent episodes
- Eliminate or overcome environmental barriers to toileting

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

- Use adaptive equipment to reduce or eliminate incontinence related to impaired mobility or dexterity
- Use portable urinary collection devices or urine containment devices when access to the toilet is not feasible

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Urinary Habit Training; Urinary Incontinence Care

Example NIC Activities—Urinary Habit Training

Keep a continence-specification record for 3 days to establish voiding pattern; Establish interval for toileting of preferably not less than 2 hours

Nursing Interventions and Rationales

I

- Introduce yourself to the client and anyone accompanying him or her and inform them of your role. *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the bases for building trust on which to base the provision of care (Howatson-Jones et al, 2012).*
- Gain consent to carry out care before proceeding further with the assessment. In clients unable to give consent, liaise with relevant health care professionals and/or family members. *Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Avery, 2013).*
- Wash hands using a recognized technique. *Evidence shows that strict hand hygiene regimens significantly reduce the incidence of methicillin-resistant Staphylococcus aureus and Clostridium difficile (Health Protection Agency, 2013).*
- Assess usual pattern of bladder management and establish the extent of the problem to include the following: *A detailed and accurate assessment of the client enables the nurse to plan interventions, monitor outcomes, and evaluate care, ensuring no unnecessary treatment is carried out (Matthews, 2011).*
- Bladder Habits:
 - Episodes of incontinence during the day and night
 - Alleviating and aggravating factors
 - Current management strategies to include containing/collection devices, restriction of fluid intake, and avoidance of fluid/food groups that cause bladder irritation
- Lifestyle and Risk Assessment: Toilet facility access and ability to use including:
 - Distance of the toilet from the bed, chair, and living quarters
 - Characteristics of the bed, including presence of side rails and distance of the bed from the floor
 - Characteristics of the pathway to the toilet, including barriers such as stairs, loose rugs on the floor, and inadequate lighting
 - Characteristics of the bathroom, including patterns of use, lighting, height of the toilet from the floor, presence of handrails to assist transfers to the toilet, and breadth of the door and its accessibility for a wheelchair, walker, or other assistive device

For older adults who may have limited mobility, the nurse must assess environmental barriers that may restrict access to the toilet (Dowling-Castronovo & Specht, 2009).
- Physical and Mental Abilities:
 - Ability to rise from chair and bed, transfer to the toilet, and ambulate, and the need for physical assistive devices such as a cane, walker, or wheelchair. *Urinary incontinence can occur as a direct consequence of the inability to reach and use the toilet either independently or with the assistance of aids or caregivers (Ostaszkiwicz et al, 2013).*
 - Ability to manipulate buttons, hooks, snaps, loop and pile closures, and zippers as needed to remove clothing. *Functional continence requires the ability to remove clothing to urinate; individuals with compromised visual acuity, dexterity, and mobility will need specific interventions to assist with these challenges to continence (Abrams et al, 2010).*
 - Functional and cognitive status assessment using a tool such as the Mini Mental Status Examination for the older client with functional incontinence. *Functional continence requires sufficient mental acuity*

to respond to sensory input from a filling urinary bladder by locating the toilet, moving to it, and emptying the bladder. In a cohort of nondisabled older adults, those with severe white matter changes (dementia) were found to have more urinary urge incontinence (Poggesi et al, 2008).

- Daily fluid intake included amount of types of fluids drank
- Risk of falls due to dizziness, impaired vision, and hearing
- Functional ability decline secondary to comorbidities (cerebral vascular incidents, amputation—see Past Medical History)
- Discuss quality of life issues relating to socialization and family events

A comprehensive assessment enables the problem to be identified, generating a baseline of information from which to accurately diagnose and plan treatment and care (Reid, 2014).

- Past Medical History:
 - Obstetrical/gynecological/urological history and surgeries
 - Relevant comorbidities—cardiac, respiratory, renal, or neurological
 - Recurrent urinary tract infections

Nazarko (2007) identified the importance of considering other conditions that affect an individual's ability to maintain continence.

- Teach the client, the client's care providers, or the family to complete a bladder diary; each 24-hour period is subdivided into 1- to 2-hour periods and includes number of urinations occurring in the toilet, actual episodes of incontinence and amount of urine leaked, reasons for episode of incontinence, type and amount of liquid intake, number of bowel movements, and incontinence pads or other products used. **EB:** A bladder diary provides a detailed account of patterns and factors related to incontinence and captures bladder activity more accurately than questionnaires (Dowling-Castronovo & Specht, 2009).
- Consult with the health care provider and carry out a medication review relating to side effects and contraindications. Antimuscarinic medications in clients receiving cholinesterase reuptake inhibitors for Alzheimer's-type dementia may experience adverse drug interactions. **EB:** Retrospective clinical evidence suggests that clients receiving both cholinesterase reuptake inhibitors and antimuscarinics experience more rapid functional decline than do clients taking cholinesterase reuptake inhibitors alone (Sink et al, 2008).
- Provide an appropriate, safe urinary receptacle such as a three-in-one commode, female or male hand-held urinal, no-spill urinal, or containment device when toileting access is limited by immobility or environmental barriers and while other interventions are being put in place. **EB:** Toileting aids should be generally considered as a short-term strategy and/or an addition to ongoing treatment. It is recommended that long-term management with such items should only be considered when all other options have been excluded (NICE, 2013).
- Refer to occupational therapy for help in obtaining assistive devices and adapting the home for optimal toilet accessibility. An occupational therapist may suggest adaptations to clothing or to the environment to assist with functional incontinence (Keegan & Knight, 2009).
- Provide advice to clients relating to loose-fitting clothing with stretch waistbands rather than buttoned or zippered waist; minimize buttons, snaps, and multilayered clothing; and substitute a loop-and-pile closure or other easily loosened systems such as Velcro for buttons, hooks, and zippers in existing clothing. Clients with impaired dexterity or weakness may benefit from clothing that has been modified or is without buttons and zippers (Cohen, 2008).
- Work with client on retraining the bladder by regular timed toileting regimens (every 2 hours). For the older client in the home or a long-term care facility who has functional incontinence and dementia:
 - Determine the frequency of current urination using an alarm system or check-and-change device.
 - Record urinary elimination and incontinent patterns in a bladder log to use as a baseline for assessment and evaluation of treatment efficacy.
 - Begin a prompted toileting program based on the results of this program; toileting frequency may vary from every 1.5 to 2 hours to every 4 hours.
 - Provide positive reinforcement.

Based on a systematic review of 14 clinical trials, prompted voiding has been shown to improve daytime incontinence and the percentage of appropriate toileting episodes in clients with dementia and functional incontinence (Fink et al, 2008).

- Monitor older clients in a long-term care facility, acute care facility, or home for dehydration. **EB:** Dehydration can exacerbate urine loss, and it is essential that it be considered a factor when managing incontinence, particularly in care home settings (Flanagan et al, 2014).

- Inspect the perineal and perianal skin for evidence of incontinence-associated dermatitis, including inflammation, vesicles in skin exposed to urinary leakage, and especially skin folds or denudation of the skin, particularly when incontinence is managed by absorptive pads or containment briefs. **EB:** *Skin folds and the perineal skin are at risk for dermatitis and fungal or bacterial infections (Gray, 2010).*
- Begin a preventive skin care regimen for all clients with urinary incontinence and treat clients with incontinence-associated dermatitis or related skin damage. **CEB:** *Minimizing exposure to urine, gentle cleansing, moisture protection, preferably with an emollient, and application of a skin protectant are the necessary components of a skin protection program (Gray, 2010).*
- Advise the client about the advantages of using disposable or reusable insert pads, pad-pant systems, or replacement briefs specifically designed for urinary incontinence as indicated for short-term/long-term use, including social events. *Using a combination of absorbent products (varied designs for day/night, going out/staying in) may be more effective and less costly than using the same design at all times; gender is a factor in determining the best design for absorbent products (Fader et al, 2008).*
- Consider the use of an indwelling catheter for continuous drainage in the client who is both homebound and bed-bound and is receiving palliative or end-of-life care (requires a health care provider's order). **EB:** *Indwelling catheters may be used for clients who are at the end of life, when repositioning adds to discomfort or pain (Rogers et al, 2008; Talley et al, 2014).*
- When an indwelling urinary catheter is in place, follow prescribed maintenance protocols for managing the catheter, taping and replacing the catheter, drainage bag, and care of perineal skin and urethral meatus. Teach infection control measures adapted to the home care setting. *Proper care reduces the risk of catheter-associated urinary tract infection (Centers for Disease Control and Prevention, 2015).*
- Assist the client in adapting to the catheter. Encourage discussion of the client's response to the catheter. **CEB:** *Clients living with a catheter are often keenly aware of its presence; adaptation is served by normalizing the experience. Instruction could include the fact that the client will be more aware of some sensations and sounds (e.g., urine sloshing in the bag, the weight of the bag, pressure or pain when urine flow has been altered). Rehearsing emptying of the bag when away from home will support resumption of activities. Discussion of the client's response will assist him/her in dealing with embarrassment or frustration (Wilde, 2002).*
- Provide client with comprehensive written information about bladder care. *Providing clients with well-written, evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. In addition, clients are more likely to retain important information that will assist them in making informed decisions about their care (Coulter, 2011).*
- Document all care and advice given in a factual and comprehensive manner. *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (St. Aubyn & Andrews, 2012).*

Overflow urinary Incontinence *Jane M. Kendall, RN, BS, CHT*

NANDA-I

Definition

Involuntary loss of urine associated with overdistention of the bladder

Defining Characteristics

Bladder distention; high postvoid residual volume, involuntary leakage of small volume of urine, nocturia

Related Factors

Bladder outlet obstruction; detrusor external sphincter dyssynergia; detrusor hypocontractility; fecal impaction; severe pelvic prolapse; treatment regimen; urethral obstruction

NOC, NIC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan for **Urinary Retention**.

Reflex urinary Incontinence

Amanda Andrews, MA, Ed, BSc, DN, RN, HEA Fellow, and Betty J. Ackley, MSN, EdS, RN

NANDA-I

Definition

Involuntary loss of urine at somewhat predictable intervals when a specific bladder volume is reached

Defining Characteristics

Absence of sensation of bladder fullness; absence of urge to void; absence of voiding sensation; inability to voluntarily inhibit voiding; inability to voluntarily initiate voiding; incomplete emptying of bladder with lesion above pontine micturition center; predictable pattern of voiding; sensation of bladder fullness; sensation of urgency to void without voluntary inhibition of bladder contraction

NOTE: Reflex urinary incontinence may be associated with sweating and acute elevation in blood pressure and pulse rate in clients with spinal cord injury. Refer to the care plan for **Autonomic Dysreflexia**.

Related Factors (r/t)

Neurological impairment above level of pontine micturition center; neurological impairment above level of sacral micturition center; tissue damage

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Urinary Continence; Urinary Elimination

Example NOC Outcome with Indicators

Urinary Continence as evidenced by the following indicators: Absence of urinary leakage between catheterizations or containment of micturition by condom catheter and drainage bag/Absence of symptomatic urinary tract infection (absence of leukocytes and absence of bacterial growth or >100,000 colony-forming units per milliliter)/Underclothing dry during day/Underclothing or bedding dry during night. (Rate the outcome and indicators of **Urinary Continence**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

- Follow prescribed schedule for bladder emptying
- Have intact perineal skin
- Remain clear of symptomatic urinary tract infection
- Demonstrate how to apply containment device or insert intermittent catheter or be able to provide caregiver with instructions for performing these procedures

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Urinary Catheterization: Intermittent; Urinary Elimination Management; Urinary Incontinence Care

Example NIC Activities—Urinary Elimination Management

Monitor urinary elimination including frequency, consistency, odor, volume, and color as appropriate; Teach client signs and symptoms of urinary tract infection

Nursing Interventions and Rationales

- Introduce yourself to the client and anyone accompanying him/her and inform them of your role. *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the bases for building trust on which to base the provision of care (Howatson-Jones, 2012).*
- Gain consent to carry out care before proceeding further with the assessment. *Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Avery, 2013).*
- Wash hands using a recognized technique. **EB:** *Evidence shows that strict hand hygiene regimens significantly reduce the incidence of methicillin-resistant Staphylococcus aureus and Clostridium difficile (Health Protection Agency, 2013).*
- Assess usual pattern of bladder management and establish the extent of the problem (refer to Functional urinary **Incontinence** care plan). **EB:** *A detailed and accurate assessment of the client enables the nurse to plan interventions, monitor outcomes, and evaluate care, ensuring no unnecessary treatment is carried out (Matthews, 2011).*
- Ask the client to complete a bladder diary/log to determine the pattern of urine elimination, any incontinence episodes, and current bladder management program. An electronic voiding diary may be kept whenever feasible. **EB:** *Use of a bladder diary may reduce client discrepancies in recall and is a valuable tool for assessment of the bladder (Bright et al, 2011).*

- Consult with the health care provider concerning current bladder function and the potential of the bladder to produce hydronephrosis, vesicoureteral reflux, febrile urinary tract infection, or compromised renal function. *Whether the client has urinary retention directs the method of urine management to prevent damage to the renal system from unrelieved obstruction (Dorsher & McIntosh, 2012).*
- Consult with the health care provider and physical therapist concerning the neuromuscular ability to perform bladder management. The type of neurological disorder, as well as the level of neurological impairment and the ability to use the hands effectively, determines the method of urine management in reflex incontinence. **EB:** *Bladder symptoms and management options need to be in keeping with the client's level of general disability to be effective in managing the problem (Fowler et al, 2009).*
- Inspect the perineal and perigenital skin for signs of incontinence-associated dermatitis and pressure ulcers (Gray et al, 2007). **CEB:** *Standardizing skin care routines making them an integrated part of essential care for incontinence clients will improve client care in specialized areas, thus helping reduce the incidence of associated dermatitis. A research study on use of products to protect skin found that an evidence-based practice of using a product that cleansed and also protected the skin resulted in improved client care (Foxley & Baadjies, 2009).*
- In consultation with the rehabilitation team, counsel the client and family concerning the merits and potential risks associated with each possible bladder management program, including spontaneous voiding, intermittent self-catheterization, and reflex voiding with condom catheter containment and in some cases, indwelling suprapubic catheterization. *All bladder management programs carry some risk of urinary incontinence or serious urinary system complications (Newman & Willson, 2011).* **EB:** *Spontaneous voiding and intermittent catheterization carry greater risk of urine loss than condom catheter containment or indwelling catheter. A study demonstrated increased rates of complications and a high rate of infection with indwelling catheter use compared with other modes of management (Singh et al, 2011). Some studies support the use of suprapubic catheters for long-term treatment of reflex incontinence in spinal cord injury clients (Böthig et al, 2012; Colli & Lloyd, 2011).*

Intermittent Self-Catheterization (ISC)

- Begin intermittent catheterization as ordered using sterile technique; the client may be taught to use clean technique in the home situation. **EB:** *Intermittent catheterization is considered the preferred long-term management for a neurogenic bladder. Sterile intermittent catheterization should be used in hospitals, rehabilitation centers, and extended care facilities (Newman & Willson, 2011). There is an associated risk of urinary tract infection with any type of bladder management; however, by performing ISC the risk of urinary tract infections is reduced as the residual volume in the bladder is resolved (Winder, 2012).*
- Schedule the frequency of intermittent catheterization based on the frequency/volume records of previous catheterizations, functional bladder capacity, and the impact of catheterization on the quality of the client's life. *Bladder volumes must be kept lower to prevent development of urinary tract infection from retention of urine, and draining the urine regularly helps prevent movement of bacteria into the bladder long enough to produce symptomatic infection (Dorsher & McIntosh, 2012; Newman & Willson, 2011).*
- Teach the client to recognize signs of symptomatic urinary tract infection and to seek care promptly when these signs occur. The signs of symptomatic infection are the following:
 - Discomfort over the bladder or during urination
 - Acute onset of urinary incontinence
 - Fever
 - Markedly increased spasticity of muscles below the level of the spinal lesion
 - Malaise, lethargy
 - Hematuria
 - Autonomic dysreflexia (hyperreflexia) symptoms

Signs of symptomatic urinary tract infection as indicated above should be treated promptly with antimicrobial therapy, whereas asymptomatic bacteriuria should not generally be treated (Gupta & Trautner, 2011; Newman & Willson, 2011).

- Recognize that intermittent catheterization is typically associated with asymptomatic bacteriuria, and the indwelling catheter is routinely associated with asymptomatic colonization. **EB:** *Antibiotic treatment of asymptomatic bacteriuria has not proven helpful, but prompt management of symptomatic infection is necessary to prevent urosepsis or related complications (Gupta & Trautner, 2011).*

- Teach intermittent catheterization as the client approaches discharge as per operational guidelines and best practice. Instruct the client and at least one family member in the performance of catheterization. Teach the client with quadriplegia how to instruct others to perform this procedure. **EB:** *Intermittent catheterization is a safe and effective bladder management strategy for persons with reflex urinary incontinence. Inclusion of a family member is particularly helpful for the client with limited upper extremity dexterity and reflex urinary incontinence (Woodbury et al, 2008).*
- Teach the client managed by intermittent catheterization to self-administer antispasmodic (parasympatholytic) medications as prescribed by consulting health care provider and to recognize and manage potential side effects as needed. *Antimuscarinic medications enhance catheterized volumes and reduce the frequency of incontinence episodes in persons with reflex incontinence owing to spinal cord injury or multiple sclerosis (Fowler, 2011; Verpoorten & Buysse, 2008).*

Condom Catheter/Sheath System

- For a male client with reflex incontinence who does not have urinary retention and cannot manage the condition effectively with spontaneous voiding, does not choose to perform intermittent catheterization, or cannot perform catheterization, teach the client and his family to obtain, select, and apply an external collective device and urinary drainage system. Assist the client and family to choose a product that adheres to the glans penis or penile shaft without allowing seepage of urine onto surrounding skin or clothing, that avoids provoking hypersensitivity reactions on the skin, and that includes a urinary drainage reservoir that is easily concealed under the clothing and does not cause irritation to the skin of the thigh. **EB:** *Multiple components of the external collection device affect the product's ability to contain urinary leakage, protect underlying skin, and preserve the client's dignity (Kyle, 2011; Wells, 2008). National Institute for Health and Care Excellence (NICE) guidance (2012) advocates that all risks and benefits are discussed relating to the available sheath system options.*
- Teach the client whose incontinence is managed by a condom catheter to routinely inspect the skin with each catheter change for evidence of lesions caused by pressure from the containment device or by exposure to urine, to cleanse the penis thoroughly, and to reapply a new device daily or every other day. **CEB:** *Skin breakdown is a common complication associated with routine use of the condom catheter (Wells, 2008).*
- Ensure the client is aware of when and how to report any problems and/or complications of reflex incontinence care when at home. *Early detection allows for rapid diagnosis and treatment. Information about this should be individually presented to the clients, specifically tailored to their physical condition and cognitive abilities to encourage self-management (Swain, 2012).*
- Encourage a mindset and program of self-care management. **CEB:** *Addressing self-care activities through exercise, diet, fluid intake, and protective devices helps the client to exercise control over incontinence and may reduce the substantial burden affecting a significant proportion of spouse, partner, or familial care providers (Post et al, 2005).*
- Assist the family with arranging care in a way that allows the client to participate in family or favorite activities without embarrassment. Elicit discussion of the client's concerns about the social or emotional burden of incontinence. **EB:** *Urinary incontinence has a substantial negative impact on the quality of life for clients, both socially and financially. Further studies are needed to determine the true extent of the problem and to address it (Tapia et al, 2013).*
- Teach the client to ensure good hydration. Total daily fluid intake should be approximately 2.7 L per day for women and 3.7 L per day for men. *Adequate fluid helps wash out bacteria from the urethra to prevent urinary tract infections, helps prevent kidney stones, and potentially protects the client from development of cancer of the bladder from exposure to carcinogens concentrated in the urine (Newman & Willson, 2011).*
- Teach the client with a spinal injury the signs of autonomic dysreflexia, its relationship to bladder fullness, and management of the condition. Refer to the care plan for **Autonomic Dysreflexia**.
- Provide client with comprehensive written information about bladder care. **EB:** *Providing clients with well-written, evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. In addition, clients are more likely to retain important information that will assist them in making informed decisions about their care (Coulter, 2011).*
- Document all care and advice given in a factual and comprehensive manner. *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (St. Aubyn & Andrews, 2012).*

Risk for Urge Urinary Incontinence *Betty J. Ackley, MSN, EdS, RN*

NANDA-I

Definition

Vulnerable to involuntary passage of urine occurring soon after a strong sensation or urgency to void, which may compromise health

Risk Factors

Alcohol consumption; atrophic urethritis; atrophic vaginitis; detrusor hyperactivity with impaired bladder contractility; ineffective toileting habits; involuntary sphincter relaxation; small bladder capacity; treatment regimen

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan for Urge urinary **Incontinence**.

Stress Urinary Incontinence *Amanda Andrews, MA, Ed, BSc, DN, RN, HEA Fellow*

NANDA-I

Definition

Sudden leakage of urine with activities that increase intra-abdominal pressure

Defining Characteristics

Involuntary leakage of small volume of urine (e.g., with coughing, laughing, sneezing, on exertion); involuntary leakage of small volume of urine in the absence of detrusor contraction; involuntary leakage of small volume of urine in the absence of overdistended bladder

Related Factors (r/t)

Degenerative changes in pelvic muscles; increase in intra-abdominal pressure; intrinsic urethral sphincter deficiency; weak pelvic muscles

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Urinary Continence; Urinary Elimination

Example NOC Outcome with Indicators

Urinary Continence as evidenced by the following indicators: Experiences no urine leakage with increased abdominal pressure (e.g., sneezing, laughing, lifting)/Voids in appropriate receptacle/Able to move to toilet after strong desire to urinate is perceived/Underclothing remains dry during day/Underclothing or bedding remains dry during night. (Rate the outcome and indicators of **Urinary Continence**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Report fewer stress incontinence episodes and/or a decrease in the severity of urine loss
- Experience reduction in frequency of urinary incontinence episodes as recorded on voiding diary (bladder log)
- Identify containment devices that assist in management of stress incontinence

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Pelvic Muscle Exercises; Urinary Incontinence Care

Example NIC Activities—Urinary Incontinence Care

Explain etiology of problem and rationale for actions; Modify clothing and environment to provide easy access to toilet

Nursing Interventions and Rationales

- Introduce yourself to the client and anyone accompanying him/her and inform them of your role. *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the bases for building trust on which to base the provision of care (Howatson-Jones et al, 2012).*
- Gain consent to carry out care before proceeding further with the assessment. In clients unable to give consent, liaise with relevant health care professionals and/or family members. *Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Avery, 2013).*

- Wash hands using a recognized technique. *Evidence shows that strict hand hygiene regimens significantly reduce the incidence of methicillin-resistant Staphylococcus aureus and Clostridium difficile (Health Protection Agency, 2013).*
 - Assess usual pattern of bladder management and establish pattern of bladder management and extent of the problem to include: (refer to Functional urinary **Incontinence** care plan). **EB:** *A detailed and accurate assessment of the client enables the nurse to plan interventions, monitor outcomes, and evaluate care, ensuring no unnecessary treatment is carried out (Matthews, 2011).*
 - Past Medical History (risk factors for stress incontinence): pregnancy, parity, large babies, forceps or breech deliveries, obesity, chronic cough, physical activity, previous urinary tract or gynecological surgery. *Nazarko (2007) identified the importance of considering other conditions that will affect an individual's ability to maintain continence.*
 - Medication Review (diuretics, lithium, adrenergic blockers, diabetes, and smoking). **EB:** *The most common types of urinary incontinence in adult women are stress, urge, or a combination of both (Bradley et al, 2010). Many women are reluctant to initiate a discussion regarding incontinence; identifying women at risk is essential for effective screening (Keyock & Newman, 2011). Stress incontinence is caused by activities that create an increase in intra-abdominal pressure, such as coughing, sneezing, lifting, jumping, stair climbing, or exercise, whereas urge incontinence is caused by detrusor overactivity. Individuals may have mixed incontinence, and it is important to determine which symptom is the most troublesome to the individual in order to treat that first (McKertich, 2008).*
 - Bladder Habits
 - Onset and duration of urinary leakage
 - Related lower urinary tract symptoms, including voiding frequency (day/night), urgency, severity (small, moderate, large amounts) of urinary leakage
 - Factors provoking urine loss (diuretics, bladder irritants, alcohol), focusing on the differential diagnosis of stress, urge or mixed stress, and urge urinary symptoms. Consider using a symptom questionnaire that elicits relevant lower urinary tract symptoms and provides differentiation between stress and urge incontinence symptoms.
 - ▲ **EB:** *Stress urinary incontinence is more common in young and middle-aged women (Strothers & Friedman, 2011), is characterized by incontinence in small amounts (drops, spurts), no nocturia or incontinence at night, and incontinence without sensation of urine loss. With urge incontinence, the client has a strong, uncontrolled urge before losing a moderate to large volume of urine, and experiences frequency and nocturia (Nygaard et al, 2010). Clients with mixed urinary incontinence should be treated first for the predominant problem with conservative management for 8 to 12 weeks (Abrams et al, 2010).*
 - Assess for mixed urinary incontinence (a combination of stress and urge incontinence):
 - Can you delay urination for a 2-hour movie or car ride?
 - How often do you arise at night to urinate?
 - When you have the urge to urinate, can you reach the toilet without leaking?
- CEB/EB:** *Farrell et al (2013) established that by using a questionnaire for urinary tract diagnosis, the client's ability to assess their own incontinence type was enhanced. These three questions have been found to reliably evaluate the presence of urge incontinence (Gray et al, 2001).*
- Lifestyle Assessment: impact on the individual's lifestyle. Inquire about incontinence pad use and change in daily, social, or recreational activities, as well as emotional impact. **EB:** *Incontinence is distressing and may contribute to decreased quality of life (Lasserre et al, 2009); psychological well-being, social interactions and activities, and sexual and interpersonal relationships may be negatively affected (Bartoli et al, 2010).*
 - Inspect the perineal skin for evidence of incontinence-associated dermatitis, including inflammation, vesicles in skin exposed to urinary leakage, and especially skin folds or denudation of the skin, particularly when incontinence is managed by absorptive pads or containment briefs. **EB:** *Ammonia produced from the breakdown of urea in urine causes an increase in skin pH, which increases the permeability of the skin; excess moisture and damage to the acid mantle further increases permeability and vulnerability to bacterial and fungal infections (Langemo et al, 2011). Skin exposed to urine or stool will become bright red, and the surface may appear shiny due to serous exudate; inflamed areas of individuals with darker skin tones may be a duller red or hypopigmented when compared to adjacent skin. Inspect the skin for a maculopapular red rash typical of candidiasis (Gray, 2010).*
 - Refer client for specific testing to further confirm diagnosis. If trained to do so, carry out cough stress test, request 24-hour pad test (if appropriate) and urodynamic studies (to include urine speed and flow, post-void residual measurement, leak point pressure, and pressure flow study). **EB:** *Markle et al (2011)*

established a greater agreement rating between cough stress test and urodynamics than between 24-hour pad test and urodynamics in the assessment of stress incontinence.

- Establish with client his/her current use of containment devices; evaluate the devices for their ability to adequately contain urine loss, protect clothing, and control odor. Assist the client in identifying containment devices specifically designed to contain urinary leakage. **CEB:** *Recommend the client buy incontinent products specifically designed to contain urine, utilizing hydrogel to contain fluid, and not use sanitary pads. Using a combination of products may be more effective and economical (Fader et al, 2008).* **EB:** *Recognize that incontinence products may present a significant financial burden to clients, with approximately 70% of expenditures attributed to containment devices, laundry, and dry cleaning expenses, which are often paid out of pocket (Chong et al, 2011).*
- Teach the client to complete a bladder diary by recording voiding frequency, the frequency and degree of urinary incontinence episodes, their association with urgency (a sudden and strong desire to urinate that is difficult to defer), fluid intake, and pad usage over a 3- to 7-day period. An electronic voiding diary may be kept whenever feasible. **EB:** *Use of a bladder diary may reduce client discrepancies in recall and is a valuable tool for assessment; short (24-hour) duration of the bladder diary may yield inadequate data, and excessive diary duration reduces compliance (Bright et al, 2011).*
- With the client and in close consultation with the health care provider, review treatment options, including behavioral management; drug therapy; use of a pessary, vaginal device, or urethral insert; and surgery. Outline their potential benefits, efficacy, and side effects. **CEB:** *Behavioral and nonsurgical treatments may improve symptoms in up to 70% of women; referral to a specialist may be indicated if conservative treatment is ineffective (Waetjen, 2008).*

Pelvic Floor Training Program

- *Pelvic floor muscle training is effective in the treatment of stress, urge, and mixed urinary incontinence; participation in a supervised program for at least 3 months may yield improved outcomes (Dumoulin & Hay-Smith, 2010).*
- Teach the client undergoing pelvic floor muscle training to identify, contract, and relax the pelvic floor muscles without contracting distal muscle groups (e.g., abdominal muscles or gluteus muscles) using verbal feedback based on vaginal or anal palpation, biofeedback, or electrical stimulation, utilizing the assistance of an incontinence specialist or health care provider as necessary. **EB:** *To find the proper muscles, the client may be instructed to think about trying to control the urge to pass gas; women will feel a lifting sensation in the vaginal area and a pulling in of the rectum (Keyock & Newman, 2011).* **CEB:** *When learning to control pelvic floor muscles, clients may recruit other muscles such as the rectus abdominis or gluteal muscles, which may be counterproductive; these muscles must be relaxed to avoid increasing pressure on the bladder or pelvic floor (Burgio et al, 2009).*
- Incorporate principles of exercise physiology into a pelvic muscle training program using the following strategies:
 - Begin a graded exercise program, usually starting with 5 to 10 repetitions and advancing gradually to no more than 35 to 50 repetitions every day or every other day based on baseline and ongoing evaluation of maximal strength and endurance.
 - Continue exercise sessions over a period of 3 to 6 months.
 - Integrate muscle training into activities of daily living.
 - Assess progress every 2 weeks during the first month and every 4 to 6 weeks thereafter.

Pelvic floor muscle training strengthens urethral sphincter tone (Chong et al, 2011) and is the first-line conservative approach for all types of incontinence and in particular for stress and mixed urinary incontinence; women report an improvement in symptoms and quality of life (Dumoulin & Hay-Smith, 2010).

Bladder Training Program

- Assist the client in completing a bladder diary over a period of a minimum of 3 days or up to 7 days.
 - Review the results with the client, determining typical voiding frequency and establishing goals for voiding frequency.
 - Using baseline voiding frequency, as determined by the diary, teach the client to urinate by the clock when awake, typically every 30 to 120 minutes.
 - Encourage adherence to the program with timing devices, as well as verbal encouragement and support, and address individual reasons for schedule interruption.

- Gradually increase the time between urinations to the negotiated goal. Time intervals between voiding are typically increased in increments of 15 to 30 minutes for clients with a baseline frequency of less than every 60 minutes and increments of 25 to 30 minutes for clients with a baseline frequency of more than every 60 minutes.

Bladder training reduces the frequency and severity of urinary leakage in women with stress incontinence, urge incontinence, and mixed incontinence. The result of bladder training in ambulatory, community-dwelling women is comparable to that achieved through pelvic floor muscle training (Milne, 2008).

- Teach the client to self-administer duloxetine and imipramine as ordered by consulting health care provider, and to monitor for adverse side effects. **CEB/EB:** *There are no prescriptive drugs approved for use in stress urinary incontinence in the United States. Nevertheless, several agents are sometimes prescribed to highly selected clients with stress urinary incontinence. They include duloxetine (Schagen van Leeuwen et al, 2008) and imipramine (Andersson, 2000).*
- Teach the client to self-administer topical (vaginal) estrogens as directed, and to monitor for adverse side effects. **EB:** *Postmenopausal estrogen deprivation may contribute to stress incontinence; topical vaginal medications reverse urogenital atrophic changes and may relieve lower urinary tract dysfunction (Ewies & Alfhaily, 2010).*
- Refer the female client with stress urinary incontinence and pelvic organ prolapse who wishes to employ a pessary to manage stress incontinence to a nurse specialist or gynecologist with expertise in the placement and maintenance of these devices. **CEB:** *Placement of an appropriately sized dish pessary resolved stress urinary incontinence in 60% of a group of 95 women (Noble et al, 2008).*
- Discuss potentially reversible or controllable risk factors, such as weight loss, with the client with stress incontinence and assist the client to formulate a strategy to eliminate these conditions. *Although research supports a strong familial predisposition to stress incontinence among women, other risk factors, including obesity, smoking (Mishra et al, 2008), and chronic coughing from smoking, are reversible. EB: Being obese may increase pressure on the pelvic floor and doubles the risk for incontinence (Strothers & Friedman, 2011).*
- Provide information about support resources such as the National Association for Continence, The Simon Foundation for Continence, or the Total Control Program.
- Refer the client with persistent stress incontinence to a continence service, health care provider, or nurse who specializes in the management of this condition. *All clients presenting with incontinence should be offered an initial assessment by a suitably trained individual.*
- Teach the client to ensure good hydration. Total daily fluid intake should be approximately 2.7 L per day for women and 3.7 L per day for men. **EB:** *Adequate fluid helps wash out bacteria from the urethra to prevent urinary tract infections, helps prevent kidney stones, and potentially protects the client from development of cancer of the bladder from exposure to carcinogens concentrated in the urine (Newman & Willson, 2011).*
- Provide client with comprehensive written information about bladder care. **EB:** *Providing clients with well-written, evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. In addition, clients are more likely to retain important information that will assist them in making informed decisions about their care (Coulter, 2011).*
- Encourage a mindset and program of self-care management. *Addressing self-care activities through exercise, diet, fluid intake, and protective devices helps the client exercise control over incontinence and may reduce the substantial care provider burden affecting a significant proportion of spouse, partner, or familial care providers (Post et al, 2005).*
- Assist the family with arranging care in a way that allows the client to participate in family or favorite activities without embarrassment. Elicit discussion of the client's concerns about the social or emotional burden of incontinence. **EB:** *Urinary incontinence has a substantial negative impact on the quality of life for clients, both socially and financially. Further studies are needed to determine the true extent of the problem and to address it (Tapia et al, 2013).*
- Document all care and advice given in a factual and comprehensive manner. *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (St. Aubyn & Andrews, 2012).*

Urge urinary Incontinence *Amanda Andrews, MA, Ed, BSc, DN, RN, HEA Fellow*

NANDA-I

Definition

Involuntary passage of urine occurring soon after a strong sense of urgency to void

Defining Characteristics

Inability to reach toilet in time to avoid urine loss; involuntary loss of urine with bladder contractions; involuntary loss of urine with bladder spasms; urinary urgency

Related Factors (r/t)

Alcohol consumption; atrophic urethritis; atrophic vaginitis; bladder infection; caffeine intake; decrease in bladder capacity; detrusor hyperactivity with impaired bladder contractility; fecal impaction; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Integrity: Skin and Mucous Membranes; Urinary Continence; Urinary Elimination

Example NOC Outcome with Indicators

Urinary Continence as evidenced by the following indicators: Responds in timely manner to urge/Voids in appropriate receptacle/Has adequate time to reach toilet between urge and evacuation of urine/Underclothing remains dry during day/Underclothing or bedding remains dry during night. (Rate the outcome and indicators of **Urinary Continence**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section 1](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Report relief from urge urinary incontinence or a decrease in the frequency of incontinent episodes
- Identify containment devices that assist in the management of urge urinary incontinence

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Urinary Habit Training; Urinary Incontinence Care

Example NIC Activities—Urinary Habit Training

Keep a continence specification record for 3 days to establish voiding pattern; establish interval for toileting of preferably not less than 2 hours

Nursing Interventions and Rationales

- Introduce yourself to the client and anyone accompanying him/her and inform them of your role. *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the bases for building trust on which to base the provision of care (Howatson-Jones et al, 2012).*
- Gain consent to carry out care before proceeding further with the assessment. *Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Avery, 2013).*

- Wash hands using a recognized technique. *Evidence shows that strict hand hygiene regimens significantly reduce the incidence of methicillin-resistant Staphylococcus aureus and Clostridium difficile (Health Protection Agency, 2013).*
- Assess usual pattern of bladder management and establish pattern of bladder management and extent of the problem. *A detailed and accurate assessment of the client enables the nurse to plan interventions, monitor outcomes, and evaluate care, ensuring no unnecessary treatment is carried out (Matthews, 2011).* Refer to Functional urinary **Incontinence** care plan.
- Bladder Habits and Quality of Life Issues:
 - Diurnal frequency (voiding more than once every 2 hours while awake)
 - Urgency, daytime frequency and nocturia
 - Involuntary leakage and leakage accompanied by or preceded by urgency
 - Amount of urine loss—moderate or large volume
 - Severity of symptoms
 - Alleviating and aggravating factors
 - Effect on quality of life
- ▲ **EB:** *Incontinence is distressing and may contribute to decreased quality of life (Lassere et al, 2009); psychological well-being, social interactions and activities, and sexual and interpersonal relationships may be negatively affected (Bartoli et al, 2010). Urge urinary incontinence occurs when involuntary leakage of urine is accompanied by or immediately preceded by urgency; overactive bladder is characterized by the storage symptoms of urgency with or without incontinence and is usually accompanied by frequency and nocturia (Abrams et al, 2010).*
- Ask specific questions relating to urge presentation:
 - Can you delay urination for a 2-hour movie or car ride?
 - How often do you wake at night to urinate?
 - When you have the urge to urinate, can you reach the toilet without leaking?
- ▲ **EB:** *A history of urine loss associated with urgency is the most helpful criterion for diagnosing urge urinary incontinence (Holroyd-Leduc et al, 2011). These three questions have been found to reliably evaluate the presence of urge incontinence (Gray et al, 2001).*
- In close consultation with a health care practitioner or advanced practice nurse, consider administering a symptom questionnaire that elicits relevant lower urinary tract symptoms and differentiates stress and urge incontinence symptoms. **CEB:** *The Urogenital Distress Inventory, short form (UDI-6) is a reliable and valid tool for identifying types of urinary incontinence (Dowling-Castronovo, 2008).*
- Assess the severity of incontinence as well as the impact on the individual's lifestyle; inquire about incontinence pad use and change in daily, social, or recreational activities, as well as emotional impact. **EB:** *Incontinence is distressing and may contribute to decreased quality of life, especially for women with mixed incontinence (Lassere et al, 2009).*
- Perform a focused physical assessment, if competent to do so, alternatively in close consultation with a health care practitioner or advanced practice nurse including:
 - Bladder palpation after voiding to check for retention
 - Bladder scanning for post-void residual
 - Inspection of the perineal skin
 - Vaginal examination to determine hypoestrogenic changes in the mucosa (may contribute to urge incontinence)
 - Pelvic examination to determine the presence, location, and severity of vaginal wall prolapse, and reproduction of stress urinary incontinence with the cough test
 - Anal tone and constipation should be assessed. *A thorough abdominal and pelvic examination must be completed to accurately assess incontinence; assess for neurological conditions or heart failure (cause of nocturia) as warranted (McKertich, 2008).*
- Inspect the perineal and perianal skin for evidence of incontinence-associated dermatitis, including inflammation, vesicles in skin exposed to urinary leakage, and especially skin folds or denudation of the skin, particularly when incontinence is managed by absorptive pads or containment briefs. **EB:** *Ammonia produced from the breakdown of urea in urine causes an increase in skin pH, which increases the permeability of the skin; excess moisture and damage to the acid mantle further increases permeability and vulnerability to bacterial and fungal infections (Langemo et al, 2011). Skin exposed to urine or stool will become bright red, and the surface may appear shiny due to serous exudate; inflamed areas of individuals with darker skin*

tones may be a duller red or hypopigmented when compared to adjacent skin. Inspect the skin for a maculopapular red rash typical of candidiasis (Gray, 2010).

- Teach the client to complete a bladder diary by recording voiding frequency, the frequency and degree of urinary incontinence episodes, their association with urgency (a sudden and strong desire to urinate that is difficult to defer), fluid intake, and pad usage over a 3- to 7-day period. An electronic voiding diary may be kept whenever feasible. In addition to these parameters, the client may be asked to record voided volume and fluid intake. **EB:** *Use of a bladder diary may reduce client discrepancies in recall and is a valuable tool for assessment; short (24-hour) duration of the bladder diary may yield inadequate data, and excessive diary duration reduces compliance (Bright et al, 2011).*
- Review all medications the client is receiving, paying particular attention to sedatives, opioid analgesics, diuretics, antidepressants, psychotropic drugs, and cholinergics. Consult the health care practitioner or nurse practitioner about altering or eliminating these medications if they are suspected of affecting incontinence. **EB:** *All medications should be reviewed to determine whether they are contributing to incontinence (Abrams et al, 2010).*
- Assess the client for urinary retention (see the care plan for **Urinary Retention**).
- Assess the client for functional limitations (environmental barriers, limited mobility or dexterity, impaired cognitive function). **EBN:** *Du Moulin et al (2008) analyzed a group of 2866 clients receiving home care and found that functional impairment (poor mobility) was associated with an increased likelihood of urinary incontinence. Refer to the care plan for Functional urinary Incontinence.*
- Consult the health care practitioner concerning diabetic management or pharmacotherapy for urinary tract infection when indicated. In specific cases, urgency and an increased risk of urge incontinence may be related to bacteriuria or urinary tract infection (Rodhe et al, 2008).
- Assess for signs and symptoms of atrophic vaginal changes in the perimenopausal or postmenopausal woman, including vaginal dryness, tenderness to touch, mucosal dryness, friability, and discomfort with gentle palpation. Specifically query the woman with atrophic vaginitis concerning associated lower urinary tract symptoms (usually voiding frequency, urgency, and dysuria). Refer the woman with atrophic vaginal changes and bothersome lower urinary tract symptoms to a gynecologist, urologist, or women's health nurse practitioner for further evaluation and management. *Vaginal topical estrogens may reduce urge incontinence, prevent urogenital atrophy, and prevent recurrent urinary tract infections (Hillard, 2010).*

Pelvic Floor Training Program

- *Pelvic floor muscle training is effective in the treatment of stress, urge, and mixed urinary incontinence; participation in a supervised program for at least 3 months may yield improved outcomes (Dumoulin & Hay-Smith, 2010).*
- Teach the client undergoing pelvic floor muscle training to identify, contract, and relax the pelvic floor muscles without contracting distal muscle groups (e.g., abdominal muscles or gluteus muscles) using verbal feedback based on vaginal or anal palpation, biofeedback, or electrical stimulation, utilizing the assistance of an incontinence specialist or health care practitioner as necessary. **EB:** *To find the proper muscles, the client may be instructed to think about trying to control the urge to pass gas; women will feel a lifting sensation in the vaginal area and a pulling in of the rectum (Keyock & Newman, 2011). When learning to control pelvic floor muscles, clients may recruit other muscles such as the rectus abdominis or gluteal muscles, which may be counterproductive; these muscles must be relaxed to avoid increasing pressure on the bladder or pelvic floor (Burgio, 2009).*
- Incorporate principles of exercise physiology into a pelvic muscle training program using the following strategies:
 - Begin a graded exercise program, usually starting with 5 to 10 repetitions and advancing gradually to no more than 35 to 50 repetitions every day or every other day based on baseline and ongoing evaluation of maximal strength and endurance.
 - Continue exercise sessions over a period of 3 to 6 months.
 - Integrate muscle training into activities of daily living.
 - Assess progress every 2 weeks during the first month and every 4 to 6 weeks thereafter.

Pelvic floor muscle training strengthens urethral sphincter tone (Chong, Khan, & Anger, 2011) and is the first-line conservative approach for all types of incontinence and in particular for stress and mixed urinary incontinence; women report an improvement in symptoms and quality of life (Dumoulin & Hay-Smith, 2010).

Bladder Training Program

- Assist the client in completing a voiding diary over a period of a minimum of 3 days or up to 7 days.
- Review the results with the client, determining typical voiding frequency and establishing goals for voiding frequency based on the longest time interval between voids that is comfortable for the client.
- Using baseline voiding frequency, as determined by the diary, teach the client to void first thing in the morning, every time the predetermined voiding interval passes, and before going to bed at night.
- Encourage adherence to the program with timing devices and verbal encouragement and support, and address individual reasons for schedule interruption.
- Teach distraction and urge suppression techniques (see later discussion) to control urgency while the client postpones urination.
- Gradually increase the time between urinations to the negotiated goal. Time intervals between voiding are typically increased in increments of 15 to 30 minutes for clients with a baseline frequency of less than every 60 minutes and increments of 25 to 30 minutes for clients with a baseline frequency of more than every 60 minutes. The voiding interval should be increased by 15 to 30 minutes each week (based on the client's tolerance) until a voiding interval of 3 to 4 hours is achieved. Utilize a bladder diary to monitor progress. **CEB:** *Improvement rates using bladder training range from 57% to 87% (Wyman et al, 2009). With bladder training, the goal is to restore normal bladder function through the use of a voiding schedule; the woman voids at predetermined intervals rather than in response to urgency, progressively increasing the intervals between voiding. Distraction and relaxation techniques may be used to postpone voiding (Wyman et al, 2009).*
- Review with the client the types of beverages consumed, focusing on the intake of caffeine, which is associated with a transient effect on lower urinary tract symptoms. Advise all clients to reduce or eliminate intake of caffeinated beverages or over-the-counter medications of dietary aids containing caffeine. Identify and counsel the client to eliminate other bladder irritants that may exacerbate incontinence, such as smoking, carbonated beverages, citrus, sugar substitutes, and tomato products. **CEB:** *Caffeine is a diuretic, is a bladder irritant, increases detrusor pressure, and is a risk factor for detrusor instability; reducing caffeine may decrease both stress and urge incontinence. Decrease caffeine gradually to avoid caffeine withdrawal. Carbonated beverages, citrus fruits, sugar substitutes, and tomato products may be bladder irritants (Burgio, 2009). Chemicals from smoking are bladder irritants (Wyman et al, 2009).*
- Review with the client the volume of fluids consumed; fluids may be reduced with caution, particularly in clients who do not drink more than 1500 mL during the day, to alleviate urinary frequency, especially in the evening after 6 PM or 3 to 4 hours before bedtime to reduce nocturia. **EB:** *Be aware that adequate fluid intake is essential; six 8-oz glasses per 24 hours, 1500 mL, or 30 mL/kg body weight is recommended. The type and amount of fluid intake is associated with frequency and urge urinary incontinence (Segal et al, 2011). Excessive fluid intake may exacerbate incontinence; fluid restriction may cause an increase in urine concentration, which may cause bladder mucosa irritation that promotes urgency, frequency, and urinary tract infection (Wyman et al, 2009).*
- Teach the client methods to avoid constipation (refer to **Constipation** care plans) such as increasing dietary fiber, moderately increasing fluid intake, exercising, and establishing a routine defecation schedule. **CEB:** *Women with severe constipation demonstrate changes in pelvic floor neurological function; alleviation of constipation may significantly improve frequency and urgency in older clients (Wyman et al, 2009).*

Urge Suppression

- *Urge suppression skills are essential in helping clients learn a new way of responding to the sense of urgency. Rushing to the toilet increases physical pressure on the bladder, enhances the sensation of fullness, exposes the client to visual cues that can trigger incontinence, and exacerbates urgency (Burgio, 2009).*
- Teach the client the following techniques:
 - When a strong or precipitous urge to urinate is perceived, teach the client to avoid running to the toilet.
 - Pause, sit down, and relax the entire body.
 - Perform repeated, rapid pelvic muscle contractions until the urge is relieved.
 - Use distraction: count backward from 100 by sevens, recite a poem, write a letter, balance a checkbook, do handwork such as knitting, take five deep breaths, focusing on breathing.

- Relief is followed by micturition within 5 to 15 minutes, using nonhurried movements when locating a toilet and voiding.
- Use urge suppression strategies on waking during the night. If the urge subsides, the client should be encouraged to go back to sleep. If after a minute or two it does not, clients should be instructed to get up to void to avoid sleep interruption. **EB:** *Behavioral training for urge incontinence can reduce nocturia (Burgio, 2009).*
- Teach the client to self-administer antimuscarinic (anticholinergic) drugs as directed. Teach dosage side effects and administration of the medication and the importance of combining pharmacotherapy with scheduled voiding, adequate fluid intake, restriction of bladder irritants, and urge suppression techniques. **EB:** *Antimuscarinic drugs increase bladder capacity, reduce the frequency of incontinence episodes, and diminish voiding frequency. However, they do not cure bladder dysfunction or reduce the time between perception of a strong urge and onset of an overactive detrusor contraction. Approximately two thirds of clients treated with antimuscarinic medication discontinue use within 3 to 4 months; the efficacy of pharmacotherapy for urge incontinence is enhanced when combined with behavioral interventions (Burgio et al, 2010).*
- Assist the client in selecting, obtaining, and applying a containment device for urine loss as indicated. *The use of containment devices can be useful as “stop gap” strategies used alongside long-term management options (Reid, 2014).*
- Provide the client with information about incontinence support groups such as the National Association for Continence and the Simon Foundation for Continence. A helpful website titled Total Control (<http://www.totalcontrolprogram.com/Pelvic+Health/Bladder+Health>) can be accessed to give support and information to women with incontinence. **EB:** *Knowledge contributes to effective self-management; women with incontinence often do not seek help from others and prefer to self-manage their incontinence (Holroyd-Leduc et al, 2011).*
- Assess the functional and cognitive status of all clients with urge incontinence; use interventions to improve mobility. **EB:** *Functional limitations affect the severity and management of urge urinary incontinence; strategies to improve physical function may decrease incontinence (Tamanini et al, 2009).*
- Refer client for occupational therapy for help in obtaining assistive devices and adapting the home for optimal toilet accessibility. *An occupational therapist may suggest adaptations to clothing or to the environment to assist with functional incontinence (Keegan & Knight, 2009).*
- Encourage the client to develop an action plan for self-care management of incontinence. *Making an action plan facilitates behavior change (Lippke et al, 2009).*
- Provide client with comprehensive written information about bladder care. **EB:** *Providing clients with well-written, evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. In addition, clients are more likely to retain important information that will assist them in making informed decisions about their care (Coulter, 2011).*
- Document all care and advice given in a factual and comprehensive manner. *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (St. Aubyn & Andrews, 2012).*

Disorganized Infant behavior

Mary Alice DeWys, RN, BS, CMI, and Margaret Elizabeth Padnos, RN, AB, BSN, MA

NANDA-I

Definition

Disintegrated physiological and neurobehavioral responses of infant to the environment

Defining Characteristics

Attention-Interaction System

Impaired response to sensory stimuli (e.g., difficult to soothe, unable to sustain alertness)

Motor System

Alteration in primitive reflexes; exaggerated startle response; finger splaying; fisting; hands to face; hyper-extension of extremities; impaired motor tone; jitteriness; tremor; twitching; uncoordinated movement

Physiological

Abnormal skin color (e.g., pale, dusky, cyanosis); arrhythmia; bradycardia; desaturation; feeding intolerance; tachycardia; time-out signals (e.g., gaze, hiccup, sneeze, slack jaw, open mouth, tongue thrust)

Regulatory Problems

Inability to inhibit startle reflex; irritability

State-Organization System

Active-awake (e.g., fussy, worried gaze); diffuse alpha EEG activity with eyes closed; irritable crying; quiet-awake (e.g., staring, gaze aversion); state oscillation

Related Factors

Caregiver

Cue misreading; environmental overstimulation; insufficient knowledge of behavioral cues

Environmental

Inadequate physical environment; insufficient containment within environment; insufficient sensory stimulation; sensory deprivation; sensory overstimulation

Individual

Illness; immature neurological functioning; low postconceptual age; prematurity

Postnatal

Feeding intolerance; impaired motor functioning; invasive procedure; malnutrition; oral impairment; pain

Prenatal

Congenital disorder; exposure to teratogen; genetic disorder

NOC

(Nursing Outcomes Classification)

Suggested NOC Outcomes

Child Development; Neurological Status; Preterm Infant Organization; Sleep; Thermoregulation: Newborn; Infant Nutritional Status

Example NOC Outcome with Indicators

Preterm Infant Organization as evidenced by the following indicators: O₂ saturation >85%/Thermoregulation/Sleep-awake state organization/Smooth transition between states/Ability to attend to visual and auditory stimuli/Habituation. (Rate the outcome and indicators of **Preterm Infant Organization**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see [Section 1](#)].)

Client Outcomes

Client Will (Specify Time Frame)

Infant/Child

- Display physiological/autonomic stability: cardiopulmonary, digestive functioning
- Display signs of organized motor system ([Wyngarden et al, 1999](#))
- Display signs of organized state system: ability to achieve and maintain a state, and transition smoothly between states ([Wyngarden et al, 1999](#))
- Demonstrate progress toward effective self-regulation ([Wyngarden et al, 1999](#))
- Demonstrate progress toward or ability to maintain calm attention
- Demonstrate progress or ability to engage in positive interactions
- Demonstrate ability to respond to sensory information (visual, auditory, tactile) in an adaptive way

Parent/Significant Other

- Recognize infant/child behaviors as complex communication system that express specific needs and wants (e.g., hunger, pain, stress, desire to engage or disengage)
- Educate parents/caregivers to recognize infant's avenues of neuro-behavioral communication: autonomic/physiological, motor, state, attention/interaction
- Recognize how infants respond to environmental sensory input through stress/avoidance and approach/engagement behaviors
- Recognize and support infant's self-regulatory, coping behaviors used to regain or maintain homeostasis
- Teach parents to "tune in" to their own interactive style and how that affects their infant's behavior
- Teach parents ways to adapt their interactive style in response to infant's style of communication
- Identify appropriate positioning and handling techniques that will enhance normal motor development ([Wyngarden et al, 1999](#))

- Promote infant/child's attention capabilities that support visual and auditory development (Wygarden et al, 1999)
- Engage in pleasurable parent-infant interactions that encourage bonding and attachment (Wygarden et al, 1999)
- Structure and modify the environment in response to infant/child's behavior and personal needs (Wygarden et al, 1999)
- Identify available community resources that provide early intervention services, emotional support, community health nursing, and parenting classes (Wygarden et al, 1999)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Developmental Enhancement; Infant; Positioning; Sleep Enhancement

Example NIC Activities—Developmental Enhancement, Infant

Provide information to parent about child development and child rearing; Promote and facilitate family bonding and attachment with infant

Nursing Interventions and Rationales

- Recognize the neurobehavior systems through which infants communicate organization and/or disorganization/stress (i.e., physiological/autonomic, motor, states, attention/interactional, self-regulatory). **CEB:** *The Assessment of Preterm Infants' Behavior (APIB) is based on theory that each subsystem functions independently and interactively with the other subsystems. Infant's physiological/autonomic subsystem has to be stable/organized, cardiopulmonary system enabling infant to attend and/or interact with animate and inanimate environment (Als et al, 2005).*
- Recognize behavior used to communicate stress/avoidance and approach/engagement. **CEB:** *The neurobehavior system theory provides a framework for reading, interpreting, and responding to cues that values the infant's importance and ability to affect the environment (Als et al, 2005).*
- Provide high quality individualized developmental care for low-birth-weight preterm infants shown to positively influence neurodevelopmental outcomes. **CEB:** *Study found positive correlation between neonatal intensive care units (NICUs) providing high-quality individualized developmental care and neurodevelopmental outcomes (Montirosso et al, 2012).*
- Identify and manage pain using appropriate pain management techniques during invasive procedures (e.g., tube insertion, heel sticks, intravenous lines). **EB:** *Parents shown infant pain cues and comforting techniques were better prepared to take an active role in pain management and felt more positive about their parenting role in the post-discharge period (Franck et al, 2011).* **EB:** *Pacifier with sucrose is safe and effective for reducing procedural pain from single events (Stevens et al, 2013).* **EBN:** *Skin-to-skin reduces procedural pain (Johnson et al, 2014).*
- Provide developmentally appropriate positioning to optimize musculoskeletal development and neurological development, and minimize complications; alternate positions over 24-hour period between prone, supine, and lateral side lying to support body alignment, flexion, midline orientation, and hand to mouth and to avoid head and neck hyperextension. **CEB:** *Positioning using blanket rolls and gel pillows in NICU compensates for preterm infant's immature motor system (Bobish & Stanger, 2007).* *Developmentally correct positioning can prevent neuromuscular and postural abnormalities (Halverson, 2010).*
- Provide care that supports development of state organization: ability to achieve and maintain quiet sleep and quiet awake states and to transition smoothly between sleep and awake states. **EB:** *Skin-to-skin holding (kangaroo care) was found to increase quiet sleep (Scher et al, 2009).* **EB:** *Study found infants experiencing smooth shifts between quiet sleep and awake states had more positive emotions, better cognitive and verbal skills at 5 years of age compared with those having abrupt shifts between states of high arousal, active sleep, and shorter periods of active and quiet sleep (Weisman et al, 2011).* **EB:** *Swaddled infants had less spontaneous awakening than when unswaddled (Franco et al, 2005).*

- Monitor level of noise in NICU environment; guidelines recommend 49 dB (1 ± 1.4). **EB**: Study examined noise level, collected data in three phases, results, reduction of NICU noise level (Wang, 2014). Recognize and expand infant's ability to focus attention on voices and faces. **EBN**: Assist parents to identify and support infant's attention capability (Jean & Stack, 2012).
- Provide infants with several opportunities for nonnutritive sucking. **CEB**: Infants receiving nonnutritive sucking during tube feeding exhibited less defensive behaviors, were less fussy, and fell asleep more easily (Pinelli & Symington, 2010). **CEB**: Study found infants using pacifiers proceeded to oral feedings faster than infants listening only to lullabies (Yildiz & Arikan, 2012).
- Provide parents opportunities to experience physical closeness through loving touch, massage, cuddling, skin-to-skin (kangaroo care), which enhances parent-infant attachment. **EBN**: Match preterm infants' developmental needs with parents' readiness for skin-to-skin care for best results (Lemmen et al, 2013); **EBN**: Kangaroo care positively impacts mother-infant relationship, sleep, and brain maturation (Ludington-Hoe, 2013).
- Educate parents in ways to support infant's self-regulating behaviors. **EB**: "Quality of maternal touch and still-face were associated with infants' self-regulating behaviors and effective component of infants' emotional regulation" (Jean & Stack, 2012).
- Encourage parents to be active collaborators in their infant's care. **EB**: Kangaroo care is an effective way for parents to actively engage by decreasing infant pain during invasive procedures (Akcan et al, 2009). **EBN**: If possible, time intramuscular injections during kangaroo care (Kashaninia et al, 2008). **EBN**: Fathers often hide emotions and need encouragement to express feelings and physically touch their babies (Johnson, 2008).
- Provide infants with positive sensory experiences (i.e., visual, auditory, tactile, olfactory, vestibular, proprioceptive) to enhance development of sensory pathways. **EBN**: Maternal voice along with other sensory events helped develop and mature infant's overall developmental process and gave mothers more assurance, and infants were discharged earlier from hospital (Cevasco, 2008). **EB**: Classical music by Mozart had positive effect on energy expenditure in growing preterm infants (Lubetzky et al, 2010). **EBN**: Study supported positive results of kangaroo care for parents, and promoting health and development of the preterm infant (Head, 2014). **EB**: Odor of breast milk is an effective method for decreasing transition of preterms from gavage to oral feeding (Yildiz et al, 2011).

Multicultural

- Identify cultural beliefs, norms, and values of family's perceptions of infant/child behavior. **EBN**: The theory of hot and cold espoused by many Mexican Americans has symbolic significance for the nature and process of reproduction and for the relationship between mother and child (Giger & Davidhizer, 2008).
- Recognize and support positive mother-infant interactive behaviors and be sensitive to cultural differences and ethnic backgrounds. **EBN**: Study identified similar and yet different mother-infant interactive behaviors between American Indian and African American mother-infant dyads, an important factor for nurses who work with different ethnic groups to know (Brooks et al, 2013).

Client/Family Teaching and Discharge Planning

- ▲ Provide information or refer to community-based follow-up programs for preterm/at-risk infants and their families. **EB**: Advance toward seamless communication between NICU staff and community agencies to enhance parents' confidence during the difficult transition from NICU discharge to home (Sherman et al, 2009). Request primary health care provider offer Ages & Stages Questionnaires (ASQ) to parents at regular visits to monitor infant developmental milestones (Bricker & Squires, 1995).
- Educate parents on safe "Back-to-Sleep" practice before NICU discharge. **EB**: Study found that educating parents before NICU discharge on safe to sleep practices, including follow-up phone survey, improved parental compliance of supine positioning from 39% to 83% (Gelfer et al, 2013).
- Encourage parents during infant awake periods to use a variety of development positions and handling that encourage body movement, hand-to-mouth, eye-hand coordination, and visual scanning; avoid overuse of infant carriers. **CEB**: Infants need to experience a variety of different positions during play that encourage movement and play, including pleasurable parent-infant interactions that maximize normal development (Waitzman, 2007).
- Nurture parents so that they in turn can nurture their infant/child. **EBN**: The most difficult and overlooked aspect of care of the high-risk neonate is effective, timely, and compassionate information delivery to parents and family by the medical staff (Sherman et al, 2009).

Home Care

- The preceding interventions may be adapted for home care use.
- Educate families in ways of preparing the home environment. **CEB**: *Patterns of sound, light, and caregiving tasks should minimize stress, conserve energy, and protect the developing neonate from inappropriate environmental stimuli (Akers et al, 2007).*
- Prepare families for realistic challenges occurring the first weeks and/or months of transition from NICU to home. **EBN**: *“Home visits by a nurse were a key component by providing education, support, and nursing care” (Lopez et al, 2012.)* **EBN**: *NICU discharge is a vulnerable time for parents, and nurses can educate and give opportunities to practice new skills before NICU discharge (Cleveland, 2008).*
- Encourage families to teach extended family and support persons to recognize and respond appropriately to infant’s behavioral cues; supportive help may be most appreciated doing physical tasks. **CEB**: *It is important for families to feel comfortable obtaining support from their regular support systems and supportive persons need to be taught how to support both the family and the infant (Als et al, 2005).* **EBN**: *Increase knowledge of caring for preterm infants at home from other mothers (Pula-Phillips et al, 2013).*
- Provide families information about community resources, developmental follow-up services, parent-to-parent support programs, and the like; request parents ask primary health care provider to correct age for preterm birth until child is at minimal of 2 years of age, and to monitor developmental milestones to identify adverse neurological development. **EB**: *Ages and Stages Questionnaire (Bricker & Squires, 1995) is an excellent screening tool to monitor developmental progress.* **EB**: *Simple cost of ASQ can detect severe developmental delay in preterm children regardless of maternal education; however, children with mild delays may be more limited (Halbwachs et al, 2013).* **CEB**: *Infants born at 34 to 36 weeks continually can be at risk for neurodevelopmental problems and should have close follow-up (Woythaler et al, 2011).* **EB**: *Home-based care is effective prevention for preterm infants and can have long-term benefits (Spencer-Smith et al, 2012).*

Readiness for enhanced organized infant behavior *Gail B. Ladwig, MSN, RN*

NANDA-I

Definition

A pattern of modulation of the physiological and behavioral systems of functioning (i.e., autonomic, motor, state-organization, self-regulatory, and attentional-interactional systems) in an infant, which can be strengthened

Defining Characteristics

Parent expresses desire to enhance cue recognition; parent expresses desire to enhance recognition of infant's self-regulatory behaviors

NOC, NIC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plans for Disorganized **Infant** behavior and Risk for disorganized **Infant** behavior.

Risk for disorganized infant behavior *Gail B. Ladwig, MSN, RN*

NANDA-I

Definition

Vulnerable to alteration in integration and modulation of the physiological and behavioral systems of functioning (i.e., autonomic, motor, state organization, self-regulatory, and attentional-interactional systems), which may compromise health

Risk Factors

Impaired motor functioning; insufficient containment within environment; invasive procedure; oral impairment; pain; parent expresses desire to enhance environmental conditions; prematurity; procedure

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

NOC, NIC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to Disorganized **Infant** behavior.

Risk for Infection *Ruth M. Curchoe, RN, BSN, MSN, CIC*

NANDA-I

Definition

Vulnerable to invasion and multiplication of pathogenic organisms which may compromise health

Risk Factors

Chronic illness (e.g., diabetes mellitus); inadequate vaccination; insufficient knowledge to avoid exposure to pathogens; invasive procedure; malnutrition; obesity

Inadequate Primary Defenses

Alteration in peristalsis; alteration in pH of secretions; alteration in skin integrity; decrease in ciliary action; premature rupture of amniotic membrane; prolonged rupture of amniotic membrane; smoking; stasis of body fluids

Inadequate Secondary Defenses

Decrease in hemoglobin; immunosuppression; leukopenia; suppressed inflammatory response (e.g., IL-6, C-reactive protein [CRP]); inadequate vaccination

Increased Environmental Exposure to Pathogens

Exposure to disease outbreak

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Risk Control: Infectious Process; Immune Status

Example NOC Outcome with Indicators

Risk Control: Infectious Process: Identifies signs and symptoms of infection/Maintains a clean environment/Practices infection control strategies: universal precautions, hand sanitization. (Rate the outcome and indicators of **Risk Control: Infectious Process:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free from symptoms of infection during contact with health care providers
- State symptoms of infection before initiating a health care–related procedure
- Demonstrate appropriate care of infection-prone sites within 48 hours of instruction
- Maintain white blood cell count and differential within normal limits within 48 hours of treatment initiation
- Demonstrate appropriate hygienic measures such as handwashing, oral care, and perineal care within 24 hours of instruction

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Immunization/Vaccination Management; Infection Control; Infection Protection

- = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Example NIC Activities—Infection Protection and Control

Wash hands before and after each client contact; Ensure aseptic handling of all intravenous lines; Ensure appropriate wound care technique; Teach client and family members how to avoid infections

Nursing Interventions and Rationales

- Implement targeted surveillance for methicillin-resistant *Staphylococcus aureus* (MRSA) (screen clients at risk for MRSA on admission) and other multidrug-resistant organisms. **EB:** *Universal screening for MRSA increased screenings and costs but resulted in few additional cases being detected. Where MRSA is endemic, targeted screening remains the most efficient strategy for early identification of MRSA-positive clients (Creamer et al, 2012).*
- Obtain a travel history from clients presenting to health care site (e.g., emergency department, clinic). **EB:** *Outbreaks, such as Ebola and avian flu identified in foreign countries, often present with fever and flu-like symptoms (CDC, 2014a).*
- Observe and report signs of infection such as redness, warmth, discharge, and increased body temperature. **CEB:** *Change in mental status, fever, shaking, chills, and hypotension are indicators of sepsis (Risi, 2009).*
- Assess temperature of neutropenic clients; report a single temperature of greater than 100.5° F. **CEB:** *Fever is often the first sign of an infection (NCCN, 2006).* **CEBN:** *The immunocompromised host may present with a very different clinical picture when compared to an immunocompetent host. The progress of the infection may be more rapid, and the infection may quickly become life-threatening; repeat temperature measurement if significant changes occur and report temperature changes from baseline (Risi, 2009).*
- Oral, rectal, tympanic, temporal artery or axillary thermometers may be used to assess temperature in adults and infants. **EBN:** *The use of axillary in addition to oral, tympanic, and temporal artery temperature measurement is supported (Rubia-Rubia et al, 2011).* Rectal and oral temperature measurements are more accurate than other methods of temperature measurement, such as temporal or axillary measurement (Makic et al, 2011).
- ▲ Note and report laboratory values (e.g., white blood cell count and differential, serum protein, serum albumin, and cultures). **EBN:** *While the white blood cell count may be in the normal range, an increased number of immature bands may be present (Versalovic et al, 2011).* **CEBN:** *A neutropenic client with fever represents an absolute medical emergency (Mahtani, 2010).*
- Assess skin for color, moisture, texture, and turgor (elasticity). Keep accurate, ongoing documentation of changes. **EB:** *A number of instruments have been developed to assess for risk of pressure ulcers, including the Braden scale, the Norton scale, and the Waterlow scale. All three scales include items related to activity mobility, nutritional status, incontinence, and cognition (Agency for Healthcare Quality and Research, 2011).*
- Carefully wash and pat dry skin, including skinfold areas. Use hydration and moisturization on all at-risk surfaces. **EBN:** *Moisturizers result in an increase of skin hydration and restoration of the skin barrier function and play a prominent role in the long-term management of atopic dermatitis (Miller et al, 2011).* **EB:** *Application of moisturizers containing humectants is clearly effective in enhancing skin barrier function (Kottner et al, 2013).*

Refer to care plan for Risk for impaired **Skin** integrity.

- ▲ Monitor client's vitamin D level. **EB:** *Vitamin D deficiency has been correlated with increased risk and greater severity of infection, particularly of the respiratory tract. Vitamin D influences the body's immune system by influencing the production of endogenous antimicrobial peptides and regulating the inflammatory cascade (Gunville et al, 2013).*

Refer to care plan Readiness for enhanced **Nutrition** for additional interventions.

- Use strategies to prevent health care-acquired pneumonia (IHI, 2011); assess lung sounds and sputum color and characteristics; provide daily oral care with chlorhexidine; use sterile technique when suctioning; suction secretions above tracheal tube before suctioning; drain accumulated condensation in ventilator tubing into a fluid trap or other collection device before repositioning the client; assess patency and placement of nasogastric tubes; elevate the client's head to 30 degrees or higher to prevent gastric reflux of organisms in the lung (Peyrani, 2014). **EB:** *Hospital mortality of ventilated clients who develop ventilator-associated pneumonia (VAP) is 46% compared to 32% of those ventilated clients without VAP. VAP also adds an estimated cost of \$40,000 to a typical hospital admission (IHI, 2011).*

- Encourage fluid intake. **EB:** *Fluid intake helps thin secretions and replace fluid lost during fever (Guppy et al, 2011).*
- Use appropriate hand hygiene (i.e., handwashing or use of alcohol-based hand rubs). **EBN:** *Meticulous infection prevention precautions are required to prevent health care-associated infection, with particular attention to hand hygiene and standard precautions (CDC, 2011a).* **EB:** *Handwashing is currently the recommended strategy for reducing transmission of Clostridium difficile. Alcohol gels do not inactivate C. difficile spores (Edmonds et al, 2013).*
- When using an alcohol-based hand rub, apply ample amount of product to palm of one hand and rub hands together, covering all surfaces of hands and fingers, until hands are dry. Note that the volume needed to reduce the number of bacteria on hands varies by product. **EBN:** *Adequate hand antisepsis reduces infection rates. The use of alcohol-based hand rubs is particularly effective; in contrast to handwashing, hand rubs kill susceptible bacteria more rapidly and to a greater extent, and are less time-consuming, and skin health is better preserved when moisturizers are added (Aitken et al, 2011; Hass, 2014).*
- Follow standard precautions and wear gloves during any contact with blood, mucous membranes, non-intact skin, or any body substance except sweat. Use goggles and gowns when appropriate. Standard precautions apply to all clients. You must assume all clients are carrying blood-borne pathogens (CDC, 2007). **EBN:** *Hands of health care workers are the most common cause of health care-associated infections (Hass, 2014).*
- Implement respiratory hygiene/cough etiquette. **CEB:** *Providing control measures (tissues, masks) and accessibility to hand hygiene materials reduces risks of transmission of respiratory illness (CDC, 2007).*
- Follow transmission-based precautions for airborne-, droplet-, and contact-transmitted microorganisms:
 - **Airborne:** Isolate the client in a room with monitored negative air pressure, with the room door closed and the client remaining in the room. Always wear appropriate respiratory protection when you enter the room. Limit the movement and transport of the client from the room to essential purposes only. Have the client wear a surgical mask during transport.
 - **Droplet:** Keep the client in a private room, if possible. If not possible, maintain a spatial separation of 3 feet from other beds or visitors. The door may remain open. Wear a surgical mask when you must come within 3 feet of the client. Some hospitals may choose to implement a mask requirement for droplet precautions for anyone entering the room. Limit transport to essential purposes and have the client wear a mask, if possible.
 - **Contact:** Place the client in a private room, if possible, or with someone (cohorting) who has an active infection from the same microorganism. Wear clean, nonsterile gloves when entering the room. When providing care, change gloves after contact with any infective material such as wound drainage. Remove the gloves and clean your hands before leaving the room and take care not to touch any potentially infectious items or surfaces on the way out. Wear a gown if you anticipate your clothing may have substantial contact with the client or other potentially infectious items. Remove the gown before leaving the room. Limit transport of the client to essential purposes and take care that the client does not contact other environmental surfaces along the way. Dedicate the use of noncritical client care equipment to a single client. **CEB:** *If use of common equipment is unavoidable, adequately clean and disinfect equipment before use with other clients (CDC, 2007).*
- ▲ Use alternatives to indwelling catheters whenever possible (external catheters, incontinence pads, bladder control techniques). **EB:** *It is estimated that catheter-associated urinary tract infections increase length of stay by 0.5 to 1 day and increase costs between \$1200 and \$4700 (2009 dollars) (Umschied et al, 2011; IHI, 2011).*
- If a urinary catheter is necessary, follow catheter management practices: All indwelling catheters should be connected to a sterile, closed drainage system (i.e., not broken), except for good clinical reasons. Cleanse the perineum and meatus twice daily using soap and water. **EBN:** *A nurse-driven protocol achieved a 32% reduction in the use of catheters (from 0.22 to 0.15 catheters/client-day) and a 45% reduction in catheter-associated urinary tract infection (CAUTI) (from 4.78 to 2.64 infections/1000 catheter-days) (Parry & Srinivasan, 2011).* **EB:** *Significant rates of inappropriate urinary catheter use underscore the importance of establishing guidelines and implementing policy for appropriate use of urinary catheters (Tiwari et al, 2012).*
- Use evidence-based practices and educate personnel in care of peripheral catheters: use aseptic technique for insertion and care, label insertion sites and all tubing with date and time of insertion, inspect every 8 hours for signs of infection, record, and report. **EB:** *Use of chlorhexidine gluconate for vascular catheter site care reduces catheter-related bloodstream infections and catheter colonization (CDC, 2011b).*

- Use sterile technique wherever there is a loss of skin integrity. **EBN:** *Skin and soft tissue infections arise when skin integrity is broken by treatments associated with trauma, surgery, burns, and the like (Apisaranthanara & Mundy, 2014).*
- Ensure the client's appropriate hygienic care with handwashing, bathing, oral care, and hair, nail, and perineal care performed by either the nurse or the client. **CEBN:** *Daily showers or baths can help to reduce the number of bacteria on the client's skin. The oral cavity is a common site for infection (Coughlan & Healy, 2008; NCCN, 2006).*
- Recommend responsible use of antibiotics; use antibiotics sparingly. **EB:** *Use and misuse of antibiotics diminishes their therapeutic benefit and facilitates the development of multidrug-resistant organisms (MDROs) and C. difficile-associated disease, and increases health care costs. Antibiotic stewardship is essential in reducing current and future resistance in bacteria (Moody et al, 2012).* **EB:** *The rate of damage to the fallopian tubes increases with subsequent pelvic inflammatory disease episodes, from 34% for the first episode to 54% in women with second and third episodes (Puscheck et al, 2013).* *Female genital tuberculosis is a symptomless disease inadvertently uncovered during investigation for infertility (Klaus-Dieter et al, 2013).*

Pediatric

NOTE: Many of the preceding interventions are appropriate for the pediatric client.

- Follow meticulous hand hygiene when working with children. **EB:** *Keep nails short; prohibit false fingernails and limit wearing jewelry as it interferes with effective hand hygiene (AAPeds, 2012).* *Parents recognize the importance of hand hygiene but in a study only 67% would definitely remind health care workers of its importance (Buser et al, 2012).*
- Cluster nursing procedures to decrease number of contacts with infants, allowing time for appropriate hand hygiene. **EBN:** *Audit programs to track compliance with hand hygiene identified a drop in the incidence of health care-associated infections in very low-birth-weight infants in the neonatal intensive care unit (Mendicino et al, 2014).*
- Avoid the prophylactic use of topical cream in premature infants. **CEB:** *Prophylactic application of topical ointment increases the risk of coagulase-negative staphylococcal infection and any health care-acquired infection. A trend toward increased risk of any bacterial infection was noted in infants treated prophylactically (Conner et al, 2004).*
- Encourage early enteral feeding with human milk. *Human milk enhances immune defenses of the infant (Pickering, 2012).*
- ▲ Monitor recurrent antibiotic use in children.
- Instruct parents on appropriate indicators for medical visits and the risks associated with overuse of antibiotics. **EB:** *Guidelines addressing treatment of asthma in children state that antibiotics should not be used as part of chronic asthma therapy or for acute exacerbations, with the exception of clients with comorbid bacterial infections such as pneumonia or sinusitis (Paul et al, 2011).*

Geriatric

- ▲ Suspect pneumonia when the client has symptoms of lethargy or confusion. Assess response to treatment, especially antibiotic therapy. **EB:** *Leading causes of illness and death among older adults are both community and health care-associated respiratory infections. In long-term care facilities, the risk for pneumonia ranges from 0.3 to 2.5 events per 1000 resident-days (Montoya & Moody, 2011; AOA, 2012).*
- Most clients develop health care-associated pneumonia (HCAP) by either aspirating contaminated substances or inhaling airborne particles. Refer to care plan for Risk for **Aspiration**.
- ▲ Carefully screen older women with incontinence for urinary tract infections. **CEB:** *Consider alternatives to chronic indwelling catheters, such as intermittent catheterization. CAUTI has been associated with increased morbidity, mortality, hospital cost, and length of stay (CDC, 2009).*
- Observe and report if the client has a low-grade fever or new onset of confusion. **EB:** *Those caring for older clients must be alerted to the potential presence of infection when even low-grade temperature elevations appear for short periods (Arinzon et al, 2012).*
- Recommend that the geriatric client receive an annual influenza immunization and one-time pneumococcal vaccine. **EB:** *Immunization against influenza is an effective intervention that reduces serologically confirmed cases (CDC, 2014b,c).*
- Recognize that chronically ill geriatric clients have an increased susceptibility to *Clostridium difficile* infection; practice meticulous hand hygiene; monitor antibiotic response to antibiotics. **EB:** *The incidence*

of *C. difficile* illness (CDI) is increasing with the greatest impact in persons older than 65 years. More than 90% of deaths from CDI have occurred in this population (CDC, 2012; Kelly & LaMont, 2013).

Home Care

- Adapt the above interventions for home care as needed.
- Assess and treat wounds in the home. **EBN:** *Promotion of wound healing is a nursing priority. Specific wound care regimens administered depend upon the type, size, and location of the wound and overall treatment goals (Colwell, 2013).*
- Review standards for surveillance of infections in home care. **EB:** *Challenges to surveillance in the home care setting include loss of clients to follow-up, lack of laboratory data, and difficulty in obtaining accurate numerator and denominator data (Yeung, 2014).*
- Maintain infection-prevention policies. **EBN:** *The complexity of client's conditions is frequently high as the incidence of chronic disease and MDROs is increasing (Yeung, 2014).*
- Refer for nutritional evaluation; implement dietary changes to support recovery and maintain health. **EB:** *Medical nutrition therapy (MNT) is important in preventing diabetes, managing existing diabetes, and preventing, or at least slowing, the rate of development of diabetes complications. It is, therefore, important at all levels of diabetes prevention. MNT is also an integral component of diabetes self-management education (or training) (ADA, 2012).*

Client/Family Teaching and Discharge Planning

- Teach the client risk factors contributing to surgical wound infection. **EB:** *The risk of infection is influenced by characteristics of the client such as age, obesity, and nutritional status (Murphy, 2014).*
- Teach the client and family the importance of hand hygiene in preventing postoperative infections. **EB:** *Two thirds of wound infections occur after discharge. Using good hand hygiene practices is effective for preventing these infections (Alexander 2011).*
- ▲ Encourage high-risk persons, including health care workers, to get vaccinated (CDC, 2011c).
- ▲ Influenza: Teach symptoms of influenza and importance of vaccination for influenza. **EB:** *Everyone 6 months of age and older should get the flu vaccine. Seasonal flu vaccine is effective and has a very good safety track record (CDC, 2014b,c).* Teach the client and family how to take a temperature. Encourage the family to take the client's temperature between 4 PM and 10 PM at least once daily. **CEBN:** *The lowest body temperature usually occurs between 4 AM and 5 AM, with highest readings being recorded between 4 PM and 8 PM (Peate & Wild, 2012).*

Risk for Injury *Julianne E. Doubet, BSN, RN, CEN, NREMT-P*

NANDA-I

Definition

Vulnerable to physical damage due to environmental conditions interacting with the individual's adaptive and defensive resources, which may compromise health

Risk Factors

External

Alteration in cognitive functioning; alteration in psychomotor functioning; compromised nutritional source (e.g., vitamins, food types); exposure to pathogen; exposure to toxic chemical; immunization level within community; nosocomial agent; physical barrier (e.g., design, structure, arrangement of community, building, equipment); unsafe mode of transport

Internal

Abnormal blood profile; alteration in affective orientation; alteration in sensation (resulting from, e.g., spinal cord injury, diabetes mellitus); autoimmune dysfunction; biochemical dysfunction; effector dysfunction; extremes of age; immune dysfunction; impaired primary defense mechanisms (e.g., broken skin); malnutrition; sensory integration dysfunction; tissue hypoxia

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Safety Behavior; Risk Control; Safe Home Environment; Knowledge: Fall Prevention

Example NOC Outcome with Indicators

Risk Control as evidenced by the following indicators: Monitors environmental risk factors/Develops effective risk control strategies/Follows selected risk control strategies. (Rate the outcome and indicators of **Risk Control**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of injuries
- Explain methods to prevent injuries
- Demonstrate behaviors that decrease the risk for injury

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health Education; Environmental Management; Fall Prevention

Example NIC Activities—Health Education

Identify internal or external factors that may enhance or reduce motivation for healthy behavior; Determine current health knowledge and lifestyle behaviors of individual, family, or target group

Nursing Interventions and Rationales

Prevent iatrogenic harm to the hospitalized client by following the National Patient Safety goals:

- Accuracy of Client Identification:
 - Use at least two methods (e.g., client's name and medical record number or birth date) to identify the client upon initial entrance to a client's room and before administering medications, blood products, treatments, or procedures.

- Before beginning any invasive or surgical procedure, have a final verification to confirm the correct client, the correct procedure, and the correct site for the procedure using active communication techniques.
- Label containers used for blood and other specimens in the presence of the client.
- Effectiveness of Communication Among Care Staff:
 - Verbal or telephone orders should be written and then read back for verification to the individual giving the order. Avoid verbal or telephone orders whenever possible.
 - Standardize use of abbreviations, acronyms, symbols, and dose designations that are used in the institution.
 - Ensure critical test results and values are recorded and reported in a timely manner.
 - Use a standardized approach of “handing off” communications, including opportunities to ask and answer questions.
 - Use only approved abbreviations.
 - Staff should always wear hospital nametags.
- Medication Safety:
 - Standardize and limit the number of drug concentrations used by the institution (e.g., concentrations of medications such as morphine in client-controlled analgesia pumps).
 - Label all medications and medication containers (e.g., syringes, medication cups, or other solutions on or off the surgical field).
 - Identify all of the client’s current medications upon admission to a health care facility, and ensure that all health care staff have access to the information.
 - Ensure that accurate medicine information is sent with the client throughout their care.
 - Reconcile all medication at admission and discharge, and provide list to the client.
 - Improve the effectiveness of alarm systems in the clinical area.
 - Standardize a list of medications that look alike or sound alike. This list needs to be updated yearly.
 - Identify and take extra care with clients who are on anticoagulants.
- Infection Control:
 - Reduce the risk of infections by following Centers for Disease Control and Prevention (CDC, 2014) hand hygiene guidelines.
 - Document clearly when clients obtain injuries or die of infectious disease.
 - Use proven guidelines to prevent infections that are difficult to treat.
 - Use proven guidelines to prevent infection of the blood from central lines.
 - Use safe practices to treat the surgical site of the client.
 - Use proven guidelines to prevent catheter-associated urinary tract infections.
- Fall Prevention:
 - Evaluate all clients for fall risk daily and take appropriate actions to prevent falls.
- Client Involvement in Care:
 - Educate the client and family on how to recognize and report concerns about safety issues.
- Identify Clients with Safety Risks:
 - Identify which clients are at risk for harming themselves.
- Identify Clients Who Are Susceptible to Changes in Health Status:
 - Educate staff on how to recognize changes in client condition, how to respond quickly, and how to alert specially trained staff to intervene if needed.
 - Prevent errors in surgery by following established protocols. Update protocols yearly.
 - Standardize steps to educate staff so documents for surgery are ready before surgery.
 - Educate staff to mark the body part scheduled for surgery and engage the client in this process as well.

These actions have been shown to increase client safety and are required actions for accreditation by The Joint Commission (2011).

- See care plan for Risk for Falls.
- Avoid use of physical and chemical restraints if at all possible. Restraint-free is now the standard of care for hospitals and long-term care facilities. Obtain a health care provider’s order if restraints are necessary. **CEB:** *The use of restraints has been associated with serious injuries, including rhabdomyolysis, brachial plexus injury, neuropathy, and dysrhythmias, as well as strangulation, traumatic brain injuries, and all the consequences of immobility (Park & Tang, 2007).* **EBN:** *Besides physical restraints, other nonpharmaceutical*

measures that can be used to promote safe mobility in client-centered care are staff education, balance training, sensor mats, exercise, and low-height adjustable beds (Gulpers et al, 2013).

- Consider providing individualized music of the client's choice if a client is agitated. **EB:** Livingston et al (2014) maintain that person-centered care with good communication skills, monitored sensory therapy activities, and structured music therapies diminish distress in care-home dementia residents. **EBN:** In reviewing the results of studies that addressed the effects of safe, low-cost, music therapy for agitation in dementia, Blackburn and Bradshaw (2014) found that music therapy is not only promising in the reduction of agitation in older adults with dementia, but also helps lessen anxiety and depression, and seemingly to improve cognitive function.
- Review drug profile for potential side effects and interactions that may increase risk of injury. **EB:** The use of polypharmacy, as prescribed to older adults, is the sole most significant factor in risk injury in those same adults. A mix of medications can cause a reduction in physical function, raise the risk of falls, and cause delirium and other geriatric syndromes, and is a known factor in hospital admissions and death (Scott et al, 2014). **EB:** By using certain structured strategies, such as awareness of life expectancy, comorbidity, goals, and client preferences, there is evidence that health care providers can reduce their client's risk of injury by "de-prescribing" certain medications; any drug that is of little value and/or increases the client's risk of injury should be discontinued, Scott et al (2013) say in their report.
- Provide a safe environment
 - Use one fourth- to one half-length side rails only, and maintain bed in a low position. Ensure that wheels are locked on bed and commode. Keep dim light in room at night.
 - Remove all possible hazards in environment such as razors, medications, room clutter, wet floors, and matches.
 - Place at risk for injury client in a room that is near the nurse's station. **EBN:** According to Wang et al (2014), when clients' safety culture is improved, there is a decrease in client adverse events. **EBN:** "A client-centered environment of care is not just the care provided at the client's side. It is seen throughout the facility" (Blackwell, 2014).
- Assist clients to sit in a stable chair with armrests. Avoid use of wheelchairs and geri-chairs except for transportation. **EB:** Unassisted attempts at getting up from a wheelchair are a common cause of falls (Lee et al, 2012). **EB:** In their study of wheelchair-related injuries, Chen et al (2011) found that wheelchair-associated adverse events were closely connected to wheelchair-using behaviors.
- If the client has a new onset of confusion (delirium), refer to the care plan for Acute **Confusion**. If the client has chronic confusion, see the care plan for Chronic **Confusion**.
- Involve family in helping to provide a culture of safety. **EBN:** A client centered approach to care should include the family, in both planning and decision-making (Wroblewski et al, 2014). **EB:** According to a study by Rathert et al (2012), health care policy leaders are promoting the concept that both clients and their families should take a hands-on role in providing client safety.
- ▲ Refer the client for physical therapy for strengthening as needed. **EB:** Exercise training supervised by a physiotherapist was found to have positive outcomes on physical function and quality of life, and to reduce incidence of falls (Kwok & Tong, 2014). **EB:** According to Beattie (2014), physical therapists, due to their particular place on the health care team, are able to make a major contribution to the promotion of community-based efforts to reduce fall risk and fall injuries in older adults.
- ▲ Use nonphysical forms of behavior management for the agitated psychotic client. **EB:** Agitated psychotic clients must first have a brief emergency evaluation as to the cause of their distress, which will then direct crisis interventions to calm them (Stowell et al, 2012). **EB:** Okumura et al (2014) state that there is a call for approaches to client agitation that focus on psychosocial interventions, antipsychotic withdrawal, and the need to moderate the overall incidence of antipsychotics use.

Pediatric

- Teach parents the need for close supervision of young children playing near water. **EB:** Semple-Hess and Campwala (2014) state that drowning and submersion injuries are one of the most common, yet avoidable, causes of childhood mortality and morbidity. **EB:** The Centers for Disease Control (2014) maintains that drowning can occur without warning and quickly, wherever there is water (e.g., pools, bathtubs, buckets), even when a lifeguard is present; an adult, who will not be distracted by other activities, should be chosen to oversee children playing in or near water.
- If the child has an underlying medical problem that puts them at risk for drowning, it is recommended that they be given showers, not tub baths. No unsupervised swimming is ever allowed. **EB:** Semple-Hess

and Campwala (2014) state that those children who have epilepsy, undiagnosed cardiac dysrhythmias, hyperventilate, hypoglycemia, and hypothermia are in greater danger of drowning. **EB:** Caregivers should understand the necessity for constant supervision while children are bathing, especially if the child has an underlying condition such as epilepsy (Bamber et al, 2014).

- Assess the client's socioeconomic status because financial hardship may correlate with increased rates of injury. **EB:** According to Anderson et al (2014), there may be a relationship between intentional injury rate and those children in families living below poverty level: these findings may indicate that financial hardship could be an important risk factor for finding these types of injuries. **EB:** Sociodemographic issues were connected to an increased incidence of children's burns, according to Alnababtah et al (2014): factors include low household income, living in deprived areas, living in rented accommodation, young mothers, single-parent families, and being a child of ethnic minorities. Parental education and size of living space could also play some part in the injury.
- Never leave young children unsupervised around cooking or open flames. **EB:** Risks for children's thermal injuries include inattentive attention in a depressed mother, adult alcohol overuse, and socioeconomic level; these risks are modifiable and should be addressed (Jamshidi & Sato, 2013). **EB:** According to Oram et al (2012), the third leading cause of unintentional death in the United States that affects children younger than 14 living at home is fire and burn injuries.
- Teach parents and children the need to maintain safety for the exercising child, including wearing helmets when biking. **EB:** Parents should be educated in the use of bicycle helmets for their children and set a good example by wearing helmets themselves (Baeseman & Corden, 2014). **EB:** It has been proven that the use of bicycle helmets helps prevent or reduce severe head injuries in bicycle riders (Basch et al, 2014).
- Encourage parents to insist on safety precautions in all phases of participation sports involving children. **EB:** Due to the increased participation in sports by young children, the number of overuse injuries has increased in that age group (Fournier, 2013).
- ▲ **EB:** In their study of children's sports injuries, Straccioli et al (2013) found that there is insufficient knowledge regarding sports injuries in young children who play physically challenging organized sports for which they lack physical readiness, thus opening themselves to injury.
- Provide parents of children with traumatic brain injury with written instruction and emergency phone numbers. Ensure that instructions are understood before the child is discharged from a health care setting. Instruct parents to observe for the following symptoms: nausea, mild headache, dizziness, irritability, lethargy, poor concentration, loss of appetite, and insomnia. Symptoms of concussion may occur up to 2 weeks after injury and need prompt treatment to prevent further injury (Bethel, 2012).
- ▲ **EBN:** Mason (2013) states that even if the child has suffered a mild concussion (traumatic brain injury), it could have lasting effects on health, behavior, and cognitive abilities.
- Teach both parents and children the need for gun safety; refer to hunting safety courses. **EBN:** Barton and Kologi (2014), in their study, found that thousands of children are killed or injured every year in the United States, due to access to loaded firearms not stored safely. **EB:** Health care providers, including pediatricians, can play a significant role in gun safety education, which must teach the necessity for secure storage of any firearms (Mitka, 2014).
- Educate parents regarding proper car safety seat use. **EB:** Child passenger restraint systems have been found to greatly reduce the risk of injury and death among child passengers (Muller et al, 2014).

Geriatric

- Encourage the client to wear glasses and hearing aids and to use walking aids, including nonslip footwear when ambulating. **EB:** It has been observed that gait and balance problems lead to falls and injuries in older people; the use of walking aids are meant to augment gait safety and prevent falls (Hardi et al, 2014). **EB:** Hearing loss is a common chronic health condition in older adults. Hearing aid treatment helps improve the quality of life for older adults with hearing deficits (Cox et al, 2014).
- Assess for orthostatic hypotension when getting up, teach methods to decrease dizziness, such as rising slowly, remaining seated several minutes before standing, flexing feet upward several times while sitting, sitting down immediately if feeling dizzy, and trying to have someone present when standing. **EBN:** Orthostatic hypotension is a fairly common occurrence in the older adult and is most likely due to comorbidities, polypharmacy, and physiological changes that can occur with aging (Lee, 2013). **EB:** Shibao et al (2013) maintain that the management of orthostatic hypotension should be aimed at treatment of symptoms, client's functional status, and decreasing the risk of falls and syncope.

- Discourage driving at night. **EB**: Certain vision tests could be developed to predict night vision problems in the growing number of older drivers, suggest Gruber et al (2013). **EB**: Older adult drivers who drive at night are at heightened risk for injury due to age-related changes in the amount of light reaching the retina, weaker contrast sensitivity, and variations in dark and light adaptation (Boot et al, 2014).

Multicultural

- Acknowledge racial/ethnic differences at the onset of care. **EB**: Gagnon et al (2014) assert that minority groups appear to have increased levels of distress in comparison to Caucasians. **EBN**: Alpers and Hanssen (2014) note that experience by itself does not provide nurses with sufficient knowledge for intercultural symptom assessment and culturally competent treatment and care; requirements to produce culturally competent nurses should include formal education, in-service classes, courses, feedback, and access to appropriate information is needed along with their perception of clinical practice.
- Evaluate the influence of culture on the client's perceptions of risk for injury. **EB**: Black (45%) and Hispanic children (46%), in comparison to Caucasian children, are dying in automobile crashes due to not being restrained: effective interventions and education would increase proper restraint use and save a child who is involved in a motor vehicle crash (Sauber-Schatz et al, 2014). **EB**: Spanish speaking children who were hospitalized due to an adverse event, or one that was harmful due to nonstandard practices, were found to be hospitalized longer than their English speaking counterparts: communication barriers should be addressed to help promote client safety, suggest Lion et al (2013).
- Evaluate whether exposure to community violence is a contributor to a client's risk for injury. **EB**: Chang et al (2014) assert in their study that neighborhood environment plays an important part in relation to adolescent health risk behaviors. **EB**: Exposure to violence can result in many negative consequences for youth, including use of tobacco, alcohol, and marijuana, and persisting neighborhood violence (Fagan et al, 2014).
- Use culturally relevant injury prevention programs when possible. Validate the client's feelings and concerns related to environmental risks. **EB**: According to research supported by the findings of Richardson et al (2014), inner-city neighborhoods are linked with school dropouts, substance abuse, crime, violence, homicide, HIV risk related behaviors, and imprisonment for adolescent African American males; therefore, parents of adolescent African American males are tested daily in attempting to keep their children safe in high-risk neighborhoods. **EB**: Wilson-Genderson and Pruchno (2013) found in their research that violent crime in a neighborhood, as well as convictions concerning neighborhood safety, could impact the depressive symptoms felt by community-dwelling older people.

Home Care and Client/Family Teaching and Discharge Planning

- See Risk for **Trauma** for interventions and rationales.

Risk for corneal Injury

Michelle Acorn, DNP, NP PHC-Adult, BA, BScN/PHCNP, MN/ACNP, ENC(C), GNC(C), CAP, CGP

NANDA-I

Definition

Vulnerable to infection or inflammatory lesion in the corneal tissue that can affect superficial or deep layers, which may compromise health

Risk Factors

Blinking less than five times per minute; exposure of the eyeball; Glasgow Coma Scale score < 7; intubation; mechanical ventilation; periorbital edema; pharmaceutical agent; prolonged hospitalization; tracheotomy; use of supplemental oxygen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes (Visual)

Sensory Function: Vision; Vision Compensation Behavior

Example NOC Outcome with Indicators

Vision Compensation Behavior as evidenced by the following indicators: Wears protective eye wear for prevention/Eye discomfort improves daily with healing. (Rate each indicator of **Vision Compensation Behavior**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate relaxed facial expressions
- Remain as independent as possible
- Remain free of physical harm resulting from vision injury risk
- Demonstrate improvement in visual acuity

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Visual Deficit; Environmental Management

Example NIC Activities—Communication Enhancement: Visual Deficit

Clearly identify yourself when you enter the client's space; Build on client's remaining vision, as appropriate

Nursing Interventions and Rationales

Emergency Department Visits or Primary Care Office Visit

- ▲ Perform a standard ophthalmic exam or examine eye with a slit lamp using fluorescein stain to optimize visualization of the abrasion injury if available.
- Attempt visual acuity measuring using the Snellen Eye chart (corrected with glasses).
- Ensure immunization status is current, namely tetanus-diphtheria-pertussis status (every 10 years).
- Teach the client that fingernail induced corneal abrasions are one of the most common eye injuries and are at risk for complications (Lin et al, 2014). **EB**: *Treating traumatic corneal abrasions by pressure patching, bandage contact lens, or antibiotic ointment alone was equal in reducing the abrasion area and reducing pain. The epithelium was healed in all clients at day 7. Treatment of choice should be adapted to the needs and preferences of the client (Menghini et al, 2013).* **CEB**: *Eye patching does not reduce pain in clients with corneal abrasions. Topical nonsteroidal anti-inflammatory agents (e.g., diclofenac) have been found to be effective in reducing pain (Fraser, 2010).*
- Provide analgesia as needed/prescribed. *Clients with all but the most minor abrasions usually require a strong oral narcotic analgesic initially. In addition, topical eye agents may be required to relieve*

pain and photophobia in clients with large abrasions until their healing is nearly complete (Verma & Khan, 2014).

- Injuries that penetrate the cornea are more serious. The outcome depends on the specific injury. *Corneal abrasions usually heal quickly and without vision concerns. Even after the original injury is healed, however, the surface of the cornea is sometimes not as smooth as before. Clients who have had a corneal abrasion may notice that the eye feels irritated for a while after the abrasion heals (Cleveland Clinic, 2015).*

Hospitalization

- Assess for perioperative corneal abrasion risks, including advanced age, general anesthesia, greater blood loss, eye taping during surgery, prone and Trendelenburg positions, and supplemental oxygen use (Segal et al, 2014). **EB:** *An eye protection method intraoperatively includes eye lubrication with aqueous based gel and application of clear, square occlusive dressings large enough to cover the eyelids and surrounding skin. Standardized documentation of client eye protection should occur (Vetter et al, 2012).*
- ▲ Corneal abrasion is the most common ophthalmological complication that occurs during general anesthesia for nonocular surgery and can lead to sight-threatening microbial keratitis and permanent scarring. **EB:** *Taping alone provides protection that is equivalent or superior to other interventions and has fewer side effects. Petroleum gel is flammable and best avoided when electrocautery and open oxygen are used around the face. Preservative-free eye ointment is preferred, in that preservatives can cause corneal epithelial sloughing and conjunctival hyperemia (Grixti et al, 2013).*
- Assess for corneal abrasion and eye dryness, which are common problems in clients in the intensive care unit. Eye dryness is the main risk factor for the development of corneal abrasions. *Clients receiving adhesive tape as an eye care method were twice as likely to develop corneal abrasions (Masoudi et al, 2013).* **EB:** *Sedated clients or clients in induced comas may experience ineffective eye closure, presenting higher risk for corneal injury (Werli-Alvarenga et al, 2013).* **EB:** *Consider a humidity chamber with polyethylene fill for best practice (Werli-Alvarenga et al, 2013).* **EBN:** *Eye care and eye assessment should be essential parts of nursing care for clients in intensive care. To prevent corneal abrasions, use eye lubricants, which is more effective than closing eyes by adhesive tapes (Masoudi et al, 2013).*

Client/Family Teaching and Discharge Planning

- ▲ First aid principles should be reinforced in the event of an eye injury. Clients should not attempt to remove any object in the eye. Reserve this for the provider. A referral to an ophthalmologist may be required (Jacobs, 2014).
- Teach clients to use caution when using household cleaners. Many household products contain strong acids, alkalis, or other chemicals. Drain and oven cleaners are particularly dangerous. They can lead to blindness if not used correctly (Vorvick, 2014).
- If chemical exposure has occurred, flush the eye immediately with clean water for 10 minutes. Seek prompt health care attention.
- Wear safety goggles at all times when using hand or power tools or chemicals, during high impact sports, or in other situations when eye injury is more likely.
- Wear sunglasses that screen ultraviolet light when outdoors, even in winter.
- Pain is usually improved within 3 days. If pain becomes intolerable, an analgesic may be prescribed short term. Seek medical attention if pain is not resolving.
- Driving should be restricted for safety until client's visual acuity is evaluated.

Risk for urinary tract Injury *Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN*

NANDA-I

Definition

Vulnerable to damage of the urinary tract structures from use of catheters, which may compromise health

NOTE: This nursing diagnosis overlaps with other diagnoses such as Risk for **Trauma**, Impaired **Urinary** elimination, and Risk for **Infection**. Refer to care plans for these diagnoses if appropriate.

Risk Factors

Condition preventing ability to secure catheter (e.g., burn, trauma, amputation); long-term use of urinary catheter; multiple catheterizations; retention balloon inflated to ≥ 30 mL; use of large-caliber urinary catheter

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Urinary Elimination; Risk Control: Trauma; Infection

Example NOC Outcome with Indicators

Urinary Elimination as evidenced by the following indicators: Urine clarity/Urine odor, fluid intake, pain with urination. (Rate the outcome and indicators of **Urinary Elimination**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of urinary tract injury
- State absence of pain with catheter care and during urination
- Experience unobstructed urination after removal of catheter

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Urinary Elimination Management

Example NIC Activities—Urinary Elimination Management

Monitor urinary elimination, including frequency, consistency, odor, volume, and color, as appropriate; Assess client for pain associated with catheter

Nursing Interventions and Rationales

- Monitor urinary elimination, including frequency, consistency, odor, volume, and color, as appropriate; teach client signs and symptoms of urinary tract infection.
- Assess for proper placement of a urinary catheter. Urinary catheters are among the most widely used medical devices. Proper placement is necessary to prevent trauma to the urinary tract structure as well as infections (e.g., catheter-associated urinary tract infection [CAUTI] and urosepsis). **EB**: *Complications associated with indwelling urinary catheters include delirium, accidental removal, gross hematuria, leakage, urethral injury, restriction of mobility, and infection (Hollingsworth et al, 2013; Burnett et al, 2010).*

- ▲ To prevent injury, educate the client/family as to the reason for the indwelling urinary catheter to prevent harm (Scott et al, 2014). **EB:** *Accidental or improper removal of catheter can cause urethral injury. Urinary catheters are used in up to 16% of adult hospital inpatients, most frequently in older adults. Older age and older women are more likely to have no clear indication for catheterization (Vincitorio et al, 2014). Studies found that 21% to 54% of all indwelling urinary catheters are inappropriately placed and are not medically indicated (Hooten et al, 2010; Fakhir et al, 2010). Understanding the indication for the catheter and encouraging removal of catheters that do not have a clear indication is important to prevent client harm.*
- Assess clinical indication for urinary catheter daily. **EB:** *Avoidance of unnecessary indwelling urinary catheters may reduce CAUTI incidence and bloodstream infections (Meddings et al, 2014).*
- To avoid catheterizations, evaluate alternative strategies for managing urine output for the client. **EB:** *Developing toileting schedules, providing assistance with toileting, and incorporating toileting activities into frequent, scheduled nursing staff rounding can reduce urgency and incontinence episodes. For clients with limited mobility, use a bedside commode with a toileting schedule (Uberoi et al, 2013), consider condom catheters for male clients (Saint et al, 2013), and use moisture wicking incontinence pads to reduce moisture-associated skin injury (Oman et al, 2012).*
- If an indwelling urinary catheter is determined to be clinically indicated in the care of a client, proper selection of the right catheter, technique during insertion, and evidence-based care management are needed to reduce infection and injury to the urinary tract structures.
 - Selecting the smallest catheter size (e.g., smaller than 18 French) reduces irritation and inflammation of the urethra and reduces infection risk (Gray, 2010; Hooten et al, 2010).
 - Insert the catheter using aseptic technique. Wash hands and use sterile technique when opening the catheterization kit and cleansing the urethral meatus and perineal area with an antiseptic solution. Insert the catheter using a no-touch technique (Gray, 2010; Lo et al, 2014). *Using a no-touch technique may reduce the risk of infection.*
 - Provide routine hygiene care; once a urinary catheter is placed, optimal management includes care of the urethral meatus according to “routine hygiene” (e.g., daily cleansing of the meatal surface during bathing with soap and water and as needed, e.g., following a bowel movement) (Hooten et al, 2010; Watts et al, 2011). Cleansing with antiseptics, creams, lotions, or ointment has been found to irritate the meatus, possibly increasing the risk of infection (Lo et al, 2014; Watts et al, 2011).
 - Secure the catheter after placement to reduce friction from movement (Hooten et al, 2010; Watts et al, 2011; Clarke et al, 2013).
 - Maintain a closed catheter system to reduce the risk of infection (Hooten et al, 2010; Lo et al, 2014; Memorial Sloan Kettering, 2015).
 - Maintaining the urine collection bag below the level of the bladder minimizes reflux into the catheter itself, preventing retrograde flow of urine and risk for infection (Hooten et al, 2010; Watts et al, 2011; Memorial Sloan Kettering, 2015; Clarke et al, 2013).
 - Establish workflow protocols to routinely empty the drainage bag frequently and before transport to reduce urine reflux and opportunities for infection.
 - Use an ultrasound bladder scanner to determine the estimated urine volume in the bladder and the need to insert or reinsert a urinary catheter (Saint et al, 2013).
- ▲ **EB:** *A quality improvement study found that implementing a nurse-driven protocol based on current best evidence reduced catheter use, risk of infections, and urinary tract harm (Oman et al, 2012).*

Home Care and Client/Family Teaching and Discharge Planning

- Teach the client/family proper technique for inserting a urinary catheter. Instruct the client/family to never forcefully advance the catheter. Contact a health care provider if resistance is experienced (Herter et al, 2010; Watts et al, 2011).
- Develop a personalized plan of care to teach the client/family proper catheterization technique. Consider developing a routine bladder draining schedule to avoid bladder distention or other complications (Watts et al, 2011).
- Cleanse the catheter and surrounding area during a shower (avoid tub baths) using mild soap; dry catheter and skin. Ensure catheter and drainage bag are secured to thigh and lower leg (Memorial Sloan Kettering, 2015).
- Teach the client/family methods to keep the urinary tract healthy. Refer to Client/Family Teaching in the care plan for Readiness for enhanced **Urinary** elimination.

Insomnia Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN**NANDA-I****Definition**

A disruption in amount and quality of sleep that impairs functioning

Defining Characteristics

Alteration in affect; alteration in concentration; alteration in mood; alteration in sleep pattern; compromised health status; decrease in quality of life; difficulty initiating sleep; difficulty maintaining sleep; dissatisfaction with sleep; early awakening; increase in absenteeism; increase in accidents; insufficient energy; nonrestorative sleep pattern (i.e., due to caregiver responsibilities, parenting practices, sleep partner); sleep disturbance producing next-day consequences

Related Factors (r/t)

Alcohol consumption; anxiety, average daily physical activity is less than recommended for gender and age; depression; environmental barrier (e.g., ambient noise, daylight/darkness exposure, ambient temperature/humidity, unfamiliar setting); fear; frequent naps; grieving; hormonal change; inadequate sleep hygiene; pharmaceutical agent; physical discomfort; stressors

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Comfort Level; Pain Level; Personal Well-Being; Psychosocial Adjustment: Life Change; Quality of Life; Rest; Sleep

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Example NOC Outcome with Indicators

Sleep as evidenced by the following indicators: Hours of sleep/Sleep pattern/Sleep quality/Sleep efficiency/Feels rejuvenated after sleep/Sleeps consistently through the night. (Rate the outcome and indicators of **Sleep**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize plan to implement sleep-promoting routines
- Fall asleep with less difficulty a minimum of four nights out of seven
- Wake up less frequently during night a minimum of four nights out of seven
- Sleep a minimum of 6 hours most nights and more if needed to meet next stated outcome
- Awaken refreshed and not be fatigued during day most of the time

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Sleep Enhancement

Example NIC Activities—Sleep Enhancement

Monitor/record client's sleep pattern and number of sleep hours; Encourage client to establish a bedtime routine to facilitate transition from wakefulness to sleep

Nursing Interventions and Rationales

- Obtain a sleep history including time needed to initiate sleep, duration of awakenings after the first sleep onset, total nighttime sleep amounts, and satisfaction with sleep amounts. Also explore bedtime routines, use of medications and stimulants, and use of complementary/alternative therapies for stress management (e.g., herbal agents) and relaxation before bedtime. *Assessment of sleep behavior and patterns is an important part of any health status examination (Gooneratne et al, 2014; Salas & Gamaldo, 2011).*
- From the history, assess the degree and chronic nature of insomnia. *Adults can be considered to have insomnia if their daytime tiredness and sleepiness is accompanied by one or more of the following several nights/week: (1) inability to initiate sleep; (2) awakening during the night with inability to reinitiate sleep; and/or (3) short nighttime sleep; insomnia is considered chronic if it continues beyond 4 weeks (Morgan et al, 2011).*
- Avoid negative associations with ability to sleep. **EB:** *Fear of not sleeping can interfere with sleep initiation and maintenance (Larouche et al, 2014).*
- If feasible, have client arise from bed to participate in calming activities whenever anxious about failure to fall asleep. **EB:** *Restricting use of bed to sleeping promoted sleep initiation (Matthews, 2011).*
- Avoid a focus on the clock and subsequent worry about sleep time lost to sleeplessness. **EB:** *Controlling negative stimuli promoted sleep initiation (Matthews, 2011; Larouche et al, 2014).*
- Focus on positive aspects of life. **EB:** *Subjects' focus on gratitude was related to other positive presleep cognitions, shorter times to fall asleep, longer nighttime sleep, and better daytime function. Using mindfulness cognitive behaviors has been found to reduce insomnia (Larouche et al, 2014). Consider use of full-immersion baths or foot baths in the evening in client settings with close supervision. **CEB:** *Small manipulations of core body and skin temperature were found to affect sleep onset in adults, including normal older sleepers and older insomniacs (Raymann & VanSomeren, 2008). Passive body heating via full-immersion or foot baths should be used with caution in older adults because of multiple safety issues including burns, dehydration, and potential for slips/falls in bath area.**
- ▲ Assist clients with chronic insomnia to limit use of sleeping agents and to select nights for sleeping pill use if complete discontinuance of sleeping pills is not feasible. **EB:** *Combining learned cognitive behavioral strategies for relaxing the mind and body before sleep and during the night has been found to reduce client's continual need for sleeping pills (Conroy et al, 2014). Melatonin receptor agonist agents are frequently used to treat insomnia, depression, and circadian rhythm sleep-wake disorders (Laudon & Frydman-Marom, 2014).*

- ▲ For clients with chronic insomnia, refer to a health care provider trained in cognitive behavioral therapies. **EB:** *Advanced practice nurses trained in cognitive behavioral therapies are effective providers of behavioral sleep medicine (Buysse et al, 2011; Järnefelt et al, 2012).*
- ▲ Assess pain medication use and, when feasible, recommend pain medications that promote rather than interfere with sleep (see Acute **Pain** and Chronic **Pain** care plans). **EB:** *Some pain medications also promote sleep, whereas others promote alertness and thus interfere with falling and staying asleep (Laudon & Frydman-Marom, 2014).*
- ▲ Assess level of anxiety. If chronic insomnia is accompanied by anxiety, use relaxation techniques. (See further Nursing Interventions and Rationales for **Anxiety**.) **EB:** *A recent review of the literature found that mindfulness-based cognitive relaxation techniques were successful in promoting sleep in people with chronic insomnia (Larouche et al, 2014).*
- ▲ Assess for signs of depression: depressed mood state, statements of hopelessness, poor appetite. Refer for counseling as appropriate. **EB:** *Many symptoms associated with sleep disruption arise from central nervous system hyperarousal in the depressed client (Melancon et al, 2014).*
- ▲ Assess for signs of sleep apnea and restless leg syndrome; if present, refer to an accredited sleep clinic for evaluation. If the client is waking frequently during the night, other primary sleep disorders may be the cause (Gooneratne et al, 2014; Matthews, 2011).
- ▲ Assess for signs of substance overuse/abuse including prescription, over-the-counter, and illicit drugs, as well as alcohol, caffeine, and theophylline use. Suggest lifestyle change and refer for addiction counseling as appropriate. *Stimulants and mood alternators can greatly disrupt the circadian rhythm of sleep and waking (Matthews, 2011; Conroy et al, 2014).*
- ▲ Evaluate noise and interruptions during the delivery of care of clients. **EB:** *Noise adversely affects the ability to initiate and sustain sleep. Frequent interruptions can prevent the client from achieving effective sleep (Basner et al, 2015; Kamdar et al, 2013).*
- Evidence is emerging that blue screens or light emitted from electronic devices in the hours before bedtime or attempting to sleep may delay the client's ability to fall asleep. Research suggests clients exposed to blue light from electronic devices before bedtime may take longer to fall asleep and have less restorative sleep (Chang et al, 2013).
- Supplement other interventions with teaching about sleep and sleep promotion. (See further Nursing Interventions and Rationales for Readiness for enhanced **Sleep**.)

Geriatric

- Assessment of medications used for pain and other symptoms in older adults is important because pain medications may be interfering with the client's ability to initiate and maintain sleep (Matthews, 2011; Gooneratne et al, 2014).
- Clients with heart failure, pulmonary disease, and dementia have a higher risk of sleep apnea, which may be undiagnosed. Consult with a health care provider to evaluate the client for sleep apnea in the older adult (Gooneratne et al, 2014).
- Exercise enhances sleep. Older adults should be encouraged to participate in routine exercise to enhance quality of sleep (Melancon et al, 2014).
- Most interventions discussed previously may be used with geriatric clients. In addition, see the Geriatric section of Nursing Interventions and Rationales for Readiness for enhanced **Sleep**.

Home Care

- Assessments and interventions discussed previously may be adapted for use in home care.
- In addition, see the Home Care section of Nursing Interventions and Rationales for Readiness for enhanced **Sleep**.

Client/Family Teaching

- Teach family about normal sleep and promote adoption of behaviors that enhance it. See Nursing Interventions and Rationales for Readiness for enhanced **Sleep**.
- Teach family about sleep deprivation and how to avoid it. See Nursing Interventions and Rationales for **Sleep** deprivation.
- Advise family of importance of not disrupting sleep of others unnecessarily. See Nursing Interventions and Rationales for Disturbed **Sleep** pattern.

- Advise family of importance of minimizing noise and light, including light from electronic devices in the sleep environment. See Nursing Interventions and *Rationales* for disturbed **Sleep** pattern.
- Help family differentiate insomnia from externally caused sleep disruption and resultant sleep deprivation. Family members may have direct control over interruptions in sleep and thus may help limit sleep deprivation directly. *Insomnia is generally a stress-related, medication-related, or disease-related psychophysiological activation that interferes with the client's ability to calm the mind and body adequately for initiation and maintenance of sleep. Family members can support clients' attempts to manage their health and relax at bedtime, thus having an indirect effect.*

Decreased Intracranial adaptive capacity *Laura Mcilvoy, PhD, RN, CCRN, CNRN*

NANDA-I

Definition

Intracranial fluid dynamic mechanisms that normally compensate for increases in intracranial volumes are compromised, resulting in repeated disproportionate increases in intracranial pressure (ICP) in response to a variety of noxious and non-noxious stimuli

Defining Characteristics

Baseline intracranial pressure (ICP) ≥ 10 mm Hg; disproportionate increases in intracranial pressure (ICP) following stimuli; elevated P2 ICP waveform; repeated increase in intracranial pressure (ICP) ≥ 10 mm Hg for ≥ 5 minutes following external stimuli; volume-pressure response test variation (volume: pressure ratio 2, pressure-volume index ≤ 10); wide-amplitude ICP waveform

Related Factors

Brain injury (e.g., cerebrovascular impairment, neurological illness, trauma, tumor); decreased cerebral perfusion ≥ 50 -60 mm Hg; sustained increase in intracranial pressure (ICP) of 10 to 15 mm Hg; systemic hypotension with intracranial hypertension

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Neurological Status; Neurological Status: Consciousness

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Example NOC Outcome with Indicators

Neurological Status as evidenced by the following indicators: Consciousness/Intracranial pressure/Vital signs/Central motor control/Cranial sensory-motor function/Spinal sensory-motor function. (Rate the outcome and indicators of **Neurological Status**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Experience fewer than five episodes of disproportionate increases in intracranial pressure (DIICP) in 24 hours
- Have neurological status changes that are not triggered by episodes of DIICP
- Have cerebral perfusion pressure (CPP) remaining greater than 60 to 70 mm Hg in adults

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cerebral Edema Management; Cerebral Perfusion Promotion; Intracranial Pressure Monitoring; Neurological Monitoring

Example NIC Activities—Cerebral Edema Management

Monitor for confusion, changes in mentation, complaints of dizziness, syncope; Allow ICP to return to baseline between nursing activities

Nursing Interventions and Rationales

- ▲ To assess ICP and CPP effectively:
 - Monitor and display ICP and CPP in clients with severe traumatic brain injury (TBI) and spontaneous intracranial hemorrhage (ICH). **EB**: *Lack of ICP/ CPP monitoring in severe TBI increases mortality (Farahvar et al, 2012; Barmparas et al, 2012).*
 - Maintain ICP less than 20 mm Hg and CPP greater than 60 mm Hg. **CEB**: *The Guidelines for the Management of Severe Brain Injury established the treatment threshold for ICP as greater than 20 mm Hg and CPP less than 60 mm Hg (Brain Trauma Foundation, 2007).*
 - Monitor neurological status frequently (hourly in acute situations) determining both pupillary size and reaction to light and the Glasgow Coma Scale (GCS) score, noting changes in eye opening, motor response to painful stimuli, and awareness of self, time, and place. **EB**: *The combination of a GCS score and the pupil size and reactivity are predictive of outcome and aid in discussions of prognosis with family (Hoffmann et al, 2012).*
 - Monitor brain tissue oxygen (PbtO₂). **EB**: *Low brain PbtO₂ is predictive of increased mortality in clients with severe TBI (Bohman et al, 2011; Eriksson et al, 2012).*
- ▲ To prevent harmful increases in ICP:
 - Elevate head of bed 30 to 45 degrees with head in midline position. **CEB**: *Elevating the head of the bed allows for increased venous drainage that decreases ICP (Fan, 2004; Ledwith et al, 2010).* **EB**: *If client is suffering acute stroke, CPP may be compromised with head elevation during the first 72 hours after injury (Favilla et al, 2014).* See care plan for Risk for ineffective **Cerebral** tissue perfusion.
 - Administer sedation per collaborative protocol. **EB**: *ICP was maintained <20 mm Hg in a pilot study of acute brain injury using both propofol and dexmedetomidine infusions (James et al, 2012).* Sedation was effective in 66% of episodes of decreased PbtO₂ (Bohman et al, 2011).
 - Maintain glycemic control per collaborative protocol. **CEB**: *Maintain glucose levels between 110 and 180 mg/dL using insulin therapy in critically ill brain-injured clients (Kramer et al, 2012).*
 - Maintain optimal oxygenation and ventilation, applying positive end-expiratory pressure (PEEP) as needed and avoiding hyperventilation. **CEB**: *PEEP levels of 10 cm H₂O have been found to produce no significant changes in ICP, especially when combined with head of bed elevation of 30 degrees. Hyperventilation has been found to worsen outcomes in TBI clients and should be avoided, especially in the first 24 hours after injury (Brain Trauma Foundation, 2007; Videtta et al, 2002).*

- Provide hyperbaric oxygen/normobaric hyperoxia if available during the acute phase of severe TBI. **EB:** *Sixty minutes of hyperbaric oxygen at 1.5 ATA followed by 3 hours of an FiO₂ of 100% every 24 hours during the first 72 hours of severe TBI lowered ICP for the entire 3 day study period in severe TBI clients (Rockswold et al, 2013).*
- ▲ To prevent and treat harmful decreases in CPP:
 - See care plan for Risk for ineffective **Cerebral** tissue perfusion.
- ▲ To treat sustained intracranial hypertension (ICP greater than 20 mm Hg):
 - Remove or loosen rigid cervical collars. **CEB:** *Loosening or removing these collars allows for unrestricted venous drainage that lowers ICP (Mobbs et al, 2002).*
 - Administer hypertonic saline (bolus or continuous infusion) per collaborative protocol. **EB:** *Hyperosmolar therapy reduces brain water content. A comparison of mannitol and hypertonic saline found that multiple studies, including randomized controlled trials (RCTs), demonstrated superior effectiveness of hypertonic saline in decreasing ICP (Mortazavi et al, 2012).*
 - Drain cerebrospinal fluid (CSF) from an intraventricular catheter system per collaborative protocol. **EB:** *CSF drainage has been found to be effective in decreasing ICP (Bhargava et al, 2013; Srinivasan et al, 2014).*
 - Induce moderate hypothermia (32°C to 34°C) per collaborative protocol. **EB:** *A systematic review of 13 RCTs and five observational studies found therapeutic hypothermia effective in controlling ICP in all studies (Sadaka & Veremakis, 2012).*

List of Nursing Diagnoses by Letter: J

Neonatal Jaundice

Risk for neonatal Jaundice

Neonatal Jaundice *David Wilson, MS, RNC*

NANDA-I

Definition

The yellow-orange tint of the neonate's skin and mucous membranes that occurs after 24 hours of life as a result of unconjugated bilirubin in the circulation

Defining Characteristics

Abnormal blood profile; bruised skin; yellow mucous membranes; yellow sclera; yellow-orange skin color

Related Factors (r/t)

Age <7 days; deficient feeding pattern; delay in meconium passage; infant experiences difficulty making the transition to extrauterine life; weight loss >10% (Wilson, D, original author)

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Breastfeeding Establishment: Infant; Breastfeeding Maintenance; Bowel Elimination; Parent: Knowledge: Parenting/Infant Care; Risk Detection/Control

Example NOC Outcome with Indicators

Breastfeeding Establishment: Infant as evidenced by the following indicators: Proper alignment and latch-on/Proper areolar grasp/Proper areolar compression/Correct suck and tongue placement/Audible swallow/Minimum eight feedings per day/Urinations per day appropriate for age/Weight gain appropriate for age. (Rate the outcome and indicators of **Breastfeeding Establishment: Infant**: 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see [Section I](#)].)

Client Outcomes

Client (Infant) Will (Specify Time Frame)

- Establish effective feeding pattern (breast or bottle)
- Receive bilirubin assessment and screening within the first week of life to identify potentially harmful levels of serum bilirubin
- Receive appropriate therapy to enhance indirect bilirubin excretion
- Receive nursing assessments to determine risk for severity of jaundice
- Maintain hydration: moist buccal membranes, 4 to 6 wet diapers in 24-hour period, weight loss no greater than 10% of birth weight
- Evacuate stool within 48 hours of birth, and pass 3 or 4 stools per 24 hours by day 4 of life

Client (Parent[s]) Will (Specify Time Frame)

- Receive information on neonatal jaundice prior to discharge from birth hospital
- Verbalize understanding of physical signs of jaundice prior to discharge
- Verbalize signs requiring immediate health practitioner notification: sleepy infant who does not awaken easily for feedings, fewer than 4 to 6 wet diapers in 24-hour period by day 4, fewer than 3 to 4 stools in 24 hours by day 4, breastfeeds fewer than 8 times per day
- Demonstrate ability to operate home phototherapy unit if prescribed

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Parent Education: Infant; Phototherapy: Neonate

Example NIC Activities—Phototherapy: Neonate

Review maternal and infant history for risk factors for hyperbilirubinemia (e.g., Rh or ABO incompatibility, polycythemia, sepsis, prematurity, malpresentation); Observe for signs of jaundice

Nursing Interventions and Rationales

- Evaluate maternal and delivery history for risk factors for neonatal jaundice (RhD, ABO, G6PD deficiency, direct Coombs). *Assessment of maternal and neonatal risk factors that may cause jaundice is important in the detection of neonatal jaundice (Perry et al, 2014).*
- Perform neonatal gestational age assessment once the newborn has had an initial period of interaction with mother and father. **EB:** *Gestational age assessment is important to determine potential risk factors in the neonatal population. Infants who are born late preterm (34 to 36%, weeks at birth) and early term (37 and 38%, weeks at birth) are at significantly increased risk for problems related to hyperbilirubinemia, feeding problems, and hospital readmission (Blackburn, 2013; Kuzniewicz et al, 2013).*
- Encourage breastfeeding within the first hour of the neonate's life. **EB:** *Early feedings increase neonatal intestinal activity, and infant begins establishing intestinal flora; in addition, early breastfeeding promotes enhanced maternal confidence in breastfeeding (Academy of Breastfeeding Medicine Protocol Committee, 2010; Neifert & Bunik, 2013).*
- Encourage skin-to-skin mother-newborn contact shortly after delivery. **EB:** *Early skin-to-skin mother-baby contact helps promote maternal confidence in nurturing abilities (Academy of Breastfeeding Medicine Protocol Committee, 2010; Neifert & Bunik, 2013).*
- Assess infant's skin color at birth and every 8 hours thereafter until birth hospital discharge for the appearance of jaundice. *Initial and ongoing neonatal skin assessment is important in the detection of jaundice (National Association of Neonatal Nurses, 2010).* **CEB:** *Jaundice is visible when bilirubin levels reach 5 to 6 mg/dL (Blackburn, 2013) and is reported to first appear on the face and head, then slowly advance to the trunk, arms, and lower extremities (Ambalavanan & Carlo, 2011).* **CEB:** *Skin color alone is not a reliable assessment for neonatal jaundice; therefore, it is important that such assessments be supported with empirical serum bilirubin measurements or transcutaneous bilirubin measurements when jaundice is suspected (American Academy of Pediatrics, 2004).*
- Encourage and assist mother with frequent breastfeeding (at least 8 to 12 times per day in the first week of life). *Frequent breastfeeding stimulates neonatal gut motility and enhances stooling, thus decreasing intestinal reabsorption of bilirubin; in addition, frequent breastfeeding stimulates breast milk production (Blackburn, 2013). Exclusive breastfeeding is recommended for neonatal feedings yet is associated with the development of hyperbilirubinemia, not directly as a result of the feeding substrate but perhaps due to decreased caloric intake in the first week of life and a substance in breast milk that may interfere with bilirubin excretion (Academy of Breastfeeding Medicine Protocol Committee, 2010; Blackburn, 2013).*
- Assist parents with bottle-feeding neonate. *Adequate caloric intake is essential for the promotion of stooling and the subsequent elimination of bilirubin from the intestine. Parents are assisted in feeding the neonate to ensure adequate growth and development (Blackburn, 2013; Hockenberry & Wilson, 2015).*
- Avoid feeding supplements such as water, dextrose water, or any other milk substitutes in breastfeeding neonate. **CEB:** *Supplements may act to decrease the effective establishment of breastfeeding (American Academy of Pediatrics, 2004; Blackburn, 2013).*
- Assess neonate's stooling pattern in first 48 hours of life. *Delayed stooling may indicate inadequate breast milk intake and may further increase reabsorption of bilirubin from neonate's intestine (Blackburn, 2013).*
- ▲ Collect and evaluate laboratory blood specimens as prescribed or per unit protocol. *Because visual assessments of skin color alone are inadequate to determine rising levels of bilirubin, serum bilirubin measurement may be gathered to evaluate risk for pathology (Ambalavanan & Carlo, 2011; National Association of Neonatal Nurses, 2010). The purpose in monitoring, evaluating, and implementing treatment in moderate to severe cases of neonatal hyperbilirubinemia is to prevent acute bilirubin encephalopathy, an early acute central nervous system bilirubin toxicity that is related to the amount of unbound (indirect) bilirubin. Kernicterus describes the yellow staining of brain cells and subsequent necrosis that occurs secondary to exposure to high levels of unconjugated (indirect) bilirubin; kernicterus involves long-term, permanent central nervous system changes (Blackburn, 2013). Bilirubin-induced neurologic dysfunction is a term used to describe the spectrum of symptoms associated with acute bilirubin encephalopathy and kernicterus (Johnson & Bhutani, 2011).*
- ▲ Monitor transcutaneous bilirubin level in jaundiced neonate per unit protocol or at least once every 8 hours. *Noninvasive bilirubin monitoring is a safe and effective means for monitoring bilirubin levels and determining risk for increasing serum bilirubin levels (National Association of Neonatal Nurses, 2010).*
- Perform hour-specific total serum bilirubin risk assessment before newborn's birth center discharge and document the results. **CEB:** *The use of an hour-specific nomogram for designation of risk in healthy, late*

preterm, early term, and term infants, as well as clinical risk factors, may be used to determine the relative risk of rapidly increasing bilirubin levels requiring medical intervention such as phototherapy (American Academy of Pediatrics, 2004; Maisels et al, 2009). The hour-specific nomogram estimates the total serum bilirubin (TSB) in one of four risk zones: low risk, low intermediate risk, high intermediate risk (75th to 94th percentile), and high risk (95th percentile or greater). Infants with TSB values at or above the 75th percentile in addition to risk factors such as preterm birth may require medical intervention such as phototherapy (Maisels et al, 2009). In addition to the hour-specific nomogram, risk factors that have been identified as predicting an increased probability for severe jaundice include lower gestational age, Asian ethnicity, isoimmune or hemolytic disease, significant bruising, and exclusive breastfeeding (Maisels et al, 2009; National Association of Neonatal Nurses, 2010).

- Monitor newborn for signs of inadequate breast milk or formula intake: dry oral mucous membranes, fewer than 4 to 6 wet diapers per 24 hours, no stool in 24 hours, body weight loss greater than 10%. Inadequate intake of breast milk in the neonatal period has been identified as a risk factor for the development of hyperbilirubinemia (Academy of Breastfeeding Medicine Protocol Committee, 2010).
- Assess late preterm infant (born between 34 weeks and 36% weeks' gestation) for ability to breastfeed successfully and adequate intake of breast milk. Late preterm infants are at higher risk for breastfeeding and inadequate milk intake due to physiological immaturity. Such infants are also at a much higher risk for severe jaundice than term counterparts (Radtko, 2011; Souto & Hallas, 2011).
- Assist mother with breastfeeding and assess latch-on. **EB:** Successful breastfeeding in the first few weeks of life is associated with decreased levels of serum bilirubin (Blackburn, 2013).
- Encourage alternate methods for providing expressed breast milk if maternal health status is compromised (use of expressed breast milk) and assist mother with collection of breast milk via use of breast pump or hand expression. **EB:** Alternate feeding methods for the ingestion of breast milk may be used to enhance milk intake necessary to promote stooling and enhance bilirubin excretion (Academy of Breastfeeding Medicine Protocol Committee, 2010; Lawrence & Lawrence, 2011).
- Encourage father's participation in newborn care by changing diapers, helping position newborn for breastfeeding, and holding newborn while mother rests. Paternal involvement in the care of the newborn helps solidify the father's role as a parent and strengthens the paternal-infant attachment process; paternal participation also helps the mother rest during the recovery from labor and delivery (Hockenberry & Wilson, 2015; Neifert & Bunik, 2013).
- Weigh newborn daily. **EB:** Daily weights assist in the detection of excess weight loss, which is often indicative of inadequate caloric intake (Alex & Gallant, 2008; Lawrence & Lawrence, 2011).
- ▲ When phototherapy is ordered, place seminude infant (diaper only) under prescribed amount of phototherapy lights. **EB:** Phototherapy is the primary therapy used to treat mild to moderate neonatal indirect (unconjugated) hyperbilirubinemia; phototherapy enhances indirect bilirubin excretion. In order for phototherapy to be effective, the infant must have a large skin surface area exposed to the light source (Blackburn, 2013; Stokowski, 2011). **EB:** Turning the infant periodically has not been shown to reduce circulating bilirubin levels (Stokowski, 2011).
- Protect infant's eyes from phototherapy light source with eye shields. Remove eye shields periodically when infant is removed from light source for feeding and parent-infant interaction. **EB:** Retinal damage may occur from light exposure (Bhutani & American Academy of Pediatrics, 2011; Stokowski, 2011).
- Monitor infant's hydration status, fluid intake, skin status, and body temperature while undergoing phototherapy. **EB:** Transient side effects of phototherapy include increased body temperature, increased insensible water loss, increased gastrointestinal water loss (loose stools), lethargy, irritability, and poor feeding. There is no evidence that removing the infant for parent-infant interaction during feedings and for brief caregiving activities prevents the effectiveness of phototherapy when the infant has mild to moderate hyperbilirubinemia (Blackburn, 2013; Stokowski, 2011).
- ▲ Collect and evaluate laboratory blood specimens (total serum bilirubin) while infant is undergoing phototherapy. **CEB:** Transcutaneous bilirubin measurements do not provide an adequate estimate of serum bilirubin level and are not effective once phototherapy has been initiated (American Academy of Pediatrics, 2004).
- Encourage continuation of breastfeeding and brief infant care activities such as changing diapers while infant is being treated with phototherapy; phototherapy may be interrupted for breastfeeding. **EB:** In most cases breastfeeding is not interrupted for phototherapy; the benefits of breastfeeding exceed any potential harm (Muchowski, 2014). If the infant's oral intake with breastfeeding is inadequate, supplementation with expressed breast milk or infant formula may be recommended (Lawrence & Lawrence, 2011).

- Provide emotional support for parents of infants undergoing phototherapy. **EB**: *Separation of the infant from the mother for phototherapy disrupts parent-infant interaction and may promote parental stress and decrease the effective establishment of breastfeeding (Stokowski, 2011).*

Multicultural

- Assess infants of Asian ethnicity for early rising bilirubin levels, especially when breastfeeding. **EB**: *Studies have shown Chinese and other Asian newborns to have higher peak serum bilirubin levels than Caucasian and African American newborns (Huang et al, 2009).*
- Encourage early and exclusive breastfeeding among Chinese and other Asian newborns. **EB**: *Early and exclusive breastfeeding may increase elimination of bilirubin in stool (Blackburn, 2013).*
- Assess Chinese and other Asian newborns suspected of being jaundiced with a serum bilirubin level or transcutaneous monitor. **CEB**: *Skin color alone is not a reliable assessment for neonatal jaundice; therefore, it is important that such assessments be supported with empirical serum bilirubin measurements or transcutaneous bilirubin measurements when jaundice is suspected (American Academy of Pediatrics, 2004).*

Client/Family Teaching and Discharge Planning

- Teach the breastfeeding mother and support persons about the appearance of jaundice (yellow or orange color of skin) after birth center discharge, and provide health care resource telephone number for parents to call for concerns related to newborn's care. **EB**: *Follow-up for evaluation of jaundice and feeding is recommended within the first 48 hours of discharge (Maisels et al, 2009).*
- Teach parents regarding the signs of inadequate milk intake: fewer than 3 to 4 stools by day 4, fewer than 4 to 6 wet diapers in 24 hours, and dry oral mucous membranes; additional danger signs include a sleepy baby that does not awaken for breastfeeding or appears lethargic (decreased activity level from usual newborn pattern). *Providing information about jaundice and effective breastfeeding may serve to decrease risk factors associated with increasing bilirubin levels (Blackburn, 2013; Seagraves et al, 2014).*
- ▲ Teach parents about the importance of medical follow-up in the first several days of life for the evaluation of jaundice. **CEB**: *Because of earlier postpartum hospital discharge, follow-up visits in the first 48 hours of discharge are important for the evaluation of breastfeeding, stooling and voiding pattern (hydration), and jaundice (American Academy of Pediatrics, 2004).*
- Teach parents about the use of phototherapy (hospital or home, as prescribed), the proper use of the phototherapy equipment, feedings, and assessment of hydration, body temperature, skin status, and urine and stool output. *Information is provided to the parents of the infant undergoing phototherapy to prevent misinformation about the infant's condition and treatment and to decrease parental anxiety and stress (Hockenberry & Wilson, 2015).*

Quality and Safety in Nursing

- **Client safety:** Minimizes risk of harm to client
- Knowledge: Nurses continually assess newborns for risk factors associated with the development of jaundice
- Skills: Nurses use transcutaneous and serum bilirubin measurements to determine the newborn's bilirubin risk according to the hour-specific nomogram
- Attitudes: Nurses appreciate their role as one of promoting safety for the newborn at risk for developing jaundice
- Knowledge: Nurses implement client-focused strategies to promote serum bilirubin reduction; these include but are not limited to placing the newborn to mother's breast in first hours of life and encouraging frequent breastfeeding or no less than 10 to 12 feedings per 24 hours
- Skills: Nurses identify individual clinical risk factors in the neonate that place him/her at risk for jaundice
- Attitudes: Nurses value their role as a health care team member to promote the safe care of the newborn at discharge from the birth center and beyond
- Knowledge: Nurses understand use of phototherapy to reduce levels of indirect bilirubin
- Skills: Nurses use phototherapy lights appropriately
- Skills: Nurses assess infant for untoward effects of phototherapy
- Attitudes: Nurses appreciate the role of phototherapy as a treatment

- Attitudes: Nurses value their role in the promotion of safety with the use of phototherapy
- Quality and Safety Education for Nurses: http://www.qsen.org/ksas_graduate.php#safety and http://www.qsen.org/about_qsen.php

Risk for neonatal jaundice David Wilson, MS, RN, C

NANDA-I

Definition

Vulnerable to the yellow orange tint of the neonate's skin and mucous membranes that occur after 24 hours of life as a result of unconjugated bilirubin in the circulation, which may compromise health

Risk Factors

Abnormal weight loss >10%, age <7 days; delay in meconium passage; feeding pattern not well established; infant experiences difficulty making the transition to extrauterine life; prematurity (≤ 37 weeks) (Wilson D, original author)

NOC

(Nursing Outcomes Classification)

See care plan for Neonatal **Jaundice** for suggested NOC outcomes.

Client Outcomes

- Neonatal total serum bilirubin (TSB) will be monitored and there will be no undetected TSB values in the high-risk (95th percentile or greater) or high-intermediate risk (75th to 94th percentile) zones (as determined by the hour-specific nomogram)
- Newborn will receive appropriate therapies to enhance bilirubin excretion
- Newborn will remain free of undetected signs of acute bilirubin neurotoxicity
- Establish effective feeding pattern (breast or bottle)

- Receive bilirubin assessment and screening within the first week of life to detect increasing levels of serum bilirubin
- Receive nursing assessments to determine risk for severity of jaundice prior to discharge from birth hospital
- Maintain hydration: moist buccal membranes, 4 to 6 wet diapers in 24-hour period, weight loss no greater than 10% of birth weight
- Evacuate stool within 48 hours of birth, and pass 3 to 4 stools per 24 hours by day 4 of life

NIC (Nursing Interventions Classification)

See the care plan for Neonatal **Jaundice** for suggested NIC interventions.

Nursing Interventions and Rationales

- Identify clinical risk factors that place the infant at greater risk for development of neonatal jaundice: exclusive breastfeeding, isoimmune or hemolytic disease, preterm birth (38% weeks' gestation or less), weight loss of 10% or more from birth weight, previous sibling with jaundice, East Asian ethnicity, and significant bruising or cephalhematoma. **EB:** *Exclusive breastfeeding that is not going well and preterm birth have been identified as being the most predictive of neonatal jaundice (Maisels et al, 2009). The other risk factors listed may also play a significant role in the development of neonatal jaundice and should be considered in the overall assessment.*
- Weigh daily the late preterm infant, early term, and term newborn who is at high risk for inadequate caloric intake for the first week of life. **EB:** *Daily weights assist in the detection of excess weight loss, which is often indicative of inadequate caloric intake (Alex & Gallant, 2008). Early and late preterm infants are at increased risk for inadequate caloric intake and hyperbilirubinemia; their body weight should be followed closely (Kuzniewicz et al, 2013; Souto et al, 2011).*

Refer to care plan for Neonatal **Jaundice** for additional interventions for multicultural and discharge planning.

Client/Family Teaching and Discharge Planning

- ▲ Teach parents about the importance of medical follow-up in the first several days of life for the evaluation of jaundice, especially in the late preterm infant. *Early and late preterm infants are at greater risk for feeding problems and hyperbilirubinemia, and should therefore be followed closely in the first few weeks of life (Souto et al, 2011).*

Refer to care plan for Neonatal **Jaundice** for additional interventions.

Quality and Safety in Nursing

Refer to care plan for Neonatal **Jaundice** for additional interventions.

Deficient Knowledge *Barbara J. Olinzock, MSN, EdD, RN, and Kathaleen C. Bloom, PhD, CNM*

NANDA-I

Definition

Absence or deficiency of cognitive information related to a specific topic

- = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

List of Nursing Diagnoses by Letter: K

Deficient Knowledge

Readiness for enhanced Knowledge

Defining Characteristics

Inaccurate follow through of instruction; inaccurate performance on a test; inappropriate behavior (e.g., hysterical, hostile, agitated, apathetic); insufficient knowledge

Related Factors (r/t)

Alteration in cognitive functioning; alteration in memory; insufficient information; insufficient interest in learning; insufficient knowledge of resources; misinformation presented by others

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Knowledge: Disease Process; Energy Conservation; Health Behavior; Health Resources; Healthy Diet; Infection Management; Medication; Personal Safety; Prescribed Activity; Substance Use Control; Treatment Procedure(s); Treatment Regimen

Example NOC Outcome with Indicators

Knowledge: Health Behavior as evidenced by the following indicators: Healthy nutritional practices/Benefits of regular exercise/Safe use of prescribed and nonprescribed medication. (Rate the outcome and indicators of **Knowledge: Health Behavior**: 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

K

Client Outcomes

Client Will (Specify Time Frame)

- Explain disease state, recognize need for medications, and understand treatments
- Describe the rationale for therapy/treatment options
- Incorporate knowledge of health regimen into lifestyle
- State confidence in one's ability to manage health situation and remain in control of life
- Demonstrate how to perform health-related procedure(s) satisfactorily
- Identify resources that can be used for more information or support after discharge

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Teaching: Disease Process, Individual, Learning Facilitation

Example NIC Activities—Teaching: Disease Process

Discuss therapy/treatment options; Describe rationale behind management/therapy/treatment recommendations

Nursing Interventions and Rationales

- Consider the health literacy and the readiness to learn for all clients and caregivers (e.g., mental acuity, ability to see or hear, existing pain, emotional readiness, motivation, and previous knowledge). **EBN**: *Findings from a cross-sectional study support the notion that health literacy, as a “sixth vital sign” be addressed in all settings because health literacy can vary depending on the situation and complexities of a chronic condition (Heinrich, 2012).* **CEB**: *In a descriptive study, Olinzock (2008) found that readiness to learn for persons with spinal cord injury ranged from dependent to self-directed based on situational, physical, and emotional challenges of the client.*
- Focus on the nature of spoken and written communication when teaching clients and caregivers, especially those who may have health literacy needs. **EBN**: *Lambert and Keogh (2014) provide an overview of tools for effective teaching communication including providing feedback, actively seeking questions, using a teach-back method, and providing age-appropriate client education materials that are in everyday layman language.* **EB**: *An evaluation study of 97 client education materials in three clinics found more than 90% were beyond the ninth grade reading level, although recommendations are that all educational materials should be on a fifth grade level by all adults regardless of health literacy (Ryan et al, 2014).*

- Consider the context, timing, and order of how information is presented. **EB:** A systematic review of 56 studies on educational interventions found that presenting the most important information first and the use of simplifying, “chunking,” and grouping information presented in short sessions were effective (Berkman et al, 2011).
- Use client-centered approaches that engage clients and caregivers as active vs. passive learners. **EB:** A systematic review of 38 trials with clients with asthma found that using empathy-building strategies within a framework of person-centered counseling would maximize the effectiveness of self-care interventions for those with poorly controlled asthma (Denford et al, 2014). **EBN:** A synthesis of studies by Cameron (2013) concluded that using multiple or a combination of teaching methods adapted to client learning styles and priority concerns were effective for client outcomes.
- Reinforce learning through frequent repetition and follow-up sessions. **EBN:** A systematic review of six studies found that frequent and regular educational sessions, including “boost” sessions, improved medication and self-care management outcomes for those with a chronic condition, including stroke clients (Chapman & Bogle, 2014). **EB:** In a cohort study of 400 clients at discharge, 59.2% were found to have a misunderstanding of indication, dose, and frequency of their medications, leading investigators to stress the importance of repetition of medication teaching before discharge for all clients regardless of health literacy (Mixon et al, 2014). Additional research: Cameron (2013). Additional source: Forster et al (2012).
- Use technological and multimedia methods of disbursing information as appropriate. **EB:** A Cochrane review of 24 studies with 8112 participants found that the use of multimedia education (video, audio, and self-paced computer programs) as an adjunct with current programs was most effective (Ciciriello et al, 2013). **EB:** In a Cochrane review of 16 trials with 3478 participants, the use of computer programs and the use of mobile phone interventions helped clients with diabetes type 2 improve blood glucose control, although not all clients have access (Pal et al, 2013).
- Help the client and caregivers locate appropriate post-discharge groups and resources. **CEB:** DeWalt et al (2010) offer a detailed health literacy tool kit that includes a guide for how to access nonmedical community and Internet resources for post-discharge and those transitioning home. **EB:** In focus interviews, clients shared that they learned more about themselves and their irritable bowel condition through the experience and input of others, but they were not able to relate in a group setting (Häkanson et al, 2012).
- Encourage clients and caregivers to maintain and/or expand supportive social networks as self-care learning resources when appropriate. **EB:** In a longitudinal study of clients with long-term chronic health conditions (N = 300), those who had sustained or expanded community networks were more likely to sustain self-care management, maintain behavioral change and treatment regimens, and access voluntary caregiving over formal caregiving (Reeves et al, 2014).

Pediatric

- Use family-centered approaches when teaching children and adolescents. **EBN:** According to Dunn and Board (2011), relationship building and negotiation of roles among parents and staff is considered essential, especially for families learning to manage complex medical technology and treatment.
- Guide children and adolescents to credible information about their condition. **CEB:** According to Chilman-Blair (2010), children and adolescents need to be connected to credible sources of information that children are familiar with, including visual sources, social media, and social networking groups that are relevant for their condition.
- Use teaching strategies to enhance learning that are uniquely tailored for the information needs of children and/or adolescents. **CEB:** In a study of young children at a diabetes camp, it was found that the children responded well to use of puppets, playthings, and games in teaching sessions because it gives them a sense of control (Pélicand et al, 2006). **EBN:** In a qualitative study of focus groups of adolescents who have undergone kidney transplant, adolescents voiced that they valued on-line discussion boards, mentoring, and sharing of personal experiences, but they were clear that they did not want to relinquish face to face time with health care providers (Korus et al, 2011).

Geriatric

- Educate all older clients on safety issues, including fall prevention and medication management. **QSEN:** In a meta-analysis of 19 studies, in client and post-discharge clients receiving targeted fall prevention education face to face or through multimedia had decreased falls than those either receiving no formal education or written education (Lee et al, 2014). **QSEN:** In a study of 162 medical records of older adults with heart failure, 48.1% received incomplete discharge medication instructions, leading investigators to recommend

that due to complex medication changes, clear and consistent medication information during transition at discharge needs to be improved (Foust et al, 2012).

- Consider using teaching methods and materials appropriate for older adults, especially those with cognitive challenges. **EBN:** Findings in an integrated literature review suggest that the use of simple pictograms (stick figures) vs. written instructions or photographs can be used as a universal language for those with low literacy or language needs in an older adult population (Choi, 2011). **CEB:** The use of Gerogogy or story telling can be used when educating older clients to link new information with familiar concepts from past experiences (Cangelosi & Sorrell, 2008).
- Assess readiness of older adults for use of technological resources. **EBN:** Health care providers need to assess the experience and willingness of older adults to use the Internet as a source of health information and Internet sites need to be assessed for readability, large fonts, and simple structure (Sun Ju & Eun-Ok, 2014).

Multicultural

- Use educational interventions that are culturally tailored to the health literacy needs of the client. A Cochrane review of 33 randomized controlled trials focusing on diabetes type 2 found that culturally appropriate health education improved blood sugar control among participants, compared with those receiving “usual” care, at 3, 6, 12, and 24 months after the intervention (Attridge et al, 2014). **CEB:** Educational programs that focus on the cultural context and not disease symptoms alone are more effective than generic education programs (Bailey et al, 2009).
- Assess for cultural/ethnic self-care practices. **CEB:** Folk and home remedies may interact with medications and treatment (Seeleman et al, 2009).
- Consider the potential influence of medical interpreters in information sharing and decision-making and of the possible difficulties for clients when using medical interpreters. **EBN:** Different categories of interpreters (e.g., trained, untrained, professional) may influence how information is shared and understood (Hadziabdic et al, 2011).
- Consider involving bilingual members of a community who are considered outside the traditional health care system who may assist in the teaching of community health issues. **EB:** Members of an ethnic or cultural group who are well networked may have greater influence when educating peers on needed lifestyle and health-related changes (Henderson et al, 2011).

Home Care

- All of the previously mentioned interventions are applicable to the home setting.
- Use telehealth and technology-enhanced practices as appropriate. **EBN:** Findings from a literature review of 48 papers support previous findings that technology is desired by consumers and can be effective, but the appropriateness for use should take into consideration the abilities of the clients, as well as the credibility of software applications and the accessibility of the type of technology, including computers and mobile devices (Fitzner & Moss, 2013).

Readiness for enhanced Knowledge

Barbara J. Olinzock, MSN, EdD, RN, and Kathaleen C. Bloom, PhD, CNM

NANDA-I

Definition

A pattern of cognitive information related to a specific topic or its acquisition, which can be strengthened

Defining Characteristics

Expresses desire to enhance learning

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Knowledge: Health Promotion

Example NOC Outcome with Indicators

Knowledge: Health Promotion as evidenced by the following indicators: Behaviors that promote health/Reputable health care resources. (Rate the outcome and indicators of **Knowledge: Health Promotion**: 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Meet personal health-related goals
- Explain how to incorporate new health regimen into lifestyle
- List sources to obtain information

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Health Education; Health System Guidance

Example NIC Activities—Health Education

Prioritize identified learner needs based on client preference, skills of nurse, resources available, and likelihood of successful goal attainment

Nursing Interventions and Rationales

- Assume a facilitator role vs. authority role when engaging clients seeking health-related knowledge. **EBN:** According to *Tierney et al (2011)*, advice giving is counterproductive and instead providing information and encouraging clients to “self-generate” solutions to problems can enhance self-control and confidence. **EBN:** A descriptive survey ($N = 312$) found that nurses may make inaccurate assumptions about the willingness and abilities of clients to become engaged in self-care learning (*Wu et al, 2014*).
- Consider “health coaching” and motivational interviewing techniques when focusing on health-related goals, priorities, and preferences. **EBN:** According to *Howard and Ceci (2013)*, health coaching and motivational interviewing focus on the client as an autonomous decision-maker. **CEB:** Adult learning theories and models support the use of choice with self-directed autonomous learners (*Olinzock, 2008*).
- Seek teachable moments for those with chronic conditions to enhance their knowledge of health promotion. **EB:** Findings from a qualitative study suggest that providers often miss opportunities for “teachable moments” on health promotion topics beyond treatment regimens (*Cohen et al, 2011*).
- ▲ Refer clients to lifestyle and health promotion resources delivered in the workplace or community sites outside traditional health care environments. **EB:** In a compilation of literature addressing the outcomes of workplace health promotion programs, *Goetzel et al (2014)* found overwhelming success of programs focusing on areas of wellness, especially in organizations that had a “culture of health.”
- Refer clients to interactive and Web-based technological resources as appropriate. **EB:** In a synthesis of literature by *Hordern et al (2011)*, consumer e-health, Internet, and Web-based interventions that are interactive, such as self-care assessment, decision-making, and peer support, are useful in supporting lifestyle changes.
- Refer to Deficient **Knowledge** care plan.

Pediatric

- Consider the use of mobile text messaging as a resource for delivery of health promotion information. **EBN:** A systematic review of eight studies concluded that texting messages is effective for children and adolescents across demographics and can serve as a reminder system as well as augment clinical practice through tailored interactive family-centered care (*Militello et al, 2012*).
- Incorporate health promotion education that reflects the unique cultural interests and values of diverse groups. **EB:** In a review of 80 papers, *Suarez-Balcazar et al (2013)* found that adapting physical activities, ethnic dancing, and playing games that are culturally relevant were most effective for promoting health and addressing obesity in African American and Latino youth.
- Involve children and especially adolescents in designing health promotion programs and teaching methods. **EBN:** Young people are more willing to engage in health promotion programs when the program is tailored to their specific needs rather than a standardized program (*Tall, 2011*).
- Consider settings outside traditional health care centers and interdisciplinary approaches for engaging children and adolescents in preventive health care. **EB:** A systematic review of 55 studies found that schools may be the best place to implement health-related prevention programs to reduce health risk because of the accessibility of youth and the importance of school and peer learning (*Hale et al, 2014*).

- Provide a developmentally appropriate environment when addressing health education needs of adolescents. **EB:** *Sustained involvement in peer educator and service learning programs where adolescents can reflect on health issues. Using guest speakers and Web resources has been shown to be effective and has been linked to reductions in adolescent sexual risk behaviors, violence involvement, and school disconnection (Sieving et al, 2011).*
- Refer to Deficient **Knowledge** care plan.

Geriatric and Multicultural

- Discuss healthy lifestyle changes that promote safety, health promotion, and health maintenance for older clients. **EB:** *Older people often lack knowledge about safety issues, such as fall prevention and medication management in the home and community (Dickinson et al, 2011).*
- Consider involving bilingual members of a community who are considered outside the traditional health care system who may assist in the teaching of community health issues. **EB:** *Members of an ethnic or cultural group who are well networked may have greater influence when educating peers on needed lifestyle and health-related changes (Henderson et al, 2011).*
- Refer to Deficient **Knowledge** care plan.

L

Latex Allergy response William J. Trees, DNP, FNP-BC, CNP, RN

NANDA-I

Definition

A hypersensitive reaction to natural latex rubber products

Defining Characteristics

Life-Threatening Reactions Occurring Less Than 1 Hour After Exposure to Latex

Protein

Bronchospasm; cardiac arrest; contact urticaria progressing to generalized symptoms; dyspnea; edema of the lips; edema of the throat; edema of the tongue; edema of the uvula; hypotension; respiratory arrest; syncope; tightness in chest; wheezing

• = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

List of Nursing Diagnoses by Letter: L

Latex Allergy response	Risk for Latex Allergy response	Risk for impaired Liver function
Risk for Loneliness		

Orofacial Characteristics

Edema of eyelids; edema of sclera; erythema of the eyes; facial erythema; facial itching; itching of the eyes; oral itching; nasal congestion; nasal erythema; nasal itching; rhinorrhea; tearing of the eyes

Gastrointestinal/Characteristics

Abdominal pain; nausea

Generalized Characteristics

Flushing; generalized discomfort; generalized edema; increasing complaint of total body warmth; restlessness

Type IV Reactions Occurring More Than 1 Hour After Exposure to Latex Protein

Discomfort reaction to additives such as thiuram and carbamates; eczema; irritation; redness

Related Factors (r/t)

Hypersensitivity to natural latex rubber protein

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Allergic Response: Localized, Systemic; Immune Hypersensitivity Response; Symptom Severity; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Immune Hypersensitivity Response as evidenced by the following indicators: Respiratory, cardiac, gastrointestinal, renal, and neurological function status IER/Free of allergic reactions. (Rate the outcome indicators of **Immune Hypersensitivity Response**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].) IER, In expected range.

Client Outcomes**Client Will (Specify Time Frame)**

- Identify presence of natural rubber latex (NRL) allergy
- List history of risk factors
- Identify type of reaction
- State reasons not to use or to have anyone use latex products
- Experience a latex-safe environment for all health care procedures
- Avoid areas where there is powder from NRL gloves
- State the importance of wearing a medical alert bracelet and wear one
- State the importance of carrying an emergency kit with a supply of nonlatex gloves, antihistamines, and an autoinjectable epinephrine syringe (EpiPen), and carry one

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Allergy Management; Latex Precautions

Example NIC Activities—Latex Precautions

Question client or appropriate other about history of systemic reaction or sensitization to NRL (e.g., facial or scleral edema, tearing eyes, urticaria, rhinitis, and wheezing); Place an allergy band on client

Nursing Interventions and Rationales

- Identify clients at risk: those persons who are most likely to exhibit sensitivity to NRL that may result in varying degrees of reactivity. Consider the following client groups:
 - Persons with neural tube defects including spina bifida, myelomeningocele/meningocele. **CEB**: Clients with spina bifida (myelomeningocele) are at the highest risk of latex allergy because of repeated exposure

of mucous membranes to latex during surgeries and procedures. The prevalence of latex allergy in these clients ranges from 20% to 67% (Blumchen et al, 2010; Pollart et al, 2009).

- Children with spinal cord injuries. **EB:** Sensitization apparently follows multiple procedures involving urinary tract, rectal, and thecal procedures (Schottler et al, 2012).
- Clients with history of multiple surgeries or other latex-exposing procedures. **EB:** Are at an increased risk relative to the general population (Behrman, 2013).
- Children who have experienced three or more surgeries, particularly as a neonate, and adults who have undergone multiple surgeries. **CEB:** A significant correlation between the total number of surgeries, particularly during the first year of life, and degree of sensitization has been established (Venkata & Lerman, 2011). **CEB:** Children who are likely to have multiple surgeries early in life should be treated only with latex-free products. Likewise, adults who have had more than 10 surgeries have a significantly greater risk for developing a latex allergy (Pollart et al, 2009).
- Atopic individuals (persons with a tendency to have multiple allergic conditions) including allergies to food products. Particular allergies to fruits and vegetables including bananas, avocado, celery, fig, chestnut, papaya, potato, tomato, melon, and passion fruit are significant. **CEB:** Atopic individuals generally have a higher prevalence rate, and there are known cross-reactive allergic reactions (Palosuo et al, 2011).
- Persons who possess a known or suspected NRL allergy by having exhibited an allergic or anaphylactic reaction, positive skin testing, or positive IgE antibodies against latex. **CEB:** A formal evaluation for allergy is recommended for clients who have a strong history of an IgE-mediated reaction to latex and a latex-specific IgE value of zero (Siles & Hsieh, 2011). **CEB:** The use of skin prick testing with latex extracts and specific IgE detection for the diagnosis of NRL allergy in suspected clients is directed to identification of risk factors (Venkata & Lerman, 2011).
- Persons who have had an ongoing occupational exposure to NRL, including health care workers, rubber industry workers, bakers, laboratory personnel, food handlers, hairdressers, janitors, policemen, and firefighters. **CEB:** Occupational exposure is different from that among children with spina bifida; it has been suggested that occupational exposure is from NRL glove proteins inhaled through powders rather than particle-bound latex proteins in urinary catheters (Palosuo et al, 2011). **CEB:** Health care workers have a sensitization rate three times higher than the general public, and there is a positive correlation between the risk for latex allergy and the length of employment in the health care industry (Pollart et al, 2009). **EB:** Occupational and non-occupational risk patterns are similar in other developed countries. The focus is on interventions to reduce latex allergy in health care workers such as with use of latex free gloves and instruments and working in latex free environments (Geier et al, 2012; Al-Niaimi, et al, 2013; Turner et al, 2012). **EB:** Exposure to latex in health care workers and clients continues to decrease. Some health care facilities are completely latex-free as the number of latex-free products become available (Chard, 2011).
- Latex sensitization is also prevalent in older adults but they are often overlooked as a high-risk population. **EB:** Latex allergy has not been studied extensively among older adults but a recent study demonstrated that approximately 11.4% of the older adults in the study had latex sensitization (Grieco et al, 2014).
- Take a thorough history of the client at risk. **CEB:** A clinical history is essential for diagnosing latex allergy (Pollart et al, 2009). **EB:** Prompt diagnosis and management can significantly minimize the risk of serious latex reactions (Kumar, 2012).
- Have management protocols in place for treating anaphylaxis. **EB:** Prompt initial treatment is essential in anaphylaxis because a few minutes' delay can lead to hypoxic-ischemic brain damage or death (Simons et al, 2013).
- Question the client about associated symptoms of itching, swelling, and redness after contact with rubber products such as rubber gloves, balloons, and barrier contraceptives, or swelling of the tongue and lips after dental examinations. **CEB:** Latex allergy is an IgE-mediated hypersensitivity to NRL, presenting a wide range of clinical symptoms such as angioedema, swelling, cough, asthma, and anaphylactic reactions (Deval et al, 2008).
- Consider the use of a provocation test (cutaneous, sublingual, mucous, conjunctival) for latex allergy diagnosis confirmation. **CEB:** Latex allergy diagnosis was confirmed by specific provocation tests (Nucera et al, 2006). **EB:** The nasal provocation test is a more sensitive testing method than the glove use test (Unsel et al, 2009).

- Consider a blood test to measure serum IgE levels. **CEB:** Because skin prick testing is not available in the United States, measurement of latex-specific serum IgE levels is the best option (Pollart et al, 2009). **CEB:** In theory, allergy blood testing may be safer, because it does not expose the client to any allergens (Siles & Hsieh, 2011).
- All latex-sensitive clients are treated as if they have NRL allergy. **CEB:** The primary treatment for suspected latex allergy is avoidance of exposure to the latex protein (Gawchik, 2011). **CEB:** Recent studies have demonstrated that adopting latex-free strategies in health care facilities has reduced the prevalence of latex sensitization and allergy in children with spina bifida (26.7% to 4.5%), myelomeningocele (4% to 1.2%), and a history of multiple surgeries (42% to 7%) (Venkata & Lerman, 2011).
- Clients with spina bifida and others with a positive history of NRL sensitivity or NRL allergy should have all medical/surgical/dental procedures performed in a latex-controlled environment. **CEB:** The management strategy recommended by the American Society of Anesthesiology consists of a complete medical history and questionnaire (from the parents), application for a medical alert bracelet, a latex-free card, a list of latex-free devices and alternatives, signage on the client's medical records that highlights his/her latex allergy, and "Latex Allergy" signs in the perioperative area (Venkata & Lerman, 2011). **CEB:** A latex-controlled environment is defined as one in which no latex gloves are used in the room or surgical suite and no latex accessories (catheters, adhesives, tourniquets, and anesthesia equipment) come in contact with the client (Joint Task Force on Practice Parameters, 2010). **CEB:** Clients who are latex allergic should have a surgical procedure performed as the first case in the morning, when the levels of latex aeroallergens in the environment are the lowest (Cleveland Clinic, 2011).
- In select high-risk atopic individuals, a specific immunotherapy regimen should be discussed with their health care provider. **CEB:** Current subcutaneous and sublingual immunotherapy schedules have been tested for treatment of latex allergy with evidence of efficacy, but the risks of adverse events are high (Rolland & O'Hehir, 2008). **CEB:** Sublingual immunotherapy represents an efficient therapeutic tool for the management of latex allergic clients (Nucera et al, 2008).
- ▲ The most effective approach to preventing NRL anaphylaxis is complete latex avoidance. **CEB:** Symptoms of latex allergy resolve quickly with avoidance. However, elevated IgE levels can remain detectable more than 5 years after exposure, suggesting that long-term avoidance of latex should be recommended for clients with known latex allergy (Pollart et al, 2009). **CEB:** The use of no-latex gloves is the best choice from the preventive point of view (Filon & Cerchi, 2008).
- ▲ Materials and items that contain NRL must be identified and latex-free alternatives must be found. **CEB:** Effective in September 1998, all medical devices were required to be labeled regarding their latex content (Hubbard, 1997). **CEB:** Latex-free synthetic rubber such as neoprene, nitrile, styrene butadiene rubber, butyl, and Viton are polymers that are available as alternatives to natural rubber (Deval et al, 2008).
- ▲ In health care settings, general use of latex gloves having negligible allergen content, powder-free latex gloves, and non-latex gloves and medical articles should be considered to minimize exposure to latex allergen. **CEB:** The use of low-protein, low-allergenic, powder-free gloves is associated with a significant decrease in the prevalence of type I allergic reactions to NRL among health care workers (Palosuo et al, 2011).
- ▲ If latex gloves are chosen for protection from blood or body fluids, a reduced-protein, powder-free glove should be selected. **CEB:** Evidence within Europe demonstrates that the many benefits of NRL (gloves) can be retained by purchasing low-allergen, low-protein, and powder-free gloves, thereby reducing the risk for type I and type IV sensitization as well as allergic reactions (Palosuo et al, 2011).
- **CEB:** Clients who are known to be allergic should avoid any product that might contain latex until latex content is determined by contacting the manufacturer. Even products labeled "safe latex" (which indicates lower proportions of natural latex) can cause allergic reactions. There is no safe latex for latex allergy sufferers (Deval et al, 2008).

Home Care

- Assess the home environment for presence of NRL products (e.g., balloons, condoms, gloves, and products of related allergies, such as bananas, avocados, and poinsettia plants). **CEB:** Strict compliance with latex avoidance instructions is essential both inside and outside the hospital. Greater emphasis should be placed on reducing latex exposure in the home and school environments, because such contact could maintain positive IgE antibody levels (Venkata & Lerman, 2011).

- At onset of care, assess client history and current status of NRL allergy response. **EBN:** *A complete and thorough history remains the most reliable screening test to predict the likelihood of an anaphylactic reaction (Sekiya et al, 2011).*
- ▲ Seek medical care as necessary.
- Do not use NRL products in caregiving.
- Assist the client in identifying and obtaining alternatives to NRL products. **EBN:** *Preventing exposure to latex is the key to managing and preventing this allergy. Providing a safe environment for clients with NRL allergy is the responsibility of all health care professionals (American Association of Nurse Anesthetists, 1998).* **CEB:** *Avoidance management should be individualized, taking into consideration factors such as age, activity, occupation, hobbies, residential conditions, and the client's level of personal anxiety (Joint Task Force on Practice Parameters, 2010).*

Client/Family Teaching and Discharge Planning

- Provide written information about NRL allergy and sensitivity. **CEB:** *Client education is the most important preventive strategy. Clients should be carefully instructed about “hidden” latex, cross reactions, particularly with foods, and unforeseen risks during medical procedures (American College of Allergy, Asthma & Immunology, 2010; Joint Task Force on Practice Parameters, 2010).*
- ▲ Instruct the client to inform health care professionals if he or she has an NRL allergy, particularly if the client is scheduled for surgery. **CEB:** *Although some parents may not realize their children are sensitive to latex, inquiring about their child's responses to touching a toy balloon with their lips or inserting a rubber dam in their mouths during dental surgery, as well as a history of atopy, the number of previous surgeries, and any coexisting medical conditions (including spina bifida and congenital urological abnormalities), should be included in preoperative assessment (Venkata & Lerman, 2011).*
- Teach the client what products contain NRL and to avoid direct contact with all latex products and foods that trigger allergic reactions. **EBN:** *Once an individual becomes allergic to latex, special precautions are needed to prevent exposures. Teaching is an effective strategy (Society of Gastroenterology Nurses and Associates, 2008).*
- Teach the client to avoid areas where powdered latex gloves are used, as well as where latex balloons are inflated or deflated. **CEB:** *Powdered gloves have been shown to increase airborne NRL antigens compared with nonpowdered gloves (Palosuo et al, 2011).*
- Instruct the client with NRL allergy to wear a medical identification bracelet and/or carry a medical identification card. **CEB:** *Clients with a history of severe type I allergy may benefit from wearing a medical alert identification, such as a bracelet, necklace, or keychain (Pollart et al, 2009).*
- Instruct the client to carry an emergency kit with a supply of nonlatex gloves, antihistamines, and an autoinjectable epinephrine syringe (EpiPen). **EB:** *An autoinjectable epinephrine syringe should be prescribed to sensitized clients who are at risk for an anaphylactic episode with accidental latex exposure (American College of Allergy, Asthma & Immunology, 2010; Joint Task Force on Practice Parameters, 2010).*

L

Risk for Latex Allergy response *William J. Trees, DNP, FNP-BC, CNP, RN*

NANDA-I

Definition

Risk of hypersensitivity to natural latex rubber products

Risk Factors

Allergies to avocados; allergies to bananas; allergies to chestnuts; allergies to kiwis; allergies to poinsettia plants; allergies to tropical fruits; history of allergies; history of asthma; history of reaction to latex; multiple surgical procedures, especially from infancy; professions with daily exposure to latex

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Allergic Response: Systemic; Immune Hypersensitivity Response; Risk Control; Risk Detection; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Immune Hypersensitivity Response as evidenced by the following indicators: Respiratory, cardiac, gastrointestinal, renal and neurological function status IER/Free of allergic reactions. (Rate the outcome and indicators of **Immune Hypersensitivity Response**: 1 = not controlled, 2 = slightly controlled, 3 = moderately controlled, 4 = well controlled, 5 = very well controlled [see [Section I](#)].) IER, In expected range.

Client Outcomes

Client Will (Specify Time Frame)

- State risk factors for natural rubber latex (NRL) allergy
- Request latex-free environment
- Demonstrate knowledge of plan to treat NRL allergic reaction

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Allergy Management; Latex Precautions; Environmental Risk Protection

Example NIC Activities—Latex Precautions

Question client or appropriate other about history of systemic reaction to NRL (e.g., facial or scleral edema, tearing eyes, urticaria, rhinitis, and wheezing); Place an allergy band on client

Nursing Interventions and Rationales

- Clients at high risk need to be identified, such as those with frequent bladder catheterizations, occupational exposure to latex, past history of atopy (hay fever, asthma, dermatitis, or food allergy to fruits such as bananas, avocados, papaya, chestnut, or kiwi); those with a history of anaphylaxis of uncertain etiology, especially if associated with surgery; health care workers; and women exposed to barrier contraceptives and routine examinations during gynecological and obstetrical procedures. **CEB:** *Although the prevalence of latex allergy in the general pediatric population is less than 4%, the prevalence in specific at-risk populations may be as great as 71%. Children at risk for developing latex sensitivity include those with spina bifida; those with congenital urological, gastrointestinal, and tracheoesophageal defects; those who have undergone more than five surgeries; and those with a history of atopy (Venkata & Lerman, 2011).* **CEB:** *Health care workers have the second highest risk for developing latex allergy, particularly those who work in operating rooms, laboratories, or hemodialysis centers (Pollart et al, 2009).* **EB:** *Hospital housekeepers who are regularly exposed to latex gloves and other types of rubber demonstrate more frequent glove-related symptoms than other non-clinical health care workers and are considered to be at a higher risk for developing latex allergy. Prevalence of latex allergy is eight times greater in hospital housekeepers than in the general population (Boonchai et al, 2014).* **CEB:** *A latex-directed history is the primary method of identifying latex sensitivity, although both skin and serum testing are increasingly accurate (Society of Gastroenterology Nurses and Associates, 2008).*
- Clients with spina bifida are a high-risk group for NRL allergy and should remain latex free from the first day of life. **CEB:** *Latex allergy in spina bifida children is a multifactorial situation related to a disease-associated propensity for latex sensitization, early exposure, and number of surgical procedures. Prophylactic measures to avoid the exposure, not only in the sanitary environment, through the institution of latex-safe routes and every day, prevents potentially serious allergic reactions (Ausili et al, 2007).* **CEB:** *Children with spina bifida or urogenital abnormalities, or those who are expected to have multiple surgical procedures, should avoid exposure to latex products from birth to prevent development of latex allergy (Pollart et al, 2009).*
- Children who require regular medical treatments at home (e.g., catheterization, home ventilation) should be assessed for NRL allergy. **CEB:** *The frequency of daily bladder catheterizations with latex catheters has been correlated with latex sensitivity (Venkata & Lerman, 2011).* **CEB:** *A high level of latex protein was found in medical devices such as elastic bandages, tourniquets, Foley urinary catheters, Penrose drains, and taping (Deval et al, 2008).*
- Assess for NRL allergy in clients who are exposed to “hidden” latex. **CEB:** *NRL is a ubiquitous allergen as it is a component of more than 40,000 products used in everyday life (Deval et al, 2008).* **CEB:** *A clinical history is essential because we cannot deny possibility of exposure to latex products in everyday life (Sekiya et al, 2011).*
- See care plan for **Latex Allergy** response.

Home Care

- ▲ Ensure that the client has a medical plan if a response develops. Prompt treatment decreases potential severity of response.
- See care plan for **Latex Allergy** response. Note client history and environmental assessment.

Client/Family Teaching and Discharge Planning

- ▲ A client who has had symptoms of NRL allergy or who suspects he or she is allergic to latex needs to give this information to health care providers. **EBN:** *Health care workers need to implement necessary*

precautions when a client has known latex allergies. There are specific systems in place to provide “latex-free environments.” The systems need to be used (Lankshear et al, 2008).

- ▲ Provide written information about latex allergy and sensitivity. **EB:** Client education is the most important preventive strategy. Clients should be carefully instructed about “hidden” latex; cross reactions, particularly with foods; and unforeseen risks during medical procedures. If clients have a history of anaphylaxis to NRL, it is important for them to carry autoinjectable epinephrine (Joint Task Force on Practice Parameters, 2010).
- Health care workers should avoid the use of latex gloves and seek alternatives such as gloves made from nitrile. **EB:** Latex-free synthetic rubber such as neoprene, nitrile, styrene butadiene rubber (SBR), butyl, and Viton are polymers that are available as alternatives to natural rubber (Deval et al, 2008).
- Health care institutions should develop prevention programs for the use of latex-free gloves and the absence of powdered gloves; they should also establish latex-safe areas in their facilities and emergency management plans for anaphylaxis episodes. **CEB:** A facility-wide strategy and commitment is necessary to establish a latex-free health care environment. A multidisciplinary latex-allergy task force should include broad representation from hospital staff and should have policies and protocols for the management of the latex-sensitive client, including educational programs for all health care workers (Venkata & Lerman, 2011). **EB:** This review of scientific evidence reports that main triggers of occupational anaphylaxis are from allergens derived from hymenoptera and natural rubber latex. A written emergency management treatment plan is mandatory for potential anaphylactic episodes with the availability of adrenaline and trained personnel (Moscato et al, 2014).
- Institute measures that reduce or completely avoid any latex exposure to clients. **EB:** Clients at an early stage of sensitization are less likely to progress to symptomatic disease (Draisci et al, 2011).

Risk for impaired Liver function

Betty J. Ackley, MSN, EdS, RN, Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN, and Janelle M. Tipton, MSN, RN, AOCN

NANDA-I

Definition

Vulnerable to a decrease in liver function, which may compromise health

Risk Factors

HIV co-infection; pharmaceutical agent; substance abuse; viral infection

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Knowledge: Health Behavior; Liver Function

• = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Example NOC Outcome with Indicators

Knowledge: Health Behavior as evidenced by the following indicators: Safe use of prescription drugs/Adverse health effects of alcohol misuse/Adverse health effects of recreational drug use/Healthy nutritional practices/Self-screening techniques. (Rate the outcome and indicators of **Knowledge: Health Behavior**: 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State the upper limit of the amount of acetaminophen safely taken per day
- Verbalize understanding that over-the-counter (OTC) medications may contain acetaminophen (e.g., OTC cold medicines)
- Have normal liver enzymes, serum and urinary bilirubin levels, white blood cell count, and red blood cell count
- Be free of unexplained weight loss, jaundice, pruritus, bruising, petechiae, gastrointestinal bleeding, and hemorrhage
- Be free of abdominal tenderness/pain, increased abdominal girth, and have normal-colored stool and urine
- Be able to eat frequent small meals per day without nausea and/or vomiting
- If alcohol abuse is factor, state relationship between abuse and worsening gastrointestinal and liver disease

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Teaching: Disease Process; Substance Use Treatment

Example NIC Activities—Teaching Disease Process

Appraise the client's current level of knowledge related to specific disease process; Discuss lifestyle changes that may be required to prevent future complications and/or control the disease process

Nursing Interventions and Rationales

- ▲ Watch for signs of liver dysfunction including fatigue, nausea, jaundice of the eyes or skin, pruritus, gastrointestinal bleeding, coagulopathy, infections, increasing abdominal girth, fluid overload, shortness of breath, mental status changes, light-colored stools, dark urine, and increased serum and urinary bilirubin levels. *These are symptoms and laboratory results associated with liver disorders (Ghany et al, 2012).*
- ▲ Evaluate liver function tests. Standard liver panels include the serum enzymes aspartate transaminase (AST), alanine transaminase (ALT), alkaline phosphatase, and γ -glutamyltransferase; total, direct, and indirect serum bilirubin; and serum albumin. **EB:** *Hepatitis C is often asymptomatic early in the disease state (CDC, 2015b) and may be found during a routine examination when liver function test results are elevated (Ferguson, 2014).*
- ▲ Discuss with the client/family preparations for other diagnostic studies, such as ultrasound, computed tomography, and magnetic resonance imaging exams (Beaumont & Leadbeater, 2011).
- ▲ Evaluate coagulation studies such as international normalized ratio, prothrombin time, and partial thromboplastin time, especially when there is bleeding of the mouth or gums. *Prolonged prothrombin time and decreased production of clotting factors can result in bleeding.*
- Monitor for signs of hemorrhage, especially in the upper gastrointestinal tract, as it is the most frequent site. *Synthesis of coagulation factors is affected with liver impairment (Lopez & Hendrickson, 2014).*
- Obtain a list of all medications, including OTC nonsteroidal antiinflammatory drugs, acetaminophen, and herbal remedies. Review risk of drug-induced liver disease. The list includes some antibiotics, anti-convulsants, antidepressants, antiinflammatory drugs, antiplatelets, antihypertensives, calcium channel blockers, cyclosporine, lipid-lowering drugs, chemotherapy drugs, oral hypoglycemics, and tranquilizers, among others (Dienstag, 2012). If client is taking either OTC medications or herbals, discuss signs and symptoms of toxic hepatitis. *Toxic hepatitis is caused by direct toxins, drugs, herbs, and industrial chemicals.*

The risk of toxicity with aspirin, ibuprofen, naproxen sodium, and acetaminophen increases with frequency and in combination with use of alcohol (Lopez & Hendrickson, 2014).

- ▲ In clients receiving drugs associated with liver injury, review risk factors to prevent potentially severe drug reactions. *Drug-induced liver disease accounts for about 50% of hepatitis cases. The most common risk factors are advanced age, alcohol use history, pregnancy, and genetic predisposition (Kim et al, 2010).*
- ▲ Determine the total amount of acetaminophen the client is taking per day. The amount of acetaminophen ingested should not exceed 3.25 g per day, or even lower in the client with chronic alcohol intake (Dienstag, 2012). *It is common for clients to take multiple pain medications, all containing acetaminophen. Toxicity from acetaminophen is increasing because more adolescents are taking acetaminophen in combination with opioids (Bond et al, 2012).*
- ▲ Evaluate the serum acetaminophen-protein adducts in the client with possible liver failure from excessive intake of acetaminophen. **CEB:** *This diagnostic test was helpful in determining if liver failure is associated with acetaminophen toxicity (Dienstag, 2012).*
- ▲ If the client is on statin medications, ensure that liver enzyme testing is done at intervals. Liver enzymes can become elevated from taking statin medications; it is uncommon, but possible for statins to cause actual liver damage (Zamor & Russo, 2011).
- ▲ If the client is an alcoholic, refer to a cessation program. It is essential the client stop drinking as soon as possible to allow the liver to heal. Alcoholism is associated with malnutrition, which is harmful to the liver (O'Shea et al, 2010). Alcoholism is also associated with formation of proteins called cytokines, which cause inflammation and resultant damage to the liver (Dienstag, 2012). See care plans for Ineffective **Denial** and Dysfunctional **Family** processes.
- ▲ Provide frequent smaller meals for easier digestion. Provide diet with optimal carbohydrates, proteins, and fats. Consult with a registered dietitian to discuss best nutritional support. *Proteins can be increased as tolerated and as serum protein, albumin levels, and bilirubin levels indicate improved liver function. Improved nutrition helps the client with liver dysfunction regain strength and increase activity (Dienstag, 2012).*
- ▲ Recognize that severe malnutrition may result in acute liver failure, which is reversible with improved nutrition.
- ▲ Review medical history with the client, recognizing that obesity and type 2 diabetes, along with hypertriglyceridemia and polycystic ovarian syndrome, are major risk factors in the development of liver disease, specifically nonalcoholic fatty liver disease. *For those clients showing signs of fatty liver involvement, sound nutritional support can reduce the severity as well as mitigate the already existing secondary malnutrition (Kunutsor et al, 2014).*
- Encourage vaccinations for hepatitis A and B for all ages. *Hepatitis A can affect anyone in the United States. Vaccination can prevent hepatitis A and B, which at times can cause liver failure (CDC, 2015a).*
- Measure abdominal girth if individual presents with abdominal distention and pain. *Increasing abdominal distention and pain are signs of impending portal hypertension with presence of fluid shifts, resulting in ascites (Ghany et al, 2012).*
- Assess for tenderness and/or pain level in the right upper quadrant. *Tenderness in this area is a symptom of biliary, liver, and/or pancreatic problems. This pain, along with a palpable mass and weight loss, are a classic triad for malignancies (Kunutsor et al, 2014; Ferguson 2014).*
- Use standard precautions for handling of blood and body fluids. Review sterile techniques when giving intravenous solution and/or medications. **EB:** *This is imperative in order to decrease the incidence of infection with hepatitis B and hepatitis C viruses. The viruses have been spread in health care settings when injection equipment and intravenous solutions were mishandled and became contaminated (CDC, 2015a).*
- ▲ Observe for signs and symptoms of mental status changes such as confusion from encephalopathy. Assess ammonia level if mental changes occur (Dienstag, 2012).

Pediatric/Parents

- ▲ Prescreen pregnant women for hepatitis B surface antigens. If found, recommend nursing case management during pregnancy. **EB:** *Despite advances in prevention of hepatitis B transmission, approximately half of the infections are caused by mother-to-child transmission. Efforts to prevent transmission are an essential element of perinatal maternal and infant care (Ma et al, 2014).*
- ▲ Recommend implementation of postexposure prophylaxis, including the hepatitis B virus vaccine for an infant born to a hepatitis B surface antigen-positive woman (CDC, 2015b).

- Encourage vaccinations for hepatitis A and B for all ages. *Children should be vaccinated between ages 12 months and 23 months for hepatitis A (CDC, 2015a).*
- ▲ Recognize that children can develop fatty liver disease, which can result in liver failure. Most children are asymptomatic, but others complain of malaise, fatigue, or vague recurrent abdominal pain (*Marzuillo et al, 2014*).
- ▲ During a well-baby visit, assess for signs of potential liver problems. Observe for prolonged jaundice, pale stools, and urine that is anything other than colorless. Consult with health care provider to order a split bilirubin as needed (*CDC, 2015b*).

Home Care

- Encourage rest, optimal nutrition (high carbohydrates, sufficient protein, essential vitamins and minerals) during initial inflammatory processes of the liver.

Client/Family Teaching and Discharge Planning

- Teach the client and family to examine all medications the client is taking, looking for acetaminophen as an ingredient, and reinforce the 3.25-g upper limit of intake of acetaminophen to protect liver function (*Dienstag, 2012*).
- For the caregiver or client with hepatitis A, B, or C, teach the need for careful handwashing, use of gloves, and other precautions to prevent spread of any of these diseases.
- Teach avoidance of high-risk behaviors that cause hepatitis and ways to avoid those behaviors.
- Educate clients and their caregivers about treatment options and interventions for hepatitis. Recommend other informational support: risk factors, side effects of the different treatment options, and dietary advice.
- Recommend psychological support if possible during education sessions. **EBN:** *Hepatitis can result in liver inflammation and chronic liver disease and is a common reason for a liver transplant. The client may feel stigmatized and may have had poor interactions with health care providers, and thus may seek less treatment. Developing a plan and/or services to support and to give client-centered care can provide better support to the client in dealing with liver disease (Grogan & Timmins, 2010).*
- For those clients with mental health problems, collaborate with outreach programs to teach signs/symptoms of hepatitis, risk factors, and factors that increase transmission. **EBN:** *These clients have higher potential for substance use and injected-drug use, and increased chances of transmission due to homelessness and living conditions in night shelters. Protocols have proven to be successful in developing an effective approach to meeting the needs of clients with or at risk for infection with hepatitis C virus and severe mental health problems (Lewis et al, 2010).*

Risk for Loneliness *Julianne E. Doubet, BSN, RN, CEN, NREMT-P*

NANDA-I

Definition

Vulnerable to experiencing discomfort associated with a desire or need for more contact with others, which may compromise health

Risk Factors

Affectional deprivation; emotional deprivation; physical isolation; social isolation

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Loneliness Severity; Social Interaction Skills; Social Involvement; Social Support

Example NOC Outcome with Indicators

Loneliness Severity as evidenced by the following indicators: Sense of social isolation/Difficulty in establishing contact with others. (Rate the outcome and indicators of **Loneliness Severity**: 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain one or more meaningful relationships (growth-enhancing versus codependent or abusive in nature)
- Sustain relationships that allow self-disclosure and demonstrate a balance between emotional dependence and independence
- Participate in personally meaningful activities and interactions that are ongoing, positive, and relevant socially
- Demonstrate positive use of time alone when socialization is not possible

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Family Integrity Promotion; Socialization Enhancement; Visitation Facilitation

Example NIC Activities—Socialization Enhancement

Encourage enhanced involvement in already established relationships; Help client increase awareness of strengths and limitations in communicating with others

Nursing Interventions and Rationales

- Assess the client's perception of loneliness. (Is the person alone by choice, or are there other factors that contribute to the feelings of loneliness? Is the client in one of the at-risk populations for loneliness?) **EB**: According to *Schoenmakers et al (2014)*, there are numerous risk factors that influence loneliness and the caregiver should be alert to the causes and be ready to initiate preventive actions as needed. **EBN**: Loneliness was to be found to be substantially higher for men, those who had never married, primary school

graduates, the childless, those who lived alone, and those with a chronic disease and/or in need of continuous medication (Koc, 2012).

- Refer to care plan for **Social** isolation.
- Use active listening skills. Establish a therapeutic relationship and spend quality time with the client. **EB:** *Listening is an indispensable part of nurturing care for clients: to tell one's story and be heard is in itself restorative and life supporting (Mowat et al, 2013).* **EB:** *In their study of clients and families involved in palliative health care, Ciemins et al (2014) found that one expectation of the health care provider included skillful listening abilities.*
- Assess how unmet needs challenge the client. **NOTE:** See care plan for Disturbed **Body Image** if loneliness is associated with chronic illness and/or afflictions (e.g., multiple sclerosis, skin disturbance, mental illness). **EB:** *According to Huang et al (2014), job loss is a major factor linked to the increased risk of unmet basic health care needs.* **EB:** *Unmet needs may exceed what is customary in these clients: minority and low-income community residents; caregivers with lower education; clients with early-stage dementia; those with depression (Black et al, 2013).*
- ▲ **Assess the bereaved client for risk of suicide and make appropriate referrals as necessary.** **EBN:** *Sprinks (2014) states in her article that bereavement in older people promotes loneliness, which in turn can lead to depression, therefore increasing the client's risk for suicide.* Refer to care plan for **Risk for Suicide**.
- **Assess the client who is alone for substance abuse and make appropriate referrals.** **EBN:** *Murdoch's (2014) article emphasizes that all health care professionals are responsible for raising the issue of substance misuse/abuse and referring the client to specialized services if needed.* **EB:** *The use of heroin is increasing, along with overdose deaths. Current data indicate that the use of nonmedical opioids has intensified and is followed closely by nonmedical users shifting to heroin; interventions should focus on high-risk groups, such as regular nonmedical abusers of opioids (Jones, 2013).*
- Evaluate the client's desire for social interaction. **EBN:** *In their study, Thomas et al (2013) found that older people need to be involved in leisure pastimes to be socially connected: the authors suggest that new technology and problem-solving techniques assist in keeping clients socially active.*
- Assess the client for feelings of loneliness. **EB:** *According to Pikhartova et al (2014), the report of loneliness is contingent on sociodemographic factors, such as gender, household income, household living arrangements, and health status.*
- Explore ways to increase the client's support systems. **EBN:** *Nurses must recognize those who need help in dealing with their loneliness and provide direction and support (Kirkevoid et al, 2013).*
- Show respect for the client's personal attributes. **EB:** *Grover (2014) characterizes respect as an expression of trust that another person has value.*

Adolescents

- Assess the client's social support system. **EB:** *According to Rowe et al (2014), relationship impediments and a lack of knowledge about where to go for support may hold back an adolescent from seeking help.*
- Evaluate the family stability of adolescent clients. **EBN:** *In their review of literature, Kao et al (2014) found that family efficacy, characterized as a family's confidence in its ability to manage varied situations and to realize a desired outcome, is associated with the decreased likelihood of adolescents engaging in risky health behaviors.*
- Evaluate peer relationships. **EBN:** *In comparison to those who describe poor family and peer relationships, it was found that positive familial and peer support are factors in the reduction of adolescents' reports of risky behaviors (Saftner et al, 2011).*
- Encourage social support for clients with disabilities. **EB:** *In their revisit of a 2006 study involving young adults who suffer from chronic health disorders, Sattoe et al (2014) found that social participation was strongly connected to the client's feelings of independence and self-efficacy.*
- Encourage relationships with peers and involvement with groups and organizations. **EBN:** *There is a need to provide interventions that will promote connectedness and battle loneliness for at-risk adolescents in the out-of-school time frame (Ruiz-Caseres, 2012).*

Geriatric

- Evaluate the client for any health deviations that may limit or decrease his/her ability to interact with others. **EB:** *A study by Kvaal et al (2014) makes the point that loneliness is extensive among older people suffering from chronic physical illness.*

- Assess family caregivers of older persons with chronic conditions for depression related to loneliness. **EBN:** *Caregivers of loved ones many times are subjected to physical, psychological, emotional, social, and financial effects that can be called “caregiver burden”: interventions that address caregiver burden may allow the caregivers to postpone placing the client in an extended care facility and enhance the quality of life for both the caregiver and care recipient (Sorrell, 2014).*
- Identify support systems for older adults. **EB:** *Senior centers are ideal settings for providing evidence-based health programs to the fast growing population of older adults and to help facilitate their continued good health and independence (Felix et al, 2014).*
- When relocation is necessary for older adults, evaluate relocation stress as a contributing factor to loneliness. **EB:** *This preliminary study by Theurer et al (2014) suggests that mutual support groups have potential to offset loneliness, helplessness, and depression among clients in extended care facilities.*
- Identify risk factors for loneliness in older persons. **EBN:** *In their study of loneliness in older adults who live at home and in assisted living and extended care facilities, Kirkevoid et al (2013) found loneliness was associated with devastating losses, inactivity, feelings of futility, and social isolation. EBN: Practicing clinical nurses should recognize the importance of social, not just family, support for those older persons living in an extended care facility (Drageset et al, 2011).*
- Encourage support for the client when the decision to stop driving must be made. **EB:** *In the interest of public safety, Reisman (2011) makes a case for a vastly improved policy structure to help get unsafe older drivers off the road.*
- Provide activities that are pleasurable to the client. **EB:** *In their review of one of the results of the English Longitudinal Study on Aging, Gale et al (2014) found that older people who take pleasure in life tend to live longer, indicating that psychological well-being could be a promising resource for healthier aging. Refer to the care plan for **Social** isolation for additional interventions.*

L

Multicultural

- Refer to the care plan for **Social** isolation.

Home Care

- ▲ The preceding interventions may be adapted for home care use.
- ▲ Assess for depression with the lonely older client and make appropriate referrals. **EB:** *Depression, having no caregiver, and never having been married are all identifiable risks for loneliness in older persons living alone and are indicators of possible poor quality of life and the need for social and medical interventions (Bilotta et al, 2012). EB: At risk for intensive loneliness are the divorced, the recently widowed, those who live alone, those who suffer failing health, and those in disadvantaged areas (Ferguson, 2011).*
- If the client has unexplained somatic complaints, evaluate these complaints to ensure that physical needs are being met, and assess for a possible relationship between somatic complaints and loneliness. **EBN:** *It has been found that treating widespread but underreported pain in older persons, both those confined to an extended care facility and those at home, decreases loneliness and depression (Tse et al, 2012).*
- Evaluate alternatives to being alone. **EB:** *O'Connor et al (2014) conducted a preliminary study of an online support group for those isolated while caring for clients with dementia; the study establishes the viability of interactive groups in virtual environments to connect members in significant interaction.*
- Refer to the care plan for **Social** isolation.

Client/Family Teaching and Discharge Planning

- Identify the type of loneliness that the client is experiencing: emotional and/or social. **EB:** *If both emotional and social loneliness are to be reduced in older people, strategies should be directed to widening the ranges of interventions (Dahlberg & McKee, 2014).*
- Encourage family members' involvement, if possible, in helping alleviate client's loneliness. **EBN:** *Decreased satisfaction with family support was one of the important predictors of depression levels in older people: this is a factor that should be taken into account when planning care (Tanner et al, 2014).*
- Include the family, if possible, in all client-teaching activities, and give them accurate information. **EBN:** *There is a current call to individualize client and family teaching in discharge planning (Spykopoulos et al, 2011).*

- Provide appropriate education for clients and their support persons about disease transmission and treatment if applicable. **EBN**: *It is of utmost importance to form an agreeable partnership between the client, his/her family, and/or caregivers who will provide support in the delivery of essential care and the control and prevention of infectious disease (Swanson & Jeanes, 2011).*
- Refer to the care plan for **Social** isolation for additional interventions.

List of Nursing Diagnoses by Letter: M

Risk for disturbed Maternal–Fetal dyad	Impaired Memory	Impaired bed Mobility
Impaired physical Mobility	Impaired wheelchair Mobility	Impaired Mood regulation
Moral Distress		

Risk for disturbed Maternal–Fetal dyad *Dianne Frances Hayward, RN, MSN, WHNP*

NANDA-I

Definition

Vulnerable to disruption of the symbiotic maternal–fetal dyad as a result of comorbid or pregnancy-related conditions, which may compromise health

Risk Factors

Alteration in glucose metabolism (e.g., diabetes mellitus, steroid use); compromised fetal oxygen transport (due to anemia, asthma, cardiac disease, hypertension, seizures, premature labor, hemorrhage); inadequate prenatal care; pregnancy complication (e.g., premature rupture of membranes, placenta previa/abruption, multiple gestation); presence of abuse (e.g., physical, psychological, sexual); substance abuse; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Fetal Status: Antepartum, Intrapartum; Maternal Status: Antepartum, Intrapartum; Depression Level; Diabetes Self-Management; Family Resiliency; Knowledge: Hypertension Management; Substance Use Control; Nausea and Vomiting Severity; Social Support; Spiritual Support

Example NOC Outcome with Indicators

Maternal Status: Antepartum as evidenced by the following indicators: Emotional attachment to fetus/Coping with discomforts of pregnancy/Mood lability/Blood pressure/Blood glucose/Hemoglobin. (Rate the outcome and indicators of **Maternal Status: Antepartum**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Cope with discomforts of high-risk pregnancy until delivery of baby
- Adhere to prescribed regimens to maintain homeostasis during pregnancy

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

High-Risk Pregnancy Care; Intrapartal Care: High-Risk Delivery

Example NIC Activities—High-Risk Pregnancy Care

Determine the presence of medical factors that are related to poor pregnancy outcome (e.g., diabetes, hypertension, lupus erythematosus, herpes, hepatitis, HIV, multiple gestation, substance abuse, epilepsy); Provide educational materials that address the risk factors and usual surveillance tests and procedures

Nursing Interventions and Rationales

- Standardize internal and external transport forms using SBAR format (situation, background, assessment, recommendation) to provide safe and efficient transport of a high-risk pregnant client. **EBN**: *The SBAR protocol provides a concise and prioritized structure that supports consistent, comprehensive, and client-centered reports (Cornell et al, 2013).*
- Arrange for psychotherapeutic support when woman expresses intense fear related to high-risk pregnancy and fetal outcomes. Encourage verbalization of feelings, beliefs, and concerns about fetal well-being, maternal health, and family functioning. **EB**: *A French study emphasizes the importance of delivering*

appropriate psychological support for women with high-risk pregnancies in order to prevent depressive disorders and any potential negative sequelae in the perinatal period (Denis et al, 2012). **EB**: When a pregnant woman exhibits symptoms of anxiety, she might need counseling and/or treatment to decrease her anxiety (Rubertsson et al, 2014).

- Screen all antepartum clients for depression using a tool that evaluates the biopsychosocial-spiritual dimensions in a culturally sensitive way. **EBN**: When comprehensive screening is not included during antepartum care, there is less likelihood that significant information will be revealed. Subsequently, undiagnosed clinical depression in pregnancy may lead to serious perinatal complications such as inadequate maternal weight gain, preterm birth, and low infant birth weight (Breedlove & Fryzelka, 2011).

Additional Relevant Research: Rollans et al, 2013.

- Offer flexible visiting hours, private space for families, and nursing support for management of family stressors; provide distractors such as music, TV, and laptops with Internet access when a woman is hospitalized with a high-risk pregnancy. **EBN**: Women on bed rest due to complications of pregnancy face many types of stress, which can lead to emotional distress and the anxiety of being restricted. Interventions that promote a reasonable and safe amount of client control may empower women when many things are beyond their control (Rubarth et al, 2012).
- Focus on the abilities of a woman with disabilities by encouraging her to identify her support system, resources, and needs for modification of her environment. **EBN**: Pregnant women with disabilities, in particular those labeled “high risk,” should expect equal ease of access to appropriate maternity care and consultation as that experienced by their “low risk” or “normal” counterparts. Maternity services should encourage independence and autonomy in these vulnerable women as far as practicable and uphold their identity and worth as women and as mothers (Walsh-Gallagher D et al, 2011). Additional Relevant Research: Gajjar et al, 2014.
- Recognize patterns of physical abuse in all pregnant and postpartum women, regardless of age, race, and socioeconomic status. **EB**: Women who were involved in intimate partner violence were more susceptible to negative outcomes such as preterm birth and low birth weight infants (Shneyderman & Kiely, 2013). Women enduring domestic violence are often in denial. Pregnancy and immediately postpartum are highly vulnerable times for mothers and their infants to experience domestic violence. These women also need to be assessed regularly because they may not be ready to seek help at first. This may be the only time a pregnant victim of domestic violence comes in contact with a health care provider who can assess for the abuse and take action to resolve it (Menezes Cooper, 2013).
- Perform accurate blood pressure readings at each client’s clinic encounter. **EB**: Elevated blood pressure during pregnancy, regardless of etiology and even without known risk factors, indicates high risk for pre-eclampsia and for later cardiovascular disease, chronic kidney disease, and diabetes mellitus. Close clinical monitoring, risk factor assessment, and early intervention could identify and treat women and their babies for hypertension in pregnancy and its sequelae (Mannisto et al, 2013). Additional Relevant Research: Hogan et al, 2012.
- Provide educational materials and support for personal autonomy about genetic counseling and testing options before pregnancy, that is, preimplantation genetic testing, or during pregnancy, that is, fetal nuchal translucency ultrasound, quadruple screen, cystic fibrosis. **EBN**: Ethical principles of autonomy, nonmaleficence, and justice must be considered when discussing genetic counseling and testing with a pregnant woman and her family (Lewis, 2011; McCormick, 2011). **EBN**: Direct to consumer genetic testing has presented several challenges to health care providers in that consumers now have access to tests that they may not fully understand, results of which they may act upon inappropriately (Beery, 2014).
- Identify adherence barriers and assist with meal selections to maintain optimal nutrition and safe pregnancy weight gain (25 to 35 pounds; 15 to 25 pounds if overweight). Identify cultural beliefs and nutritional patterns. A prenatal vitamin with 400 mcg of folate should also be strongly recommended. **EB**: Maternal body weight and diet quality, even before pregnancy, can affect the uterine environment, birth weight, and baby’s health into adulthood. A British task force showed that many women are not following nutritional guidelines. Pregnancy provides an opportunity for health care professionals to encourage women to make dietary improvements (e.g., following “myplate.com”), because women tend to be more motivated to change aspects of their diet and lifestyle during this time (Williamson & Wyness, 2013). All women in the reproductive years should consume at least 400 mcg of folic acid per day to reduce the risk for neural tube defects (Littleton-Gibbs & Engebretson, 2013).
- Teach pregnant women diagnosed with gestational diabetes about management and treatment. **EBN**: Gestational diabetes has short- and long-term implications for both the mother and the infant. To reduce

this morbidity, it is essential to teach the client how to maintain adequate blood glucose levels during pregnancy. When diet and exercise are not enough to control blood glucose levels, drug therapy is the next option. While insulin remains the treatment of choice, insulin therapy requires sufficient education and skills on the part of the woman with gestational diabetes to be properly managed, and may cause hypoglycemia, fear, and anxiety (Mnatsakanyan et al, 2014).

- Use the five A's (tobacco cessation interventions) to treat tobacco use and dependence in pregnant women. **CEB:** According to the *U.S. Department of Health and Human Services Clinical Practice Guidelines (2008)*, health care professionals should at every contact (1) ask if a woman is a tobacco user, (2) advise her to quit, (3) assess her willingness to quit, (4) assist with the quit attempt (such as counseling, medication), and (5) arrange for follow-up (telephone support 1-800-QUIT-NOW). The evidence is compelling that even a minimal (less than 3 minute) intervention can make a difference in motivation to quit smoking.
- When questioning at-risk clients regarding recreational drug use, ask if they have used substances such as marijuana or cocaine within the last month, instead of questioning whether they have used within the last few days. **EB:** A study demonstrated that the use of these substances correlates best with the toxicology screens if women are asked if they have used these substances within the month (Yonkers et al, 2011).
- Refer clients who self-report drug abuse or have positive toxicology screens to a comprehensive addiction program designed for the pregnant woman. Children born to addicted mothers often have poor neonatal outcomes. **EBN:** The drug addict is obsessed by the drug of choice because of a change in the pathophysiology of the brain. Treating addiction as a chronic disease instead of a moral weakness is more supportive to women who abuse drugs. It is important to involve a pregnant woman in a treatment program like a methadone clinic to help to stabilize the maternal–fetal dyad. Methadone prevents withdrawal symptoms and eliminates drug craving. Methadone blocks the euphoric effects of illegal self-administered narcotics. It also supports stable maternal opioid levels to protect the fetus from repeated occurrences of withdrawal and decreases the risk for sexually transmitted infections by decreasing drug-seeking behaviors such as prostitution. When a woman makes the decision to enroll in a methadone treatment program, she is taking a significant step toward recovery (Maguire, 2014).
- Encourage pregnant women to use electronic resources, such as Text4Baby or whattoexpect.com, to track pregnancy progress and provide education and motivation to make healthy lifestyle choices (abstinence from poor nutrition, smoking, alcohol). **EBN:** Making education fun, interactive, and personal can encourage women to make behavior modifications for healthier outcomes (Jordan et al, 2011).

Impaired Memory Graham J. McDougall, Jr., PhD, RN, FAAN, FGSA

NANDA-I

Definition

Inability to remember or recall bits of information or behavioral skills

Defining Characteristics

Forgetfulness; forgets to perform a behavior at scheduled time; inability to learn new skill; inability to perform a previously learned skill; inability to recall events; inability to recall factual information; inability to recall if a behavior was performed; inability to retain new information.

Related Factors (r/t)

Alterations in fluid volume; anemia; decrease in cardiac output; distractions in the environment; electrolyte imbalance hypoxia; neurological impairment (e.g., positive EEG, head trauma, seizure disorders)

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cognitive Orientation; Memory; Neurological Status: Consciousness

Example NOC Outcome with Indicators

Memory as evidenced by the following indicators: Recalls immediate information accurately/Recalls recent information accurately/Recalls remote information accurately (Rate each indicator of **Memory**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate use of techniques to help with memory loss
- State he or she has improved memory for everyday concerns

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Intervention

Memory Training; Realistic Appraisal of Memory

Example NIC Activities—Memory Training

Stimulate memory by repeating client's last expressed thought, as appropriate; Provide opportunity to use memory for recent events, such as questioning client about a recent outing; Give examples of external memory strategies, such as using a calendar

Nursing Interventions and Rationales

- Assess overall cognitive function and memory. The emphasis of the assessment is everyday memory, the day-to-day operations of memory in real-world ordinary situations. A screening instrument such as the

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Mini-Mental State Examination (MMSE) is useful as a first level of evaluation. **EB:** *The MMSE can help determine whether the client has cognitive impairment and delirium and needs to be referred for further evaluation and treatment (Lacy et al, 2014).*

- Determine whether onset of memory loss is gradual or sudden. If memory loss is sudden, refer the client to a health care provider or neuropsychologist for evaluation. **EB:** *Acute onset of memory loss may be associated with neurological disease, medication effect, electrolyte disturbances, hypoxia, hypothyroidism, mental illness, post-traumatic stress disorder, drug addiction, or many other physiological factors (Schwabe et al, 2014).*
- Determine amount and pattern of alcohol intake. *Alcohol intake has been associated with blackouts; clients may function but not remember their actions. Higher average weekly quantity and frequency of alcohol consumed in midlife were associated in old age with faster decline in all cognitive domains (Gross et al, 2011; Sabia et al, 2014).*
- ▲ Note the client's current medications and intake of any mind-altering substances, such as benzodiazepines, ecstasy, marijuana, cocaine, or glucocorticoids. *Benzodiazepines, oxybutynin, amitriptyline, fluoxetine, and diphenhydramine can produce memory loss for events that occur after taking the medication; information is not stored in long-term memory.*
- ▲ Note the client's current level of anxiety and stress. Ask if there has been a recent traumatic event (Luijten et al, 2014). *Post-traumatic stress and anxiety-inducing general life factors may induce memory problems. Stress or elevated cortisol levels temporarily block memory retrieval (Bauer et al, 2013; Zlomuzica et al, 2014).*
- Encourage the client to develop an aerobic exercise program. **EB:** *Reviews demonstrated that diet and lifestyle may prevent the onset of age-related problems and can lead to improvements in cognition and memory (Meeusen, 2014; Wang et al, 2014).*
- Determine the client's sleep patterns. If sleep quantity and quality is insufficient, refer to care plan for Disturbed Sleep pattern. **EB:** *A review provided evidence of a range of cognitive deficits identified in untreated obstructive sleep apnea clients. Clients reported difficulty in concentrating, increased forgetfulness, an inability to make decisions, and falling asleep at the wheel of a motor vehicle (Jackson et al, 2011).*
- ▲ Determine the client's blood sugar levels. If they are elevated, refer to health care provider for treatment and encourage healthy diet and exercise. *Oxidative stress was found to be associated with type 2 diabetes mellitus, but was not a risk factor for the development of Alzheimer's disease (Butterfield et al, 2014). However, the need to rule out diabetes is a relevant concern for a differential diagnosis.*
- ▲ If signs of depression such as weight loss, insomnia, or sad affect are evident, refer the client for psychotherapy. *Depression may result in deficits in executive functions (Alves et al, 2014; Baune & Renger, 2014).*
- ▲ Question the client about cholesterol level. If it is high, refer to health care provider or dietitian for help in lowering. Encourage the client to eat a healthy diet, avoiding saturated fats and trans-fat acids. **EB:** *A systematic review of studies found that statins could not be recommended as a preventive treatment for dementia (Stranahan & Mattso, 2012).*
- Suggest clients use cues, including alarm watches, electronic organizers, calendars, lists, or pocket computers, to trigger certain actions at designated times. *Cues and external cognitive strategies can help remind clients of certain actions, particularly for future intentions known as prospective memory (Yubero et al, 2011).*
- Encourage the client to participate in a multicomponent cognitive rehabilitation program that recommends stress and relaxation training, physical activity, and external memory devices, such as a calendar for appointments and reminder lists. *Using reminders can serve as cues for memory-impaired clients (Nouchi et al, 2012).*
- Help the client set up a medication box that reminds him/her to take medication at prescribed times; assist the client with refilling the box at intervals if necessary. *Medication boxes are effective because clients will know whether medication has been taken when corresponding compartments are empty.*
- If safety is an issue with certain activities (e.g., the client forgets to turn off stove after use or forgets emergency telephone numbers), suggest alternatives such as using a microwave or a whistling teakettle for heating water and programming emergency numbers in the telephone so that they are readily available.
- ▲ Refer the client to a memory clinic (if available), a neuropsychologist, or an occupational therapist. *Memory clinics can help the client learn ways to improve memory. Clinics may be more effective for minority older adults if work is done in groups because of increased support, reinforcement, and motivation. Of 677*

eligible Hispanic clients approached in Los Angeles, 329 (49%) were screened and 77 (23%) met criteria for memory impairment (Harris et al, 2011).

- For clients with memory impairments associated with dementia, see care plan for Chronic Confusion.

Geriatric

- Assess for signs of depression. *Depression is an important affective variable for memory loss in older adults. Antidepressant drug therapy has not been associated with reducing the burden of depression in older adults and often causes side effects in older adults, which may limit the effectiveness of treatment for depression (Mulsant et al, 2014).* **EB:** *In a study, those participants with current depression had significantly higher levels of psychological distress and anxiety, and lower life satisfaction, and performed worse on memory and executive function compared to participants without depression. After controlling for anxiety, the effect on executive function was no longer significant while the effect on memory remained significant. When someone had a history of depression, he/she was likely to have worse executive function, higher levels of psychological distress and anxiety, and lower life satisfaction (Reppermund et al, 2011).*
- Perform a nutritional assessment. If nutritional status is marginal, confer with a dietitian and primary health care practitioner to evaluate whether the client needs supplementation with foods or vitamins. Teach the client the need to eat a healthy diet with adequate intake of whole grains, fruits, and vegetables to decrease cerebrovascular infarcts. *Moderate, long-term deficiencies of nutrients, particularly vitamin B₁₂ deficiency in older adults may lead to irreversible neurological damage, anemia, osteoporosis, cerebrovascular cardiovascular diseases, and cognitive deficits. This condition may be preventable or diminished (Chatthanawaree, 2011).* **EB:** *A large study demonstrated a protective effect against stroke in people who had high daily intake of raw fruits and vegetables (Griep et al, 2011).*
- Evaluate all medications that the client is taking to determine whether they are causing the memory loss. (Evaluate all *herbal and/or nutraceutical products* that the individual might be using to improve memory function, particularly Ginkgo biloba (Diamond & Bailey, 2013).
- Recommend that older clients maintain a positive attitude and active involvement with the world around them and that they maintain good nutrition. **CEB:** *Of the total of 1672 brain autopsies from the Adult Changes in Thought study, Honolulu-Asia Aging Study, Nun Study, and Oregon Brain Aging Study, 424 met the criteria for cognitively normal (CN). The lesions in each individual and the associated comorbidity varied widely within each study but were similar across studies. There was a convergence of subclinical diseases in the brains of older CN adults that varied widely (Sonnen et al, 2011).*
- Encourage older adults to believe in themselves and to work to improve their memory. Negative attitudes and beliefs may decrease motivation and impair everyday memory function. *Research has shown that there is formation of new neurons in the brain, a process called neurogenesis, throughout the lifespan, and stimulation of the brain is necessary for this formation (McDougall et al, 2010a).* **CEB:** *Octogenarians were able to improve their memory performance when they challenged their limits, used appropriate strategies, practiced yoga, and invested the energy and time in learning novel memory techniques (McDougall et al, 2015).*
- Refer the client to a memory improvement class that focuses on helping older adults learn memory strategies. **CEB/EB:** *Research has demonstrated that cognitive training focused on memory strategies and stress reduction may improve memory performance and decrease negative control beliefs (McDougall et al, 2010a). A 195-hour training program used a tablet computer and associated software applications (Chan et al, 2014). Episodic memory and processing speed improved in the older adults in the experimental condition.*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the family or caregiver's understanding of impaired memory. *Minority elders have misconceptions in knowledge, awareness, and beliefs about Alzheimer's disease (Darnell et al, 2011).*
- When assessing memory in Mexican Americans, the MMSE has been used with success. **EB:** *Cultural factors and variables related to preferred language use determined variations in MMSE performance. However, the memory domain of the MMSE is less affected by education and is appropriate to use with other cognitive tests for early detection of cognitive decline in older populations with low education (Matallana et al, 2011).*
- Inform the client's family or caregiver of meaning of and reasons for common behavior observed in the client with impaired memory. **CEB:** *Memory training in a triethnic sample produced differential benefits.*

Both Hispanics and blacks performed better than whites on visual memory, and blacks performed better over time on instrumental activities of daily living (McDougall et al, 2010b).

- Attempt to validate family members' feelings regarding the impact of the client's behavior on family lifestyle. **EBN:** Validation therapy is a communication technique that lets the client with dementia know that the nurse has heard and understands what was said. In this nurse-client relationship, however, there is insufficient evidence to make any conclusion about its efficacy for reducing or reversing symptoms of dementia or cognitive impairment (Zimmerman et al, 2013).

Home Care

- The above interventions may be adapted for home care use.
- Assess the client's need for outside assistance with recall of treatment, medications, and willingness/ability of family to provide needed support. *During initial phase of home care, increased frequency of visits may be necessary to compensate for the client's inability to recall treatment and medications. Counting of medications may be needed to determine whether the client is following the medication regimen. Telephone calls from family/friends may help remind the client of treatment schedule.*
- Identify a checking-in support system (e.g., Lifeline or significant others). *Checking in ensures the client's safety.*
- Keep furniture placement and household patterns consistent. *Change increases risk of impaired memory and decreased functioning.*

Client/Family Teaching and Discharge Planning

- When teaching the client, determine what the client knows about memory techniques and then build on that knowledge. *New material is organized in terms of what knowledge already exists, and efficient teaching should attempt to take advantage of what is already known in order to graft on new material (McDougall et al, 2014).*
- When teaching a skill to the client, set up a series of practice attempts that will enhance motivation. Begin with simple tasks so the client can be positively reinforced and progress to more difficult concepts. *Distributed practice with correct recall attempts can be a very effective teaching strategy. Widely distribute practice over time if possible (Gross et al, 2014).*
- Teach clients to use memory techniques such as concentrating and attending, repeating information, making mental associations, and placing items in strategic places so that they will not be forgotten. *These methods increase recall of information the client thinks is important. The internal methods of increasing memory can be effective, especially if used along with external methods such as calendars, lists, and other methods (Rebok et al, 2013).*

Impaired bed Mobility Wendie A. Howland, MN, RN-BC, CRRN, CCM, CNLCP, LNCC

NANDA-I

Definition

Limitation of independent movement from one bed position to another

Defining Characteristics

Impaired ability to move between long sitting and supine positions; impaired ability to move between prone and supine positions; impaired ability to move between sitting and supine positions; impaired ability to reposition self in bed; impaired ability to turn from side to side

Related Factors

Alteration in cognitive functioning; environmental barrier (e.g., bed size, bed type, equipment, restraints); insufficient knowledge of mobility strategies; insufficient muscle strength; musculoskeletal impairment; neuromuscular impairment; obesity; pain; pharmaceutical agent; physical deconditioning

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Immobility Consequences: Physiological; Mobility; Self-Care: Activities of Daily Living (ADLs)

Example NOC Outcome with Indicators

Immobility Consequences: Physiological as evidenced by the following indicators: Pressure sores/Constipation/Hypoactive bowel/Paralytic ileus/Urinary calculi/Contracted joints/Venous thrombosis/Pneumonia. (Rate the outcome and indicators of **Immobility Consequences: Physiological**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate optimal independence in positioning, exercising, and performing functional activities in bed
- Demonstrate ability to direct others on how to do bed positioning, exercising, and functional activities

NIC Interventions (Nursing Interventions Classification)

Suggested NIC interventions

Bed Rest Care

Example: NIC Activities—Best Rest Care

Position in proper body alignment; Teach bed exercises, as appropriate

Nursing Interventions and Rationales

- Choose therapeutic bed positions based on client's history and risk profile; assess to determine if positioning for one condition may negatively affect another; use critical thinking skills for risk-benefit analysis. *Because aspiration is a threat to oxygenation, for some clients this risk is greater and provides a more immediate concern than pressure ulcers risk in critically ill clients (Metheny & Frantz, 2013). Increased acuity of a client should drive turning frequency, which may include small shifts in weight and/or hourly repositioning (Makic et al, 2014).*
- Assess risk for aspiration; if present, elevate head of bed (HOB) to 30 to 45 degrees unless contraindicated and elevate HOB to 90 degrees during oral intake of fluids, solids, and oral medications. **EB**: *Implementing an aspiration prevention protocol was effective in reducing the occurrence of postoperative pneumonia (Starks & Harbert, 2011).*
- Raise HOB to 30 degrees for clients with acute increased intracranial pressure and brain injury. Refer to care plan for Decreased **Intracranial** adaptive capacity.
- ▲ Consult health care provider for HOB elevation for acute stroke and monitor response. Refer to care plan for Decreased **Intracranial** adaptive capacity.
- Raise HOB as close to 45 degrees as possible for critically ill ventilated clients to prevent pneumonia (this height may place clients at higher risk for pressure ulcers). Elevating the HOB decreases regurgitation and risk for aspiration of gastric contents. **EB**: *Researchers reviewed random controlled trials/reviews of prevention of ventilator-associated pneumonia (VAP), and their recommendations included elevating HOB to 30 to 45 degrees unless contraindicated. Implementing an aspiration prevention protocol was effective in reducing the occurrence of postoperative pneumonia (Starks & Harbert, 2011; American Association of Critical-Care Nurses, 2011).*
- Assist client with dysphagia to sit as upright as possible for oral intake, including solids, fluids, and oral medications. Refer to care plan for Impaired **Swallowing**.
- Periodically sit client as upright as tolerated in bed; dangle client, if vital signs and oxygen saturation levels remain stable. *Placing a client who is generally immobilized in a recliner is a good alternative to the bed (Gefen et al, 2013). Being vertical reduces the work of the heart, improves circulation/lung ventilation/strength, and stimulates reflexes and awareness of surroundings.*

- To prevent pressure ulcers, maintain HOB at lowest elevation that is medically possible and raise the foot of the bed to prevent shear-related injury. Assess the client's sacrum, ischial tuberosities, and heels at least every 2 hours. **EB:** *Shear results when external friction stretches the top layers of the skin as it slides against underlying layers and as internal tissues slide over deeper muscle and bone. These forces increase over the ischial tuberosities and sacrum when the backrest of the bed is elevated and result in tissue damage. Raising the foot of the bed in proportion to the head of the bed to distribute weight brings the body into maximum contact with the supporting surface, helping to eliminate shear. Placing a client who is generally immobilized in a recliner is a good alternative to the bed (Gefen et al, 2013; Berowitz et al, 2014).*
- Try prone positioning for clients with acute respiratory distress syndrome (ARDS), acute lung injury (ALI), and amputation and monitor their tolerance/response. **EB:** *Evidence varies but suggests that oxygenation, VAP, and mortality may be positively affected by prone positioning. In cases of severe ARDS, early prone positioning sessions significantly decreased 28- and 90-day mortality (Guerin et al, 2013). Prone positioning after both above the knee and below the knee amputations promotes extension, preventing flexor contractions in lower extremity residual joints (Gosselin & Smith, 2014; Wright & Flynn, 2011; Gattinoni et al, 2013).*
- Assess client's risk for falls using a valid fall risk assessment tool, such as the Morse Fall Scale (Morse et al, 1987). **CEB:** *Establish individualized fall prevention strategies and perform post-fall assessment to further refine fall prevention interventions. EB:* *The fall prevention program should include fall prevention interventions as well as assessment of risk and assessment of a fall (Hill & Fauerbach, 2014).*
- Beds should be kept locked and in the lowest position when occupied. Specialty low beds in which mattresses are approximately 8 to 12 inches from the floor are helpful for clients at risk for falls. Cushioned mats, two to three inches thick, with beveled edges lined with reflective tape and covered by a rubberized material are also helpful. *Mats seemed to provide "a protective effect" for the pelvis during head-first falls and for the thorax during feet-first falls (Hill & Fauerbach, 2014).*
- ▲ Bed rails and restraints must be prescribed by a health care provider.
- ▲ While placing all four bed rails up is considered a form of restraint and requires a health care provider's order, two and even three rails up can be a support for bed mobility. *Nursing staff can work with physical and occupational therapists to determine the most effective techniques for bed mobility, including recommendations on the number of bedrails (Hill & Fauerbach, 2014).*
- Place frequently used items within client's reach; demonstrate use of call bell (Hill & Fauerbach, 2014).
- Use a formalized screening tool to identify clients who are at high risk for thromboembolism, or deep venous thrombosis. **EB:** *Best clinical practice encourages the use of a clinical decision tool that determines deep venous thrombosis risk based on predisposing factors and certain clinical signs and symptoms (Anthony, 2013).*
- ▲ Implement thromboembolism prophylaxis and treatment as prescribed (e.g., anticoagulants, antiembolic stockings, elastic leg wraps, sequential compression devices, feet/ankle exercises, and hydration). Refer to care plan for Ineffective peripheral **Tissue Perfusion**.
- Use a valid and reliable tool to assess a client's risk for pressure ulcers. **EB:** *Braden sensory perception and friction/shear subscales and Waterlow mobility and appetite subscales were the most relevant predictors (Serpa et al, 2011).*
- Implement the following interventions to prevent pressure ulcers and complications of immobility:
 - Position sitting clients with special attention to the individual's anatomy, postural alignment, distribution of weight, and foot support.
 - Placing a client who is generally immobilized in a recliner is a good alternative to the bed (Gefen et al, 2013).
 - Turn (logroll) clients at high risk for pressure/shear/friction frequently and regularly. **EBN:** *Pressure redistribution surfaces cannot replace turning and repositioning. Most pressure ulcers are avoidable; however, clients with hemodynamic instability that is worsened with movement, inability to maintain nutrition and hydration status, and advanced directive prohibiting turning may result in unavoidable pressure ulcers (National Pressure Ulcer Advisory Panel, 2011).*
- Pressure redistribution surfaces cannot replace turning and repositioning.
 - Use static/dynamic bed surfaces and assess for "bottoming out" under susceptible bony areas (body sinks into mattress, thus the recommended 1 inch between mattress/bones is absent). Refer to care plan for Risk for impaired **Skin** integrity.
 - Use heel protection devices that completely float or offload heels (National Pressure Ulcer Advisory Panel, 2011).

- Implement a 2-hour on/off schedule for heel protector boots or high-top tennis shoes with socks underneath in clients with paralyzed feet, and check condition of heels when removed.
- Strictly maintain leg abduction in persons with a surgical hip pinning or replacement by placing an abductor splint/pillow between legs as prescribed.
- Place bariatric beds along a corner wall, which helps keep the bed from moving during repositioning.
- Identify/modify hospital beds with large gaps between bed rail/mattress that create an entrapment hazard. Ensure that mattresses fit the bed; install gap fillers/rail inserts, then monitor effectiveness.
- Use devices such as trapeze, friction-reducing slide sheets, mechanical lateral transfer aids, and ceiling-mounted or floor lifts to move (rather than drag) dependent or obese clients in bed to prevent injury to staff.
 - Use special beds and equipment to move bariatric (very obese) clients, such as mattress overlay, sliding/roller board, trapeze, stirrup, and pulley attached to overhead traction system (holds one leg up during pericare).
 - Place bariatric clients in free-standing or ceiling-mounted lifts with padded slings while changing bed linen. **EB:** *The potential for reductions in injury rates in the United States is greatest from improving training and ensuring adequate time for resident care, in that most facilities currently have lifts available (D'Arcy et al, 2012).*
- Apply elbow pads to comatose and/or restrained clients and to those who use their elbows to prop or scoot up in bed. Apply nocturnal elbow splint as ordered if ulnar nerve palsy exists or if painful elbow with paresthesia in ulnar side of fourth/fifth fingers develops. *The use of pads assists with preventing prolonged compression or flexion pressure on the ulnar nerve, causing neuropathy/nerve damage. Consider using an enclosure bed for agitated clients to alleviate restraints, thus preventing arm abrasions, nerve damage, and pain.*
- Explain importance of exhaling versus holding one's breath (Valsalva maneuver) and straining during bed activities.
- Reassess pain level, especially before movement and/or exercising, and accept clients' pain rating and level they think is appropriate for comfort. Administer analgesics based on clients' pain rating. Refer to Acute **Pain** or Chronic **Pain**.

Exercise

- Test strength in bilateral grips, arms at elbow flexion and extension, bilateral arm abduction and adduction, bilateral leg or thigh raise (one at a time in bed or chair), and quadriceps and hamstring strength to extend and flex at knee to assess baseline and interval strength gains.
- Perform passive range of motion (ROM) of three repetitions, at least twice a day, to immobile joints. *Perform ROM slowly and rhythmically. Do not range beyond point of pain. Range only to point of resistance in those with loss of sensation and mentation. Fast, jerky ROM increases pain and tone. Slow, rhythmical movements relax/lengthen spastic muscles so they can be ranged further. For clients with Parkinson's disease, consult with physical therapy for ROM exercises.*
- Range or move a hemiplegic arm with the shoulder slightly externally rotated (hand up).
- ▲ Encourage client's practice of exercises taught by therapists (muscle setting, strengthening, contraction against resistance, and weight lifting). *Exercises and weight lifting help maintain muscle tone, strength, and lengthening.*

Bed Positioning

- Incorporate the following measures to promote normal tone and prevent complications in clients with neurological impairment:
 - Use a flat head pillow when clients are supine. Use a small pillow behind the head and/or between shoulder blades if neck extension occurs. *Prevents contractures of the cervical spine and abnormal tone of the neck (Potter & Perry, 2013).*
 - Abduct the shoulders of clients with high paraplegia or quadriplegia horizontally to 90 degrees briefly two to three times a day while client is supine.
 - Position a hemiplegic shoulder fairly close to the client's body.
- ▲ Elevate a client's paralyzed forearms on a pillow when client is supine and apply Isotoner gloves. Elevate edematous legs on a pillow supporting the knees to prevent hyperextension. Apply elastic wraps and compression garments as prescribed.

- Tilt hemiplegics onto both unaffected and affected sides with the affected shoulder slightly forward (e.g., move/lift the affected shoulder, not the forearm/hand).
- ▲ Apply resting wrist, hand, and foot/ankle splints or other devices. Range joints before applying splints. Adhere to on/off schedule as prescribed by the physical therapist. *Check underlying tissues for signs of pressure/poor circulation every 2 hours or more often if client resists or manipulates them.*
- ▲ Recognize that components of normal bed mobility include rolling, bridging, scooting, long sitting, and sitting upright. Activity starts with the client supine, flat in bed, and promotes normal movements that are bilateral, segmental, well timed, and involve set positions such as weight bearing and trunk centering. Refer to a physical therapist (PT) for individualized instructions and mobility strategies.

Geriatric

- Assess caregiver's strength, health history, and cognitive status to predict ability/risk for assisting bed-bound clients at home. *Explore alternatives if risk is too high. Caregivers are often frail older adults with chronic health problems who cannot physically help loved ones.* Refer to care plan for **Caregiver Role Strain**.
- Assess the client's stamina and energy level during bed activities/exercises; if limited, spread out activities and allow rest breaks.

Home Care

- ▲ Collaborate with nurse case managers, care coordinators, social workers, and physical/occupational therapists to assess home support systems and needs, and to provide for home modifications, durable medical equipment, assistive technology, and home health services.
- Encourage use of the client's bed unless contraindicated. Raise HOB with commercial blocks or grooved-out pieces of wood under legs; set bed against walls in a corner. Emotionally, clients may benefit from sleeping in their own beds with familiar partners.
- Stress psychological/physical benefits of clients being as self-sufficient as possible with bed mobility/care even though it may be time-consuming. Allowing independence and autonomy may help prevent disuse syndromes and feelings of helplessness and low self-esteem.
- Offer emotional support and help client identify usual coping responses to help with adjustment and loss issues. The home environment may trigger the reality of lost function and disability.
- Discuss support systems available for caregivers to help them cope. Refer to care plan for **Caregiver Role Strain**.
- ▲ In the presence of medical disorders, institute case management for frail older adult to support continued independent living.
- Refer to the home care interventions in the care plan for Impaired physical **Mobility**.

Client/Family Teaching and Discharge Planning

- Use various sensory modalities to teach client/caregivers correct range of motion, exercises, positioning, self-care activities, and use of devices. Readiness and learning styles vary but may be enhanced with visual/auditory/tactile/cognitive stimulus as follows:
 - Provide visual information such as demonstrations, sketches, instructional videos, written directions/schedules, notes.
 - Provide auditory information such as verbal instructions, recorded audiotapes, timers, reading aloud written directions, and self-talk during activities.
 - Use tactile stimulation such as motor task practice/repetition, return demonstrations, note taking, manual guidance, or staff's hand-on-client's-hand technique.
- ▲ Schedule time with family/caregivers for education and practice for nursing, physical therapy, and occupational therapy. Suggest family come prepared with questions and wear comfortable, safe clothing/shoes. Practice provides opportunity for learning; repetition helps memory retention.
- ▲ Implement safe approaches for caregivers/home care staff and reinforce adequate number of people and handling equipment (e.g., friction pads, slide boards, lifts) during bed mobility, exercise, toileting, and bathing to decrease risk of injury.
- ▲ Coordinate evaluations for bariatric equipment for home use before discharge, including a weight-rated bed, a wheelchair or mobility device (scooter), and lift device. Doorways may need to be widened, floors reinforced, and ramps added for safety.

M

Impaired physical Mobility *Sherry H. Pomeroy, PhD, RN*

NANDA-I

Definition

Limitation in independent, purposeful physical movement of the body or of one or more extremities

Defining Characteristics

Alteration in gait, decrease in fine motor skills; decrease in gross motor skills; decrease in range of motion; decrease in reaction time; difficulty turning; discomfort; engages in substitutions for movement (e.g., attention to other's activity, controlling behavior, focus on pre-illness activity), exertional dyspnea; movement-induced tremor; postural instability; slowed movement; spastic movement; uncoordinated movement

Related Factors (r/t)

Activity intolerance; alteration in bone structure integrity; alteration in cognitive functioning; alteration in metabolism; anxiety; body mass index >75th percentile for age; contractures; cultural belief regarding appropriate activity; decrease in endurance; decrease in muscle control; decrease in muscle mass; decrease in muscle strength; depression; developmental delay; disuse; insufficient environmental support (e.g., physical, social); insufficient knowledge of value of physical activity; joint stiffness; malnutrition; musculo-skeletal impairment; neuromuscular impairment; pain; pharmaceutical agent; physical deconditioning; prescribed movement restrictions; reluctance to initiate movement; sedentary lifestyle; sensory-perceptual impairment

NOC

(Nursing Outcomes Classification)

Suggested NOC Outcomes

Ambulation; Ambulation: Wheelchair; Mobility; Self-Care: Activities of Daily Living (ADLs); Instrumental Activities of Daily Living (IADLs); Transfer Performance

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Example NOC Outcome with Indicators

Ambulation as evidenced by the following indicators: Walks with effective gait/Walks at moderate pace/Walks up and down steps/Walks moderate distance. (Rate the outcome and indicators of **Ambulation**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Meet mutually defined goals of increased ambulation and exercise that include individual choice, preference, and enjoyment in the exercise prescription
- Verbalize feeling of increased strength and ability to move
- Verbalize less fear of falling and pain with physical activity
- Demonstrate use of adaptive equipment (e.g., wheelchairs, walkers, gait belts, weighted walking vests) to increase mobility
- Increase exercise to 20 minutes per day for those who were previously sedentary (less than 150 minutes per week). NOTE: Light to moderate intensity exercise may be beneficial in deconditioned persons. In very deconditioned individuals exercise bouts of less than 10 minutes are beneficial.
- Increase pedometer step counts by 1000 steps per day every 2 weeks to reach a daily step count of at least 7000 steps per day, with a daily goal for most healthy adults of 10,000 steps per day (approximately 5 miles)
- Perform resistance exercises that involve all major muscle groups (legs, hips, back, chest, abdomen, shoulders, and arms) performed 2 or 3 days per week
- Perform flexibility exercise (stretching) for each of the major muscle-tendon groups 2 days per week for 10 to 60 seconds to improve joint range of motion; greatest gains occur with daily exercise
- Engage in neuromotor exercise 20 to 30 minutes per day including motor skills (e.g., balance, agility, coordination, and gait), proprioceptive exercise training, and multifaceted activities (e.g., tai chi and yoga) to improve and maintain physical function and reduce falls in those at risk for falling (older persons)
- Engage in purposeful moderate-intensity cardiorespiratory (aerobic) exercise for 30 to 60 minutes per day on at least 5 days per week for a total of 2 hours and 30 minutes (150 minutes) per week

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Exercise Therapy: Ambulation; Joint Mobility; Positioning

Example NIC Activities—Exercise Therapy: Ambulation

Assist the client to use footwear that facilitates walking and prevents injury; Instruct in availability of assistive devices, if appropriate

Nursing Interventions and Rationales

- Adults with disabilities should follow the adult guidelines; however, if not possible these persons should be as physically active as their abilities allow and avoid inactivity (U.S. Department of Health & Human Services, 2008). Use “start low and go slow” approach for intensity and duration of physical activity if client highly deconditioned, functionally limited, or has chronic conditions affecting performance of physical tasks. When progressing client’s activities, use an individualized and tailored approach based on client’s tolerance and preferences (American College of Sports Medicine [ACSM], 2014).
- Screen for mobility skills in the following order: (1) bed mobility; (2) supported and unsupported sitting; (3) transition movements such as sit to stand, sitting down, and transfers; and (4) standing and walking activities. **CEB**: Use a tool such as the *Assessment Criteria and Care Plan for Safe Patient Handling and Movement* (Sedlak et al, 2009). **EBN**: Assess for low mobility, functional difficulties, cognitive impairment and multiple comorbidities that require both client safety and rehabilitation interventions (Kneafsey et al, 2013).

- Screen for additional measures of physical function to assess strength of muscle groups, including unassisted leg stand, use of a balance platform, elbow flexion and knee extension strength, grip strength, timed chair stands, and the 6-minute walk. **CEB:** *The nursing assessment should include factors related to mobility problems (e.g., ability to walk and move), with nursing goals and interventions developed to promote maximum mobility (Kneafsey, 2007).* **EBN/QSEN:** *Client assessment and use of facility or organizational safe client handling algorithms and processes should be used to determine safe client movement (e.g., equipment introduction and safety huddles) and protect nurses from musculoskeletal injuries to reduce preventable disability, nursing turnover, and burnout (Hodgson et al, 2013).*
- Assess the client for cause of impaired mobility. Determine whether cause is physical, psychological, or motivational. *Some clients choose not to move because of psychological factors such as fear of falling or pain, an inability to cope, or depression.* **EBN:** *Because fear of falling is associated with immobility and functional dependence, it requires effective assessment and measurement (Greenberg, 2012).* Refer to care plans for Risk for Falls, Acute Pain, Chronic Pain, Ineffective Coping, or Hopelessness.
- Use Self-Efficacy for Exercise Scale (Resnick & Jenkins, 2000) and the Outcome Expectation for Exercise Scale (Resnick et al, 2001) to determine client's self-efficacy and outcome expectations toward exercise (Resnick & D'Adamo, 2011). **CEB:** *Use a fear of falling assessment, such as a one-item fear of falling question, Falls Efficacy Scale, or Mobility Efficacy Scale (Messecar, 2008).* **EBN:** *An integrative review concluded that fear of falling in high-risk community-dwelling older adults is best measured by the Falls Efficacy Scale-International (Greenberg, 2012).*
- Function focused care should be used, such as encouraging self performance of bathing, walking to the bathroom instead of using a bedpan/urinal, and taking the older adult to an exercise class (Resnick & Galik, 2013). **EBN:** *An integrative review concluded that fear of falling in high-risk community-dwelling older adults is best measured by the Falls Efficacy Scale-International (Greenberg, 2012).*
- Monitor and record the client's ability to tolerate activity and use all four extremities; note pulse rate, blood pressure, dyspnea, and skin color before and after activity. Refer to the care plan for Activity intolerance. **EB:** *Use valid and reliable screening procedures and tools to assess the client's preparticipation in exercise health screening and risk stratification for exercise testing (low, moderate, or high risk) (ACSM, 2014).*
- ▲ Before activity, observe for and, if possible, treat pain with massage, heat pack to affected area, or medication. Ensure that the client is not oversedated. *Pain limits mobility and if exacerbated by specific movements should be temporarily avoided (ACSM, 2014).*
- ▲ Consult with physical therapist for further evaluation, strength training, gait training, and development of a mobility plan. **CEB:** *Prescribing a regimen of regular physical activity that includes both aerobic exercise and muscle strengthening activities is beneficial to minimizing impaired mobility; use exercise diary or log to improve adherence to mobility enhancement recommendations. Develop mobility enhancement programs that are specific to gender and ethnicity and are culturally appropriate (Yeom et al, 2009).*
- Before the activity begins, obtain any assistive devices needed for activity, such as gait belt, weighted vest, walker, cane, crutches, or wheelchair, ergonomic shower chairs, ceiling and floor-based lifts, and air-assisted lateral transfer devices. *Assistive devices can help increase mobility (Hodgson et al, 2013).*
- If the client is immobile, perform passive range-of-motion (ROM) exercises at least twice a day unless contraindicated; repeat each maneuver three times. **EB:** *Physical rehabilitation interventions were found to be safe, reduced disability, and resulted in few adverse events (Foster et al, 2011).*
- ▲ If the client is immobile, consult with health care provider for a safety evaluation before beginning an exercise program; if program is approved, begin with the following exercises:
 - Active ROM exercises using both upper and lower extremities (e.g., flexing and extending at ankles, knees, hips)
 - Chin-ups and pull-ups using a trapeze in bed (may be contraindicated in clients with cardiac conditions)
 - Strengthening exercises such as gluteal or quadriceps sitting exercises
- If client is immobile, consider use of vertical transfer techniques such as air-assisted lateral transfer devices or gait belt pending weight-bearing status and client cooperation. *Using a transfer chair that can bend into a stretcher position and then upright can help previously immobile clients get out of bed (Gonzalez et al, 2009).* **CEB:** *Critical care clients are at high risk for complications related to immobility such as ventilator-associated pneumonia (VAP), atelectasis, and long-lasting functional limitations; therefore, once hemodynamically stable, use progressive mobilization to dangle legs, sit in a chair, stand and bear weight,*

and walk. Use rotation therapy (kinetic and continuous lateral) to reduce risk of VAP for clients on mechanical ventilation (Rauen et al, 2008).

- Help the client achieve mobility and start walking as soon as possible if not contraindicated. **EBN:** To prevent hospital-acquired disability, organizational values should consider both safety (e.g., fall prevention) and injury protection in concert with a philosophy that enables older adults to be self-directed and independent (Boltz et al, 2013). **CEB:** Early mobilization of orthopedic clients generally prevents medical complications such as deep vein thrombosis, allows clients time to practice using assistive devices or changes in weight-bearing status, and promotes improved function, reduces pain, and facilitates earlier return to independence (Radawiec et al, 2009).
- Use a gait-walking belt when ambulating the client. If the client is able to partially bear weight on one or both lower extremities, use a stand and pivot maneuver with a gait or transfer belt or powered standing assist lift (Gonzalez et al, 2009).
- ▲ Apply any ordered brace before mobilizing the client. Braces support and stabilize a body part, allowing increased mobility.
- Initiate a “no lift” policy where appropriate assistive devices are used for manual lifting. **EBN:** Relevance of manual client handling policies that may promote overuse of equipment should be openly discussed among nurse managers and direct care providers to avoid hospital-related loss of mobility among clients (Kneafsey et al, 2015). **CEB:** Use the algorithms provided by the National Association of Orthopaedic Nurses for safe client handling and moving during the following high-risk tasks: turning in bed side to side, vertical transfer of postoperative total hip replacement client and extremity cast/splint client, ambulation, and lifting or holding a limb without a cast or splint (Sedlak et al, 2009).
- Increase independence in ADLs, encouraging self-efficacy and discouraging helplessness as the client gets stronger. Providing unnecessary assistance with transfers and bathing activities may promote dependence and a loss of mobility. **EBN:** A function-focused care intervention (designed to optimize physical activity and function in clients with Parkinson’s disease) demonstrated a significant effect on increasing outcome expectations for exercise, improving functional performance, and increasing time spent in exercise and physical activity (Pretzer-Abhoff et al, 2011).
- ▲ If the client has osteoarthritis or rheumatoid arthritis, ask for a referral to a physical therapist to begin an exercise program that includes aerobic exercise, resistance exercise, and flexibility exercise (stretching). **EB:** Studies of functional outcomes of exercise in older adults and adults with knee arthritis found only a modest beneficial effect of progressive resistance training and cardiorespiratory programs on pain, strength, and function in both groups (Keysor & Brems, 2011). **EB:** In a study examining the achievement of physical activity (PA) goals in relation to quality of life and self-reported pain in persons with rheumatoid arthritis (RA), it was found that persons with higher levels of self-efficacy for PA were more likely to achieve personal PA goals. Higher quality of life scores and less perceived arthritis pain were also related to achieving PA goals. Clinicians can therefore support goal achievement by working with clients to foster self-efficacy, set realistic exercise goals with action plans, and provide feedback regarding progress (Knittle, 2011).
- ▲ If client has had a cerebrovascular accident (CVA) with hemiparesis, consider use of constraint-induced movement therapy, wherein the functional extremity is purposely constrained and the client is forced to use the involved extremity. **CEB:** The plasticity of the brain allows the brain to rewire and reroute neural connections to take up the work of the injured area of the brain. Constraint therapy was effective with improved motor function and health-related quality of life (Wu et al, 2007).
- If the client has had a CVA, recognize that balance and mobility are likely impaired, and engage client in fall prevention strategies and protect from falling. **EBN:** A randomized controlled trial studied the effects of a 6-month treadmill-training program versus a stretching program for stroke survivors. Both groups experienced increased self-efficacy for exercise and a significant increase in outcome expectations for exercise and ADLs on the Stroke Impact Scale (Shaughnessy et al, 2012).
- If the client does not feed or groom self, sit side-by-side with the client, put your hand over the client’s hand, support the client’s elbow with your other hand, and help the client feed self; use the same technique to help the client comb hair. **EBN:** Hospitalized older adults who received a family centered intervention to promote functional and cognitive recovery (Family-Centered Function-Focused Care) had improved ADLs and walking ability and less severe and shorter duration of delirium (Boltz et al, 2014). **CEB:** The effectiveness of a restorative care intervention on nursing home resident outcomes included significant improvements in the Tinetti Mobility Score and the subscores for gait and balance, as well as improved walking, bathing, and stair climbing (Resnick et al, 2009).

Geriatric

- Assess ability to move using valid and reliable criterion-referenced standards for fitness testing (e.g., senior fitness test) designed for older adults that can predict the level of capacity associated with maintaining physical independence into later years of life (e.g., get up and go test). *Interventions can subsequently be designed to target weak areas and therefore help reduce the risk of immobility and dependence (Rikli & Jones, 2012).*
- Help the mostly immobile client achieve mobility as soon as possible, depending on physical condition. **EB:** *A meta-analysis found exercise beneficial in increasing gait speed and improving balance and ADL performance (Chou et al, 2012).*
- For a client who is mostly immobile, minimize cardiovascular deconditioning by positioning the client in the upright position several times daily. *The hazards of bed rest in older adults are multiple, serious, quick to develop, and slow to reverse. Deconditioning of the cardiovascular system occurs within days and involves fluid shifts, fluid loss, decreased cardiac output, decreased peak oxygen uptake, and increased resting heart rate (Longo et al, 2012).* **EBN:** *A study of function-focused care (FFC) in hospitalized older adults found physical functional declines in both study groups, but less decline was associated with the group receiving FFC. The role of the gerontological rehabilitation nurse is essential throughout the hospital stay and during transitional care (Boltz et al, 2011).*
- ▲ Refer the client to physical therapy for resistance exercise training as able, involving all major muscle groups (e.g., abdominal crunch, leg press, leg extension, leg curl, and calf press) (ACSM, 2014). **CEB:** *A Cochrane review found that progressive resistance-strength training for physical disability in older clients resulted in increased strength and positive improvements in some limitations (Liu & Latham, 2009).*
- Use the FFC rehabilitative philosophy of care in older adults in residential nursing facilities to prevent avoidable functional decline. The primary goals of FFC are to alter how direct care workers provide care to residents to maintain and improve time spent in physical activity and improve or maintain function. **EBN:** *Residents in the FFC intervention group had less functional decline and a greater percentage who were not ambulating returned to ambulatory status for short functional distances (Resnick et al, 2011).*
- If client is scheduled for an elective surgery that will result in admission into the intensive care unit and immobility, or recovery from a joint replacement, for example, initiate a prehabilitation program that includes warm-up, aerobic activity, strength, flexibility, neuromotor, and functional task work. **EBN:** *The risk of declines in functional status when older adults are hospitalized requires using evidence-based strategies to reduce the incidence and impact of decreased mobility, pressure ulcers, pain, dehydration, malnutrition, and sequelae of invasive treatments. Examples of such strategies include completing comprehensive and interdisciplinary geriatric assessment at admission, implementing early mobilization, using assistive devices, ensuring appropriate footwear to encourage mobility and prevent falls, using environmental enhancements such as large clocks and calendars and elevated toilet seats, and evaluating benefits of medications versus side effects (American Academy of Nursing's Expert Panel on Acute and Critical Care, 2012).* **CEB:** *Aerobic training along with strength and interval training is effective and results in fewer postoperative complications, shorter postoperative stays, and reduced functional disabilities (Carli & Zavorsky, 2005).*
- ▲ Evaluate the client for signs of depression (flat affect, insomnia, anorexia, frequent somatic complaints), anxiety, or cognitive impairment (use Mini-Mental State Exam [MMSE]). Refer for treatment and counseling as needed. **CEB:** *Interventions to increase physical activity can reduce anxiety in healthy persons. Supervised physical activity (e.g., group or fitness center) as well as individual delivery and moderate to high intensity physical activity seem to be the most effective components in reducing anxiety (Conn, 2010).*
- Watch for orthostatic hypotension when mobilizing older clients. Have the client dangle at the side of the bed with legs hanging over the edge of the bed, flex and extend feet several times after sitting up, then stand up slowly with someone holding the client. If client becomes lightheaded or dizzy, return client to bed immediately. *Postural hypotension is common in older adults (Krecinic et al, 2009).*
- Do not routinely assist with transfers or bathing activities unless necessary. *The nursing staff may contribute to impaired mobility by helping too much. Encourage client independence (Resnick & Galik, 2013).*
- Use gestures and nonverbal cues when helping clients move if they are anxious or have difficulty understanding and following verbal instructions. *Nonverbal gestures are part of a universal language that can be understood when the client is having difficulty with communication.*
- Recognize that wheelchairs are not a good mobility device and often serve as a mobility restraint.
- Ensure that chairs fit clients. Chair seat should be 3 inches above the height of the knee. Provide a raised toilet seat if needed. *Raising the height of a chair can dramatically improve the ability of many older clients*

to stand up. Low, deep, soft seats with armrests that are far apart reduce a person's ability to get up and down without help.

- If the client is mainly immobile, provide opportunities for socialization and sensory stimulation (e.g., television and visits). Refer to the care plan for Deficient **Diversional** activity.
- Recognize that immobility and a lack of social support and sensory input may result in confusion or depression in older adults ([American Academy of Nursing's Expert Panel on Acute and Critical Care, 2012](#)). Refer to nursing interventions for Acute **Confusion** or **Hopelessness** as appropriate.

Home Care

- The preceding interventions may be adapted for home care use.
- ▲ Begin discharge planning as soon as possible with a personal health navigator (e.g., nurse care coordinator or case manager) to assess need for home support systems, assistive devices, and community or home health services ([Paulus et al, 2008](#)).
- ▲ Assess home environment for factors that create barriers to physical mobility. Refer to occupational therapy services if needed to assist the client in restructuring home environment and daily living patterns. **EB:** *Use the Home Safety Self-Assessment Tool to identify fall risk, prevent falls, and improve mobility and function* ([Tomita et al, 2014](#)). **EBN:** *Assess person-environment fit (P-E Fit) using a reliable and valid instrument such as the Housing Enabler (<http://www.enabler.nu>) to evaluate the impact of the relationship between the person and his/her environment and subsequently how P-E Fit affects physical activity, mobility, and function* ([Pomeroy et al, 2011](#)).
- ▲ Refer to home health aide services to support the client and family through changing levels of mobility. Reinforce need to promote independence in mobility as tolerated. *Providing unnecessary assistance with transfers, bathing, and dressing activities may promote dependence and a loss of mobility rather than optimizing a person's underlying physical capability. Such attentive care may actually prevent older adults from using their remaining abilities* ([Resnick et al, 2011](#)).
- ▲ Refer to physical therapy for gait training, strengthening, and balance training. Physical therapists can provide direct interventions as well as assess need for assistive devices (e.g., cane, walker). **CEB:** *An outpatient group exercise intervention (twice per week for 5 weeks) for people with impaired mobility resulted in significantly better balance, sit to stand, and gait; however, strength did not improve* ([Sherrington et al, 2008](#)).
- Discuss with client and caregiver the possibility of a service dog to support the more immobile client. **CEB:** *Service dogs can pull wheelchairs, find keys, open the door, bring the telephone, and more. Use of service dogs was found to increase socialization, increase self-esteem, and give peace of mind to caregivers* ([Rintala et al, 2005](#)).
- Assess skin condition at every visit. Establish a skin care program that enhances circulation and maximizes position changes. *Impaired mobility decreases circulation to dependent areas. Decreased circulation and shearing place the client at risk for skin breakdown.*
- Once the client is able to walk independently, suggest the client enter an exercise program, or walk with a friend. *Recommend the client use the Exercise Assessment and Screening for You (EASY) tool to help determine appropriate exercise for the older adult client. This tool is available online at <http://www.easyforyou.info>* ([Resnick et al, 2008](#)). **EBN:** *In a longitudinal data analysis of clients with osteoarthritis, being less sedentary was related to more time spent in physical activity at a moderate to vigorous level and less future functional decline* ([Semanik et al, 2015](#)). **CEB:** *Nurse practitioners providing primary care should prescribe regular physical activity to minimize progressive impaired mobility. Clients should be instructed to use exercise logs or a diary to improve adherence to the mobility enhancement prescription* ([Yeom et al, 2009](#)).
- Provide support to the client and family/caregivers during long-term impaired mobility. *Long-term impaired mobility may necessitate role changes within the family and precipitate caregiver stress.* Refer to the care plan for **Caregiver Role Strain**.
- ▲ Institute a personal health navigator (e.g., nurse care coordinator or case manager) and transitional care management of frail older adults to support continued independent living ([Paulus et al, 2008](#)).

Client/Family Teaching and Discharge Planning

- Consider using motivational interviewing techniques when working with both children and adult clients to increase their activity. Refer to the care plan for **Sedentary** lifestyle or *rationales* for motivational interviewing.

- Teach the client progressive mobilization (e.g., dangle legs, get out of bed slowly when transferring from the bed to the chair).
- Teach the client relaxation techniques such as deep breathing and stretching to use during activity.
- Teach the client to use assistive devices such as a cane, a walker, gait belt, weighted vest, or crutches or wheelchair to increase mobility (Yeom et al, 2009).
- Teach family members and caregivers to work with clients actively during self-care activities using a restorative care philosophy for eating, bathing, grooming, dressing, and transferring to restore the client to maximum function and independence (Resnick et al, 2009).
- Work with the client using self-efficacy interventions using single or multiple methods. Teach client and family members to assess fear of falling and develop strategies to mitigate its effect on mobility progression. **CEB:** *Use of self-efficacy-based interventions resulted in increased exercise* (Resnick et al, 2009). **EBN:** *A study found an association between higher EASY cumulative scores and decreased days limited from usual activity, and decreased unhealthy physical health days* (Smith et al, 2011).
- Work with the client using theory-based interventions (e.g., social cognitive theoretical components such as self-efficacy; transtheoretical model). **CEB:** *In a study that examined validity of evidence for physical activity stage of change, physical activity stage of change was found to be behaviorally valid evidenced by self-reported exercise, physical activity, pedometers, sedentary behaviors, and physical functioning. Physical fitness and weight indicators were not related to physical activity stage of change* (Hellsten et al, 2008).

Impaired wheelchair Mobility *Wendie A. Howland, MN, RN-BC, CRRN, CCM, CNLCP, LNCC*

NANDA-I

Definition

Limitation of independent operation of wheelchair within environment

Defining Characteristics

Impaired ability to operate power wheelchair on a decline; Impaired ability to operate power wheelchair on an incline; Impaired ability to operate power wheelchair on curbs; Impaired ability to operate power wheelchair on even surface; Impaired ability to operate power wheelchair on uneven surface

Related Factors

Alteration in cognitive functioning; alteration in mood; decrease in endurance; environmental barrier (e.g., stairs, inclines, uneven surfaces, obstacles, distance); impaired vision; insufficient knowledge of wheelchair use; insufficient muscle strength; musculoskeletal impairment; neuromuscular impairment; obesity; pain; physical deconditioning

NOC (Nursing Outcomes Classification)**Suggested NOC Outcome**

Ambulation: Wheelchair

Example NOC Outcome with Indicators

Ambulation: Wheelchair as evidenced by the following indicators: Propels wheelchair safely/Transfers to and from wheelchair/Maneuvers curbs, doorways, ramps. (Rate the outcome and indicators of **Ambulation: Wheelchair**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see [Section I](#)].)

Client Outcomes**Client Will (Specify Time Frame)**

- Demonstrate independence in operating and moving a wheelchair or other device with wheels
- Demonstrate the ability to direct others in operating and moving a wheelchair or other device
- Demonstrate therapeutic positioning, pressure relief, and safety principles while operating and moving a wheelchair or other device equipped with wheels

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Exercise Therapy: Muscle Control; Positioning: Wheelchair

Example NIC Activities—Positioning: Wheelchair

Select the appropriate wheelchair for the client: standard adult, semi-reclining, fully reclining, amputees; Monitor for client's inability to maintain correct posture in wheelchair

Nursing Interventions and Rationales

- Assist client to put on and take off equipment (e.g., braces, orthoses, abdominal binders, compression stockings) in bed. *These provide stabilization and alignment; abdominal binder prevents postural hypotension and increases vital capacity (for hemodynamic stability, binder and stockings must be put on and taken off in bed).*
- Inspect skin where orthoses, braces, and other equipment rested, once they are removed. **EB:** *Early detection of pressure allows for early pressure relief strategy implementation and a review of outcomes for preventing the development of pressure ulcers and facilitating wound healing (Requejo et al, 2015).*
- ▲ Refer to physical and occupational therapy or wheelchair seating clinic. *Seating for wheelchair-dependent clients should be assessed by health care specialists in conjunction with client/caregiver education on weight shift maneuvers (Sprigle & Sonenbaum, 2011).*
- Recognize that use of support surfaces on chairs and beds redistributes pressure and should be used for at-risk clients as an adjunct to reduce risk of pressure ulcer. However, using support surfaces does not replace the need for repositioning the client on a regular schedule (i.e., weight shifts) (Sprigle & Sonenbaum, 2011; Requejo et al, 2015). *Sitting-acquired pressure ulcers occur primarily over the ischial tuberosities; sacral ulcers primarily result from excessive loading in bed (Gefen et al, 2013; AHRQ, 2014).*
- ▲ **EBN/EB:** *A randomized clinical trial studied elders at risk for pressure ulcers by pressure mapping and measuring the peak pressure index of subjects placed on standard 3-inch foam cushions compared to two common pressure-reducing cushions. Results demonstrated those with high peak pressure indexes using foam cushions acquired more pressure ulcers than those using pressure-reducing cushions (Akins et al, 2011). There are many pressure-relieving cushions. Several that are commonly used are the ROHO cushion, Varilite Evolution, and Invacare Matrix cushions.*
- Intervene to maintain continence or use absorbent diapers/underpads to help prevent skin breakdown due to excessive moisture and macerated skin. Some wheelchair cushions have moisture-wicking characteristics. *Pressure mapping alone insufficiently describes tissue health (Kim et al, 2012; National Pressure Ulcer Advisory Panel, 2014).*

- Routinely assess client's sitting posture and frequently reposition him/her into alignment. **CEB:** *A study demonstrated nursing personnel could reliably use the Resident Ergonomic Assessment Profile for Seating to assess posture of persons in their wheelchair (Gavin-Dreschnack et al, 2009).*
- Assess client satisfaction with function and positioning using a standardized tool if available (Kumar et al, 2013).
- Sit dysphagic clients as upright as possible in individualized wheelchair versus geri-chair when eating. *Clients with potential risk for aspiration (dysphagic clients) should have aspiration prevention strategies in place.* See care plan for Risk for **Aspiration**.
- Implement use of friction-coated projection hand rims and leather gloves for clients to propel manual wheelchairs. *Friction-coated projection rims are less invasive and slipperier than aluminum rims; gloves absorb forces of propulsion and help prevent nerve damage/carpal tunnel.*
- Manually guide or explain to the client to push forward on both wheel rims to move ahead, push the right rim to turn left and vice versa, and pull backward on both wheel rims to back up.
- Recommend that clients back wheelchair into an elevator. If entering face first, instruct them to turn chair around to face the elevator doors. **CEB:** *Clients can see the control panel, floor monitor display, and doors opening and can exit wheeling forward. Be aware that feet/legs are at risk for injury if door panels close prematurely or if there is insufficient room to accommodate the wheelchair (Pierson & Fairchild, 2008).*
- ▲ In conjunction with physical therapy for teaching and assessment, reinforce principle of descending a curb backward (“popping a wheelie”) if balance, trunk control, strength, and timing are adequate. *Backward descent carries less risk of clients losing control and falling forward out of wheelchair.*
- Ascend curbs in a forward position by popping a wheelie or having someone aid in tilting the chair back, place front wheels over curb, and roll chair up. If surface is muddy or sandy, ascend backward. *Front casters will not roll on soft surfaces; a backward approach requires less energy and prevents getting stuck or falling forward.*
- During assisted wheelies, helper must hold wheelchair until all four wheels are back on the ground and client has control of wheelchair. *Releasing one's grip too soon may alter client's balance and cause injury.*
- ▲ Follow therapist's recommendations for how clients should propel manual wheelchairs to prevent upper extremity pain and joint degeneration. *Excessive load on the shoulder muscles should be reduced by producing wheelchairs with adjustable chair heights and by using a wheelchair with consideration for an individual's body size (Le et al, 2012).*
- Inform clients that ultra-lightweight, push-rim-activated, power-assisted, or electric wheelchairs may be more therapeutic than manual ones. *Consider push rim-activated power-assist wheelchairs (manual wheelchairs with a motor linked to the pushrim in each rear hub) that reduce energy needed for propulsion and reserve energy for uneven terrain or obstacle negotiation. EB: Power-assisted wheelchair propulsion decreased muscle work and forces on the shoulder in all directions (Kloosterman et al, 2012).*
- Help clients transition from a manual to a powered wheelchair/scooter if progressive disability occurs. **CEB:** *If the client does not have sufficient strength or motor control of the extremities to propel a standard wheelchair, the client may need to be evaluated for a power chair (Pierson & Fairchild, 2008).*
- ▲ Reduce floor clutter and establish safety rules for drivers of electric/power mobility devices; make referrals to physical or occupational therapy for driver reevaluations if accidents occur or client's health deteriorates. *Safe driving prevents injury to client, pedestrians, and property. Waist belt restraints are attached to the frame of the wheelchair and are designed to prevent the driver from falling out of or sliding forward in the chair (Pierson & Fairchild, 2008).*
- Request and receive client's permission before moving unoccupied wheelchair in room or out to hallway. *Wheelchair-dependent clients may view chair as part of their identity and independence.*
- Reinforce compensatory strategies for unilateral neglect and agnosia (e.g., visual scanning, self-talk, self-questioning as to what could be wrong) as clients propel wheelchair through doorways and around obstacles. *Too often nurses physically move wheelchair or obstacle instead of cueing client to detect and solve problems.* Refer to care plan for **Unilateral Neglect**.
- Offer support to help clients cope with issues related to physical disability. *Depression and anxiety may occur with physical loss.* Refer to care plan for Ineffective **Role** performance.
- Provide information on support group and reliable Internet resource options.
- Provide information about advocacy, accessibility, assistive technology, and issues under the Americans with Disabilities Act.

- ▲ Make social service or wheelchair clinic referral to educate clients on financial coverage/regulations of third-party payers and Health Care Financing Association for wheelchairs. *It is wise to recognize cost, advantages, and durability of different wheelchair models before purchasing one.*
- Recommend that clients test-drive wheelchairs and try out cushions/postural supports with the advice of a qualified seating professional before purchasing them. *Equipment is expensive, and different models have different advantages and disadvantages.*

Pediatric

- ▲ **EB:** Consult physical or occupational therapist for special considerations for wheelchair fitting and positioning for pediatric client. In children with cerebral palsy, poor trunk control can lead to spinal deformity and pulmonary compromise. Evidence links posture and pulmonary function; special techniques for measuring these may be necessary (Barks & Shaw, 2011).
- ▲ Help client/family transition from a manual to a powered wheelchair/scooter if disability is severe. Compared to a control group using manual wheelchairs, disabled children using power wheelchairs evidenced enhanced development, functional skills, and communication, and decreased caregiver burden (Jones et al, 2012).

Geriatric

- Avoid using restraints on fidgeting clients who slide down in a wheelchair; rather, assess for deformities, spinal curvatures, abnormal tone, discomfort, and limited joint range.
- Ensure proper seat depth/leg positioning and use custom foot rests (not elevated leg rests) to prevent older adults from sliding down in wheelchairs.
- ▲ Assess for side effects of medications and potential need for dosage readjustments to increase wheelchair tolerance. Give prescribed hydration and medications to treat orthostatic hypotension. Consider leg wraps. Client should perform warm-up bed exercises (Le, 2012). Cerebral hypoperfusion is a common cause of orthostatic intolerance and hypotension (Le, 2012). Severe spinal cord injury above T6-8 is a risk factor for orthostatic hypotension due to reduced efferent sympathetic nervous activity and loss of reflex vasoconstriction at arterial baroreceptors below the level of injury (Phillips et al, 2012).
- Allow client to propel wheelchair independently at his/her own speed. Older adults may move slowly due to diminished range of motion/strength, stiff/sore joints, and cardiopulmonary compromise.

Home Care

- ▲ Establish a support system for emergency and contingency care (e.g., remote monitoring, emergency call system, alert local emergency medical system). *Wheelchair dependence may be life-threatening during a crisis (e.g., fall, fire, or other environmental emergency).*
- Recommend the following changes to the home to accommodate the use of a wheelchair:
 - Arrange traffic patterns so they are wide enough to maneuver a wheelchair.
 - Recognize a 5-foot turning space is necessary to maneuver wheelchairs; doorways need to have 32 to 36 inches clear width; and entrance ramps/path slope should be assessed before permanent ramps are installed because standardized slopes may not be appropriate. Temporary ramps are cost-effective and easier to adjust (Sofka, 2011).
 - Replace door hardware with fold-back hinges, remove doorway encasements (if too narrow), remove/replace thresholds (if too high), hang wall-mounted sinks/handrails, grade floors in showers for roll-in chairs, use nonskid/nonslip floor coverings (e.g., nonwaxed wood, linoleum, or Berber carpet).
 - Rearrange room functions, furniture, and storage so that toileting, sleeping, bathing, and preparing/eating meals can safely take place on one level of the home.
 - Refer to the Easter Seals Summary on Home Accessibility for further details: http://www.easterseals.com/shared-components/document-library/easy_access_housing.pdf.
- ▲ Request physical and occupational therapy referrals to evaluate wheelchair fitting, skills, safety, and maintenance. Suggest community resources for servicing and tuning up wheelchairs and/or locating parts so clients can service their own chairs; an annual tune-up is recommended.

Client/Family Teaching and Discharge Planning

- ▲ Assess pain levels of long-term wheelchair users and make referrals to therapists or wheelchair clinics for modifications as needed.

- Instruct and have client return demonstrate reinflation of pneumatic tires; encourage client to monitor tire pressure every 2 to 3 weeks.
- Instruct family/clients to remove large wheelchair parts (leg rests, arm rests) when lifting wheelchair into car for transport; when reassembling, check that all parts are fastened securely and temperature is tepid. *This reduces weight that needs to be lifted; locked parts and a safe temperature prevent injury/thermal injury.*
- Teach the critical importance of using seatbelts and secure chair tie-downs when riding in motor vehicles in a wheelchair. Never transport a client in an unsecured wheelchair in any kind of vehicle.
- For further information, refer to care plan for Impaired **Transfer** ability.

Impaired Mood regulation *Wolter Paans, MSc, PhD, RN*

NANDA-I

Definition

A mental state characterized by shifts in mood or affect and which comprises a constellation of affective, cognitive, somatic, and/or physiological manifestations varying from mild to severe

Defining Characteristics

Changes in verbal behavior; disinhibition; dysphoria; excessive guilt; excessive self-awareness; excessive self-blame; flight of thoughts; hopelessness; impaired concentration; influenced self-esteem; irritability; psychomotor agitation; psychomotor retardation; sad affect; withdrawal

Related Factors

Alteration in sleep pattern; anxiety; appetite change; chronic illness; functional impairment; hypervigilance; impaired social functioning; loneliness; pain; psychosis; recurrent thoughts of death; recurrent thoughts of suicide; social isolation; substance misuse; weight change

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Hope: Symptom Control: Mood Equilibrium

Example NOC Outcome with Indicators

Mood Equilibrium as evidenced by the following indicators: Exhibits affect that fits situation/Exhibits impulse control/ Shows interest in surroundings. (Rate the outcome and indicators of **Mood Equilibrium**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section 1].)

Client Outcomes

Client Will (Specify Time Frame)

- State feelings related to changes in mood
- Eat appropriate diet for height and weight
- Follow exercise plan
- Have no attempts at self-harm

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Mood Management; Suicide Prevention; Exercise Promotion; Health Education

Nursing Interventions and Rationales

- Provide nutritional intake for a client who is unable to feed self. **EB**: *This study aimed to define the role of nutritional interventions in the prevention and treatment of malnutrition in head and neck cancer clients undergoing chemo-radiotherapy as well as their impact on CRT-related toxicity and survival. Head and neck cancer clients are frequently malnourished at the time of diagnosis and prior to the beginning of treatment. In addition, chemo-radiotherapy causes or exacerbates symptoms, such as alteration or loss of taste, mucositis, xerostomia, fatigue, and nausea and vomiting, with consequent worsening of malnutrition. Nutritional counseling and oral nutritional supplements should be used to increase dietary intake and prevent therapy-associated weight loss and interruption of radiation therapy (Bossola, 2015). Some of the symptoms (e.g., fatigue, loss of taste) are also present in clients with the diagnostic concept “impaired mood regulation.” This study clearly demonstrates that nutritional counseling should be used to increase dietary intake and to prevent weight loss.*
- Encourage regular physical exercise to maintain or advance to a higher level of fitness and health. **EB**: *Negative affective states such as anxiety, depression, and stress are significant risk factors for cardiovascular disease, particularly in cardiac and postcardiac rehabilitation populations. In this study, yoga is used as physical exercise. Breathing control and meditation can reduce psychosocial symptoms as well as improve cardiovascular and cognitive function (Yeung et al, 2014). This study shows the interest of physical exercise to advance a higher level of health.*
- Reduce the risk of self-inflicted harm for a client in crisis or severe depression with a planned treatment program. **CEB/EBN**: *This study is about childhood suicidal behavior. This is a complex symptom that requires a carefully planned treatment program that includes multiple modalities of care. Treatment requires a long-term approach that constantly reassesses potential for serious suicidal risk. Psychiatric hospitalization may be required to protect the child from self-inflicted harm and to allow evaluation and appropriate intervention (Pfeffer, 1984). This study is not recent but it confirms that the risk of self-inflicted harm for a client in crisis should be reduced.*
- Facilitate the safe and effective use of prescription and over-the-counter drugs. **EB**: *This article explains the importance of safe medicine use (Calsbeek, 2007). This article shows clearly that it is important to inform clients about their medicine use.*

Client/Network Interventions

- Provide a treatment involving the cooperation of several aide workers in neighborhood teams and providing customized treatment at the place where the client resides. **EB/EBN:** *The use of teams is a well-known approach in a variety of settings, including health care, in both developed and developing countries. Team performance comprises teamwork and task work, and ascertaining whether a team is performing as expected to achieve the desired outcome has rarely been done in health care settings in resource-limited countries (Yeboah-Antwi et al, 2013). This article shows that this intervention is still used.*

Moral Distress Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

Response to the inability to carry out one’s chosen ethical/moral decision/action

Defining Characteristics

Anguish about acting on one’s moral choice (e.g., powerlessness, anxiety, fear)

Related Factors (r/t)

Conflict among decision makers; conflicting information available for ethical decision-making; conflicting information available for moral decision-making; cultural incongruence; end of life decisions; loss of autonomy; physical distance of decision maker; time constraint for decision-making; treatment decision

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Autonomy; Client Satisfaction: Protection of Rights

Example NOC Outcomes with Indicators

Client Satisfaction: Protection of Rights as evidenced by the following indicators: Requests respected/Included in decisions about care/Care consistent with religious and spiritual needs. (Rate the outcome and indicators of **Client Satisfaction: Protection of Rights**: 1 = not at all satisfied, 2 = somewhat satisfied, 3 = moderately satisfied, 4 = very satisfied, 5 = completely satisfied [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Be able to act in accordance with values, goals, and beliefs
- Regain confidence in the ability to make decisions and/or act in accord with values, goals, and beliefs
- Express satisfaction with the ability to make decisions consistent with values, goals, and beliefs
- Have choices respected

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Patient Rights Protection; Emotional Support

Example NIC Activities—Patient Rights Protection

Provide environment conducive for private conversations between client, family, and health care professionals

Nursing Interventions and Rationales

- Assess if moral distress is present and its relationship to intrinsic or extrinsic factors. **EB: Lester (2014)** found in an ethnographic study that women with eating disorders often do not take prescribed medications, purge them, or hoard them because they have a moral imperative that is different from the usually assumed one, which is that everyone strives for health. **EBN: Hmaideh (2014)** studied moral distress among psychiatric nurses and found that it was strongly correlated to case load and burnout.
- Affirm the distress, commitment “to take care of yourself,” and your obligations. Validate feelings and perceptions with others. **EBN: Sirilla (2014)** studied moral distress in nurses on different types of nursing units and found high levels of moral distress in oncology nurses who care for clients and families who often make difficult health care decisions. **EBN: Robinson et al (2014)** found that by implementing a course to increase ethical competency among nurses ($N = 67$) using methods based in adult learning theory, client scenarios, classroom discussion, simulation, and clinical practice, there was a decrease in moral distress and an increase in moral agency, which was defined as the enhanced ability to act to bring about change.
- Implement strategies to change situations causing moral distress. **EBN: LeBaron et al (2014)** used an ethnographic approach to explore moral distress and found that education is the most important aspect when considering moral obligations. **EBN: Mason et al (2014)** studied moral distress in medical intensive care units (ICUs) where there are clients and families faced with sudden life-threatening, life-changing situations and found that as work engagement (helping families, long-time relationships with colleagues, and satisfaction) increased, moral distress decreased.
- Assess sources and severity of distress. **EBN:** A qualitative study identified sources of moral distress as bullying, lateral violence, and retribution. Additionally, inadequate staffing and perceived incompetent coworkers were high items on the moral distress scale (**Sauerland et al, 2014a**). **EBN: Strachan et al (2014)** conducted a qualitative descriptive study about the experiences of long-term care nurses and residents with heart failure and found that decision-making was negatively influenced by (1) approaching heart failure reactively, (2) not having the skill to identify heart failure signs, (3) poor communication, (4) poor resources, and (5) moral distress.
- Give voice/recognition to moral distress and express concerns about constraints to supportive individuals. **EBN: Wojtowicz et al (2014)** completed a qualitative study about nursing students ($N = 13$) who reported significant moral distress due to the manner in which nurses and health care providers treated psychiatric clients even when their nursing instructor attempted to change client conditions. **EBN: Sauerland et al (2014b)** did a mixed method study and found that moral distress can be pervasive and the situations in which ethical issues are identified call for open discussion to decrease moral distress.
- Engage in healthy problem solving. **EBN: Manara et al (2014)** used a phenomenological-hermeneutic case analysis and found that moral action requires deliberate reflective thinking about the important things that are happening in a situation. **EB: Tambuyzer et al (2014)** studied mental health care clients’ involvement in decision-making as an ethical requirement through a literature search ($N = 45$) and found a need for a comprehensive model of client involvement for ethical decision-making because three issues were identified: (1) a proliferation of conceptualizations of the topic, (2) vagueness, and (3) a lack of quantitative data.
- Engage in interdisciplinary problem-solving forums including family meeting and/or interdisciplinary rounds. **EB: Dean et al (2014)** did long-term (5-year) review of decision-making to administer sedative drugs during end of life care and found family discussions about sedatives improved by using a decision-making checklist. **EB: Mah et al (2014)** used vignettes in public health policy research to study moral reasoning about food advertising to children and found vignettes can effectively focus on moral conflicts and support moral reasoning for families.
- Implement multidisciplinary interventions/strategies to address moral distress. **EB: Penny et al (2014)** studied moral distress and found that a population that has high moral distress is individuals with chronic

physical disabilities. **EB:** Piers et al (2014) used a cross-sectional study of nurses (N = 1,218), junior (N = 180) and senior (N = 227) health care providers in ICUs to assess perceived inappropriate care (PIC) and found by multivariate analysis that nurses have higher PIC rates compared with junior and senior health care providers, but all agreed that excessive care for ICU clients is a major issue and ethical discussions among teams may decrease moral distress.

- Identify/use a support system. **EBN:** Kaplan and Tivnan (2014) used a survey to study college students' (N = 546) moral motivation and emotions and found compassion, distress, anger, and hate among the most reported moral emotions and concluded that increasing emotional awareness positively related to developing better moral decision-making and motivation. **EB:** Schroy et al (2014) used decision aids for colorectal cancer screening in a cross-sectional survey of providers (N = 29). Sixty percent felt that the tool increased client knowledge, helped clients identify a preferred option, improved decision-making, saved time, and increased clients' desire to be screened.
- Initiate an ethics consult or ethics committee review. **EBN:** McLeod (2014) qualitatively studied nurses' (N = 6) ethical principles in relation to treatment withdrawal in ICUs and identified three themes: (1) their personal set of moral beliefs, (2) their experience, and (3) the decision-making process. McLeod concluded that consensus in decision-making is a major factor to reduce moral distress. **EBN:** An investigation of Muslim nurses' (N = 306) attitudes toward do not resuscitate (DNR) orders using a descriptive-comparative research process found that nurses were willing to learn more about DNR orders, but many had negative attitudes toward DNR orders, which may be changed through education (Mogadasiyan et al, 2014) and use of ethics committees.

Pediatric

- Consider the developmental age of children when evaluating decisions and conflict. **EBN:** Nsar and Rehm (2014) studied the long-term emotional consequences of live liver donations on donors and families by semi-structured interviews (N = 13) and found the experience as transformational with three themes: (1) self-awareness, (2) a clarification of familial relationships, and (3) a change on community perspective. **EBN:** Brandon et al (2014) conducted a before and after cross-sectional study to assess a Pediatric Quality of Life Program's relationship to moral distress of pediatric nurses, health care providers, social workers, therapists, dietitians, chaplains, and administrators and found that a palliative care program reduced moral distress.

Multicultural

- Acknowledge and understand cultural differences that may influence a client's moral choices. **EBN:** Moral et al (2014) used a cross-sectional study of clients' (N = 658) roles in decision-making with health care providers and in 60% of the situations (390 encounters), clients wished they could have been involved in the decision. **EBN:** Karanikola et al (2014) explored moral distress and its relationship to (1) nurse-health care provider collaboration, (2) autonomy, (3) professional satisfaction, (4) intention to resign, and (5) workload among Italian ICU nurses (N = 566) and found that moral distress was correlated with the intention to resign and poor nurse-health care provider interactions.

Geriatric and Home Care

- Previous interventions may be adapted for geriatric or home care use. **EBN:** Boot and Wilson (2014) used advance care planning conversations with terminally ill clients (N = 8) and through interviews found that the top considerations were (1) an assessment of the client's readiness to discuss the topic, (2) the client's physical condition, and (3) the nurse-client (and family) relationship. **EBN:** Lee and King (2014) conducted a quantitative study to assess the effect of educational classes on death anxiety and burnout among outpatient hemodialysis caregivers and found that education decreased the level of death anxiety and emotional exhaustion.

Nausea *Janelle M. Tipton, MSN, RN, AOCN*

NANDA-I

Definition

A subjective, phenomenon of an unpleasant feeling in the back of the throat and stomach, which may or may not result in vomiting

Defining Characteristics

Aversion to food; gagging sensation; increase in salivation; increase in swallowing; nausea; sour taste

Related Factors

Biophysical

Biochemical dysfunction (e.g., uremia, diabetic ketoacidosis); esophageal disease; exposure to toxin; gastric distention; gastrointestinal irritation; increase in intracranial pressure; intra-abdominal tumors; labyrinthitis; liver capsule stretch; localized tumors (e.g., acoustic neuroma, brain tumor, bone metastasis); Ménière's disease; meningitis; motion sickness; pancreatic disease; pregnancy; splenic capsule stretch; treatment regimen

Situational

Anxiety; fear; noxious environmental stimuli; noxious taste; psychological disorder; unpleasant visual stimuli

List of Nursing Diagnoses by Letter: N

Nausea	Noncompliance	Readiness for enhanced Nutrition
Imbalanced Nutrition: less than body requirements		

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Comfort Level; Hydration; Nausea and Vomiting Severity; Nutritional Status: Food and Fluid Intake; Nutrient Intake

Example NOC Outcome with Indicators

Nausea and Vomiting Severity as evidenced by the following indicators: Frequency of nausea/Intensity of nausea/Distress of nausea. (Rate the outcome and indicators of **Nausea and Vomiting Severity**: 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State relief of nausea
- Explain methods clients can use to decrease nausea and vomiting (N&V)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Distraction; Medication Administration; Progressive Muscle Relaxation; Simple Guided Imagery; Therapeutic Touch

Example NIC Activities—Distraction

Encourage the individual to choose the distraction techniques desired, such as music, engaging in conversation or telling a detailed account of event or story, guided imagery, or humor; Advise client to practice the distraction technique before the time needed, if possible

N

Nursing Interventions and Rationales

- ▲ Determine cause or risk for N&V (e.g., medication effects, infectious causes [viral and bacterial gastroenteritis], disorders of the gut and peritoneum [mechanical obstruction, motility disorders, or other intra-abdominal causes], central nervous system causes [including anxiety], endocrine and metabolic causes [including pregnancy], postoperative-related status). *Because N&V are clinically identifiable symptoms, it is important for the cause to be determined and appropriate plan and interventions to be developed. Reviewing the client's medication record, alcohol history, and electrolytes as appropriate for early identification of cause of nausea (Goel & Wilkinson, 2013). EB: Prophylactic interventions given before chemotherapy have proven to be most successful in preventing N&V. Client expectancy of nausea after chemotherapy is predictive of that treatment-related side effect (Tipton, 2014; Kamen et al, 2014).*
- ▲ Evaluate and document the client's history of N&V, with attention to onset, duration, timing, volume of emesis, frequency of pattern, setting, associated factors, aggravating factors, and past medical and social histories. *The onset and duration of N&V may be distinctly associated with specific events and may be treated differently (Grunberg, 2012).*
- Document each episode of nausea and/or vomiting separately, as well as effectiveness of interventions. Consider an assessment tool for consistency of evaluation. **EB:** *A systematic approach can provide consistency, accuracy, and measurement needed to direct care. It is important to recognize that nausea is a subjective experience (Wood et al, 2011).*
- Identify and eliminate contributing causative factors. This may include eliminating unpleasant odors or medications that may be contributing to nausea. *These interventions are theory-based; however, there is no research evidence to support outside of expert opinion.*
- ▲ Implement appropriate dietary measures such as NPO status as appropriate; small, frequent meals; and low-fat meals. It may be helpful to avoid foods that are spicy, fatty, or highly salty. Reverting to previous practices when ill in the past and consuming "comfort foods" may also be helpful at this time. *Expert opinion consensus recommends these interventions, with no research data available (Irwin & Johnson, 2014).*

- ▲ Recognize and implement interventions and monitor complications associated with N&V. This may include administration of intravenous fluids and electrolytes. *Recognition of complications of N&V is critical to prevent and manage complications of dehydration, electrolyte imbalance, and malnourishment. Adequate hydration corrects imbalances and reduces further emesis (Gan et al, 2014)*
- ▲ Administer appropriate antiemetics, according to emetic cause, by most effective route, considering the side effects of the medication, with attention to and coverage for the timeframes that the nausea is anticipated. **EB:** *Antiemetic medications are effective at different receptor sites and treat different causes of N&V. A combination of agents may be more effective than single agents (Jordan et al, 2014; Rao & Faso, 2012).*
- Consider nonpharmacological interventions such as acupressure, acupuncture, music therapy, distraction, and slow, deliberate movements. **EB:** *Nonpharmacological interventions can augment pharmacological interventions because they predominantly affect the higher cortical centers that trigger N&V. Nonpharmacological interventions are often low cost, relatively easy to use, and have few adverse events. The nonpharmacological interventions most likely to be effective include progressive muscle relaxation, hypnosis for anticipatory chemotherapy-induced nausea and vomiting (CINV), and managing client expectations. Effectiveness has not been established for several other nonpharmacological interventions, primarily due to study limitations, lack of effect in small studies, and inconsistent results (Irwin & Johnson, 2014).*
- Provide oral care after the client vomits. Oral care helps remove the taste and smell of vomitus, thus reducing the stimulus for further vomiting.

Nausea in Pregnancy

- Early recognition and conservative measures are recommended to successfully manage nausea in pregnancy, and to prevent progression to hyperemesis gravidarum. Dietary and lifestyle modifications should be implemented before pharmacological interventions. Avoidance of any aversive odors or foods is recommended. Eating multiple small meals per day is also recommended to have some food in the stomach at all times, thereby avoiding hypoglycemia and gastric overdistention. Foods with higher protein and carbohydrate and lower fat content are helpful. Drinking smaller volumes of liquids at multiple times throughout the day is recommended. *These are traditional strategies for alleviating nausea during pregnancy and are considered expert opinion (Clark et al, 2014).*
- ▲ Due to the high incidence of coexisting gastroesophageal reflux disease (GERD), it is important to assess and manage these symptoms of heartburn, belching, and indigestion. **EB:** *Dietary and lifestyle factors are recommended first, with the use of calcium or aluminum-containing antacids. H2 receptor blockers or proton pump inhibitors (PPIs) may be needed if antacids have failed (Clark et al, 2014; Naumann et al, 2012).*
- ▲ It is well-established that *Helicobacter pylori* (*H. Pylori*) infection is associated with hyperemesis gravidarum. *It may also be recommended to test for H. pylori if there are persistent symptoms of nausea with pregnancy, prolonged symptoms of GERD, or a previous history of H. pylori infection (Clark et al, 2014).*
- ▲ Coexisting psychosocial factors may also influence the severity of N&V with pregnancy. Symptoms of anxiety and depression can occur in early pregnancy, especially when N&V is severe and can make the treatment of the N&V more challenging and even ineffective. *Timely diagnosis and treatment is recommended (Clark et al, 2014).*
- ▲ The American Congress of Obstetricians & Gynecologists (ACOG) currently recommends a combination of oral pyridoxine hydrochloride (vitamin B6, 25 mg) and doxylamine succinate (antihistamine 12.5 mg) be used as first-line treatment for N&V of pregnancy after failure of pyridoxine alone. This combination agent (Diclegis) is the only U.S. Food and Drug Administration pregnancy Category A approved therapy for N&V of pregnancy. There are, however, several pharmacological treatments outlined by the American College of Obstetrics and Gynecology (ACOG). *A stepwise, cost-effective strategy may be helpful in approaching nausea with pregnancy. Considerable N&V with associated dehydration may require intravenous antiemetics, hydration, and/or parenteral nutrition (Clark et al, 2014).*

Nausea Following Surgery

- ▲ Evaluate for risk factors for postoperative nausea and vomiting (PONV). **EB:** *Strong evidence suggests that client-related risk factors such as female gender, age group (<50 years), history of PONV, history of motion sickness, nonsmoking behavior, and environmental risk factors such as postoperative opioid use, emetogenic surgery (type and duration), and volatile anesthetics may increase the risk for PONV. It is important to determine this risk in the preoperative period, to better plan strategies to reduce baseline risk (Gan et al, 2014; Kovac, 2013). Childhood risk factors include surgery duration of more than 30 minutes, age older than 3 years, strabismus surgery, and a history of postoperative vomiting or a relative with PONV (Gan, 2014).*

- ▲ Reduction of risk factors associated with PONV is beneficial for both adults and children. **EB:** *Avoidance of the use of general anesthesia by the use of regional anesthesia has been associated with a decreased incidence of PONV. The avoidance of both nitrous oxide and volatile anesthetics has also minimized PONV. Decreased and minimal use of intraoperative and postoperative opioids has demonstrated reduction in PONV. Adequate hydration is also an intervention to decrease the risk of PONV (Gan et al, 2014; Skolnik & Gan, 2014).*
- ▲ Medicate the client prophylactically for nausea as ordered, throughout the period of risk. **EB:** *Antiemetic medications can reduce the incidence of PONV and use of combination treatment such as 5-HT₃ antagonist plus dexamethasone is more effective than monotherapy. This recommendation is for clients at moderate or high risk for PONV. Other antiemetics, such as the neurokinin (NK-1) receptor antagonists, may have a role, particularly in preventing vomiting and severity 24 to 48 hours after surgery (Gan et al, 2014; Kovac, 2013).*
- ▲ Alleviate postoperative pain using ordered analgesic agents (refer to care plan for Acute **Pain**). *Pain is known to be a factor in the development of PONV.*
- Consider the use of nonpharmacological techniques, such as P6 acupoint stimulation, as an adjunct for controlling PONV, which has been shown to be effective. **EB:** *Acupuncture and acustimulation have been studied with the most consistent results, similarly effective across methods of stimulation (acupuncture or acupressure or wrist-like electrical stimulation) (Gan et al, 2014).*
- Include client education on the management of PONV for all outpatients and discuss key assessment criteria (Odom-Forren et al, 2014).

Nausea Following Chemotherapy

- Perform risk assessment before chemotherapy administration. Risk factors include female gender, younger age, history of low alcohol consumption, history of morning sickness during pregnancy, anxiety, previous history of chemotherapy, client expectancy of nausea, and emetic potential of the regimen. *It is important to recognize the many risk factors individual clients may have and tailor the antiemetic strategy accordingly. Far too often, the degree of N&V is underestimated by health care providers (Grunberg, 2012; Rao & Faso, 2012).*
- ▲ Initiate antiemetic strategy prophylactically or when N&V occurs in accordance with evidence-based guidelines. *Preventing N&V is important; one failure in antiemetic therapy can result in anticipatory nausea for the remainder of the client's treatments, and interventions are less likely to be effective (Grunberg, 2012; Kamen et al, 2014).*
- ▲ Drug classes that are recommended for practice include the serotonin receptor antagonists, the neurokinin (NK-1) receptor antagonists, and cannabinoids. *Triple-drug regimens including serotonin receptor antagonists, NK-1 receptor antagonists, and dexamethasone are recommended for adults and children receiving highly emetogenic chemotherapy (Irwin & Johnson, 2014).*
- ▲ Consider the use of progressive muscle relaxation and guided imagery with antiemetics. **EB:** *There has been benefit associated with these interventions; however, the evidence has been weak, and further data are warranted (Irwin & Johnson, 2014).*
- Consider managing client expectations about CINV. **EBN:** *Benefit has been shown, particularly for anticipatory nausea (Irwin & Johnson, 2014).*

Geriatric

- There are no specific guidelines that address the prophylaxis of CINV specifically in older adults. Risk still needs to be assessed, although many older clients are often treated with less emetic chemotherapy. Chemotherapy, however, can cause increased toxicity due to age-related decreases in organ function, comorbidities, and drug-drug interactions secondary to polypharmacy. Additionally, adherence may be an issue, due to cognitive decline, impaired senses, and economic issues. *Increased caution is warranted in this population due to increased safety concerns (Hu et al, 2011).*

Pediatric

- Interventions for CINV should be implemented before and after chemotherapy. *Despite the extensive use of antiemetics, up to 58% of school-aged and adolescent children receiving highly emetogenic chemotherapy is reported. Delayed CINV occurs most frequently with greater severity and distress (Rodgers et al, 2012).*
- Relatively few studies exist examining the antiemetic medications used for CINV in children. It appears that 5-HT₃ antagonists combined with dexamethasone are better than older agents (Basch et al, 2011).

Home Care

- Previously mentioned interventions may be adapted for home care use.
- ▲ In hospice care clients, assess for causes of nausea, such as constipation, bowel obstruction, adverse effects of medications, and onset of increased intracranial pressure. Refer the client to a primary health care provider if needed. *There can be multiple causes of nausea in clients with advanced cancer (Gordon et al, 2014).* **EBN:** Nausea can effectively be controlled if a cause can be identified. An N&V protocol (e.g., Horvitz Center for Palliative Medicine N&V Protocol) can be used to identify and resolve any reversible causes of nausea, such as metabolic abnormalities or medications (Gupta et al, 2013). If none are found and symptoms persist, a flat plate radiograph of the abdomen is done to evaluate for obstruction or constipation. Appropriate medications can then be used to treat central nervous system causes, obstruction, or non-obstructive causes (Gordon et al, 2014).
- Assist the client and family with identifying and avoiding irritants in the home that exacerbate nausea (e.g., strong odors from food, plants, perfume, and room deodorizers). All medications except antiemetics should be given after meals to minimize the risk of nausea. **EB:** Nausea triggered by odors is related to altered chemoreceptors and pathology (Glare et al, 2011).

Client/Family Teaching and Discharge Planning

- Teach the client techniques to use before and after chemotherapy, including antiemetics/medication management schedules and dietary approaches, such as eating smaller meals, avoiding spicy and fatty foods, and avoiding an empty stomach before chemotherapy (Irwin & Johnson, 2014).

Noncompliance *Betty J. Ackley, MSN, EdS, RN, and Gail B. Ladwig, MSN, RN*

NANDA-I

Definition

Behavior of person and/or caregiver that fails to coincide with a health-promoting or therapeutic plan agreed on by the person (and/or family and/or community) and health care professional; in the presence of an agreed-on, health-promoting, or therapeutic plan, person's or caregiver's behavior is fully or partially non-adherent and may lead to clinically ineffective or partially ineffective outcomes

Defining Characteristics

Behavior indicative of failure to adhere; evidence of development of complications; evidence of exacerbation of symptoms; failure to keep appointments; failure to progress; objective tests (e.g., physiological measures, detection of physiological markers)

Related Factors (r/t)

Health System

Access to care; communication skills of the provider; convenience of care; credibility of provider; difficulty in client-provider relationship; individual health coverage; provider continuity; provider regular follow-up; provider reimbursement; satisfaction with care; teaching skills of the provider

Health Care Plan

Complexity; cost; duration; financial flexibility of plan; intensity

Individual Factors

Cultural influences; developmental abilities; health beliefs; deficient knowledge relevant to the regimen behavior; individual's value system; motivational forces; personal abilities; significant others; skill relevant to the regimen behavior; spiritual values

Network

Involvement of members in health plan; perceived beliefs of significant others; social value regarding plan

NOTE: The nursing diagnosis **Noncompliance** is judgmental and places blame on the client for some things the client has no control over. The authors recommend use of the diagnosis **Ineffective Health management** in place of the diagnosis **Noncompliance**. The diagnosis **Ineffective Health management** has interventions that are developed by both the health care providers and the client. It is a more respectful and efficacious nursing diagnosis.

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching Discharge Planning, Rationales, and References

Refer to care plans for Ineffective **Health** management.

Readiness for enhanced Nutrition

Betty J. Ackley, MSN, EdS, RN, and Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A pattern of nutrient intake that can be strengthened

Defining Characteristics

Expresses desire to enhance nutrition

- = Independent
- CEB = Classic Research
- ▲ = Collaborative
- EBN = Evidence-Based Nursing
- EB = Evidence-Based

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Nutritional Status; Nutritional Status: Food and Fluid Intake; Nutrient Intake; Weight Control

Example NOC Outcome with Indicators

Nutritional Status as evidenced by the following indicators: Food and fluid intake/Hydration/Body mass index/Weight-height ratio/Hematocrit. (Rate the outcome and indicators of **Nutritional Status**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

- Explain how to eat according to the U.S. Dietary Guidelines
- Design dietary modifications to meet individual long-term goal of health, using principles of variety, balance, and moderation
- Maintain weight within normal range for height and age

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Nutrition Management; Nutritional Counseling; Weight Reduction Assistance

Example NIC Activities—Nutrition Management

Determine the client's motivation for changing eating habits; Develop with the client a method to keep a daily record of intake

Nursing Interventions and Rationales

- Assess the meaning and importance of food in the client's life. **EB**: *Research findings demonstrate that implicit attitudes significantly predict purchases of healthy and unhealthy foods (Prestwich et al, 2011). Research found that youth held some negative associations related to healthy foods and some positive associations linked to unhealthy foods (Harrison & Jackson, 2009).*
- Assess the client's current nutrition through a 1- to 3-day food diary in which everything ingested orally is recorded. Analyze the following areas:
 - Intake of food and beverage calories and fat
 - Portion sizes
 - Underconsumption or overconsumption of nutrients
 - Use of supplements
 - Use of meal replacements
 - Timing/consistency of meals and snacks

Use of a food diary is helpful for both the client and the nurse, to examine usual foods eaten and patterns of eating (Shay et al, 2009). EB: A study found that use of a personal digital assistant for self-monitoring of food intake was more effective than use of a paper record, yet both groups had a similar weight loss (Acharya et al, 2011).

- Counsel the client to measure regularly consumed foods periodically. Help the client learn usual portion sizes. *Measuring food alerts the client to normal portion sizes. Estimating amounts can be extremely inaccurate. EB: A study demonstrated that obese people had significantly larger portion sizes, plus ate later in the day (Berg et al, 2009).*
- Help the client determine his/her body mass index (BMI) and understand the significance of the result. Use a chart or a website such as <http://www.cdc.gov/healthyweight/assessing/bmi/index.html> (Centers for Disease Control and Prevention [CDC], 2014). *A normal BMI is 20 to 25; 26 to 29 is overweight; and*

a BMI of 30 or greater is obese. Clients with increased muscle mass may be labeled overweight, when in reality they are very physically fit. Also, clients who have lost large amounts of muscle mass may be in the healthy range, when in reality they may be malnourished (Camden, 2009). **EB:** An analysis of 57 studies demonstrated that mortality was lowest for people with a BMI of 22.5 to 25. Each 5-unit increase above a BMI of 25 resulted in an increased mortality rate by 30% (Whitlock et al, 2009).

- Recommend the client follow the U.S. Dietary Guidelines to determine foods to eat, which can be found at <http://www.choosemyplate.gov/weight-management-calories/weight-management/better-choices/amount-calories.html>. Dietary guidelines are written by national experts and are based on research in nutrition (U.S. Department of Agriculture, 2014).
- Recommend the client use Super Tracker (<http://www.choosemyplate.gov/food-groups>) to determine the number of calories to eat and gain more information on how to eat in a healthy fashion. To lose weight, the client must eat fewer calories (U.S. Department of Agriculture, 2014).
- Recommend the client eat a healthy breakfast every morning. **CEB:** A study found that that people who skip breakfast are more likely to overeat in the evening (Masheb & Grillo, 2006). Another study demonstrated that people who skipped breakfast were 450 times more likely to be obese (Ma et al, 2003).
- Recommend the client avoid eating in fast food restaurants. **CEB:** A 15-year study demonstrated that people who frequently eat fast foods gain an average of 10 lb more than those who eat fast food less often and were two times more likely to develop insulin resistance, which can lead to diabetes (Pereira et al, 2005).
- Demonstrate the use of food labels to make healthful choices. Alert the client/family to focus on serving size, total fat, and simple carbohydrate. The standardized food label in bold type simplifies the search for information. Fats and sugars contribute the least to a healthful diet and the most to excessive calorie intake.

Carbohydrates/Sugars

- Encourage the client to decrease intake of sugars, including intake of soft drinks, desserts, and candy. Limit sugar intake to 6.5 teaspoons of added sugars for women and 9.5 teaspoons of added sugar for men daily.
- Share with client the names of sugars include glucose, dextrose, corn syrup, maple syrup, brown sugar, molasses, evaporated cane juice, sucrose, honey, orange juice concentrate, grape juice concentrate, apple juice concentrate, brown rice syrup, high-fructose corn syrup, agave, and fructose (Nutrition Action, 2011). Sugar predisposes to type 2 diabetes, heart disease, high blood pressure, high triglycerides, gout, and weight gain. **EB:** Studies comparing sugary and diet drinks demonstrated that sugary drinks increase visceral fat, which expands waistlines and drives insulin resistance, predisposing to type 2 diabetes and heart disease (Hu & Malik, 2010; Odegaard et al, 2012).
- Limit intake of fruit juice to 1 cup per day. **EB:** Studies have shown that people who drank more fruit juice had a greater risk of type 2 diabetes or weight gain (Odegaard et al, 2010; Pan et al, 2012).
- Recommend the client eat whole grains whenever possible, and explain how to find whole grains using the food label. **EB:** A review of studies found strong evidence that eating whole grains is associated with a decreased BMI and reduced the risk of being overweight (Williams et al, 2008). Intake of whole grains has been shown to decrease the incidence of heart failure (Nettleton et al, 2008) and, when eaten with other healthier foods, resulted in lower incidence of diabetes in a multiethnic study (Nettleton et al, 2008).
- Assess the client's usual intake of fiber. Recommended intake is 25 g per day for women and 38 g per day for men. Increase intake of whole grains, beans, fruits, and vegetables to obtain needed fiber. Wheat bran is an excellent source of fiber, but cannot be tolerated by all people; beans are the second-best source of fiber (Nutrition Action, 2011). In general, high-fiber foods take longer to eat, increase satiety, and contain fewer calories than most other foods (Slavin, 2008).
- Recommend the client eat five to nine fruits and vegetables per day, with a minimum of two servings of fruit and three servings of vegetables. Encourage client to eat a rainbow of fruits and vegetables because bright colors are associated with increased nutrients. Both fruits and vegetables are excellent sources of vitamins and also phytochemicals that help protect from disease, strokes, some kinds of cancer, and possibly macular degeneration (Liebman & Hurley, 2009). **EB:** A study done on older men found that ingesting foods high in vitamin C resulted in decreased thickening of the carotid arteries (Ellingsen et al, 2009).

Fats

- Recommend the client limit intake of saturated fats and avoid trans fatty acids completely; instead increase intake of vegetable oils such as polyunsaturated and monounsaturated oils. **EB:** A Cochrane study

showed that decreasing intake of saturated fats, replacing them with unsaturated oils, was effective in decreasing cardiovascular risk (Hooper et al, 2012). Intake of both saturated fat and trans fatty acids raises the low-density lipoprotein (LDL) level, which predisposes to atherosclerosis with cardiovascular disease (Zelman, 2011).

- Recommend client use low-fat choices when selecting and cooking meat, and also when selecting dairy products. **EB:** A large population based study found an approximate 50% relative risk reduction of pancreatic cancer, among both men and women who consumed a diet that included low-fat dairy products and lean protein sources (Chan et al, 2013).
- Recommend that the client eat cold-water fish such as salmon, tuna, or mackerel at least two times per week to ensure adequate intake of omega-3 fatty acids. If client is unwilling to eat fish, suggest sources such as flaxseed, soy, or walnuts. **NOTE:** Fish oil capsules should be taken cautiously; some brands can be contaminated with mercury or pesticides. Intake of excessive omega-3 fatty acids can result in bleeding. Ingestion of omega-3 fats results in lower triglycerides and total cholesterol and also decreases the risk of heart disease and stroke (Neville, 2009). **CEB:** The intake of omega-3 fatty acids by eating fish or fish oil capsules results in decreased incidence of sudden cardiac death (von Schacky, 2007).

Protein

- Recommend the client decrease intake of red meat and processed meats, and instead eat more poultry, fish, soy, and dairy sources of protein. **EB:** Red and processed meat intakes were associated with increases in mortality, for cancer, and cardiovascular disease (Sinha et al, 2009). **EB:** A large population-based study found an approximate 50% relative risk reduction of pancreatic cancer among both men and women who consumed a diet that included low-fat dairy products and lean protein sources (Chan et al, 2013).
- Recommend the client eat meatless meals at intervals and try alternative sources of protein, including nuts, especially almonds (one handful), and nut butters. **EB:** Consumption of nuts and peanut butter was shown to decrease the incidence of cardiovascular disease in women with type 2 diabetes (Li et al, 2009). A study found that diabetic people who ate walnuts regularly had improved endothelial function and healthier blood vessels, as well as lower low-density lipoproteins and total cholesterol (Ma et al, 2010).
- Recommend the client eat beans and soy as an alternative to animal proteins at intervals. Introduce the client to soy products such as flavored soy milk and tofu. **NOTE:** Women with diagnosed estrogen-dependent cancer of the breast should generally avoid eating soy foods. **EB:** In a Chinese study, research showed that intake of soy foods as a child may cut the incidence of breast cancer by half and may protect women from breast cancer, but further research is needed (Welland, 2007).

Fluid and Electrolytes

- Recommend the client choose and prepare foods with less salt, aiming for a maximum of 2300 mg per day (Harvard Health Letter, 2012). The CDC (2009) recommends that all salt-sensitive Americans, including everyone 40 years or older, should decrease daily sodium intake. **EB:** A study found that decreased sodium intake helped lower blood pressure, as well as increase flexibility in blood vessels, improving the health of the blood vessels (CDC, 2009).
- If the client drinks alcohol, encourage him or her to drink in moderation—no more than one drink per day for women and two drinks per day for men. **EB:** A study found an increased incidence of cancer of the upper gastrointestinal tract, liver cancer, and also renal cancer (Thygesen et al, 2009).
- Recommend client increase intake of water to at least 2000 mL or 2 quarts per day. A guideline is 1 to 1.5 mL of fluid for each calorie needed, so an average intake would be between 2000 and 3000 mL/day or at least 8 cups of fluid. **EB:** The adequate intake recommendation is 3 L for the 19- to 30-year-old male and 2.2 L for the 19- to 30-year-old female. Water balance studies suggest that adult men require 2.5 L per day (Institute of Medicine, 2004).

Supplements

- Recommend that clients use dietary supplements such as vitamins and minerals only after consulting with their primary health care provider (Mayo Clinic Health Letter, 2012). **EB:** A large study performed in women found that those who took more supplements had an increased risk for death, especially with intake of multivitamins, vitamin B₆, folic acid, iron, magnesium, zinc, and copper. Calcium seemed to

decrease the risk of death (Mursu et al, 2011). **CEB**: A review of 14 randomized trials demonstrated that intake of antioxidant supplementation did not prevent gastrointestinal cancers, and intake seemed to increase mortality (Bjelakovic et al, 2004).

Pediatric

- Recommend that families eat together for at least one meal per day. *Mealtime together has been shown to improve children's eating habits: children eat more fruits and vegetables when the family eats together.*
- Recommend involving the family in planning meals and food preparation. Children can learn about nutrition as they help plan and make meals. *Children are more likely to eat foods that they help select or prepare.*
- Suggest that parents work at being good role models of healthy eating. *Setting a good example is key for children; children learn the value of healthy eating early, and it can continue for a lifetime.*
- Recommend that the family try new foods, either a new food or recipe every week. *More variety can increase the intake of fruits and vegetables.*
- Suggest the parents keep healthy snacks on hand. Store the snacks in a purse, the car, a desk drawer. *Suggestions include crackers and peanut butter, small boxes of cereal, fresh fruit, and vegetables (Academy of Nutrition and Dietetics, 2014).*
- Plan ahead before eating out. *Visit restaurant websites to see the nutritional value of foods on the menu; also call ahead to see what is offered for healthy foods. Most mothers want their families to eat healthier, but with busy schedules, this can be difficult.*

Geriatric

- Use a nutritional screening tool designed for older adults, such as the Mini Nutrition Assessment (MNA), the Malnutrition Universal Screening Tool (MUST), or the Nutrition Risk Screening (NRS). *The MNA is helpful for older adults living in the community or in an extended care facility; the NRS is more helpful for clients in the acute care setting (Sieber, 2006).*
- Assess changes in lifestyle and eating patterns. Older clients need to decrease portion size as they age because they do not burn as many calories as when they were younger. *Energy needs decrease an estimated 5% per decade after age 40 years, but often eating patterns remain unchanged from youth (Lutz & Przytulski, 2011).*
- Assess fluid intake. Recommend routine drinks of water regardless of thirst. Monitor older adults for deficient fluid volume carefully, noting new onset of weakness, dizziness, and postural hypotension. *Older adults have a higher osmotic point for thirst sensation and a diminished sensitivity to thirst relative to younger adults (Wotton et al, 2008).*
- Observe for socioeconomic factors that influence food choices (e.g., funds, cooking facilities, food insecurity). *Even those on restricted budgets and with limited facilities can be assisted to choose healthy food sources for a balanced diet. **EB**: Food security is a factor that can indicate a need for nutrition assistance in older adults (Lee et al, 2011).*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's nutritional knowledge. *What the client considers normal dietary practices may be based on cultural perceptions (Giger & Davidhizar, 2008).*
- Tailor nutritional interventions to be consistent with cultural beliefs, norms, and values. **EBN**: *Mexican American women responded positively to nutritional education and physical activity promotion when families were involved (Vincent, 2009).*
- Offer tailored lifestyle counseling via the telephone. **EB**: *Low socioeconomic status African Americans and Latinos experienced positive nutritional change and weight loss after participating in a community-based translational lifestyle program (Kanaya et al, 2012).*

Client/Family Teaching and Discharge Planning

- The majority of the preceding interventions involve teaching.
- Work with the family members regarding information on how to improve nutritional status.

Imbalanced Nutrition: less than body requirements

Andrea G. Steiner, MS, RD, LD, CNSC

NANDA-I

Definition

Intake of nutrients insufficient to meet metabolic needs

Defining Characteristics

Abdominal cramping; abdominal pain; alteration in taste sensation; body weight 20% or more below ideal weight range; capillary fragility; diarrhea; excessive loss of hair; food aversion; food intake less than recommended daily allowance; hyperactive bowel sounds; insufficient information; insufficient interest in food; insufficient muscle tone; misinformation; misperception; pale mucous membranes; perceived inability to ingest food; satiety immediately upon ingesting food; sore buccal cavity; weakness of muscles required for mastication; weakness of muscles required for swallowing; weight loss with adequate food intake

Related Factors (r/t)

Biological factors; economically disadvantaged; inability to absorb nutrients; inability to digest food; inability to ingest food; insufficient dietary intake; psychological factors

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Nutritional Status; Nutritional Status: Food and Fluid Intake; Nutrient Intake; Weight Control

Example NOC Outcome with Indicators

Nutritional Status as evidenced by the following indicators: Food and fluid intake/Body mass index/Weight-height ratio/Hematocrit. (Rate the outcome and indicators of **Nutritional Status**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Progressively gain weight toward desired goal
- Weigh within normal range for height and age
- Recognize factors contributing to being underweight
- Identify nutritional requirements
- Consume adequate nourishment
- Be free of signs of malnutrition

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Feeding; Nutrition Management; Nutrition Therapy; Weight Gain Assistance

Example NIC Activities—Nutrition Management

Ascertain the client's food preferences; provide the client with high-protein, high-calorie, nutritious finger foods and drinks that can be readily consumed, as appropriate

Nursing Interventions and Rationales

- ▲ Conduct a nutrition screen on all clients within 24 hours of admission and refer to a dietitian as deemed necessary. **EB:** *A study showed that the presence of early nutrition intervention in severely malnourished clients significantly decreased length of hospital stay (Somanchi et al, 2011).*
- ▲ The screening tool should be based on the client population, and the validity and reliability of the screening tool. The 3-Minute Nutrition Screening (3-MinNS) tool, for example, assesses weight loss, dietary intake, and muscle wasting. **EB:** *A study found that the best cutoff score to identify all adult clients at risk for malnutrition using the 3-MinNS was 3, and it had a strong correlation with the Subjective Global Assessment, making it a reliable tool for nurses to identify clients at risk for malnutrition (Lim et al, 2012).*
- Recognize the importance of rescreening and monitoring oral intake in hospitalized individuals to help facilitate the early identification and prevention of nutritional decline.
- Recognize the characteristics that classify individuals as malnourished and refer to a dietitian for a complex nutritional assessment and intervention. *According to the Academy of Nutrition and Dietetics and the American Society of Parenteral and Enteral Nutrition, two or more of the following characteristics are recommended to support the diagnosis of malnutrition: insufficient energy intake, weight loss, loss of muscle mass, loss of subcutaneous fat, localized or generalized fluid accumulation, and/or decreased functional status (White et al, 2012).*
- Recognize clients who are likely to experience malnutrition in the context of social or environmental circumstances, characterized by pure chronic starvation and anorexia nervosa without the presence of an inflammatory process (White et al, 2012).
 - Chronic disease-related malnutrition: those with organ failure, pancreatic cancer, rheumatoid arthritis, sarcopenic obesity
 - Acute disease or injury-related malnutrition: those with major infection, burns, trauma, closed head injuries accompanied by a marked inflammatory response (White et al, 2012).
- ▲ Note laboratory values cautiously; albumin and prealbumin may be indicators of the inflammatory response that often accompanies acute malnutrition. *Other potential indicators of inflammatory response include C-reactive protein, white blood cell count, and blood glucose values (White et al, 2012).*
- Weigh the client daily in acute care, weekly to monthly in extended care at the same time (usually before breakfast), with same amount of clothing.
- Observe for potential barriers to eating such as willingness, ability, and appetite. **EB:** *Depression, impaired function, and poor oral intake are associated with increased likelihood of weight loss, low BMI, and poor nutrition in nursing home residents (Tamura et al, 2013).*

NOTE: If the client is unable to feed self, refer to Nursing Interventions for Feeding **Self-Care** deficit. If the client has difficulty swallowing, refer to Nursing Interventions for Impaired **Swallowing**. If the client is receiving tube feedings, refer to the Nursing Interventions for Risk for **Aspiration**.

- Advocate for the implementation of a feeding protocol, if not already in place, to avoid unnecessary and/or prolonged nothing per os (mouth)/clear liquid (NPO/CL) status in hospitalized clients. **EB:** *A study conducted at a hospital found an NPO order to be appropriate only 58.6% of the time and a CL diet order to be appropriate only 25.6% of the time (Franklin et al, 2011).*
- For the client with anorexia nervosa, consider offering high-calorie foods and snacks often. **EB:** *A study found that higher calorie diets led to faster weight gain in hospitalized adolescents with anorexia nervosa compared to lower calorie diets (Garber et al, 2013).*
- For the client who is able to eat but has a decreased appetite, try the following activities:
 - Offer oral nutritional supplements (ONS) early after admission and continue to encourage intake of ONS throughout the hospital stay. **EB:** *A study found that use of ONS in the inpatient population decreased*

length of stay, episode cost, and 30-day readmission risk (Philipson et al, 2013). A meta-analysis found that use of ONS significantly reduced hospital readmissions, particularly in older adults (Stratton et al, 2013). Consumption of ONS was associated with lower risk of underfeeding (Thibault et al, 2011).

- Avoid interruptions during mealtimes and offer companionship; meals should be eaten in a calm and peaceful environment. **EB:** A study found that the implementation of protected mealtimes and use of additional assistant-in-nursing assistance alone and in combination improved nutritional intake of hospitalized clients (Young et al, 2013a).
- Allow for access to meals or snacks during “off times” if the client is not available at time of meal delivery, monitor food and ONS intake, and communicate with dietitian/health care provider. **EB:** The Alliance Nutrition Care Recommendations include a multidisciplinary approach to address adult hospital malnutrition which includes the rapid implementation of nutrition intervention and continued monitoring (Tappenden et al, 2013).
- If the client lacks endurance, schedule rest periods before meals, and open packages and cut up food for the client. Nursing assistance will conserve the client’s energy for eating.
- For the client with fracture due to fall, consider the need for vitamin D supplementation. **EB:** A study found that 77% of acute rehabilitation clients are 25(OH)D insufficient or deficient at admission, and most inpatients with fracture due to fall were transferred to acute inpatient rehabilitation without supplementation (Pellicane et al, 2011).
- For the client who has had a stroke, repeat nutritional screenings weekly and provide timely interventions for those at risk or who may already be malnourished. **EB:** According to a recent study, the prevalence of malnutrition and risk of malnutrition in clients with acute stroke increases significantly during the first 10 days of admission (Mosselman et al, 2013). A separate study conducted in stroke clients found a significantly increased risk for malnutrition and continued insufficient oral intake at discharge when compared with the first assessment after hospital admission (Nip et al, 2011).
- Recognize the importance of offering high protein foods to most hospitalized individuals (use caution with those with compromised renal/liver function). **EB:** A study found that among clients who met their energy and protein requirements less often were those with higher BMI, younger age, cancer, or nausea, or had undergone surgery. This study found that only one in four clients had a protein and energy intake that met their requirements at the fourth day of admission. Protein requirements were met less often than energy requirements (Leistra et al, 2011).
- Monitor state of oral cavity (gums, tongue, mucosa, teeth). Provide good oral hygiene before each meal. Good oral hygiene enhances appetite; the condition of the oral mucosa is critical to the ability to eat. The oral mucosa must be moist, with adequate saliva production to facilitate and aid in the digestion of food.
- ▲ Administer antiemetics and pain medications as ordered and needed before meals. The presence of nausea or pain decreases the appetite.
- Anorexia. If client is nauseated, remove cover of food tray before bringing it into the client’s room. The sudden, concentrated food odors that come when the cover is removed in front of the client can trigger nausea.
- Work with the client to develop a plan for increased activity. Immobility leads to negative nitrogen balance that fosters anorexia.

Critical Care

- Recognize the need to begin enteral feeding within 24 to 48 hours of admission to the critical care environment, once the client is free of hemodynamic compromise, if the client is unable to eat. **CEB:** The guidelines for the provision and assessment of nutrition support therapy in the adult critically ill client call for early enteral feeding (McClave et al, 2009). **EB:** Delay in initiation of enteral feeding has been shown to prolong duration of mechanical ventilation and length of stay in critical care clients (Nguyen et al, 2012).
- Recognize that it is important to administer feedings to the client and that frequently checking for gastric residual and fasting clients for procedures can be a limiting factor to adequate nutrition in the tube-fed client. **EBN:** A study found that implementing a protocol for managing gastric residual volumes, not fasting clients for procedures, and reducing fasting times when weaning clients for extubation reduced the number of interruptions to enteral feeding (Williams et al, 2013). Refer to care plan for Risk for **Aspiration**.

Pediatric

- ▲ Use a nutritional screening tool designed for nurses such as the Paediatric Yorkhill Malnutrition Score (PYMS) tool, and if the child has a score of 2 or more, make a referral to a dietitian. **EB:** A study found

that use of the PYMS was helpful in identifying children with malnutrition and was able to identify children with malnutrition who would not have been referred for treatment (Gerasimidis et al, 2011).

- Watch for symptoms of malnutrition in the child including short stature, thin arms and legs, poor condition of skin and hair, visible vertebrae and rib cage, wasted buttocks, wasted facial appearance, lethargy, and in extreme cases, edema.
- Weigh and measure the length (height) of the child and use a growth chart to help determine growth pattern, which reflects nutrition. *Age-related growth charts are available from this website: www.cdc.gov/growthcharts/.*
- ▲ Refer to a health care provider and a dietitian a child who is underweight for any reason. *Good nutrition is extremely important for children to ensure sufficient growth and development of all body systems.*
- Work with the child and parent to develop an appropriate weight gain plan. *The goal for a child is sometimes to maintain existing weight as the body grows taller.*
- Recognize that a large percentage of girls and teenagers are dieting, which can result in nutritional problems.

Geriatric

- Screen for malnutrition in older clients. **EB:** *A study found that the following screening tools were accurate in identifying malnutrition and can be recommended for use in the older adults who are hospitalized: the Malnutrition Screening Tool (MST), the Mini Nutritional Assessment—Short Form (MNA-SF), the Malnutrition Universal Screening Tool (MUST), the SNAQ (Short Nutritional Assessment Questionnaire), and the Simplified Nutritional Appetite Questionnaire (Young et al, 2013a).*
- Screen for dysphagia in all older clients. **EB:** *Dysphagia is common in older adults for multiple reasons and is associated with onset of pneumonia (Serra-Prat et al, 2012). See care plan Impaired Swallowing.*
- Recognize that geriatric clients with moderate or severe cognition impairment have a significant risk for developing malnutrition. **EBN:** *A study demonstrated that older adults with cognitive impairment had a risk for developing malnutrition, regardless of living and housing arrangement (Fagerstrom et al, 2011).*
- ▲ Interpret laboratory findings cautiously. Watch the color of urine for an indication of fluid balance; darker urine demonstrates dehydration. Low axillary moisture could indicate mild to moderate dehydration. **CEB/EB:** *Because urine color is correlated with urine specific gravity and urine osmolality, observing urine color is a low-cost method of monitoring dehydration (Wakefield et al, 2002). Compromised kidney function makes reliance on blood and urine samples for nutrient analyses less reliable in older adults than in younger persons. Findings of a small pilot study suggest that measuring the axillary moisture of older adults has potential as a simple tool for detecting dehydration at home and in nursing homes (Kinoshita et al, 2013).*
- Consider using dining assistants, trained non-nursing staff, to provide feeding assistance care in extended care facilities to ensure adequate time for feeding clients as needed. **EBN:** *A study found that dining assistants spent more time assisting residents, and the quality of care was comparable to that of nurse aides (Bertrand et al, 2011).*
- Consider offering healthy snacks such as yogurt, which is a good source of protein, calcium, zinc, B vitamins, and probiotics. **EB:** *Observational studies suggest that yogurt could play an important role in improving the nutritional health of older adults when combined with a healthy diet (El-Abbadi et al, 2014).*
- Encourage high protein foods for the older client, unless medically contraindicated by organ failure. **EB:** *A study found protective effects against weight loss in healthy older adults who had protein intakes greater than 1 g/kg/d (Gray-Donald et al, 2014). Anorexia of aging has been found to have an independent association with sarcopenia (Landi et al, 2013). Increased protein is thought to increase muscle protein anabolism and help decrease the development of progressive muscle loss, sarcopenia, with aging. Combining increased protein with resistance exercises is even more effective in maintaining or increasing muscle. Clients taking a high-protein supplement had reduced complications, reduced readmissions to the hospital, improved grip strength, and increased protein intake along with increased energy (Cawood et al, 2012).*
- Encourage physical activity throughout the day as tolerated. **EB:** *A study found that moderate acute increase in physical activity, such as aerobic exercise, followed by intake of a protein and carbohydrate liquid enhanced skeletal muscle protein synthesis and anabolic responses in healthy older adult. (Timmerman et al, 2012).*
- Recognize the implications of malnutrition on client strength and mobility. **EB:** *Malnutrition is associated with an increased risk of falling and impaired activity in older long-term care residents; malnourished residents were able to decrease their risk for fall after receiving nutritional intervention (Neyens et al, 2013). A study found that providing oral nutritional supplements and calcium and vitamin D supplementation as*

well as dietitian counseling in malnourished older adults decreased the number of falls and fall incidents (Neelemaat et al, 2012).

- Consider the need for a multivitamin if food intake is low. **EB:** According to the Academy of Nutrition and Dietetics: Food and Nutrition for Older Adults: Promoting Health and Wellness, there is strong and imperative evidence to support the recommendation for a multivitamin when food intake is low (Bernstein & Munoz, 2012).
- Monitor for onset of depression. **EB:** A systematic review of the literature found that depression, impaired function, and poor oral intake were factors consistently associated with increased likelihood of weight loss, low BMI, and poor nutrition (Tamura et al, 2013).
- Consider offering nutritional supplement drinks served in a glass rather than with a straw inserted directly into the container. **EBN:** A study found that among people with dementia who are able to feed themselves, they drank statistically significantly more when a nutritional supplement was served in a glass than when consumed directly from the container (Allen et al, 2014).
- Recommend to families that enteral feedings may or may not be indicated for clients with dementia (Chang & Roberts, 2011). **EB:** There is still insufficient evidence regarding the benefits in function, mobility, and quality of life resulting from nutrition support in disabled older adults; the risks associated with the percutaneous endoscopic gastrostomy procedure may exceed potential benefits in such clients as those with dementia (Monod et al, 2011). For strategies for feeding clients with dementia, please refer to the article by Chang and Roberts (2011).

NOTE: If the client is unable to feed self, refer to Nursing Interventions and Rationales for Feeding **Self-Care** deficit. If client has impaired physical function, malnutrition, depression, or cognitive impairment, refer to care plan for **Frail Elderly** syndrome.

- Emphasize importance of good oral care in the older client. **EB:** Poor oral health was found to be strongly associated with malnutrition in older hospitalized clients (Poisson et al, 2014).
- Consult the dietitian if the client has pressure ulcers. **EBN:** A study found that an interdisciplinary approach including nutrition intervention improved pressure ulcer wound healing and decreased both hospital length of stay for treatment of pressure ulcer as well as total hospital length of stay in geriatric clients who were admitted with or developed a pressure ulcer from stage 2 to stage 3 during hospitalization (Allen, 2013).

Home Care

- The preceding interventions may be adapted for home care use.
- Screen for malnutrition using the MUST, which is easy and simple. Recognize that the client may also use MUST as a self-screening tool in the home setting. **EB:** A study found that most clients were able to complete the self-screen in less than 5 minutes, they found the tool easy to understand and complete, and their results were associated with good agreement with screens conducted by screens conducted by home care providers (Cawood et al, 2012).
- Monitor food intake. Instruct the client in intake of small frequent meals of foods with increased calories and protein.
- Assess the client's willingness to eat. **EB:** Poor intake among older adults has been found to be associated with poor appetite, a diagnosis of infection or cancer, a need for assistance or supervision with feeding, and delirium (Mudge et al, 2011).
- Consider social factors that may interfere with nutrition (e.g., lack of transportation, inadequate income, lack of social support).
- Continue to encourage intake of ONS to help optimize oral intake. **EB:** A meta-analysis of randomized controlled trials suggested that oral nutritional support may be considered for older malnourished medical and surgical clients after discharge from hospital (Beck et al, 2013).
- ▲ Recognize that the client on home parenteral nutrition requires regularly scheduled lab work for electrolyte monitoring. Clients should also be educated regarding home parenteral nutrition before discharge from the hospital (Kumpf & Tillman, 2012).

Client/Family Teaching and Discharge Planning

- Help the client/family identify the area to change that will make the greatest contribution to improved nutrition.
- Build on the strengths in the client/family's food habits. Adapt changes to their current practices.
- Select appropriate teaching aids for the client/family's background.

- Implement instructional follow-up to answer the client/family's questions.
- Recommend that clients discuss with their primary health care provider before taking any supplements such as vitamins and minerals. **EB:** *A large study in women found that those who took more supplements had an increased risk of death, especially with intake of multivitamins, vitamin B6, folic acid, iron, magnesium, zinc, and copper. Calcium seemed to decrease the risk of death (Mursu et al, 2011). A systematic review found no data to support the widespread use of dietary supplements, except possibly vitamin D and omega-3 fatty acids, in industrialized nations; indeed, many of these supplements may be harmful (Marik & Flemmer, 2012).*
- Suggest community resources, such as Meals on Wheels and community centers as suitable food sources.
- Teach the client and family how to manage tube feedings or parenteral therapy at home as needed.

NANDA-I

Definition

A condition in which an individual accumulates abnormal or excessive fat for age and gender that exceeds overweight

Defining Characteristics

ADULT: Body mass index (BMI) >30 kg/m²; CHILD <2 years: term not used with children at this age; CHILD 2 to 18 years: BMI >30 kg/m² or >95th percentile for age and gender

Related Factors

Average daily physical activity is less than recommended for gender and age; consumption of sugar sweetened beverages; disordered eating behaviors; disordered eating perceptions; economically disadvantaged; energy expenditure below energy intake based on standard assessment (e.g., WAVE assessment [weight, activity, variety in diet, excess]); excessive alcohol consumption; fear regarding lack of food supply; formula- or mixed-fed infants; frequent snacking; genetic disorder; heritability of interrelated factors (e.g., adipose tissue distribution, energy expenditure, lipoprotein lipase activity, lipid synthesis, lipolysis); high disinhibition and restraint eating behavior score; high frequency of eating restaurant or fried food; low dietary calcium intake in children; maternal diabetes mellitus; maternal smoking; overweight in infancy; parental obesity; portion sizes larger than recommended; premature pubarche; rapid weight gain during childhood; rapid weight gain during infancy, including the first week, first 4 months, and first year; sedentary behavior occurring more than 2 hours per day; shortened sleep time; sleep disorder; solid foods as major food source in infants younger than 5 months of age

List of Nursing Diagnoses by Letter: O

Obesity	Impaired Oral Mucous Membrane	Risk for impaired Oral Mucous Membrane
Overweight	Risk for Overweight	

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Nutritional Status; Nutritional Status: Food and Fluid Intake; Nutrient Intake; Weight Control

Example NOC Outcome with Indicators

Nutritional Status as evidenced by the following indicators: Food and fluid intake/Hydration/Body mass index/Weight-height ratio/Hematocrit. (Rate the outcome and indicators of **Nutritional Status**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Explain how to eat according to the U.S. Dietary Guidelines
- Design dietary modifications to meet individual long-term goal of health, using principles of variety, balance, and moderation
- Maintain weight within normal range for height and age

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Nutrition Management; Nutritional Counseling; Weight Reduction Assistance

Example NIC Activities—Nutrition Management

Determine the client's motivation for changing eating habits; Develop with the client a method to keep a daily record of intake

Nursing Interventions and Rationales

- Assess the meaning and importance of food in the client's life. **EB**: *Research findings demonstrate that implicit attitudes significantly predict purchases of healthy and unhealthy foods (Prestwich et al, 2011).*
- Counsel the client to eat breakfast daily. **EB**: *Research has determined that skipping breakfast is a lifestyle risk significantly associated with a higher BMI (Ghrayeb et al, 2014).*
- Assess the client with a Patient Readiness Scale to determine if the client is ready to discuss weight loss and/or would like weight loss information. **EB**: *Readiness to change is an important part of treatment for behavior change (Steele et al, 2012).*
- Assess the client's current nutrition through a 1- to 3-day food diary in which everything ingested orally is recorded. Analyze the following areas:
 - Intake of food and beverage calories and fat
 - Portion sizes
 - Underconsumption or overconsumption of nutrients
 - Use of supplements
 - Use of meal replacements
 - Timing/consistency of meals and snacks

Use of a food diary is helpful for both the client and the nurse, to examine usual foods eaten and patterns of eating (Shay et al, 2009). **EB**: *A study found that use of a personal digital assistant for self-monitoring of food intake was more effective than use of a paper record, yet both groups had a similar weight loss (Acharya et al, 2011).*

- Counsel the client to measure regularly consumed foods periodically. Help the client to learn usual portion sizes. *Measuring food alerts the client to normal portion sizes. Estimating amounts can be extremely inaccurate.* **EB**: *A study demonstrated that obese people had significantly larger portion sizes, plus ate later in the day (Berg et al, 2009).*
- Assist the client to develop a system of self-management, which may include self-monitoring of weight, BMI, and food intake, interpreting food labels, portion control, recipe modification, restaurant and social

food negotiation, and physical activity. A key component of successful weight loss and maintenance is regular self-monitoring (Fitch et al, 2013).

- Document the client's height and weight and teach significance of his/her BMI in relationship to current health. Use a chart or a website such as <http://www.cdc.gov/healthyweight/assessing/bmi/index.html> (Centers for Disease Control and Prevention [CDC], 2014).
- Assist the client to use Super Tracker (<http://www.choosemyplate.gov/food-groups>) to determine the number of calories to eat and gain more information on how to eat in a healthy fashion. *To lose weight, the client must eat fewer calories* (U.S. Department of Agriculture, 2014).
- Encourage the client to engage in regular physical activity for at least 150 minutes weekly. **EB:** Research found that normal weight reproductive-aged women who do not engage in recommended levels of physical activity are at risk for becoming overweight or obese (Hillemeier et al, 2011). Studies determine that increased physical activity in conjunction with improved eating behavior scores resulted in greater weight loss (Jakicic et al, 2011).
- Recommend the client eat a healthy breakfast every morning. **CEB:** A study found that that people who skip breakfast are more likely to overeat in the evening (Masheb & Grillo, 2006).
- Recommend the client avoid eating in fast food restaurants. **CEB:** A 15-year study demonstrated that people who frequently eat fast foods gain an average of 10 lb more than those who eat fast food less often and were two times more likely to develop insulin resistance, which can lead to diabetes (Pereira et al, 2005).
- Assist the client to reframe slips in weight loss or physical activity behavior as lapses that are a single event and not a full return to previous unhealthy behaviors. *Relapse prevention strategies include managing lapses in healthy behavior, identifying high-risk situations for relapses, enhancing skills for coping, and increasing self-efficacy for avoiding relapse* (Fitch et al, 2013).
- Teach problem-solving strategies to deal with barriers to changing eating and physical activity patterns. *Strategies such as defining the problem, brainstorming solutions, seeking solutions, and evaluating the outcome of the solution are problem-solving strategies that facilitate weight loss* (Fitch et al, 2013).
- Assist clients to engage their social support systems in ways that facilitate weight loss, as well as eating and physical activity behavior change. *Significant others, family, friends, and co-workers can facilitate or hinder weight loss success* (Fitch et al, 2013).
- Assist the client to reframe the goal focus from outcome (weight loss) to process (eating behaviors) for weight loss. **EB:** A study of overweight women found that focusing on the process of dieting (the eating behavior) was related to actual weight loss as well as to subjective dieting success (Freund & Hennecke, 2012).
- Assist the client to develop stimulus control techniques designed to reduce environmental cues associated with eating behaviors. Specifically clients should be taught to limit the presence of high-calorie/high-fat foods in the home; to reduce the visibility of unhealthy food choices in the home; to limit where and when they eat; to avoid distractions like reading, using the computer, or watching television when eating; and to eat more slowly. *Stimulus control strategies are a key to successful weight loss and weight maintenance* (Fitch et al, 2013).
- Use the motivational interviewing technique when working with clients to promote healthy eating and weight loss. **EB:** A pilot study with use of motivational interviewing in women found it resulted in a significant weight loss (Low et al, 2012). A review found that use of motivational interviewing was effective in causing weight loss (Armstrong et al, 2011).
- Refer the client to tailored weight management programs that provide opportunities for ongoing support. **CEB:** Tailored weight loss interventions and ongoing support were identified by obese clients as facilitating longer term weight management (Visram et al, 2009).
- Refer the client to a weight-loss related therapy group. **EBN:** A British study showed that addressing psychological factors associated with eating and weight in a group setting offers an important contribution to the treatment of obesity (Yilmaz, 2011).
- Recommend that clients use dietary supplements such as vitamins and minerals after consulting with their primary health care provider. **EB:** Research shows a prevalence of low micronutrient status in obese individuals who can benefit from safeguarding vitamin and mineral adequacy by taking a multivitamin supplement in conjunction with increased intake of nutrient-rich foods (Ruxton, 2011).
- Behavior methods of losing weight are diverse and effective for weight loss through developing methods to control eating behavior, changing habits, and mindset. **EB:** Behavioral-based treatments are safe and effective for weight loss (LeBlanc et al, 2011). **EB:** A study found that behavior treatment that was done

either in person or remotely through computer teaching, email, and the phone resulted in a significant loss of weight in obese clients versus a control group (Appel et al, 2011).

Pediatric

- Offer obese or overweight adolescents healthy methods for weight loss. **CEBN:** Research shows that overweight adolescents who demonstrate a desire to lose weight often choose unhealthy methods (Chen et al, 2009).
- Offer families of obese or overweight children prejudice-free, individually accepting, and supportive interventions to address weight loss. **EBN:** Obese children showed signs of stress, stigmatization, and marginalization, while their families reported feeling rejected by health care professionals (Lorentzen et al, 2012).
- Use motivational interviewing counseling techniques to implement weight loss interventions. **EBN:** Obese children treated with motivational interviewing showed significant improvement in their weight-related behavior and obesity-related anthropometric measures (Wong & Cheng, 2013).
- Recommend that families eat together for at least one meal per day. *Mealtime together has been shown to improve children's eating habits: children eat more fruits and vegetables when the family eats together.*
- Recommend involving the family in planning meals and food preparation. *Children can learn about nutrition as they help plan and make meals. Children are more likely to eat foods that they help select or prepare.*
- Suggest that parents work at being good role models of healthy eating. *Setting a good example is key for children; children learn the value of healthy eating early, and it can continue for a lifetime.*
- Recommend that the family try new foods, either a new food or recipe every week. *More variety can increase the intake of fruits and vegetables.*
- Suggest the parents keep healthy snacks on hand. Store the snacks in a purse, the car, a desk drawer. *Suggestions include crackers and peanut butter, small boxes of cereal, fresh fruit, and vegetables (Academy of Nutrition and Dietetics, 2014).*

Geriatric

- Recognize that it is generally not appropriate to have an older client on a calorie-restrictive diet. *Older clients deserve to eat and not be hungry.* **EB:** Strength training and dietary modifications can improve body composition, muscle strength, and physical function in overweight and obese older adults (Straight et al, 2012).
- Observe for socioeconomic factors that influence food choices (e.g., funds, cooking facilities, food insecurity). *Even those on restricted budgets and with limited facilities can be assisted to choose healthy food sources for a balanced diet.* **EB:** Food security is a factor that can indicate a need for nutrition assistance in older adults (Lee et al, 2011).

Multicultural

- Tailor nutritional interventions to be consistent with cultural beliefs, norms, and values. **CEBN:** Mexican American women responded positively to nutritional education and physical activity promotion when families were involved (Vincent, 2009).
- Offer tailored lifestyle counseling via the telephone. **EB:** Low socioeconomic status African Americans and Latinos experienced positive nutritional change and weight loss after participating in a community-based translational lifestyle program (Kanaya et al, 2012).
- Integrate weight loss and weight maintenance interventions with church faith based concepts for cultural congruence with African American clients. **EB:** Recent research suggests that integrating faith themes into a weight loss maintenance program may increase its long-term impact on participants' health behavior change (Seale et al, 2013).

Client/Family Teaching and Discharge Planning

- The majority of the preceding interventions involve teaching.
- Work with the family members regarding information on how to support and promote weight loss and healthy intakes.

Impaired Oral Mucous Membrane

Betty J. Ackley, MSN, EdS, RN, and Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

NANDA-I

Definition

Injury to the lips, soft tissue, buccal cavity, and/or oropharynx

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Defining Characteristics

Bad taste in mouth; bleeding; cheilitis; coated tongue; decrease in taste sensation; desquamation; difficulty eating; difficulty speaking; enlarged tonsils; exposure to pathogen; geographic tongue; gingival hyperplasia; gingival pallor; gingival pocketing deeper than 4 mm; gingival recession; halitosis; hyperemia; fissures; geographic tongue; gingival hyperplasia; gingival pallor; gingival recession; halitosis; hyperemia; impaired ability to swallow; macroplasia; mucosal denudation; oral discomfort; oral edema; oral fissure; oral lesion; oral mucosal pallor; oral nodule; oral pain; oral papule; oral ulcer; oral vesicles; presence of mass (e.g., hemangioma); purulent oral-nasal drainage; purulent oral-nasal exudates; smooth atrophic tongue; spongy patches in mouth; stomatitis; white patches in mouth; white plaque in mouth; white, curd-like oral exudate; xerostomia

Related Factors (r/t)

Alcohol consumption; allergy; alteration in cognitive functioning; autoimmune disease; autosomal disorder; barrier to dental care; barrier to oral self-care; behavior disorder (e.g., attention deficit, oppositional defiant); chemical injury agent (e.g., burn, capsaicin, methylene chloride, mustard agent); cleft lip; cleft palate; decrease in hormone level in women; decrease in platelets; decrease in salivation; dehydration; depression; immunodeficiency; immunosuppression; infection; insufficient knowledge of oral hygiene; insufficient oral hygiene; loss of oral support structure; malnutrition; mechanical factor (e.g., ill-fitting dentures, braces, endotracheal/nasogastric tube, oral surgery); mouth breathing; nil per os (NPO) more than 24 hours; oral trauma; smoking; stressors; syndrome (e.g., Sjögren's); treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Oral Health; Oral Hygiene; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Oral Health as evidenced by the following indicators: Cleanliness of mouth and teeth/Moisture of oral mucosa and tongue/Color of mucous membranes/Oral mucosa/tongue/gum integrity. (Rate the outcome and indicators of **Oral Health**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain intact, moist oral mucous membranes that are free of ulceration, inflammation, infection, and debris
- Demonstrate measures to maintain or regain intact oral mucous membranes

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Oral Health Restoration

Example NIC Activities—Oral Health Restoration

Monitor condition of client's mouth including character of abnormalities; Instruct client to avoid commercial mouthwashes

Nursing Interventions and Rationales

- ▲ Inspect the oral cavity/teeth at least once daily and note any discoloration, presence of debris, amount of plaque buildup, presence of lesions such as white lesions or patches, edema, or bleeding, and intactness of teeth. Refer to a dentist or periodontist as appropriate. *Systematic inspection can identify impending problems. White lesions are often leukoplakia, which is a precursor to squamous cell carcinoma. If the lesion is cancerous, prompt treatment is needed (Engelke & Pravikoff, 2010; Chen 2014a; Worthington et al, 2011).*

- If the client does not have a bleeding disorder and is able to swallow, encourage the client to brush the teeth with a soft toothbrush using fluoride-containing toothpaste at least twice per day. **EB:** *Toothbrush is the most effective method for reducing plaque and controlling periodontal disease (Barnes, 2014).*
- Recommend the client use a powered toothbrush if desired for removal of dental plaque and prevent gingivitis. **EB:** *Two systematic reviews found the powered/oscillating toothbrush to be safe for use on both hard and soft dental tissues and more effective in cleaning teeth (Yaacob et al, 2014; Slade, 2013).*
- Use foam sticks to moisten the oral mucous membranes, clean out debris, and swab out the mouth of the edentulous client. **Do not use foam sticks to clean the teeth** unless the platelet count is very low and the client is prone to bleeding gums. Foam sticks are useful for cleansing the oral cavity of a client who is edentulous. **CEB/EB:** *Foam sticks are not effective for removing plaque; the toothbrush is much more effective (Pearson & Hutton, 2002; Chen, 2014a).*
- If the client does not have a bleeding disorder, encourage the client to floss once per day or use an interdental cleaner. **EB:** *Floss is useful to remove plaque buildup between the teeth (American Dental Association [ADA], 2015a).*
- Use an antimicrobial mouthwash as ordered or tap water or saline only for a mouth rinse. Do not use commercial mouthwashes containing alcohol or hydrogen peroxide. Also, do not use lemon-glycerin swabs. *Some antimicrobial mouthwashes have demonstrated effective action in decreasing bacterial counts in plaque and decreasing gingivitis (ADA, 2015a).* **CEB/EB:** *Hydrogen peroxide can cause mucosal damage and is extremely foul-tasting to clients (Tombs & Gallucci, 1993). Use of lemon-glycerin swabs can result in decreased salivary amylase and oral moisture, as well as erosion of tooth enamel (Foss-Durant & McAfee, 1997). Chlorhexidine mouthwash and sodium bicarbonate appropriately diluted may be used during oral care (Chen 2014b).*
- Provide oral hygiene if the client is unable to care for himself/herself. The nursing diagnosis Bathing **Self-Care** deficit is then applicable.
- If the client is unable to brush own teeth, follow this procedure:
 - Position the client sitting upright or on side.
 - Use a soft bristle toothbrush.
 - Use fluoride toothpaste and tap water or saline as a solution.
 - Brush teeth in an up-and-down manner.
 - Suction as needed.

Each client must receive oral care including toothbrushing two times every day to maintain healthy teeth and mouth and to prevent complications associated with periodontitis (the advanced form of gum disease that can cause tooth loss), which is associated with health problems, such as cardiovascular disease, stroke, and bacterial pneumonia (ADA, 2015a).

- Monitor the client's nutritional and fluid status to determine if it is adequate. Refer to the care plan for Deficient **Fluid** volume or Imbalanced **Nutrition**: less than body requirements if applicable. *Dehydration and malnutrition predispose clients to impaired oral mucous membranes.*
- Encourage fluid intake of up to 3000 mL/day if not contraindicated by the client's medical condition. *Fluids help increase moisture in the mouth, which protects the mucous membranes from damage.*
- Determine the client's usual method of oral care and address any concerns regarding oral hygiene.
- ▲ If the client has a dry mouth (xerostomia):
 - Recognize that more than 500 medications may cause xerostomia, and at times the medication can be discontinued to increase the client's comfort (Schub et al, 2010a).
 - Provide saliva substitutes as ordered. *Saliva substitutes are helpful to decrease the discomfort of dry mouth and may help prevent stomatitis (ADA, 2015c).*
 - Suggest the client chew sugarless gum or sugarless sour candy to promote salivary flow. *Both sugarless gum and candy stimulate the formation of saliva (ADA, 2015c; Schub et al, 2010a).*
 - Examine the oral cavity for signs of mucositis ulceration and oral candidiasis. *Untreated xerostomia may result in these conditions (Schub et al, 2010a).*
- Recommend the client decrease or preferably stop intake of soft drinks. Sugar-containing soft drinks can cause cavities, and the low pH of the drink can cause erosion in teeth (ADA, 2015a).
- If client has halitosis, review good oral care with the client including brushing teeth, using floss, and brushing the tongue. Halitosis can be a beginning sign of gingivitis and can be eradicated by a good program of dental hygiene (ADA, 2015b).

- Instruct the client with halitosis to clean the tongue when performing oral hygiene; brush tongue with tongue scraper or toothbrush and follow with a mouth rinse. **CEB:** A Cochrane review found that tongue cleaning was effective for short-term control of halitosis (*Van der Sleen et al, 2010; ADA 2015b*).
- ▲ Assess the client for underlying medical condition that may be causing halitosis. *Causes of halitosis can be subdivided into three categories: oral origin where good mouth care can help prevent, halitosis from the upper respiratory tract including the sinuses and nose, and halitosis from systemic diseases that is blood-borne, volatilized in the lungs, and expelled from the lower respiratory tract. Potential sources of blood-borne halitosis are some systemic diseases, metabolic disorders, medication, and certain foods such as onions and garlic (ADA, 2015b).*
- Keep the lips well lubricated using a lip balm that is water- or aloe-based. *This is a comfort measure (Radvansky et al, 2013).*

Client Receiving Chemotherapy/Radiation

- Ensure that the client receives a comprehensive oral examination before initiation of chemotherapy or radiation, with aggressive preventive dental care given as needed (*Radvansky et al, 2013*).
- Provide both verbal and written instruction about the need for and method of providing frequent oral care to the client before radiation therapy or chemotherapy. Assess the condition of the oral cavity daily in the client receiving radiation or chemotherapy (*Radvansky et al, 2013*).
- For measurement of presence or severity of mucositis, use the Oral Mucositis Assessment Scale (OMAS). **CEBN:** *This is an instrument that has two components: clinician's assessment of presence and severity of mucositis, and client report about pain, difficulty swallowing, and ability to eat (Harris et al, 2008).*
- Use a protocol to prevent/treat mucositis that includes the following:
 - Use a soft toothbrush that is replaced on a regular basis; brush teeth at least two times a day and for at least 90 seconds.
 - Continue to floss teeth daily.
 - Use a bland, alcohol-free rinse to remove debris and moisten the oral cavity. Rinse the mouth often (every 2 hours while awake) if the client has mouth sores.
 - Avoid tobacco, alcohol, and irritating foods (hot, rough, acidic, or spicy).
 - Use a valid and reliable pain assessment tool and treatment of pain as needed.
- ▲ **EB:** *Use of an oral care protocol helps to decrease oral mucositis in clients receiving treatment for cancer (Radvansky et al, 2013; Eilers et al, 2014).*
- Help the client use a mouth rinse of normal saline or salt and soda every 1 to 2 hours for prevention and treatment of stomatitis. A typical mixture is 1 teaspoon of salt or sodium bicarbonate per pint of water. Clients are directed to take a tablespoon of the rinse and swish it in the mouth for 30 seconds, then expectorate. *Rinses are helpful to remove debris and hydrate the oral mucous membranes; sodium bicarbonate can discourage yeast colonization (Schub et al, 2010b).*
- ▲ If the mouth is severely inflamed and it is painful to swallow, contact the health care provider for a topical anesthetic or analgesic order. Modification of oral intake (e.g., soft or liquid diet) may also be necessary to prevent friction trauma. The nursing diagnosis Imbalanced **Nutrition:** less than body requirements may apply.
- If the client's platelet count is lower than 50,000/mm³ or the client has a bleeding disorder, use a specially made toothbrush designed for sensitive or diseased tissue, or a toothette that is not soaked in glycerin or flavorings; if the client cannot tolerate a toothbrush or a toothette, a piece of gauze wrapped around a finger can be used to remove plaque and debris (*Radvansky et al, 2013*).

Critical Care—Client on a Ventilator

- Use a soft toothbrush to brush teeth to clean the client's teeth at least every 12 hours; use suction to remove secretions. Provide oral moisturizer to oral mucosa and lips every 4 hours. Recognize that good oral care is paramount in the prevention of ventilator-associated events (VAE) and ventilator-associated pneumonia (VAP). **CEB/EBN:** *Increased plaque on the teeth is associated with increased contamination of the mouth and incidence of VAP (Munro et al, 2009). An integrative review of the literature found that consistently performing frequent oral care along with other interventions (e.g., head of bed >30°, adequate endotracheal tube cuff pressure to reduce aspiration, daily evaluation of client's readiness for extubation)*

and oral moisturizing reduced VAP as well as decreased overall health care expenses (Parsons et al, 2013; Hillier et al, 2013; Chu, 2014; Alhazzani et al, 2013).

- ▲ Apply chlorhexidine gluconate mouthwash or gel in the oral cavity after performing tooth brushing, which may reduce the risk of the client developing VAE and VAP. **EB:** *The use of chlorhexidine gluconate has been associated with a 40% reduction in the odds of a client developing VAP (Shi et al, 2013).* Routine oral care with chlorhexidine gluconate in the care of the mechanically ventilated cardiac surgery clients reduces the risk of VAP (Klompas et al, 2014; Xue, 2015).

Geriatric

- Determine the functional ability of the client to provide his/her own oral care. Refer to Bathing **Self-Care** deficit. *Interventions must be directed toward both treatment of the functional loss and care of oral health.*
- Provide appropriate oral care to older adults with a self-care deficit, brushing the teeth after breakfast and in the evening. **EBN:** *Oral care is often poor for older clients and clients with dementia. CEB/EB: Several studies have shown that the rate of pneumonia was decreased by providing oral care (Sarin et al, 2008; Le, 2015).*
- If the client has dementia or delirium and exhibits care-resistant behavior such as fighting, biting, or refusing care, use the following method:
 - Ensure client is in a quiet environment such as own bathroom, sitting or standing at the sink to prime memory for appropriate actions.
 - Approach the client at eye level within his/her range of vision.
 - Approach with a smile and begin conversation with a touch of the hand and gradually move up.
 - Use mirror-mirror technique, standing behind the client, and brush and floss teeth.
 - Use respectful adult speech, not elder speak—sing-song voice, calling “dearie,” “honey,” and so forth. *Elder speak is a documented trigger for care-resistant behavior (Herman & Williams, 2009).*
 - Promote self-care where client brushes own teeth if possible.
 - Use distractors when needed, such as singing, talking, reminiscing, or use of a teddy bear. **EBN:** *Use of specific techniques can decrease the fear-evoked response to nursing care and increase the effectiveness of nurses providing oral care to clients (Jablonski et al, 2011).*
- Carefully observe the oral cavity and lips for abnormal lesions such as white or red patches, masses, ulcerations with an indurated margin, or a raised granular lesion. *Malignant lesions are more common in older adults than in younger persons, especially if there is a history of smoking or alcohol use (Engelke & Pravikoff, 2010; Le, 2015).*
- Ensure that dentures are removed and cleaned regularly, preferably after every meal and before bedtime. *Dentures left in the mouth at night may impede circulation to the palate and predispose the client to oral lesions.*

Home Care

- The interventions described previously may be adapted for home care use.
- ▲ Instruct the client in ways to soothe the oral cavity (e.g., cool beverages, Popsicles, viscous lidocaine).
- ▲ If necessary, refer for home health aide services to support the family in oral care and observation of the oral cavity.

Client/Family Teaching and Discharge Planning

- Teach the client how to inspect the oral cavity and monitor for signs and symptoms of infection or complications, and when to call the health care provider (Radvansky et al, 2013; Eilers et al, 2014).
- Recommend the client not smoke, use chewing tobacco, or drink excessive amounts of alcohol. *Tobacco use, either smoking or chewing, is a common cause of leukoplakia. Also, alcohol and human papillomavirus have been associated with squamous cell carcinoma in the oral cavity (Engelke & Pravikoff, 2010).*
- Teach the client and family if necessary how to perform appropriate mouth care. Use the motivational interviewing technique. **EB:** *A study demonstrated improved dental hygiene with decreased amount of plaque when motivational interviewing compared with a usual teaching session on dental care (Godard et al, 2011).* A systematic review found motivational interviewing more effective in changing oral health than usual care (Watt, 2010). See *Motivational Interviewing in Appendix C.*

Risk for impaired Oral Mucous Membrane

Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

NANDA-I

Definition

Vulnerable to injury to the lips, soft tissues, buccal cavity, and/or oropharynx, which may compromise health

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Risk Factors

Alcohol consumption; allergy; alteration in cognitive functioning; autoimmune disease; autosomal disorder; barriers to dental care; barrier to oral self-care; behavior disorder (e.g., attention deficit, oppositional defiant); chemotherapy; decrease in hormone level in women; economically disadvantaged; immunodeficiency; immunosuppression; inadequate nutrition; infection; insufficient knowledge of oral hygiene; insufficient oral hygiene; mechanical factor (e.g., orthodontic appliance, device for ventilation or food, ill-fitting dentures); radiation therapy; smoking; stressors; surgical procedure; syndrome (e.g., Sjögren's); trauma

NIC, Client Outcomes, Nursing Interventions, Client/Family Teaching, Rationales, and References

Refer to care plan for Impaired **Oral Mucous Membrane**.

Overweight *Marina Martinez-Kratz, MS, RN, CNE*

NANDA-I

Definition

A condition in which an individual accumulates abnormal or excessive fat for age and gender

Defining Characteristics

Children age 2 or younger

Weight-for-length percentiles >95th percentile

Childhood (age 2 to 18 years)

Body mass index (BMI) >85th but <95th percentile or kg/m² (whichever is smaller)

Adult

BMI >25 kg/m²

Related Factors

Average daily physical activity is less than recommended for gender and age; consumption of sugar sweetened beverages; disordered eating behaviors (e.g., binge eating, extreme weight control); disordered eating perceptions; economically disadvantaged; energy expenditure below energy intake based on standard assessment (e.g., weight, activity, variety in diet, excess [WAVE] assessment); excessive alcohol consumption; fear regarding lack of food supply; formula or mixed fed infants; frequent snacking; genetic disorder heritability of interrelated factors (e.g., adipose tissue distribution, energy expenditure, lipoprotein lipase activity, lipid synthesis, lipolysis); high disinhibition and restraint eating behavior score; high frequency of restaurant or fried food; low dietary calcium intake in children; maternal diabetes mellitus; maternal smoking; obesity in childhood; parental obesity; portion sizes larger than recommended; premature pubarche; rapid weight gain during childhood; rapid weight gain during infancy, including the first week, first 4 months, and first year; sedentary behavior occurring for >2 hours/day; shortened sleep time; sleep disorder; solid foods as major food source of <5 months of age

Nursing Interventions and Rationales

- Assess the meaning and importance of food in the client's life. **EB:** *Research findings demonstrate that implicit attitudes significantly predict purchases of healthy and unhealthy foods (Prestwich et al, 2011). Research found that youth held some negative associations related to healthy foods and some positive associations linked to unhealthy foods (Harrison & Jackson, 2009).*
- Counsel the client to eat breakfast daily. **EB:** *Research has determined that skipping breakfast is a lifestyle risk significantly associated with higher BMI (Ghrayeb et al, 2014).*
- Assess the client with a Patient Readiness Scale to determine if the client is ready to discuss weight loss and/or would like weight loss information. **EB:** *Readiness to change is an important part of treatment for behavior change (Steele et al, 2012).*

- Assess the client's current nutrition through a 1- to 3-day food diary in which everything ingested orally is recorded. Analyze the following areas:
 - Intake of food and beverage calories and fat
 - Portion sizes
 - Underconsumption or overconsumption of nutrients
 - Use of supplements
 - Use of meal replacements
 - Timing/consistency of meals and snacks
- ▲ **EB:** *Use of a food diary is helpful for both the client and the nurse, to examine usual foods eaten and patterns of eating (Shay et al, 2009).* **EB:** *A study found that use of a personal digital assistant for self-monitoring of food intake was more effective than use of a paper record, yet both groups had a similar weight loss (Acharya et al, 2011).*
- Counsel the client to measure regularly consumed foods periodically. Help the client learn usual portion sizes. *Measuring food alerts the client to normal portion sizes. Estimating amounts can be extremely inaccurate.* **EB:** *A study demonstrated that obese people had significantly larger portion sizes, plus ate later in the day (Berg et al, 2009).*
- Assist the client to develop a system of self-management, which may include self-monitoring of weight, BMI, and food intake, interpreting food labels, portion control, recipe modification, restaurant and social food negotiation, and physical activity. *A key component of successful weight loss and maintenance is regular self-monitoring (Fitch et al, 2013).*
- Document the client's height and weight and teach significance of his/her BMI in relationship to current health. Use a chart or a website such as <http://www.cdc.gov/healthyweight/assessing/bmi/index.html> (CDC, 2015).
- Assist the client to use Super Tracker (<http://www.choosemyplate.gov/food-groups>) to determine the number of calories to eat and gain more information on how to eat in a healthy fashion. To lose weight, the client must eat fewer calories (U.S. Department of Agriculture, 2014).
- Encourage the client to engage in regular physical activity for at least 150 minutes weekly. **EB:** *Research found that normal weight reproductive-aged women who do not engage in recommended levels of physical activity are at risk for becoming overweight or obese (Hillemeier et al, 2011). Studies determined that increased physical activity in conjunction with improved eating behavior scores resulted in greater weight loss (Jakicic et al, 2011).*
- Recommend the client eat a healthy breakfast every morning. **CEB:** *A study found that that people who skip breakfast are more likely to overeat in the evening (Masheb & Grillo, 2006). Another study demonstrated that people who skipped breakfast were 450 times more likely to be obese (Ma et al, 2003).*
- Recommend the client avoid eating in fast food restaurants. **CEB:** *A 15-year study demonstrated that people who frequently eat fast foods gain an average of 10 lb more than those who eat fast food less often and were two times more likely to develop insulin resistance, which can lead to diabetes (Peirera et al, 2005).*
- Assist the client to reframe slips in weight loss or physical activity behavior as lapses that are a single event and not a full return to previous unhealthy behaviors. *Relapse prevention strategies include managing lapses in healthy behavior, identifying high-risk situations for relapses, enhancing skills for coping, and increasing self-efficacy for avoiding relapse (Fitch et al, 2013).*
- Teach problem-solving strategies to deal with barriers to changing eating and physical activity patterns. *Strategies such as defining the problem, brainstorming solutions, seeking solutions, and evaluating the outcome of the solution are problem-solving strategies that facilitate weight loss (Fitch et al, 2013).*
- Assist clients to engage their social support systems in ways that facilitate weight loss, as well as eating and physical activity behavior change. *Significant others, family, friends and co-workers can facilitate or hinder weight loss success (Fitch et al, 2013).*
- Assist the client to reframe the goal focus from outcome (weight loss) to process (eating behaviors) for weight loss. **EB:** *A study of overweight women found that focusing on the process of dieting (the eating behavior) was related to actual weight loss as well as to subjective dieting success (Freund & Hennecke, 2012).*
- Assist the client to develop stimulus control techniques designed to reduce environmental cues associated with eating behaviors. Specifically clients should be taught to limit the presence of high-calorie/high-fat foods in the home; to reduce the visibility of unhealthy food choices in the home; to limit where and when they eat; to avoid distractions like reading, using the computer or watching television when eating;

and to eat more slowly. *Stimulus control strategies are a key to successful weight loss and weight maintenance (Fitch et al, 2013).*

- Use the motivational interviewing technique when working with clients to promote healthy eating and weight loss. **EB:** *A pilot study with use of motivational interviewing in women found it resulted in a significant weight loss (Low et al, 2012).* A review found that use of motivational interviewing was effective in causing weight loss (Armstrong et al, 2011).
- Refer the client to tailored weight management programs that provide opportunities for ongoing support. **CEB:** *Tailored weight loss interventions and ongoing support were identified by obese or overweight clients as facilitating longer term weight management (Visram et al, 2009).*
- Refer the client to a weight-loss related therapy group. **EBN:** *A British study showed that addressing psychological factors associated with eating and weight in a group setting offers an important contribution to the treatment of obesity (Yilmaz, 2011).*
- Recommend that clients use dietary supplements such as vitamins and minerals after consulting with their primary health care provider. **EB:** *Research shows a prevalence of low micronutrient status in obese individuals who can benefit from safeguarding vitamin and mineral adequacy by taking a multivitamin supplement in conjunction with increased intake of nutrient-rich foods (Ruxton, 2011).*
- Behavior methods of losing weight are diverse and effective for weight loss through developing methods to control eating behavior, changing habits, and mindset. **EB:** *Behavioral based treatments are safe and effective for weight loss (LeBlanc et al, 2011).* **EB:** *A study found that behavior treatment that was done either in person or remotely through computer teaching, email, and the phone resulted in a significant loss of weight in obese clients versus a control group (Appel et al, 2011).* A Cochrane review found that behavioral therapy used independently as a stand-alone therapy resulted in significant weight loss (Shaw et al, 2009).

Pediatric

- Offer obese or overweight adolescents healthy methods for weight loss. **CEBN:** *Research shows that overweight adolescents who demonstrate a desire to lose weight often choose unhealthy methods (Chen et al, 2009).*
- Offer families of obese or overweight children prejudice-free, individually accepting, and supportive interventions to address weight loss. **EBN:** *Obese children showed signs of stress, stigmatization, and marginalization, while their families reported feeling rejected by health care professionals (Lorentzen et al, 2012).* **EBN:** *Obese children treated with motivational interviewing showed significant improvement in their weight-related behavior and obesity-related anthropometric measures (Wong & Cheng, 2013).*
- Recommend that families eat together for at least one meal per day. *Mealtime together has been shown to improve children's eating habits: children eat more fruits and vegetables when the family eats together.*
- Recommend involving the family in planning meals and food preparation. Children can learn about nutrition as they help plan and make meals. *Children are more likely to eat foods that they help select or prepare.*
- Suggest that parents work at being good role models of healthy eating. *Setting a good example is key for children; children learn the value of healthy eating early, and it can continue for a lifetime.*
- Recommend that the family try new foods, either a new food or recipe every week. *More variety can increase the intake of fruits and vegetables.*
- Suggest the parents keep healthy snacks on hand. Store the snacks in a purse, the car, and a desk drawer. *Suggestions include crackers and peanut butter, small boxes of cereal, fresh fruit, and vegetables (Academy of Nutrition and Dietetics, 2014).*

Geriatric

- Recognize that it is generally not appropriate to have an older client on a calorie-restrictive diet. *Older clients deserve to eat and not be hungry.* **EB:** *Strength training and dietary modifications can improve body composition, muscle strength, and physical function in overweight and obese older adults (Straight et al, 2012).*
- Observe for socioeconomic factors that influence food choices (e.g., funds, cooking facilities, food insecurity). *Even those on restricted budgets and with limited facilities can be assisted to choose healthy food sources for a balanced diet.* **EB:** *Food security is a factor that can indicate a need for nutrition assistance in older adults (Lee et al, 2011).*

Multicultural

- Tailor nutritional interventions to be consistent with cultural beliefs, norms, and values. **CEBN**: *Mexican American women responded positively to nutritional education and physical activity promotion when families were involved* (Vincent, 2009).
- Offer tailored lifestyle counseling via the telephone. **EB**: *Low socioeconomic status African Americans and Latinos experienced positive nutritional change and weight loss after participating in a community-based translational lifestyle program* (Kanaya et al, 2012).
- Integrate weight loss and weight maintenance interventions with church faith based concepts for cultural congruence with African American clients. **EB**: *Recent research suggests that integrating faith themes into a weight loss maintenance program may increase its long-term impact on participants' health behavior change* (Seale et al, 2013).

Client/Family Teaching and Discharge Planning

- The majority of the preceding interventions involve teaching.
- Work with the family members regarding information on how to support and promote weight loss and healthy intakes.

Risk for Overweight Marina Martinez-Kratz, MS, RN, CNE

*Previously Risk for imbalanced Nutrition: more than body requirements

NANDA-I

Definition

Vulnerable to abnormal or excessive fat accumulation for age and gender, which may compromise health

Risk Factors

ADULT: Body mass index (BMI) approaching 25 kg/m²; average daily physical activity is less than recommended for gender and age; CHILD older than 2 years: weight for length approaching 95th percentile; CHILD 2 to 18 years: BMI approaching 85th percentile, or 25 kg/m² (whichever is smaller); children who are crossing BMI percentiles upward; children with high BMI percentiles; consumption of sugar-sweetened beverages; disordered eating behaviors (e.g., binge eating, extreme weight control); disordered eating perceptions; eating in response to external cues (e.g., time of day, social situations); eating in response to internal cues other than hunger (e.g., anxiety); economically disadvantaged; energy expenditure below energy intake based on standard assessment (e.g., WAVE [weight, activity, variety in diet, excess]); excessive alcohol consumption; fear regarding lack of food supply; formula- or mixed-fed infants; frequent snacking; genetic disorder; heritability of interrelated factors (e.g., adipose tissue distribution, energy expenditure, lipoprotein lipase activity, lipid synthesis, lipolysis); high disinhibition and restraint eating behavior score; high frequency of eating restaurant or fried food; higher baseline weight at beginning of each pregnancy; low dietary calcium intake in children; maternal diabetes mellitus; maternal smoking; obesity in childhood; parental obesity; portion sizes larger than recommended; premature pubarche; rapid weight gain during childhood; rapid weight gain during infancy, including the first week, first 4 months, and the first year; sedentary behavior occurring for more than 2 hours per day; shortened sleep time; sleep disorder; solid foods as major food sources of less than 5 months of age

Nursing Interventions and Rationales

- Assess the meaning and importance of food in the client's life. **EB:** *Research findings demonstrate that implicit attitudes significantly predict purchases of healthy and unhealthy foods (Prestwich et al, 2011). Research found that youth held some negative associations related to healthy foods and some positive associations linked to unhealthy foods (Harrison & Jackson, 2009).*
- Counsel the client to eat breakfast daily. **EB:** *Research has determined that skipping breakfast is a lifestyle risk significantly associated with a higher BMI (Ghrayeb et al, 2014).*
- Assess the client with a Patient Readiness Scale to determine if the client is ready to discuss weight loss and/or would like weight loss information. **EB:** *Readiness to change is an important part of treatment for behavior change (Steele et al, 2012).*
- Assess the client's current nutrition through a 1- to 3-day food diary in which everything ingested orally is recorded. Analyze the following areas:
 - Intake of food and beverage calories and fat
 - Portion sizes

- Underconsumption or overconsumption of nutrients
- Use of supplements
- Use of meal replacements
- Timing/consistency of meals and snacks
- ▲ **EB:** *Use of a food diary is helpful for both the client and the nurse, to examine usual foods eaten and patterns of eating (Shay et al, 2009). EB: A study found that use of a personal digital assistant for self-monitoring food intake was more effective than use of a paper record, yet both groups had a similar weight loss (Acharya et al, 2011).*
- Counsel the client to measure regularly consumed foods periodically. Help the client learn usual portion sizes. *Measuring food alerts the client to normal portion sizes. Estimating amounts can be extremely inaccurate. EB: A study demonstrated that obese people had significantly larger portion sizes, plus ate later in the day (Berg et al, 2009).*
- Assist the client to develop a system of self-management, which may include self-monitoring of weight, BMI and food intake, interpretation of food labels, portion control, recipe modification, restaurant and social food negotiation, and physical activity. *A key component of successful weight loss and maintenance is regular self-monitoring (Fitch et al, 2013).*
- Document the client's height and weight and teach significance of his/her BMI in relationship to current health. *Use a chart or a website such as <http://www.cdc.gov/healthyweight/assessing/bmi/index.html> (Centers for Disease Control and Prevention, 2015).*
- Assist the client to use Super Tracker (<http://www.choosemyplate.gov/food-groups>) to determine the number of calories to eat and gain more information on how to eat in a healthy fashion. *To lose weight, the client must eat fewer calories (U.S. Department of Agriculture, 2014).*
- Encourage the client to engage in regular physical activity for at least 150 minutes weekly. **EB:** *Research found that normal weight reproductive-aged women who do not engage in recommended levels of physical activity are at risk for becoming overweight or obese (Hillemeier et al, 2011). Studies determine that increased physical activity in conjunction with improved eating behavior scores resulted in greater weight loss (Jakicic et al, 2011).*
- Recommend the client eat a healthy breakfast every morning. **CEB:** *A study found that that people who skip breakfast are more likely to overeat in the evening (Masheb & Grillo, 2006). Another study demonstrated that people who skipped breakfast were 450 times more likely to be obese (Ma et al, 2003).*
- Recommend the client avoid eating in fast food restaurants. **CEB:** *A 15-year study demonstrated that people who frequently eat fast foods gain an average of 10 lb more than those who eat fast food less often and were two times more likely to develop insulin resistance, which can lead to diabetes (Pereira et al, 2005).*
- Assist the client to reframe slips in weight loss or physical activity behavior as lapses that are a single event and not a full return to previous unhealthy behaviors. *Relapse prevention strategies include managing lapses in healthy behavior, identifying high-risk situations for relapses, enhancing skills for coping, and increasing self-efficacy for avoiding relapse (Fitch et al, 2013).*
- Teach problem-solving strategies to deal with barriers to changing eating and physical activity patterns. *Strategies such as defining the problem, brainstorming solutions, seeking solutions, and evaluating the outcome of the solution are problem-solving strategies that facilitate weight loss (Fitch et al, 2013).*
- Assist clients to engage their social support systems in ways that facilitate weight loss, as well as eating and physical activity behavior change. *Significant others, family, friends, and co-workers can facilitate or hinder weight loss success (Fitch et al, 2013).*
- Assist the client to reframe the goal focus from outcome (weight loss) to process (eating behaviors) for weight loss. **EB:** *A study of overweight women found that focusing on the process of dieting (the eating behavior) was related to actual weight loss as well as to subjective dieting success (Freund & Hennecke, 2012).*
- Assist the client to develop stimulus control techniques designed to reduce environmental cues associated with eating behaviors. Specifically clients should be taught to limit the presence of high-calorie/high-fat foods in the home; to reduce the visibility of unhealthy food choices in the home; to limit where and when they eat; to avoid distractions like reading, using the computer, or watching television when eating; and to eat more slowly. *Stimulus control strategies are a key to successful weight loss and weight maintenance (Fitch et al, 2013).*

- Use the motivational interviewing technique when working with clients to promote healthy eating and weight loss. **EB**: *A pilot study with use of motivational interviewing in women found it resulted in a significant weight loss (Low et al, 2012). A review found that use of motivational interviewing was effective in causing weight loss (Armstrong et al, 2011).*
- Refer the client to tailored weight management programs that provide opportunities for ongoing support. **CEB**: *Tailored weight loss interventions and ongoing support were identified by obese or overweight clients as facilitating longer term weight management (Visram et al, 2009).*
- Refer the client to a weight-loss related therapy group. **EBN**: *A British study showed that addressing psychological factors associated with eating and weight in a group setting offers an important contribution to the treatment of obesity (Yilmaz, 2011).*
- Recommend that clients use dietary supplements such as vitamins and minerals after consulting with their primary health care provider. **EB**: *Research shows a prevalence of low micronutrient status in obese individuals who can benefit from safeguarding vitamin and mineral adequacy by taking a multinutrient supplement in conjunction with increased intake of nutrient-rich foods (Ruxton, 2011).*
- Use behavioral methods to control eating behavior, and change habits and mindset. **EB**: *Behavioral-based treatments are safe and effective for weight loss (LeBlanc et al, 2011).* **EB**: *A study found that behavior treatment that was done either in person or remotely through computer teaching, email, and the phone resulted in a significant loss of weight for obese clients versus a control group (Appel et al, 2011).* A Cochrane review found that behavioral therapy used independently as a stand-alone therapy resulted in significant weight loss (Shaw et al, 2009).

Pediatric

- Offer obese or overweight adolescents healthy methods for weight loss. **EBN**: *Research shows that overweight adolescents who demonstrate a desire to lose weight often choose unhealthy methods (Chen et al, 2009).*
- Offer families of obese or overweight children prejudice-free, individually accepting, and supportive interventions to address weight loss. **EBN**: *Obese children showed signs of stress, stigmatization, and marginalization, while their families reported feeling rejected by health care professionals (Lorentzen et al, 2012).*
- Use motivational interviewing counseling techniques to implement weight loss interventions. **EBN**: *Obese children treated with motivational interviewing showed significant improvement in their weight-related behavior and obesity-related anthropometric measures (Wong & Cheng, 2013).*
- Recommend that families eat together for at least one meal per day. *Mealtime together has been shown to improve children's eating habits: children eat more fruits and vegetables when the family eats together.*
- Recommend involving the family in planning meals and food preparation. Children can learn about nutrition as they help plan and make meals. *Children are more likely to eat foods that they help select or prepare.*
- Suggest that parents work at being good role models of healthy eating. *Setting a good example is key for children; children learn the value of healthy eating early, and it can continue for a lifetime.*
- Recommend that the family try new foods, either a new food or recipe every week. *More variety can increase the intake of fruits and vegetables.*
- Suggest the parents keep healthy snacks on hand. Store the snacks in a purse, the car, a desk drawer. *Suggestions include crackers and peanut butter, small boxes of cereal, fresh fruit, and vegetables (Academy of Nutrition and Dietetics, 2014).*

Geriatric

- Recognize that it is generally not appropriate to have an older client on a calorie-restrictive diet. *Older clients deserve to eat and not be hungry.* **EB**: *Strength training and dietary modifications can improve body composition, muscle strength, and physical function in overweight and obese older adults (Straight et al, 2012).* *Loss of muscle (sarcopenia) occurs with normal aging; when paired with excessive fat, it leads to increased weakness and disability (Jarosz & Bellar, 2009).*
- Observe for socioeconomic factors that influence food choices (e.g., funds, cooking facilities, food insecurity). *Even those on restricted budgets and with limited facilities can be assisted to choose healthy food sources for a balanced diet.* **EB**: *Food security is a factor that can indicate a need for nutrition assistance in older adults (Lee et al, 2011).*

Multicultural

- Tailor nutritional interventions to be consistent with cultural beliefs, norms, and values. **CEBN**: *Mexican American women responded positively to nutritional education and physical activity promotion when families were involved* (Vincent, 2009).
- Offer tailored lifestyle counseling via the telephone. **EB**: *Low socioeconomic status African Americans and Latinos experienced positive nutritional change and weight loss after participating in a community-based translational lifestyle program* (Kanaya et al, 2012).
- Integrate weight loss and weight maintenance interventions with church faith based concepts for cultural congruence with African American clients. **EB**: *Recent research suggests that integrating faith themes into a weight loss maintenance program may increase its long-term impact on participants' health behavior change* (Seale et al, 2013).

Client/Family Teaching and Discharge Planning

- The majority of the preceding interventions involve teaching.
- Work with the family members regarding information on how to support and promote weight loss and healthy intakes.

Acute Pain *Maureen F. Cooney, DNP, FNP-BC, Chris Pasero, MS, RN-BC, FAAN, and Denise Sullivan, MSN, ANP-BC*

NANDA-I

Definition

An unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage ([International Association for the Study of Pain, 1979](#)); sudden or slow onset of any intensity from mild to severe with an anticipated or predictable end

Defining Characteristics

Appetite change; change in physiological parameter (e.g., blood pressure, heart rate, respiratory rate, oxygen saturation, and end-tidal CO₂); diaphoresis; distraction behavior; evidence of pain using standardized pain behavior checklist for those unable to communicate verbally (e.g., Neonatal Infant Pain Scale, Pain Assessment Checklist for Seniors with Limited Ability to Communicate); expressive behavior (e.g., restlessness, crying, vigilance); facial expression of pain (e.g., eyes lack luster, beaten look, fixed or scattered movement, grimace); guarding behavior; hopelessness; narrowed focus (e.g., time, perception, thought processes, interaction with people and environment); positioning to ease pain; protective behavior; proxy report of pain behavior/activity changes (e.g., family member, caregiver); pupil dilation; self-focused; self-report of intensity using standardized pain scale (e.g., Wong-Baker FACES scale, visual analog scale, numerical rating scale); self-report of pain characteristics using standardized pain instrument (e.g., McGill Pain Questionnaire, Brief Pain Inventory)

Related Factors (r/t)

Biological injury agent (e.g., infection, ischemia, neoplasm); chemical injury agent (e.g., burn, capsaicin, methylene chloride, mustard agent); physical injury agent (e.g., abscess, amputation, burn, cut, heavy lifting, operative procedure, trauma, overtraining)

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Pain Control; Pain Level; Pain: Adverse Psychological Response

Example NOC Outcome

Pain Level as evidenced by severity of observed or reported pain.

NOTE: **Pain Level** is the NOC Outcome label; this text recommends use of the self-report numerical pain rating scale in place of the NOC indicator scales because of the amount of research supporting its use.

List of Nursing Diagnoses by Letter: P

Acute Pain	Chronic Pain	Labor Pain
Chronic Pain syndrome	Impaired Parenting	Readiness for enhanced Parenting
Risk for impaired Parenting	Risk for Perioperative Positioning injury	Risk for Peripheral Neurovascular dysfunction
Risk for Poisoning	Post-Trauma syndrome	Risk for Post-Trauma syndrome
Readiness for enhanced Power	Powerlessness	Risk for Powerlessness
Risk for Pressure ulcer	Ineffective Protection	

Client Outcomes

Client Will (Specify Time Frame)

For the client who is able to provide a self-report

- Use a self-report pain tool to identify current pain intensity level and establish a comfort-function goal
- Report that pain management regimen achieves comfort-function goal without side effects
- Describe nonpharmacological methods that can be used to help achieve comfort-function goal
- Perform activities of recovery or activities of daily living (ADLs) easily
- Describe how unrelieved pain will be managed
- State ability to obtain sufficient amounts of rest and sleep
- Notify member of the health care team promptly for pain intensity level that is consistently greater than the comfort-function goal, or occurrence of side effects

For the client who is unable to provide a self-report

- Decrease in pain-related behaviors
- Perform activities of recovery or ADLs easily as determined by client condition
- Demonstrate the absence of side effects of analgesics
- No pain-related behaviors will be evident in the client who is completely unresponsive; a reasonable outcome is to demonstrate the absence of side effects related to the prescribed pain treatment plan

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Analgesic Administration; Pain Management; Patient-Controlled Analgesia (PCA) Assistance

Example NIC Activities—Pain Management

Ensure client attentive analgesic care; Perform a comprehensive assessment of pain to include location, characteristics, onset/duration, frequency, quality, intensity or severity of pain, and precipitating factors

Nursing Interventions and Rationales

P

- During the initial assessment and interview, if the client is experiencing pain, conduct and document a comprehensive pain assessment, using appropriate pain assessment tools. **CEB:** *Determining location, temporal aspects, pain intensity, characteristics, and the impact of pain on function and quality of life are critical to determine the underlying cause of pain and effectiveness of treatment (McCaffery, 1968; McCaffery et al, 2011). The initial assessment includes all pain information that the client can provide for the development of the individualized pain management plan (McCaffery et al, 2011).* Implement or request orders to implement pain management interventions to achieve a satisfactory level of comfort. Components of this initial assessment include location, quality, onset/duration, temporal profile, intensity, aggravating and alleviating factors, and effects of pain on function and quality of life. **(Please refer to the Hierarchy of Pain Measures presented later for assessment approach in clients who are unable to provide self-report of pain.)**
- Assess if the client is able to provide a self-report of pain intensity, and if so, assess pain intensity level using a valid and reliable self-report pain tool, such as the 0-10 numerical pain rating scale. **CEB:** *Self-report is considered the single most reliable indicator of pain presence and intensity and single-dimension pain ratings are valid and reliable as measures of pain intensity level (McCaffery et al, 2011).* **EB:** *Regularly and routinely assess the client for pain presence during activity and rest and with interventions or procedures likely to cause pain.* **CEB:** *Acute pain should be reliably assessed both at rest (important for comfort) and during movement (important for function and decreased client risk for cardiopulmonary and thromboembolic events) (McCaffery et al, 2011).*
- Ask the client to describe prior experiences with pain, effectiveness of pain management interventions, responses to analgesic medications including occurrence of side effects, and concerns about pain and its treatment (e.g., fear about addiction, worries, or anxiety) and informational needs. **EBN:** *Obtaining an individualized pain history helps identify potential factors that may influence the client's willingness to report pain, as well as factors that may influence pain intensity, the client's response to pain, anxiety, and pharmacokinetics of analgesics (Pasero 2009a; Pasero & Portenoy, 2011).*
- Using a self-report pain tool, ask the client to identify a comfort-function goal that will allow the client to perform necessary or desired activities easily. **EBN:** *The comfort-function goal provides the basis for*

individualized pain management plans and assists in determining effectiveness of pain management interventions (McCaffery et al, 2011).

- ▲ Describe the adverse effects of unrelieved pain. **CEB/EBN:** *Unrelieved acute pain can have physiological and psychological consequences that facilitate negative client outcomes. Ineffective management of acute pain has the potential for neurohumoral changes, neuronal remodeling, an impact on immune function, and long-lasting physiological, psychological, and emotional distress, and it may lead to persistent pain syndromes (Pasero, 2011; Pasero & Portenoy, 2011).*
- Use the Hierarchy of Pain Measures as a framework for pain assessment (McCaffery et al, 2011): (1) attempt to obtain the client's self-report of pain; (2) consider the client's condition and search for possible causes of pain (e.g., presence of tissue injury, pathological conditions, or exposure to procedures/interventions that are thought to result in pain); (3) observe for behaviors that may indicate pain presence (e.g., facial expressions, crying, restlessness, and changes in activity); (4) evaluate physiological indicators, with the understanding that these are the least sensitive indicators of pain and may be related to conditions other than pain (e.g., shock, hypovolemia, anxiety); and (5) conduct an analgesic trial. **EBN:** *When a client is unable to use a self-report tool (e.g., cognitively impaired, critically ill, anesthetized or sedated), the presence of pain may be assessed by observing specific client behaviors using a valid and reliable behavioral tool (e.g., Critical Care Observation Tool in critically ill or Checklist of Nonverbal Pain Indicators in cognitively impaired older adults) (Puntillo et al, 2014; McCaffery et al, 2011). In a study involving turning of neurocritically ill clients after elective brain surgery, self-report was obtained when possible, behaviors were found to be valid indicators of pain, and fluctuations in vital signs suggested the presence of pain, but their validity for such use was not supported, suggesting they should only be used in combination with other validated pain assessment tools (Kapoustina et al, 2014).*
- Assume that pain is present if the client is unable to provide a self-report and has tissue injury, a pathological condition, or has undergone a procedure that is thought to produce pain, and conduct an analgesic trial. **CEB:** *Pain is associated with actual or potential tissue damage such as pathological conditions (e.g., cancer) and procedures (e.g., surgery or trauma, fractures). In the absence of self-report (e.g., anesthetized, critically ill, or cognitively impaired client), the health care provider should use clinical judgment and assume pain is present, then implement pain management interventions accordingly (McCaffery et al, 2011).*
- ▲ Obtain and review an accurate and complete list of medications the client is taking or has taken. **EB:** *Accurate medication reconciliation can guide analgesic plan development and prevent errors associated with incorrect medications, dosages, omission of components of the home medication regimen, drug-drug interactions, and toxicity that can occur when incompatible drugs are combined or when allergies are present (Ignatavicius, 2013; Pasero et al, 2011b).*
- ▲ Explain to the client the pain management approach, including pharmacological and nonpharmacological interventions, the assessment and reassessment process, potential side effects, and the importance of prompt reporting of unrelieved pain. **EB:** *One of the most important steps toward improved control of pain is a better client understanding of the nature of pain, its treatment, and the role the client needs to play in pain control (Ignatavicius, 2013).*
- ▲ Manage acute pain using a multimodal approach. **EB:** *A multimodal approach (combining two or more drugs that act by different mechanisms for providing analgesia) enhances pain relief and allows the lowest effective dose of each drug to be administered, resulting in fewer or less severe side effects, such as nausea, sedation, and respiratory depression (Pasero et al, 2011c).*
- ▲ Select the route for administration of analgesics based upon client condition and pain characteristics. **EB:** *Routes have different rates of onset and duration. Oral route is preferred because of its convenience and the relatively steady blood levels that can result; the rectal route may be used when the oral route is not feasible; the IV route is preferred for rapid control of severe pain and would therefore not generally be used for chronic pain; intramuscular injections are avoided due to variable absorption and the potential for nerve injury and tissue damage (Pasero et al, 2011c).*
- ▲ Provide perineural infusions and intraspinal analgesia when appropriate and available. **CEBN:** *Superior analgesia can be provided through regional analgesic techniques compared with systemic opioids (Nishimori et al, 2012).*
- ▲ Use diverse analgesic delivery methods such as PCA to increase client's satisfaction with pain management, to lower cost, and to decrease occurrence of adverse reactions. **EBN:** *Intravenous PCA provides superior analgesia compared to intravenous injection in the first 12 hours after total hysterectomy (Hong & Lee, 2014).*

- ▲ Administer a nonopioid analgesic for mild to moderate pain and add an opioid analgesic if indicated for moderate to severe acute pain. **EB:** *Nonopioids, such as acetaminophen and nonsteroidal anti-inflammatory drugs, are first-line analgesics for the treatment of mild and some moderate acute pain, while opioids are included for the treatment of moderate to severe acute pain (Pasero et al, 2011a; Young & Buvanendran, 2012).*
- Administer analgesics around-the-clock for continuous pain (expected to be present approximately 50% of the day, such as postoperative pain) and PRN (as needed) for intermittent or breakthrough pain. **CEB:** *If pain is present most of the day, the use of PRN medications alone will lead to periods of undermedication and poor pain control and periods of excessive medication and adverse effects (Pasero, 2010).*
- Prevent pain by administering analgesia before painful procedures whenever possible (e.g., endotracheal suctioning, wound care, heel puncture, venipunctures, and peripherally inserted intravenous catheters). **EB:** *Adult clients in the intensive care setting experience numerous sources of procedural pain and chest tube removal, wound drain removal, and arterial line insertion are identified as the most painful procedures (Puntillo et al, 2014). The use of topical lidocaine 1% before removal of extremity vacuum-assisted closure wound dressings results in reduced pain and opioid use (Christensen et al, 2013).*
- Administer supplemental analgesic doses as ordered to keep the client's pain level at or below the comfort-function goal, or desired outcome based on clinical judgment or behaviors if client is unable to provide a self-report. **EB:** *An order for PRN supplemental analgesic doses between regular doses is essential in providing comprehensive pain management (Pasero et al, 2011c).*
- Perform nursing care during the peak effect of analgesics to optimize client comfort and participation in care. **CEB:** *Providing care such as mobilization and bathing should be performed when analgesics have reached peak effect: oral medications peak in 60 minutes, subcutaneous opioids in 30 minutes, and intravenous analgesics in 15 to 30 minutes (McCaffery et al, 2011; Pasero et al, 2011c).*
- ▲ Discuss the client's fears of undertreated pain, side effects, and addiction. **EBN:** *Cogan et al (2014) report that among 379 clients scheduled for cardiac surgery, 31% stated that it is easy to become addicted to pain medication, 20% report that "good patients" do not talk about their pain, and 35% believe that pain medication should be "saved in case the pain worsens."*
- The assessment of clients with acute pain on opioids should be done at regular intervals and include frequent assessment of pain level, assessment of respiratory status (including rate, rhythm, noisiness, depth), and systematic assessment of sedation level using a sedation scale (Pasero, 2009b). **EB:** *Opioid induced respiratory depression occurs with the greatest frequency in postoperative clients during the first 24 hours after surgery, and factors contributing to postoperative respiratory depression include the intervention of multiple prescribers (33%), concurrent administration of nonopioid sedating medications (34%), and inadequate nursing assessments or response (31%) (ASA, 2012; Jarzyna et al, 2011; Lee et al, 2015).*
- ▲ Provide the client with a stool softener and stimulant to prevent/treat opioid related constipation, and ask about other opioid related side effects including nausea, pruritus, lack of appetite, and changes in rest and sleep. **EB:** *In a study of postoperative orthopedic clients, more than half of the clients experienced one or more opioid related side effects including constipation, nausea, emesis, pruritus, and confusion, and the presence of side effects was associated with increased length of stay (Pizzi et al, 2012).*
- Review the client's pain flow sheet and medication administration record to evaluate effectiveness of pain relief, previous 24-hour opioid requirements, and occurrence of side effects. **EBN:** *Systematic tracking of pain is an important factor in improving pain management and making adjustments to the pain management regimen (McCaffery et al, 2011).*
- Advocate for the use of "as needed" opioid range orders to provide effective and appropriate pain relief. **EB:** *Correctly prescribed range orders for the delivery of intravenous opioids give nurses the flexibility needed to treat clients' pain in a timely manner while allowing for differences in client response to pain and to analgesia (Pasero et al, 2011c).*
- Choose analgesic and dose based on orders that reflect the client's report of pain severity and response to the previous dose in terms of pain relief, occurrence of side effects, and ability to perform the activities of recovery or ADLs. **EB:** *Safe and effective pain management requires opioid dose adjustment based on individualized adequate pain and sedation assessment, opioid administration, and evaluation of the response to treatment (Ignatavicius, 2013).*
- ▲ When converting opioids from parenteral doses to oral doses (the preferred route when the client can tolerate and absorb oral medications), use equianalgesic dosing charts and carefully monitor the client's

response to the new medication route and dose. **EBN:** *Equianalgesic dosing calculations should be used cautiously to guide dose conversion of an opioid from one route to another to avoid the toxicity associated with overdosing and the inadequate pain control due to underdosing (Shaheen et al, 2009).*

- Support the client's use of nonpharmacological methods to supplement pharmacological analgesic approaches to help control pain, such as distraction, imagery, music therapy, simple massage, relaxation, and application of heat and cold. **EBN:** *Although more evidence is needed to conclude effectiveness, non-pharmacological methods (which are low cost and low risk) can be used to complement pharmacological treatment of pain (Gelinas & Arbour, 2009; Ignatavicius, 2013).*
- Assist client to identify resources for coping with psychological impact of pain. **EBN:** *Cognitive-behavioral (mind-body) strategies can restore the client's sense of self-control, personal efficacy, and active participation in his or her own care (Bruckenthal, 2010).*
- Teach and implement nonpharmacological interventions when pain is relatively well controlled with pharmacological interventions. **EB:** *Pain causes cognitive impairment (Moriarty et al, 2011; Pasero et al, 2011a).*

Pediatric

- Assess for the presence of pain using a valid and reliable pain scale based on age, cognitive development, and the child's ability to provide a self-report. **EBN:** *Scales that depict faces at various levels of pain intensity are commonly used in young children and have been shown to be reliable and valid in children as young as 3 years old (Oakes, 2011).* **EB:** *Behavioral tools such as the FLACC Scale may be used to assess pain in infants and children who cannot provide a self-report (Crellin et al, 2015).*
- ▲ Administer prescribed analgesics using a multimodal approach to treat pain in children, infants, and neonates. **EB:** *PCA may be used by children as young as 4 years of age, and intraspinal and perineural analgesic techniques may be used for major surgical procedures (Oakes, 2011).*
- Prevent procedural pain in neonates, infants, and children by using opioid analgesics and anesthetics, as indicated, in appropriate dosages. **EBN:** *Czarnecki et al (2011) found that several barriers exist to the treatment of procedural pain in children including insufficient medication orders before procedures, insufficient time to premedicate children before procedures, the perception of low priority given to pain management by medical staff, and parents' reluctance to have their children medicated.*
- Use a topical local anesthetic such as eutectic mixture of local anesthetics (EMLA) cream or LMX-4 before performing venipuncture in neonates, infants, and children. **EBN:** *The use of EMLA with prolonged application time for pediatric venipuncture in the emergency department results in improved venipuncture success and reduced pain (Baxter et al, 2013).*
- For the neonate, use oral sucrose and nonnutritional sucking (NNS) or human milk for pain of short duration such as heel stick or venipuncture. Neonates, especially preterm neonates, are more sensitive to pain than older children. **EBN:** *In an integrated literature review, Naughton (2013) found that the combination of oral sucrose and NNS is a safe and effective method of relieving pain in neonates and increases the calming effect in infants undergoing painful procedures.*
- Recognize that breastfeeding has been shown to reduce behavioral indicators of pain. **EB:** *Breastfeeding has not been shown to have a better analgesic effect than sucrose in late preterm infants (Simonse et al, 2012).*

As with adults, use nonpharmacological analgesic interventions to supplement, not replace, pharmacological interventions in pediatric clients. **EB:** *Heel pain associated with lancet heel sticks in preterm newborns was shown to provide greater reduction in pain scores when pharmacological methods (fentanyl injections) were combined with nonpharmacological techniques (sensory saturation) (Gitto et al, 2012).* **CEB:** *Complementary therapies such as relaxation, distraction, hypnotics, art therapies, and imagery may play an important role in holistic pain management (Oakes, 2011).* Nonpharmacological interventions reduce procedure-related distress (Oakes, 2011).

Geriatric

- Refer to the Nursing Interventions and Rationales in the care plan for Chronic Pain.

Multicultural

- Refer to the Nursing Interventions and Rationales in the care plan for Chronic Pain.

Home Care

- ▲ Develop the treatment plan with the client and caregivers. **EB:** *Client education and motivation play important roles in self-management of clients with pain. Self-management is influenced by client-provider communication (Dorflinger et al, 2013).*
- ▲ Assess the client's full medication profile, including medications prescribed by all health care providers and all over-the-counter medications for drug interactions, and instruct the client to refrain from mixing medications without health care provider approval. **EB:** *Pain medications may significantly affect or be affected by other medications and may cause severe side effects; in a study of diabetic pregabalin and duloxetine users, potential duloxetine drug-drug interactions and drug-condition interactions were associated with significant increases in mean health care costs (Johnston et al, 2013).*
- ▲ Assess the client/family's knowledge of side effects and safety precautions associated with pain medications. **EB:** *Educational activities related to pain medications are necessary to ensure that clients are knowledgeable about opioid side effects and safety. McCarthy et al (2015) found that clients who were read and given a one page information sheet about hydrocodone-acetaminophen safety had better knowledge of precautions related to acetaminophen dosing, and were less likely to drive a car within 6 hours of taking the medication than those who did not receive this educational intervention.*
- If medication is administered using highly technological methods, assess the home for the necessary resources (e.g., electricity) and ensure that there will be responsible caregivers available to assist the client with administration. **EB:** *With appropriate assessment of home resources, it is possible to provide home management of clients with complex pain management technologies as demonstrated in a study of children with cleft palate repair who received home infusion of local anesthetic via peripheral nerve block catheter (Visoiu, 2014).*
- Assess the knowledge base of the client and family with regard to highly technological medication administration and provide necessary education, including the procedure to follow if analgesia is unsatisfactory. **EB:** *With appropriate education and training, outpatient families can successfully manage infusions of local anesthetics through peripheral nerve catheters for analgesia in clients recovering from cleft palate surgery (Visoiu, 2014).*

P

Client/Family Teaching and Discharge Planning

NOTE: To avoid the negative connotations associated with the words “drugs” and “narcotics,” use the term “pain medicine” when teaching clients.

- Discuss the various discomforts encompassed by the word “pain” and ask the client to give examples of previously experienced pain. Explain the pain assessment process and the purpose of the pain rating scale. **CEB:** *It is often difficult for clients to understand the concept of pain and describe their pain experience. Using alternative words and providing a complete description of the assessment process, including the use of scales, ensures that an accurate treatment plan is developed (McCaffery et al, 2011).*
- Teach the client to use the self-report pain tool to rate the intensity of past or current pain. Ask the client to set a comfort-function goal by selecting a pain level on the self-report tool that will allow performance of desired or necessary activities of recovery with relative ease (e.g., turn, cough, deep breathe, ambulate, participate in physical therapy). If the pain level is consistently above the comfort-function goal, the client should take action that decreases pain or notify a member of the health care team so that effective pain management interventions may be implemented promptly. **CEB:** *The use of comfort-function goals provides the basis for the direction and modification of the treatment plan (McCaffery et al, 2011).*
- Provide written educational materials on various aspects of pain control to improve client understanding of pain and pain-related interventions. **EB:** *Written materials and other educational tools assist in improving clients' knowledge related to pain management. In knee replacement clients, the use of an educational pamphlet and a compact disc was associated with decreased postoperative pain and increased participation in physical rehabilitation (Chen et al, 2014).*
- Discuss and evaluate the client's understanding about the total plan for pharmacological and nonpharmacological treatment, including the medication plan for around-the-clock administration and supplemental doses, and the use of supplies and equipment. **CEB:** *Appropriate instruction increases the accuracy and safety of medication administration (Pasero et al, 2011b).*

- Teach basic principles of pain management using a variety of educational strategies, and evaluate learning. **EB:** *Client educational strategies that have been shown to increase knowledge, decrease anxiety, and increase satisfaction include the use of computer technology, audio and videotapes, written materials, and demonstrations, or combinations of these strategies (Friedman et al, 2011).*
- ▲ Reinforce the importance of taking pain medications to maintain the comfort-function goal. **CEB:** *Teaching clients to stay on top of their pain and prevent it from getting out of control will improve the ability to accomplish the goals of recovery (McCaffery et al, 2011).*
- ▲ Reinforce that taking opioids for pain relief is not addiction and that addiction is very unlikely to occur. **CEB:** *The development of addiction when opioids are taken for pain relief is rare (Pasero et al, 2011c).*
- ▲ Demonstrate the use of appropriate nonpharmacological approaches in addition to pharmacological approaches to help control pain, such as application of heat and/or cold, distraction techniques, relaxation breathing, visualization, rocking, stroking, listening to music, and watching television. **CEB:** *Nonpharmacological interventions are used to complement, not replace, pharmacological interventions (Bruckenthal, 2010).*

Chronic Pain

Maureen F. Cooney, DNP, FNP-BC, Denise Sullivan, MSN, ANP-BC, and Chris Pasero, MS, RN-BC, FAAN

NANDA-I

Definition

Unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage ([International Association for the Study of Pain, 1979](#)); sudden or slow onset of any intensity from mild to severe, constant or recurring without an anticipated or predictable end and a duration of greater than 3 months

Defining Characteristics

Alteration in ability to continue previous activities; alteration in sleep pattern; anorexia; evidence of pain using standardized pain behavior checklist for those unable to communicate verbally (e.g., Neonatal Infant Pain Scale, Pain Assessment Checklist for Seniors with Limited Ability to Communicate); facial expression of pain (e.g., eyes lack luster, beaten look, fixed or scattered movement, grimace); proxy report of pain behavior/activity changes (e.g., family member, caregiver); self-focused; self-report of intensity using standardized pain scale (e.g., Wong-Baker FACES scale, visual analog scale, numerical rating scale); self-report of pain characteristics using standardized pain instrument (e.g., McGill Pain Questionnaire, Brief Pain Inventory)

Related Factors (r/t)

Age older than 50 years; alteration in sleep pattern; chronic musculoskeletal condition; contusion; crush injury; damage to the nervous system; emotional distress; fatigue; female gender; fracture; genetic disorder; history of abuse (e.g., physical, psychological, sexual); history of genital mutilation; history of indebtedness; history of static work postures; history of substance abuse; history of vigorous exercise; imbalance of neurotransmitters, neuromodulators, and receptors; immune disorder (e.g., HIV-associated

neuropathy, varicella-zoster virus); impaired metabolic functioning; increase in body mass index; ineffective sexuality pattern; injury agent (may be present, but not required; pain may be of unknown etiology); ischemic condition; malnutrition; muscle injury; nerve compression; post-trauma related condition (e.g., infection, inflammation); prolonged computer use (>20 hours/week); prolonged increase in cortisol level; repeated handling of heavy loads; social isolation; spinal cord injury; tumor infiltration; whole-body vibration

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Comfort Level; Pain Control; Pain: Disruptive Effects; Pain Level

Example NOC Outcome with Indicators

Pain Level as evidenced by use of a numerical pain rating scale, asking the client to rate the level of pain from 0 to 10. Self-report is considered the single most reliable indicator of pain presence and intensity (American Pain Society [APS], 2008; McCaffery et al, 2011)

NOTE: **Pain Level** is the NOC Outcome label; this text recommends use of the self-report numerical pain rating scale in place of the NOC indicator scales because of the amount of research supporting its use.

Client Outcomes

Client Will (Specify Time Frame)

For the client who is able to provide a self-report

- Provide a description of the pain experience including physical, social, emotional, and spiritual aspects
- Use a self-report pain tool to identify current pain level and establish a comfort-function goal
- Report that the pain management regimen achieves comfort-function goal without the occurrence of side effects
- Describe nonpharmacological methods that can be used to supplement, or enhance, pharmacological interventions and help achieve the comfort-function goal
- Perform necessary or desired activities at a pain level less than or equal to the comfort-function goal
- Demonstrate the ability to pace activity, taking rest breaks before they are needed
- Describe how unrelieved pain will be managed
- State the ability to obtain sufficient amounts of rest and sleep
- Notify a member of the health care team for pain level consistently greater than the comfort-function goal or occurrence of side effect

For the client who is unable to provide a self-report

- Demonstrate decrease or resolved pain-related behaviors
- Perform desired activities as determined by client condition
- Demonstrate the absence of side effects
- No pain-related behaviors will be evident in the client who is completely unresponsive; a reasonable outcome is to demonstrate the absence of side effects related to the prescribed pain treatment plan

P

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Analgesic Administration; Pain Management

Example NIC Activities—Pain Management

Ensure that the client receives attentive analgesic care; Perform comprehensive assessment of pain, including location, characteristics, onset and duration, frequency, quality, intensity or severity, and precipitating factors

Nursing Interventions and Rationales

- ▲ During the initial assessment and interview, if the client is experiencing pain, conduct and document a comprehensive pain assessment, using appropriate pain assessment tools. **EBN:** *Determining location, temporal aspects, pain intensity, characteristics, and the impact of pain on function and quality of life are critical to determine the underlying cause of pain and effectiveness of treatment (McCaffery et al, 2011).*
- ▲ Determine the quality of the pain and whether the pain has persisted beyond the usual duration for tissue healing. **EB:** *Chronic pain is persistent, lasting beyond the expected time or usual time of tissue healing (usually 3 months). Descriptors such as “sharp,” “shooting,” or “burning” assist in discriminating neuropathic pain from nociceptive pain (Linl et al, 2011; McCaffery et al, 2011).* **Please refer to the Hierarchy of Pain Measures for assessment approach in clients who are unable to provide self-report of pain.**
- ▲ Assess pain intensity level in a client using valid and reliable self-report pain tools, such as the 0-10 numerical pain rating scale (NRS), pain relief scale (PRS), or chronic pain grade scale. **EB:** *Lee et al (2014) report that the NRS together with the PRS increased the objectivity of pain assessment in chronic spinal pain compared to the use of either scale alone.*
- ▲ Ask the client to describe prior experiences with pain, effectiveness of pain management interventions, responses to analgesic medications including occurrence of side effects, and concerns about pain and its treatment (e.g., fear about addiction, worries, or anxiety) and informational needs. **EB:** *Pain management regimens must be individualized to the client and consider medical, psychological, and physical condition; age; level of fear or anxiety; client goals and preference; and previous response to analgesics (Pasero et al, 2011a).*
- Using a self-report tool, ask the client to identify a comfort-function goal that will allow the client to perform necessary or desired activities easily. **EBN:** *The comfort-function goal provides the basis for individualized pain management plans and assists in determining effectiveness of pain management interventions (McCaffery et al, 2011).* Assess the client for the presence of acute pain (see care plan for Acute **Pain**).
- ▲ Assess chronic pain regularly including the impact of chronic pain on activity, sleep, eating habits, social conditions including relationships, finances, and employment. **CEB:** *Regular assessment of clients with chronic pain is critical because changes in the underlying pain condition, presence of comorbidities, and changes in psychosocial circumstances can affect pain intensity and characteristics and require revision of the pain management plan (Chou et al, 2009).*
- ▲ Assess the client for the presence of psychiatric conditions, including anxiety and depression. **EB:** *Among chronic pain clients, 30% to 50% have been found to have depression as a comorbidity, and there is a four-fold higher risk of suicide attempt than in the general population (Breivik et al, 2014). Nearly half of chronic pain clients screen positive for anxiety disorders (Kroenke, 2013).*
- ▲ If opioid therapy is considered, assist the provider with aspects of an opioid risk assessment, which includes a comprehensive client interview and examination with a pain focus, mental health screening, use of an opioid risk assessment tool, examination of prescription drug monitoring program results, and urine drug screening. **EB:** *There is evidence of opioid misuse, abuse, and addiction among chronic noncancer pain clients with varying prevalence rates thus reduce risk and optimize safe opioid use, risk assessment and stratification is recommended (Cheatle & Barker, 2014; Chou et al, 2014).*
- ▲ For the client who is receiving outpatient opioid therapy, at each visit, assess effect of opioids on pain status, function, goal achievement, and presence of side effects including sleep disturbance and sexual dysfunction; assessment for signs of opioid misuse, abuse, and addiction should be included, which may involve the use of random urine drug toxicology screening, pill counts, and review of prescription monitoring database. **EB:** *Opioid therapy is associated with risk for misuse, abuse, and addiction as well as overdose, while the evidence for the long-term use of opioid therapy in chronic pain is inconclusive. To minimize risk, a number of risk mitigation practices, including careful assessment of the client response to opioid therapy, are recommended (Cheatle & Barker, 2014; Chou et al, 2014).*
- Ask the client to maintain a diary (if able) of pain ratings, timing, precipitating events, medications, and effectiveness of pain management interventions. **EBN:** *Systematic tracking of pain has been demonstrated to be an important factor in improving pain management (Hager & Brockopp, 2009; McCaffery et al, 2011). In a study of smartphone-based interventions with diaries among women with chronic widespread pain, it was found that the use of the smartphone intervention with diaries and personalized feedback reduced catastrophizing and prevented increases in functional impairment and symptoms (Kristjansdottir et al, 2013).*

- ▲ Obtain and review an accurate and complete list of medications the client is taking or has taken. **CEB:** *Accurate medication reconciliation can guide analgesic plan development and prevent errors associated with incorrect medications, dosages, omission of components of the home medication regimen, drug-drug interactions, and toxicity that can occur when incompatible drugs are combined or when allergies are present (Gleason et al, 2004).*
- ▲ Explain to the client the pain management approach that has been ordered or revised, including therapies, medication administration, side effects, and complications. **EB:** *One of the most important steps toward improved control of pain is a better client understanding of the nature of pain, its treatment, and the role the client needs to play in pain control (Pasero & Portenoy, 2011).*
- Discuss the client's fears of undertreated pain, addiction, and overdose. **EBN:** *Because of the many misconceptions regarding pain and its treatment, education about the ability to control pain effectively and correction of myths about the use of opioids should be included as part of the treatment plan (McCaffery et al, 2011).*
- ▲ Manage chronic pain using an individualized, multimodal approach. **EB:** *A multimodal approach (combining two or more drugs that act by different mechanisms for providing analgesia) such as an anticonvulsant, antidepressant, and opioid in chronic pain enhances pain relief and allows the lowest effective dose of each drug to be administered, resulting in fewer or less severe side effects such as nausea, sedation, and respiratory depression (Pasero et al, 2011a; Turk et al, 2011).*
- ▲ Select the route of administration of analgesics based on client condition and pain characteristics. **CEB:** *The least invasive route of administration capable of providing adequate pain control is recommended. Oral route is preferred because of its convenience and the relatively steady blood levels that can result (American Geriatric Society [AGS], 2009); the rectal route may be used when the oral route is not feasible; the intravenous route is preferred for rapid control of severe pain and would therefore not generally be used for chronic pain; intramuscular injections are avoided due to variable absorption and the potential for nerve injury and tissue damage (APS, 2008; Pasero et al, 2011a).*
- ▲ When chronic pain has a neuropathic component, treat with adjuvant analgesics, such as anticonvulsants, antidepressants, and topical local anesthetics. **EB:** *First-line analgesics for neuropathic pain belong to the adjuvant analgesic group and include anticonvulsants, antidepressants, and some topical local anesthetics. Analgesic efficacy with opioids in chronic neuropathic pain is inconclusive (Gilon et al, 2015; McNicol et al, 2013).*
- ▲ Administer a nonopioid analgesic for mild to moderate chronic pain and as a component of the treatment for all levels of pain for clients with cancer pain. **CEB:** *Nonopioids, such as acetaminophen and nonsteroidal antiinflammatory drugs (NSAIDs), are first-line analgesics for the treatment of mild and moderate pain conditions (e.g., osteoarthritis pain) and are recommended for cancer pain in all intensities (AGS, 2009; National Comprehensive Cancer Network [NCCN], 2015; Pasero et al, 2011b).*
- ▲ Recognize that opioid therapy may be indicated for some clients experiencing chronic pain. **EB:** *Opioids are often used in the management of moderate to severe chronic cancer pain; the evidence to support the long-term use of opioids for chronic, noncancer pain is limited due to a lack of long-term high-quality studies, yet with careful client selection, opioids may be considered when nonopioid analgesics are ineffective alone or are contraindicated (AGS, 2009; Chou et al, 2009; Manchikanti et al, 2012; Turk et al, 2011).*
- ▲ Administer analgesics around-the-clock for continuous pain and PRN (as needed) for intermittent or breakthrough pain as may be experienced by clients with cancer pain. **EB:** *More than one in two clients with cancer pain also experience breakthrough cancer pain, and if pain is present most of the day, the use of PRN medications alone will lead to periods of undermedication and poor pain control and to periods of excessive medication and adverse effects (Chou, 2009; Deandrea et al, 2014).*
- ▲ At regular intervals, assess inpatient clients with chronic pain for opioid-related adverse events and include frequent assessment of pain level, assessment of respiratory status (including rate, rhythm, noisiness, depth), and systematic assessment of sedation level using a sedation scale. **CEB:** *Tolerance to opioid-induced respiratory depression develops within days of regular daily opioid dosing, making this side effect less likely to occur in clients who are taking opioids for underlying chronic pain and are opioid tolerant than in those who are not; however, opioid-tolerant clients are at similar risk for this side effect when they are admitted to the hospital for surgery or experience any other acute pain condition and are given opioid doses in addition to their usual dose (APS, 2008; Pasero et al, 2011a).*
- ▲ Provide the client with a stool softener and stimulant to prevent/treat opioid-related constipation. Ask about other opioid-related side effects including nausea, pruritus, lack of appetite, and changes in rest and sleep. **EB:** *While clients may develop tolerance to nausea, pruritus, and other opioid side effects, they*

do not develop tolerance to opioid-induced constipation. A study of 489 people on long-term opioids revealed varying utilization and responses to laxatives continues to add to the burden of chronic pain (Coyne et al, 2015; Pasero et al, 2011).

- ▲ Question the client about any disruption in sleep. **EB:** Chronic low back pain is associated with reduced sleep duration and quality (Kelly et al, 2011).
- ▲ In addition to administering analgesics, support the client's use of nonpharmacological methods to help control pain, such as distraction, imagery, relaxation, and application of heat and cold. **CEB:** Cognitive behavioral (mind-body) strategies such as cognitive restructuring, relaxation, meditation, goal setting, and pacing can restore the client's sense of self-control, personal efficacy, and active participation in his/her own care. The use of Web-based cognitive behavioral therapy (CBT) has shown that participants improved in self-efficacy for pain management and self-regulation, as well as reduced catastrophizing and fearful avoidance of activity (Bruckenthal, 2010; Carpenter et al, 2012).
- Teach and implement nonpharmacological interventions when pain is relatively well controlled with pharmacological interventions. **EB:** Pain causes cognitive impairment (Moriarty et al, 2011; Pasero et al, 2011a).
- ▲ Encourage the client to plan activities around periods of greatest comfort whenever possible. **EB:** Some literature supports the use of pacing (a CBT strategy), an active self-management strategy in which individuals learn to balance activity and rest for the purpose of increasing function (Pigeon et al, 2012).
- ▲ Explore appropriate resources for management of pain on a long-term basis (e.g., hospice, pain care center). **EB:** Outpatient pain management resources must be identified to ensure appropriate chronic pain management. A telecare collaborative management study demonstrated that participants with chronic musculoskeletal pain who received telecare management monthly for a year experienced at least 30% improvement in pain scores after 12 months as well as improved secondary pain (Kroenke et al, 2014).
- ▲ If the client has progressive cancer pain, assist the client and family with handling issues related to death and dying and provide access to palliative care programs and hospice services. **EB:** Hui et al (2014) report that in a study of advanced cancer clients, those who were referred to outpatient palliative care had improved end-of-life care compared to those who received inpatient palliative care.

Pediatric

- Assess for the presence of pain using a valid and reliable pain scale based on age, cognitive development, and the child's ability to provide a self-report. **EBN:** Scales that depict faces at various levels of pain intensity are commonly used in young children and have been shown to be reliable and valid in children as young as 3 years old (Oakes, 2011). **CEB:** Behavioral tools such as the FLACC scale may be used to assess pain in infants and children who cannot provide a self-report (Merkel et al, 2002).
- ▲ Administer prescribed analgesics using a multimodal approach to treat pain in children, infants, and neonates. **EB:** As with adults, pharmacological interventions are first-line approaches to the management of pain in children, infants, and neonates. A multimodal approach using nonopioid and opioid analgesics is recommended (Oakes, 2011).
- As with adults, use nonpharmacological analgesic interventions to supplement, not replace, pharmacological interventions in pediatric clients. **EBN:** Complementary therapies such as cognitive behavioral strategies, mindfulness-based approaches, and other nonpharmacological approaches may play an important role in chronic pain management in children and adolescents (Song et al, 2014; van der Veek et al, 2013).

Geriatric

- ▲ An older client's report of pain should be taken seriously and assessed and treated. **CEB:** Pain is not an expected part of normal aging and unrecognized, untreated, or undertreated pain may result in adverse effects such as decreased cognition, delirium, mood changes (depression, anxiety), sleep disturbances, and significant physical and social disability (AGS, 2009; McCaffery et al, 2011).
- When assessing pain, speak clearly, slowly, and loudly enough for the client to hear, ensure hearing aids and glasses are in place as appropriate; enlarge pain scales and written materials; and repeat information as needed. **CEB:** Older clients often have difficulty hearing and seeing, and comprehension is improved when instructions are given slowly and clearly and when clients can see visual aids (Herr & Bjoro, 2008; McCaffery et al, 2011).
- Handle the client's body gently and allow the client to move at his or her own speed. **CEB:** Older adults are particularly susceptible to injury during care activities. Caregivers must be patient and expect that older

clients will move more slowly than younger clients; they may also perform better and experience less pain when they are allowed to move themselves (Herr & Titler, 2009).

- ▲ Use nonopioid analgesics for mild to moderate pain. **CEB:** Acetaminophen (maximum dosage 3000 mg/day) is recommended, unless contraindicated, as first-line therapy for older persons with persistent pain; NSAIDs (preferably in topical form due to less system absorption than oral form) should be used short term and with extreme caution due to the higher gastrointestinal, cardiovascular, and renal adverse effects (AGS, 2009; U.S. Food and Drug Administration, 2009).
- ▲ Use opioids cautiously in the older client with moderate to severe pain. **CEB:** Even though data are lacking in all groups regarding the use of opioids for persistent pain, due to the adverse effects of some nonopioid analgesics in older clients, the initiation of opioids for persistent pain in clients with increased functional impairment or decreased quality of life may be considered, starting with a short-acting low-dose opioid, carefully and slowly titrating to attain therapeutic goal, and converting to a long-acting opioid if needed for persistent around-the-clock pain (AGS, 2009; Pasero et al, 2011a).
- ▲ Avoid the use of meperidine (Demerol) in older clients. **EB:** Meperidine's metabolite, normeperidine, can produce central nervous system irritability, seizures, and even death; normeperidine is eliminated by the kidneys, which makes meperidine a particularly poor choice for older clients, many of whom have at least some degree of renal insufficiency (Pasero et al, 2011a).
- ▲ Use nonpharmacological approaches in addition to analgesics. **EB:** Physical and occupational rehabilitation, behavioral approaches, and movement-based interventions tailored to the older person's needs and capabilities have been shown to be effective and should be used to treat chronic pain when possible (Makris et al, 2014; Bruckenthal, 2010).
- ▲ Monitor for signs of depression in older clients and refer to specialists with relevant expertise. **EB:** Depression is often associated with pain and decreased levels of independence with activities of daily living in the older client. Treatment has been demonstrated to decrease pain and improve functional abilities (Tarakci et al, 2015; AGS, 2009).

Multicultural

- ▲ Assess for pain disparities among racial and ethnic minorities. **EB:** Individuals of ethnic and racial minorities often receive fewer treatment options and less effective pain treatment than others because of barriers imposed by health care professionals and health care systems (Mossey, 2011; Tait & Chibnall, 2014).
- ▲ Assess for the influence of cultural beliefs, norms, and values on the client's perception and experience of pain. **EBN:** Mexican American women with chronic pain are reluctant to take prescribed analgesics due to perceived negative associations with pain medications (Monsivais, 2012).
- ▲ Assess for the effect of fatalism on the client's beliefs regarding the current state of comfort. **EBN:** Asian clients' perceived barriers to managing cancer pain were found to be higher than those reported for Western clients, and Asian clients expressed a fatalistic belief that cancer pain is inevitable; these fatalistic beliefs toward pain and pain management may predispose Asian clients to hesitate to report pain and request pain medications (Chen et al, 2012).
- ▲ Use a family-centered approach to care. **EB:** Involving the family in care through early regular communication and decision-making may reduce anxiety, alleviate uncertainty, and improve coping strategies (Michael et al, 2014).
- Use culturally relevant pain scales to assess pain in the client. **CEB:** Clients from minority cultures may express pain differently than clients from the majority culture. The Faces Pain Scale-Revised was shown to be preferred over other self-report pain rating tools in older minority adults (Ware, 2006) and in Chinese adults (Li et al, 2007). A later study demonstrated that the Iowa Pain Thermometer was the preferred tool in older Chinese adults (Li et al, 2009). The Oucher scale is available in African American and Hispanic versions and is used to assess pain in children (Oakes, 2011). Ensure that directions for medication use are available in the client's language of choice and are understood by the client and caregiver. **CEB:** Use of bilingual instructions for medication administration increased compliance with the pain management plan (Juarez et al, 1998).

Home Care

- The interventions previously described may be adapted for home care use. Refer to the Nursing Interventions and Rationales in the care plan for Acute Pain.

Client/Family Teaching and Discharge Planning

NOTE: To avoid the negative connotations associated with the words “drugs” and “narcotics,” use the term “pain medicine” when teaching clients.

- Discuss the various discomforts encompassed by the word “pain” and ask the client to give examples of previously experienced pain. Explain the pain assessment process and the purpose of the pain rating scale. **EB:** *It is often difficult for clients to understand the concept of pain and describe their pain experience. Using alternative words and providing a complete description of the assessment process, including the use of scales, ensures that an accurate treatment plan is developed (McCaffery et al, 2011).*
- Teach the client that if the pain level is consistently above the comfort-function goal, the client should take action that decreases pain or should notify a member of the health care team so that effective pain management interventions may be implemented promptly. (See information on teaching clients to use the pain rating scale.) **EB:** *The use of comfort-function goals provides direction for the treatment plan. Changes are made according to the client’s response and achievement of the goals of recovery or rehabilitation (McCaffery et al, 2011).*
- Provide educational materials on various aspects of pain control to improve client understanding of pain and pain-related interventions. **EB:** *Written materials and other educational tools assist in improving clients’ knowledge related to pain management. In knee replacement clients, the use of an educational pamphlet and a compact disc was associated with decreased postoperative pain and increased participation in physical rehabilitation (Chen et al, 2014).*
- Discuss and evaluate the client’s understanding about the total plan for pharmacological and nonpharmacological treatment, including the medication plan for around-the-clock administration and supplemental doses, the maintenance of a pain diary, and the use of supplies and equipment. **EB:** *Appropriate instruction increases the accuracy and safety of medication administration (Pasero et al, 2011a).*
- Reinforce the importance of taking pain medications to maintain the comfort-function goal. **EBN:** *Teaching clients to stay on top of their pain and prevent it from getting out of control will improve the ability to accomplish the goals of recovery (McCaffery et al, 2011).*
- ▲ Reinforce that taking opioids for pain relief is not addiction and that addiction is very unlikely to occur. **CEB:** *The development of addiction when opioids are taken for pain relief is rare (APS, 2008; Pasero et al, 2011a).*
- Demonstrate the use of appropriate nonpharmacological approaches in addition to pharmacological approaches for helping control pain, such as application of heat and/or cold, distraction techniques, relaxation breathing, visualization, rocking, stroking, listening to music, and watching television. Teach these methods when pain is relatively well controlled, because pain interferes with cognition. **CEB:** *Non-pharmacological interventions are used to complement pharmacological interventions (Bruckenthal, 2010; Pasero et al, 2011a).*
- ▲ Emphasize to the client the importance of participating in a structured, individualized pacing activity and taking rest breaks before they are needed. **CEB:** *In a study of adults with knee or hip osteoarthritis, it was shown by Murphy et al (2010) that an individualized, tailored activity pacing intervention provides more pain relief and less fatigue than general instructions related to fatigue (Murphy et al, 2010).*
- Teach nonpharmacological methods when pain is relatively well controlled. **EB:** *Pain interferes with cognition (Moriarty et al, 2011; Pasero et al, 2011a).*

Labor Pain *Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN*

NANDA-I

Definition

Sensory and emotional experience that varies from pleasant to unpleasant, associated with labor and childbirth

Defining Characteristics

Alteration in blood pressure; alteration in heart rate; alteration in muscle tension; alteration in neuroendocrine functioning; alteration in respiratory rate; alteration in sleep pattern; alteration in urinary functioning; decrease in appetite; diaphoresis; distraction behavior; expressive behavior; facial expression of pain (e.g., eyes lack luster, beaten look, fixed or scattered movement, grimace); increase in appetite; narrowed focus; nausea; pain; perineal pressure; positioning to ease pain; protective behavior; pupil dilation; self-focused; uterine contraction; vomiting

Related Factors (r/t)

Cervical dilation; fetal expulsion

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan for Acute **Pain**.

Chronic Pain syndrome *Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN*

NANDA-I

Definition

Recurrent or persistent pain that has lasted at least 3 months and that significantly affects daily functioning or well-being

Defining Characteristics

Anxiety; constipation; deficient knowledge; disturbed sleep pattern; fatigue; fear; impaired mood regulation; impaired physical mobility; insomnia; obesity; social isolation; stress overload

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan for Acute **Pain** and Chronic **Pain**.

Impaired Parenting *Kimberly Silvey, MSN, RN*

NANDA-I

Definition

Inability of the primary caretaker to create, maintain, or regain an environment that promotes the optimum growth and development of the child

Defining Characteristics

Infant/Child

Behavioral disorders (e.g., attention deficit, oppositional defiant); delay in cognitive development; diminished separation anxiety; failure to thrive; frequent accidents; frequent illness; history of abuse (e.g., physical, psychological, sexual); history of trauma (e.g., physical, psychological, sexual); impaired social functioning; insufficient attachment behavior; low academic performance; runaway

Parental

Abandonment; decrease in ability to manage child; decrease in cuddling; deficient parent-child interaction; frustration with child; history of childhood abuse (e.g., physical, psychological, sexual); hostility; inadequate child health maintenance; inappropriate caretaking skills; inappropriate childcare arrangements; inappropriate stimulation (e.g., visual tactile auditory); inconsistent behavior management; inconsistent care; inflexibility in meeting needs of child; neglects needs of child; perceived inability to meet child's needs; perceived role inadequacy; punitive; rejection of child; speaks negatively about child; unsafe home environment

Related Factors (r/t)

Infant/Child

Alteration in perceptual abilities; behavior disorder (e.g., attention deficit, oppositional defiant); chronic illness; developmental delay; difficult temperament; disabling condition; gender other than desired; multiple births; parent-child separation; prematurity; temperament conflicts with parental expectations

Knowledge

Alteration in cognitive functioning; ineffective communication skills; insufficient cognitive readiness for parenting; insufficient knowledge about child development; insufficient knowledge about child health maintenance; insufficient knowledge about parenting skills; insufficient response to infant cues; low educational level; preference for physical punishment; unrealistic expectation

Physiological

Physical illness

Psychological

Alteration in sleep pattern; closely spaced pregnancies; depression; difficult birthing process; disability condition; high number of pregnancies; history of mental illness; history of substance abuse; insufficient prenatal care; sleep deprivation; young parental age

Social

Change in family unit; compromised home environment; conflict between partners; economically disadvantaged; father of child not involved; history of abuse (e.g., physical, psychological, sexual); history of being abusive; inability to put child's needs before own; inadequate childcare arrangements; ineffective coping strategies; insufficient family cohesiveness; insufficient parental role model; insufficient problem-solving skills; insufficient resources (e.g., financial social, knowledge); insufficient social support; insufficient transportation; insufficient valuing of parenthood; legal difficulty; low self-esteem; mother of child not involved; relocation; single parent; social isolation; stressors; unemployment; unplanned pregnancy; unwanted pregnancy; work difficulty

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Cessation; Abuse Protection; Abuse Recovery: Abusive Behavior Self-Restraint; Child Development (all); Coping; Family Functioning; Family Social Climate; Knowledge: Child Physical Safety; Neglect Recovery; Parent-Infant Attachment; Parenting Performance, Psychosocial Safety; Role Performance; Social Support

Example NOC Outcome with Indicators

Parenting Performance: Psychosocial Safety as evidenced by the following indicators: Fosters open communication/Recognizes risks for abuse/Uses strategies to eliminate risks for abuse/Selects appropriate supplemental caregivers/ Uses strategies to prevent high-risk social behaviors/Provides required level of supervision/Sets clear rules for behavior/Maintains structure and daily routine in child's life. (Rate the outcome and indicators of **Parenting Performance:**

Psychosocial Safety: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Initiate appropriate measures to develop a safe, nurturing environment
- Acquire and display attentive, supportive parenting behaviors and child supervision
- Identify appropriate strategies to manage a child's inappropriate behaviors
- Identify strategies to protect child from harm and/or neglect and initiate action when indicated

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Abuse Protection Support: Child; Attachment Promotion; Caregiver Support; Developmental Enhancement: Adolescent, Child; Environmental Management: Family Integrity Promotion; Impulse Control Training; Infant Care; Parent Education: Adolescent, Childrearing Family, Infant; Parenting Promotion; Role Enhancement; Substance Use Prevention, Treatment; Teaching: Infant Stimulation; Toddler Nutrition; Toddler Safety

Example NIC Activities—Family Integrity Promotion

Identify typical family coping mechanisms; Determine typical family relationships for each family; Counsel family members on additional effective coping skills for their own use; Assist family with conflict resolution; Monitor current family relationships; Facilitate a tone of togetherness within and among the family; Encourage family to maintain positive relationships; Refer for family therapy, as indicated

Nursing Interventions and Rationales

- Use the Parenting Sense of Competence (PSOC) scale to measure parental self-efficacy. **EB:** *The PSOC contains three useful factors that reflect satisfaction with the parental role, parenting efficacy, and interest in parenting. Mothers and father will differ in parenting of their children and their sense of competence (Slagt et al, 2012).*
- Examine the characteristics of parenting style and behaviors. Consider dysfunctional child-centered and parent-centered cognitions as potentially critical correlates of abusive behavior. **EB:** *Dysfunctional parenting can lead to abuse and should be monitored closely (Wolfe & McIsaac, 2011).*
- ▲ Institute abuse/neglect protection measures if evidence exists of an inability to cope with family stressors or crisis, signs of parental substance abuse are observed, or a significant level of social isolation is apparent. **EBN:** *Helping parents identify stressors will assist parents with coping in a crisis (Mowery, 2011).*
- ▲ For a mother with a toddler, assess maternal depression. Make appropriate referral. **EB:** *Helping mothers identify systems of depression through self-assessment or home visits is beneficial for both mother and toddler (Bocknek et al, 2012).*

- Appraise the parent's resources and the availability of social support systems. Determine the single mother's particular sources of support, especially the availability of her own mother and partner. Encourage the use of healthy, strong support systems. **EB:** *Clinicians should help mothers evaluate what resources and support that they have and encourage healthy relationships (Letourneau et al, 2013).* Provide education to at-risk parents on behavioral management techniques such as looking ahead, giving good instructions, providing positive reinforcement, redirecting, planned ignoring, and instituting time-outs. **EB:** *Parents with mental health issues need education to help them better care for their children (Houlihan et al, 2013).*
- Promotion of better quality relationships between parents and children is an effective strategy that can lead to enhanced learning. Good quality parenting leads to improved cognitive and social skills for children. **EB:** *Promoting quality relationships promotes optimal health and development (Titze et al, 2014).*
- Support parents' competence in appraising their infant's behavior and responses. **EBN:** *Encourage and support the presence of the parents with the care of the infant (Felgen, 2011).*
- Aim supportive interventions at minimizing parents' experience of strain. **EBN:** *Support caregivers to enhance the family relationship (Tomlinson et al, 2012).*
- Model age-appropriate and cognitively appropriate caregiver skills by doing the following: communicating with the child at an appropriate cognitive level of development, giving the child tasks and responsibilities appropriate to age or functional age/level, instituting safety considerations such as the use of assistive equipment, and encouraging the child to perform activities of daily living as appropriate. **EBN:** *Children learn from the interactions with family, parents, and even medical staff (Rich et al, 2014).*
- Encourage mothers to understand and capitalize on their infant's capacity to interact, particularly in the early months of life. **EBN:** *Mother-infant bonding is very important during the first months of life (Lee et al, 2013).*
- ▲ Provide programs for homeless mothers with severe mental illness who have lost physical custody of their children. **EB:** *Providing education and support to homeless mothers helps empower them (Sleed et al, 2013).*
- ▲ Provide a recovery program that includes instruction in parenting skills and child development for mothers who are addicted to cocaine. **EB:** *Women need additional assistance for recovery from substance abuse and need to understand the effect that it will have on their child (Eiden et al, 2011).*
- Refer to Readiness for enhanced **Parenting** for additional interventions.

Multicultural

- Acknowledge that value conflicts from acculturation stresses may contribute to increased anxiety and significant conflict with children. **EBN:** *Help parents develop a plan to address conflicts within the family (Kim, 2011).*
- Approach individuals of color with respect, warmth, and professional courtesy. **EBN:** *All clients should be cared for in a cultural congruent manner (Wiebe & Young, 2011).*
- Clarify parents' feelings, expectations, perceptions, and availability regarding participation in the care of their sick child. **EBN:** *Cultural differences in regard to parent participation in the care of ill or hospitalized children should be considered (Mutair et al, 2014).*
- Carefully assess meaning of terms used to describe health status when working with Native Americans. **EB:** *Health care providers should allow clients to participate in spiritual care according to their beliefs (Hodge & Wolosin, 2014).*
- Provide support for Chinese families caring for children with disabilities. **EBN:** *The care of the sick in China is based on old world beliefs. It is important to ensure that all aspects of cultural beliefs are included in care (Zhang et al, 2014).*
- Facilitate modeling and role playing to help the family improve parenting skills. **EB:** *Families need to be able to practice parenting in a safe setting (Franks et al, 2013).*

Home Care

- The interventions previously described may be adapted for home care use.
- Assess parenting stress at each home visit to provide appropriate support and anticipatory guidance to families of children with a chronic disease. **EB:** *Assessing parental stress in the home assists the health care provider in identifying interventions that can be implemented at home (Gabler et al, 2014).*
- ▲ Assess the single mother's history regarding childhood and partner abuse and current status regarding depressive symptoms, abusive parenting attitudes (lack of empathy, favorable opinion of corporal punishment, parent-child role reversal, and inappropriate expectations). Refer for mental health services as

indicated. **EB**: A mother's history can contribute to the stress and the care of her children (Boeckel et al, 2014).

- Provide a parenting program of Planned Activities Training (PAT). **EB**: PAT is a five-session intervention aimed at improving parent-child interactions, increasing child engagement in daily activities, and reducing challenging child behaviors. Parents in this program demonstrated improvements in their parenting behaviors (Bigelow et al, 2008).
- Provide follow-up support for the PAT via cell phone and text messaging. **EB**: Cellular phones afford the opportunity for home visitors to maintain regular communication with parents between intervention visits and thus retain high-risk families in parenting interventions. The use of cell phones may also increase the dosage of intervention provided to families and the fidelity with which parents implement the intervention, thus resulting in improved outcomes for parents and children. Parents have rated text messaging and cell phone call enhancements very positively (Bigelow et al, 2008).

Client/Family Teaching and Discharge Planning

- Consider individual and/or group-based parenting programs for teenaged mothers. **EB**: Offering parenting programs to teenaged parents helps them to better care for their child (Mills et al, 2013).
- Consider group-based parenting programs for parents of children younger than 3 years with emotional and behavioral problems. **EBN**: A study shows that group-based parenting programs assist both the parent and the children (Merry, 2011; Kendall et al, 2013).
- Consider group-based parenting programs for parents with anxiety, depression, and/or low self-esteem. **EB**: Parenting programs assist parent with being able to identify issues they may have (Maher et al, 2011).
- ▲ Refer adolescent parents for comprehensive psychoeducational parenting classes. **EBN**: Adolescent parenting class helps teens to learn the best ways to care for their infant (Allen et al, 2014).
- Parent training is one of the most effective interventions for behavior problems in young children. **EBN**: Parent training programs assist with the improving family functioning and interactions (Arkan et al, 2013). Encourage positive parenting: respect for children, understanding of normal development, and creative and loving approaches to meet parenting challenges rather than using anger, manipulation, punishment, and rewards. **EBN**: Encouraging a male caregiver can reduce challenging behaviors and promote a positive bond with child and caregiver (Salinas et al, 2011).
- ▲ Initiate referrals to community agencies, parent education programs, stress management training, and social support groups. Consider the use of technology and the media. **EB**: Family use of technology to interact with health care providers can broaden the support that the family can receive (Hanlon-Dearman et al, 2014).
- Provide information regarding available telephone counseling services and Internet support. **EBN**: Using the Internet allows parents to communicate with and gain support from others all over the world (Niela-Vilén et al, 2014). Refer to the care plans for Risk for disproportionate **Growth**, Risk for delayed **Development**, Risk for impaired **Attachment**, and Readiness for enhanced **Parenting** for additional teaching interventions.

Readiness for enhanced Parenting *Kimberly Silvey, MSN, RN*

NANDA-I

Definition

A pattern of providing an environment for children or other dependent persons to nurture growth and development, which can be strengthened

Defining Characteristics

Children express desire to enhance home environment; expresses desire to enhance parenting; parent expresses desire to enhance emotional support of children; parent expresses desire to enhance emotional support of other dependent person

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Child Development; Knowledge: Child Physical Safety; Parenting Performance; Parenting: Psychosocial Safety

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Example NOC Outcome with Indicators

Parenting Performance as evidenced by the following indicators: Provides preventive and episodic health care/Stimulates cognitive and social development/Stimulates emotional and spiritual growth/Empathizes with child/Expresses satisfaction with parental role/Expresses positive self-esteem. (Rate the outcome and indicators of **Parenting Performance**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client/Family Will (Specify Time Frame)

- Affirm desire to improve parenting skills to further support growth and development of children
- Demonstrate loving relationship with children
- Provide a safe, nurturing environment
- Assess risks in home/environment and take steps to prevent possibility of harm to children
- Meet physical, psychosocial, and spiritual needs or seek appropriate assistance

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anticipatory Guidance; Attachment Promotion; Developmental Enhancement: Adolescent; Child; Family Integrity Promotion: Childbearing Family; Infant Care; Newborn Care; Parent Education: Adolescent; Childrearing Family; Infant; Parenting Promotion; Teaching: Infant Stimulation

Example NIC Activities—Parenting Promotion

Assist parents to have realistic expectations appropriate to developmental and ability level of child; Assist parents with role transition and expectations of parenthood

P

Nursing Interventions and Rationales

- Use family-centered care and role modeling for holistic care of families. **EB**: *Incorporating family-centered care helps enhance the parents' role in caring for their child (Kuo et al, 2012).*
- Assess parents' feelings when dealing with a child who has a chronic illness. **EB**: *Nursing should assist parents (Byczkowski et al, 2014) to identify their feelings about their child to help the parents develop coping mechanisms.*
- Promote low-technology interventions, such as massage and multisensory interventions (maternal voice, eye-to-eye contact, and rocking) and music to reduce maternal and infant stress and improve mother-infant relationship. **EBN**: *Infant massage and gentle touch may represent a support to the mother-child bonding and to the newborn's development (Leni, 2011).*
- Support kangaroo care for infants at risk at birth; keep infants in an upright position in skin-to-skin contact. **EB**: *Kangaroo care helps the mother and infant to not only start bonding but also assist in the infant's growth and development (de Leon-Mendoza & Mokhachane, 2011).*
- When the person who is ill is the parent, use family-centered assessment skills to determine the impact of an adult's illness on the child, and then guide the parent through those topics that are most likely to be of concern. **EB**: *Nurses should be educated on how to communicate and identify the needs of young children when a parent is ill (Sutter & Reid, 2012).*
- Provide practical and psychological assistance for parents of clients with psychiatric diagnoses, such as schizophrenia. **EB**: *Help parents understand the diagnosis of mental illness and the things they can do to help their child (Kusumi & Ross, 2012).*
- Refer to the care plan for Impaired **Parenting** for additional interventions.

Multicultural

- Assess the influence of cultural beliefs, norms, and values on the client's perception of parenting. **EB**: *Understanding the cultural beliefs of the family will assist in parental satisfaction with care (Hamilton et al, 2013).*

- Acknowledge racial and ethnic differences at the onset of care and provide appropriate health information and social support. **EB**: *Acknowledgment of racial and ethnicity issues enhances communication, establishes rapport, and promotes treatment outcomes (Tavallali et al, 2014).*
- Support programs for parents of young children in specific cultural communities. **EBN**: *Parents and children benefit when a support group is incorporated in the care (Wei et al, 2012).*
- Clarify parents' feelings, expectations, perceptions, and availability regarding participation in the care of their sick child. **EBN**: *Cultural differences in regard to parent participation in the care of ill or hospitalized children should be considered (Smits et al, 2012).*
- Acknowledge and praise parenting strengths noted. **EBN**: *Clinicians could explore and support the positive qualities of parenting in a culturally congruent way (Whittaker & Cowley, 2012).*

Home Care

- The nursing interventions previously described should be used in the home environment with adaptations as necessary. **EBN**: *Clinicians should educate parents on the care the child will need at home and modify to meet the family's needs (Doyle & Buckley, 2012).*
- ▲ Refer to a parenting program to facilitate learning of parenting skills. **EBN**: *The study shows that parenting programs can increase parental knowledge as well as confidence (Kendall et al, 2013).*

Client/Family Teaching and Discharge Planning

- Refer to Client/Family Teaching and Discharge Planning for Impaired **Parenting** for suggestions that may be used with minor adaptations.
- Teach parents home safety: reduction of hot water temperature, proper poison storage, use of smoke alarms, and installation of safety gates for stairs. **EB**: *Education may reduce injury and promote children's home safety (Lehna et al, 2014).*
- Teach parents and young teens conflict resolution by using a hypothetical conflict solution with and without a structured conflict resolution guide. Support self-direction of the families with minimal therapist intervention. **EB**: *Encouraging parent participation in positive-parenting programs can decrease the conflict for parents and teens (Salari et al, 2013).*
- Refer mothers of children with type 1 diabetes for community support in babysitting, child care, or respite. **EB**: *Mothers raising children with diabetes need to have support and interventions to assist with the care of the child to help reduce their stress (Monaghan et al, 2011).*
- Teach families the importance of monitoring television viewing and limiting exposure to violence. **EBN**: *Media violence can be hazardous to children's health, and studies overwhelmingly point to a causal connection between media violence and aggressive attitudes, values, and behaviors in some children (McBride, 2011).*
- Promotion of better quality relationships between parents and children is an effective strategy that can lead to enhanced learning. Good quality parenting leads to improved cognitive and social skills for children. **EB**: *Programs can help parents identify strategies that can develop social skills (Ayoub et al, 2011).*

Risk for impaired Parenting *Gail B. Ladwig, MSN, RN*

NANDA-I

Definition

Vulnerable to inability of the primary caretaker to create, maintain, or regain an environment that promotes the optimum growth and development of the child, which may compromise the well-being of the child

Risk Factors

Infant or Child

Altered in perceptual abilities; behavior disorder (e.g., attention deficit, oppositional defiant); developmental delay; difficult temperament; disabling condition; gender other than desired; illness; multiple births; prematurity; prolonged separation from parent; temperament conflicts with parental expectations

Knowledge

Alteration in cognitive functioning; ineffective communication skills; insufficient cognitive readiness for parenting; insufficient knowledge about child development; insufficient knowledge about child health maintenance; insufficient knowledge about parenting skills; insufficient response to infant cues; low educational level preference for physical punishment; unrealistic expectations

Physiological

Physical illness

Psychological

Closely spaced pregnancies; depression; difficult birthing process; disabling condition; high number of pregnancies; history of mental illness; history of substance abuse; nonrestorative sleep pattern (i.e., due to caregiver responsibilities, parenting practices, sleep partner); sleep deprivation; young parental age

Social

Change in family unit; compromised home environment; conflict between partners; economically disadvantaged; father of child not involved; history of abuse (e.g., physical, psychological, sexual); history of being abusive; inadequate child care arrangements; ineffective coping strategies; insufficient access to resources; insufficient family cohesiveness; insufficient parental role model; insufficient prenatal care; insufficient problem-solving skills; insufficient resources (e.g., financial, social, knowledge); insufficient social support; insufficient transportation; insufficient valuing of parenthood; late-term prenatal care; legal difficulty; low self-esteem; mother of child not involved; parent-child separation; relocation; role strain; single parent; social isolation; stressors; unemployment; unplanned pregnancy; unwanted pregnancy; work difficulty

NOC, NIC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plans for Readiness for enhanced **Parenting** and Impaired **Parenting**.

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Risk for Perioperative Positioning injury

Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

NANDA-I

Definition

Vulnerable to inadvertent anatomical and physical changes as a result of posture or equipment used during an invasive/surgical procedure, which may compromise health

Risk Factors

Disorientation; edema; emaciation; immobilization; muscle weakness; obesity; sensory-perceptual disturbance from anesthesia

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Circulation Status; Immobility Consequences: Physiological; Joint Movement; Neurological Status; Respiratory Status; Risk Control; Sensory Function; Skeletal Function; Tissue Integrity: Skin and Mucous Membranes; Tissue Perfusion: Peripheral

Example NOC Outcome with Indicators

Tissue Perfusion: Peripheral as evidenced by the following indicators: Peripheral edema/Localized extremity pain/Skin breakdown/Muscle cramps/Peripheral pulses/Numbness/Tingling/Necrosis. (Rate the outcome and indicators of **Tissue Perfusion: Peripheral**: 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate unchanged skin condition, with exception of the incision, throughout the perioperative experience
- Demonstrate resolution of redness of the skin at points of pressure within 30 minutes after pressure is eliminated
- Remain injury-free related to surgical positioning, including intact skin and absence of pain and/or numbness associated with surgical positioning
- Demonstrate unchanged or improved physical mobility from preoperative status
- Demonstrate unchanged or improved peripheral sensory integrity from preoperative status

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Circulatory Precautions; Fall Prevention; Neurological Monitoring; Peripheral Sensation Management; Positioning: Intraoperative; Pressure Ulcer Prevention; Risk Identification; Skin Surveillance; Surgical Precautions

Example NIC Activities—Positioning: Intraoperative

Use an adequate number of personnel to transfer client; Maintain client's proper body alignment

Nursing Interventions and Rationales

General Interventions for Any Surgical Client

- Assess the client's skin integrity throughout the perioperative process to avoid skin breakdown during surgical/invasive procedures. **EB**: *Developing skin breakdown manifested as a skin tear, pressure ulcer, deep tissue injury, or burn is a significant client complication impacted by the duration of surgery and client positioning (Fred et al, 2012; National Pressure Ulcer Advisory Panel and European Pressure Ulcer Advisory Panel [NPUAP/EPUAP], 2014).*

Prevention of Pressure Ulcers

- Complete a preoperative assessment to identify physical alterations that may require additional precautions for procedure-specific positioning and to identify specific procedural positioning needs, type of anesthesia, and so on. **EBN:** *Factors to consider when assessing the surgical client to plan for proper positioning are preexisting conditions, range of motion, presence of prostheses and/or fractures, age, height, and weight (Spruce & Van Wicklin, 2014). Use resources (e.g., positioning aids, padding, transfer devices) to reduce the risk of tissue injury in the care of the older client (AORN, 2015b).*
- Identify risk factors such as length and type of surgery, potential for intraoperative hypotensive episodes, low core temperatures, and decreased mobility on postoperative day 1. **EB:** *Assess the client for additional risk factors to include the duration of immobilization before and during the surgical procedure, client severity of illness, and preoperative nutritional status (Spruce et al, 2014; NPUAP/EPUAP, 2014). Surgeries lasting more than 4 hours provide a significant risk for pressure ulcer development (Sterner et al, 2011). EBN:* *A recent study showed that vasopressor use is a significant risk factor for pressure ulcer development. The study also showed that the number of surgeries a client has during his/her inpatient stay and the length of surgery (over 1 hour), body mass index, Braden score, mortality risk, and history of diabetes are also risk factors for pressure ulcer development. This study did not show that age was related to pressure ulcer development (Tschannen et al, 2012).*
- Recognize that all surgical clients should be considered at high risk for pressure ulcer development, because pressure ulcers can develop in as little as 20 minutes in the operating room.
- Protect the heels during surgery by elevating the heels completely. **EB:** *Ensure the heels are free of the surface of the operating table (NPUAP/EPUAP, 2014). Heel pressure ulcers are one of the most common sites for pressure injury during surgery. Traditional devices such as egg crates, booties, and heel pads do not decrease the pressure.*
- Use pressure-reducing devices and pressure-relieving mattresses as necessary to prevent ulcer formation. **EB:** *Use a high specification reactive or alternating pressure support surface on the operating table for all individuals identified as being at risk for pressure ulcer development (NPUAP/EPUAP, 2014). Additional support surfaces may be indicated to offload pressure points on the face and body when the client is placed in a prone position (Spruce et al, 2014; NPUAP/EPUAP, 2014). Assess for shearing forces that may cause tissue injury when placing the client in Trendelenburg position for selected robotic surgical procedures (Sutton et al, 2013).*
- Avoid using rolled sheets and towels as positioning devices; they tend to produce high and inconsistent pressures. Special positioning devices are available that redistribute pressure. **EBN:** *Towels and rolled sheets contribute to friction injuries (AORN, 2015).*
- Avoid covering positioning devices or placing extra blankets on top of a pressure-reducing surface. **CEB:** *Adding material to a pressure reduction surface actually increases the pressure, thus producing a negative result (Aronovitch, 2007; St. Arnaud & Paquin, 2008). Use of rolled sheets and towels beneath overlays decreases the overlay's effectiveness and causes pressure.*
- The nurse should demonstrate knowledge not only of the equipment, but also of anatomy and the application of physiological principles in order to properly position the client. **EBN:** *Preplanning ensures that the correct positioning devices are available and in good working condition, and that appropriate numbers of personnel are available to position the client safely and appropriately (AORN, 2015a).*
- Monitor pressure being applied to the client intraoperatively by staff, equipment, and/or instruments (AORN, 2015a).
- Pad all bony prominences. **EB:** *Some positioning devices are solid and can increase pressure over bony prominences (Sutton et al, 2013).*
- Recognize that reddened areas or areas injured by pressure should not be massaged. **EB:** *Rubbing causes friction that can lead to damage to skin/tissue (NPUAP/EPUAP, 2014).*
- Implement measures to prevent inadvertent hypothermia. *Anesthesia can compromise perfusion by causing hypotension and hypothermia. When coupled with the client being immobile on a noncompliant surface for an extended time period, hypothermia increases vulnerability for pressure ulcer development during surgery (St. Arnaud & Paquin, 2008).*
- Many surgical clients have medical devices placed as a part of the surgical procedure. Avoid positioning the client on the medical device and perform frequent assessments of the skin under and around the device (Apold et al, 2012; NPUAP/EPUAP, 2014).

Positioning the Perioperative Client

- Ensure that linens on the operating room table are free of wrinkles. *Wrinkles may cause pressure/injury to the skin if the client is unable to move for prolonged periods of time.*
- Lock the operating room table, cart, or bed and stabilize the mattress before transfer/positioning the client. Monitor the client while on the operating room table at all times. **EB:** *Studies showed that a lack of clear communication about who should be watching the client has contributed to falls (AORN, 2015a).*
- Lift rather than pull or slide the client when positioning to reduce the incidence of skin injury from shearing and/or friction. **EB:** *Sliding or pulling the client can cause shearing force and/or friction (AORN, 2015a; NPUAP/EPUP, 2014).*
- Ensure that appropriate numbers of personnel are present to assist in positioning the client. **EBN:** *A minimum of two people should assist an awake client to transfer from a cart/bed to the operating room table: one person on the stretcher side to assist the client onto the table and a second person on the far side of the table to prevent the client from falling off (AORN, 2015a). A minimum of four persons are necessary when transferring/positioning an anesthetized, unconscious, obese, or weak client (AORN, 2015a).*
- Recognize that, optimally, clients (especially those with limited range of motion/mobility) should be asked to position themselves under the nurse's guidance before induction of anesthesia so that he/she can verify that a position of comfort has been obtained.
- Ensure that nerves are protected by positioning extremities carefully. **EB:** *Nerves can be injured by stretching and compression, which is caused by a loss of protective muscle tone and pressure between two fixed points. Careful attention to proper body alignment and padding is necessary to prevent peripheral nerve injury (Bouyer-Ferullo, 2013).*
- Use slow and smooth movements during positioning to allow the circulatory system to readjust.
- Reassess the client after positioning and periodically during the procedure to maintain proper alignment and skin integrity. **EBN:** *Changes in position can expose or injure body parts (e.g., shearing, friction, compression) that were originally protected, and the safety strap can shift and apply increased pressure (AORN, 2012).*
- Frequently assess the eyes and/or monitor intraocular pressure, especially when client is in prone or knee-chest position. **CEB/EB:** *The cornea can easily be injured during surgery due to a decrease in lacrimation and/or improperly applied face masks, or prolonged prone positioning (Spruce et al, 2014; Ellsworth et al, 2009).*
- Position hips in proper alignment with knees flexed. Unaligned hips can cause pressure to the low back and hip joints.
- Position the arms extended on arm boards so that they do not extend beyond a 90-degree angle. Do not position arms at sides unless surgically necessary. **CEB:** *Positioning at less than a 90-degree angle, with elbows slightly flexed and hands supine, decreases the risk of a stretching injury to the brachial plexus and possible compression or occlusion injury to the subclavian and axillary arteries (Ellsworth et al, 2009). When positioning arms at sides is necessary, place the arms beneath the sheet and bring the sheet over the top of the arm and then tuck the sheet beneath the mattress, so the arm cannot fall off the mattress and hang over the metal edge of the table, where the surgical team could lean against it (AORN, 2015a).*
- Protect the client's skin surfaces from injury by preventing pooling of preparative solutions, blood, irrigation, urine, and feces. **EBN:** *Prep solutions may change the pH of the skin and remove protective oils, making the skin more susceptible to pressure and friction. Pooling also increases the risk of maceration (AORN, 2015a).*
- Keep the client appropriately covered during the procedure. *Reducing unnecessary exposure provides privacy and dignity for the client during positioning and helps prevent hypothermia (AORN, 2015a).*
- When positioning the client prone, care should be taken to ensure the head and neck are properly positioned. **EB:** *Inappropriate positioning of the head and neck in the prone position can lead to vertebral artery obstruction and possible stroke. Standard foam prone pillows should be used because they stabilize the neck in neutral, and the endotracheal tube can be positioned away from the face to decrease excessive pressure (Ellsworth et al, 2009; Spruce et al, 2014).*
- Recognize that clients positioned in lithotomy position should be kept in this position for as short a time as possible. **EB:** *One research review suggests that the client's legs be removed from lithotomy positioning devices every 2 hours when the procedure is expected to last 4 hours or longer (AORN, 2015a).*

- The lowest heel position should be used in the lithotomy position. **EBN:** *In one study, as the height of the calf support increased, pressure also increased (Lopes & Galvao, 2010).*
- Position the client's legs parallel and uncrossed.
- Maintain normal body alignment. *Misalignment, flexion, extension, and rotation may cause muscle and nerve damage, as well as airway interference; pressure on the carotid sinus can cause arrhythmias; and restricted venous outflow can occur with extreme rotation of the head (St. Arnaud & Paquin, 2008).*
- When applying body supports and restraint straps (safety belt), apply loosely and secure over waist or mid-thigh at least 2 inches above knees, avoiding bony prominences by placing a blanket between the strap and the client. **EB:** *Belts positioned directly over the knees cause compression of the peroneal nerve against the fibula (St. Arnaud & Paquin, 2008).*
- Assess the client's skin integrity immediately postoperatively. **EB:** *Assess and document postoperative skin/tissue integrity focusing on areas with constant pressure during the procedure and limb function for nerve damage (St. Arnaud & Paquin, 2008; Sutton et al, 2013; NPUAP/EPUAP, 2014).*
- Ensure that complete, concise, accurate documentation of client assessment and use of positioning devices is in the client's medical record.

Risk for Peripheral Neurovascular dysfunction

Betty J. Ackley, MSN, EdS, RN, and Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

NANDA-I

Definition

Vulnerable to disruption in the circulation, sensation, and motion of an extremity, which may compromise health

Risk Factors

Burns; fractures; immobilization; mechanical compression (e.g., tourniquet, cane, cast, brace, dressing, restraint); orthopedic surgery; trauma; vascular obstruction

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Circulation Status; Neurological Status: Spinal Sensorimotor Function; Tissue Perfusion: Peripheral

Example NOC Outcome with Indicators

Tissue Perfusion: Peripheral as evidenced by the following indicators: Radial or pedal pulse strength/Capillary refill in fingers or toes/Extremity skin temperature/Localized extremity pain/Numbness/Tingling/Skin color/Muscle strength/Skin integrity/Peripheral edema. (Rate the outcome and indicators of **Tissue Perfusion: Peripheral**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

- Maintain circulation, sensation, and movement of an extremity within client's own normal limits
- Explain signs of neurovascular compromise

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Exercise Therapy: Joint Mobility; Peripheral Sensation Management

Example NIC Activities—Peripheral Sensation Management

Monitor for paresthesia: numbness, tingling, hyperesthesia, and hypoesthesia; Monitor for thrombophlebitis and deep vein thrombosis

P

Nursing Interventions and Rationales

- ▲ Recognize situations in the Risk Factors that may result in peripheral neurovascular dysfunction. Compartment syndrome may be due to increased volume of the contents of a compartment, or reduced capacity of the compartment sheath. Reduced capacity is associated with tight dressings, bandages, or casts (Mabvuure et al, 2012).
- ▲ Assess for the early onset of compartment syndrome, and report to health care provider promptly. Perform neurovascular assessment every 15 minutes to every 4 hours as ordered or needed based on client's condition. Use the five Ps of assessment as outlined below. *The goal is to prevent ischemia (cell death). Delay in recognizing compartment syndrome can lead to paralysis, rhabdomyolysis, contracture, and amputation of the limb (Garner et al, 2014). Compartment syndrome is primarily diagnosed by physical examination, and because of the devastating consequences of a missed compartment syndrome, a fasciotomy should be considered. Assess for presence of any of the six Ps.*
 - Pain: Assess severity (on a scale of 1 to 10), quality, radiation, and relief by medications. Pain is usually “out of proportion” to the injury, requiring strong opiates, and is often described as burning, feeling deep in the muscle or structure, and elicited with passive stretching of the compartment (Donaldson et al, 2014).
 - Pulses: Check the pulses distal to the injury. *Palpate pulses in area of concern; for example, for a tibial fracture, assess dorsalis pedis and posterior tibial pulses. Compartment syndrome can occur in the face of an intact pulse. Always assess the uninjured or unaffected side and compare with the area of concern.*
 - Pallor: Check color and temperature changes below the injury site. Check capillary refill. *If pallor is present, record the level of coldness carefully and report to health care provider promptly. A cold, pale, or bluish extremity indicates arterial insufficiency or arterial damage, and a health care provider should be notified.*

- Paresthesia (change in sensation): Check by lightly touching the skin proximal and distal to the injury. Ask if the client has any unusual sensations such as hypersensitivity, tingling, prickling, decreased feeling, or numbness. Check nerve function (e.g., whether the client can feel a touch to the area of concern, such as the first web space of the foot [deep peroneal nerve] with tibial fracture). *Irreversible damage from compartment syndrome occurs when compression to tissue and nerves is left unchecked (Garner et al, 2014).*
- Paralysis: Ask the client to perform appropriate range-of-motion exercises in the unaffected and then the affected extremity. *Loss of movement (paralysis) is a late symptom of compartment syndrome. Decreased range of motion and loss of movement can indicate impending muscle, nerve, and cellular death (Donaldson et al, 2014).*
- Pressure: Check by feeling the extremity; note new onset of firmness or swelling of the extremity, as well as a firm “wooden” feeling upon deep palpation. *Internal pressure or external confinement or restriction can proceed to the point at which cellular exchange is diminished. Swelling and tightness of the involved compartment are indications of increased pressure. Not only are surgical or trauma clients at risk for neurovascular compromise, but also are clients on bed rest because of changes in blood flow through the cardiovascular system (Donaldson et al, 2014).*
- ▲ All of the Ps may not be present, and they are not specific for compartment syndrome. Have a high index of suspicion for any of the Ps. Noting two or more of the Ps increases the probability of compartment syndrome. Monitor the client for compartment syndrome of the nonoperated leg as well as the operated leg.
- Monitor appropriate application and function of corrective device (e.g., cast, splint, traction) every 1 to 4 hours as needed. *Compartment syndrome can result from improper casting or splinting and is the most serious complication of casting or splinting. The condition results from increased pressure within a closed space that compromises blood flow. After immobilization (casting or splinting), if pain worsens or there is any tingling or numbness, swelling, delayed capillary refill, or change in color of exposed digit, immediate evaluation is needed. Casting or splinting can cause thermal injuries or skin breakdown; therefore, proper padding is essential. Position the extremity in correct alignment with each position change; check every hour to ensure appropriate alignment.*
- ▲ For prevention of deep vein thrombosis (DVT), nursing care of DVT, and pulmonary embolism, refer to the interventions on DVT prevention and treatment in the care plan for Ineffective peripheral **Tissue Perfusion**.

Risk for Poisoning Melodie Cannon, DNP, MSc/FNP, BHScN, RN(EC), NP-PHC, CEN, GNC(C)

NANDA-I

Definition

Vulnerable to accidental exposure to, or ingestion of, drugs or dangerous products in sufficient doses that may compromise health

Risk Factors

External

- Access to dangerous product
- Access to illicit drugs potentially contaminated by poisonous additives
- Access to large supply of pharmaceutical agents in house
- Access to pharmaceutical agent

Internal

- Alteration in cognitive functioning
- Emotional disturbance
- Inadequate precautions against poisoning
- Insufficient knowledge of pharmacological agents
- Insufficient knowledge of poisoning prevention
- Occupational setting without adequate safeguards
- Reduced vision
- Addiction

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Knowledge: Child Physical Safety, Medication, Personal Safety; Parenting Performance; Risk Control; Risk Control: Alcohol Use, Drug Use; Risk Detection; Safe Home Environment

Example NOC Outcome with Indicators

Knowledge: Child Physical Safety as evidenced by the following indicators: Appropriate activities for child's developmental level/Strategies to prevent medication misuse/Strategies to prevent exposure to toxic chemicals or substances. (Rate the outcome and indicators of **Knowledge: Child Physical Safety**: 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

- Prevent inadvertent ingestion of or exposure to toxins or poisonous substances
- Explain and undertake appropriate safety measures to prevent ingestion of or exposure to toxins or poisonous substances
- Verbalize appropriate response to apparent or suspected toxic ingestion or poisoning

P

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Environmental Management: Safety, First Aid; Health Education; Medication Management; Surveillance; Surveillance: Safety

Example NIC Activities—Environmental Management: Safety

Identify safety hazards in the environment (i.e., physical, biological, and chemical); Remove hazards from the environment, when possible

Nursing Interventions and Rationales

- When a client comes to the hospital with possible poisoning, begin care following the ABCs and administer oxygen if needed. **EB**: *Poisoning is a major cause of morbidity/mortality worldwide. Initial evaluation should include vital signs, mental status, pupil size, oxygenation, finger stick glucose, and cardiac monitoring. Management is geared to supportive care, prevention of poison absorption, antidote use, and elimination techniques (Rhyee, 2013).*
- ▲ It is important for the triage nurse to call the poison control center. *The poison control hotline is 1-800-222-1222. Poison centers are a valuable tool for medical consultations. They are staffed by nurses, pharmacists, toxicologists, and other specialists in poisons and toxins who can recommend treatment advice (American Association of Poison Control Centers, 2014).*
- Obtain a thorough history of what was ingested, how much, and when, and ask to look at the containers. Note the client's age, weight, medications, medical conditions, and any history of vomiting, choking, coughing, or change in mental status. Also take note of any interventions performed before seeking

treatment. **EB:** *The history is important to confirm the diagnosis and is often unreliable when provided by clients with intentional ingestion. Additional information should be obtained from paramedics, police, family, and friends when possible (Rhyee, 2013).*

- Carefully inspect for signs of ingestion of poisons, including an odor on the breath, a trace of the substance on the clothing, burns, or redness around the mouth and lips, as well as signs of confusion, vomiting, or dyspnea. **CEB:** *It is important to look for signs of ingestion of poison before initiating treatment because up to 40% of children who present with poisoning have not actually been exposed to the suspected toxin (Hwang et al, 2003).*
- ▲ Note results of toxicology screens, arterial blood gases, blood glucose levels, and any other ordered laboratory tests. *If information about what was ingested is incomplete or inaccurate, laboratory tests may be needed to determine treatment. The poison control center will provide valuable information regarding appropriate labs and investigations specific to the suspected toxin.*
- ▲ Initiate any ordered treatment for poisoning quickly. The poison control center will specify any treatment or medications that need to be administered. **EB:** *Client decontamination consisting of water or saline irrigation for topical exposures or the administration of activated charcoal may be required. Early decontamination helps prevent poison absorption (Rhyee, 2013).*
- ▲ *Ensure recommendations from the poison control center are clearly documented and readily accessible in the client's chart.*
- ▲ *If the client's condition deteriorates, contact the poison control center again for further direction and notify the most responsible provider.*

Safety Guidelines for Medication Administration

- Prevent iatrogenic harm to the hospitalized client by following these guidelines for administering medications:
 - Use at least two methods to identify the client before administering medications or blood products, such as the client's name and medical record number or birth date. Do not use the client's room number. Use bar code scanning system for client identification if used by your facility.
 - When taking verbal or telephone orders, the orders should be written down and read back for verification to the individual giving the order. The health care provider who gave the orders for the medication then needs to confirm the information that was read back.
- Standardize use of abbreviations, acronyms, symbols, and dose designations and eliminate those that are prone to cause errors. (Refer to The Joint Commission, Critical Access Hospital National Patient Safety Goals for list of abbreviations, acronyms, symbols, and dose designations that should not be used.)
 - Be aware of the medications that look/sound alike and ensure that the correct medication is ordered and administered.
 - Use the eight rights of medication administration to decrease the potential for error:
 - Right client, right medication, right reason, right dose, right frequency, right route, right site, and right time (College of Nurses of Ontario, 2014). Take high-alert medications off the nursing unit, such as potassium chloride. Standardize concentrations of medications such as morphine in patient-controlled analgesia pumps.
 - Follow agency policy/procedures for medications that require two-person check and co-signature.
 - Label all medications and medication containers or other solutions that are on or off a sterile field for a procedure. Label them when they are first taken out of the original packaging to another container. Label with medication name, strength, amount, and expiration date/time. Review the labels whenever there is a change of personnel.
 - Use only intravenous (IV) pumps that prevent free flow of IV solution when the tubing is taken out of the pump.
- Identify all the client's current medications on admission to a health care facility and compare the list with the current ordered medications. Reconcile any differences in medications. Use the expertise of the pharmacy department if there is any uncertainty regarding the accuracy of the client's medications.
- Reconcile the list of medications if the client is transferred from one unit to another, when there is a handoff to the next provider of care, and when the client is discharged.

Adverse drug events occur with disturbing frequency, and communication problems between settings of care are a significant factor in their occurrence (Safer Healthcare Now, 2012).

- Detect possible interactions and cumulative or other adverse effects among prescribed medications, self-administered over-the-counter products, culturally based home treatments, herbal remedies, and foods.

Medication reconciliation is an important safety issue due to the number of people taking multiple medications and involves determining what medications the person should be taking, medications they are actually taking, and resolving discrepancies (The Joint Commission, 2014).

Pediatric

- ▲ Evaluate lead exposure risk and consult the health care provider regarding lead screening measures as indicated (public/ambulatory health). *Children can be exposed to lead from multiple sources: house paint, dust, soil, imported toys, imported candy or food, and traditional medications, ceramic housewares, drinking water, and living near lead smelters or battery recycling plants (Barn & Kosatsky, 2011; Ness, 2013).*
- Provide guidance for parents and caregivers regarding age-related safety measures, including the following:
 - Store prescription and over-the-counter medications, vitamins, herbs, and alcohol in a locked cabinet far from children's reach.
 - Do not take medications in front of children (Rodgers et al, 2012).
 - Store cleaning products including things like dishwashing liquids in a high cabinet, out of children's reach.
 - Use safety latches on cabinets that contain poisonous substances.
 - Store potentially harmful substances in the original containers with safety closures intact.
 - Recognize that no container is completely childproof.
 - Do not store medications or toxic substances in food containers or near or with food products.
 - Do not leave alcoholic drinks, cosmetics, or toiletries where children can reach them.
 - Remove poisonous houseplants from the home. Teach children not to put leaves or berries in their mouths (Oerther, 2011).
 - Do not suggest that medications are candy.
 - If interrupted when using a harmful product, take it with you; children can get into it within seconds.
 - Store poisonous automotive or gardening supplies in a locked area.
 - Use extreme caution with pesticides and gardening materials close to children's play areas.
 - When visitors enter the home, place their handbags or backpacks up high where children are unable to reach them, and ask about any potential poisonous substances.
- Children naturally put things in their mouths and experience new taste sensations as a part of child development. Prevention of this is unrealistic and interventions should target environmental and caregiver behaviors to reduce harm (Rosenberg et al, 2011). **EB:** *A study found that pediatric poisoning most commonly occurred in 1- to 2-year-olds who ingested prescription or over-the-counter medications (Vilke et al, 2011). Pediatric poisoning deaths most commonly come from ingestion of opioids, other analgesics, cardiovascular medications, antihistamines, and sedatives (Safekids, 2014).*
- Advise families that syrup of ipecac is no longer recommended to be kept and used in the home. Previous studies have shown unreliable performance with ipecac and the number of poison control centers that have stopped recommending ipecac use for poisonings has increased significantly over the last decades (Gutierrez et al, 2011). Advise families that over-the-counter cough and cold suppressant medications are not recommended and are no longer considered safe for children 2 or younger (U.S. Food and Drug Administration, 2014). *Colds are self-limiting and improve on their own; over-the-counter medications may help relieve symptoms in older children, but will not change the natural course of the illness (U.S. Food and Drug Administration, 2014).* **EB:** *Since the U.S. Food and Drug Administration advised against the use of cough/cold medicines in children younger than 2 in 2008, there has been a decline in childhood poisonings in this category and a decrease in infant emergency department visits with adverse events due to cough/cold medications (Spiller et al, 2013).*
- Recognize that some children may have been exposed to methamphetamines or the components used to make methamphetamines. *From year 2000 through the first quarter of 2005, more than 15,000 children were reported as being affected in clandestine laboratory-related incidents (Grant, 2007).*
- Advise families to contact state or local government agencies or pharmacies to ask about safe disposal programs for used, excess, or expired medications (U.S. Food and Drug Administration, 2014).

Geriatric

- Caution the client and family to avoid storing medications with similar appearances close to one another (e.g., nitroglycerin ointment near toothpaste or denture creams). *Confusion and visual impairment can place the older person at risk of incorrectly identifying the contents. Place medications in a medication organizer that indicates when they are to be taken. Failing eyesight, the use of multiple drugs, and difficulty*

in remembering whether a medication was taken are among the causes of accidental poisoning in older persons. **EB:** A study demonstrated that older adults who had purposely overdosed had ingested different drugs than younger clients and had poorer outcomes with increased morbidity and mortality (Doak et al, 2009).

- Remind older clients to store medications out of reach when young children come to visit. Childhood poisonings are common events that involve exposure to both prescription and nonprescription pharmaceuticals in the home, resulting in an increased number of serious outcomes (Spiller et al, 2013). Medications used by older adults such as heart medication, antihypertensive medication, and antidepressants can be extremely toxic to children; some medications such as calcium channel blockers can cause death with only one pill (Vroman, 2008).
- Perform medication reconciliation in all older clients entering the health care system as well as upon discharge. Older clients do not compare drugs that they have at home with new prescriptions and often take multiple drugs with the same indications, leading to toxicity. Encourage older clients to speak with their pharmacist to ensure their medications are reviewed whenever a change occurs. Pharmacists can assist clients with strategies to differentiate medications such as visual, tactile, or audible labeling (Smith & Bailey, 2014). Encourage the consistent use of a pharmacy to promote understanding of medications and any changes. Advise clients who use dosettes or pre-packaged medications that the appropriate changes will need to be made before continuing to use the current administration method.

Home Care

- The interventions previously described may be adapted for home care use.
- Provide the client and/or family with a poison control poster to be kept on the refrigerator or a bulletin board. Ensure that the telephone number for local poison control information is readily available and/or preprogrammed into household telephones.
- Pre-pour medications for a client who is at risk for ingesting too much of a given medication because of mistakes in preparation. Delegate this task to the family or caregivers if possible. Older clients who live alone are at greatest risk of poisoning.
- Identify poisonous substances in the immediate surroundings of the home, such as a garage or barn, including paints and thinners, fertilizers, rodent and bug control substances, animal medications, gasoline, and oil. Label with the name, a poison warning sign, and a poison control center number. Lock out of the reach of children. Dangerous poisonous substances can be found in areas other than the internal home setting. Curious children are at risk for ingestion when exploring.
- Identify the risk of toxicity from environmental activities such as spraying trees or roadside shrubs. Contact local departments of agriculture or transportation to obtain material safety data sheets or to prevent the activity in desired areas. Very young children, women who are of childbearing age or who are pregnant, and older adults are at greatest risk of poisoning.
- To prevent carbon monoxide poisoning, instruct the client and family in the importance of using a carbon monoxide detector in the home and changing it every 6 months, having the home heating system serviced every year by a qualified technician, and ensuring proper installation and venting of all combustion equipment. Carbon monoxide results from fumes produced by portable generators, stoves, lanterns, gas ranges, running vehicles, or burning charcoal and wood, which can build up in enclosed or partially enclosed spaces and result in harm or death for people and animals exposed (Centers for Disease Control and Prevention, 2014).

Multicultural

- Assess housing for pathways of lead poisoning. **EB:** Refugee children arriving in the United States in recent years have increased rates of lead levels at their time of arrival and are at above average risk for lead poisoning from ongoing exposures after arrival because they often settle into high-risk areas with older housing (Centers for Disease Control and Prevention, 2013).
- Prompt caregivers to take action to prevent lead poisoning. **EB:** A lead poisoning awareness campaign targeted at an urban population of parents of newborns resulted in increased blood lead screening rates and demonstrated that most homes had lead hazards (Campbell et al, 2011).
- If children live in a high-lead environment, teach the need for handwashing before each meal, annual blood testing for lead levels, and avoidance of high lead areas. **EB:** A study of a community-based lead prevention programs was shown to be effective for a rural Native American population who lived near a Superfund site containing contamination from mining waste (Kegler et al, 2010).

- Work with immigrant Mexican families to implement medication, household cleaners, and carbon monoxide safety interventions in the home to prevent accidental poisoning in children. Use the Hispanic social network. **EB:** *A study found that urban Mexican immigrant families often lived in unsafe homes, with child-accessible medications and the possibility of carbon monoxide poisoning (Diquiseppi et al, 2012).*

Client/Family Teaching and Discharge Planning

- Teach parents that any substance that is absorbed by the body by a variety of means and can affect health and cause mortality is considered a poison. The increasing use of medications and home cleaning products puts children at risk for poison due to the potential for access in the home environment. **EB:** *Research has shown that 94% of children who were poisoned accessed the agent in their own home or another home (Nalliah et al, 2014).*

Safety Guidelines

- Counsel the client and family members regarding the following points of medication safety:
 - Avoid sharing prescriptions.
 - Always use good light when preparing medication. Do not dispense medication during the night without a light on.
 - Read the label before you open the bottle, after you remove a dose, and again before you give it.
 - Always use child-resistant caps and lock all medications away from your child or confused older adult.
 - Give the correct dose. *Never* guess.
 - Do not increase or decrease the dose without calling the health care provider.
 - Always follow the weight and age recommendations on the label.
 - Avoid making conversions. If the label calls for 2 tsp and you have a dosing cup labeled only with ounces, do not use it.
 - Be sure the health care provider knows if you are taking more than one medication at a time.
 - Never let young children take medication by themselves.
 - Read and follow labeling instructions on all products; adjust dosage for age.
 - Avoid excessive amounts and/or frequency of doses. (“If a little does some good, a lot should do more.”)
 - Every day in the United States, about 165 children are treated in emergency departments after getting into medication. Unintentional ingestion of medications is the leading cause of child poisoning among young children and the number of children dying of poisoning has more than doubled since 1999 (Safekids.org, 2014).
 - *Each year, thousands of adverse drug-related events occur, including poisoning. Poisoning is a major cause of morbidity and mortality (American Academy of Pediatrics Committee on Injury, Violence, and Poison Prevention, 2003).*
 - Advise the family to post first-aid charts and poison control center instructions in an accessible location. Poison control center telephone numbers should be posted close to each telephone and the number programmed into cell phones. *A poison control center should always be called immediately before initiating any first-aid measures. The national toll-free number is (800) 222-1222.*
 - Advise family when calling the poison control center to do the following:
 - Give as much information as possible, including your name, location, and telephone number, so that the poison control operator can call back in case you are disconnected or summon help if needed.
 - Give the name of the potential poison ingested and, if possible, the amount and time of ingestion. If the bottle or package is available, give the trade name and ingredients if they are listed.
 - Be prepared to divulge the child’s height, weight, age, and medical history.
 - Describe the state of the poisoning victim. Is the victim conscious? Does he or she have any symptoms? What is the person’s general appearance, skin color, respiration, breathing difficulties, mental status (alert, sleepy, unusual behavior)? Is the person vomiting? Having convulsions?
- Rapid initiation of proper treatment reduces mortality and morbidity rates. Consultation with a poison control center is necessary to assess and treat poisoned clients. **EB:** Optimal management of the poisoned client depends on the poison, the severity of the symptoms, and time between exposure and presentation. Poison control centers can provide assistance (Rhyee, 2013).*
- Encourage the client and family to take first-aid and other types of safety-related programs. *These programs raise participants’ level of emergency preparation.*
 - ▲ Initiate referrals to peer group interventions, peer counseling, and other types of substance abuse prevention/rehabilitation programs when substance abuse is identified as a risk factor.

- Teach parents and other caregivers that cough and cold medication bought over-the-counter are not safe for children younger than 2 unless specifically ordered by a health care provider. Analysis of exposures to cough/cold preparations supports the concept that poisoning exposure occurs in children with substances that they can easily access (Spiller et al, 2013).
- Teach parents about home prevention strategies to prevent accidental poisonings (Gutierrez et al, 2011).
- Teach parents that they can be a source of lead exposure for their children via contaminated work clothing from a lead-related occupation such as transportation workers or automobile repair or if they engage in certain hobbies such as stained glass or ceramic (Schnur & John, 2014). Precautions should be taken to eliminate the risk of exposure.

Post-Trauma syndrome Mary Jane Roth, RN, BSN, MA

NANDA-I

Definition

Sustained maladaptive response to a traumatic, overwhelming event

Defining Characteristics

Aggression; alienation; alteration in concentration; alteration in mood; anger; anxiety; avoidance behaviors; compulsive behavior; denial; depression; dissociative amnesia; enuresis; exaggerated startle response; fear; flashbacks; gastrointestinal irritation; grieving; guilt; headache; heart palpitations; history of detachment; hopelessness; horror; hypervigilance; intrusive dreams; intrusive thoughts; irritability; neurosensory irritability; nightmares; panic attacks; rage; reports feeling numb; repression; shame; substance abuse

Related Factors

Destruction of one's home; event outside the range of usual human experience; exposure to disaster (natural or man-made); exposure to epidemic; exposure to event involving multiple deaths; exposure to war; history of abuse (e.g., physical, psychological, sexual); history of being a prisoner of war; history of criminal victimization; history of torture; self-injurious behavior; serious accident (e.g., industrial, motor vehicle); serious injury to loved one; serious threat to loved one; serious threat to self; witnessing mutilation; witnessing violent death

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Cessation; Abuse Protection; Abuse Recovery: Emotional, Aggression Self-Control, Anxiety Self-Control, Grief Resolution, Impulse Self-Control; Self-Mutilation Restraint; Sleep

Example NOC Outcome with Indicators

Abuse Recovery: Emotional as evidenced by the following indicators: Trauma-induced psychoneurotic behaviors, conduct disorders, and learning difficulties. (Rate outcome and indicators of **Abuse Recovery: Emotional**: 1 = extensive, 2 = substantial, 3 = moderate, 4 = limited, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Return to pretrauma level of functioning as quickly as possible
- Acknowledge traumatic event and begin to work with the trauma by talking about the experience and expressing feelings of fear, anger, anxiety, guilt, and helplessness
- Identify support systems and available resources and be able to connect with them
- Return to and strengthen coping mechanisms used in previous traumatic event
- Acknowledge event and perceive it without distortions
- Assimilate event and move forward to set and pursue life goals

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Counseling; Support System Enhancement

Example NIC Activities—Counseling

Encourage expression of feelings; Assist client to identify strengths and reinforce them

Nursing Interventions and Rationales

- Observe for a reaction to a traumatic event in all clients regardless of age or sex. **EB**: Clinicians need to be aware of the differences between injury and PTSD symptoms for women compared with men and assess

• = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

for a full range of traumatic combat experiences; injury was more strongly associated with PTSD symptoms for women (Maguen et al, 2012).

- After a traumatic event, assess for intrusive memories, avoidance and numbing, and hyperarousal. **EB:** *The inability to complete goal-directed behavior by actively maintaining information while inhibiting irrelevant information is specific to symptoms of PTSD (Bornyey et al, 2013).*
- Remain with the client and provide support during periods of overwhelming emotions. **EB:** *Hansen et al (2014) studied the effects of an intervention for female victims of intimate partner violence on perceived social support and found the overall aim of the stabilization part of this treatment was to provide the woman with a sense of control over her physical safety as well as her psychological and social situation. CEB:* *The importance of trust was found to be a key element in a nurse client relationship (Bell & Duffy, 2009).*
- Help the individual try to comprehend the trauma if possible. **CEB:** *A stronger sense of coherence as the ability to perceive a stressor as comprehensible, manageable, and meaningful renders the client somewhat resilient to symptoms of PTSD (Engelhan et al, 2003).*
- Use touch with the client's permission (e.g., a hand on the shoulder, holding a hand). *Appropriate physical touching such as holding a person's hand may improve comfort and communication with the client (Baker, 2011).*
- Explore and enhance available support systems. **EB:** *The efficacy of a self-guided Internet intervention based on techniques from cognitive behavioral therapy (CBT) for prevention of PTSD symptoms was not supported (Mouthaan et al, 2014).*
- Help the client regain previous sleeping and eating habits. **EB:** *Babson et al (2010) found that post-traumatic stress symptom severity is related to difficulty initiating and maintaining sleep and experiencing nightmares.*
- ▲ Provide the client pain medication if he/she has physical pain. **EB:** *A quality of pain care study showed that aggressive medication management by an acute pain services team in a combat support hospital is associated with decreased pain intensity and increased pain relief in combat-injured veterans (Buckenmaier et al, 2012).*
- ▲ Assess the need for pharmacotherapy. **EB:** *The two most common interventions for PTSD are pharmacological treatment with SSRIs such as paroxetine and psychological treatment such as trauma-focused cognitive behavioral therapy. This study showed that trauma-focused cognitive behavioral therapy (TF-CBT) was superior to paroxetine in terms of sustainability, effectiveness, and cost effectiveness for the treatment of PTSD (Polak et al, 2012).*
- ▲ Refer for appropriate psychotherapy: cognitive therapy, exposure therapy, eye movement desensitization and reprocessing (EMDR), and CBT. *All of these approaches can help the client gain control of the fear and distress that happen after a traumatic event (Mayo Clinic, 2014). EB: Chen et al (2014) confirmed that EMDR significantly reduces the symptoms of PTSD.*
- Help the client use positive cognitive restructuring to reestablish feelings of self-worth. **EB:** *Anke et al (2013) showed that cognitive therapy was well tolerated and led to a very large improvement in PTSD symptoms, depression, and anxiety; the majority of clients showed reliable improvement that was clinically significant.*
- Provide the means for the client to express feelings through therapeutic drawing. **EB:** *The creative arts therapies may be particularly effective in the treatment of PTSD because they offer a sensory means for children and adults to express traumatic memories (Green, 2011).*
- Encourage the client to return to the normal routine as quickly as possible. **EBN:** *For families following an intensive care unit admission, written information about possible psychological sequelae and psychological follow-up was found to be preferable, complemented by telephone support and guidance (Gledhill et al, 2014).*
- Talk to and assess the client's social support after a traumatic event. **EB:** *Given the high number of physical, mental, and social problems in trauma clients, identifying and strengthening support sources can be effective in the adaption of the effects of an amputation on an individual and improvement of the quality of their life (Valizadeh et al, 2014).*

Pediatric

- Refer to nursing care plan Risk for **Post-Trauma** syndrome.
- ▲ Carefully assess children exposed to disasters and trauma. Note behavior specific to developmental age. Refer for therapy as needed. **EBN:** *Zhang et al (2014) found continuous screening is recommended to identify adolescent earthquake survivors with PTSD symptoms, especially survivors who are prone to adapt passive coping strategies and who own external causal attribution.*

Geriatric

- Carefully screen older adults for signs of PTSD, especially after a disaster. **CEB:** *Clients with PTSD are often not recognized or incorrectly diagnosed. Increased knowledge about vulnerability factors for PTSD can facilitate diagnostic procedures and health management in older adults. Because of age-related changes and associated disease processes, stress reaction in older adults may lead to a deterioration of function and a worsening of existing conditions (Marren & Christianson, 2005).* **EB:** *The association between PTSD and traumatic stress underscored the importance of screening for traumatic experiences in a geriatric German population (Glaesmer et al, 2011).*
- Consider using the Horwitz Impact of Event Scale, an appropriate instrument to measure the subjective response to stress in the older population. *The Impact of Event Scale—Revised is one of the most widely used self-report measures in the trauma literature (Beck et al, 2008).*
- ▲ Monitor the client for clinical signs of depression and anxiety; refer to a health care provider for medication if appropriate. **EB:** *Chan et al (2011) found that depressed older adult clients with comorbid PTSD are more functionally impaired and may take longer to respond to depression treatment than those without PTSD, but collaborative care (compared to usual care) produced similar improvements in depression severity in both groups.*
- Instill hope. **EBN:** *Hope was intentionally used in this study as an intervention in a group setting in a nursing home; it was evident that hope is not static and can change over time (Moore et al, 2014).*

Multicultural

- Assess the influence of cultural beliefs, norms, and values on the client's ability to cope with a traumatic experience. **EB:** *When receiving treatment, African Americans may feel differently toward a European American clinician due to cultural mistrust. Furthermore, racism and discrimination experienced before or during the traumatic event may compound post-trauma reactions, impacting the severity of symptoms (Williams et al, 2014).*
- Acknowledge racial and ethnic differences at the onset of care. **EBN:** *Sabri et al (2014) showed that blacks and Asians were less likely than whites to be knowledgeable about workplace violence resources or use resources to address workplace violence.*
- ▲ Carefully assess refugees for PTSD and refer for treatment as appropriate; encourage them to learn the language of their new residence. **EB:** *Two possible explanations were found for the persistently high prevalence of PTSD among refugees; one is the late onset of PTSD and the other is the low utilization of mental health care (Lamkaddem et al, 2014).*
- Use a family-centered approach when working with Latin, Asian, African American, and Native American clients. **CEB:** *Latinos may perceive the family as a source of support, solver of problems, and source of pride. Asian Americans may regard the family as the primary decision-maker and influence on individual family members (D'Avanzo & Naegle, 2001).* **EB:** *Parent and self-reported mental health service use for social anxiety among high school students showed Asian American students endorsed a greater number of social anxiety symptoms than other ethnic groups. There were no differences in parent-reported impairment or service utilization (Brice et al, 2014).*
- When working with Asian American clients, provide opportunities by which the family can save face. **CEB:** *Asian American families may avoid situations and discussion of issues that they perceive will bring shame on the family unit (D'Avanzo & Naegle, 2001).* **EBN:** *This study showed that an overwhelming number of abused Chinese women have depression; these women need more attention not only in a health care setting but also in the community, especially if the immigrants are from Mainland China (Wong et al, 2011).*
- Incorporate cultural traditions as appropriate. **EBN:** *This study identified important culture-specific themes that relate to the treatment of native clients within the setting of trauma medicine; Native American healers were more comfortable with the genre of storytelling as interview rather than with a question-and-answer format (Basset et al, 2012).*

Home Care

- ▲ Assess family support and the response to the client's coping mechanisms. Refer the family for medical social services or other counseling as necessary. **EB:** *Nicholls et al (2014) studied the role of relationship attachment in psychological adjustment to cancer to improve the ability of those working with cancer clients and their families to better understand and provide for their support needs.*

- Assess the impact of the trauma on significant others (e.g., a father may have to take over his partner's parenting responsibility after she has been raped and injured). Provide empathy and caring to significant others. Refer for additional services as necessary. **EBC**: *Homicide causes negative unintended consequences for family members; a weekend family retreat intervention was studied and found to ameliorate the effects of complicated grief and overwhelming loss (Tuck et al, 2012).*

Client/Family Teaching and Discharge Planning

- Teach positive coping skills and avoidance of negative coping skills. **EB**: *CBT coupled with an exercise intervention was associated with positive results in an intervention for ovarian cancer client (Moonsammy et al, 2013).*
- Teach stress reduction methods such as deep breathing, visualization, meditation, and physical exercise. Encourage their use especially when intrusive thoughts or flashbacks occur. **EB**: *Bormann et al (2013) explored the efficacy of private meditation-based mantra intervention for veterans to enhance spiritual well-being in outpatient veterans diagnosed with military-related PTSD.*
- Encourage other healthy living habits of proper diet, adequate sleep, regular exercise, family activities, and spiritual pursuits. **EBC**: *A cluster randomized study suggested The Health Promotion Model can be used to develop physical activity interventions with spiritual strategies for older African American women in faith communities (Anderson et al, 2012).*
- Refer the client to peer support groups. **EB**: *Public stereotypes impact help seeking at least early in the course of illness; peer-based outreach and therapy groups may help veterans engage in treatment and resist stigma (Mittal et al, 2013).*
- Consider the use of complementary and alternative therapies. **EB**: *Stankovic (2011) showed evidence to suggest that PTSD symptoms can be reduced with mindfulness-based stretching exercises.*

Risk for Post-Trauma syndrome *Mary Jane Roth, RN, BSN, MA*

NANDA-I

Definition

Vulnerable to sustained maladaptive response to a traumatic, overwhelming event, which may compromise health

Risk Factors

Diminished ego strength; displacement from home; duration of traumatic event; environment not conducive to needs; exaggerated sense of responsibility; human service occupations (e.g., police, fire, rescue, corrections, emergency room, mental health); insufficient social support; perceives event as traumatic; survivor role

NOC

(Nursing Outcomes Classification)

Refer to the care plan for **Post-Trauma** syndrome for suggested NOC outcomes

Example NOC Outcome with Indicators

Risk Detection as evidenced by the following indicators: Recognizes signs and symptoms that indicate risk/Uses health care services congruent with need. (Rate the outcome and indicators of **Risk Detection**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify symptoms associated with PTSD and seek help
- Acknowledge event and perceive it without distortions
- Identify support systems and available resources and be able to connect with them
- State that he/she is not to blame for the event

NIC

(Nursing Interventions Classification)

Refer to the care plan for **Post-Trauma** syndrome for suggested NIC interventions

Nursing Interventions and Rationales

- Assess for PTSD in a client who has chronic/critical illness, anxiety, or personality disorder; was a witness to serious injury or death; or experienced sexual molestation. **EB:** *Kross et al (2011) found intensive care unit (ICU) care associated with symptoms of increased PTSD symptoms among family members of clients who die in the ICU.*
- Consider the use of a self-reported screening questionnaire. **EB:** *Client self-reported screening questionnaires are efficient ways to assess for PTSD (National Center for PTSD, 2014).* **EB:** *Mouthaan et al (2014) support the use of the SPAN, TSQ, and IES-R for early detection of post-traumatic self-reporting of PTSD symptoms.*
- Assess for ongoing symptoms of dissociation, avoidance behavior, hypervigilance, and reexperiencing. **EB:** *The symptoms for individuals with PTSD can vary considerably; they generally fall into three categories: reexperience, avoidance, and increased arousal (National Alliance on Mental Illness, 2014).* **EB:** *Diagnostic criteria for PTSD in the Diagnostic and Statistical Manual of Mental Disorders, 5th Edition (DSM-5), includes the above symptoms that continue for more than 1 month after the occurrence of a traumatic event (American Psychiatric Association, 2013).* **EB:** *He et al (2014) explored the generalizability of the DSM-5 for subpopulations and found differential symptom functioning, such as gender, race, and educational level to be small but recommended that diagnosticians always perform an analysis of subpopulations to ensure validity for research.*
- Assess for past experiences with traumatic events. **EB:** *Multiple lifetime exposures contribute to the development and persistence of PTSD among childhood victims of violence (Kulkarni et al, 2011).*
- Consider screening for PTSD in a client who is a high user of medical care. **EB:** *Dorrington et al (2014) showed that despite high rates of exposure to trauma, a middle income population had lower rates of PTSD than high-income populations; there are high rates of non-PTSD diagnoses associated with trauma exposure that could be considered in interventions for trauma-exposed populations.*
- ▲ Provide deployed combat veterans with previous history of low mental or physical health status before deployment with appropriate referral after deployment. **EB:** *Results of a longitudinal study by Pietrzak et al (2012) indicated that combat exposure, not deployment in general, had an adverse effect on mental health and that health outcomes were affected by both individual characteristics and post-deployment life events that changed over time.*
- Provide peer support to contact co-workers experiencing trauma to remind them that others in the organization are concerned about their welfare. **CEB:** *Trauma risk management (TRM) is a peer-support system that aims to promote help-seeking in the aftermath of traumatic events. This study showed that using TRM is beneficial and may lead to a valuable culture shift (Greenberg et al, 2010).*
- Provide post-trauma debriefings. Effective post-trauma coping skills are taught, and each participant creates a plan for his/her recovery. During the debriefing, the facilitators assess participants to determine their needs for further services in the form of post-trauma counseling. For maximal effectiveness, the debriefing should occur within 2 to 5 days of the incident (Guess, 2006). **EB:** *Fakour et al (2014) showed the effectiveness of psychological debriefing in treatment of PTSD after an earthquake; the means of PTSD symptom frequency and severity of avoidance symptoms were reduced during the 3-month period of study.*
- Provide post-trauma counseling. Counseling sessions are extensions of debriefings and include continued discussion of the traumatic event and post-trauma consequences and the further development of coping skills. **EB:** *Evidence suggests that the response to cognitive behavioral therapy may be enhanced in PTSD clients by preparing them with emotion regulation skills; however, a high attrition of participants during the study limits the conclusions (Bryant et al, 2013).*

- Consider exposure therapy for civilian trauma survivors following a nonsexual assault or motor vehicle crash. **EB:** *Early intervention with modified prolonged exposure can be successful at reducing symptoms after trauma and is safe and feasible in a civilian emergency department setting (Rothbaum et al, 2012).*

Things to Try: Critical Incident Stress Debriefing

- Instruct the client to use the following critical incident stress management techniques:
 - Within the first 24 to 48 hours, engaging in periods of appropriate physical exercise alternated with relaxation to alleviate some of the physical reactions; structure your time; keep busy; you are normal and are having normal reactions; do not label yourself as “crazy”; talk to people; talk is the most healing medicine; be aware of numbing the pain with overuse of drugs or alcohol; you do not need to complicate the stress with a substance abuse problem; reach out; people do care; maintain as normal a schedule as possible; spend time with others; help your co-workers as much as possible by sharing feelings and checking out how they are doing; give yourself permission to feel rotten and share your feelings with others; keep a journal; write your way through those sleepless hours; do things that feel good to you; realize that those around you are under stress; do not make any big life changes; do make as many daily decisions as possible to give you a feeling of control over your life (e.g., if someone asks you what you want to eat, answer the person even if you are not sure); get plenty of rest; recurring thoughts, dreams, or flashbacks are normal; do not try to fight them because they will decrease over time and become less painful; eat well-balanced and regular meals (even if you do not feel like it). *The critical incident stress debriefing process is specifically designed to prevent or mitigate the development of PTSD among emergency services professions. Critical incident stress debriefing interventions are especially directed toward the mitigation of post-traumatic stress reactions (Agency for Healthcare Research and Quality, 2012).*
 - ▲ Assess for a history of life-threatening illness such as cancer and provide appropriate counseling. The physical and psychological impact of having a life-threatening disease, undergoing cancer treatment, and living with recurring threats to physical integrity and autonomy constitute traumatic experiences for many cancer clients (National Cancer Institute, 2013). **EB:** *Problematic post biopsy symptoms can lead to increased anxiety, distinct from distress related to diagnosis of prostate cancer (Wade et al, 2013).*

Pediatric

- Children with cancer should continue to be assessed for PTSD into adulthood. **EB:** *The presence of health outcomes was ascertained using systematic exposure-based medical assessments among adult survivors of childhood cancer; using clinical criteria, the crude prevalence of adverse health outcomes for neurocognitive impairment was 48% (Hudson et al, 2013).*
- Provide protection for a child who has witnessed violence or who has had traumatic injuries. Help the child acknowledge the event and express grief over the event. **EB:** *Lafta et al (2014) showed that more than half of the total sample in Baghdad had reported multiple experiences of trauma like fear/and or terror and the painful recall of traumatic events pointing to the need for medical educational opportunities.*
- Assess for a medical history of anxiety disorders. **EB:** *Findings from this study suggest that parents with social anxiety disorder may exhibit a unique pattern of behaviors when interacting with their children that includes high levels of criticism and low levels of warmth; this parenting style has been linked to an increased risk for development of anxiety (Budinger et al, 2013).*
- ▲ Assess children of deployed parents for PTSD and provide appropriate referrals. **EB:** *Mansfield et al (2011) reported that, overall, children with parental deployment represented an excess of 6579 mental health diagnoses during the 4-year period of this study compared with children with parents who did not deploy.*
- Consider implementation of a school-based program for children to decrease PTSD after catastrophic events. **EB:** *Tol et al (2014) used an evidence base from previous studies to draw conclusions about the benefits and risks of school-based intervention in reducing PTSD, anxiety, and depression.*

Geriatric and Multicultural

- Refer to the care plan for **Post-Trauma** syndrome.

Home Care

- ▲ Evaluate the client's response to a traumatic or critical event. If screening warrants, refer to a therapist for counseling/treatment. **EBN:** *Nurse-Family Partnership is an evidence-based nurse home visitation*

program for disadvantaged first-time mothers. *Jack et al (2012)* developed an intervention model and modification process to address the needs of women at risk for intimate partner violence or its recurrence.

- Refer to the care plan for **Post-Trauma** syndrome.

Client/Family Teaching and Discharge Planning

- Instruct family and friends to use the following critical incident stress management techniques:
 - ▲ Listen carefully; spend time with the traumatized person; offer your assistance and a listening ear, even if the person has not asked for help; help the person with everyday tasks such as cleaning, cooking, caring for the family, and minding children; give the person some private time; do not take the individual's anger or other feelings personally, and do not tell the person that he/she is "lucky it wasn't worse"; such statements do not console traumatized people. Instead, tell the person that you are sorry such an event has occurred and you want to understand and assist him or her ([National Interagency Fire Center, CISM Information Sheets, 2014](#)).
 - ▲ After exposure to trauma, teach the client and family to recognize symptoms of PTSD and seek treatment for "recurrent and intrusive distressing recollections of the traumatic event," insomnia, irritability, difficulty concentrating, hypervigilance. **EB:** *Post-traumatic stress symptoms are associated with higher levels of general health symptoms and lower levels of social group functioning over time (Jones et al, 2012)*.
- Provide education to explain that acute stress disorder symptoms are normal when preparing combatants for their role in deployment. Instruct clients to seek help if the symptoms persist. **EB:** *Pre-deployment mental health screening was associated with significant reductions in occupationally impaired mental health problems, medical evacuations from Iraq for mental health reasons, and suicidal ideation (Warner et al, 2011)*.

Readiness for enhanced Power Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A pattern of participating knowingly in change for well-being, which can be strengthened

Defining Characteristics

Expresses desire to enhance awareness of possible changes; expresses desire to enhance identification of choices that can be made for change; expresses desire to enhance independence with actions for change; expresses desire to enhance involvement in change; expresses desire to enhance knowledge for participation in change; expresses desire to enhance participation in choices for daily living; expresses desire to enhance participation in choices for health; expresses desire to enhance power

P

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health Beliefs: Perceived Control; Participation in Health Care Decisions; Personal Autonomy

Example NOC Outcome with Indicators

Health Beliefs: Perceived Control as evidenced by the following indicators: Belief that own actions and decisions control health outcomes/Perceived responsibility for health decisions/Efforts at gathering information. (Rate the outcome and indicators of **Health Beliefs: Perceived Control** as 1 = very weak, 2 = weak, 3 = moderate, 4 = strong, 5 = very strong [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Describe power resources
- Identify realistic perceptions of control
- Develop a plan of action based on power resources
- Seek assistance as needed

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Mutual Goal Setting; Self-Esteem Enhancement; Self-Responsibility Facilitation

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Example NIC Activities—Mutual Goal Setting

Encourage the identification of specific life values; Identify with client the goals of care; Assist client in examining available resources to meet goals

Nursing Interventions and Rationales

- Develop partnerships for shared power. **EBN:** *The client's right to influence their treatment and health care allows the client power (Aasen et al, 2012).*
- Focus on the positive aspects of power, rather than prevention of powerlessness. **EBN:** *Numerous studies conducted during development of the health promotion model show that promotion differs from prevention and requires a positive rather than negative approach (Fisher & Howell, 2010; Pender et al, 2011).*
- Listen with intent. **EBN:** *In a study of successful adaptation of women with chronic illness, partnerships with health care providers contributed to positive outcomes. These partnerships were enhanced by careful listening on the part of the health care provider (Cudney et al, 2011).*
- Collaborate with and encourage the person to identify resources to put a plan into action. **EBN:** *Collaborating with clients provides opportunities for learning and growth and is a client-empowering behavior that improves client health outcomes (Jerofke et al, 2014).*
- Assess the meaning of the event to the person. **EBN:** *Assessing meaning gives a voice to clients and makes it more likely that solutions reached will have meaning and be useful to the individual (Bevan, 2013).*
- Identify the client's health literacy and provide access to information. **EBN:** *Providing clients with access to information is a client-empowering behavior that improves client health outcomes (Jerofke et al, 2014).*
- Facilitate trust in self and others. **EBN:** *Trust in the competence of the health care staff is an empowering to the client (Nygårdh et al, 2012).*
- Help client to mobilize social supports, a power resource. **EBN:** *Assisting clients with access to resources is a client-empowering behavior that improves client health outcomes (Jerofke et al, 2014).*
- Support beliefs of power and perceptions of behavioral control. **CEBN:** *A positive correlation was identified between beliefs and motivation toward control of health-promoting behaviors and blood pressure control (Peters & Templin, 2010).*
- Promote the client's optimum level of physical functioning. **EBN:** *Younger (2011) identifies the relationship between physical health and the ability to heal.*
- Reframe professional image, role, and values to incorporate a vision of clients as the experts in their own care. **EBN:** *Professional development for nurse practitioners in methods of communication and education was identified as key in promoting effective medication management in people with diabetes (Sibley et al, 2011).*

P

Home Care

- The preceding interventions may be adapted for home care use.

Client/Family Teaching and Discharge Planning

- Assess motivation to learn specific content. **CEBN:** *Motivation is a basic element of a teaching model and of participation in health care decisions (Pender et al, 2011).*

Powerlessness *Marina Martinez-Kratz, MS, RN, CNE*

NANDA-I

Definition

The lived experience of lack of control over a situation, including a perception that one's actions do not significantly affect an outcome

Defining Characteristics

Alienation; dependency; depression; doubt about role performance; frustration about inability to perform previous activities; inadequate participation in care; insufficient sense of control; shame

Related Factors

Complex treatment regimen; dysfunctional institutional environment; insufficient interpersonal interactions

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Depression Self-Control; Health Beliefs; Health Beliefs: Perceived Ability to Perform, Perceived Control, Perceived Resources; Participation in Health Care Decisions

Example NOC Outcome with Indicators

Health Beliefs: Perceived Control as evidenced by the following indicators: Perceived responsibility for health decisions/Beliefs that own decisions and actions control health outcomes. (Rate the outcome and indicators of **Health Beliefs: Perceived Control**: 1 = very weak belief, 2 = weak belief, 3 = moderately strong belief, 4 = strong belief, 5 = very strong belief [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State feelings of powerlessness and other feelings related to powerlessness (e.g., anger, sadness, hopelessness)
- Identify factors that are uncontrollable
- Participate in planning and implementing care; make decisions regarding care and treatment when possible
- Ask questions about care and treatment
- Verbalize hope for the future and sense of participation in planning and implementing care

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cognitive Restructuring; Complex Relationship Building; Mutual Goal Setting; Self-Esteem Enhancement; Self-Responsibility Facilitation

Example NIC Activities—Self-Responsibility Facilitation

Encourage independence but assist client when unable to perform; Assist client to identify areas in which they could readily assume more responsibility

Nursing Interventions and Rationales

NOTE: Before implementation of interventions in the face of client powerlessness, nurses should examine their own philosophies of care to ensure that control issues or lack of faith in client capabilities will not bias the ability to intervene sincerely and effectively.

- Observe for factors contributing to powerlessness (e.g., immobility, hospitalization, unfavorable prognosis, lack of support system, misinformation about situation, inflexible routine, chronic illness, addiction, history of trauma, gender). Help clients channel their behaviors in an effective manner. **EB**: *Many studies identify factors contributing to feelings of powerlessness are related to losses of person, place, health, or social relationships, gender, or the impact of trauma (An & Kim, 2012; Doyle, 2014; Milberg & Strang, 2011; Salomé et al, 2013).*
- Engage with clients using respectful listening and questioning to develop an awareness of clients' most important concerns. **EB**: *Engaging clients will integrate clinician expertise with client needs and can diminish feelings of powerlessness (Sheridan et al, 2015).*
- Assess the client's locus of control related to his or her health. **EBN**: *In a quasi-experimental study of hemodialysis clients and the use of interactive media, powerlessness was associated with feelings of loss of control (Wang & Chiou, 2011).*
- Establish a therapeutic relationship with the client by spending one-on-one time with him or her, assigning the same caregiver, keeping commitments (e.g., saying, "I will be back to answer your questions in the next hour"), providing encouragement and social support, and being empathetic. **EBN**: *In a study of Korean adults with type 2 diabetes, it appears that lower levels of social support are associated with increased measures of powerlessness (An & Kim, 2012).* **EBN**: *In a study of successful adaptation of women with chronic illness, establishment of a therapeutic relationship contributed to positive outcomes. These relationships were enhanced by careful listening on the part of the health care provider (Cudney et al, 2011).*
- Encourage the client to share his or her beliefs, thoughts, and expectations about his or her illness. **CEBN**: *The Health Belief Model identifies perceived barriers and perceived susceptibility to disease as powerful predictors of clients' motivation in taking action to prevent disease and participate in self-care management (Pender et al, 2010).*
- Help the client assist in planning care and specify the health goals he or she would like to achieve, prioritizing those goals with regard to immediate concerns and identifying actions that will achieve the goals. Goals may need to be small to be attainable (e.g., dangle legs at bedside for 2 days, then sit in chair 10 minutes for 2 days, then walk to window). **CEBN**: *People need goals that have value for them; the discrepancy between these goals and reality motivates action to reduce the discrepancy. Goals must be realistic and achievable; otherwise, the inability to perceive progress will increase hopelessness and powerlessness (Pender et al, 2010).*
- Encourage the client in goal-directed activities that promote a sense of accomplishment, especially regular exercise. **EB**: *People with arthritis were asked to set goals for themselves in terms of exercise. Self-efficacy was found to be a mediator between accomplishment of goals and quality of life. Goal direction enhances self-efficacy (Knittle et al, 2011).*
- Empower clients by providing access to health education in conjunction with counseling and opportunities for discussion. **EBN**: *A study reported that clients had a reduction in health risk behaviors and an increase in knowledge, self-efficacy, and health-related quality of life with a targeted empowerment program (Ok Ham & Jeong, 2011).*
- Encourage the client to take control of as many activities of daily living (ADLs) as possible; keep the client informed of all care that will be given. Keep items the client uses and needs within reach (e.g., a urinal, tissues, telephone, and television controls). **CEBN**: *Choice in ADLs such as eating, sleeping, and grooming contributes to a sense of control. Clients are more amenable to therapy if they know what to expect and can perform some tasks independently. Dependence can be alleviated by fostering an expectation of control over activities, which leads to the development of a sense of mastery (Pender et al, 2010).*
- Give realistic and sincere praise for accomplishments. **CEBN**: *Frequent positive reinforcement helps clients feel successful and competent, especially when it is immediate and is used to balance feedback about errors (Pender et al, 2010).*
- Use a Rehabilitative Behavioral Learning Model that assists clients to understand how the mechanisms of habit and ritual work to reinforce powerlessness in their lives. *For clients with addiction, understanding the learning processes and mechanisms of powerlessness is an important part of recovery (Butler et al, 2015).*

- Consider using one of the measures of powerlessness that are available for general and specific client groups:
 - Measure of Powerlessness for Adult Patients (De Almeida & Braga, 2006)
 - Personal Progress Scale—Revised, tested with women (Johnson et al, 2005)
 - Life Situation Questionnaire—Powerlessness subscale, tested with stroke caregivers (Larson et al, 2005)
 - Making Decisions Scale, tested in clients with mental illness (Hansson & Bjorkman, 2005)
- Refer to the care plans for **Hopelessness** and **Spiritual** distress.

Pediatric

- Assess for power differentials in the dating relationships of female adolescent clients and provide teaching that addresses relationship power and dating violence. **EBN:** *Research indicates that romantic relationships are an important part of adolescent development. Adolescent clients that report relationship control and power imbalances will benefit from learning about relationship equity, effective communication, and negotiation skills to positively influence relationship power and improve health outcomes (Volpe et al, 2012).*
- Provide nursing care that shifts the focus from the illness to the child. **EBN:** *Research indicates that children with a new diagnosis of cancer feel powerless and can benefit from being viewed as a competent individual who requires information and is able to participate in their care (Darcy et al, 2014).* Recognize that a sense of powerlessness can prevent children and adolescents from reporting peer victimization. Be supportive, encourage disclosure without pressure, and help the child or adolescent problem-solve options to deal with stressors. **EBN:** *School nurses are poised to provide a supportive and safe haven for children who are being bullied (Carter, 2011).*

Geriatric

- In addition to the preceding interventions as appropriate:
 - Assist older adults to retain a sense of power and control as they are making the transition to residential care. **EB:** *Older adults report greater satisfaction during transition to residential care when they have the feeling of power and control over the process and are able to perceive their residence as their new home (Riedl, 2011).*
 - Initiate focused assessment questioning and education of client and caregivers regarding syndromes common in the older adults, including dementia. **EB:** *A disease management model used by a multidisciplinary team in a nursing home was found to improve quality of life in older clients (Boorsma et al, 2011).*
 - Assess for the presence of elder abuse. Initiate referral to Adult Protective Services and help client regain a sense of safety and control. **EB:** *Elder abuse can be seen in the form of emotional, financial, physical, and sexual abuse. In addition, neglect and self-neglect can be viewed as forms of abuse (Mosqueda & Dong, 2011).*

Multicultural

- In addition to the preceding interventions as appropriate:
 - Assess for the influence of communication patterns, cultural differences in medical consultations, and client perceptions of inequalities in care quality as contributors to client feelings of powerlessness. **EB:** *Understanding and addressing client perceptions of power disparities may decrease clients' feelings of powerlessness (Akhavan & Karlson, 2013).*

Home Care

- In addition to the preceding interventions as appropriate:
 - Develop a therapeutic relationship in the home setting that respects the client's domain. **EB:** *Respect for the client's living quarters supports development of a therapeutic relationship that fosters trust (Harkness & DeMarco, 2011).*
 - Empower the client by encouraging the client to guide specifics of care such as wound care procedures and dressing and grooming details. Confirm the client's knowledge and document in the chart that the client is able to guide procedures. Document in the home and in the chart the preferred approach to procedures. Orient the family and caregivers to the client's role. **EBN:** *The use of focus groups to acknowledge expertise and foster decision-making in mental health consumers contributed to greater self-health management (Mahone et al, 2011).*

- Assess the affective climate within the family and family support system, including other caregivers. Instruct the family in appropriate expectations of the client and in the specifics of the client's illness. Assist the family and caregivers to assert personal needs and develop closer proximity to health care providers. **EB:** *Caregivers and family members often experience a sense of isolation and powerlessness that goes unrecognized by health care providers. Assessment will identify support needs that go beyond the physical and emotional care of the dying client (Clark et al, 2011).*
- Evaluate the powerlessness of caregivers to ensure they continue their ability to care for the client. Provide assistance using interventions from this care plan. **EB:** *Powerlessness of caregivers of terminally ill clients was studied during care and 3 to 9 months after the client's death. Some aspects that protected the family members from powerlessness were access to information regarding palliative care, believing they were doing good for the client, and social support (Milberg & Strang, 2011).*
- Assist family caregivers, especially fathers, to take an active role in the client's care. **EBN:** *A study determined that cooperation between the adult client with chronic mental illness, parental caregivers, and health care providers could increase the parent caregiver's ability to support the client, understand the illness, and manage the symptoms. This in turn would decrease feelings of caregiver powerlessness (Johansson et al, 2012).*
- Assess for denial in clients with cancer and provide support for caregivers. **EB:** *While denial may be a protective mechanism for the client with cancer, it can create additional burdens for caregivers who may experience powerlessness and an inability to meet their own needs (Kogan et al, 2013).*
- Be aware of and assist clients with potential needs for help in negotiating the health care system. **EBN:** *The use of electronic dosing and monitoring devices, in conjunction with other measures of adherence, has contributed to adherence to medication regimen (Cook et al, 2012).* **EB:** *Adherence to medications and self-health regimens is facilitated by payers' knowledge and use of value-based insurance designs (Cohen et al, 2012).*
- Teach stress reduction, relaxation, and imagery. Many audio recordings are available on relaxation and meditation. **CEBN:** *In this study of clients with breast cancer, participants reported the importance of engaging passive and active imagery. Imagery practice improved mood state (Freeman et al, 2008).*
- Teach cognitive-behavioral activities, such as active problem solving, reframing (reappraising the situation from a different perspective), or thought stopping (in response to a negative thought, such as picturing a large stop sign and replacing the image with a prearranged positive alternative). Teach the client to confront his or her own negative thought patterns (cognitive distortions). **CEBN:** *Through cognitive-behavioral interventions, clients become more aware of their cognitive choices in adopting and maintaining their belief systems, thereby exercising greater control over their own reactions (Hagerty & Patusky, 2008).*
- Identify the strengths of the caregiver and efforts to gain control of unpredictable situations. Help the caregiver stay connected with a client who may be behaving differently than usual to make life as routine as possible, help the client set goals and sustain hope, and allow the client space to experience progress. **EBN:** *A positive correlation was identified between beliefs and motivation toward control of health-promoting behaviors and blood pressure control (Peters & Templin, 2010).*

P

Client/Family Teaching and Discharge Planning

- The preceding interventions may be adapted for home care use.

Risk for Powerlessness Gail B. Ladwig, MSN, RN

NANDA-I

Definition

Vulnerable to the lived experience of lack of control over a situation, including a perception that one's actions do not significantly affect the outcome, which may compromise health

Risk Factors

Anxiety; caregiver role; economically disadvantaged; illness; ineffective coping strategies; insufficient knowledge to manage a situation; insufficient social support; low self-esteem; pain; progressive illness; social marginalization; stigmatization; unpredictability of illness trajectory

NOC, NIC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

See the care plan for **Powerlessness**.

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Risk for Pressure ulcer

Karen Zulkowski, DNS, RN, and Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

NANDA-I

Definition

Vulnerable to localized injury to the skin and/or underlying tissue usually over a bony prominence as a result of pressure, or pressure in combination with shear (NPUAP, 2007)

Risk Factors

Adult

Braden scale score <18; alteration in cognitive functioning; alteration in sensation; American Society of Anesthesiologist (ASA) Physical Status classification score ≥ 2 ; anemia; cardiovascular disease

Child

Braden Q scale ≤ 16 ; decrease in mobility; decrease in serum albumin level; decrease in tissue oxygenation; decrease in tissue perfusion; dehydration; dry skin; edema; elevated skin temperature by 1° C to 2° C; extended period of immobility on hard surface (e.g., surgical procedure ≥ 2 hours); extremes of age; extremes of weight; female gender; hip fracture; history of cerebral vascular accident; history of pressure ulcer; history of trauma; hyperthermia; impaired circulation; inadequate nutrition; incontinence; insufficient caregiver knowledge of pressure ulcer prevention; low score on Risk Assessment Pressure Sore (RAPS) scale; lymphopenia; New York Heart Association (NYHA) functional classification ≥ 2 ; nonblanchable erythema; pharmaceutical agents (e.g., general anesthesia, vasopressors, antidepressant, norepinephrine); physical immobilization; pressure over bony prominence; reduced triceps skin fold thickness; scaly skin; self-care deficit; shearing forces; skin moisture; smoking; surface friction; use of linens with insufficient moisture wicking property

NOC

Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Intact Tissue Integrity: Skin and Mucous Membranes as evidenced by the following indicators: Skin intactness/Skin lesions absent/Tissue perfusion/Skin temperature. (Rate the outcome and indicators of **Tissue Integrity: Skin and Mucous Membranes**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Report any altered sensation or pain at site of tissue impairment
- Skin, without redness over bony prominences and capillary refill of less than 6 seconds over areas of redness
- Be repositioned off of bony prominences frequently if risk for pressure ulcers is high (e.g., Braden scale score <18)
- Demonstrate understanding of plan to reduce pressure ulcer risk
- Describe measures to protect the skin

NIC

Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Pain Management; Pressure Ulcer Care; Pressure Ulcer Prevention; Risk Identification; Skin Care: Topical Treatments; Skin Surveillance

Example NIC Activities—Pressure Ulcer Care

Monitor color of skin, temperature, edema, erythema, moisture, and appearance of surrounding skin; Note characteristics of skin over bony prominences or medical devices

Nursing Interventions and Rationales

- *Skin breakdown in the form of pressure ulcers is defined as localized injury to the skin and/or underlying tissue usually over a bony prominence as a result of pressure, or pressure in combination with shearing forces (National Pressure Ulcer Advisory Panel/European Pressure Ulcer Advisory Panel [NPUAP/EPUAP], 2014).*
- Routinely assess clients for risk of pressure ulcers using a valid and reliable risk assessment tool (NPUAP/EPUAP, 2014). A validated risk assessment tool such as the Norton or Braden scale should be used to identify clients at risk for pressure related skin breakdown (NPUAP/EPUAP, 2014). **EB:** *Targeting variables (e.g., Braden Scale Risk Subscale Categories, age, severity of illness) can focus assessment on particular risk factors (e.g., pressure, immobility, perfusion) and help guide the plan of prevention and care (NPUAP/EPUAP, 2014; McCulloch & Kloth, 2010; Sussman & Bates-Jensen, 2012).*
- Pressure ulcer risk assessment should be completed on admission, daily, and after procedures or changes in the client's condition (Kelleher et al, 2012; NPUAP/EPUAP, 2014).
- Inspect the skin daily, especially bony prominences and dependent areas for pallor, redness, and breakdown. In addition to assessing pressure ulcer risk client specific interventions should be implemented to prevent tissue injury. Implement interventions to prevent tissue breakdown:
 - Assist client to turn at least every 2 hours unless contraindicated
 - Position client properly; use pressure-reducing or pressure-relieving devices (e.g., pillows, gel or foam cushions, alternating pressure mattress, air-fluidized bed, kinetic bed) if indicated
 - Lift and move client carefully using a turn sheet and adequate assistance; keep bed linens dry and wrinkle-free
 - Perform actions to keep client from sliding down in bed (e.g., bend knees slightly when head of bed is elevated 30 degrees or higher) in order to reduce the risk of skin surface abrasion and shearing
 - Instruct or assist client to shift weight at least every 30 minutes
 - Keep client's skin clean; thoroughly dry skin after bathing and as often as needed, paying special attention to skin folds and opposing skin surfaces (e.g., axillae, perineum, beneath breasts); pat skin dry rather than rub; use a mild soap for bathing and apply moisturizing lotion at least once a day
 - Protect the skin from contact with urine and feces (e.g., keep perineal area clean and dry, apply a protective ointment or cream to perineal area)
 - Encourage a fluid intake of 2500 mL/day unless contraindicated
 - Apply a protective covering such as a hydrocolloid or transparent membrane dressing to areas of the skin susceptible to breakdown (e.g., coccyx, heels, elbows)
 - Consult with nutrition/dietary specialist to evaluate client's nutritional status
 - Increase activity as allowed
- ▲ **EB:** *Pressure ulcers result in additional pain and treatment for the client as well as additional health care services and costs. A comprehensive assessment of the client's risk for pressure ulcers and proactive interventions are necessary to reduce the risk for tissue injury (NPUAP/EPUAP, 2014).*
- A medical device-related pressure ulcer (MDRPU) is a localized injury to the skin or underlying tissue as a result of sustained pressure from a medical device. The tissue injury will often have the same configuration as the device (NPUAP 2014; Baharestani, 2013; Black, 2010).
 - The head/face/neck, heel/ankle/foot, coccyx/buttocks, abdomen, and extremities are common body regions for MDRPU.
 - Common devices associated with pressure-related tissue injury include oxygen delivery and monitoring devices (e.g., face mask, nasal cannula, pulse oximetry, BiPAP mask); feeding tubes (e.g., nasogastric, gastric, jejunal tubes); endotracheal devices (oral and/or nasal endotracheal tubes, tracheostomy tubes); urinary and bowel elimination (indwelling urinary catheter, fecal containment catheter); musculoskeletal (cervical collar, splints, braces).
 - Assess and evaluate the purpose and function of the medical device

- Assess proper fit of the medical device and securement to prevent rubbing, torque, or pulling on the device and skin
- Protect the skin below and around the device to reduce pressure
- ▲ **EB:** Incorporate daily and frequent skin inspection around and under the medical device. See the National Pressure Ulcer Advisory Panel Best Practice flyer to help provide education about MDRPU (<http://www.npuap.org/wp-content/uploads/2013/04/BestPractices-CriticalCare1.pdf>).
- Critically ill clients are at increased risk for pressure ulcers, often requiring frequent skin risk assessment and preventive interventions. **EB:** Support surfaces are often needed to reduce pressure risk in the critically ill client (Behrendt et al, 2014). Frequently reposition the client often more frequently than every 2 hours (Makic et al, 2014; NPUAP/EPUAP, 2014). Frequently assess skin for shear injury as well as pressure areas when the client is in prone positioning or lateral rotation therapy is used (NPUAP/EPUAP, 2014).
- Interprofessional pressure ulcer prevention programs in acute and long-term care facilities are needed to reduce client's risk for developing pressure ulcers and associated complications (Padula et al, 2014; Niederhauser et al, 2012).
- If tissue breakdown occurs, notify a health care provider or wound care specialist. See care plan for Impaired Skin integrity for additional interventions if a pressure ulcer occurs.

Pediatric

- Perform an age-appropriate pressure ulcer risk assessment using a valid and reliable tool. **CEB/EB:** The Braden Q and Glamorgan Scale are valid and reliable scales to assess pediatric client risks for compromised skin integrity related to pressure (Anthony et al, 2010; Galvin et al, 2012; Tume et al, 2013). The Neonatal Skin Risk Assessment Scale was developed to assess unique skin breakdown risk in neonates (Huffines et al, 1997; Dolack et al, 2013).
- Implement a comprehensive plan to reduce the client's risk of skin breakdown from pressure. Assessment should include the following:
 - Client independent activity and mobility levels
 - Body mass index and/or birth weight; lower weight may increase client risk of pressure associated skin breakdown
 - Skin maturity
 - Adequate nutritional and hydration status
 - Perfusion and oxygenation
 - Presence of external devices
 - Duration of hospital stay
- ▲ **EB:** Pediatric clients with medical devices are at higher risk for pressure ulcers. Inspect the skin under and around the device at least twice a day. Frequent (e.g., daily and after procedures) and ongoing assessment of the client's risk for pressure ulcer is an important prevention intervention. Carefully assess the skin on the client's occiput as part of the assessment (NPUAP/EPUAP, 2014).
- Select an age-appropriate support surface for premature neonates and pediatric clients at high risk for pressure ulcers. **EBN:** A longitudinal study found that the use of continuous and reactive low-pressure mattresses reduced the observed incidence of pressure ulcers (Garcia-Molina et al, 2012). Select a support surface to prevent occipital pressure ulcers for at-risk clients (NPUAP/EPUAP, 2014).
- Engage the client/family/legal guardian in the development of a client specific plan of care to reduce pressure-related risk for skin breakdown (NPUAP/EPUAP, 2014).
- Document risk assessment and interventions implemented to reduce the client's risk for pressure ulcer development.

Geriatric

- Consider the older client's cognitive status when assessing the skin and in developing a comprehensive plan of care to prevent pressure ulcers (NPUAP/EPUAP, 2014).
- Aging skin, medications (e.g., steroids), and moisture place the older client at increased risk for pressure-associated skin breakdown. **EB:** Assess the client for pressure ulcer risk as well as skin tear and moisture associated skin breakdown. It is important to differentiate the cause of the older client's skin breakdown to effectively implement prevention and treatment strategies. Frequently interventions complement each other in the overall goal to prevent a compromise in the client's skin integrity (NPUAP/EPUAP, 2014; Holmes et al, 2013).

- Use atraumatic wound dressings to prevent and treat pressure ulcers to reduce further injury to frail older client's skin (NPUAP/EPUAP, 2014).
- For older clients with continence concerns, develop and implement an individualized continence management program (NPUAP/EPUAP, 2014). **EB:** Use skin barrier products and moisture wicking pads to reduce moisture-associated skin irritation that increases the risk for pressure ulcer development; avoid the use of diapers except when the client is ambulating (NPUAP/EPUAP, 2014; Willson et al, 2014; Makic et al, 2011).
- Regularly reposition the older client who is unable to reposition independently. Consider pressure redistribution support surface for client's assessed to be at high risk for pressure ulcers (NPUAP/EPUAP, 2014; Makic et al, 2014).

Home Care

- The interventions described previously may be adapted for home care use.
- Instruct and assist the client and caregivers in how to assess the skin for excessive pressure. Provide written instructions for actions they can implement to reduce the risk of pressure ulcer development.
- Educate client and caregivers on proper nutrition and when to call the agency and/or healthcare provider with concerns.
- ▲ It may be beneficial to initiate a consultation in a case assignment with a wound, ostomy, continence nurse (or wounds specialist) to establish a comprehensive plan for pressure ulcer risk reduction for clients at high risk for skin breakdown.

NANDA-I

Definition

Decrease in the ability to guard self from internal or external threats such as illness or injury

Defining Characteristics

Altered in clotting; alteration in perspiration; anorexia; chilling; coughing; deficient immunity; disorientation; dyspnea; fatigue; immobility; insomnia; itching, maladaptive stress response; neurosensory impairment; pressure ulcer; restlessness; weakness

Related Factors (r/t)

Abnormal blood profiles; cancer; extremes of age; immune disorder (e.g., HIV-associated neuropathy varicella zoster virus); inadequate nutrition; pharmaceutical agent; substance abuse; treatment regimen)

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health-Promoting Behavior; Blood Coagulation; Endurance; Immune Status

Example NOC Outcome with Indicators

Immune Status as evidenced by the following indicators: Recurrent infections/Tumors/Weight loss. (Rate the outcome and indicators of **Immune Status**: 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of infection while in contact during contact with health care
- Remain free of any evidence of new bleeding as evident by stable vital signs
- Explain precautions to take to prevent infection including hand hygiene
- Explain precautions to take to prevent bleeding including fall prevention

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Bleeding Precautions; Infection Prevention; Infection Protection

Example NIC Activities—Infection Protection

Monitor for systemic and localized signs and symptoms of infection; Inspect skin and mucous membranes for redness, extreme warmth, or drainage

Nursing Interventions and Rationales

- Take temperature, pulse, and blood pressure (e.g., every 1 to 4 hours). **EBN**: *Changes in vital signs can indicate the onset of bleeding or infection. Rectal and oral temperature measurements are more accurate than other methods of temperature measurement such as temporal or axillary measurement (Makic et al, 2011).*
- ▲ Observe nutritional status (e.g., weight, serum protein and albumin levels, muscle mass, and usual food intake). Work with the dietitian to improve nutritional status if needed. **EB**: *Clients diagnosed with asthma or repeated respiratory infections should have a nutritional assessment. EB: Vitamin D influences the body's immune system by influencing the production of endogenous antimicrobial peptides and regulating the inflammatory cascade (Gunville et al, 2013).*
- Observe the client's sleep pattern; if altered, see Nursing Interventions and Rationales for Disturbed Sleep pattern.

- Identify stressors in the client's life. If stress is uncontrollable, see Nursing Interventions and Rationales for Ineffective Coping. **EB:** Nearly 30% of older clients experience delirium during hospitalization; the incidence is higher in intensive care units. Among older clients who have had surgery, the risk for delirium varies from 10% to more than 50% (Francis & Young, 2012).

Prevention of Infection

- ▲ Monitor for and report any signs of infection (e.g., fever, chills, flushed skin, drainage, edema, redness, abnormal laboratory values, and pain) and notify the health care provider promptly. **EBN:** While the white blood cell count may be in the normal range, an increased number of immature bands may be present (Versalovic, 2011). **CEBN:** A neutropenic client with fever represents an absolute medical emergency (Mahtani, 2010). If the client's immune system is depressed, notify the health care provider of elevated temperature, even in the absence of other symptoms of infection. **EB:** Clients with depressed immune function are unable to mount the usual immune responses to the onset of infection; fever may be the only sign of infection. A neutropenic client with fever represents an absolute medical emergency. **CEBN:** A neutropenic client with fever represents an absolute medical emergency (Mahtani, 2010).
- If white blood cell count is severely decreased (i.e., absolute neutrophil count of less than 1000/mm³), initiate the following precautions:
 - Take vital signs every 2 to 4 hours
 - Complete a head-to-toe assessment twice daily, including inspection of oral mucosa, invasive sites, wounds, urine, and stool; monitor for onset of new reports of pain
- ▲ Avoid any invasive procedures, including catheterization, injections, or rectal or vaginal procedures unless absolutely necessary. **EBN:** Classic organisms such as influenza cause infections in the immunocompromised host; often their presentation is different and more serious (Flood, 2014).
 - Consider warming the client before elective surgery. Normothermia is associated with low postoperative infection rates (Alexander, 2011).
- ▲ Administer granulocyte growth factor as ordered. **EB:** Clients most likely to benefit from therapy would be those with profound neutropenia or neutropenia with infections not responding to antimicrobial therapy (Flood, 2014). **EB:** Granulocyte macrophage colony-stimulating factor is mostly well tolerated, although some cancer and kidney disease clients have demonstrated significant complications such as leukopenia (Tovey et al, 2011).
 - Take meticulous care of all invasive sites; use chlorhexidine gluconate for cleansing. **EB:** Use of chlorhexidine gluconate for vascular catheter site care reduces catheter-related bloodstream infections and catheter colonization (Centers for Disease Control and Prevention [CDC], 2011).
 - Provide frequent oral care. **EBN:** The effects of chemotherapy or radiation can cause changes in taste and smell resulting in pain and nutritional deficiencies (Poirier, 2013).
 - Follow Standard Precautions, especially performing hand hygiene to prevent health care-associated infections. **EBN:** Hands of health care workers are the most common cause of health care-associated infections (CDC, 2011; Haas, 2014).
- ▲ Refer for appropriate prophylactic antifungal treatment and avoid pathogen exposure (through air filtration, regular hand hygiene, and avoidance of plants and flowers). Practical measures can be taken to avoid exposing the client to fungi (Flood, 2014). **EB:** Highly active imidazoles have had a major impact on human fungal infections (Ferrara et al, 2011).
 - Have the client wear a mask when leaving the room. **EB:** To prevent health care-acquired pulmonary aspergillosis during hospital construction, neutropenic clients may be at lesser risk if masked when leaving their room (Thom, 2013). Limit and screen visitors to minimize exposure to contagion.
 - Help the client bathe daily.
 - Practice food safety; a neutropenic diet may not be necessary. **EBN:** No clear evidence exists that the neutropenic diet makes a difference in overall rates of infection (Thom, 2013).
 - Ensure that the client is well nourished. Provide food with protein, and consider vitamin supplements. If appetite is suppressed, institute a dietary referral. Keep track of serum albumin levels, as well as transferrin and prealbumin levels. **CEB:** Levels of the visceral proteins (albumin, transferrin, and prealbumin) are an indirect measure of nutritional status (Geismar, 2014).
 - Help the client cough and practice deep breathing regularly. Maintain an appropriate activity level.
 - Obtain a private room for the client. Use high-energy particulate air filters if available and appropriate. Protective isolation is not recommended. Recognize that cotton cover gowns may not be effective in decreasing infection. **EBN:** Complete an infection control risk assessment (ICRA) considering such issues

as the type of transplant performed, the environment, and prior infection rates. Use the ICRA to decide the types of infections, processes, practices, and risk to be monitored (Harris, 2014).

- ▲ Watch for signs of sepsis, including change in mental status, fever, shaking, chills, and hypotension. If present, notify the health care provider promptly. *Change in mental status, fever, shaking, chills, and hypotension are indicators of sepsis (Curchoe, 2013).*
- Refer to care plan for Risk for **Infection**.
- Refer to care plan for Readiness for enhanced **Nutrition** for additional interventions.

Pediatric

- Suggest kangaroo care, frequent and exclusive or nearly exclusive breastfeeding, and early discharge from hospital for low-birth-weight infants. **EBN:** *Kangaroo mother care, frequent and exclusive or nearly exclusive breastfeeding, and early discharge from hospital was associated with a decreased risk of mortality) and severe infection/sepsis for low-birth-weight infants (Conde-Agudelo et al, 2011).*
- Assess postoperative fever in pediatric oncology clients promptly. **EB:** *Fever is a physiological mechanism that has beneficial effects in fighting infection. There is no evidence that fever itself worsens the course of an illness or that it causes long-term neurological complications (Sullivan & Farrer, 2011).*
- For hand hygiene with low-birth-weight infants, use alcohol hand rub and gloves. **EBN:** *Audit programs to track compliance with hand hygiene identified a drop in the incidence of health care-associated infections in very low-birth-weight infants in the neonatal intensive care unit (Academy of Pediatrics, 2012).*

Geriatric

- If not contraindicated, promote exercise to promote improved quality of life in older adults. **EB:** *A study of 95 healthy adults 65 years and older suggests that the effects of resistance-type exercise training can counteract the loss of muscle mass and strength with aging (Leenders et al, 2013).* Give older clients with imbalanced nutrition a vitamin D supplement to reduce risk of fracture. **EB:** *Lack of vitamin D may exacerbate osteoporosis in older or postmenopausal women (Rizzoli et al, 2013).*
- Refer to the care plan for Risk for **Infection** for more interventions related to the prevention of infection.

Prevention of Bleeding

- ▲ Monitor the client's risk for bleeding; evaluate results of clotting studies and platelet counts. *Laboratory studies give a good indication of the seriousness of the bleeding disorder.*
- Watch for hematuria, melena, hematemesis, hemoptysis, epistaxis, bleeding from mucosa, petechiae, and ecchymoses. **EBN:** *A study of 200 clients with idiopathic thrombocytopenic purpura revealed that 57% had ecchymoses, 42% petechiae, 23% bleeding from the gums, and 31.5% epistaxis; 8% had two or more signs and symptoms and 73% were asymptomatic when the diagnosis was established (Garcia-Stivalet et al, 2014).*
- ▲ Give medications orally or intravenously only; avoid giving intramuscularly, subcutaneously, or rectally (Shuey, 1996).
- Apply pressure for a longer time than usual to invasive sites, such as venipuncture or injection sites. *Additional pressure is needed to stop bleeding of invasive sites in clients with bleeding disorders.*
- Take vital signs often; watch for changes associated with fluid volume loss. Excessive bleeding causes decreased blood pressure and increased pulse and respiratory rates.
- Monitor menstrual flow if relevant; have the client use pads instead of tampons. **EB:** *Menstruation can be excessive in clients with bleeding disorders. Adolescents presenting with heavy menstrual bleeding at or near menarche assessment should include bleeding disorders (Singh, 2013).*
- Have the client use a moistened toothette or a very soft child's toothbrush instead of an adult toothbrush. Follow the dentist's recommendation for flossing and appropriate rinses to use. Control gum bleeding by applying pressure to gums with gauze pad soaked in ice water. *These actions help prevent trauma to the oral mucosa, which could result in bleeding (Medline Plus, 2011).*
- Ask the client either to not shave or to use only an electric razor. *This helps prevent any unnecessary trauma that could result in bleeding (Shuey, 1996).*
- ▲ To decrease risk of bleeding, avoid administering salicylates or nonsteroidal antiinflammatory drugs (NSAIDs) if possible. **CEB:** *Gastrointestinal bleeding due to NSAIDs, acetylsalicylic acid, or warfarin was the most common adverse drug reaction that resulted in hospital admission and represented 40% of all ADRs (12 of 30), according to WHO causality criteria (Brvar et al, 2009).*

Home Care

- Some of the interventions previously described may be adapted for home care use.
- ▲ Consider using a nurse-led client-centered medical home (PCMH) for monitoring anticoagulant therapy. **EBN:** *Establishment of nurse-led medical homes to monitor anticoagulation therapy management clinics leads to improvements in quality of care in terms of improved control of international normalized ratio and reduced complications. Data support a conclusion that PCMHs do improve quality, access, and cost (Scudder, 2011).*
- For terminally ill clients, teach and institute all of the aforementioned noninvasive precautions that maintain quality of life. Discuss with the client, family, and health care provider the consequences of contracting infection. Determine which precautions do not maintain quality of life and should not be used (e.g., physical assessment twice daily or multiple vital sign assessments). **CEB:** *Multiple assessments and other invasive procedures are recovery-based and cure-focused activities. The client and provider must agree on an approach to care for the clients during their remaining life (Periyakoil et al, 2013).*

Client/Family Teaching and Discharge Planning

Depressed Immune Function

- Teach the client and family how to take a temperature. Encourage the family to take the client's temperature between 3 PM and 7 PM at least once daily. **EBN:** *For most people, the difference between high and low values throughout the day is approximately 2° F (1.1° C) (97° to 99° F [36.1° to 37.2° C]), with the lowest value typically occurring in the early morning hours (2 am to 5 am) and the highest values commonly occurring in the evening (Fetzer, 2013).*
- Teach precautions to use to decrease the chance of infection (e.g., avoiding uncooked fruits and vegetables, using appropriate self-care including good hand hygiene, and ensuring a safe environment). Teach the client to avoid crowds and contact with persons who have infections. Teach the need for good nutrition, avoidance of stress, and adequate rest to maintain immune system function. **CEBN:** *Approaches to avoiding infection at home for the client with neutropenia include good hand hygiene and careful management of food, drink, and the client's environment (Hawkins, 2009).*

Bleeding Disorder

- Teach the client to wear a medical alert bracelet and notify all health care personnel of the bleeding disorder. **CEB:** *Emergency identification schemes such as medical alert bracelets use emblems that alert health care professionals to potential problems and can ensure appropriate and prompt treatment (National Comprehensive Cancer Network, 2006).* Teach the client and family the signs of bleeding, precautions to take to prevent bleeding, and action to take if bleeding begins. Caution the client to avoid taking over-the-counter medications without the permission of the health care provider. *Medications containing salicylates can increase bleeding.*
- Teach the client to wear loose-fitting clothes and avoid physical activity that might cause trauma.

Rape-Trauma syndrome

Julianne E. Doubet, BSN, RN, CEN, NREMT-P

NANDA-I

Definition

Sustained adaptive response to a forced, violent sexual penetration against the victim's will and consent

Defining Characteristics

Aggression; agitation; anger; anxiety; change in relationships; confusion; denial; dependence; depression; disorganization; dissociative disorders; embarrassment; fear; guilt; helplessness; humiliation; hyperalertness; impaired decision-making; loss of self-esteem; mood swings; muscle spasms; muscle tension; nightmares; paranoia; phobias; physical trauma; powerlessness; revenge; self-blame; sexual dysfunction; shame; shock; sleep disturbances; substance abuse; suicide attempts; vulnerability

Related Factors (r/t)

Rape

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

List of Nursing Diagnoses by Letter: R

Rape-Trauma syndrome	Ineffective Relationship	Readiness for enhanced Relationship
Risk for ineffective Relationship	Impaired Religiosity	Readiness for enhanced Religiosity
Risk for impaired Religiosity	Relocation stress syndrome	Risk for Relocation stress syndrome
Risk for ineffective Renal perfusion	Impaired Resilience	Readiness for enhanced Resilience
Risk for impaired Resilience	Parental Role conflict	Ineffective Role performance

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Cessation; Abuse Protection; Abuse Recovery: Emotional, Sexual, Coping; Impulse Self-Control; Self-Mutilation Restraint

Example NOC Outcome with Indicators

Abuse Recovery: Sexual as evidenced by the following indicators: Acknowledgment of right to disclose abusive situation/ Expression of right to have been protected from abuse. (Rate the outcome and indicators of **Abuse Recovery: Sexual**: 1 = none, 2 = limited, 3 = moderate, 4 = substantial, 5 = extensive [see Section 1].)

Client Outcomes

Client Will (Specify Time Frame)

- Share feelings, concerns, and fears
- Recognize that the rape or attempt was not client's own fault
- State that, no matter what the situation, no one has the right to assault another
- Describe medical/legal treatment procedures and reasons for treatment
- Report absence of physical complications or pain
- Identify support resources and attend psychotherapy/group assistance in coping with the trauma and effects of the traumatic experience
- Function at same level as before crisis, including sexual functioning
- Recognize that it is normal for full recovery to take a minimum of 1 year

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Counseling; Rape-Trauma Treatment

Example NIC Activities—Rape-Trauma Treatment

Explain rape protocol and obtain consent to proceed through protocol; Implement crisis intervention counseling

R

Nursing Interventions and Rationales

- Escort the client to a treatment room immediately upon arrival to the emergency department. Stay with (or have a trusted person stay with) the client. **EBN**: *Victims of sexual assault require special attention from caregivers, so as not to feel victimized a second time in the medical facility; the presence of the nurse at every step of the care process supports the victim (Durieux, 2014).* **EB**: *Cybulski (2013) states that the immediate needs of sexual assault victims begin with privacy and safety.*
- Assure the client of confidentiality. **EB**: *It is suggested that not all criminal justice and medical professionals understand the statutory provision of privilege to communications between rape victim advocates and victims (Cole, 2011).* **EB**: *Burns et al (2014) noted in their research that U.S. servicewomen did not report sexual assaults due to humiliation and anxiety concerning confidentiality.*
- ▲ Provide a sexual assault response team (SART), if available, that includes a sexual assault nurse examiner (SANE), rape counseling advocate, and representative of law enforcement for best possible outcomes. **EB**: *According to a study by Patterson (2014), a team of forensic nurses and victim advocates partner together to provide treatment not only for the necessary physical and medical requirements of sexual assault survivors, but also for dealing with the complex legal and mental health needs that necessitate follow-up.* **EBN**: *A study of the available literature demonstrates that SANE/SART programs provide emotional and mental support that allows a victim of sexual assault to take control over her/his options and choices, and assists the client in navigating the criminal justice system and accessing health services (Henry & Force, 2011).*
- Observe for signs of physical injury. **EBN**: *Assessment and documentation of injuries and physical findings are all-important, both in furnishing a baseline for determining intervention priorities and for any possible legal action (Carter-Snell, 2011).* **EB**: *Some locations to assess for obvious genital injuries would include*

tears or abrasions of the posterior fourchette labia, abrasion or bruising of the labia minora and fossa navicularis, and ecchymosis or tears of the hymen; document these injuries as evidence for any future legal proceedings (Linden, 2011).

- Document the client's chief complaint and request an event history of the sexual assault in her/his own words. **EB:** Taking time to listen to the victim's story is essential in directing the forensic examination and subsequent samples that are collected (Rey-Salmon, 2012). **EB:** It is agreed that awareness of the client's sexual victimization history is invaluable in personalizing cases and determining treatment interventions (Probst et al, 2011).
- Encourage the client to verbalize her/his feelings. **EB:** There is widely accepted documentation that early intervention in cases of trauma significantly lessens the risk of anxiety, depression, self-harm, addiction issues, eating disorders, and suicide (Marshall, 2012).
- Make sure that the victim understands everything you are doing. **EBN:** The preservation of client dignity must be maintained, not only for the victim's protection, but also to show respect and caring; respecting dignity is one of the essential behaviors that nurtures caring (Gustafsson et al, 2013). **EBN:** Clarify the medical aspects of the forensic examination for the victim and obtain consent, but ensure that the client is aware that, although she/he has given consent for the exam, she/he can stop it at any point (Learner, 2012).
- Explain to the client that all or some of the client's clothing may be kept for evidential purposes and photographs may be taken (with consent) to document the client's injuries. **EBN:** For victims of sexual assault, the forensic examination is the inaugural step in the advancement of justice. Assessment and treatment of victims, as well as the precise collection and documentation of evidence, are critical for a solid case (Fitzpatrick et al, 2012).
- ▲ If a law enforcement interview is permitted, provide support by staying with the client at her/his request. **EB:** A study authorized by the Bureau of Justice (Kruttschnitt et al, 2014) surmises that we must take into consideration the frequency and environment under which rape and sexual assault are committed, because this is vital information in targeting resources for law enforcement and support for victims. **EBN:** By keeping the victim of sexual assault calm and comfortable, the nurse's actions at the bedside may benefit the legal investigation and leave the victim less traumatized and better able to give a complete report of the assault (Campbell et al, 2011).
- Use the sexual assault evidence collection kits that have been reviewed by the SART members and provided by your state to collect adequate and accurate evidence for analysis by a forensic laboratory. **EB:** The health care provider who examines victims of sexual assault must be responsible to act in accordance with state and local statutory or policy requirements for the use of evidence-gathering kits (ACOG, 2014). **EB:** Standardized evidence-collection kits usually contain forms for documentation to assist examiners. Evidence collection requires the victim's permission during each of the necessary steps, and the client should be given the opportunity to set the tempo of the exam and to be aware that she/he may decline any part of the examination (Linden, 2011).
- ▲ Discuss the possibility of pregnancy and sexually transmitted infections (STIs) and the treatments available. **EB:** Victims of sexual assault should be advised that they are at risk for pregnancy, sexually transmitted infections, and post-traumatic stress disorder; as a victim of sexual assault, she/he should be monitored and offered emergency contraception and STI prophylaxis (Committee on Health Care for Underserved Women, 2014). **EB:** Treatment of injuries and prevention of unwanted pregnancy and sexually transmitted infections, including HIVs, should be offered to any victim of sexual assault (Cybulski, 2013).
- ▲ Encourage the client to report the sexual assault to law enforcement agency. **EB:** Rape survivors' decisions to assist in legal actions are influenced by three social groups: family/friends, service providers, and police (Anders & Christopher, 2011). **EBN:** In her study, Marchetti (2012) concludes that sexual assault (SA) and the underreporting of SA are highly prevalent in the United States and that regret may play a considerable part in the unwillingness to report the rape.
- ▲ For those interested in a spiritual connection, make the appropriate recommendation. **EBN:** According to Hellman (2014), research should be introduced to develop theory using religious and spiritual beliefs to aid in the recovery process of sexual assault victims.
- ▲ Stress the necessity of follow-up care with a mental health professional to recognize and intervene with problems associated with the effects of rape-trauma/sexual assault. **EB:** In the aftermath of rape, victims often experience evidence of depression, anxiety, post-traumatic stress disorder (PTSD), self-harm, and increased risk of suicide (Marshall, 2012). **EB:** Price et al (2014) state that although sexual assault increases the risk for psychiatric disorders and while there is treatment available, few victims choose mental health care after their attack.

- Stress the importance of awareness throughout the community of the scope and severity of the effects of sexual abuse as a means of additional healing empowerment. **EB:** *Ullman and Peter-Hagene (2014) suggest in their study of community reactions to a victim's divulgence of sexual assault that negative community reactions were associated with greater PTSD symptoms due to the victim's inability to cope and a sense of loss of control. EB: Recovery from sexual assault/rape is frequently hindered by the public's failure to believe the victim and the need to obtain justice (Chapleau & Oswald, 2014).*

Geriatric

- Build a trusting relationship with the client. **EBN:** *Trust begins by acting with integrity and caring, which then conveys investment in another's welfare (Laskowski-Jones, 2011).*
- All examinations should be done in older adults as they would be done on any adult client after sexual assault, with modifications for comfort if necessary. **EB:** *In a study by Nobrega et al (2014) of the forensic assessment of older victims of sexual assault, the forensic evaluation was found to be essential in positive judicial outcomes and invaluable in identifying physical and biological confirmation of sexual assault. EBN: Elder abuse can be difficult to identify (Kleba & Falk, 2014), in that accidental injuries are more common in older adults and mental disorders, such as dementia, can impede the victim's capacity to recall the occurrences of abuse.*
- Assess for mobility limitations and cognitive impairment. **EB:** *As the aging population swells, a rise in morbidity can be validated, and with it, not only an increase in chronic illnesses, but also the recognition of significant cognitive changes and physical disabilities (Kizie et al, 2014).*
- Explain and encourage the client to report sexual abuse. **EB:** *In this study, it was found that the case worker and the older victims might hold contradictory views regarding the perpetrators' motivations for abuse and what would be the likely outcomes of reporting it; this was most likely to occur when the perpetrator was a family member. Adjusting these differences can raise the likelihood of effective interventions (Jackson & Hafemeister, 2011). EBN: According to Marchetti (2012), new approaches are called for in the development of a basis for medical professionals to assist victims of sexual assault in making decisions concerning their health care.*
- Observe for psychosocial distress. **EBN:** *Changes in behavior, such as becoming more withdrawn, depressed, confused, fearful, or agitated, may be the consequences of sexual abuse in older adults (Nazarko, 2011). EB: According to Barton et al (2014), older adults with anxiety disorders have difficulty dealing with their everyday lives and are therefore at risk for comorbidities such as depression, falls, physical and functional disability, and loneliness.*
- ▲ Consider arrangements for safe housing. **EB:** *Practical implications—collaboration and an integrated community response are vital to enhancing the safety and quality of life of the older victim of abuse (Brandl & Dawson, 2011). EB: In Dakin's (2014) study involving a diverse group of older women who were given scenarios, in which the scenario subjects, due to circumstances, had the option of choosing autonomy or protection; when asked which alternative the subject should pick, the majority of women chose protection, suggesting that autonomy may be limited and would only delay needed security and health care at a later time.*

Male Rape

- ▲ **EB:** *Male rape is markedly under-reported and, consequently, the victim rarely receives essential sexual assault aftercare (McClean, 2013). EB: Hiquet and Gromb-Monnoyeur (2013) maintain that the cause of the underreporting of male sexual assault is due to the stigma attached to the victim's disclosure of rape.*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's ability to cope with the trauma of the rape experience. **EBN:** *It is suggested that divergences among minority women in the frequency of rape, reports of rape, and use of available resources will vary based on ethnicity, race, cultural standards, help-seeking behaviors, and availability of accessible services (Lawson, 2011). EB: A paper by Huong (2012) highlights the fact that rape disclosure in a collective society is often contiguous with the concepts of family honor, kinship, gender, society, and responsibility.*
- Assess to determine if physically abused women are also victims of sexual assault. **EB:** *Care for those victims of sexual assault and domestic violence should include crisis services: legal advocacy, medical advocacy, counseling, support group, and shelter (Macy et al, 2011).*

Home Care

- Some of the interventions described previously may be adapted for home care use.
- Corroborate the client's feelings of self-worth. This study proposes that the feeling of self-worth moderates the effects of violence—especially violent loss—on PTSD and depression (Mancini et al, 2011). **EB:** *It is theorized by Ban Hong et al (2012) that there is a connection between the signs of insecure attachment, which appear in victims of interpersonal trauma and is linked to post-traumatic stress and a diminished feeling of self-worth.*
- Assist the client with realistically assessing the home setting for safety and/or selecting a safe environment in which to live. **EBN:** *The protection or safeguarding of vulnerable adults must be an integral part of everyday nursing practice (Straughair, 2011).*
- ▲ Ensure that the client has systems in place for long-term support. **EB:** *Survivors of abuse noted that a cooperative model of health care, particularly between mental health and physical health professionals, was an asset to their recovery (Dunleavy & Slowik, 2012).* **EB:** *According to Brandl and Dawson (2011), it is imperative that community and private resources join together to promote safety and the quality of life for the older adult victims of trauma.*
- ▲ Design a practical discharge plan to include a safe shelter if needed, follow-up care for physical injury, and follow-up referral for psychological support. **EB:** *Safety, medical, and psychological plans for discharge are critical to the victim of sexual assault (Linden, 2011).* **EBN:** *It is vital to abused older adults to be sheltered in a safe, protected, violence free, and medically suitable environment (Heck & Gillespie, 2013).*
- ▲ Assess for other client vulnerabilities such as mental health issues or addiction and refer the client to social agencies for implementation of a therapeutic regimen. **EB:** *Client support should be in response to the whole person; the assault should be addressed in both its social and cultural elements, with sensitivity to the client's distinct needs and by sharing information with other social services, if so allowed by the client (Marshall, 2012).*

Client/Family Teaching and Discharge Planning

- Emphasize the client's needs for safety and to decrease the opportunities for repeat attacks. **EBN:** *The client should be made aware that the results of continued abuse may include more abuse, chronic pain, physical and emotional illness, and even death (Symes, 2011).*
- Recognize the vulnerability of the client. **EB:** *Conceptualizations of present control over the recovery process were related to lower levels of psychological distress (Walsh & Bruce, 2011).* **EBN:** *In a qualitative study by Arend et al (2013) involving survivors of sexual assault in South Africa, it was found that nurses have numerous opportunities to improve the quality of post-sexual assault care, which in turn advances the clients' emotional and psychosocial outcomes.*
- **NOTE:** PTSD has a high probability of being a psychological sequela to rape. Research demonstrated two effective treatments for improvement of PTSD in rape victims: prolonged exposure and stress inoculation training. Prolonged exposure involves reliving the rape experience; by imagining it as vividly as possible, describing it aloud in the present tense, taping this description, and listening to the tape at least once daily. Stress inoculation training uses breathing exercises to diminish anxiety and instruction in coping skills, thought stopping, cognitive restructuring, self-dialogue, and role playing. Research suggests that a combination of both treatments may provide the optimal effect. Furthermore, for those who reported the assault to police, lower levels of legal system success and satisfaction were linked to higher levels of perceived control over present recovery.

Ineffective Relationship *Gail B. Ladwig, MSN, RN*

NANDA-I

Definition

A pattern of mutual partnership that is insufficient to provide for each other's needs

Defining Characteristics

Delay in meeting of developmental goals appropriate for family life-cycle stage; dissatisfaction with complementary relationship between partners; dissatisfaction with emotional need fulfillment between partners; dissatisfaction with idea sharing between partners; dissatisfaction with information sharing between partners; dissatisfaction with physical need fulfillment between partners; inadequate understanding of partner's compromised functioning (e.g., physical, psychological social); insufficient balance in autonomy between partners; insufficient balance in collaboration between partners; insufficient mutual respect between partners; insufficient mutual support in daily activities between partners; partner not identified as support person; unsatisfying communication with partner

Related Factors

Alteration in cognitive functioning in one partner; developmental crisis; history of domestic violence; incarceration of one partner; ineffective communication skills; stressors; substance abuse; unrealistic expectations

NOC, NIC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan Readiness for enhanced **Relationship**.

Readiness for enhanced Relationship

Gail B. Ladwig, MSN, RN, and Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A pattern of mutual partnership to provide for each other's needs, which can be strengthened

Defining Characteristics

Expresses desire to enhance autonomy between partners; expresses desire to enhance collaboration between partners; expresses desire to enhance communication between partners; expresses desire to enhance emotional need fulfillment for each partner; expresses desire to enhance mutual respect between partners; expresses desire to enhance satisfaction with complementary relationship between partners; expresses desire to enhance satisfaction with emotional need fulfillment for each partner; expresses desire to enhance satisfaction with idea sharing between partners; expresses desire to enhance satisfaction with information sharing between partners; expresses desire to enhance satisfaction with physical need fulfillment for each partner; expresses desire to enhance understanding of partner's functional deficit (e.g., physical, psychological social)

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Family Functioning/Integrity; Role Performance; Social Support

Example NOC Outcome with Indicators

Family Integrity as evidenced by the following indicators: Members share thoughts, feelings, interests, concerns/Members communicate openly and honestly with one another/Members encourage individual autonomy and independence/Members assist one another in performing roles and daily tasks. (Rate the outcome and indicators of **Family Integrity**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Client Will (Specify Time Frame)

- Share thoughts and feelings with each other
- Communicate openly with each other
- Assist in performing family roles and tasks
- Provide support for each other
- Obtain appropriate assistance

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Family Integrity Promotion; Role Enhancement

Example NIC Activities—Family Integrity Promotion

Facilitate a tone of togetherness within/among the family; Encourage family to maintain positive relationships; Facilitate open communication among family members

Nursing Interventions and Rationales

- ▲ Assess for signs of depression in the family when one partner is depressed, and make appropriate referrals. **EB:** *Depressive symptoms affect functioning of the whole family (Hinton et al, 2009).*
- ▲ Assist couples to identify sources of their own perceived dyadic empathy in the relationship. **EB:** *Higher perceived empathy toward the relationship partner is associated with relationship satisfaction (Kimmes et al, 2014).*
- Assist families to identify sources of gratitude in their lives. **EB:** *Research showed that gratitude fostered all facets of post-traumatic growth, such as relationships, personal strengths, and awareness of meaningful possibilities (Ruini & Vescovelli, 2013).*
- Assist clients to identify sources of gratitude in their lives using a future oriented focus. **EB:** *Research shows that clients with a regulatory focus of promotion were more likely to express gratitude, which inspired them to strengthen their relationships with helpful and responsive partners (Mathews & Shook, 2013).*
- Support “relationship talk” between couples (talking with a partner about the relationship, what one needs from one’s partner, and/or the relationship implications of a shared stressor). Such discussions in couples with lung cancer have been shown to help partners better define their relationships and repair relationships that are functioning poorly (Badr et al, 2008). **EB:** *These discussions may help alleviate the negative impact that sexual problems have on prostate cancer clients’ and their partners’ marital adjustment (Badr & Taylor, 2009).*
- Encourage couples to participate and share in exciting and satisfying leisure activities and to share stories. **EB:** *This study demonstrated that couples feel connected with their partners and more satisfied with their relationships when they engage in these types of activities (Graham, 2008). When stories are used as a way to understand the lives of couples, they have the potential for enhancing individual and relational growth (Skerrett, 2010).*
- Assist couples in establishing boundaries between work and home. *This study demonstrates that for both men and women, job demands foster their own work-family conflict (WFC), which in turn contributes to their partner’s home demands, family-work conflict (FWC), and exhaustion. In addition, social undermining mediates the relationship between an individual’s WFC and his/her partner’s home demands (Bakker et al, 2008).*
- Assist couples in regulating negative emotions. **EB:** *The results of this study of newlyweds support theories suggesting that the ability to regulate negative emotions may help intimates avoid perpetrating intimate partner violence (IPV), particularly when faced with a partner’s IPV perpetration (McNulty & Hellmuth, 2008).*
- Assist couples in dealing with anger and communication when the diagnosis is cancer. **EB:** *The anger-expression styles of both clients and their partners seem to modify the family atmosphere, and together, they are important determinants of the long-term quality of life of the cancer clients. Interventions for couples facing cancer should include a focus on ways of dealing with anger and thereby support dyadic coping with*

cancer (Julkunen et al, 2009). Couples who are survivors of prostate cancer are faced with interruptions in their intimate relationships, communication, and overall quality of life. They need recommendations for appropriate resources (Galbraith et al, 2011).

- Refer to care plans Readiness for enhanced **Family** processes and Readiness for enhanced family **Coping**.

Pediatric

- Provide guidance and information on communication techniques for teenagers, especially those involved in intimate relationships. **EBN:** *The findings of this study suggest that many female adolescents desired the love of a male partner and were willing to concede to his request of practicing unprotected sex. Findings support the urgent need for interventions that will promote skill-building techniques to negotiate safer sex behaviors among youth who are most likely to be exposed to STIs through risky behaviors (Bralock & Koniak-Griffin, 2009).*
- Encourage supportive relationships among parents and teenagers. **EB:** *This study suggests that parenting may be associated with multiple benefits to teenagers' sexual relationships including delayed intercourse and greater condom use (Parkes et al, 2011).*

Geriatric

- ▲ Assess for spousal depression when one partner has cardiovascular disease, and make appropriate referrals. **EB:** *Exposure to spousal suffering is an independent and unique source of distress in married couples that contributes to psychiatric and physical morbidity (Schulz et al, 2009).*
- ▲ Assess for depression and anxiety, and make appropriate referrals for “prewidows” caring for spouses with chronic life-limiting conditions. **EB:** *In this study, health deficits associated with spousal bereavement may be evident earlier in the marital transition than previously thought, warranting attention to the health of older adults whose spouses have chronic/life-limiting conditions (Williams et al, 2008).*
- Support older couples' positive collaborative communication. **EB:** *In this study of older couples, the couples displayed a unique blend of warmth and control during collaborative communication, suggesting that a greater focus on emotional and social concerns during problem solving is important (Smith et al, 2009).*
- Encourage collaborative coping (i.e., spouses pooling resources and problem solving jointly) among older adults. **EB:** *This study of older adults whose husbands had prostate cancer suggested that collaborative coping may be associated with better daily mood and greater marital satisfaction because of heightened perceptions of efficacy in coping with stressful events and problems surrounding illness (Berg et al, 2008).*

Multicultural

- Provide culturally tailored community-level interventions to raise awareness about HIV and bisexuality, and decrease HIV and sexual orientation stigma. **EB:** *Culturally tailored interventions may increase comfort of African American and Latino MSMWs (men who have sex with men and women) in communicating with their female partners about sexuality, HIV, and condoms (Mutchler et al, 2008). Sociocultural factors and HIV-related misinformation contribute to the increasing number of Chilean women living with HIV. Future HIV prevention should stress partner communication, empowerment, and improving the education of women vulnerable to HIV (Cianelli et al, 2008).*

Home Care

- Provide home-based psychoeducation to assist new parent couples with parenting and their couple relationship. **EB:** *The best outcomes for psychoeducational interventions for effective parenting of infants and sustaining a mutually satisfying couple relationship seem to be achieved when programs are accessible by couples at home, when skill training is provided, and possibly when programs target couples at high risk for maladjustment to parenthood (Petch & Halford, 2008).*

Client/Family Teaching and Discharge Planning

- Encourage clients and spouses to participate together in interventions to lower low-density lipoprotein cholesterol (LDL-C). Teach spouses how to provide emotional and instrumental support, allow clients to decide which component of the intervention they would like to receive, and have clients determine their own goals and action plans. Provide telephone calls to clients and spouses separately. During each client telephone call, client progress is reviewed, and clients create goals and action plans for the upcoming month. During spouse telephone calls, which occur within 1 week of client calls, spouses are informed of clients' goals and action plans and devise strategies to increase emotional and instrumental support.

EB: *The behaviors required to lower LDL-C levels may be difficult to adhere to if they are inconsistent with spouses' health practices, and, alternatively, may be enhanced by enlisting support from the spouse. Interventions that teach spouses to provide instrumental and emotional support may help clients initiate and adhere to behaviors that lower their LDL-C levels. Moreover, allowing clients to retain autonomy by deciding which behaviors they would like to change, and how, may improve adherence and clinical outcomes (Voils et al, 2009). Interventions to reduce cardiovascular risk factors should be addressed jointly to both members of a marital couple (Di Castelnuovo et al, 2009).*

Risk for ineffective Relationship *Gail B. Ladwig, MSN, RN*

NANDA-I

Definition

Vulnerable to developing a pattern that is insufficient for providing a mutual partnership to provide for each other's needs

Risk Factors

Alteration in cognitive functioning in one partner; developmental crisis; history of domestic violence; incarceration of one partner ineffective communication skills; stressors; substance abuse; unrealistic expectations

NOC, NIC, Client Outcomes, Nursing Interventions, Rationales, and References

Refer to care plan for Ineffective **Relationship**.

Impaired Religiosity *Lisa Burkhart, PhD, RN, ANEF, and Barbara Baele Vincensi, PhD, RN, FNP***NANDA-I****Definition**

Impaired ability to exercise reliance on beliefs and/or participate in rituals of a particular faith tradition

Defining Characteristics

Desire to reconnect with previous belief pattern; desire to reconnect with previous customs; difficulty adhering to prescribed religious beliefs; difficulty adhering to prescribed religious rituals (e.g., ceremonies, regulations, clothing, prayer, services, holiday observances); distress about separation from faith community; questioning of religious belief patterns; questioning of religious customs

Related Factors (r/t)**Developmental and Situational**

Aging; end-stage life crises; life transitions

Physical

Illness; pain

Psychological

Anxiety; fear of death; history of religious manipulation; ineffective coping strategies; insufficient social support; personal crisis

Sociocultural

Cultural barriers to practicing religion; environmental barriers to practicing religion; insufficient social integration; insufficient sociocultural interaction

Spiritual

Spiritual crises; suffering

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Client Satisfaction: Cultural Needs Fulfillment

Example NOC Outcome with Indicators

Client Satisfaction: Cultural Needs Fulfillment as evidenced by the following indicators: Respect for religious beliefs/Respect for cultural health behaviors/Incorporation of cultural beliefs in health teaching/Respect for personal values. (Rate each indicator of **Client Satisfaction: Cultural Needs Fulfillment**: 1 = not at all satisfied, 2 = somewhat satisfied, 3 = moderately satisfied, 4 = very satisfied, 5 = completely satisfied [see [Section 1](#)].)

Client Outcomes**Client Will (Specify Time Frame)**

- Express satisfaction with the ability to express religious practices
- Express satisfaction with access to religious materials and rituals
- Demonstrate balance between religious practices and healthy lifestyles
- Avoid high-risk, controlling religious relationships that inflict physical, sexual, or emotional harm and/or exploitation

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Religious Ritual Enhancement; Culture Brokerage; Religious Addiction Prevention

Example NIC Activities—Religious Ritual Enhancement

Encourage the use of and participation in usual religious rituals that are not detrimental to health

Nursing Interventions and Rationales

- Recognize when clients integrate religious practices in their life. **EBN:** *Eighty percent of clients with emphysema who participated in the randomized 2-year longitudinal study of the National Emphysema Treatment Trial increased their use of religiosity and spirituality as coping strategies to improve their quality of life (Green et al, 2011).* **EB:** *In clients with traumatic brain injury, religious well-being (personal connection to a higher power) predicted life satisfaction, whereas public religious practice did not (Waldron-Perrine et al, 2011).*
- Encourage and/or coordinate the use of and participation in usual religious rituals or practices that support coping. **EB:** *In a cross-sectional correlational descriptive study of 292 people living with HIV/AIDS, a relationship was found between decreased use of religious coping strategies and higher rates of depressive symptoms, which affected HIV medication adherence, immune function, and health-related quality of life (HRQOL) (Dalmida et al, 2013).*
- Encourage the use of prayer or meditation as appropriate. **CEB:** *A controlled study of 84 college students revealed that those who participated in a religious spiritual meditation exercise experienced significantly less anxiety and more positive mood, spiritual health, and spiritual experiences and higher pain tolerance (Wachholtz & Pargament, 2005).*
- Promote family coping using religious practices to help cope with loss, as appropriate. **EB:** *A descriptive correlational study found one's religious beliefs and values moderated perinatal grief and despair in women who had experienced traumatic late pregnancy loss due to fetal death or serious fetal anomalies (Cowchock et al, 2011).*
- ▲ Refer to religious leader, professional counseling, or support group as needed. **EBN:** *In a grounded theory study, it was found that chaplains promoted spirituality, which was validated in a psychometric study (Burkhart et al, 2011).*

Geriatric

- Promote established religious practices in older adults. **EBN:** *Increasing physical limitations and worsening chronic disease (emphysema) promoted a higher level of use of religious coping practices in older adults in a randomized longitudinal study (Green et al, 2011).*

Multicultural

- Promote religious practices that are culturally appropriate:
 - **African American.** **EBN/EB:** *Higher levels of praying for one's health and use of spiritual and religious practices were found among African Americans in a cross-sectional study of 9105 cancer survivors by Canada et al (2013).* **EBN:** *In a descriptive-correlational study, 17 African American women with breast cancer were found to use more positive religious coping to decrease distress and improve spiritual well-being (Gaston-Johansson et al, 2013).*
 - **Korean.** **EB:** *In a cross-sectional study by Lee and Woo (2013), 147 Korean-born immigrants identified religious and cultural practices as increasing general well-being and coping with health concerns.*
 - **African.** **EBN:** *In a qualitative study on help-seeking behaviors in childbearing women in Ghana, the majority used their religious or spiritual healers or leaders for spiritual protection during pregnancy, a time considered a vulnerable period in a woman's life (Farnes et al, 2011).*
 - **Jordanian.** **EBN:** *In a qualitative study by Nabolsi and Carson (2011), 19 Jordanian Muslim men with coronary artery disease found direction from their religious beliefs and values to pursue health seeking behaviors.*

Readiness for enhanced Religiosity

Lisa Burkhart, PhD, RN, ANEF, and Barbara Baele Vincensi, PhD, RN, FNP

NANDA-I

Definition

A pattern of reliance on religious beliefs and/or participation in rituals of a particular faith tradition, which can be strengthened

Defining Characteristics

R

Expresses desire to enhance belief patterns used in past; expresses desire to enhance connection with a religious leader; expresses desire to enhance forgiveness; expresses desire to enhance participation in religious experiences; expresses desire to enhance participation in religious practices (e.g., ceremonies, regulations, clothing, prayer, services, holiday observances); expresses desire to enhance religious customs used in the past; expresses desire to enhance religious options; expresses desire to enhance use of religious material

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family and Discharge Planning, Rationales, and References

See care plan for Impaired **Religiosity**.

**Pediatric**

- Provide spiritual care for children based on developmental level. **CEB:** *When nurses are comfortable providing spiritual care, they can implement numerous spiritual care activities and interventions to meet the spiritual needs of the child and family. After determining the child's spiritual beliefs and spiritual needs, a plan of care is developed based on the child's developmental age (Burkhart, 2011; Elkins & Cavendish, 2004; Fowler, 1981, 1987).*
 - **Infants:** Have the same nurse care for the child on a daily basis. Encourage holding, cuddling, rocking, playing with, and singing to the infant. **CEB:** *Continuity of care will promote the establishment of trust because nurses provide much of the needed ongoing support. The infant who is ill or dying still needs to be sung to, talked to, played with, held, cuddled, and rocked (Elkins & Cavendish, 2004).*
 - **Toddlers:** Provide consistency in care and familiar toys, music, stories, clothing blankets, pillows, and any other individual object of contentment. Schedule home religious routines into the plan of care, and support home routines regarding good and bad behavior. **CEB:** *The importance of consistency in care and routine with this age group cannot be overemphasized. The nurse should support parents' home routines during hospitalization as much as possible and encourage them to continue to have the same*

expectations regarding good and bad behavior. If particular religious routines are carried out at certain times of the day, the nurse should schedule them in the care plan (Elkins & Cavendish, 2004). **EB:** In a qualitative exploratory study, McCarthy (2013) explored interrelated themes regarding age and culturally appropriate nonverbal, visuals, sound, touch, and storytelling as different ways the arts can be used to help toddlers cope with illness and the world around them within a spiritual caregiving framework.

- **School-age children and adolescents:** Encourage both groups to express their feelings regarding spirituality. Ask them, “Do you wish to pray, and what do you want to pray about?” Offer age-appropriate complementary therapies such as music, art, videos, and connectedness with peers through cards, letters, and visits. **EBN:** Three hundred and ten African American (AA) female teens who frequently participated in spiritual health activities, such as attending church services and praying, had significantly higher self-rated health scores and were more likely to participate in healthy lifestyle choices (Powell-Young, 2012). **EB:** In a systematic literature review, religiosity and spirituality were identified as protective factors, providing children and adolescents with a sense of meaning, self-esteem, coherence, and purpose in life, while promoting positive coping strategies and reducing stress (Bryant-Davis et al, 2012).

Risk for impaired Religiosity *Gail B. Ladwig, MSN, RN*

NANDA-I

Definition

Vulnerable to an impaired ability to exercise reliance on religious beliefs and/or participate in rituals of a particular faith tradition, which may compromise health

Risk Factors

Developmental

Life transitions

Environmental

Barriers to practicing religion; lack of transportation

Physical

Hospitalization; illness; pain

Psychological

Depression; ineffective caregiving; ineffective coping strategies; insecurity; insufficient social support

Sociocultural

Cultural barrier to practicing religion; insufficient social interaction

Spiritual

Suffering

NOC, NIC, Client Outcomes, Nursing Interventions, Rationales, and References

Refer to care plan for Impaired **Religiosity**.

● = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Relocation stress syndrome

Rebecca Johnson, PhD, RN, FAAN, FNAP, and Jessica Bibbo, MA

NANDA-I**Definition**

Physiological and/or psychosocial disturbance following transfer from one environment to another

Defining Characteristics

Alienation; aloneness; alteration in sleep pattern; anger; anxiety; concern about relocation; dependency; depression; fear; frustration; increase in illness; increase in physical symptoms; increase in verbalization of needs; insecurity; loneliness; loss of identity; loss of self-worth; low self-esteem; pessimism; unwillingness to move; withdrawal; worried

Related Factors (r/t)

Compromised health status; history of loss; impaired psychosocial functioning; ineffective coping strategies; insufficient predeparture counseling; insufficient support system; language barrier; move from one environment to another; powerlessness; social isolation; unpredictability of experience

NOC**(Nursing Outcomes Classification)****Suggested NOC Outcomes**

Relocation Adaptation; Anxiety Self-Control; Child Adaptation to Hospitalization; Coping; Depression Level; Depression Self-Control; Loneliness Severity; Psychosocial Adjustment: Life Change, Quality of Life; Stress Level

Example NOC Outcome with Indicators

Relocation Adaptation as evidenced by the following indicators: Recognizes reason for change in living environment/ Participates in decision-making in new environment/Expresses satisfaction with daily routine/Expresses satisfaction with level of independence/Compares care needs with available resources/Expresses satisfaction with social relationships/Expresses satisfaction with variety of food/Expresses satisfaction with food preparation/Expresses satisfaction with retained personal belongings/Expresses satisfaction with living arrangements/Exhibits positive mood/Appears content/Respects others' rights/Maintains positive relationships with family/Maintains positive relationships with friends/Maintains positive relationships with others in new environment/ Participates in social activities/Seeks information to reduce anxiety/Plans coping strategies for stressful situations/Uses effective coping strategies/Uses relaxation techniques to reduce anxiety/Maintains social relationships/Maintains adequate sleep/Controls anxiety response. (Rate the outcome and indicators of **Relocation Adaptation**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)].)

Client Outcomes**Client Will (Specify Time Frame)**

- Recognize and know the name of at least one staff member or new neighbor within 1 week of relocating
- Express concern about move when encouraged to do so during individual contacts within 24 hours of awareness of impending relocation
- Carry out activities of daily living (ADLs) in usual manner
- Maintain previous mental and physical health status (e.g., nutrition, elimination, sleep, social interaction, physical activity) within 2 months of relocating

NIC**(Nursing Interventions Classification)****Suggested NIC Interventions**

Anxiety Reduction; Coping Enhancement; Discharge Planning; Hope Instillation; Self-Responsibility Facilitation; Animal-Assisted Therapy; Art Therapy; Music Therapy; Massage; Mood Management; Active Listening

Example NIC Activities—Anxiety Reduction

Stay with client to promote safety and reduce fear; Provide objects that symbolize safeness to the client

Nursing Interventions and Rationales

- Be aware that relocation to supportive housing may be a positive change. **CEB**: *Relocation stress syndrome is not a universally occurring phenomenon. Relocation was found to be no more stressful than other life changes (Walker et al, 2007).*
- Begin relocation planning as early in the decision process as possible. **CEB/EBN**: *Having a well-organized plan for the move with support and advocacy through the process may reduce anxiety (Davis, 2005; Johnson, 2008; Kao et al, 2004; Sørensen et al, 2011).*
- Obtain a history, including the reason for the move, the client's usual coping mechanisms, history of losses, and family support for the client. **EBN**: *A history helps the nurse determine the amount of support needed and appropriate interventions to decrease relocation stress (Brownie et al, 2014).*
- Identify to what extent the client can participate in the relocation decisions and advocate for this participation. **EBN**: *Engaging older adults in the decision making process is likely to increase the level of adjustment following the relocation (Bekhet & Zauszniewski, 2013) and promote psychological well-being (Ewen & Chahal, 2013; Street & Burge, 2012).* **CEB**: *Older adults with poor mental functioning may be less able to be involved in the decisions and more vulnerable to disempowerment by others (Johnson et al, 2010).*
- Assess client's readiness to relocate and relocation self-efficacy. **CEB**: *A validated relocation readiness instrument was used successfully with older adults (Rossen, 2007; Rossen & Gruber, 2007).*
- Consult an evidence-based practice guide for relocation. **EBN**: *Researchers compiled latest findings to develop a protocol to assist in relocating older adults (Hertz et al, 2007).*
- Assess family members' perceptions of client's ability to participate in relocation decisions. Particularly in cases of dementia, be alert to care workers' involvement in making the decision to relocate. They may need support and encouragement through the process. **EB**: *Care workers were found to be highly stressed during the relocation decision-making process and "walking a tightrope" between the older adult's needs and those of the person's family members (Hortana et al, 2010).*
- Consider the client's and family's cultural and ethnic values as much as possible when choosing room-mates, foods, and other aspects of care. **CEB/EBN**: *Nurses need to be aware of the differences in values and practices of different cultures and ensure that they give culturally appropriate care that is respectful of older adults and family caregivers' beliefs about elder care (Caron & Bowers, 2003; Johnson, 2008; Johnson & Tripp-Reimer, 2001a, 2001b; Bekhet & Zauszniewski, 2013).*
- Promote clear communication between all participants in the relocation process. **CEB**: *Case studies revealed the importance of using an integrated approach to planning with clear communication among practitioners (LeClerc & Wells, 2001).*
- Observe the following procedures if the client is being transferred to an extended care facility or assisted living facility:
 - Facilitate the client's participation in decisions and choice of placement, and arrange a preadmission visit if possible. **CEB/EBN**: *Clients who are more involved in the decision-making process appear to have fewer problems adjusting to the new environment (Newson, 2008b). Research has shown a link between the loss of independence with transfer to a nursing home and depression (Johnson, 2008; Loeher et al, 2004). Decreased relocation control was significantly related to poorer adjustment (Bekhet et al, 2008).*
 - If the client cannot visit the new facility, arrange for a visit or telephone call by a member of the staff to welcome the client and show a videotape or at least provide pictures of the new care facility.
 - Have a familiar person accompany the client to the new facility. *This lessens client and family anxiety, confusion, and dissatisfaction.*
 - Recommend that the caregiver write a journal of thoughts and feelings regarding the relocation of his/her loved one. **CEB**: *Writing has been found to improve physical and emotional health among caregivers of older adults (Dellasega & Haagen, 2004).*
 - Continue to assess caregiver psychological distress during a 6-month period following relocation. *Caregivers experience distress because of the responsibility of moving their loved one. EB*: *Caregivers may begin to resolve conflicted feelings during this time and need support (Smit et al, 2011).*
- Identify previous routines for ADLs. Try to maintain as much continuity with the previous schedule as possible. **CEB**: *Continuity of routines has been shown to be a crucial factor in positively influencing adjustment to a new environment (Kao et al, 2004).*
- Bring in familiar items from home (e.g., pictures, clocks, afghans). Familiarity eases transition and symbolizes safeness.

- Establish the way the client would like to be addressed (Mr., Mrs., Miss, first name, nickname). *Calling clients by their desired name shows respect.*
- Thoroughly orient the client and the family to the new environment and routines; repeat directions as needed. **CEB:** *The stress of the move may interfere with the client's ability to remember directions. A progressive introduction and orientation for both the client and the family should be done (Kao et al, 2004).*
- Spend one-to-one time with the client. Allow the client to express feelings and convey acceptance of them; emphasize that the client's feelings are real and individual and that it is acceptable to be sad or angry about moving. **CEB:** *Expressing feelings can help the client deal with the change and facilitate grief work that accompanies loss of independence (Tracy & DeYoung, 2004).*
- Allocate a caring staff member to help the client adjust to the move. Assign the same staff members to the client for care if compatible with client; maintain consistency in the personnel with whom the client interacts. **CEB/EB:** *Consistency hastens adjustment and increases quality of care (Iwasiw et al, 2003). A caring practitioner can support the client through the journey of adapting to a new environment (Newson, 2008b).*
- Ask the client to state one positive aspect of the new living situation each day. Helping the client focus on the positive aspects of the move can help change attitude and reframe the situation in a positive fashion. **EBN:** *Learned resourcefulness through positive thinking significantly affected relocation adjustment (Bekhet et al, 2008).*
- Ask the client to state one positive aspect of the new living situation each day. *Helping the client focus on the positive aspects of the move can help change attitude and reframe the situation in a positive fashion.* **CEB:** *Learned resourcefulness through positive thinking significantly affected relocation adjustment (Bekhet et al, 2008).*
- Monitor the client's health status and provide appropriate interventions for problems with social interaction, nutrition, sleep, new onset of infection, or elimination problems. **CEB/EBN:** *Health problems may appear first as declines in ADLs (e.g., bathing, eating, and dressing) (Chen & Wilmoth, 2004). Older adults who moved in the previous year reported increased comorbidity, disability, functional limitation, and worse self-rated health (Hong & Chen, 2009).*
- If the client is being transferred within a facility, have staff members from the new unit visit the client before transfer.
- Work with the caregivers and family members helping them deal with stages of "making the best of it," "making the move," and "making it better." **EBN:** *A study demonstrated that relatives of clients entering a nursing home can work in partnership with health care staff to ease the transition for their loved one more effectively (Newson, 2008b).*
- If a client is being transferred from the intensive care unit (ICU), have previous staff make occasional visits until the client is comfortable in the new surroundings. Ensure that the family is told relevant information. **CEB:** *Leaving the ICU staff may be the most negative component of transfer (McKinney & Deeny, 2002). A review of the literature in this area demonstrated that information needs were most important to families of clients transferred out of ICU (Mitchell et al, 2003).*
- Watch for coping problems (e.g., withdrawal, regression, angry behavior, impaired sleeping, refusal to eat, flat affect, anxiety) and intervene immediately. **EB:** *Research has shown a link between the loss of independence with transfer to a nursing home and depression (Johnson, 2008).*
- Encourage the client to express grief for the loss of the old situation; explain that it is normal to feel sadness over change and loss. **CEB/EB:** *Older adults in long-term care grieve loss of home, possessions, and independence (Newson, 2008a; Pilkington, 2005).*
- Pay special attention to assessing and giving psychosocial care. **EB:** *Although physical care may predicate the relocation, meeting psychosocial care needs must be individualized via careful assessment (Salarvand et al, 2008).*
- Encourage the client to participate in care as much as possible and make own decisions when possible (e.g., placement of the bed, choice of roommate, bathing routines). *Having choices helps prevent feelings of powerlessness that may lead to depression.* **CEB:** *Research showed that residents who viewed the nursing home move negatively after 3 months felt powerless, vulnerable, and isolated (Iwasiw et al, 2003).*

R

Pediatric

- Assess family history and contact information from children relocated to rescue shelters. **EB:** *No unified system exists in the United States to reunite children with their families after natural disaster or terrorist attack, so nursing has a major role to play in locating children's families and facilitating reunification (Chung & Shannon, 2007).*

- Be aware that community relocation may be beneficial for children, and assess community resources of new location. **EB:** *African American children who relocated from an inner city to a suburb benefitted especially from available institutional resources (Keels, 2008).*
- Provide support for a child and family who must relocate to be near a transplant center. **CEB:** *Recognizing the unique needs of parents who must relocate for a child's transplantation procedure supports the delivery of individualized nursing care and the effective allocation of program resources (Stubblefield & Murray, 2002).*
- In divorce situations, recommend alternative dispute resolution versus traditional litigated settlement. **EBN:** *This nonadversarial approach may mitigate some of the trauma of divorce experienced by children (Stein & Oler, 2010).*
- Encourage child to verbalize concerns in divorce situations when they and/or a parent relocate. **CEB:** *Relocation of a parent in divorce has been linked with children's financial concerns, hostility toward parents, views of parents as not socially supportive, and poorer self-perceived health (Braver et al, 2003).*
- Assess presence of allergies before and after relocation. **EB:** *Six-year-old children who relocated were found to have significant allergy sensitization over those who did not relocate (Herberth et al, 2007).*
- If the client is an adolescent, try to avoid a move in the middle of the school year, find a newcomers' club for the adolescent to join, and refer for counseling if needed. **CEB/EB:** *Most adolescents who relocate suffer a brief period of loss of companionship and intimacy with close friends (Vernberg et al, 2006; McBride, 2015).*
- Assess adolescents' perceptions of their acceptance by peers. **CEB:** *Poor perceptions of peer acceptance have been related to less initiation of social interactions in new settings (Aikins et al, 2005; McBride 2015).*
- Help parents recognize that relocation stress syndrome may persist for prolonged periods (e.g., 2 years) in adolescents. **EB:** *Adolescents were found to commonly express their ideology of the relocation (Nuttman-Shwartz et al, 2010).*
- Be aware that young people may cope with the transition by exerting control in particular domains. **EBN:** *Adolescents may be at risk of developing eating disorders following a major transition (Berge et al, 2012).*
- The effects of frequent relocation may not manifest immediately and may have long-term impacts on physical and mental health. **EBN:** *Longitudinal analysis found that frequent relocation in adolescence were associate with higher rates of stress and physical exhaustion in adulthood (Lin et al, 2012).*

Geriatric

- Monitor the need for transfer and transfer only when necessary. **CEB:** *Older adults often experience loss of function after relocation (Chen & Wilmoth, 2004).* **EBN:** *Relocation has been associated with death (Laughlin et al, 2007).*
- Implement discharge planning early so that it is not rushed. **CEB:** *Early discharge planning enhanced information levels for older adults and decreased their concerns (Kleinpell, 2004).*
- Protect the client from injuries such as falls. **CEB:** *Older adults who fell were more likely to be admitted to a nursing home (Seematter-Bagnoud et al, 2006).* *Having one fall increases the likelihood of additional falls (Quadri et al, 2005).*
- Utilize technologies such as sensing devices to measure average in-home gait speed (AIGS) as a predictor of fall risk. **EBN:** *AIGS was found to be a more reliable and valid predictor of fall risk than traditional physical performance assessments (Stone et al, 2015).*
- Implement a registered nurse (RN) care coordination model to restore older adults' health, maintain their independence, and reduce care costs. **EBN:** *RN care coordination was found to significantly and positively impact older adult outcome variables and to result in lesser costs of care (Rantz et al, 2014).*
- After the transfer, determine the client's mental status. *Document and observe for any new onset of confusion. Confusion can follow relocation because of the overwhelming stress and sensory overload.*
- Facilitate visits from companion animals. **CEB:** *A randomized trial of 6 weeks of animal-assisted therapy (dog visits) decreased loneliness among nursing home residents (Banks & Banks, 2002).*
- Encourage reminiscence of happy times. **EB:** *Nine weeks of group reminiscence therapy enhanced self-esteem among 24 nursing home residents in a two-group, nonrandomized study (Chao et al, 2006).*

Client/Family Teaching and Discharge Planning

- Teach family members and remind direct care staff about relocation stress syndrome. Encourage them to monitor for signs of the syndrome. **CEB:** *Relocation stress syndrome begins to ease at approximately 4 weeks after the move (Hodgson et al, 2004).*
- Help significant others learn how to support the client in the move by setting up a schedule of visits, arranging for holidays, bringing familiar items from home, and establishing a system for contact when

the client needs support. **EBN**: *Social support of family and friends was significantly related to relocation adjustment (Bekhet et al, 2008).*

- Assist family members and the relocating older adult to use webcam technology for interaction to supplement in-person visits. **EB**: *When older adults in a care facility have less than one visitor per week, interaction can be supplemented with technological “visits” (Meyer et al, 2011).*

Risk for Relocation stress syndrome

Betty J. Ackley, EdS, MSN, RN, and Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

R

NANDA-I

Definition

Vulnerable to physiological and/or psychosocial disturbance following transfer from one environment to another that may compromise health

Risk Factors

Compromised health status; deficient mental competence; history of loss; ineffective coping strategies; insufficient predeparture counseling; insufficient support system; move from one environment to another; powerlessness; significant environmental change; unpredictability of experience

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan for **Relocation** stress syndrome.

Risk for ineffective Renal perfusion

Pauline McKinney Green, PhD, RN, CNE

NANDA-I

Definition

Vulnerable to a decrease in blood circulation to the kidney that may compromise health

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Risk Factors

Abdominal compartment syndrome; alteration in metabolism; bilateral cortical necrosis; burns; cardiac surgery; cardiopulmonary bypass; diabetes mellitus; exposure to nephrotoxin; extremes of age; female gender; glomerulonephritis; hypertension; hypovolemia; hypoxemia; hypoxia; infection; interstitial nephritis; malignancy; malignant hypertension; polyneuropathy; renal disease (e.g., polycystic kidney, renal artery stenosis, failure); smoking; substance abuse; systemic inflammatory response syndrome; trauma; treatment regimen; vascular embolism; vasculitis

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Perfusion: Renal; Kidney Function

Example NOC Outcome with Indicators

Kidney Function as evidenced by the following indicators: 24-hour intake and output balance/Blood urea nitrogen/Serum creatinine/Urine color/Serum electrolytes. (Rate the outcome and indicators of **Kidney Function**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain normal blood urea nitrogen and serum creatinine levels
- Maintain urine output of 0.5 mL/kg/hr
- Maintain urine output that is yellow and clear
- Maintain serum electrolytes (K⁺, PO₄, Na⁺) within normal limits
- Maintain glomerular filtration rate of 60 to 89 mL/min/1.73 m²
- Maintain normal fluid balance

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Medication Management; Acid-Base Monitoring; Fluid/Electrolyte Management; Laboratory Data Interpretation; Electrolyte Management

Example NIC Activities—Fluid/Electrolyte Management

Monitor for serum electrolyte levels, as available; Weigh daily and monitor trends; Monitor vital signs, as appropriate

Nursing Interventions and Rationales

- ▲ Be aware of major risk factors that increase the risk for decreased renal perfusion. **EB**: *The KDIGO (Kidney Disease Improving Global Outcomes) guidelines indicate shock, nephrotoxic exposure, intravenous contrast media with iodine, cisplatin, amphotericin B, autoimmune disease, infection, sepsis, hypoxemia, and multi-system failure are major risk factors for ineffective pre renal and intrarenal perfusion and the development of acute kidney injury (Kellum & Lameire, 2013; Chao et al, 2014).*
- ▲ Be aware of the RIFLE classification system used to indicate progression in severity of acute kidney injury in adults. **CEB/EB**: *The RIFLE system classifies kidney injury based on serum creatinine and urine output determinants, and includes the following categories: Risk, Injury, Failure, Loss of kidney function, and End stage kidney disease (Akcan-Arikan et al, 2007). A retrospective observational study of post discharge information on 49,518 admissions showed effective discrimination with both the RIFLE criteria and the KDIGO criteria for kidney damage and hospital mortality (Fujii et al, 2014).*
- Review client's medical and social history for evidence of chronic conditions such as hypertension and diabetes, exposure to tropical disease, and exposure to nephrotoxins at work, home, or recreation. **EB**: *Certain conditions and exposures adversely affect renal perfusion (Kellum & Lameire, 2013).*
- Assess clients for fluid imbalance by examining 24-hour fluid intake and output measurements. *Initiating intake and output measurement is standard practice for clients with diseases or conditions that place them at risk for fluid overload or deficit.*

- Assess vital signs, carefully noting new onset of hypertension, hypotension, or dysrhythmia; communicate findings promptly to health care provider. **EB:** *Normal systolic pressure is less than 120 mm Hg and normal diastolic pressure is less than 80 mm Hg. Mean arterial pressure (MAP) of 72 to 82 mm Hg is necessary to avoid acute kidney insufficiency in clients with septic shock (Badin et al, 2011).*
- Assess for early signs of fluid deficit (skin turgor, tongue turgor, thirst, decreased urinary output). *Dehydration from high output renal damage can lead to hypovolemia and decreased renal perfusion.*
- Weigh the client daily. *Fluid retention related to decreased renal perfusion will cause weight to increase.*
- Assess for early signs of fluid overload. *Fluid overload secondary to decreased renal perfusion will be reflected in bounding pulse, lung sounds (rales), distended neck veins, polyuria, dependent edema, and weight gain over a short period of time.*
- Assess for early changes in mental status (irritability, drowsiness, headache, muscle weakness, difficulty concentrating, disorientation, confusion). *Changes in mental status may result from fluid/electrolyte disturbances from impaired renal function. Refer to care plan for Acute Confusion.*
- ▲ Monitor at-risk clients for increasing levels of serum creatinine and decreasing glomerular filtration rate and urine output. **EB:** *Clinical practice guidelines recommend evaluation of kidney function using the following indicators: increase in serum creatinine of 0.3 mg/dL within 48 hours despite fluid resuscitation; increase in serum creatinine to 1.5 times baseline or within the last 7 days; urine output <0.5 mL/kg/hr for 6 consecutive hours (KDIGO Work Group, 2012).*
- ▲ Use isotonic crystalloids rather than colloids (albumin or starches) to provide expansion of intravascular volume in hypovolemic clients who are at risk for or have acute kidney injury. **EB:** *A Cochrane review concluded that there is no evidence that the use of colloids, instead of crystalloids, reduces the risk for death in clients with trauma or burns, or following surgery (Kellum & Lameire, 2013).*
- ▲ Maintain normal to somewhat increased levels of glucose in critically ill clients with insulin therapy. **EB:** *Maintaining plasma glucose at a target level of 110 to 149 mg/dL prevents complications from hyperglycemia and hypoglycemia that can adversely affect perfusion to the renal macrovasculature and microvasculature (Kellum & Lameire, 2013).*
- ▲ Advocate for at-risk clients by notifying health care providers when clients have concurrent use of nephrotoxic drugs. *Administration of multiple nephrotoxic drugs increases risk for renal toxicity.*
- ▲ Communicate to radiology departments when clients scheduled for testing with contrast media had contrast media testing within the last 24 hours or recently received cisplatin or high-dose methotrexate. **EBN:** *Intravenous contrast media with iodine or gadolinium increases risk for contrast-induced nephropathy (Matich, 2014).*
- ▲ Monitor that peak and trough serum levels of aminoglycosides are within acceptable ranges when multiple daily dosing is administered for more than 24 hours. **EB:** *Risk for acute kidney injury with aminoglycoside use is high; KDIGO guidelines recommend not using aminoglycosides for infections unless no suitable, less nephrotoxic therapeutic alternative exists (Kellum & Lameire, 2013).*
- Ensure that at-risk clients having diagnostic testing with contrast media are well hydrated with intravenous isotonic sodium chloride or sodium bicarbonate solutions as ordered before and after the procedure. **CEB:** *Hydration with crystalloids has been shown to prevent acute kidney injury (KDIGO, 2012).* Refer to care plan for Risk for adverse reaction to iodinated **Contrast Media**.
- Collect a 24-hour urine specimen for examination as ordered. *A 24-hour urine specimen to measure urinary excretion of electrolytes is used to assess kidney function; in addition, a glomerular filtration rate can be determined if a blood creatinine is also obtained (Dugdale, 2013).*
- ▲ Note the results of diagnostic studies such as renal ultrasound, radionuclide scanning, abdominal/pelvic computed tomography (CT), magnetic resonance angiography, magnetic resonance imaging (MRI), and arteriography. *These tests are commonly done for diagnosing acute kidney injury and renal failure (American College of Radiology, 2013).*
- Monitor results of serum and urine tests of kidney function as ordered or per protocol and promptly notify health care provider of abnormal results. **EB:** *Results of laboratory tests of kidney function are used to distinguish prerenal from intrarenal causes of acute kidney injury (White et al, 2011).*

Geriatric

- Be aware that advanced age is a risk factor that increases the probability of ineffective renal perfusion. **CEB:** *Older clients have less renal reserve because of reduced glomerular filtration rates due to the aging process and comorbid conditions (Yilmaz & Erdem, 2009).*

- Assess for signs of dehydration in older adults who have less thirst and consume less fluid than young adults when experiencing fluid deprivation. Refer to care plan for Deficient **Fluid** volume.
- Ensure older clients receive sufficient fluids to prevent dehydration and hypovolemia (Pinto & Schub, 2013).

Pediatric

- Be aware that renal development in infants and neonates may be adversely affected by nephrotoxic drugs. **EB:** *Nephrotoxic medication during fetal and postnatal life may interfere with nephron generation and further increase risk for renal failure (Misurac, et al, 2013).*
- ▲ Be aware of the Pediatric RIFLE classification system used to indicate progression in severity of acute kidney injury in children. **CEB:** *The Pediatric RIFLE system supports recognition and classification of kidney injury in children (Akcan-Arikan et al, 2007).*

Client/Family Teaching and Discharge Planning

- Instruct at-risk clients and families to inform health care professionals about their kidney status if scheduled for a CT scan, MRI scan, or angiogram (National Kidney Foundation, 2013a).
- Instruct at-risk clients to avoid overuse of analgesics such as acetaminophen and nonsteroidal antiinflammatory drugs (NSAIDs). **EB:** *Studies in both adults and children demonstrated a significant increase in acute kidney injury in clients who ingested NSAIDs (Leonard et al, 2012; Misurac et al, 2013).*
- Instruct clients about risk factors for renal insufficiency or acute renal failure including signs and symptoms of acute renal failure and lifestyle changes that can improve renal function. *Client education is a vital part of nursing care for the client with possible renal disease (National Kidney Foundation, 2013a).*
- ▲ Instruct at-risk clients to alert health care providers about renal status before obtaining new medication prescriptions. *Promote client safety for at-risk clients by encouraging communication with health care providers regarding issues with renal status.*
- ▲ Encourage smoking cessation. Effects of nicotine include increased pulse and blood pressure and constriction of blood vessels; vasoconstriction and atherosclerosis exacerbate existing problems with kidney perfusion (National Kidney Foundation, 2013b).

Impaired Resilience *Shelly Eisbach, PhD, RN, PMHNP-BC*

NANDA-I

Definition

Decreased ability to sustain a pattern of positive responses to an adverse situation or crisis

Defining Characteristics

Decreased interest in academic activities; decreased interest in vocational activities; depression; guilt; impaired health status; ineffective coping strategies; low self-esteem; renewed elevation of distress; shame; social isolation

Related Factors (r/t)

Community violence; demographics that increase chance of maladjustment; economically disadvantaged; ethnic minority status; exposure to violence; female gender; inconsistent parenting; insufficient impulse control; large family size; low intellectual ability; low maternal educational level; parental mental illness; perceived vulnerability; psychological disorder; substance abuse

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Resiliency; Decision-Making; Self-Esteem

Example NOC Outcome with Indicators

Personal Resiliency as evidenced by the following indicators: Adapts to adversities as challenges. (Rate the outcome and indicators of **Personal Resiliency**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section 1](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate reduced or cessation of drug and alcohol usage
- State effective life events on feelings about self
- Seek help when necessary
- Verbalize or demonstrate cessation of abuse
- Adapt to unexpected crises or challenges
- Verbalize positive outlook on illness, family, situation, and life
- Use available resources to meet coping needs
- Identify role models
- Identify available assets and resources
- Be able to verbalize meaning of one's life

R

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Resiliency Promotion; Self-Esteem Enhancement

Example NIC Activities—Resiliency Promotion

Encourage positive health-seeking behaviors; Facilitate family communication

Nursing Interventions and Rationales

- Encourage positive, health-seeking behaviors. **EBN**: *Promoting health will provide a foundation for enhancing the abilities of individuals to cope, find resources, use resources, and evaluate resources for appropriate decision-making (Landau, 2010).*

• = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

- Ensure access to biological, psychological, and spiritual resources. **EBN:** *Identifying and linking persons to available resources will foster engagement in resources that enhance protective factors and resilience (Landau, 2010; Tuck & Anderson, 2014).*
- Foster communication skills through basic communication skill training. **EBN:** *Individuals who are skilled communicators have fewer problems with family relationships and are able to articulate their own viewpoint (Szanton & Gill, 2010).*
- Foster cognitive skills in decision-making. **EB:** *Assist in the identification of problems and situational factors that contribute to problems, offering options for resolution (Burton et al, 2010).*
- Assist client in cognitive restructuring of negative thought processes. **EBN:** *Positive thinking has been associated with increased feelings of coherence and resourcefulness when dealing with adversity (Everly et al, 2014).*
- Facilitate supportive family environments and communication. **EBN:** *Individuals found to be resilient if raised in families with greater levels of parental supervision and consistent expectations, rules, and consequences for problem behaviors, and effective systems for monitoring children and adolescents (Schofield et al, 2014).*
- Promote engagement in positive social activities. **EB:** *Facilitating involvement with positive peers decreases the potential for involvement in risky behavior (Veselska et al, 2009).*
- Assist client to identify strengths, and reinforce these. **EBN:** *Positive self-esteem can be seen as an essential feature of mental health, as well as a facilitator of social engagement (Veselska et al, 2009).*
- Help the client identify positive emotions in the midst of adverse situations. **EBN:** *Recovering from negative emotions in the midst of adverse situations and focusing on positive emotions helps buffer against life adversity (Szanton & Gill, 2010).*
- Build on supportive counseling and therapy. **EB:** *Facilitating and mobilizing supportive systems external to individuals and families promote social connectedness, problem solving, resource accessing, and cognitive restructuring (Burton et al, 2010).*
- Identify protective factors such as assets and resources to enhance coping. **EB:** *According to the protective factor model of resilience, a protective factor that interacts with a stressor reduces the likelihood of negative outcomes (Vahia et al, 2011).*
- Provide positive reinforcement and emotional support during the learning process. **EBN:** *Positive outcomes and adherence to interventions are attained when clients are supported and reinforced for positive behavior or steps in the learning process (Tetlie et al, 2009).* **EB:** *Clients with positive, supportive educational environments show self-efficacy in attaining goals in the midst of adverse situations (Masten, 2014).*
- Encourage mindfulness, a conscious attention and awareness of self. **EB:** *This will help the client identify strengths, as well as promote relaxation and stress reduction (Coholic, 2011).*
- Educate and encourage the use of stress reduction techniques such as guided imagery in which the client focuses on positive images and emotions. **EB:** *Negative thoughts influence both emotions and behaviors. Positive imagery has been shown to reduce subjective feelings of stress (Park et al, 2013).*
- Enhance knowledge and use of self-care strategies. **EB:** *Promoting stress reduction and enhancing self-care has been shown to positively impact quality of life (Bryant & Nickerson, 2014).*
- Assist the client to have an optimistic world view. **EBN:** *Promoting positive thinking and empowering individuals to address adverse situations in a positive frame has been associated with reduced mortality and improved psychological well-being (Szanton & Gill, 2010).*

Pediatric

- The preceding interventions may be adapted for the pediatric client.
- Promote nurturing, supportive relationships with family. **CEB:** *Secure attachment and early life experience affect the development of the brain, which provides integral foundation for learning and health (National Scientific Council on the Developing Child, 2004).*
- Support the seeking of opportunities to improve cognitive abilities, such as tutoring and other resources; the development of positive and supportive relations, such as family, community members, or mentors; and the improvement of general health. **EBN:** *These activities help encourage the promotion of protective factors of adolescent resilience such as positive coping and positive self-esteem (Lau & van Niekerk, 2011).*
- Promote the development of positive mentor relationships. **EB:** *Avoidance of risk-taking behavior is linked to attachment with caring adults (Yadav et al, 2010).* **EB:** *Children exposed early to caring adults experienced support, encouragement, guidance, and admonishment (Anthony et al, 2009).*

- ▲ Consider referral to appropriate community resources, such as faith-based communities for children who have had adverse childhood experiences. *There is a critical need to identify cost-effective community resources that optimize stress resilience. Faith-based communities may promote forgiveness rather than retaliation, opportunities for cathartic emotional release, and social support, all of which have been related to neurobiology, behavior, and health outcomes. While spirituality and religion can be related to guilt, neurotic, and psychotic disorders, they also can be powerful sources of hope, meaning, peace, comfort, and forgiveness for the self and others (Brewer-Smyth & Koenig, 2014).*

Readiness for enhanced Resilience Shelly Eisbach, PhD, RN, PMHNP-BC

NANDA-I

Definition

A pattern of positive responses to an adverse situation or crisis, which can be strengthened

Defining Characteristics

Demonstrates positive outlook; exposure to crisis; expresses desire to enhance available resources; expresses desire to enhance communication skills; expresses desire to enhance environmental safety; expresses desire to enhance goal setting; expresses desire to enhance involvement in activities; expresses desire to enhance own responsibility for action; expresses desire to enhance progress toward goal; expresses desire to enhance relationships with others; expresses desire to enhance resilience; expresses desire to enhance self-esteem; expresses desire to enhance sense of control; expresses desire to enhance support system; expresses desire to enhance use of conflict management strategies; expresses desire to enhance use of coping skills; expresses desire to enhance use of resource

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Personal Resiliency; Family Resiliency; Quality of Life

Example NOC Outcome with Indicators

Personal Resiliency as evidenced by the following indicator: Adapts to adversities and challenges. (Rate the outcome and indicators of **Personal Resiliency**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)].)

Client Outcomes**Client Will (Specify Time Frame)**

- Adapt to adversities and challenges
- Communicate clearly and appropriately for age
- Take responsibility for own actions
- Make progress towards goals
- Use effective coping strategies
- Express emotions

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Resiliency Promotion; Self-Efficacy Enhancement; Counseling; Emotional Support

Example NIC Activities—Self-Efficacy Enhancement

Explore individual's perception of his or her capability to perform the desired behavior

R

Nursing Interventions and Rationales

- Listen to and encourage expressions of feelings and beliefs. **EBN**: *Communication assists individuals and families resolve conflicts and facilitate potential for growth, identify inherent strengths, and problem solve effectively (Doherty & Thompson, 2014).*
- Establish a therapeutic relationship based on trust and respect. **EBN**: *Therapeutic relationships between therapists, nurses, and clients are essential to help individuals establish goals, communicate concerns, and empower the client (Halldórsdóttir & Svavarsdóttir, 2012).*
- Assist client in rating current level of resilience: www.resiliencescale.com. **EBN**: *Provides a baseline assessment of current status so that the nurse can identify the effectiveness of interventions (Wagnild, 2009).*
- Facilitate supportive family environments and communication. **EBN**: *Individuals were found to be resilient if raised in families with greater levels of parental supervision and consistent expectations, rules, and consequences for problem behaviors, and effective systems for monitoring children and adolescents (Schofield et al, 2014).*
- Assist client to identify and reinforce strengths. **EB**: *Fostering the use of protective factors promotes the ability of an individual to overcome adverse situations (Poteat et al, 2014).*
- Enhance skills associated with social and executive functioning. **EB**: *Research has shown that social and self-regulation skills enhance one's ability to respond sensitively and are associated with better school adjustment, increased competence, and life success (Masten, 2014).*
- Provide positive reinforcement and emotional support during implementation of care. **EB**: *Providing positive reinforcement and emotional support will enhance a client's self-esteem, which is a key component of physical and mental health; individuals with higher self-esteem are more likely to be resilient than peers with less self-esteem (Veselska et al, 2008; Masten, 2014).*

- ▲ Facilitate the development of mentorship and volunteer opportunities. **EB**: *Mentoring programs have been shown to prevent negative outcomes and foster a sense of social and community engagement for clients across the lifespan (Yadav et al, 2010; Klinedinst & Resnick, 2014).*
- Determine how family behavior affects the client. **EB**: *Resilience models are based on the presupposition that individuals and families are connected to each other and their community and have collective strengths, which help them compensate for their adversity (Swanson et al, 2011; Masten, 2014).*
- Promote use of mindfulness and other stress reduction techniques. **EB**: *Mindfulness-based approaches have been shown to assist in coping with stress and provide a sense of relaxation and awareness of self, others, and the environment (Davis & Kurzban, 2012).* Establish individual/family/community goals. **EBN**: *Individuals, families, and communities that set goals will focus on attaining or achieving positive outcomes despite adversity (Masten, 2014).*

Pediatric

- The preceding interventions may be adapted for the pediatric client.
- Encourage the promotion of protective factors by fostering the seeking of opportunities to improve cognitive abilities, such as tutoring and other resources; the development of positive and supportive relations such as family, community members, or mentors; and the improvement of general health. **EBN**: *These factors are associated with adolescent resilience and promote positive coping and positive self-esteem (Ahern et al, 2008).*

Multicultural

- Use teaching strategies that are culturally and age appropriate. **EB**: *Nurses who use currently existing family and community resources will promote a context that allows solutions to emerge in a culturally appropriate and sustainable way (Ungar, 2010).*

Risk for impaired Resilience Shelly Eisbach, PhD, RN, PMHNP-BC

NANDA-I

Definition

Vulnerable to decreased ability to sustain a pattern of positive response to an adverse situation or crisis, which may compromise health

- = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Risk Factors

Chronicity of existing crisis; multiple coexisting adverse situations: new crisis (e.g., unplanned pregnancy, loss of housing, death of family member)

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Personal Resiliency; Family Resiliency; Knowledge: Health Resources

Example NOC Outcome with Indicators

Personal Resiliency as evidenced by the following indicator: Takes responsibility for own actions. (Rate the outcome and indicators of **Personal Resiliency**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

- Identify available community resources
- Propose practical, constructive solutions for disputes
- Identify and access community resources for assistance
- Accept assistance with activities of daily living from family and friends
- Verbalize an enhanced sense of control
- Verbalize meaningfulness of one's life

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Resiliency Promotion; Assertiveness Training; Values Clarification; Parenting Promotion

Example NIC Activities—Resiliency Promotion

Encourage family involvement with child's schoolwork and activities; Assist family in providing atmosphere conducive to learning

Nursing Interventions and Rationales

- Determine how family behavior affects client. **EBN**: *The model of resilience is based on the presupposition that individuals and families are connected to each other and their community and have collective strengths, which will help them compensate for their adversity (West et al, 2011; Deist & Greeff, 2015).*
- Help identify personal rights, responsibilities, and conflicting norms. **EB**: *Maintaining a sense of control and positive perspective about one's environment helps individuals positively cope with adversity (Kia-Keating et al, 2011).*
- Encourage consideration of values underlying choices and consequences of the choice. **EB**: *Improving social skills, enhancing self-efficacy, and considering values behind choices will promote character building and life satisfaction (Kia-Keating et al, 2011).*
- Help client practice conversational and social skills. **EB**: *Social competence and social support have been shown to improve academic achievement for minority low-income school children; cognitive skills are protective factors to assist individuals with resilience (Elias & Haynes, 2008).*
- Assist client to prioritize values. **EB**: *Nurses can help individuals prioritize positive values in order to resist engagement in risky behaviors such as smoking, drinking, or violence (Veselska et al, 2009).*
- Create an accepting, nonjudgmental atmosphere. **EB**: *Assisting families and individuals to create stable and positive communication skills helps minimize unreasonable expectations and concentrate on positive outcomes (Anthony et al, 2009).*
- Help identify self-defeating thoughts. **EBN**: *Cognitive reframing is a tool that assists individuals in reflecting and shifting negative thinking toward positive perspectives (Resnick, 2014).*

- ▲ Refer to community resources/social services as appropriate. **EB**: *Attending community resources, such as support groups, helps disseminate and develop health promotion activities that improve well-being and quality of life (Landau, 2010).*
- ▲ Help clarify problem areas in interpersonal relationships. **EBN**: *Individuals who were socially connected to their environment, family, and sense of self are able to maintain a supportive mindset and experience a good quality of life despite compromising health conditions, serious diagnosis, and poor prognosis (Stuckey et al, 2014).*
- ▲ Promote a sense of an individual's autonomy and control over choices to be made in one's environment. **EBN**: *Autonomy promotes a sense of self-efficacy and has been linked to increased quality of life and positive health outcomes for clients (Resnick, 2014).* Identify and enroll high-risk families in follow-up programs. **EBN**: *Families with adequate resources and positive relationships have a better chance of managing stress and restoring balance in the presence of adversity and limited resources (West et al, 2011; Lester et al, 2013).*

Parental Role conflict *Kimberly Silvey, MSN, RN*

NANDA-I

Definition

Parent's experience of role confusion and conflict in response to crisis

Defining Characteristics

Anxiety; concern about family (e.g., functioning, communication, health); disruption in caregiver routines; fear; frustration; guilt; perceived inadequacy to provide for child's needs (e.g., physical, emotional); perceived loss of control over decisions relating to child; reluctance to participate in usual caregiver activities

Related Factors (r/t)

Change in marital status; home care of a child with special needs; interruptions in family life due to home care regimen (e.g., treatments, caregivers, lack of respite); intimidated by invasive modalities (e.g., intubation); intimidation by restrictive modalities (e.g., isolation); living in nontraditional setting (e.g., foster, group or institutional care); parent-child separation

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Caregiver Lifestyle Disruption; Coping; Parenting Performance; Family Coping

● = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Establishes role flexibility/Manages family problems/Uses family-centered stress reduction activities. (Rate the outcome and indicators of **Family Coping**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section 1].)

Client Outcomes

Client Will (Specify Time Frame)

- Express feelings and perceptions regarding impacts of illness, disability, and/or hospitalization on parental role
- Participate in hospital and home care as much as able given the availability of resources and support systems
- Exhibit assertiveness and responsibility in active family decision-making regarding care of the child
- Describe and select available resources to support parental management of the child's and family's needs

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Caregiver Support; Counseling; Decision-Making Support; Family Process Maintenance; Family Therapy; Role Enhancement

Example NIC Activities—Role Enhancement

Teach new behaviors needed by client/parent to fulfill a role; Serve as role model for learning new behaviors as appropriate

Nursing Interventions and Rationales

- Assess and support parent's previous coping behaviors. **EBN**: *Understanding what experience a parent has with coping will enable the nurse to support the parents in the current situation (Dashiff et al, 2011).*
- Determine parent/family sources of stress, usual methods of coping, and perceptions of illness/condition. Maximize the identified strengths. **EB**: *Helping to identify stressors in a family's life can help parents better cope with their child's illness (Pritchard & Montgomery-Hönger, 2014).*
- Evaluate the family's perceived strength of its social support system, including religious beliefs. Encourage the family to use social support. **EB**: *Parents use their support from their family to help reduce anxiety (Nabors et al, 2013).*
- Determine the older childbearing woman's support systems and expectations for motherhood. **EBN**: *Supporting mothers will help mothers better care for their infants (Rossiter et al, 2012).*
- Consider the use of family-centered theory as the conceptual foundation to help guide interventions. **EB**: *When planning care for a child, family is always the constant in their lives and should be included in all decision-making (Kuo et al, 2012).*
- Be available to accept and support parents by listening and discussing concerns. **EBN**: *The nurse's ability to observe and listen to parents helps parents gain confidence in caring for their child (Panicker, 2013).*
- ▲ Maintain parental involvement in shared decision-making with regard to care by using the following steps: incorporate parents' information concerning the child's typical routines, behaviors, fears, likes, and dislikes; provide clear and direct firsthand information concerning the child's condition and progress; normalize the home/hospital environment as much as possible; collaborate in care by providing choices when possible. **EB**: *Understanding the ways decision are made by the parents will help the nurse better care for the child (Schmidt, 2014).*
- Seek and support parental participation in care. **EBN**: *Nurses should support the parents in whatever way they choose to participate in care and involve them in as much as the parents feel comfortable (Romaniuk et al, 2014).*
- Provide support for each parent's primary coping strategies and needs. **EBN**: *Parent support at home can enhance parents' confidence in caring for their child (Callery et al, 2013).*
- ▲ Inform parents of financial resources, respite care, and home support to assist them in maintaining sufficient energy and personal resources to continue caregiving responsibilities. **EB**: *There can be a financial*

burden on parents of children with chronic illness and a need to help the family identify their resources (George et al, 2011).

- Encourage the parent to meet his/her own needs for rest, nutrition, and hygiene. Provide bed space so that the parent may stay with the sick child. **EB:** *Children with an illness can have an impact on parent sleep, which in turn can cause parental fatigue and lead to other health problems (Mörelus & Hemmingsson, 2014).*
- Provide family-centered care: allow parents to touch and talk to the child, and assist in the handling of medical equipment; offer a comfortable chair, preferably a rocking chair. Provide opportunities and offer praise for successful caregiving. **EBN:** *Allowing the parents to participate in care as they feel comfortable enhances family-centered care (Romaniuk et al, 2014).*
- Refer parents to available telephone and/or Internet support groups. **EB:** *Many parents find that Internet support groups help in coping with their child's illness (Clifford & Minnes, 2013).*
- Involve new mother's partner or parents in clinical encounters and invite family members to discuss their expectations and parenting experiences. **EB:** *Health care providers realize the importance of involving partners and family members in the care of the infant to help the mother caring for the infant (Gremigni et al, 2011).*

Multicultural

- Acknowledge racial/ethnic differences at the onset of care. **EB:** *Providing culturally competent care is important to health care equality (Bagchi et al, 2012).*
- Assess for the influence of cultural beliefs, norms, and values on the client's perceptions of the parental role. **EB:** *Understanding the cultures and beliefs of parents can enhance the interactions between nurse and family (Grant & Luxford, 2011).*
- Acknowledge that value conflicts arising from acculturation stresses may contribute to increased anxiety and significant conflict with the parental role. **EBN:** *Nurses should assess for any care that may interfere with a family's cultural beliefs and practices (Majdalani et al, 2014).*
- Promote the female parenting role by providing a treatment environment that is culturally based and woman-centered. **EBN:** *Mothers should be the main focus for shorter hospital stays and better infant bonding (Miah, 2013).*
- Support the client's parenting role in her usual setting via social exchange, including online support. **EBN:** *Online messaging boards can be very helpful and support the client's parenting role (Porter & Ispa, 2013).*

Home Care

- The interventions described previously may be adapted for home care use.
- Assess family adjustment prenatally and postpartum; assist new parents to renegotiate parenting roles and responsibilities with co-parenting. Encourage the father to take an active role in infant care with the mother's support. **EBN:** *Home visits can have a positive impact on both the mother and father (Ferguson & Vanderpool, 2013).*

Client/Family Teaching and Discharge Planning

- Offer family-led education interventions to improve participants' knowledge about their condition and its treatment and decreasing their information needs. **EBN:** *Education of client and family on the condition can improve self-care at home (Swerczek et al, 2013).*
- For children and their parents involved in bereavement support groups, identify the family's positive way of coping. **EB:** *Support groups and bereaving programs can help parents better cope with the death of a child (Ayers et al, 2013).*
- ▲ Refer parents of children with behavioral problems to parenting programs. **EB:** *Parenting programs can help parents identify and reduce problem behaviors in children (Salari et al, 2013).*
- Involve parents in formal and/or informal social support situations, such as Internet support groups. **EBN:** *Online support groups can allow families to receive support from their peers from around the world and share the knowledge and problems of their child (Mo & Coulson, 2014).*
- Teach the client about available community resources (e.g., therapists, ministers, counselors, self-help groups). **EBN:** *Community-based resources can support caregivers and ensure that they can identify needed services (Borrow et al, 2011).*
- Encourage parents with chronic illnesses to implement custody plans for their children. **EBN:** *Support chronically ill parents to plan for the future care of their children (Janatha, 2011).*

Ineffective Role performance

Gail B. Ladwig, MSN, RN, and Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Patterns of behavior and self-expression that do not match the environmental context norms and expectations

Defining Characteristics

Alteration in role perceptions; anxiety; change in capacity to resume role; change in other's perception of role; change in self-perception of role; change in usual patterns of responsibility; depression; discrimination; domestic violence; harassment; inappropriate developmental expectations; ineffective adaptation to change;

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

ineffective coping strategies; ineffective role performance; insufficient confidence; insufficient external support for role enactment; insufficient knowledge of role requirements; insufficient motivation; insufficient opportunity for role enactment; insufficient self management; insufficient skills; pessimism; powerlessness; role ambivalence; role conflict; role confusion; role denial; role dissatisfaction; role strain; system conflict; uncertainty

Related Factors (r/t)

Knowledge

Insufficient role model; insufficient role preparation (e.g., role transition, skill rehearsal, validation); low education level; unrealistic role expectations

Physiological

Alteration in body image; depression; fatigue; low self-esteem; mental health issue (e.g., depression, psychosis, personality disorder, substance abuse); neurological defect; pain; physical illness; substance abuse

Social

Conflict; developmental level inappropriate for role expectation; domestic violence; economically disadvantaged; inappropriate linkage with the healthcare system; insufficient resources (e.g., financial, social, knowledge); insufficient rewards; insufficient role socialization; insufficient support system; stressors; young age

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Psychosocial Adjustment: Life Change; Role Performance

Example NOC Outcome with Indicators

Role Performance as evidenced by the following indicators: Knowledge of role transition periods/Reported comfort with role changes. (Rate the outcome and indicators of **Role Performance**: 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify realistic perception of role
- State personal strengths
- Acknowledge problems contributing to inability to carry out usual role
- Accept physical limitations regarding role responsibility and consider ways to change lifestyle to accomplish goals associated with role performance
- Demonstrate knowledge of appropriate behaviors associated with new or changed role
- State knowledge of change in responsibility and new behaviors associated with new responsibility
- Verbalize acceptance of new responsibility

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Role Enhancement

Example NIC Activities—Role Enhancement

Assist client to identify behaviors needed for role development; Assist client to identify positive strategies for managing role changes

Nursing Interventions and Rationales

Social

- Assess the client’s level of resilience and implement nursing actions that increase client resilience. **EBN**: *High resilience is associated with higher role functioning (Melvin et al, 2012).*

- Assess the impact of uncertainty on the client's role. **EB:** *Role uncertainty may interfere with the individual's ability to articulate his/her role expectations (Stewart et al, 2012).*
- Ask the client direct questions regarding new roles and how the health care system can help him or her continue in roles. **EBN:** *All participants in this study of clients who had had a stroke described the loss of valued roles that they had previously enjoyed. Health care professionals need to recognize and provide psychological support for clients and significant others who are adjusting to these changes (Thompson, 2008).*
- ▲ Allow the client to express feelings regarding the role change; refer for support as needed. **EBN:** *For women with cancer and with children living at home, the demands of being a good mother while undergoing treatments and recovering from illness have been described as a difficult life process. All of the women included in this study expressed the need for professional support to help them endure treatment procedures as well as sustain their moral responsibility as good mothers (Elmberger et al, 2008).*
- ▲ Assist the client to identify rewards associated with his or her roles. **EB:** *Research indicates that role rewards buffers the negative impact of stress on social functioning and depression (Lanza di Scalea et al, 2012).*
- ▲ Refer for support as needed for home caregivers of military families during the deployment of spouses. **EBN:** *Caregivers affiliated with the National Guard and those with more months of deployment reported significantly poorer emotional well-being and more household and relationship hassles. Given the important effect that maternal well-being has on child and family functioning, it is critical to understand how the stress of deployment is affecting mothers in their daily routines, especially during potentially high-stress periods (Lara-Cinisomo et al, 2012).*
- ▲ Refer the client to Acceptance and Commitment Therapy (ACT). **EB:** *ACT is a therapy that focuses on the development of psychological flexibility through acceptance of what is out of personal control and a commitment to action that improves and enriches one's life (Hayes et al, 2011).*
- Reinforce the client's strengths and internalized values. **CEB:** *Participants in this study whose intentions were more aligned with their moral norm were more likely to perform healthy behaviors (driving within speed limit, applying universal precautions, exercising, not smoking) (Godin et al, 2005).*
- Support the client's religious practices. **EBN:** *Clients dealing with role change associated with health crisis may be at risk for spiritual crisis and need an interdisciplinary approach to assist them through this time (Agrimson & Taft, 2009).*

Physiological

- Identify ways to compensate for physical disabilities (e.g., have a ramp built to provide access to house, put household objects within the client's reach from wheelchair) and provide technological assistance when available. **CEB:** *Among people with disability, use of assistive technology was associated with use of fewer hours of personal assistance (Hoenig et al, 2003).*
- Refer to the care plans for Readiness for enhanced family **Coping**, Readiness for enhanced **Decision-Making**, Impaired **Home** maintenance, Impaired **Parenting**, Risk for **Loneliness**, Readiness for enhanced community **Coping**, Readiness for enhanced **Self-Care**, and Ineffective **Sexuality** pattern.

Pediatric

- Assist new parents to adjust to changes in workload associated with childbirth. Mothers may need additional support. **EB:** *In most cases, mothers are the primary caregivers and are, therefore, responsible for the majority of the work related to infant care tasks (Barkin et al, 2010).*
- Assess mothers who present with depressive symptoms in the postpartum period for evidence of role performance distress. **EBN:** *Nursing research indicates that role performance disturbances are correlated with depressive symptoms in the postpartum period (Cavalcanti et al, 2014).*
- ▲ Refer teen parents and families to a community-based, multifamily group intervention strategy (e.g., Families and Schools Together babies). **EB:** *This program showed statistically significant increases in parental self-efficacy for the teenage mothers, improved parent-child bonds, reduced stress and family conflict, and increased social support (McDonald et al, 2009).*
- ▲ Refer to home health agency for home visits when there is an infant who has excessive crying. **EBN:** *Mother-infant relationships can be improved through early home visiting interventions by trained nursing staff (Geçkil et al, 2009). The crying baby is the most common presentation in every clinician's office in the first 16 weeks of life (Kvitvør et al, 2012).*
- Provide parents with coping skills when the role change is associated with a critically and chronically ill child. **CEB:** *Results from mothers who received the Creating Opportunities for Parent Empowerment (COPE)*

program indicate the need to educate parents regarding their children's responses as they recover from critical illness and how they can assist their children in coping with the stressful experience (Melnyk et al, 2006). Involving parents of chronically ill children in ongoing discussions about their positions in management may help promote their active and informed participation (Swallow, 2008).

- ▲ Assist families how to manage day-to-day needs of a child with cerebral palsy (CP). Teach family members to value the small things children do, connect with other families, locate community resources, and understand the short- and long-term needs of the child. **CEB:** *In families of children with CP, strategies for optimizing caregiver physical and psychological health include supports for behavioral management and daily functional activities as well as stress management and self-efficacy techniques. These data support clinical pathways that require biopsychosocial frameworks that are family centered (Raina et al, 2005).*
- Consider the use of media-based behavioral treatments for children with behavioral disorders. **EBN:** *Behavior problems in children are common. For straightforward cases, media-based interventions may be enough to make clinically significant changes in a child's behavior. Media-based therapies appear to have both clinical and economic implications for the treatment of children with behavioral problems (Montgomery, 2005).* **EB:** *This paper discussed using media-based strategies for delivery of parenting interventions (Barlow & Calam, 2011).*

Geriatric

- Assess older adults' choices regarding their care and enable them to live as they wish and receive the help they want by carefully listening to their stories. **EB:** *In this study, "appreciative inquiry" was used to enable older adults, some with dementia, to tell their stories and describe their choices for care (Seebohm et al, 2010). This study showed an association of perceived control and successful aging (Infurna et al, 2010).*
- Provide support and practice for older adults to use assistive devices. **EB:** *This study indicates that frail older people need specifically developed support in the process of becoming assistive device users (Skymne et al, 2012).*
- Support the client's religious beliefs and activities and provide appropriate spiritual support persons. **EB:** *For individuals like most participants in this study (Christians), incorporating spirituality/religion into counseling for anxiety and depression was desirable (Stanley et al, 2011).*
- Explore community needs after assessing the client's strengths. Encourage older adults to participate in volunteer programs. **EB:** *Engagement in social and generative activities has benefits for the well-being of older adults; programs such as Experience Corps Baltimore provide a social model for health promotion for older adult volunteers in public schools (Martinez et al, 2006).*
- Provide educational materials for older clients who are recovering from hip surgery or fractures to promote early mobility. **EBN:** *The results of this study of older adults suggest that the provision of basic information is essential for successful recovery (early mobility) from hip surgery. Hip fracture clients should be provided with an educational booklet containing basic information on mobility to promote optimal recovery (Murphy et al, 2011).*
- ▲ Refer to appropriate support groups for mental stress related to role changes. **EB:** *Within this sample, caregivers of clients with Parkinson's disease reported far greater burden from "mental stress" (e.g., worrying about individual's safety) than from "physical stress" (e.g., lifting individual into bed) (Roland et al, 2010).*
- ▲ Refer clients to therapeutic recreation programs that use humor. **EB:** *Older adults' life satisfaction showed significant improvement when participating in "the happiness and humor group" (Mathieu, 2008).*
- Provide music of choice for clients with Alzheimer's disease. **EB:** *The findings in this study suggest that music enhances autobiographical recall for clients with Alzheimer's disease by promoting positive emotional memories (El Haj et al, 2012).*
- Provide support for grandparents raising grandchildren. **EBN:** *Grandparent caregivers are at risk for multiple physical, mental, and emotional problems due to the stresses and strains of care provision (Lo & Liu, 2009).*

Multicultural

- Assess for the influence of cultural beliefs, norms, values, and expectations on the individual's role. **CEB:** *The individual's role may be based on cultural perceptions (Leininger & McFarland, 2002).* **EBN:** *It is important to gain an understanding of cultural beliefs and traditional practices relating to the postpartum care of women and their babies (Geçkil et al, 2009).*
- Assess for conflicts between the caregiver's cultural role, obligations, and competing factors, such as employment or school. **CEB:** *Mexican immigrant children provide essential help to their families, including*

translating, interpreting, and caring for siblings (Orellana, 2003). A recent study found that African American caregivers experienced a wide range of caregiver role strain (Wallace Williams et al, 2003).

- Negotiate with the client regarding the aspects of their role that can be modified and still honor cultural beliefs. **CEB:** Give-and-take with the client will lead to culturally congruent care (Leininger & McFarland, 2002).
- Encourage family to use support groups or other service programs to assist with role changes. **EB:** Black clients have a history of not participating in support groups (Seebohm et al, 2010).
- Refer new moms to a new mothers' Internet-based social support network. **EBN:** Many single, low-income African-American mothers lack social support, experience psychological distress, and encounter difficulties caring for their infants during the transition to parenthood. The New Mothers Network may be an effective social support nursing intervention for improving single, low-income African American mothers' psychological health outcome, parenting outcome, and health care utilization outcomes (Hudson et al, 2008).

Home Care

- The preceding interventions may be adapted for home care use.
- ▲ Offer a referral to medical social services to assist with assessing the short- and long-term impacts of role change. **EB:** The discharge planner's role, especially for older adults, is important (Preyde et al, 2009).

Client/Family Teaching and Discharge Planning

- Provide educational materials to family members on client behavior management plus caregiver stress-coping management. **EB:** The capacity for caregivers to rate mild cognitive change in Parkinson disease (PD) may be useful to assist in early screening and intervention approaches (Naismith et al, 2011).
- Help the client identify resources for assistance in caring for a disabled or aging parent (e.g., adult day care, nursing home placement). **EBN:** There is a need for support when a family member is placed in a nursing home (Wilkes et al, 2008). In this study, day care was effective in reducing behavioral and psychological symptoms of clients with dementia and in alleviating caregivers' burden (Mossello et al, 2008).
- Consider pet therapy for college students in a new role, their first semester away from home. **EBN:** In this study, students away from home for the first time felt that a pet therapy program could temporarily fill the absence of previous support systems and be a catalyst for establishing new social relationships (Adamle et al, 2009).

Sedentary lifestyle Sherry H. Pomeroy, PhD, RN

NANDA-I

Definition

Reports a habit of life that is characterized by a low physical activity level

Defining Characteristics

Average daily physical activity is less than recommended for gender and age; physical deconditioning; preference for activity low in physical activity

Related Factors (r/t)

Insufficient interest in physical activity; insufficient knowledge of health benefits associated with physical exercise; insufficient motivation for physical activity; insufficient resources for physical activity; insufficient training for physical exercise

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Ambulation; Activity Tolerance; Endurance; Exercise Participation; Health Promoting Behavior; Lifestyle Balance; Personal Health Status; Physical Fitness; Exercise Promotion

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

List of Nursing Diagnoses by Letter: S

Sedentary lifestyle	Readiness for enhanced Self-Care	Bathing Self-Care deficit
Dressing Self-Care deficit	Feeding Self-Care deficit	Toileting Self-Care deficit
Readiness for enhanced Self-Concept	Chronic low Self-Esteem	Risk for chronic low Self-Esteem
Risk for situational low Self-Esteem	Situational low Self-Esteem	Self-Mutilation
Risk for Self-Mutilation	Self-Neglect	Sexual dysfunction
Ineffective Sexuality pattern	Risk for Shock	Impaired Sitting
Impaired Skin integrity	Risk for impaired Skin integrity	Readiness for enhanced Sleep
Sleep deprivation	Disturbed Sleep pattern	Impaired Social interaction
Social Isolation	Chronic Sorrow	Spiritual distress
Risk for Spiritual distress	Readiness for enhanced Spiritual well-being	Impaired Standing
Stress overload	Risk for Sudden Infant Death syndrome	Risk for Suffocation
Risk for Suicide	Delayed Surgical recovery	Risk for Delayed Surgical recovery
Impaired Swallowing		

Example NOC Outcome with Indicators

Ambulation as evidenced by the following indicators: Walks with effective gait/Walks at moderate pace/Walks up and down steps/Walks moderate distance. (Rate the outcome and indicators of **Ambulation**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Engage in purposeful moderate-intensity cardiorespiratory (aerobic) exercise for 30 to 60 minutes per day on 5 or more days per week for a total of 2 hours and 30 minutes (150 minutes) per week
- Increase exercise to 20 minutes per day (less than 150 minutes per week); light to moderate intensity exercise may be beneficial in deconditioned persons
- Increase pedometer step counts by 1000 steps per day every 2 weeks to reach a daily step count of at least 7000 steps per day, with a daily goal for most healthy adults of 10,000 steps per day
- Perform resistance exercises that involve all major muscle groups (legs, hips, back, chest, abdomen, shoulders, and arms) performed on 2 to 3 days per week
- Perform flexibility exercise (stretching) for each of the major muscle-tendon groups 2 days per week for 10 to 60 seconds to improve joint range of motion; greatest gains occur with daily exercise
- Engage in neuromotor exercise 20 to 30 minutes per day including motor skills (e.g., balance, agility, coordination, and gait), proprioceptive exercise training, and multifaceted activities (e.g., tai chi and yoga) to improve and maintain physical function and reduce falls in those at risk for falling (older persons)
- Meet mutually defined goals of exercise that include individual choice, preference, and enjoyment in the exercise prescription (American College of Sports Medicine [ACSM], 2011b)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Exercise Therapy: Ambulation; Joint Mobility; Positioning; Exercise Promotion; Activity Therapy; Energy Management

Example NIC Activities—Exercise Therapy: Ambulation

Assist the client to use footwear that facilitates walking and prevents injury; Instruct in availability of assistive devices, if appropriate

Nursing Interventions and Rationales

- Observe the client for cause of sedentary lifestyle. Determine whether cause is physical, psychological, social, or ecological. *Some clients choose not to move because of physical pain, social or psychological factors such as an inability to cope, fear, loneliness, or depression, or environmental factors that can influence physical activity (Resnick et al, 2010).* See care plans for Ineffective **Coping** or **Hopelessness**.
- ▲ Assess for reasons why the client would be unable to participate in an exercise program; refer for evaluation by a primary health care provider as needed. *Reducing barriers may increase activity level.*
- Use the Self-Efficacy for Exercise Scale (Resnick & Jenkins, 2000) and the Outcome Expectation for Exercise Scale (Resnick et al, 2001) to determine client's self-efficacy and outcome expectations toward exercise (Resnick & D'Adamo, 2011). **CEB:** *In a meta-analysis of interventions to promote physical activity among chronically ill adults, interventions increased physical activity by an equivalent of 945 steps per day, or 48 minutes of physical activity per week per participant, although the effects on physical activity were variable (Conn et al, 2008; Ruppap & Conn, 2010). Interventions most effective in promoting physical activity were those that focused only on the targeted behavior of physical activity and those that used behavioral strategies (e.g., rewards, contracts, goal setting, feedback and cueing) and self-monitoring (e.g., tracking physical activity using logs or websites). Supervised exercise, tailoring, contracting, exercise prescription, intensity recommendations, behavioral cueing, and fitness testing were also effective, although only modestly supported (Ruppap & Conn, 2010).*

- Recommend the client enter an exercise program with a person who supports exercise behavior (e.g., friend or exercise buddy). **EBN:** *Recommend using fitness smartphone applications for customizing, cueing, tracking, and analyzing an exercise program (Altena, 2012).*
- Recommend the client begin a walking program using the following criteria:
 - Obtain a pedometer by purchase or from community/public health resources.
 - Determine common times when brisk walking for at least 10-minute intervals can be incorporated into lifestyle and daily activities.
 - Set incremental walking goal and increase it by 1000 steps per day every 2 weeks for a minimum of 7,000 steps per day with a daily goal for most healthy adults of 10,000 steps per day (approximately 5 miles) (ACSM, 2011a).
 - Toward the end of day, if client has not met walking goal, look for opportunities to increase activity level (e.g., park farther from destination; use stairs) or go for a walk indoors or outdoors until designated goal of 7000 to 10,000 steps per day is reached (ACSM, 2011a).
- ▲ **EB:** *Use of a pedometer with health care provider counseling and referral to a community action site resulted in a significant increase in physical activity after 6 weeks with inactive participants (Trinh et al, 2011).* **EBN:** *A nurse-monitored 7-week group exercise training program (ETP) with obese women improved adherence to some type of physical activity program 1 year after the intervention period and the likelihood of adherence increased with the number of ETP sessions attended (del Rey-Moya et al, 2013). Recommend client begin performing resistance exercises for additional health benefits of increased bone strength and muscular fitness.*
- Encourage prescriptive resistance exercise of each major muscle group (hips, thighs, legs, back, chest, shoulders, and abdomen) using a variety of exercise equipment such as free weights, bands, stair climbing, or machines 2 to 3 days per week. Involve the major muscle groups for 8 to 12 repetitions to improve strength and power in most adults; 10 to 15 repetitions to improve strength in middle-aged and older persons starting exercise; 15 to 20 repetitions to improve muscular endurance. Intensity should be between moderate (5 to 6) and hard (7 to 8) on a scale of 0 to 10 (ACSM, 2014, 2011b).
- Encourage gradual progression of greater resistance, more repetitions per set, and/or increasing frequency using concentric, eccentric, and isometric muscle actions. Perform bilateral and unilateral single and multiple joint exercises. Optimize exercise intensity by working large before small muscle groups, multiple joint exercises before single-joint exercises, and higher intensity before lower intensity exercises (ACSM, 2011b). **CEB:** *After 8 weeks of high-resistance muscle strength exercise and low-resistance exercise for persons with osteoarthritis, there was significant improvement in both groups for pain, function, walking time, and muscle torque (Jan et al, 2008).*

Pediatric

- Children and adolescents should participate in 60 minutes (1 hour) or more of physical activity daily.
- Aerobic: Sixty or more minutes a day should be either moderate- or vigorous-intensity aerobic physical activity, and should include vigorous-intensity physical activity at least 3 days a week.
- Muscle-strengthening: As part of daily physical activity, children and adolescents should include muscle-strengthening physical activity on at least 3 days of the week.
- Bone-strengthening: As part of daily physical activity, children and adolescents should include bone-strengthening physical activity on at least 3 days of the week.
- Providing activities that are age appropriate, enjoyable, and offer a variety will encourage young people to participate in physical activities (U.S. Department of Health and Human Services, 2012).
- Encourage child to increase the amount of walking done per day; if child is willing, ask him/her to wear a pedometer to measure number of steps. **EB:** *A study demonstrated that the recommended number of steps per day to have a healthy body composition for the 6- to 12-year-old is 10,000 to 13,000 steps for a girl and 12,000 to 16,000 steps for a boy. Evidence shows that adolescents steadily decrease steps/day until approximately 8000 to 9000 steps/day are observed in 18-year-olds (Tudor-Locke et al, 2011).*
- Recommend the child decrease television viewing, watching movies, and playing video games. Ask parents to limit television to 1 to 2 hours per day maximum. **CEB:** *A study demonstrated that watching television was not connected to an increased body mass index (BMI), but watching television advertising, including food advertisements, was associated with obesity in children (Zimmerman & Bell, 2010).*

Geriatric

- Use valid and reliable criterion-referenced standards for fitness testing (e.g., Senior Fitness Test) designed for older adults that can predict the level of capacity associated with maintaining physical independence

into later years of life (e.g., get up and go test). *Interventions can subsequently be designed to target weak areas and therefore help reduce the risk of immobility and dependence (Rikli & Jones, 2012).*

- Recommend the client begin a regular exercise program, even if generally active. **EB:** *A meta-analysis of the association between time in sedentary behavior and hospitalizations, mortality, cardiovascular disease, cancer, and diabetes found prolonged sedentary time associated as an independent risk factor for poor health outcomes despite engagement in physical activity (Biswas et al, 2015).* **CEB:** *Walking is an effective exercise in older adults (Resnick, 2009).* **EB:** *A meta-analysis to determine the effect sizes of exercise on physical function, activities of daily living (ADLs), and quality of life of frail older adults found exercise beneficial in increasing gait speed and improving balance and ADL performance (Chou et al, 2012).*
- ▲ Refer the client to physical therapy for resistance exercise training, as able, involving all major muscle groups. **CEB:** *A Cochrane review found that progressive resistance-strength training for physical disability in older clients resulted in increased strength and positive improvements in some limitations (Liu & Latham, 2009).*
- Use the Function-Focused Care (FFC) rehabilitative philosophy of care with older adults in residential nursing facilities to prevent avoidable functional decline. **EBN:** *The primary goals of FFC are to alter how direct care workers provide care to residents to maintain and improve time spent in physical activity and improve or maintain function. Residents receiving FFC had less functional decline, and a greater percentage who were not ambulating returned to ambulatory status for short functional distances, while residents with dementia also had a significant decrease in falls (28% vs. 50% in the control group) (Resnick et al, 2011; Galik et al, 2013).*
- Recommend the client practice tai chi. **CEB:** *Tai chi resulted in increased function and quality of life for clients with osteoarthritis of the knee (Lee et al, 2009).* Another study demonstrated that clients performing tai chi had better balance (Wong et al, 2009).
- If client is scheduled for an elective surgery that will result in admission into the intensive care unit and immobility, or recovery from a joint replacement, for example, initiate a prehabilitation program that includes a warm-up followed by aerobic, strength, flexibility, neuromotor, and functional task work. **EBN:** *A study of FFC with hospitalized older adults found physical functional declines in both study groups, but less decline was associated with the group receiving FFC. The role of the gerontological rehabilitation nurse is essential throughout the hospital stay and during transitional care (Boltz et al, 2011).*

Home Care

- The preceding interventions may be adapted for home care use.
- ▲ Assess home environment for factors that create barriers to mobility. Refer to physical and occupational therapy services if needed to assist the client in restructuring home environment and daily living patterns. Use home safety assessment tool to prevent falls and improve mobility and function such as the tool found at <http://agingresearch.buffalo.edu/hssat/index.htm>. **EBN:** *Assess person-environment fit (P-E fit) using a reliable and valid instrument such as the Housing Enabler (<http://www.enabler.nu/>) to evaluate the impact of the relationship between the person and his/her environment and subsequently how P-E fit affects physical activity and function (Pomeroy et al, 2011).*

Client/Family Teaching and Discharge Planning

- Work with the client using theory-based interventions (e.g., social, cognitive, theoretical components such as self-efficacy; transtheoretical model). **EBN:** *Residents living in senior housing who attended a 12-week intervention including education, motivational modalities, and exercise classes reported stronger outcome expectations for exercise, less pain, and decreased intake of fat and salt (Resnick et al, 2014).* **CEB:** *In a behavioral validity study that examined the evidence for physical activity stage of change across nine studies, physical activity stage of change was found to be behaviorally valid, evidenced by self-reported exercise, physical activity, pedometers, sedentary behaviors, and physical functioning. Physical fitness and weight indicators were not related to physical activity stage of change (Hellsten et al, 2008).*
- Recommend the client use the Exercise Assessment and Screening for You (EASY) tool to help determine appropriate exercise for the older adult client. This tool is available online at <http://www.easyforyou.info> (Resnick, 2009). **EBN:** *A study found an association between higher EASY cumulative scores with decreased days limited from usual activity and decreased unhealthy physical health outcomes (Smith et al, 2011).*
- Consider using motivational interviewing techniques when working with both children and adult clients to increase their activity. **EBN:** *A study found that use of motivational interviewing along with evidence-based nutritional guidelines and exercise prescriptions was effective in decreasing the BMI and size of*

waistline in children (Tripp et al, 2011). **EB**: Another study found that clients with low back pain who received motivational interviewing were more compliant with performing ordered exercises and had improved physical function (Vong et al, 2011). **CEB**: A study that evaluated compliance of diabetic clients with prescribed exercise found that use of motivational interviewing resulted in increased oxygenation and improved muscle strength and lipid profile (Lohmann et al, 2010).

Readiness for enhanced Self-Care

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

A pattern of performing activities for oneself to meet health-related goals, which can be strengthened

Defining Characteristics

Expresses desire to enhance independence with health; expresses desire to enhance independence with life; expresses desire to enhance independence with personal development; expresses desire to enhance independence with well-being; expresses desire to enhance knowledge of self-care strategies; expresses desire to enhance self-care

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Adherence Behavior; Health-Seeking Behavior; Self-Care Status

Example NOC Outcome with Indicators

Health-Seeking Behavior as evidenced by the following indicators: Completes health-related tasks/Performs self-screening/Obtains assistance from health professionals. (Rate the outcome and indicators of **Health-Seeking Behavior**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Evaluate current levels of self-care as optimum for abilities
- Express the need or desire to continue to enhance levels of self-care
- Seek health-related information as needed
- Identify strategies to enhance self-care
- Perform appropriate interventions as needed
- Monitor level of self-care
- Evaluate the effectiveness of self-care interventions at regular intervals

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Energy Management; Learning Facilitation; Multidisciplinary Care Conference; Mutual Goal Setting; Self-Care Assistance

Example NIC Activity—Self-Care Assistance

Encourage person to perform normal activities of daily living to level of ability

Nursing Interventions and Rationales

- For assessment of self-care, use a valid and reliable screening tool if available for specific characteristics of the person, such as arthritis, diabetes, stroke, heart failure, or dementia. **EBN:** *Graven et al (2015) used a cross-sectional study to examine the relationships among heart failure (HF) clients' (N = 201) physical symptoms, social support, problem solving, depressive symptoms, and self-care behaviors and found that the most reliable predictors of self-care behavior were social support and physical symptoms.* **EBN:** *Asplin et al (2014) developed a new scale to measure basic mobility and self-care, the interdisciplinary Traffic Light System-BasicADL. Testing of the new assessment, which measured the function of older clients in acute care settings, demonstrated high interrater and fair intrarater reliability, making it useful for other self-care studies.*
- Conduct mutual goal setting with the person. **EBN:** *Miertova et al (2014) analyzed two case studies of self-care changes in clients with Parkinson's disease (PD) using semistructured interviews, observation, and analysis of health care records and found that self-care needs to be addressed in the initial stages of PD to promote self-sufficiency in activities of daily living (ADLs).* **EBN:** *Basak et al (2014) studied the effects of the multiple sclerosis (MS), ADLs, and self-care in clients (N = 67) who have had MS for 10 years and found that self-care levels are mainly dependent on the duration of the disease and nursing care should be planned with the client accordingly.*
- Support the person's awareness that enhanced self-care is an achievable, desirable, and positive life goal. **EBN:** *A study was completed to determine the items needed in a prostate cancer survivor's toolkit by asking men (N = 22) who underwent a radical prostatectomy. The preferred items were those that aided in managing urinary symptoms for early postoperative clients, and managing erectile dysfunction aids were preferred by men who were postoperative over 100 days (Weber & Roberts, 2015).* **EBN:** *Using a secondary data analysis, researchers evaluated clients (N = 803) with lower extremity primary lymphedema report of self-care, symptom burden, and reported infections and found a significant relationship among self-care, symptom burden, and reported infections that prompted almost half of them to conduct positive self-care activities, such as using compression garments and participating in skin care (Deng et al, 2015).*
- Show respect for the person, regardless of characteristics and/or background. **EBN:** *This study examined foot care among diabetic Jordanian clients (N = 1085) by questionnaire and found a discrepancy between knowledge and practice, prompting efforts to improve foot self-care education that is appropriate to the client's education and culture (Abu-Qamar, 2014).* **EBN:** *Bagnasco et al (2014) performed a systematic review to find the factors that influence self-management of type 2 diabetes by clients searching specifically for interventions, comparators, outcomes, and study design, which were found to be variables for self-care motivation and empowerment.*
- Promote trust and enhanced communication between the person and health care providers. **EBN:** *Akohoue et al (2015) conducted focus groups to improve type 2 diabetes self-management among low-income minority clients (N = 17), caregivers (N = 5), and health care providers (N = 15) and found the most important self-management issues to be providers' accessibility and compassion, and flexible clinic hours.* **EBN:** *Researchers descriptively studied the relationship between quality of life (QOL) and self-care agency in hemodialysis clients (N = 112) and found a relationship between dialysis adequacy, the emotional role, and physical functioning; therefore, communication about dialysis adequacy is important for the client's self-care agency (Kalender & Tosum, 2014).*
- Promote opportunities for spiritual care and growth. **EBN:** *Hatamipour et al (2015) qualitatively studied the spiritual needs of clients diagnosed with cancer (N = 18) and identified four themes (connection, peace, meaning and purpose, and transcendence) that should be recognized to assist cancer clients with self-care.* **EB:** *Researchers studied the uncertainty experienced by clients (N = 200) with multiple sclerosis (MS) and their spiritual well-being and found that health care professionals should afford clients opportunities to reflect on their spirituality, experiences, feelings, actions, and reactions as a method to constructive self-care learning (Iranmanesh et al, 2014).*
- Promote social support through facilitation of family involvement. **EB:** *Researchers examined clients (N = 100) with type 2 diabetes and the relationship of coping skills and social support with self-care activities and glycated hemoglobin and found a significant relationships between self-care activities producing glycated hemoglobin control, coping styles, and social support (Shaveghian et al, 2015).* **EBN:** *Leikkola et al (2014) assessed aspects of nursing staff support provided to postoperative herniation or spinal stenosis clients (N = 92) and family members (N = 55) and found the most important factor for family and clients in promoting self-care was client education.*

- Provide opportunities for ongoing group support through establishment of self-help groups on the Internet. **EB:** *Koenig et al (2014) studied the relationship between biopsychosocial functioning and pain and pain self-efficacy in clients (N = 99) with low back pain and found that lower biological and social functioning predicted higher pain severity; lower social functioning was found to significantly predict lower pain self-efficacy.* **EB:** *Hartmann-Boyce et al (2015) reviewed 23 weight loss studies and found that interactive interventions were most effective in the first 6 months.*
- Help the person identify and reduce the barriers to self-care. **EBN:** *Researchers descriptively studied the relationship between fatigue, self-care, and loneliness in hemodialysis clients (N = 325) and found that as the levels of loneliness and fatigue increased, self-care ability decreased (Akin et al, 2014).* **EB:** *Shreck et al (2014) studied the relationship between risk perceptions and diabetic self-care (diet and exercise) in a year-long randomized trial in clients (N = 526) who were taking at least one oral diabetes medication; they found no relationships between risk perceptions and glycemic control, but did find a difference in dietary and exercise adherence.*
- Provide literacy-appropriate education for self-care activities. **EBN:** *Clients with heart failure (HF) may have mild cognitive impairment (MCI). A descriptive correlation study assessed levels of self-care and knowledge and found that clients had the knowledge but were unable to maintain self-care scores, indicating that different methods are needed to educate HF clients with MCI on self-care (Davis et al, 2015).* **EB:** *Watson et al (2014) studied veterans (N = 219) with chronic pain by providing them with a 12-week educational program and found the program useful and easy to use, and could be integrated into their self-care. Additionally, veterans would recommend the program to others.*
- Facilitate self-efficacy by ensuring the adequacy of self-care education. **EBN:** *Wu et al (2014) examined perceptions of clients with type 2 diabetes (N = 312) and nurses (N = 202) about self-care activities in Taiwan and found that clients perceived themselves to be more successful at completing self-care tasks than nurses, indicating additional self-care education may be needed.* **EBN:** *A quasi-experimental single group pre-test, post-test investigation was conducted to evaluate an intervention for self-management in overweight African American clients (N = 19). The results demonstrated that patient activation and self-efficacy were strongly related to self-management (Onubogu et al, 2014).*
- Provide alternative mind-body therapies such as reiki, guided imagery, yoga, and self-hypnosis. **EBN:** *Sackett et al (2014) conducted an integrative review (N = 25) of older clients' use of folk medicine and other nontraditional therapies and found that there is significant use by older adults for self-care purposes.* **EBN:** *Fouladbakhsh et al (2014) studied yoga intervention for clients with non-small cell lung cancer and its relationship to sleep mood, salivary cortisol levels, and QOL and found that it did not compromise breathing and had a positive mind-body effect on managing stress, improving mood and sleep, and potentially enhancing QOL.*
- Promote the person's hope to maintain self-care. **EBN:** *Self-care needs of clients with HF were studied by systematic review of the literature (N = 47); researchers concluded that clients with HF often had difficulty translating self-care into ADLs, thereby indicating that individual self-care approaches would best assist clients with HF (Harkness et al, 2015).* **EBN:** *Warnock and Tod (2014) used a qualitative interview technique to explore the experiences, concerns, and priorities of clients (N = 10) with advanced malignant spinal cord compression. Maintaining hope emerged as an important theme in maintaining a positive outlook.*

Pediatric

- Assess and evaluate a child's level of self-care and adjust strategies as needed. **EBN:** *Quaranta et al (2014) conducted focus groups with rural-dwelling adolescents (N = 7) to explore self-management of asthma and its relationship to influences from health care providers, school nurses, teachers, family, and friends. The researchers found that the clients did not perceive that others expected them to change their lifestyle to control their asthma and that they were just expected to use medication.* **EB:** *Chien et al (2014) studied children's hand skills to assess self-care in children with disabilities (N = 114) compared to typically developed children (N = 139) and found through regression analysis that children's hand skill was the strongest variance for children's self-care function. Assessment of hand skill in real-life contexts is needed.*
- Assist families to engage in and maintain social support networks. **EB:** *Interviews of adolescents (N = 28) about their first episode of psychosis identified five themes that assisted clients with self-management; (1) symptom recognition, (2) awareness of change, (3) negative appraisals, (4) positive appraisals, and (5) treatment self-management (Gearing et al, 2014).* **EB:** *Meaux et al (2014) qualitatively studied adolescent clients' (N = 4) and parents' (N = 6) transition to self-management after heart transplantation using online focus*

groups and found that medication management was the most important issue identified for both parents and adolescents.

- Encourage activities that support or enhance spiritual care. **EBN:** *Riet et al (2014)* reported about a healing environment called a “Fairy Garden” created for sick children to enhance holistic care and found that the Fairy Garden supported psychosocial and physical benefits. These benefits improve hospital stay and provide potential for improved clinical self-care outcomes. **EB:** Researchers used a qualitative methodology in children ($N = 9$) and themes that were important to children in their relationships with adults were identified, including making sense of spirituality and keeping spirituality confidential (*Karlsen et al, 2014*).

Multicultural

- Identify cultural beliefs, values, lifestyle practices, and problem-solving strategies when assessing the client's level of self-care. **EBN:** *Yang et al (2014)* used a secondary data analysis to identify variables related to self-care behaviors among hypertensive, older, low-income Korean women ($N = 234$) and found that significant self-care factors included (1) self-efficacy about hypertension control, (2) social support, and (3) age. **EB:** *Rajagopal et al (2014)* studied the standards of palliative care from 57% of Indian palliative care organizations that participated in the study to establish a “standards tool” that can be applied to assist clients to maintain self-care while on palliative care protocols.
- Enhance cultural knowledge by seeking out information regarding different cultural or ethnic groups. **EBN:** *Kleier and Welch Dittman (2014)* studied African American clients ($N = 100$) with diabetes mellitus and variables believed to be important in self-care. The researchers found understanding of diabetes, its treatment, and engagement in self-care activities did not correlate with body mass index and A1c values. **EB:** Researchers qualitatively examined the policies for aging in place for older Czech citizens and study results revealed that allowing clients to remain at home despite their worsening capacity to manage ADLs increased the need for practical support in order for older clients to maintain self-care (*Kubalcikova & Havlikova, 2015*).
- Recognize the impact of culture on self-care behaviors. **EB:** *Paxton et al (2014)* consented African American clients ($N = 291$) with breast cancer to test the validity and reliability of a modified Sedentary Behavior Strategy Self-Management Scale and found that the tool was reliable and valid and considered weight, education, and years since diagnosis of breast cancer but did not consider age. Therefore, further tests are needed to use the tool with older breast cancer survivors. **EBN:** *PeAarrieta-de Cardova et al (2014)* studied the validation the Self-care in Chronic Conditions Partners in Health Scale to use as a screening tool to assess the self-care skills and abilities of Mexican clients with a chronic illness. Study results demonstrated high reliability and validity of the instrument with three themes identified: knowledge, adherence, and dealing with and managing side effects.
- Provide culturally competent care. **EBN:** Researchers performed a systematic review to develop a self-management program for clients with chronic kidney disease in China and used evidence from studies ($N = 22$) to develop clinical guidelines. The researchers sent the program to a panel of experts and the content validity score was 0.98; now it is ready to use and be tested in client populations (*Yu-Chin et al, 2014*). **EB:** *Iten et al (2014)* investigated the relationship between Mexican clients' experience of health care, diabetes self-management, and clinical outcomes and found no significant differences in measures of diabetes management between undocumented and documented immigrants, including clinical outcomes in glycemic, systolic blood pressure, and lipid control.
- Support independent self-care activities. **EBN:** *Omisakin (2014)* examined the health care support of clients ($N = 88$) living with HIV/AIDS and found five different needs including (1) medical support for medication and emergency services, (2) physical support of supplies for the home and nutritional supplement, (3) psychosocial help for emotional and spiritual issues, (4) socioeconomic help with jobs and engagement in community life, and (5) information about HIV/AIDS. **EB:** *Sav et al (2015)* conducted qualitative interviews about how rural residents ($N = 32$) living with chronic conditions self-managed their chronic conditions in locations with limited resources and found that self-managing required creativity in order for clients to take care of their health care needs.

Home Care

- The nursing interventions described previously may also be used in home care settings. **EB:** *Lawn et al (2014)* examined interprofessional health care provider-client interactions during care planning for the home setting ($N = 19$) and found that health care providers need to be more aware of their power and their

communication style in order for clients with chronic condition to improve their self-care management at home. **EBN:** This study examined outpatient oncology treatments using a client report checklist that looked at 12 symptoms: hair loss, feeling sluggish, nausea, taste change, loss of appetite, depression, difficulty sleeping, weight loss, difficulty concentrating, constipation, skin changes, and numb fingers and toes. Helpful self-care strategies reported included diet and nutrition changes, lifestyle changes, mind-body control, and spiritual activities (Williams et al, 2014).

- Support the new sense of self that may occur with complex health problems. **EBN:** Peng et al (2014) examined goal-setting practices of physical therapists in the community who worked with clients (N = 296) with chronic conditions and found no significant relationship between sex, age, or number of chronic conditions and self-management goals, thereby acknowledging that it is possible to set goals regardless of the client's sex, age, or number of chronic conditions. **EB:** A study examined whether older clients (N = 200) would decrease sarcopenia and impaired self-sufficiency during acute illnesses with nutritional therapy and intensive rehabilitation and the interventions prevented the muscle loss, thereby improving function when compared to a control group (Hegerova et al, 2015).
- Assist individuals and families to prevent exacerbations of chronic illness symptoms so rehospitalization is not necessary. **EBN:** Bratzke et al (2015) completed a literature review about self-management related to priority setting and decision-making among clients with multiple morbidities and found most studies (N = 13) addressed processes, facilitators, and self-management barriers, and health care providers need to be cognizant that individuals with multiple morbidities engage in day-to-day priority setting and decision-making as self-care activities for multiple chronic illnesses and treatments.
- In complex chronic illnesses such as heart failure, help individuals and families to accept continued functional disabilities and work toward maintenance of optimum functional status, considering the reality of illness status. **EB:** Evangelista et al (2015) used remote monitoring systems to determine its effect on activation, self-care, and QOL in older clients (N = 21) with HF and found greater improvements in activation, self-care, and QOL. **EBN:** Tao et al (2014) qualitatively studied families/clients' (N = 7) self-care behavior when caring for their colostomy and identified that "taking good care of myself" involved (1) "taking care of my colostomy with a proper degree of independence," (2) "taking care of my life by dealing with limitations," and (3) "taking care of my mood in a positive way."
- Use educational guidelines for stroke survivors. **EB:** Hale et al (2014) examined the UK Bridges stroke self-management program through case study analysis with a focus group (N = 60) and neurorehabilitation therapists (N = 17) and found the program to be acceptable and beneficial for developing skills to self-manage recovery following stroke. **EBN:** Researchers studied self-management interventions in clients who experienced a stroke to specifically look at medication adherence. A literature review (N = 6) demonstrated that interventions to assist with self-care improved medication adherence in this population (Chapman & Bogle, 2014).
- Ensure appropriate interdisciplinary communication to support client safety. **EBN:** Cramm et al (2014) investigated whether communication and coordination is greater between primary care health care professionals and community health nurses than among other professionals and found that it was and assisted with the self-care of older adults in the community setting. **EB:** Maneze et al (2014) explored multidisciplinary care of clients with type 2 diabetes (N = 13) and qualitatively demonstrated that clients found it a barrier to be referred to multiple professionals and that communication among the health care team members was poor.
- Enhance individual and family coping with chronic illnesses. **EBN:** Shaw and Oneal (2014) studied asthma-related emergency department using a grounded-theory approach (N = 20) and identified the theoretical basis of "living with asthma" included categories of balancing, losing control, seeking control, and transforming, all of which can assist the health care provider in understanding clients' asthma self-care. **EBN:** Arestedt et al (2014) studied the lived experience of living as a family in the midst of chronic illness and narrative interviews (N = 7) revealed a phenomenon that is ongoing and moves the family toward well-being. Analysis identified two themes: co-creating a context for living with illness and co-creating alternative ways for everyday life, demonstrating ways that family members manage situations together.
- Implement a community care management program. **EBN:** The development of a self-care program for clients aged 65 years and older demonstrated an increased QOL and coherence among older adults who were living at home (Tan et al, 2014). **EB:** Cassani (2014) states that studies demonstrate that intermittent self-catheterization is a better option than long-term catheters for clients in the community because they decrease morbidity, increase QOL, and decrease health care visits.

Client/Family Teaching and Discharge Planning

- Teach clients how to regularly assess their level of self-care.
- Instruct clients that a variety of interventions may be needed to enhance self-care.
- Help clients to understand that enhanced self-care is an achievable goal.
- Empower clients.
- Teach clients about the decision-making process and self-care activities needed to manage their illness state and promote well-being.
- Continuously stress that all self-care activities must be regularly evaluated to ensure that enhanced levels of self-care can be maintained.

Bathing Self-Care deficit *Linda S. Williams, RN, MSN*

NANDA-I

Definition

Impaired ability to perform or complete bathing activities for self

Defining Characteristics

Impaired ability to dry body; impaired ability to access bathroom; impaired ability to access water; impaired ability to gather bathing supplies; impaired ability to regulate bath water; impaired ability to wash body

Related Factors (r/t)

Alteration in cognitive functioning; anxiety; decrease in motivation; environmental barrier; impaired ability to perceive body part; impaired ability to perceive spatial relationships; musculoskeletal impairment; neuromuscular impairment; pain; perceptual impairment; weakness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Self-Care: Activities of Daily Living (ADLs); Self-Care: Bathing; Self-Care: Hygiene

Example NOC Outcome with Indicators

Self-Care: Activities of Daily Living (ADLs) as evidenced by the following indicators: Bathing/Hygiene. (Rate outcome and indicators of **Self-Care: Activities of Daily Living (ADLs)**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see [Section 1](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of body odor and maintain intact skin
- State satisfaction with ability to use adaptive devices to bathe
- Use methods to bathe safely and effectively with minimal difficulty
- Bathe with assistance of caregiver as needed and report satisfaction, and dignity maintained during bathing experience
- Bathe with assistance of caregiver as needed without exhibiting defensive (aggressive) behaviors

S

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Self-Care Assistance: Bathing/Hygiene

Example NIC Activities—Self-Care Assistance: Bathing/Hygiene

Determine amount and type of assistance needed; Consider the culture of the client when promoting self-care activities; Provide assistance until client is fully able to assume self-care

Nursing Interventions and Rationales

- **QSEN** (Patient-Centered): Ask patients their bathing preferences, which can increase patient privacy and satisfaction. **EBN**: *Perceptions of patients (N = 71) after an acute myocardial infarction who received bed baths were not as positive as those of patients who took showers (Lopes et al, 2013).*
- **QSEN** (Safety): Warm bathing area above 25.1° C (77.18° F) while bathing, especially on cold days. **EB**: *Bathing and ambient temperature decreasing from 25.1° C can be a trigger for increasing occurrence of out-of-hospital cardiac arrest (Nishiyama et al, 2011).*

• = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

- QSEN (Safety): Use chlorhexidine-impregnated cloths rather than soap and water for daily patient bathing. **EB:** *Chlorhexidine reduces hospital-acquired infection risk from the potentially harmful pathogens methicillin-resistant Staphylococcus aureus (MRSA) and vancomycin-resistant Enterococcus (VRE) (Kassakian et al, 2011).*
- QSEN (Safety): Consider using a prepackaged bath, especially for patients at high risk for infection (older adult, immunocompromised, invasive procedures, wounds, catheters, drains), to avoid patient exposure to multidrug-resistant pathogens from contaminated bath basins. **EB:** *In a 44-month study by Marchaim et al (2012), hospital bath basins (N = 1103) were found 62.2% of the time to be contaminated with hospital-acquired pathogens.*
- QSEN (Safety): Use chlorhexidine gluconate for bath basin bathing. **EBN:** *Powers et al (2012) found in a study (N = 90) that when patients are bathed with chlorhexidine gluconate and a bath basin that the bacterial growth in the bath basin is significantly reduced.*
- QSEN (Patient-Centered): Use patient-centered bathing interventions: plan for patient's comfort and bathing preferences, show respect in communications, critically think to solve issues that arise, and use a gentle approach. **CEB:** *Focusing on the patient rather than the task of bathing results in greater comfort and fewer aggressive behaviors, which are likely defensive behaviors that result from feeling threatened or anxious, and increase with shower (especially) and tub bathing (Hoeffler et al, 2006).*
- ▲ Provide pain relief measures, such as ice packs, heat, and analgesics for sore joints 45 minutes before bathing; move extremities slowly and carefully; and inform the client before movements associated with pain occur (walking; transferring to a new location; moving joints; and washing genitals, face, and between toes and under arms). Have the client wash painful areas; recognize indicators of pain and apologize for any pain caused. **CEB:** *Pain relief and client participation reduce discomfort, preserve dignity, and give a sense of control (Rader et al, 2006).*
- Use a comfortable padded shower chair with foot support, or adapt a chair: pad it with towels/washcloths, cover the cold back with dry towels, and cover the arms with foam pipe insulation. **CEB:** *Unpadded shower chairs with large openings and no foot support contribute to pain by allowing clients to sink into the opening with their feet unsupported (Rader et al, 2006).*
- Ensure that bathing assistance preserves client dignity through use of privacy with a traffic-free bathing area and posted privacy signs, timeliness of personal care, and conveyance of honor and recognition of the deservedness of respect and esteem of all persons. **CEBN:** *Older adults report that dignity is promoted via respect, independence, exerting control, timeliness, privacy for the body, cleanliness, independence and sufficient time from staff, attitudes to older people, and communication (Webster & Bryan, 2009).*
- For cognitively impaired clients, avoid upsetting factors associated with bathing: instead of using the terms *bath, shower, or wash*, use comforting words, such as *warm, relaxing, or massage*. Start at the client's feet and bathe upward; bathe the face last after washing hands and using a clean cloth. Use a beautician/barber or wash hair at another time to avoid water dripping in the face. **CEB:** *Some words are associated with unpleasant bathing experiences, whereas others convey a pleasant bathing experience. Starting with the face or hair is distressing, because water drips on the face and the head becomes cold and wet (Rader et al, 2006).*
- Use towel bathing to bathe client in bed, a bath blanket, and warm towels to keep the client covered the entire time. Warm and moisten towels/washcloths and place in plastic bags to keep them warm. Use the towels to massage large areas (front, back) and one washcloth for facial areas and another one for genital areas. No rinsing or drying is needed as is commonly thought for bathing. **CEB:** *Towel bathing is a gentle experience with less discomfort that significantly reduces aggression as well as bathing time and soap residue over showering without accumulation of pathogenic bacteria (Hoeffler et al, 2006).*
- QSEN (Patient-Centered): For shower bathing: use patient-centered techniques, keep patient covered with towels and cleanse under the towels, use no-rinse products, use favorite bathing items, and use a handheld shower with adjustable spray. **CEB:** *Covering the patient is an easy means to maintain dignity, reduce embarrassment, and keep the patient warm and unexposed without increasing bathing time (Rader et al, 2006).*
- ▲ QSEN (Teamwork and Collaboration): Request referral of patient who has had a stroke to rehabilitation services. **EB:** *In a systematic review of 19 studies, Mehrholz et al (2012) found that electromechanical and robot-assisted arm training devices used in rehabilitation may assist in improving arm function after stroke, which is important for activities of daily living such as bathing.*
- ▲ QSEN (Patient-Centered): Use a wrapped warm footbath for relaxation in patients with cancer. **EBN:** *Yamamoto and Nagata (2011) found in a randomized controlled trial that the wrapped warm footbath in patients with cancer can increase relaxation and provide pain relief.*

Geriatric

- **QSEN (Patient-Centered, Safety):** Advocate for the use of the Bathing Without a Battle educational program for patients with dementia. **EB:** *In a randomized crossover diffusion study, the Bathing Without a Battle educational program that trains caregivers in methods for improving the bathing experience of patients with dementia in nursing homes was found to be effective in reducing the rate of aggressive and agitated behaviors (Gozalo et al, 2014).*
- **QSEN (Patient-Centered):** Provide night time bathing options for nursing home residents. **EBN:** *Hashimoto (2014) in an interview survey of administrators of nursing homes (N = 3) found that night time bathing options provided more flexibility for bathing needs, improved sleep and quality of life for the residents, and for caregivers improved care quality and ability to provide patient-centered care.*
- Design the bathing environment for comfort: **Visual.** Reduce clutter and use partitions to hide equipment storage. Laminate and put artwork or decorative objects in bather's view, or place cue cards to bathing process (wall, ceiling, shower). Stand or sit in bather's position to experience what he/she sees. Decrease glare from tiles, white walls, and artificial lights. Use contrasting colors and soft but adequate lighting on a dimming switch for adjustment. *Bathing rooms are sterile, institutional, and frightening spaces filled with unfamiliar equipment—tubs with sides that open up and look like they might swallow you, or gurneys with arms that look like construction cranes. Overhead lights can be bright and shine into the bather's eyes. Glare can cause visual discomfort, especially in clients with visual changes or cataracts (Calkins, 2005).*
- Arrange the bathing environment to promote sensory comfort: **Auditory.** Reduce noise of voices and water. Do not allow traffic into bathing room. Add fabric to absorb sound (three to four times the width of the opening for sound-absorbing folds). Play soft music. **CEB:** *Noise discomfort can result from high-echo tiled walls, loud voices, and running water. Traffic can compromise privacy. Absorb negative sounds, and add positive sounds through music (Calkins, 2005).* **EBN:** *In an observational study (N = 53) by Joosse (2012), sound was a predictor of agitation for those with dementia.*
- Design the bathing environment for comfort: **Tactile.** Use heat lamps or radiant heat panels to keep the room warm. Use powder-coated grab bars in decorative colors with nonslip grip. Provide a soft rug to stand on. Ensure that flooring is not slippery (a high coefficient of friction, ideally above 80, is desired and obtained through flooring coatings). **CEB:** *If the caregiver is warm to the point of sweating, room temperature is about right for an older person being bathed. Appealing, stable grab bars are needed for balance. Preventing the floor from becoming slippery from water is essential (Calkins, 2005).*
- Use music during shower for clients with dementia. *Music may reduce agitation and improve moods to increase job satisfaction (Ray & Fitzsimmons, 2014).*
- Train caregivers bathing clients with dementia to avoid behaviors that can trigger assault: confrontational communication, invalidation of the resident's feelings, failure to prepare a resident for a task, initiating shower spray or touch during bathing without verbal prompts beforehand, washing the hair/face, speaking disrespectfully to the client, and hurrying the pace of the bath. **CEB:** *During bathing, assaults (defensive behavior) by nursing home residents with dementia are frequently triggered by caregiver actions that startle, frighten, hurt, or upset the resident. This might happen when caregivers spray water on a resident without warning or when they touch a resident's feet, axilla, or perineum, possibly due to the startle reflex (Somboontanont et al, 2004).*
- Develop awareness of the ethics of presence during bathing to better meet clients' needs. **Raholm (2012)** found in a phenomenological study of nurses in elder care (N = 7) who discussed bathing that one must go beyond being physically present and enter into a caring relationship in which there is no indifference to the client's unique needs.
- Focus on the abilities of the client with dementia to obtain client's participation in bathing. **EBN:** *The use of an abilities-focused approach increases the ability of people with dementia to participate in their care (Sidani et al, 2012).*
- **QSEN (Patient-Centered):** Use a Chinese herb formula in bath water to reduce paraplegia spasm. **EB:** *In a randomized controlled trial by Liu et al (2014), Chinese herbs placed in bath water (N = 160) reduced paraplegia spasticity.*

Multicultural

- **QSEN (Patient-Centered):** Ask the patient for input on bathing habits and cultural bathing preferences. **CEB:** *Bathing is a personal experience with variability in attitudes, preferences, and adaptations to disability to be considered when developing interventions for bathing (Ahluwalia et al, 2010).*

Home Care

- If in a typical bathing setting for the client, assess the client's ability to bathe self via direct observation using physical performance tests for ADLs. *Observation of bathing performed in an atypical bathing setting may result in false data.*
- **QSEN (Safety):** Turn down temperature of water heater and recommend use of a water temperature-sensing shower valve to prevent scalding. *Older or disabled people have slower reflexes to respond to hot water and may be unable to regulate water temperature, yet they may be left unattended. Water at 130° F produces a first-degree burn in 20 seconds; at 135° F to 140° F, exposure for 5 to 6 seconds causes third-degree burns (Fathers, 2004).*

Client/Family Teaching and Discharge Planning

- Inform clients with extremity casts or bandages of inexpensive options to protect these devices during showering such as with plastic newspaper bags or bread bags. In a case study, [Naram et al \(2011\)](#) report on the use of inexpensive or free cast and bandage protector bags.

Dressing Self-Care deficit *Linda S. Williams, RN, MSN*

NANDA-I

Definition

Impaired ability to perform or complete dressing activities for self

Defining Characteristics

Decrease in motivation; discomfort; environmental barrier; fatigue; impaired ability to choose clothing; impaired ability to fasten clothing; impaired ability to gather clothing; impaired ability to maintain appearance; impaired ability to pick up clothing; impaired ability to put clothing on lower body; impaired ability to put clothing on upper body; impaired ability to put on various items of clothing (e.g., shirt, socks, shoes); impaired ability to remove clothing item (e.g., shirt, socks, shoes); impaired ability to use assistive device; impaired ability to use zipper; musculoskeletal impairment; neuromuscular impairment; pain

Related Factors (r/t)

Alteration in cognitive functioning; anxiety; perceptual impairment; weakness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Self-Care: Activities of Daily Living (ADLs), Dressing, Hygiene

Example NOC Outcome with Indicators

Self-Care: Dressing as evidenced by the following indicators: Gets clothing from drawer and closet/Puts clothing on upper body and lower body. (Rate outcome and indicators of **Self-Care: Dressing**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Dress and groom self to optimal potential
- Use assistive technology to dress and groom
- Explain and use methods to enhance strengths during dressing and grooming
- Dress and groom with assistance of caregiver as needed

S

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Self-Care Assistance: Dressing/Grooming

Example NIC Activities—Self-Care Assistance: Dressing/Grooming

Be available for assistance in dressing, as necessary; Reinforce efforts to dress self; Maintain privacy while the client is dressing

Nursing Interventions and Rationales

- ▲ **QSEN** (Teamwork and Collaboration): Assess functional impairment and report functional changes to health care provider to aid in earlier cancer diagnosis. **EB**: *Functional impairments were found to be symptoms during the diagnostic phase that occurred in clusters based on cancer site: head/neck—impairments in dressing, eating/feeding, bathing, toileting, and walking (Fodeh et al, 2013).*
- **QSEN** (Patient-Centered): Assess a patient's range of movement, upper limb strength, balance, coordination, functional grip, dexterity, sensation, and ability to detect limb position. *Dressing requires complex functions, and any impairment in these areas causes problems with dressing (Swann, 2011a).*

• = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

- ▲ QSEN (Patient-Centered): Assess independence in dressing and bathing skills after rehabilitation to determine the need for follow-up care. **EB:** *It was found that dressing and bathing independence at rehabilitation discharge were predictors of independence at 5 years after stroke (De Wit et al, 2014).*
- ▲ QSEN (Teamwork and Collaboration): Refer patients with hand deformities due to rheumatoid arthritis to occupational therapy for self-care rehabilitation. **EB:** *Patients with rheumatoid arthritis who had hand deformities were found to have difficulty with dressing and grooming (Köybaş et al, 2011).*
- QSEN (Patient-Centered): Recognize that dressing is a private task; encourage patient to participate as much as possible regardless of length of time needed. *Patients may be embarrassed when needing assistance to dress, so discreet help should be provided (Swann, 2011a).*
- QSEN (Safety): Encourage patient to sit while dressing to reduce exertion and provide safety for poor balance or postural hypotension. *Dressing and undressing is a complex and tiring event that can be carried out from a seated position (Swann, 2011a).*
- QSEN (Patient-Centered): Dress the affected side first, then the unaffected side; reverse the process for undressing. *Dressing the affected side first allows for easier manipulation of clothing (Swann, 2011a).*
- QSEN (Patient-Centered): Use adaptive dressing and grooming equipment as needed (e.g., long-handled brushes, long grasping devices, button hooks, elastic shoelaces, Velcro shoes, soap-on-a-rope, suction holders). *Adaptive devices increase self-care ability and can decrease exertion (Swann, 2011b).*

Geriatric

- QSEN (Patient-Centered): Offer residents choices in what to wear and ensure staff is trained to do so. *A controlled study by Schnelle et al (2013) provided training of nursing aides on how to offer long-term care residents (N = 169) morning care choices that resulted in increased frequency of choice being offered in timing for getting out of bed, clothing selection, and incontinence care.*
- QSEN (Patient-Centered): Allow post-stroke patients who are cognitively impaired, especially if unimanual, to practice dressing. **EB:** *Fletcher-Smith et al (2012) found that bimanual cognitively impaired stroke survivors did better with dressing skills than those who are unimanual although with practice those with arm paresis improved significantly.*
- QSEN (Patient-Centered): Maintain resident's individualized style in clothing as select adaptive clothing: loose clothing; elastic waistbands and cuffs; square, large arm holes; seamless or reversible clothing without a specific front or back; dresses that open down the back and short coats (for wheelchair users); Velcro fasteners; larger or magnetic buttons; zipper pulls for grasping; and absorbent scarves for drooling that can be easily changed. *Adapting clothing can make dressing easier for those with impaired mobility or fine motor skills and help prevent pressure sores (Swann, 2011b).*
- QSEN (Patient-Centered): Lay clothing upon a contrasting color surface for patient selection. *Ensure patients can see clothing for selection by placing it on a contrasting surface (Swann, 2011a).*
- QSEN (Patient-Centered): Inform patient that a winter coat with a funnel sleeve design can be easier to put on. **EB:** *Green et al (2011) found that older adults (N = 8) required less shoulder range of motion in putting on a winter coat with a funnel sleeve design, which could reduce social isolation in winter.*
- Use clocks and explanations for the client with dementia to convey that it is morning and time to get ready for the day's activities by dressing. *Clients with memory issues can be assisted to establish a routine for dressing by (Swann, 2011a).*
- Lay clothing out (with label in back facing up) in the order that it will be put on by the client, either one item at a time or in piles with first item on top of pile. *Clients with dementia may have difficulty recognizing what a clothing item is and in what order and how to put it on (Swann, 2011a).*

Multicultural

- Consider use of assistive technology versus personal care assistance for Native Americans. **CEB:** *Older American Indians use more assistive technology for assistance with ADLs than the general same-age population (Goins et al, 2010).*

Home Care

- QSEN (Patient-Centered): Teach assisted living staff the philosophy and methods to increase resident participation in dressing. **EBN:** *Staff awareness and knowledge increased significantly after a training program to encourage residents to participate more in dressing themselves (Walker et al, 2013).*
- QSEN (Patient-Centered): Refer and encourage patients to participate in occupational therapy home rehabilitation programs. **EB:** *A case study revealed that rehabilitation in the home setting showed significant*

functional improvement over inpatient rehabilitation, with the client reporting more empowerment in the home setting (Lackie & Bisset, 2012).

Client/Family Teaching and Discharge Planning

- **QSEN (Patient-Centered):** Assess previously independent patients upon hospital admission for risk factors for new-onset disability that will require assistance with ADLs to plan preventive disability care and/or discharge care. **EB:** Mehta et al (2011) found that a clinical index can identify previously independent hospitalized older adults for new onset disability: age older than 80 years, dependence in three or more IADLs 2 weeks before admission, mobility 2 weeks before admission, dependent for 2 or more ADLs, meta-static cancer or stroke, severe cognitive impairment, albumin less than 3 g/dL.
- ▲ **QSEN (Patient-Centered):** Request referral for occupational therapy for clients who have had a stroke for dressing rehabilitation. **EB:** A descriptive study of energy expenditure of upper and lower body dressing in clients after stroke (N = 23) found that more energy was used to dress the upper body and length of time to dress was four times longer than in the control group (Singh et al, 2011).

Feeding Self-Care deficit *Linda S. Williams, RN, MSN*

NANDA-I

Definition

Impaired ability to perform or complete self-feeding activities

Defining Characteristics

Impaired ability to bring food to the mouth; impaired ability to chew food; impaired ability to get food onto utensils; impaired ability to handle utensils; impaired ability to manipulate food in mouth; impaired ability to open containers; impaired ability to pick up cup; impaired ability to prepare food; impaired ability to self-feed a complete meal; impaired ability to self-feed in an acceptable manner; impaired ability to swallow food; impaired ability to swallow sufficient amount of food; impaired ability to use assistive device

Related Factors (r/t)

Alteration in cognitive functioning; anxiety; decrease in motivation; discomfort; environmental barrier; fatigue; musculoskeletal impairment; neuromuscular impairment; pain; perceptual impairment weakness

NOTE: Specify level of independence using a standardized functional scale.

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Self-Care: Activities of Daily Living (ADLs), Eating

Example NOC Outcome with Indicators

Self-Care: Eating as evidenced by the following indicators: Opens containers/Uses utensils/Completes a meal. (Rate the outcome and indicators of **Self-Care: Eating**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section 1].)

Client Outcomes**Client Will (Specify Time Frame)**

- Feed self safely and effectively
- State satisfaction with ability to use adaptive devices for feeding
- Use assistance with feeding when necessary (caregiver)

NIC (Nursing Interventions Classification)**Suggested NIC Intervention**

Self-Care Assistance: Feeding

Example NIC Activities—Self-Care Assistance: Feeding

Provide adaptive devices to facilitate the client's feeding self (e.g., long handles, handle with large circumference, or small strap-on utensils), as needed; Provide frequent cueing and close supervision as appropriate

S**Nursing Interventions and Rationales**

- **QSEN (Safety)**: Consider assessment of patients in the intensive care unit (ICU) and stepdown patients or of patients with acute stroke for readiness of an oral diet with a 3-oz water swallow challenge by a trained provider. **EB**: *If a 3-oz water swallow challenge, administered by a trained provider to a patient in ICU or to a stepdown patient, is passed, then an individualized diet plan can be made safely (Leder et al, 2011).* **EB**: *Leder et al (2012) studied (N = 75) patients with acute stroke who were given a 90-mL water swallow challenge and found that specific oral diets could be successfully recommended after passing the 90-mL water swallow challenge.*
- **QSEN (Patient-Centered)**: Conduct repeat structured observations of patients at mealtime after a stroke to detect patients with eating difficulties to prevent possible social and functional consequences. **EBN**: *In a longitudinal and comparative study (N = 36), Medin et al (2012) found eating difficulties continued among clients 3 months after stroke despite improvement in other physical functions, indicating that factors such as psychological well-being should be assessed.*
- ▲ **QSEN (Patient-Centered)**: Develop an overriding guideline for assisted feeding so it is less dependent on a caregiver's own beliefs, time pressures, and organizational characteristics. **EBN**: *Martinsen and Norlyk (2012a) conducted a qualitative study interviewing caregivers (N = 12) on their experience with assisted feeding and found a focus on nutrition blended with their own beliefs and societal norms about eating.*
- ▲ **QSEN (Patient-Centered)**: Prioritize assisted feeding as important in a caregiver's assignment to allow adequate dedicated time to the activity. **EBN**: *The experience of assisted feeding for clients with language impairment (N = 42) depends on the caregiver's availability and goal for efficiency rather than the relational and affective aspects of meals, which institutions could address with flexible feeding assistance times that are free from other responsibilities (Martinsen & Norlyk, 2012b).*

- ▲ QSEN (Teamwork and Collaboration): Give priority to continuity in the cooperation between the parties involved in assisted feeding for those who are completely dependent. **CEBN**: *The continuity in the cooperation between the parties involved in assisted feeding is significant in creating a new eating pattern (Martinsen et al, 2008).*
- QSEN (Patient-Centered): Consult patient on the benefit or desire to use assistive devices for feeding. **CEBN**: *The value of a particular assistive device can only be determined by the patient, who may feel that it is insulting (Martinsen et al 2008).*
- QSEN (Safety): Presentation of feeding: provide 1 teaspoon of solid food or 10 to 15 mL of liquid at a time; wait until patient has swallowed the prior food/liquid. **CEB**: *Feeding large volumes and feeding quickly occurred commonly because caregivers lacked knowledge that this could exacerbate dysphagia and increase the risk of health problems (Pelletier, 2004).* **EBN**: *For a water swallow to accurately identify dysphagia, it is critical to administer 10 teaspoons (Martino et al, 2014).*
- QSEN (Safety): Ensure oral care is provided to all patients regardless of type of feeding. **EBN**: *Patients receiving tube feedings had inferior oral hygiene in comparison to those receiving oral feeding, creating a higher risk for aspiration pneumonia for patients receiving tube feedings (Maeda et al, 2011).*

Geriatric

- QSEN (Safety): Assess for tooth loss in older patients prior to feeding. **EB**: *Tooth loss contributes to swallowing difficulties that can increase risk of aspiration in the older patient (Okamoto et al, 2012).*
- QSEN (Patient-Centered): Assess the ability of patients with dementia to self-feed, and supervise the feeding of those with moderate dependency by providing verbal or physical assistance. **CEBN**: *Although low-dependency patients can self-feed, and those with severe dependency are fed, food intake among residents with moderate dependence is often ignored (Lin et al, 2010).*
- QSEN (Patient-Centered): Implement Montessori interventions for patients with dementia who have eating problems, such as playing music to signal learning session start for hand-eye coordination, scooping, pouring, and squeezing activities. **EBN**: *In an experimental crossover design, Lin et al (2011) confirmed that use of a Montessori intervention method for those with dementia helps maintain self-feeding ability and can reduce caregiver feeding frequency.*
- ▲ QSEN (Patient-Centered): Reduce interruptions during mealtimes and provide additional feeding assistance for older patients, especially those with cognitive impairment. **EB**: *Additional assistance with feeding and protected mealtimes while hospitalized can improve nutritional intake in older clients (Young et al, 2013).*
- QSEN (Patient-Centered): Use high-calorie oral supplements for patients with advanced dementia. **EB**: *Desirable weight gain has been shown with the use of high-calorie oral supplements in patients with dementia who have feeding problems (Hanson et al, 2011).*
- QSEN (Patient-Centered): Provide nutritional supplement drinks in a glass to older adults with cognitive impairment. **EBN**: *Allen et al (2014) conducted a non-blind randomized control trial that identified that the best method to provide nutritional supplement drinks to older adults with cognitive impairment is in a glass/beaker rather than using a straw in the container.*
- QSEN (Patient-Centered): Allow a resident an average of 42 minutes of staff time per meal and 13 minutes per between-meal snack to improve oral intake. **CEB**: *When these time frames are provided for staff to assist with meals and snacks, improved oral intake and weight gain in residents at risk for weight loss results (Simmons et al, 2008).*
- QSEN (Patient-Centered): Discuss meaningful life topics, as identified by family members, with residents with dementia during mealtimes. **EB**: *Cleary et al (2012) found that conversations during meals that generated reminiscence may improve food intake during the reminiscence state for residents with dementia.*
- QSEN (Patient-Centered): Encourage family visits at mealtimes for patients with dementia. **EB**: *Family participation at mealtimes increased feeding assistance and helped promote satisfactory adaptation to the nursing home environment, Durkin et al (2014) found in a study of 74 residents and their visitors during mealtimes.*
- QSEN (Patient-Centered): Play familiar music during meals for clients with dementia. **EB**: *Agitation often increases at mealtimes in patients with dementia, which music seems to reduce (Whear et al, 2014).*
- Use aromatherapy with the smell of baking bread for those with dementia. **CEB**: *The smell of baking bread increased intake of food and self-feeding in those with dementia (Cleary et al, 2008).*
- ▲ QSEN (Teamwork and Collaboration): Provide feeding training and education programs for nursing home staff. **EBN**: *Wen et al (2014) did a systematic review of the literature about interventions for mealtime*

difficulties in older adults with dementia and found that training and education programs for professionals demonstrated moderate evidence to increase eating time and decrease feeding difficulty.

Multicultural

- **QSEN** (Patient-Centered): For those with impaired hand function who use chopsticks, suggest adapted chopsticks. **CEB**: *In a pilot equipment study, adapted chopsticks, which can be inexpensive and easily constructed, for those with lower cervical spinal cord injury and residual gross grasp were found to convert gross grasp into 2-point pinch (Chang et al, 2006).*
- **QSEN** (Patient-Centered): Use the simplified Chinese Edinburgh Feeding Evaluation in Dementia scale to measure feeding problems in people with dementia from Mainland China and other Chinese cultural groups. **EBN**: *Identifying patient behaviors during feeding allows development of effective interventions for feeding (Liu et al, 2014).*

Home Care

- **QSEN** (Teamwork and Collaboration): Request referral for physical therapy and occupational therapy to assess client's ability to position and self-feed and provide client and caregiver support with feeding. **EB**: *Ingestive skill difficulties are frequent among acutely-hospitalized frail elderly patients (Hansen et al, 2012).*

Client/Family Teaching and Discharge Planning

- **QSEN** (Teamwork and Collaboration): Discuss with family caregivers, who are involved in the feeding of a family member with advanced dementia, the feeding experience to provide support to ensure that the mealtime purpose is preserved. **EBN**: *Lopez et al (2011) in a phenomenological study interviewed family caregivers (N = 16) of those with advanced dementia who indicated that the feeding assistance experience was like living in a time warp with an uncertain future.*
- ▲ **QSEN** (Patient-Centered): Educate family members that neither insertion of a feeding tube nor timing of its insertion affects client survival for those with advanced dementia who have eating problems. **EB**: *Teno et al (2012) studied all nursing home residents with advanced dementia who had eating problems from 1999 to 2007 (N = 36,492) and found that survival was not affected by insertion of or timing of insertion of a percutaneous endoscopic gastrostomy feeding tube.*

Toileting Self-Care deficit *Linda S. Williams, RN, MSN*

NANDA-I

Definition

Impaired ability to perform or complete self-toileting activities

Defining Characteristics

Impaired ability to complete toilet hygiene; impaired ability to flush toilet; impaired ability to manipulate clothing for toileting; impaired ability to reach toilet; impaired ability to rise from toilet; impaired ability to sit on toilet

Related Factors (r/t)

Alteration in cognitive functioning; anxiety; decrease in motivation; environmental barrier; fatigue; impaired ability to transfer; impaired mobility; musculoskeletal impairment; neuromuscular impairment; pain; perceptual impairment; weakness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Self-Care: Activities of Daily Living (ADLs), Toileting

Example NOC Outcome with Indicators

Self-Care: Toileting as evidenced by the following indicators: Responds to full bladder and urge to have a bowel movement in a timely manner/Gets to toilet between urge and passage of urine/between urge and evacuation of stool. (Rate the outcome and indicators of **Self-Care: Toileting**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of incontinence and impaction with no urine or stool on skin
- State satisfaction with ability to use adaptive devices for toileting
- Explain and demonstrate use of methods to be safe and independent in toileting

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Environmental Management; Self-Care Assistance: Toileting

Example NIC Activities—Self-Care Assistance: Toileting

Assist client to toilet/commode/bedpan/fracture pan/urinal at specified intervals; Institute a toileting schedule, as appropriate

Nursing Interventions and Rationales

- **QSEN** (Safety): Assess patients for fall risk using established and valid fall risk assessment tools (Morse, Heindrich) and implement fall prevention interventions for those at risk for falling or in physical restraints. **EBN**: *In a retrospective study of 3 years of acute care fall incident reports (N = 547), Huey-Ming and Chang-Yi (2012) found 45.2% of falls were related to toileting and that predictors of toileting-related falls were having a previous fall, being physically restrained, and being a fall risk.*
- **QSEN** (Patient-Centered): Assess patient's prior use of incontinence briefs and avoid use for hospitalized continent but limited mobility patient. **EBN**: *Use of adult incontinence briefs for low-mobility continent clients versus self-toileting occurs more frequently for females and can be associated with adverse outcomes (Zisberg, 2011).*
- **QSEN** (Patient-Centered): Assess patients who have had sphincter-saving surgery for self-care strategies to manage bowel symptoms in order to help support these strategies. **EBN**: *In a quantitative descriptive study of self-care strategies used by patients who had sphincter-saving surgery and bowel symptoms (N = 143), the strategy of proximity and knowing the location of a toilet at all times was used most by those with more bowel symptoms (Landers et al, 2014).*
- **QSEN** (Safety): Make assistance call button readily available to the client and answer call light promptly. **CEBN**: *Falls often occur related to toileting, and individualized planning for safe transfer to toilet is essential to safety (Tzeng, 2010).*
- **QSEN** (Safety): Provide folding commode chairs in client bathrooms/at bedside. **EBN**: *Availability of a folding commode chair as part of a fall prevention program can increase accessibility and efficiency in patient care (Tzeng, 2011).*
- **QSEN** (Patient-Centered): Before use of a bedpan, discuss its use with clients. **CEBN**: *When nurses facilitate discussion about bedpan use with orthopedic patients, they may be less anxious about its use (Cohen, 2009).*
- **QSEN** (Patient-Centered): Use necessary assistive toileting equipment. **EB**: *Amyotrophic lateral sclerosis clients reported satisfaction and usefulness of all bathroom assistive technology such as elevated toilet seat and arm rails by the toilet (Gruis et al, 2011).*
- **QSEN** (Safety): Close toilet lid before flushing toilet and teach patient to do so. **EB**: *A literature review of studies of toilet plume aerosols found that potential infectious aerosols during toilet flushing are produced, which can continue to expose toilet users later when some of the aerosols become droplet nuclei in air currents (Johnson et al, 2013). EB: A study revealed viral contamination of aerosol and surfaces through toilet use (Verani et al, 2014).*

Geriatric

- Assess residents without dementia for risk factors associated with toileting disability: rating health as fair or poor, living in a residence with four or less residents or that is for-profit, incontinence, physical, visual or hearing impairment, and need for ADL or transferring assistance, to guide prevention interventions. **EBN**: *In a cross-sectional analysis of adults 65 years or older without dementia in residential care facilities (N = 2395), 15% were found to have toileting disability that was associated with rating health as fair or poor, living in a residence with four or fewer residents or that is for-profit, incontinence, physical, visual, or hearing impairment, and need for ADL or transferring assistance (Talley et al, 2014).*
- **QSEN** (Patient-Centered): Consider use of urine alarms systems for patients with dementias. **EB**: *Caregivers preferred use of urine alarms over time toileting to reduce urinary accidents (Lancioni et al, 2011).*
- **QSEN** (Patient-Centered): Assess the patient's functional ability to manipulate clothing for toileting, and if necessary modify clothing with Velcro fasteners, elastic waists, drop-front underwear, or slacks. *For*

clients with impaired dexterity or weakness, wearing dresses, athletic bottoms, or skirts with a stretch waistband makes it easier to use the toilet than wearing clothing with buttons and zippers (Cohen, 2008).

- **QSEN** (Patient-Centered): Provide patients with dementia access to regular exercise. **EBN**: ADL performance improved with a regular exercise program of stretching, walking, and leg weight bearing (Chang et al, 2011).

Multicultural

- **QSEN** (Patient-Centered): Remove barriers to toileting, support patient's cultural beliefs, and preserve dignity. **CEB**: The physical and sociocultural environments in long-term care require older patients to overcome greater physical and cognitive challenges to maintain their participation, autonomy, and dignity in toileting than if they were at home (Sacco-Peterson & Borell, 2004).

Home Care

- **QSEN** (Patient-Centered): To design a bathroom for an older adult, consider adaptable bath fixtures/furniture and safety needs. **EB**: Poor bathroom design requires use of assistive adaptive devices, reduces quality of life, and contributes to safety concerns such as falls (Burton et al, 2011).

Client/Family Teaching and Discharge Planning

- Teach men who perform routine clean intermittent catheterization that a 40-cm intermittent catheter was found to provide ease of use, instill confidence in bladder emptying, and draining of urine into a receptacle. **EB**: Costa et al (2013) found in a randomized controlled study of self-catheterizing wheelchair-using men (N = 81) that a 40-cm intermittent catheter was preferred over one that was 30 cm.
- Have the family install a toilet seat of a contrasting color. **CEB**: Visualization of the toilet is aided by installing a toilet seat of a contrasting color (Gerdner et al, 2002).
- Explain to family and caregivers of clients with dementia that toilet self-care activities decrease when self-awareness is lost. An observational study of toileting self-care in older adults with dementia revealed that toilet activities are affected and decline when self-awareness is lost (composed of theory of mind, self-evaluation, and self-consciousness) (Uchimoto et al, 2013).

Readiness for enhanced Self-Concept

Gail B. Ladwig, MSN, RN, and Marina Martinez-Kratz, RN, MS, CNE

NANDA-I

Definition

A pattern of perceptions or ideas about the self, which can be strengthened

Defining Characteristics

Acceptance of limitations; acceptance of strengths; actions are congruent with verbal expression; confidence in abilities; expresses desire to enhance role performance; expresses desire to enhance self-concept; satisfaction with body image; satisfaction with personal identity; satisfaction with sense of worth; satisfaction with thoughts about self

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Self-Esteem; Personal Well-Being; Psychosocial Adjustment Life Change

Example NOC Outcome with Indicators

Self-Esteem as evidenced by the following indicators: Verbalizations of self-acceptance/Open communication/Confidence level/Description of pride in self. (Rate the outcome and indicators of **Self-Esteem**: 1 = never positive, 2 = rarely positive, 3 = sometimes positive, 4 = often positive, 5 = consistently positive [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- State willingness to enhance self-concept
- State satisfaction with thoughts about self, sense of worthiness, role performance, body image, and personal identity
- Demonstrate actions that are congruent with expressed feelings and thoughts
- State confidence in abilities
- Accept strengths and limitations

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Self-Esteem Enhancement

Example NIC Activities—Self-Esteem Enhancement

Encourage client to identify strengths; Assist client in setting realistic goals to achieve higher self-esteem

Nursing Interventions and Rationales

- Assess and support activities that promote developmental self-concept. **EB**: *Early identification of developmental coordination disorder and associated negative outcomes, also based on child's self-reports, should receive special attention in intervention programs in order to enhance children's self-confidence, feelings of belonging, optimal development, and participation in daily activities (Engel-Yeger & Hanna Kasis, 2010).*
- Engage client in relaxation training. **EB**: *Results indicate that relaxation training is a useful clinical intervention for clients who have breast cancer and who are experiencing low self-esteem (Kovačić & Kovačić, 2011).*

- Refer to nutritional and exercise programs to support weight loss. **CEB**: *Changes in weight using a community wellness center with exercise and nutrition information resulted in body satisfaction and an increase in the physical self-concept scale (Annesi, 2007).*
- Refer clients to massage therapy as an adjunct treatment. **CEB**: *Clients with advanced cancer who received six 30-minute massages over 2 weeks reported less pain and improved mood after each session (Kutner et al, 2008).*
- Refer homeless clients to work skills training programs. **EB**: *Research found that homeless clients that completed a work skills training program had improvements in self-esteem and self-efficacy, which also predicted stable housing situations at follow-up (Nelson et al, 2012).*
- Refer clients receiving government assistance to Welfare to Work programs. **EBN**: *Participants who participated in a Work Wellness program credited the program with decreasing negative thoughts and improving self-esteem (Martin et al, 2012).*
- Support establishing church-based community health promotion programs with the following key elements: partnerships, positive health values, availability of services, access to church facilities, community-focused interventions, health behavior change, and supportive social relationships. **EB**: *This study supported that “spiritual dwelling” (students at Protestant University) is associated with well-being (Jankowski & Sandage, 2012).*
- ▲ For clients who have had breast surgery and need a prosthesis, provide the appropriate prosthesis before the client leaves the health care facility. **EBN**: *A good-quality external breast prosthesis and prosthesis-fitting service is an integral part of the recovery process after mastectomy (Gallagher et al, 2010).*
- Offer client choices in clothing while client is hospitalized. **CEBN**: *Client clothes were experienced as being comfortable and practical, but also as being stigmatizing symbols of illness, confinement, and depersonalization (Edvardsson, 2009).*
- ▲ Refer clients with history of childhood sexual abuse for intensive therapy that uses narrative life stories to promote positive sense of self. *The participants in this study of women with a history of childhood sexual abuse experienced a more positive sense of self after being in the program (Saha et al, 2011).*

Pediatric

- Consider the development of a Healthy Kids Mentoring Program that has four components: (1) relationship building, (2) self-esteem enhancement, (3) goal setting, and (4) academic assistance (tutoring). Mentors met with students twice each week for 1 hour each session on school grounds. During each meeting, mentors devoted time to each program component. **CEB**: *The Healthy Kids Mentoring Program results indicated that students’ overall self-esteem, school connectedness, peer connectedness, and family connectedness were significantly higher at posttest than at pretest (Kelly et al, 2011).*
- Provide activities to bolster physical self-concept. **EB**: *Research indicates that physical self-concept acts a moderator for negative events in a child’s life (Nguyen & Scott, 2013).*
- ▲ Consider wheelchair dancing for disabled adolescents. **EB**: *A wheelchair dancing intervention was associated with an improvement in self-esteem among disabled adolescents (de Villiers et al, 2013).*
- ▲ Provide overweight adolescents to access to group-based weight control interventions. **EB**: *Findings demonstrate benefits of group-based weight-control treatment for enhancing adolescent self-perceived social functioning across multiple domains including self-concept (Jelalian et al, 2011).*
- ▲ Assess and provide referrals to mental health professionals for clients with unresolved worries associated with terrorism. **EBN**: *The National Association of Pediatric Nurse Practitioners initiated a national campaign titled Keep Your Children/Yourself Safe and Secure. Interventions are urgently needed to assist children and teens in coping with the multitude of stressors related to growing up in today’s society (Melnyk et al, 2002).*
- Provide an alternative school-based program for pregnant and parenting teenagers. **CEB**: *The girls who attended this program developed close relationships with their peers and teachers. Many of them experienced academic success for the first time and reported that pregnancy and impending motherhood motivated them to do better in school (Spear, 2002).*

Geriatric

- Encourage clients to consider a web-based support program when they are in a caregiving situation. **EBN**: *Technology, such as telephone networks and the Internet, helps in supporting isolated and lonely older people. It helps to alleviate anxiety and increase self-confidence (Cattan et al, 2011).*

- Encourage activity and a strength, mobility, balance, and endurance training program. **EB**: *Participants in this physical activity program demonstrated increased self-worth (Huberty et al, 2008).*
- Provide opportunities for clients to engage in life skills (themed collections of everyday items based upon general activities that residents may have previously carried out). *Life skill centers offer residents a means of purposeful occupation in tasks that they have undertaken for decades using skills that are inherent and not forgotten (Swann, 2009).*
- Provide information on advance directives. **EBN**: *In this study elders stated that the optimal time for advance care planning was during periods of wellness. They are ready and eager to discuss advance planning (Malcomson & Bisbee, 2009).*
- Use an approach that reduces the emphasis put on “old age” self-concept attributions when working with older clients. **EB**: *Research found that older adult clients who attribute the onset of chronic illness (e.g., heart disease, cancer, diabetes) to old age predicted the experience of more perceived health symptoms (Stewart et al, 2012).*

Multicultural

- Carefully assess each client and allow families to participate in providing care that is acceptable based on the client's cultural beliefs. **EBN**: *An understanding of client suffering that is shaped by traditional cultural values helps nurses communicate empathy in a culturally sensitive manner to facilitate the therapeutic relationship and clinical outcomes (Hsiao et al, 2006). Spiritual well-being, the perception of health and wholeness, can boost self-confidence and self-esteem. These behaviors were demonstrated by older Amish in this study. This information will assist nurses in serving this population (Sharpnack et al, 2011).*
- Provide education and support for health-promoting behaviors and self-concept for clients from diverse cultures. **EB**: *This study of older adults in Korea demonstrated significant changes in self-esteem, depression, and social network after completing the Older Paraprofessional Training Program (Lee & Choi, 2012).*
- Refer to the care plans Disturbed **Body Image**, Readiness for enhanced **Coping**, Chronic low **Self-Esteem**, and Readiness for enhanced **Spiritual** well-being.

Home Care

- Previously discussed interventions may be used in the home care setting.

Chronic low Self-Esteem *Gail B. Ladwig, MSN, RN; revised by Marina Martinez-Kratz, MS, RN, CNE*

NANDA-I

Definition

Longstanding negative self-evaluating/feelings about self or self-capabilities

Defining Characteristics

Dependent on others' opinions; exaggerates negative feedback about self; excessive seeking of reassurance; guilt; hesitant to try new experiences; indecisive behavior; nonassertive behavior; overly conforming; passivity; poor eye contact; rejection of positive feedback; repeatedly unsuccessful in life events; shame; underestimates ability to deal with situation

Related Factors (r/t)

Cultural incongruence; exposure to traumatic situation; inadequate belonging; inadequate respect from others; ineffective coping with loss; insufficient group membership; psychiatric disorder; receiving insufficient affection; receiving insufficient approval from others; repeated failures; repeated negative reinforcement; spiritual incongruence

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Self-Esteem

Example NOC Outcome with Indicators

Demonstrates improved **Self-Esteem** as evidenced by the following indicators: Verbalizations of acceptance of self and limitations/Open communication. (Rate the outcome and indicators of **Self-Esteem**: 1 = never positive, 2 = rarely positive, 3 = sometimes positive, 4 = often positive, 5 = consistently positive [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate improved ability to interact with others (e.g., maintains eye contact, engages in conversation, expresses thoughts/feelings)
- Verbalize increased self-acceptance through positive self-statements about self
- Identify personal strengths, accomplishments, and values
- Identify and work on small, achievable goals
- Improve independent decision-making and problem-solving skills

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Self-Esteem Enhancement

Example NIC Activities—Self-Esteem Enhancement

Encourage patient to identify strengths; Assist in setting realistic goals to achieve higher self-esteem

Nursing Interventions and Rationales

- Actively listen to and respect the client. **EBN:** *Listening and nurturing are important aspects of care (Parrish et al, 2008).* **EB:** *This study described active listening as essential in uncovering patients' emotions (Del Piccolo et al, 2014).*
- Assess the client's environmental and everyday stressors, including physical health concerns and the potential for abusive relationships. **EBN:** *It is difficult to determine whether a woman's depressive symptoms are related to physical abuse or to other risk factors (Al-Modallal et al, 2008).* **EB:** *Findings in this study suggest that early adverse conditions have lasting implications for physical health and that continued exposure to increased levels of both social and nonsocial stress in adolescence, as well as the presence of depression, might be important mechanisms by which early adversity impacts later physical health (Raposa et al, 2014).*
- Assess existing strengths and coping abilities, and provide opportunities for their expression and recognition. **CEB:** *Supporting a client's beliefs and self-reflection and helping him/her cope can affect self-esteem (Räty & Gustaffson, 2006).* *Persons with psychiatric illness need help to stop their "negative self-image" and become more conscious of affirmative self-evaluation (Kunikata, 2010).*
- Assess the client's self-esteem using valid and established tools like the Rosenberg Self-Esteem Scale. **EBN:** *The use of valid and established measures of self-esteem will facilitate the identification of appropriate nursing interventions that strengthen self-esteem (McMullen & Resnick, 2013).*
- Reinforce the personal strengths and positive self-perceptions that a client identifies. **EB:** *In this study of clients with spinal cord injury, clients attributed their success in rehabilitation to positive self-esteem (Belciug, 2012).*
- Identify client's negative self-assessments. **EBN:** *Body-esteem and self-esteem are significantly related to one another (Jones et al, 2008).*
- Encourage realistic and achievable goal setting and resources and identify impediments to achievement. **CEB:** *This promotes self-acceptance, which is associated with psychological well-being (Macinnes, 2006).*
- Demonstrate and promote effective communication techniques; spend time with the client. **EBN:** *Presence and caring during communication are important (Mantha et al, 2008).*
- Encourage independent decision-making by reviewing options and their possible consequences with client. **EBN:** *Decision-making capacity is vital to a sense of autonomy (Burke et al, 2008).*
- Assist client to challenge negative perceptions of self and performance. **CEBN:** *Reduction in negative thinking will increase self-esteem (Day & Deutsch, 2004).*
- Use failure as an opportunity to provide valuable feedback. **CEB:** *This allows clients to change expectations of what would happen given the reality of what did happen (Pierce & Hicks, 2001).*
- Promote maintaining a level of functioning in the community. **EB:** *Driving cessation is one factor associated with increased depressive symptoms and decreased social integration among older adults (Mezuk & Rebok, 2008).*
- Assist client with evaluating the effect of family and peer group on feelings of self-worth. **EBN:** *Nurses are encouraged to actively assess the condition of social contacts among older adults in their care and to assist in strengthening relationships with family members and others (Yao et al, 2008).*
- Support socialization and communication skills. **EBN:** *Social support increases the client's ability to cope with problems (Johnson, 2008).*
- Encourage journal/diary writing as a safe way of expressing emotions. **EB:** *Daily diary writing has been shown to decrease symptoms of depression (Hopko & Mullane, 2008).*
- Encourage clients to develop their artistic abilities. **EB:** *Using an art kit and DVD increased self-confidence and self-esteem and socialization in this study of clients in hospitals and hospices in the United Kingdom (Hull & Stickley, 2010).*

Pediatric

- Assess children/adolescents with chronic illness for evidence of reduced self-esteem and make needed referrals. **EB:** *Children and adolescents with chronic illness have lower levels of self-esteem when compared with their healthy peers; experiences of success and positive peer relations are important sources of self-esteem (Pinquart, 2013).*
- Encourage mothers of premature infants to use kangaroo care for at least 30 minutes per day. **EBN:** *Research shows that mothers of premature infants who used 30 minutes of kangaroo care showed improved measures of self-esteem (Lee & Bang, 2011).*
- Implement interventions that promote and maintain positive peer relations for adolescent patients. **EB:** *Peer relationships had the greatest impact on self-esteem for adolescent patients (Farineau et al, 2013).*
- ▲ Assess children/adolescents with low self-esteem for evidence of cyber bullying either as a victim or an offender. **EB:** *Students who experienced cyber bullying, either as a victim or an offender had significantly lower self-esteem than those who had little or no experience with cyber bullying (Patchin & Hinduja, 2010).*
- ▲ Provide bully prevention programs and include information on cyber bullying. **EBN:** *This study supported those students who were victims or offenders of bullying and demonstrated low self-esteem. Technology, computers, and cell phones are means for bullying so prevention programs need to address these issues (Patchin & Hinduja, 2010).*

Geriatric

- Support client in identifying and adapting to functional changes. **EBN:** *The ability to adjust goals was shown to be critical as a way of preventing the development of depressive symptoms following negative life events in older adults (Bailly et al, 2012).*
- Use reminiscence therapy and productive activities. **EB:** *This study suggests that productive activities with reminiscence therapy may alleviate depressive symptoms and improve task performance of older people with dementia (Nakamae et al, 2014).*
- Encourage older adult clients to participate in flexibility, toning, and balance exercise. **EB:** *Older adults showed improvements in attractiveness esteem after participation in physical activity that emphasized toning, flexibility, and balance (Gothe et al, 2011).*
- Encourage participation in peer group activities. **CEB:** *Withdrawal and social isolation are detrimental to feelings of self-worth (Stuart-Shor et al, 2003).*
- Encourage activities in which a client can support/help others. **EB:** *The findings of this study reveal that late-life productive engagement is widespread, with the majority of older individuals involved in multiple forms of activity concurrently. Non-market-based activities such as caregiving, informal assistance, and volunteering are most prevalent (Hinterlong, 2008).*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's sense of self-esteem. **CEB:** *How the client values self may be based on cultural perceptions (Giger & Davidhizar, 2008). Asian American youths demonstrate lower levels of self-esteem than their non-Asian peers (Rhee et al, 2003).*
- Assess socioeconomic issues. **EB:** *Racial minorities and those who are economically disadvantaged are up to three times more likely to experience disability than are whites and those who are not economically disadvantaged, respectively (Louie & Ward, 2011).*
- Assess for drug and alcohol use in individuals with low self-esteem. **CEB:** *Among Mexican American female adolescents, poor self-confidence predicts higher levels of alcohol use (Swaim & Wayman, 2004).*
- Validate the client's feelings regarding ethnic or racial identity. **CEB:** *Individuals with strong ethnic affiliation have higher levels of self-esteem than others (Greig, 2003).*

Home Care

- Assess a client's immediate support system/family for relationship patterns and content of communication. **CEBN:** *Family strength assessments help the nurse to incorporate family strengths into nursing care, especially in times of crisis (Sittner et al, 2007).*
- Encourage the client's family to provide support and feedback regarding client value or worth. **CEBN:** *There are significant relationships between adolescents' practice of healthy behaviors, self-efficacy of those behaviors, self-care abilities, and their support systems, among other factors (Callaghan, 2006).*

- ▲ Refer to medical social services to assist the family in pattern changes that could benefit the client. **EB:** *The best nursing plan may be to access specialty services for the client and family (Holmberg et al, 2012).*
- ▲ If a client is involved in counseling or self-help groups, monitor and encourage attendance. Help the client identify the value of group participation after each group encounter. *Discussion about group participation clarifies and reinforces group feedback and support.*
- ▲ If a client is taking prescribed psychotropic medications, assess for knowledge of medication side effects and reasons for taking medication. Teach as necessary. **EBN:** *Education that helps clients understand their illness, particular symptoms, and how medications help them may be beneficial in promoting adherence (Wu et al, 2008).*
- ▲ Assess medications for effectiveness and side effects and monitor client for compliance. **EBN:** *A positive working relationship with the health care provider may result in improved adherence to taking medications to assist with problems (Wu et al, 2008).*

Client/Family Teaching and Discharge Planning

- ▲ Refer to community agencies for psychotherapeutic counseling. **EB:** *Family-led programs are an effective resource for families with mental illness (Pickett-Schenk et al, 2008). Cognitive behavioral therapy has a unique role in realizing and overcoming negative core beliefs and feelings of low self-worth (Johnson, 2012).*
- ▲ Refer to psychoeducational groups on stress reduction and coping skills. **EB:** *Research findings indicated that participants reported improved self-esteem and knowledge of healthy relationship dynamics after enrollment in psychoeducation groups (Marrs Fuchsel, 2014).*
- ▲ Refer to self-help support groups specific to needs. **EB:** *Research shows that client participation in support groups increases self-esteem (Seeborn et al, 2013).*

Risk for chronic low Self-Esteem Gail B. Ladwig, MSN, RN

NANDA-I

Definition

Vulnerable to longstanding negative self-evaluating/feelings about self or self-capabilities, which may compromise health

Risk Factors

Cultural incongruence; exposure to traumatic situation; inadequate affection received; inadequate group membership; inadequate respect from others; ineffective coping with loss; insufficient feeling of belonging; psychiatric disorder; repeated failures; repeated negative reinforcement; spiritual incongruence

NOC, NIC, Client Outcomes, Nursing Interventions, Rationales, and References

Refer to care plan for Chronic low **Self-Esteem**.

Risk for situational low Self-Esteem

Gail B. Ladwig, MSN, RN, and Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Vulnerable to developing a negative perception of self-worth in response to a current situation, which may compromise health

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Risk Factors

Alteration in body image; alteration in social role; behavior inconsistent with values; decrease in control over environment; developmental transition; functional impairment; history of abandonment; history of abuse (e.g., physical, psychological, sexual); history of loss; history of neglect history of rejection; inadequate recognition; pattern of failure; pattern of helplessness; physical illness; unrealistic self-expectations

NOC (Nursing Outcomes Classification)

See chronic low **Self-Esteem** for suggested NOC outcomes.

Client Outcomes

Client Will (Specify Time Frame)

- State accurate self-appraisal
- Demonstrate the ability to self-validate
- Demonstrate the ability to make decisions independent of primary peer group
- Express effects of media on self-appraisal
- Express influence of substances on self-esteem
- Identify strengths and healthy coping skills
- State life events and change as influencing self-esteem

NIC (Nursing Interventions Classification)

See chronic low **Self-Esteem** for suggested NIC interventions.

Nursing Interventions and Rationales

- Assess the client's previous experiences with health care and coping with illness to determine the level of education and support needed. **EBN:** *Assessing illness self-concept in developing a treatment plan may prove useful (Morea et al, 2008).*
- Assess for low and negative affect (expression of feelings). **EB:** *In this study, both an increase in anxiety and a decrease in self-esteem were associated with emotional responses such as paranoia, depression, or anger/irritability (Thewissen et al, 2011).*
- Assess the client's self-esteem using valid and established tools like the Rosenberg Self-Esteem Scale. **EBN:** *The use of valid and established measures of self-esteem will facilitate the identification of appropriate nursing interventions that strengthen self-esteem (McMullen & Resnick, 2013).*
- Encourage client to maintain highest level of community functioning. **EB:** *In this study, clients with serious mental illness were matched with community volunteers for weekly social activities. Clients experienced increased self-esteem, self-worth, and self-confidence (McCorkle et al, 2009).*
- Treat the client with respect and as an equal to maintain positive self-esteem. **CEB:** *Clients with higher self-esteem need to be confirmed as being equal with care providers (Räty & Gustaffson, 2006).*
- Help the client identify and encourage use of available resources and social support networks. Make referrals as needed. **EBN:** *Transitions might be significantly enhanced by the presence of intimate ties, positive perceptions of one's health limitations, and residence in a healthy, safe, and resource-rich physical environment that provides the social support needed (Low et al, 2008).*
- Encourage the client to find a self-help or therapy group that focuses on self-esteem enhancement. Encourage utilization of above. **CEBN:** *Cognitive behavioral group therapy decreases depression levels and increases self-esteem in depressed clients (Chen et al, 2006).*
- Encourage the client to create a sense of competence through short-term goal setting and goal achievement. **EBN:** *Sense of competence is related to global self-esteem when goals are set and met (Lauder et al, 2008).*
- ▲ Assess the client for symptoms of depression and anxiety. Refer to specialist as needed. Prompt and effective treatment can prevent exacerbation of symptoms or safety risks. **EB:** *Well-documented suicide risk assessments are a core measure of quality of care (Simon, 2009).*
- See care plans for Disturbed personal **Identity**, Situational low **Self-Esteem**, and Chronic low **Self-Esteem**.

Pediatric

- Assess children/adolescents with chronic illness for evidence of reduced self-esteem and make needed referrals. **EB:** *Children and adolescents with chronic illness have lower levels of self-esteem when compared with their healthy peers; experiences of success and positive peer relations are important sources of self-esteem (Pinquart, 2013).*
- Identify environmental and/or developmental factors that increase risk for low self-esteem, especially in children/adolescents, to make needed referrals. **CEB:** *Self-esteem enhancement programs can improve self-esteem in school-age children (Dalgas-Pelish, 2006).*
- Assess children/adolescents who are either a victim or an offender of cyber bullying for low self-esteem. **EB:** *Students who experienced cyber bullying, either as a victim or an offender, had significantly lower self-esteem than those who had little or no experience with cyber bullying (Patchin & Hinduja, 2010).*
- ▲ Provide support for children who do not have supportive families, and provide a haven outside of the home. **EB:** *This study demonstrates that children from dysfunctional families are at risk for low self-esteem (Okada et al, 2012).*
- ▲ Encourage a combination of extracurricular activity for adolescents in a safe, supportive, and empowering environment. **EB:** *Research shows that participation in a variety of extracurricular activities has a positive effect on self-esteem, develops personal identity, and validates a sense of self (Kort-Butler, 2012).*

Geriatric

- Support humor as a coping mechanism. **EB:** *This study identified a sense of humor as a mechanism for managing the inevitable stresses of aging (Marziali et al, 2008).*
- Assist the client in life review and identifying positive accomplishments. *Life review is a developmental task that increases a person's sense of peace and serenity.*
- Help client establish a peer group and structured daily activities. *Social isolation and lack of structure increase a client's sense of feeling lost and worthless.*
- See care plans for Situational low **Self-Esteem** and Chronic low **Self-Esteem**.

Home Care

- Assess current environmental stresses and identify community resources. *Accessing resources to help decrease environmental stress will increase the client's ability to cope. CEB:* *Nurses who identify older women with low self-esteem, high depressive symptoms, and low quality of life before relocation can make interventions to ease the transition process (Rossen & Knafel, 2007).*
- Encourage family members to acknowledge and validate the client's strengths. *Validation allows the client to increase self-reliance and to trust personal decisions.*
- Assess the need for establishing an emergency plan. *Openly assessing safety risks increases the client's sense of limits, boundaries, and safety.*
- See care plans for Situational low **Self-Esteem** and Chronic low **Self-Esteem**.

Client/Family Teaching and Discharge Planning

- ▲ Refer the client/family to community-based self-help and support groups. **EB:** *Research shows that clients who participate in support groups show increased self-esteem (Seebohm et al, 2013).*
- ▲ Refer the client to educational classes on stress management, relaxation training, and so on. **CEB:** *Cognitive behavioral therapy, psychoeducation for anxiety disorders appears to be helpful for a number of clients and largely acceptable for most clients who attend (Houghton & Saxon, 2007).*
- ▲ Refer the client to community agencies that offer support and environmental resources. Make referrals as needed.
- See care plans for Situational low **Self-Esteem** and Chronic low **Self-Esteem**.

Situational low Self-Esteem *Gail B. Ladwig, MSN, RN, and Marina Martinez-Kratz, MS, RN, CNE*

NANDA-I

Definition

Development of a negative perception of self-worth in response to a current situation

Defining Characteristics

Helplessness; indecisive behavior; nonassertive behavior; purposelessness; self-negating verbalizations; situational challenge to self-worth; underestimates ability to deal with situation

Related Factors (r/t)

Alteration in body image; alteration in social role; behavior inconsistent with values; developmental transition; functional impairment; history of loss; history of rejection; inadequate recognition; pattern of failure

NOC (Nursing Outcomes Classification)

Refer to Chronic low **Self-Esteem** for suggested NOC outcomes.

Client Outcomes

Client Will (Specify Time Frame)

- State effect of life events on feelings about self
- State personal strengths
- Acknowledge presence of guilt and not blame self if an action was related to another person's appraisal
- Seek help when necessary
- Demonstrate self-perceptions are accurate given physical capabilities
- Demonstrate separation of self-perceptions from societal stigmas

NIC (Nursing Interventions Classification)

Refer to Chronic low **Self-Esteem** for suggested NIC interventions.

Nursing Interventions and Rationales

- ▲ Assess the client for signs and symptoms of depression and potential for suicide and/or violence. If present, immediately notify the appropriate personnel of symptoms. See care plans for Risk for

other-directed **Violence** and Risk for **Suicide**. **EB**: Well-documented suicide risk assessments are a core measure of quality of care (Simon, 2009).

- Assess the client's environmental and everyday stressors, including evidence of abusive relationships. **EBN**: High everyday stressors and a history of abuse in relationships are associated with low self-esteem and depression (Al-Modallal et al, 2008).
- ▲ Assess the client's self-esteem using valid and established tools like the Rosenberg Self-Esteem Scale. **EBN**: The use of valid and established measures of self-esteem will facilitate the identification of appropriate nursing interventions that strengthen self-esteem (McMullen & Resnick, 2013). Assess for unhealthy coping mechanisms, such as substance abuse, and make appropriate referrals. **EB**: Numerous factors influence the onset and continuation of alcohol use, including the complex ways that genes interact with one another and with the environment (Faye et al, 2015). A health risk assessment that helps refer clients to medical management programs helped increase overall wellness in this health care plan (Case Management Advisor, 2012).
- Assist in the identification of problems and situational factors that contribute to problems, offering options for resolution. **EBN**: Recognize that the client's own personal resources strengthen client's self-determination (Meijers & Gustafsson, 2008).
- Mutually identify strengths, resources, and previously effective coping strategies. **EBN**: A common action for supporting self-determination is supplying the client with information and engaging the client in making a plan (Meijers & Gustafsson, 2008). **EB**: Helping the client identify positive traits may contribute to living a "happier life" (Bernard et al, 2010).
- Have client list strengths. **EBN**: In this study of women with addiction, it was identified that helping the client identify strengths empowered her in the recovery process (Payne, 2010).
- Accept client's own pace in working through grief or crisis situations. **EBN**: Recommended therapeutic communication skills such as eye contact, use of therapeutic touch, and active listening can be enhanced by an understanding of the grief process (Wright & Hogan, 2008).
- Accept the client's own defenses in dealing with the crisis. **EBN**: The SAUC modes (Sympathy-Acceptance-Understanding-Competence) help strengthen and preserve the individual's positive self-relation (Meijers & Gustafsson, 2008).
- Provide information about support groups of people who have common experiences or interests. **EBN**: Research shows that client participation in support groups increases self-esteem (Seebohm et al, 2013).
- Teach the client mindfulness techniques to cope more effectively with strong emotional responses. **EB**: Mindfulness training has direct positive effects on self-esteem (Pepping et al, 2013).
- Support client's decisions in health care treatment. **EBN**: Self-esteem is enhanced when clients are able to make their own decisions regarding cancer treatment (Kitamura, 2010).
- Encourage objective appraisal of self and life events and challenge negative or perfectionist expectations of self. **CEB**: Positive life events improve self-esteem and positive affect (Drew & Mabry, 2004).
- Provide psychoeducation to client and family. **EB**: Research findings indicated that participants reported improved self-esteem and knowledge of healthy relationship dynamics after enrollment in psychoeducation groups (Marrs Fuchsel, 2014).
- Validate confusion when feeling ill but looking well. **CEB**: Validation of emotions is related to a client's experience of caring (Räty & Gustafsson, 2006).
- Acknowledge the presence of societal stigma. Teach management tools. **EBN**: Stigma toward mental illness is poorly understood, often unrecognized by nurses, and affects both treatment-seeking behavior and treatment adherence (Pinto-Foltz & Logsdon, 2008).
- Validate the effect of negative past experiences on self-esteem and work on corrective measures. **CEB**: People with low self-esteem have a need to be affirmed regarding their value (Räty & Gustafsson, 2006).
- See care plan for Chronic low **Self-Esteem**.

Geriatric and Multicultural

- See care plan for Chronic low **Self-Esteem**.

Home Care

- Establish an emergency plan and contract with the client for its use. *Having an emergency plan is reassuring to the client. Establishing a contract validates the worth of the client and provides a caring link between the client and society.*
- Access supplies that support a client's success at independent living.
- See care plan for Chronic low **Self-Esteem**.

Client/Family Teaching and Discharge Planning

- Assess the person's support system (family, friends, and community) and involve them if desired. **CEB:** *Family strength assessments help the nurse incorporate family strengths into nursing care, especially in times of crisis (Sittner et al, 2007).*
- Educate client and family regarding the grief process. *Understanding this process normalizes responses of sadness, anger, guilt, and helplessness. Recommended therapeutic communication skills such as eye contact, use of therapeutic touch, and active listening can be enhanced by an understanding of the grief process (Wright & Hogan, 2008).*
- Teach client and family that the crisis is temporary. *Knowing that the crisis is temporary provides a sense of hope for the future.*
- ▲ Refer to appropriate community resources or crisis intervention centers.
- ▲ Refer to resources for handicap and/or disability services.
- Refer to illness-specific consumer support groups. *Mutual help support groups aid the client with chronic illness to cope with their illness (Chen et al, 2008).*
- See care plan for Chronic low **Self-Esteem**.

Self-Mutilation *Kathleen L. Patusky, MA, PhD, RN, CNS*

NANDA-I

Definition

Deliberate self-injurious behavior causing tissue damage with the intent of causing nonfatal injury to attain relief of tension

Defining Characteristics

Abrasing; biting; constricting a body part; cuts on body; hitting; ingestion of harmful substances; inhalation of harmful substances; insertion of object into body orifice; picking at wounds; scratches on body; self-inflicted burn; severing of a body part

• = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Related Factors (r/t)

Absence of family confidant; adolescence; alteration in body image; autism; borderline personality disorder; character disorder; childhood illness; childhood surgery; depersonalization; developmental delay; dissociation; disturbance in interpersonal relationships; eating disorders; emotional disorder; family divorce; family history of self-destructive behaviors; family substance abuse; feeling threatened with loss of significant relationship; history of childhood abuse (e.g., physical, psychological, sexual); history of self-directed violence; impaired self-esteem; impulsiveness; inability to express tension verbally; incarceration; ineffective communication between parent and adolescent; ineffective coping strategies; irresistible urge for self-directed violence; irresistible urge to cut self; isolation from peers; labile behavior; living in nontraditional setting (e.g., foster, group or institutional care); low self-esteem; mounting tension that is intolerable; negative feeling (e.g., depression, rejection, self-hatred, separation anxiety, guilt, depersonalization); pattern of inability to plan solutions; pattern of inability to see long-term consequences; peers who self-mutilate; perfectionism; psychotic disorder; requires rapid stress reduction; sexual identity crisis; substance abuse; use of manipulation to obtain nurturing relationship with others; violence between parental figures

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Self-Control; Distorted Thought Self-Control; Impulse Self-Control; Mood Equilibrium; Risk Detection; Self-Mutilation Restraint

Example NOC Outcome with Indicators

Self-Mutilation Restraint as evidenced by the following indicators: Refrains from gathering means for self-injury/Obtains assistance as needed/Upholds contract not to harm self/Maintains self-control without supervision/Refrains from injuring self. (Rate the outcome and indicators of **Self-Mutilation Restraint**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)].)

Consider using a measure of self-harm risk that is available for clients: Self-Injury Questionnaire addresses intention for self-harm (Santa Mina et al, 2006).

Client Outcomes

Client Will (Specify Time Frame)

- Have injuries treated
- Refrain from further self-injury
- State appropriate ways to cope with increased psychological or physiological tension
- Express feelings
- Seek help when having urges to self-mutilate
- Maintain self-control without supervision
- Use appropriate community agencies when caregivers are unable to attend to emotional needs

S

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening; Anger Control Assistance; Behavior Management: Self-Harm; Calming Technique; Environmental Management: Safety; Limit Setting; Mood Management; Mutual Goal Setting; Risk Identification; Self-Responsibility Facilitation

Example NIC Activities—Behavior Management: Self-Harm

Anticipate trigger situations that may prompt self-harm and intervene to prevent it; Teach client and reinforce effective coping behaviors and appropriate expression of feelings

Nursing Interventions and Rationales

NOTE: Before implementing interventions in the face of self-mutilation, nurses should examine their own knowledge base and emotional responses to incidents of self-harm to ensure that interventions will not be

- = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

based on countertransference reactions. **EBN/EB:** *Lack of educational background on self-harm can influence response to self-harm clients. Nurses' tendency to focus on physical care, especially when working under stressful conditions, can hinder awareness of and response to psychosocial issues (Cleaver, 2014; Muehlenkamp et al, 2013).*

- ▲ Provide medical treatment for injuries. Use aseptic technique when caring for wounds. Care for the wounds in a matter-of-fact manner. **EBN:** *A significant impediment to wound healing is infection. A matter-of-fact approach avoids positive reinforcement and may decrease repetition of behavior (Catledge et al, 2012).*
- Assess for risk of suicide or other self-damaging behaviors. **EBN:** *Although self-mutilation should not be viewed simply as failed suicide, it is a significant indicator of suicide risk. Clients may also engage in other self-damaging behaviors, including substance abuse or eating disorders (Cleaver, 2014; Moller et al, 2013).* Refer to the care plan for Risk for **Suicide**.
- Assess for signs of psychiatric disorders, including depression, anxiety, borderline personality disorder, dissociative disorders, eating disorders, and impulsivity. **EB:** *Self-mutilation has been associated with multiple psychiatric disorders (Moller et al, 2013).*
- Assess for presence of hallucinations. Ask specific questions such as, "Do you hear voices that other people do not hear? Are they telling you to hurt yourself?" **CEB:** *Command hallucinations occurring with schizophrenia or brief psychotic episodes may direct the client to hurt himself or herself or others (Barrowcliff & Haddock, 2010).*
- ▲ Assure the client that he or she will be safe during hallucinations, and engage supportively. Provide referrals for medication. **EBN:** *Hallucinations can be very frightening; therefore, clients need reassurance that they will be kept safe, while avoiding a sense of intrusion that overstimulates clients (Ray et al, 2011).*
- ▲ Assess for the presence of medical disorders, mental retardation, medication effects, or disorders such as autism that may include self-mutilation. Initiate referral for evaluation and treatment as appropriate. **CEB:** *Self-mutilation has been reported as a presenting or ongoing symptom with medical disorders, such as the genetic Lesch-Nyhan syndrome (Robey et al, 2003).* (Additional relevant research: Singh et al, 2006.)
- ▲ Case finding and referral by school nurses for psychological or psychiatric treatment is critical. **CEB:** *Treatment includes starting therapy and medications, increasing coping skills, facilitating decision making, encouraging positive relationships, and fostering self-esteem (McDonald, 2006).*
- Monitor the client's behavior closely, using engagement and support as elements of safety checks while avoiding intrusive overstimulation. When lack of control exists, client safety is an important issue, and close observation is essential. **EBN:** *Clients were found to feel overstimulated by intrusive close observation, resulting in agitation (Ray et al, 2011).*
- Establish trust, listen to client, convey safety, and assist in developing positive goals for the future. **EBN:** *Clients reported that nurses were helpful when they took charge of unsafe situations, performed bodily interventions (e.g., holding hand), conveyed safety, and respected the autonomy of the client (Schoppmann et al, 2007).* Promoting trust and enhancing privacy are considered important (Catledge et al, 2012).
- Recognize that self-mutilation may serve a variety of functions for the client. **EBN:** *Self-mutilation is identified by clients as a way to help with the regulation of dysphoric affect and cope with dissociative states (Catledge et al, 2012).*
- ▲ Refer to family or group psychotherapy as appropriate. **EBN:** *A systematic review of treatment modalities suggests that systemic family therapy or developmental group psychotherapy (using a combination of cognitive behavior therapy, dialectic behavior therapy, and psychodynamic therapy) can be effective (Pryjmachuk & Trainor, 2010).*
- ▲ Use a collaborative approach for care. A collaborative approach to care is more helpful to the client.
- Refer to the care plan for Risk for **Self-Mutilation** for additional information.

Risk for Self-Mutilation *Kathleen L. Patusky, MA, PhD, RN, CNS*

NANDA-I

Definition

Vulnerable to deliberate self-injurious behavior causing tissue damage with the intent of causing nonfatal injury to attain relief of tension

Risk Factors

Adolescence; alteration in body image; battered child; borderline personality disorders; character disorders; childhood illness; childhood surgery; depersonalization; developmental delay; dissociation; disturbed interpersonal relationships; eating disorders; emotional disorder; family divorce; family history of self-destructive behavior; family substance abuse; feeling threatened with loss of significant relationship; history of childhood abuse (e.g., physical, psychological, sexual); history of self-directed violence; impaired self-esteem; impulsiveness; inability to express tension verbally; incarceration; ineffective coping strategies; irresistible urge for self-directed violence; isolation from peers; living in nontraditional setting (e.g., foster, group, or institutional care); loss of control over problem-solving situation; loss of significant relationship (s); low self-esteem; mounting tension that is intolerable; negative feelings (e.g., depression, rejection, self-hatred, separation anxiety, guilt, depersonalization); pattern of inability to plan solutions; pattern of inability to see long term consequences; peers who self-mutilate; perfectionism; psychotic disorder; requires rapid stress reduction; sexual identity crisis; substance abuse; use of manipulation to obtain nurturing relationship with others; violence between parental figures

NOC (Nursing Outcomes Classification)

See care plan for **Self-Mutilation** for suggested NOC outcomes.

Client Outcomes

Client Will (Specify Time Frame)

- Refrain from self-injury
- Identify triggers to self-mutilation
- State appropriate ways to cope with increased psychological or physiological tension
- Express feelings
- Seek help when having urges to self-mutilate
- Maintain self-control without supervision
- Use appropriate community agencies when caregivers are unable to attend to emotional needs

NIC (Nursing Interventions Classification)

See care plan for **Self-Mutilation** for suggested NIC interventions.

Nursing Interventions and Rationales

NOTE: Before implementing interventions in the face of self-injury, nurses should examine their own knowledge base and emotional responses to incidents of self-injury to ensure that interventions will not be based on countertransference reactions. **EBN:** *Lack of educational background on self-harm can influence response to self-harm clients. Nurses' tendency to focus on physical care, especially when working under stressful conditions, can hinder awareness of and response to psychosocial issues (Cleaver, 2014; Muehlenkamp et al, 2013a).*

- Assess client's ability to regulate his/her own emotional states, which may be influenced by the client's perception of his or her body. **EB:** *Clients who self-injure are more likely to be lower in emotional self-regulation than persons who do not self-injure. They may use self-harm to increase or decrease feelings. Self-injury has been associated with low body regard (Muehlenkamp, et al, 2013b).*
- Assess client's degree of self-criticism and use of effective coping skills. Self-harm serves as a coping mechanism for clients. **CEB:** *Persecutory self-criticism and limited coping skills are linked with self-harm (Gilbert et al, 2010; Hall & Place, 2010).*
- Assess client's perception of powerlessness. Refer to the care plan for **Powerlessness**. **CEB:** *Testing of the Cry of Pain model of suicidality and repeat self-harm, which identifies defeat, no escape potential, and no rescue as contributory, supports use of this model to understand self-harm (Rasmussen et al, 2010).*
- Assessment data from the client and family members may have to be gathered at different times; allowing a family member or trusted friend with whom the client is comfortable to be present during the assessment may be helpful. **EBN:** *Self-mutilation sometimes occurs if clients have been victims of abuse or other types of adverse family experiences (Catledge et al, 2012). Clients or family members may be more willing to disclose the presence of abuse if greater privacy is afforded them, or if presence of a trusted family member or friend helps clients to respond more comfortably to the interview situation.*
- Assess for risk factors of self-mutilation described above. **CEB:** *Self-mutilation has been associated with multiple psychiatric disorders and psychosocial difficulties (Barnes et al, 2010; Holm & Severinsson, 2010; Joyce et al, 2010; Peebles et al, 2011).*
- Perform a thorough skin assessment at least annually and check for behavioral cues of self-harm. **EBN:** *Skin assessment must cover body areas normally clothed. Signs of self-harm include scratches, burns, lacerations, objects embedded under the skin (e.g., razor blades), multiple scars, or carved words. Scars may vary in age and depth. Behavioral cues include wearing long sleeves and pants, wristbands or bulky bracelets, and avoiding situations that would result in exposed skin (e.g., physical education class) (Catledge et al, 2012).*
- Assess for co-occurring disorders that require response, specifically childhood abuse, substance abuse, and suicide attempts. Implement reporting or referral as indicated. **EB:** *Self-mutilation has been associated with multiple psychiatric disorders (Moller et al, 2013).*
- Assess family dynamics and the need for family therapy and community support. **EBN:** *Self-harm is associated with childhood abuse and family dysfunction (Catledge et al, 2012).*
- Assess for the presence of medical disorders, mental retardation, medication effects, or disorders such as autism that may include self-mutilation. Initiate referral for evaluation and treatment as appropriate. **CEB:** *Lesch-Nyhan syndrome is a rare genetic disorder, which is characterized by compulsive self-mutilation (Zilli & Hasselmo, 2008).*
- Be alert to other risk factors of self-mutilation in clients with psychosis, including acute intoxication, dramatic changes in body appearance, preoccupation with religion and sexuality, and anticipated or perceived object loss. *Many psychiatric disorders have shown a connection with self-mutilation. CEB: Command hallucinations occurring in schizophrenia or brief psychotic episodes may direct the client to hurt himself or herself or others (Barrowcliff & Haddock, 2010).*
- Monitor the client's behavior closely, using engagement and support as elements of safety checks while avoiding intrusive overstimulation. Offer activities that will serve as a distraction. *When lack of control exists, client safety is an important issue and close observation is essential. EBN: Clients were found to feel overstimulated by intrusive close observation, resulting in agitation (Ray et al, 2011).*
- Establish trust, listen to client, convey safety, and assist in developing positive goals for the future. **EBN/EB:** *Clients reported that nurses were helpful when they took charge of unsafe situations, performed bodily interventions (e.g., holding hand), conveyed safety, and respected the autonomy of the client (Schoppmann et al, 2007). Promoting trust and enhancing privacy are considered important (Catledge et al, 2012). Refer to mental health counseling. Multiple therapeutic modalities are available for treatment. EBN: A systematic review of treatment modalities suggests that systemic family therapy or developmental group*

psychotherapy (using a combination of cognitive behavior therapy, dialectic behavior therapy, and psychodynamic therapy) can be effective (Prymachuk & Trainor, 2010). Inform the client of expectations for appropriate behavior and consequences within the unit. Emphasize that the client must comply with the rules. Give positive reinforcement for compliance and minimize attention paid to disruptive behavior while setting limits. Clients benefit from clear guidance regarding behavioral expectations and consequences, providing much-needed structure. It is important to reinforce appropriate behavior to encourage repetition. **CEB:** Treatment should involve assisting the client to learn healthier affective regulation skills (Gilbert et al, 2010; Hall & Place, 2010).

- Clients need to learn to recognize distress as it occurs and express it verbally rather than as a physical action against the self. **CEB:** Treatment should involve assisting the client to learn healthier affective regulation skills (Gilbert et al, 2010; Hall & Place, 2010).
- Assist the client to identify the motives/reasons for self-mutilation that have been perceived as positive. Self-harm serves as a defense mechanism. **CEB:** Persecutory self-criticism and limited coping skills are linked with self-harm (Gilbert et al, 2010; Hall & Place, 2010).
- Help the client identify cues that precede impulsive behavior. **CEBN:** The dialectical behavior therapy (DBT) technique of behavioral chain analysis was found to reduce self-harm behaviors by processing events that precipitate self-mutilation (Alper & Peterson, 2001).
- Assist clients to identify ways to soothe themselves and generate hopefulness when faced with painful emotions. **CEB:** Women with a history of childhood abuse may not have developed the internal ability to comfort themselves, or self-soothe, resulting in neurobiological disruptions that lead to self-harm as a means of relieving pain (Gallop, 2002). Generating hopefulness is an important self-comforting intervention (Weber, 2002).
- Reinforce alternative ways of dealing with depression and anxiety, such as exercise, engaging in unit activities, or talking about feelings. Goal direction enhances self-efficacy, an important antecedent of empowerment (Self-injury.net, 2012).
- Keep the environment safe; remove all harmful objects from the area. Use of unbreakable glass is recommended for the client at risk for self-injury. Client safety is a nursing priority. Unbreakable glass would eliminate this type of injury.
- Anticipate trigger situations and intervene to assist the client in applying alternatives to self-mutilation. **CEB:** When triggers occur, client stress level may obstruct ability to apply recent learning. Cognitive strategies can be useful to correct irrational beliefs that are part of the trigger (Claes & Vandereycken, 2007).
- If self-mutilation does occur, use a calm, nonpunitive approach. Whenever possible, assist the client to assume responsibility for consequences (e.g., dress self-inflicted wound). Refer to the care plan for **Self-Mutilation**. This approach does not promote inappropriate attention-getting behavior, may decrease repetition of behavior, and reinforces self-responsibility and self-care management.
- If the client is unable to control self-mutilation behavior, provide interactive supervision, not isolation. Isolation and deprivation take away the individual's coping abilities and place him or her at risk for self-harm. Implementing seclusion for clients who have injured themselves in the past may actually facilitate self-injury. Clients are extraordinarily resourceful at identifying environmental objects with which to self-mutilate.
- Involve the client in planning his/her care and problem solving, and emphasize that the client can make choices. **CEB:** Clients reported negative responses to having no input into their treatment plan (Fish & Duperouzel, 2008; Rasmussen et al, 2010).
- ▲ Refer to protective services if evidence of abuse exists. It is the nurse's legal responsibility to report abuse.
- Refer to the care plan for **Self-Mutilation**.

Pediatric

- The same dynamics described previously apply to adolescents. **EBN:** Self-harm is a major public health issue arising in persons aged 12 to 24 years, most often in females (Catledge et al, 2012).
- Maintaining a therapeutic relationship with teens requires explicit assurances of confidentiality, consistency of clinical routines, and a nonjudgmental communication style. **CEB:** Even adolescents younger than age 18 years need assurances that confidentiality will be maintained unless there is a serious risk of harm to themselves or others. However, teens of all ages should be advised that parental notification will be made to ensure the teen's safety and to implement a treatment plan (Derouin & Bravender, 2004).
- Encourage expression of painful experiences and provide supportive counseling. **EBN:** Among female adolescents, themes from a qualitative study included living with childhood trauma, feeling abandoned, being

an outsider, loathing self, silently screaming, releasing the pressure, feeling alive, being ashamed, and being hopeful (Lesniak, 2010; Rissanen et al, 2011).

- Multiple treatment modalities may be used in addressing the themes of young people who self-harm. **EBN:** *A systematic review identified individual, family, group, and psychopharmacological therapies as being used for treatment; however, limited research exists to determine which are most effective (Pryjmachuk & Trainor, 2010).*
- Teach coping skills as an important intervention for adolescents. **EB:** *Studies suggest that negative emotional coping skills such as rumination, self-blame, and helplessness contribute to self-harm. Social and active coping was significantly associated with noncutting behavior (Hall & Place, 2010).*
- Assess for the presence of an eating disorder or substance abuse. Attend to the themes that preoccupy teens with eating disorders who self-mutilate. **CEB:** *Self-harmers with a history of childhood sexual abuse reported more eating disorders (Murray et al, 2008; Wright et al, 2009).*
- Evaluate for suicidal ideation/suicide risk. Refer to the care plan for Risk for **Suicide** for additional information. **CEB:** *Adolescents who attempted suicide by overdose admitted to some method of self-mutilation. The self-mutilators were significantly more likely than non-self-mutilators to be diagnosed with oppositional defiant disorder, major depression, and dysthymia and had higher scores on measures of hopelessness, loneliness, anger, risk-taking, and alcohol use (Guertin et al, 2001).*
- Be aware that there is not complete overlap between self-mutilation and suicidal behavior. The motivation may be different (coping with difficult feelings rather than ending life), and the method is usually different. **CEB:** *In one study, about half of the participants reported both attempted suicide and self-mutilation; the other half reported no overlap in types of acts (Bolognini et al, 2003).*
- Use treatment approaches detailed in nursing interventions, with modifications as appropriate for this age group.

Geriatric

- Provide hand or back rubs and calming music when older clients experience anxiety. *Calming music or hand massage can soothe agitation for up to 1 hour. No additional benefit was found from combining the two interventions.*
- Provide soft objects for older clients to hold and manipulate when self-mutilation occurs as a function of delirium or dementia. Apply mitts, splints, helmets, or restraints as appropriate. *Delirious or demented clients may scratch or pick at themselves. Soft objects may provide a substitute object to pick at; mitts or restraints may be necessary if the client is unable to exercise self-restraint. They should only be used for a limited amount of time as they may contribute to delirium.*
- Be aware that older adults may demonstrate self-neglect. Older adults who show self-destructive behaviors should be evaluated for dementia. **EB:** *In a qualitative study of unsupervised assisted living residents, more than half of participants showed self-neglect behaviors (Caspi, 2014).*

Home Care

- Communicate degree of risk to family/caregivers; assess the family and caregiving situation for ability to protect the client and to understand the client's self-mutilative behavior. Provide family and caregivers with guidelines on how to manage self-harm behaviors in the home environment. *Client safety between home visits is a nursing priority. Appropriate family/caregiver support is important to the client. Appropriate support will only be forthcoming if all parties understand the basis of the behavior and how to respond to it.*
- Establish an emergency plan, including when to use hotlines and 911. Develop a contract with the client and family for use of the emergency plan. Role-play access to the emergency resources with the client and caregivers. *Having an emergency plan reassures the client and caregivers and promotes client safety. Contracting gives guided control to the client and enhances self-esteem.*
- Assess the home environment for harmful objects. Have family remove or lock objects as able. *Client safety is a nursing priority.*
- ▲ If client behaviors intensify, institute an emergency plan for mental health intervention. The degree of disturbance and the ability to manage care safely at home determine the level of services needed to protect the client.
- ▲ Refer for homemaker or psychiatric home health care services for respite, client reassurance, and implementation of therapeutic regimen. *Responsibility for a person at high risk for self-mutilation provides high caregiver stress. Respite decreases caregiver stress. The presence of caring individuals is reassuring to both the client and caregivers, especially during periods of client anxiety. A client with self-mutilative behavior,*

especially if accompanied by depression, can benefit from the interventions described previously, modified for the home setting.

- ▲ If the client is on psychotropic medications, assess client and family knowledge of medication administration and side effects. *Teach as necessary. Knowledge of the medical regimen promotes compliance and promotes safe use of medications.*
- ▲ Evaluate the effectiveness and side effects of medications. Accurate clinical feedback improves health care provider's ability to prescribe an effective medical regimen specific to client needs.

Client/Family Teaching and Discharge Planning

- Explain all relevant symptoms, procedures, treatments, and expected outcomes for self-mutilation that is illness based (e.g., borderline personality disorder, autism). **CEB:** *Clients prefer to participate in their treatment planning to gain a sense of control (Fish & Duperouzel, 2008; Rasmussen et al, 2010).*
- Assist family members to understand the complex issues of self-mutilation. Provide instruction on relevant developmental issues and on actions that parents can take to avoid media that glorify self-harm behaviors. **CEB:** *Family members need to understand the behaviors they are dealing with, receive positive reinforcement that will promote their patience and perseverance, and know that they can take positive action to remove media triggers for self-mutilation (Rasmussen et al, 2010; Rissanen et al, 2009).*
- Provide written instructions for treatments and procedures for which the client will be responsible. *A written record provides a concrete reference so that the client and family can clarify any verbal information that was given.*
- Instruct the client in coping strategies (assertiveness training, impulse control training, deep breathing, progressive muscle relaxation). *Clients who self-mutilate have difficulty dealing with stress and painful emotions, which serve as triggers to self-harm. Once clients are able to identify these triggers, they need to learn how to respond to them more effectively through assertiveness, impulse control, or relaxation, as appropriate.*
- Role play responses to stressful situations (e.g., say, "Tell me how you will respond if someone ignores you"). *Role playing is the most commonly used technique in assertiveness training. It deconditions the anxiety that arises from interpersonal encounters by allowing the client to practice how he or she might respond in a given situation. Anxiety levels tend to be higher in situations that are unfamiliar.*
- Teach cognitive-behavioral activities, such as active problem solving, reframing (reappraising the situation from a different perspective), or thought-stopping (in response to a negative thought, picture a large stop sign and replace the image with a prearranged positive alternative). Teach the client to confront his or her own negative thought patterns (or cognitive distortions), such as catastrophizing (expecting the very worst), dichotomous thinking (perceiving events in only one of two opposite categories), or magnification (placing distorted emphasis on a single event). *Cognitive-behavioral activities address clients' assumptions, beliefs, and attitudes about their situations, fostering modification of these elements to be as realistic and optimistic as possible. Through cognitive-behavioral interventions, clients become more aware of their cognitive choices in adopting and maintaining their belief systems, thereby exercising greater control over their own reactions (Hagerty & Patusky, 2011).*
- ▲ Provide the client and family with phone numbers of appropriate community agencies for therapy and counseling. Continuous follow-up care should be implemented; therefore, the method to access this care must be given to the client.
- ▲ Give the client positive things on which to focus by referring to appropriate agencies for job-training skills or education. **CEB:** *Clients expressed the desire for goals they could aim for as a means of regaining a positive view of the future (Fish & Duperouzel, 2008).*

Self-Neglect Susanne W. Gibbons, PhD, C-ANP/GNP

NANDA-I

Definition

A constellation of culturally framed behaviors involving one or more self-care activities in which there is a failure to maintain a socially accepted standard of health and well-being (Gibbons et al, 2006)

Defining Characteristics

Insufficient environmental hygiene; insufficient personal hygiene; nonadherence to health activities

Related Factors (r/t)

Alteration in cognitive functioning; Capgras syndrome; deficient executive function; fear of institutionalization; frontal lobe dysfunction; functional impairment; inability to maintain control; learning disability; lifestyle choice; malingering; psychiatric disorder; psychotic disorder; stressors; substance abuse

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Self Neglect; Self-Care Status; Self-Care: Activities of Daily Living (ADLs); Risk Detection; Nutritional Status; Social Support

Examples of NOC Outcome with Indicator

Self-Care Status as evidenced by the following indicators: Maintains personal cleanliness, recognizes safety needs in the home. (Rate outcome and indicators of **Self-Care Status**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Show improvement in mental health problems
- Show improvement in chronic medical problems
- Reveal improvement in cognition (e.g., if reversible and treatable)
- Demonstrate improvement in functional status (e.g., basic and instrumental activities of daily living)
- Demonstrate adherence to health activities (e.g., medications and medical appointments)
- Exhibit improved personal hygiene
- Exhibit improved environmental hygiene
- Have fewer hospitalizations and emergency room visits
- Increase safety of client
- Increase safety of community in which client lives
- Agree to necessary personal and environmental changes that eliminate risk/endangerment to self or others (e.g., neighbors)

NOTE: Because self-neglect is a culturally framed and socially defined phenomenon, change in a client's status must occur in such a way that it respects individual rights while ensuring individual health and well-being. This is accomplished through client-nurse partnership as well as interdisciplinary collaboration and team work, and in some instances, assistance of next of kin and/or adult protective services (APS) may be needed (e.g., a state agency or local social services program).

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Self Neglect; Self-Care Assistance: Activities of Daily Living; Support System Enhancement

Example NIC Activities—Self-Care Assistance: Activities of Daily Living

Determine individual's need for assistance with ADLs (e.g., shopping, cooking, housekeeping, laundry, use of transportation, managing money, managing medications, use of communication, and use of time)

Nursing Interventions and Rationales

- Monitor individuals with acute or chronic mental and complex physical illness for defining characteristics for self-neglect. **EBN/EB**: *Medical and psychiatric conditions probably underlie most cases of self-neglect, as demonstrated in studies of impaired older adults (Dong et al, 2012; Gibbons et al, 2006; Pavlou & Lachs, 2008).*
- Assist individuals with complex mental and physical health issues to adopt positive health behaviors so that they may maintain their health status in the community. **EBN/EB/CEB**: *A variety of mental illnesses have been correlated with self-neglect in younger adults. However, in the older adult population, depression has been particularly associated with self-neglecting behavior, with inadequately treated medical disease identified more often in self-neglecters who are also depressed (Burnett et al, 2006; Gibbons et al, 2006).*
- Assess persons with complex health issues for adequate coping abilities, and assist those with coping problems to maintain their health and well-being in the community. **EBN**: *Personal control and protecting*

self are coping strategies seen in community-dwelling self-neglecters and in those identified by APS. Individuals use these strategies to compensate, which sometimes causes them to appear uncooperative or resistant to care and change (Gibbons, 2009; Lauder & Roxburgh, 2012).

- Assist individuals with reconnecting with family, friends, and other social networks available to them. **CEB/EBN:** Social isolation is a risk for self-neglect: as seen in a case control study, 91 confirmed self-neglecting older adults were more likely to live alone, even if married, had less frequent visits from family, friends, and neighbors, and were less likely to participate in religious activities (Burnett et al, 2006; Gibbons, 2009).
- Assist individuals whose self-care is failing with managing their medication regimen. **EBN/EB:** Individuals who exhibit self-neglect may have difficulty managing medication, as seen in a community study of 100 APS-confirmed older adults with self-neglect, in which researchers found the average rate of medication adherence to be 59% (Turner et al, 2014).
- Assess individuals with failing self-care for noncompliance (e.g., diagnostic testing, medication regimen, therapeutic regimen, and safety precautions). **EBN:** Individuals who exhibit self-neglect may demonstrate noncompliance with other therapeutic regimens as well (Gibbons et al, 2006; Naik et al, 2008).
- Assist persons with self-care deficits due to ADL or IADL impairments. **EBN/EB/CEB:** Individuals with self-care deficits may have difficulty with ADLs. Greater self-neglect severity has been associated with lower levels of physical function among older adults (Ernst & Smith, 2011; Dong et al, 2009).
- Assess persons with failing self-care for changes in cognitive function (e.g., dementia or delirium). **EBN:** Individuals with failing self-care may have changes in cognition. Decline in executive function has been associated with risk of reported and confirmed elder self-neglect, and decline in global cognitive function has been associated with risk of greater self-neglect severity (Naik et al, 2008).
- ▲ Refer persons with failing self-care to appropriate specialists (e.g., psychologist, psychiatrist, social work) and therapists (e.g., physical therapy, occupational therapy). **EBN/EB:** Individuals with self-care deficits may need assistance from other health professionals (Burnett et al, 2014; Lauder & Roxburgh, 2012).
- Use behavioral modification as appropriate to bring about client changes that lead to improvement in personal hygiene, environmental hygiene, and adherence to medical regimen. **EBN/EB/CEB:** Behavioral modification approaches have been effective in reversing self-neglect in older adults who had triggers or events that brought about the behavior (Fraser, 2006; Gibbons, 2009; Thibault, 2008).
- Monitor persons with substance abuse problems (i.e., drugs, alcohol, smoking) for adequate safety. **EBN/EB:** Because mental health and substance use disorders can go unrecognized and untreated in this population, identified self-neglecting clients should be screened as appropriate by nurses and other health professionals (Gibbons, 2009; Paveza et al, 2008). Self-neglecters demonstrate a unique pattern of controlled prescription drug use as seen in a matched control community study of pain, insomnia, and anxiety, where self-neglecting subjects were less likely to take non-opioid pain medications (e.g., Tylenol) and were four times as likely to use benzodiazepines (Culberson et al, 2011).
- ▲ Refer persons with failing self-care who are significantly impaired cognitively or functionally and who are suspected victims of abuse to APS. **EB/CEB:** Self-neglect has been associated with mistreatment in older adults, especially those who live alone (Dyer et al, 2007; Pavlou & Lachs, 2008).
- Monitor clients with changes in cognitive function for adequate safety. **EB:** Dementia is one of the leading causes for self-neglect (Dong et al, 2010; Dong et al, 2012; Dyer et al, 2007).
- Monitor clients with functional impairments for adequate safety. **EBN/CEB:** Functional impairment, often associated with depression in the older adult, is correlated with self-neglect (Lachs et al, 2002).
- Assist individuals with complex mental and physical health needs with maintaining their health and well-being in the community. **EB:** Those self-neglecters institutionalized in nursing homes have a higher mortality rate than those never identified, and for this reason, maintaining a client's health and well-being in the community setting is essential to a more positive outcome (Gibbons, 2009; Lauder & Roxburgh, 2012).

S

Geriatric

- ▲ Assess client's socioeconomic status and refer for appropriate support. **EB:** Findings from several studies associate elder self-neglect/neglect with frail older adults' and their families' lack of resources to pay for essential goods and services, leading to inadequate health care and lack of other formal support programs for these older adults and their caregivers (Choi et al, 2009; Dong et al, 2009).
- ▲ Refer persons demonstrating a significant decline in self-care abilities (e.g., posing a threat to themselves or to their community) for evaluation of capacity and executive function. **EB:** Current evidence indicates

that executive dyscontrol contributes to self-neglect in the older adult population, where it might be considered a geriatric syndrome (Dyer et al, 2007; Pavlou & Lachs, 2006).

- ▲ Obtain the assistance of APS in the case of refusal of professional health care services when there is a clear indication of self-endangerment. **EB**: Evidence from a systematic review of the medical literature and a roundtable discussion with an interdisciplinary group of experts in the field of gerontology and elder mistreatment led to this important distinction for intervention (Pavlou & Lachs, 2008).

Multicultural

- Deliver health care that is sensitive to the culture and philosophy of individuals whose self-care appears inadequate. **EBN**: Nurses must be careful not to prematurely judge clients' health choices or living arrangements, because personal choice or lifestyle does not necessarily indicate self-neglect until client behavior poses a risk to self and/or others. For this reason, it is imperative that nurses assess values and beliefs of persons with inadequate self-care to better identify their individual health needs (Gibbons et al, 2006).
- Awareness that racial differences for self-neglect may exist, putting some older adults more at risk than others. **EB/CEB**: When assessing psychological health and social factors of self-neglecters identified in a biracial community, it was found that there was a significant association between self-neglect severity and health and social factors. Older black adults had more days away from usual activities and less social engagement and suffered greater mortality related to self-neglect than their white counterparts (Dong et al, 2010a; Dong et al, 2011).

Sexual dysfunction *Elaine E. Steinke, PhD, APRN, CNS-BC, FAHA, FAAN*

NANDA-I

Definition

A state in which an individual experiences a change in sexual function during the sexual response phases of desire, excitation, and/or orgasm, which is viewed as unsatisfying, unrewarding, or inadequate

Defining Characteristics

Alteration in sexual activity; alteration in sexual excitation; alteration in sexual satisfaction; change in interest toward others; change in self-interest; change in sexual role; decrease in sexual desire; perceived/actual sexual limitation; seeks confirmation of desirability; undesired change in sexual function

Related Factors (r/t)

Absent of privacy; absence of significant other; alteration in body function (due to anomaly, age disease, medication, pregnancy, radiation, surgery, trauma); alteration in body structure (due to anomaly, disease, pregnancy, radiation, surgery, trauma); inadequate role model; insufficient knowledge about sexual function; misinformation about sexual function; presence of abuse (e.g., physical, psychological, sexual); psychosocial abuse (e.g., controlling, manipulation, verbal abuse); value conflict; vulnerability

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Recovery: Sexual; Knowledge: Sexual Function, Physical Aging; Psychosocial Adjustment: Life Change; Risk Control: Sexually Transmitted Diseases (STDs); Sexual Functioning; Sexual Identity

Example NOC Outcome with Indicators

Sexual Functioning as evidenced by the following indicators: Expresses comfort with sexual expression/Expresses comfort with body/Expresses sexual interest. (Rate the outcome and indicators of **Sexual Functioning**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

S

Client Outcomes

Client Will (Specify Time Frame)

- Identify individual cause of sexual dysfunction
- Identify stressors that contribute to dysfunction
- Discuss alternative, satisfying, and acceptable sexual practices for self and partner
- Identify the degree of sexual interest by the client and partner
- Adapt sexual technique as needed to cope with sexual problems
- Discuss with partner concerns about body image and sex role

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Sexual Counseling; Teaching: Sexuality

Example NIC Activities—Sexual Counseling

Provide privacy and ensure confidentiality; Discuss necessary modifications in sexual activity, as appropriate; Provide referral/consultation with other members of the health care team, as appropriate

Nursing Interventions and Rationales

- Gather the client's sexual history, noting normal patterns of functioning and the client's vocabulary, and encouraging clients to ask questions or discuss sexual problems experienced. **EBN**: *Women should be*

evaluated for female sexual dysfunction (FSD), with attention to problems with desire, arousal, orgasm, and pain, as part of a complete history and physical exam (Albaugh, 2014). **EB:** In a cross-sectional study of 388 men evaluated in the cardiology office setting, 56% had erectile dysfunction (ED), and of these 46% expressed interest in discussing ways to improve sexual function with the cardiologist, and 55% wanted a consultation with a specialized nurse (Nicolai et al, 2014b).

- ▲ Assess duration and risk factors for sexual dysfunction and explore potential causes such as medications, medical problems, aging process or psychosocial issues. **EB:** Erectile dysfunction shares many of the same risk factors of cardiovascular disease (CVD), and a systematic review suggests that erectile dysfunction may be an early marker of CVD in men, preceding CVD by an average of 3 years (Gandaglia et al, 2014). **EB:** Novel approaches may be needed for effective ED care; e-medicine has been shown to improve uniform questioning, history taking, physical exam, screening, and client education, with outcomes greater than that with more traditional care and with improved client-provider communication (Smith et al, 2013).
- Assess for history of sexual abuse. **EB:** Risk factors for adult sexual victimization included being a woman, living alone, economically disadvantaged, and a history of childhood abuse/neglect or parental psychopathology; adult sexual victimization was linked with post-traumatic stress disorder and drug abuse (Xu et al, 2013).
- Determine the client and partner's current knowledge and understanding, and validate that it is normal to have sexual concerns. **EBN:** A qualitative study of women's understanding of sexual problems illustrated that while diagnostic criteria typically do not take into account the partner, women expressed that partner and relationship factors are fundamental factors within the context of the sexual relationship, and inclusive of physical and psychological perspectives (Bellamy et al, 2013). **EBN:** Only 41% of 115 clients with MI and 31% of partners reported a discussion of sex and relationships with health care professionals, and in comparing sexual knowledge from 1 month post-MI to 1 year, knowledge increased for clients and not for partners, illustrating the need to include partners in discussions; the Sex After MI Knowledge Test could be used to facilitate discussion and evaluate knowledge (Brännström et al, 2014).
- ▲ Assess and provide treatment for sexual dysfunction, involving the person's partner in the process, and evaluating pharmacological and nonpharmacological interventions. **EB:** The use of phosphodiesterase type 5 (PDE5) inhibitors is generally safe in men with cardiovascular disease, although they should be avoided for those receiving nitrate therapy (Levine et al, 2012). **EB:** A review of trials related to sexual satisfaction and PDE5 inhibitors showed a positive relationship between erectile function and both individual sexual satisfaction and satisfaction with erections, as well as satisfaction between the couple and the sexual relationship (Mulhall et al, 2011).
- Assess risk factors for sexual dysfunction, especially with varying sexual partners. **EB:** Men having sex with men had sexual dysfunction with progressive HIV infection (Shindel et al, 2011). **EB:** In Chinese men who had sex with men, sexual dysfunction was prevalent in more than half of study participants, although contributing factors to sexual dysfunction is not well understood in China or other countries (Tsui et al, 2014).
- Observe for stress and anxiety as possible causes of dysfunction. **EBN:** A survey of cardiac rehabilitation clients revealed that ED and lack of interest in sex were commonly reported, with deterioration in sexual function after a cardiac event, and higher anxiety and being male predictive of sexual problems (Byrne et al, 2013). **EB:** Sexual problems and concerns were prevalent among women post-MI, including fears about causing another MI and the risks and safety in resuming sexual activity (Abramsohn et al, 2013).
- ▲ Assess for depression as a possible cause of sexual dysfunction, and institute appropriate treatment, as depression is commonly observed in clients with chronic disease and chronic pain. **EB:** Adolescents in a trial using a group delivered HIV prevention intervention, and either a general health or sexual health intervention, reported significantly fewer depressive symptoms for both groups, and even more so for those in the sexual health intervention group (Brown et al, 2014). **EBN:** Sexually active cardiac clients reported less sexual depression than those not sexually active; measures to promote sexual function and treatment of sexual dysfunction are important for sexual quality of life (Steinke et al, 2013b). (Additional relevant research: Mosack et al, 2011.)
- Observe for grief related to loss (e.g., amputation, mastectomy, ostomy), as a change in body image often precedes sexual dysfunction. See care plan for Disturbed **Body Image**. **EB:** Changes in body image occur in over half of cancer survivors and 41% experience a decrease in sexual function (Averyt & Nishimoto, 2014). **EB:** A study using a psychoeducational group intervention to examine quality of life in breast cancer survivors had improved relationship adjustment and increased satisfaction with sex (Rowland et al, 2011).

- ▲ Explore physical causes of sexual dysfunction such as diabetes, cardiovascular disease, arthritis, or benign prostatic hypertrophy (BPH). **EB:** *In men and women with heart failure, approximately 60% experienced sexual problems related to performance, overall sexual function, and decreased sexual pleasure and satisfaction. Contributing factors included lack of energy, decreased exercise capacity, and depressed mood (Jaarsma et al, 2014).* **EB:** *Women with diabetes who were insulin dependent were more likely to report problems with vaginal lubrication and orgasm than nondiabetic women, and in all diabetic women, factors associated with decreased sexual function were heart disease, stroke, renal dysfunction, and peripheral neuropathy (Copeland et al, 2012).*
- Certain chronic diseases such as cancer often have significant effects on sexual function. Both the disease process and treatment can contribute to sexual dysfunction. **EBN:** *Side effects from cancer treatments such as surgery, chemotherapy, radiation, and other medications contribute to FSD in women with cancer, making treatment such as medications, devices, counseling, and support important interventions (Anderson, 2013).* **EB:** *In male and female colorectal cancer survivors (N = 261), older age and destructive surgery were associated with poorer erectile function in men, and for women, older age and decreased overall quality of life were associated with lower sexual function scores (Milbury et al, 2013).*
- Consider that neurological diseases such as multiple sclerosis (MS) affect sexual function directly, but with secondary effects due to disability related to the illness, social, and emotional effects. **EBN:** *Approximately one half to three fourths of men and women with MS experience sexual problems, which may include erectile dysfunction, delayed ejaculation, and decreased sensation in men, while women may experience decreased libido, impaired genital sensation, problems with orgasm, and vaginal dryness (Ward-Abel & Hall, 2012).*
- Explore behavioral or other causes of sexual dysfunction, such as smoking, dietary factors, or obesity. **EB:** *In a small case controlled study of Iranian women, higher body mass index (BMI) was significantly associated with sexual dysfunction, particularly for sexual arousal and pain (Raisi et al, 2013).* **EB:** *Dyslipidemia contributed to impaired sexual function in men and women with coronary artery disease, in addition to any sexual dysfunction such as ED (Assari et al, 2014).*
- ▲ Consider medications as a cause of sexual dysfunction. **EB:** *A systematic review of the effects of cardiovascular drugs on sexual function revealed overall negative effects of beta blockers, cardiac glycosides, and diuretics; neutral effects with alpha blockers, angiotensin converting enzyme inhibitors, and calcium channel blockers; and positive effects from angiotensin receptor blockers and statins on sexual function, although there are mixed results for some of these drug classes (Nicolai et al, 2014a).* **EB:** *A meta-analysis from 63 studies of second generation antidepressants in clients with major depressive disorder showed that bupropion conferred a significantly lower risk of sexual dysfunction, and citalopram and paroxetine were significantly associated with higher risk of sexual dysfunction, when compared with other second generation drugs (Reichenpfader et al, 2014).*
- Provide privacy when discussing sexual problems and be verbally and nonverbally nonjudgmental. **EB:** *It is important for health care professionals to balance the sensitivity of discussing sexual issues with the support and educational needs of clients and partners (Steinke et al, 2013b).* **EB:** *The use of open-ended questions can facilitate sexual discussions (Steinke & Jaarsma, 2014).*
- Explain the need for the client to share concerns with partner. **EB:** *Among cardiac clients, partner concerns are prevalent, including fear of causing another cardiac event with sexual activity (Steinke et al, 2013a).*
- ▲ Refer to appropriate medical providers for consideration of medication for premature ejaculation, erectile dysfunction, or orgasmic problems. **EB:** *Phosphodiesterase type 5 (PDE5) inhibitors are often first line of treatment for ED, with first time response rates of 60% to 70%, overall treatment success rates of 89%, and similar efficacy among the currently available drugs (Smith et al, 2013).* **EB:** *In a Japanese study, self-confidence and sexual spontaneity in men taking vardenafil and tadalafil were significantly higher than those taking sildenafil, but with clients' time concerns, a preference was shown for taking sildenafil versus tadalafil, which seemed to be related to feeling pressured by having to keep track of time related to drug action and sexual activity (Tsujiura et al, 2014).*
- Refer women for possible pharmacological intervention for sexual dysfunction. **EBN:** *Therapies for female sexual dysfunction include testosterone replacement therapy, DHEA, and topical preparations for arousal disorders, atrophy (e.g., topical estrogen), or pain (e.g., lidocaine) (Albaugh, 2014).*

Geriatric

- ▲ Carefully assess the sexuality needs and sexual dysfunction of older adults and refer for counseling if needed. **EB:** *In older men and women with heart failure, sexual problems occurred in 59%, compared with*

56% in community controls, and sexual problems occurred more frequently in men and those partnered; discussion of sexual problems and implementing appropriate management is an integral part of heart failure care (Hoekstra et al, 2012).

- Teach about normal changes that occur with aging that may be perceived as sexual dysfunction, such as reduction in vaginal lubrication and reduction in duration and resolution of orgasm for women; and for men, increased time required for erection and for subsequent erections, erection without ejaculation, less firm erection, and decreased volume of seminal fluid. **EB:** A significant barrier among older adults included the perception that sexual problems were a normal part of aging, and older adults were more likely to seek help if a proactive approach by health care providers was used to assess sexual health (Hinchliff & Gott, 2011).
- Explore various sexual gratification alternatives (e.g., caressing, sharing feelings) with the client and partner. **EBN:** Many satisfying alternatives are available for expressing sexual feelings and, if sexual intercourse is not possible, exploring other types of sexual activities such as hugging, kissing, and sexual touching (Steinke, 2013).
- Discuss the difference between sexual function, sexuality, and sexual dysfunction, including that all individuals possess sexuality from birth to death, regardless of changes occurring over the life span. **EBN:** Sexual problems can be caused by psychological, interpersonal, or social problems and can significantly affect both physical and psychological well-being (Garrett, 2014). **EB:** Successful aging includes positive sexual satisfaction, although sexual problems related to arousal, desire, and ability to climax are associated with increased age (Thompson et al, 2011).
- If prescribed, instruct clients with chronic pain to take pain medication before sexual activity. **EBN:** Nitroglycerin can be used for anginal pain; pain inhibits satisfying sexual activity (Steinke et al, 2013a). **EBN:** Treatment of chronic pain can improve libido and sexual function (Richards et al, 2011).
- See care plan for Ineffective **Sexuality** pattern.

Multicultural

- Evaluate culturally influenced risk factors for sexual dysfunction. **EBN:** Women may be reluctant to discuss sexual dysfunction because the topic may be viewed as taboo, and sociocultural factors such as arranged marriages or non-satisfying relationships (Erten et al, 2013). **EB:** Nationally targeted communication campaigns related to HIV often overlook black heterosexual men in prevention efforts, although these men report wanting more information on HIV prevention to better protect themselves and their partners, as well as to educate and protect their children (Bowleg et al, 2013).
- Validate client feelings and emotions regarding the changes in sexual behavior, letting the client know that the nurse heard and understands what was said, and promoting the nurse-client relationship. **EB:** Assessment of sexual dysfunction throughout cancer treatment is important to facilitate discussion and to evaluate the needs and concerns of clients (Averyt & Nishimoto, 2014). **EBN:** A holistic approach that considers cultural, relationship, psychosocial, and health-related concerns is important to avoid “medicalizing” the sexual problems of women (Bellamy et al, 2013).

Home Care

- Previously discussed interventions may be adapted for home care use.
- ▲ Identify specific sources of concern about sexual dysfunction and provide reassurance and instruction on appropriate expectations as indicated. **EB:** Clients with schizophrenia and sexual dysfunction had significantly worse subjective quality of life, and aspects of physical arousal such as vaginal lubrication and penile erection were commonly affected; it is important to address causes of sexual dysfunction and implement management strategies tailored to the client (Bushong et al, 2013).
- ▲ Confirm that physical reasons for dysfunction have been addressed, and refer for therapy and/or support groups if appropriate. **EB:** For all cancers, cancer treatments affected intimacy and sexual functioning related to fatigue, treatment-related hair loss, weight gain, scarring, or organ loss, along with other disease-specific changes such as gastrointestinal problems with colorectal cancer, dyspnea with lung cancer, and incontinence with prostate cancer (Flynn et al, 2011). **EB:** In clients with post-traumatic pelvic fracture, urinary tract injury and open surgical treatment were independently associated with sexual dysfunction, and significant predictors of decreased quality of life were male gender, severity of the fracture, pain, and sexual dysfunction (Harvey-Kelly et al, 2014).
- Reinforce or teach the client about sexual functioning, alternative sexual practices, and necessary sexual precautions, and update teaching as client status changes. **EB:** Attendance at a rural nurse led clinic for

women resulted in significant increases in sexual desire, satisfaction, and quality of orgasm at both 1 and 6 months after the last clinic visit (Hakanson et al, 2014).

- See care plan for Ineffective Sexuality pattern.

Client/Family Teaching and Discharge Planning

- Provide accurate information for clients concerning sexual activity after a cardiac event; consider using cognitive and behavioral strategies. **EB:** *Interventions that have been successfully used for sexual counseling include cognitive behavioral therapy, social and psychological support, specific and deliberate sexual counseling, a team approach, sexual counseling over several sessions, and the inclusion of both the client and their partner (Steinke et al, 2013a).*
- Include the partner/family in discharge instructions, because partner concerns are often overlooked in regard to sexual issues. **EBN:** *Psychoeducational interventions and counseling have been shown to improve urinary and/or fecal incontinence, and erectile function in men after radical prostatectomy, and may assist both the client and the client's partner in recovery (Lassen et al, 2013).* **EB:** *Partners may have even greater sexual concerns than clients themselves, thus it is important to include partners in sexual counseling (Steinke et al, 2013a).*
- Teach the client and partner about condom use, for those at risk. **EB:** *A meta-analysis evaluated sexual communication and condom use among adolescents, finding that those who engaged in sexual communication with their partners were more likely to use condoms, illustrating that encouraging sexual communication between the adolescent and sexual partner is critical (Widman et al, 2014).*
- ▲ Teach the client with cardiovascular disease that sexual activity can be resumed within a few weeks for those with minimal symptoms with moderate physical activity, although clients at higher risk or with exercise intolerance may need further evaluation. **EB:** *Clients can usually resume sexual activity after 1 week for an uncomplicated MI, or in 3 to 4 weeks for most clients; some clients may need to undergo exercise testing to determine tolerance for sexual activity before sexual activity can be resumed (Levine et al, 2012; Steinke et al, 2013a).*
- For cardiac clients, discuss being well rested, reporting any cardiac warning signs, using foreplay to determine tolerance for sexual activity, not using alcohol or eating heavy meals before sex, and having sex with a familiar partner and in the usual setting to decrease any stress the couple might feel. **EB:** *Sexual activity can be discussed in the context of exercise, comparing the energy expenditure to that required for sexual activity; clients who are able to walk one mile on a flat surface in 20 minutes, briskly climb 2 flights of stairs in 10 seconds, or walk 4 minutes on a treadmill using the Bruce protocol without symptoms, can generally safely resume sexual activity (Nehra et al, 2012).*
- Provide written educational materials that address sexual issues for clients and families of clients with implantable cardiac defibrillators (ICDs). **EBN:** *Addressing the fears and concerns related to sexual function of ICD clients and partners is essential to rehabilitation and recovery, and the areas of greatest concern for clients were lack of sexual interest, ED, and an overprotective partner, and fewer clients were sexually active after ICD implantation than before (Berg et al, 2013).*
- Discuss sexual problems and adaptations needed for sexual activity with spinal cord injury. **EB:** *Women with spinal cord injury reported that intimacy was negatively affected by urinary incontinence, they had excessive concern about autonomic dysreflexia, and body image was negatively affected, often delaying sexual activity or ceasing activity altogether (Cramp et al, 2014).*
- ▲ Refer to appropriate community resources, such as a clinical specialist, family counselor, or cardiac rehabilitation, including the partner if appropriate; for complex issues, a referral to a sex counselor, urologist, gynecologist, or other specialist may be needed. **EB:** *Sexuality was rated as an important issue by clients after stroke (71%), although sexual dysfunction was common (47%); clients expressed the need for counseling by health care providers, within cardiac rehabilitation, and within 1 year of their stroke (Stein et al, 2013).* **EB:** *A pilot study of a telephone-based sexual counseling intervention for couples that emphasized establishing rapport, couple communications, and enhancing intimacy, provided participants with successful skills to cope with the effects of cancer treatment and to maintain their sexuality (Reese et al, 2012).*
- Teach the importance of diabetic control and its effect on sexuality to clients with diabetes. **EB:** *Predictors of ED in men with diabetes mellitus type 2 were HbA1c, fasting plasma glucose, and systolic blood pressure; age and taking calcium channel blockers were independent predictors of ED (Sharifi et al, 2012).* **EB:** *The role of HbA1c was studied in clients with type 2 diabetes mellitus who had a penile prosthesis implanted, finding that HbA1c was reduced, along with improved sexual functioning (Talib et al, 2014).*

- ▲ Refer for medical advice when ED lasts longer than 2 months or is recurring. **EB**: ED can be treated, and underlying causes need to be investigated through a thorough medical and sexual history (Glina et al, 2014). **EB**: There are four commonly used PDE5 inhibitors available in the U.S. that have shown effectiveness in treating ED; these drugs include sildenafil, vardenafil, tadalafil, and avanafil (Huang & Lie, 2013).
- Teach the following interventions to decrease the likelihood of ED: limit or avoid the use of alcohol, stop smoking, exercise regularly, reduce stress, get enough sleep, deal with anxiety or depression, and see a health care provider for regular checkups and medical screening tests. **EB**: Worse scores for erectile function were associated with older age, smoking status, BMI, and resting heart rate ($P < .001$) in men without a history of CVD or MI; long-term cigarette smoking interfered with sympathovagal balance and negatively affected erectile tumescence (Harte, 2014).

Ineffective Sexuality pattern Elaine E. Steinke, PhD, APRN, CNS-BC, FAHA, FAAN

NANDA-I

Definition

Expressions of concern regarding own sexuality

Defining Characteristics

Alterations in relationship with significant other; alteration in sexual activity; alteration in sexual behavior; change in sexual role; difficulty with sexual activity; difficulty with sexual behavior; value conflict

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Related Factors (r/t)

Absence of privacy; absence of significant other; conflict about sexual orientation; conflict about variant preference; fear of pregnancy; fear of sexually transmitted infection; impaired relationship with a significant other; inadequate role model; insufficient knowledge about alternatives related to sexuality; skill deficit about alternatives related to sexuality

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Abuse Recovery: Sexual, Body Image; Child Development: Middle Childhood/Adolescence; Client Satisfaction: Teaching; Knowledge: Sexual Function; Psychosocial Adjustment: Life Change; Risk Control: Sexually Transmitted Diseases (STDs); Risk Control: Unintended Pregnancy; Role Performance; Self-Esteem; Sexual Functioning; Sexual Identity

Example NOC Outcome with Indicators

Risk Control: Sexually Transmitted Diseases (STDs) as evidenced by the following indicators: Acknowledges personal risk factors for STD/Uses strategies to prevent STD transmission. (Rate the outcome and indicators of **Risk Control: Sexually Transmitted Diseases (STDs)**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

- State knowledge of difficulties, limitations, or changes in sexual behaviors or activities
- State knowledge of sexual anatomy and functioning
- State acceptance of altered body structure or functioning
- Describe acceptable alternative sexual practices
- Identify importance of discussing sexual issues with significant other
- Describe practice of safe sex with regard to pregnancy and avoidance of STIs

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Sexual Counseling; Teaching: Sexuality

Example NIC Activities—Sexual Counseling

Provide privacy and ensure confidentiality; Provide information about sexual functioning, as appropriate

Nursing Interventions and Rationales

- After establishing rapport or therapeutic relationship, give the client permission to discuss issues dealing with sexuality, for example: “Have you been or are you concerned about functioning sexually because of your health status?” **EBN/EB**: Use the *PLISSIT* model to uncover additional concerns (*Permission, Limited Information, Specific Suggestions, referral to Intensive Therapy*), and begin with more general questions and then those more personal; for example, discuss exercise recommendations and then sex as another form of exercise (McLeod & Hamilton, 2013; Steinke et al, 2013a).
- Use assessment questions and standardized instruments to assess sexual problems, where possible. **EBN/EB**: Use specific assessment questions to obtain information on current level of sexual activity, changes in sexual satisfaction, the nature of any problems experienced, underlying causes, and beliefs and misconceptions (Steinke, 2013; Steinke & Jaarsma, 2014).
- ▲ Assess any risks associated with sexual activity, particularly coronary risks. **EB**: Cardiac patients without angina or with mild angina who can exercise at a rate of at least 3 to 5 METS (amount of energy expenditure), and without experiencing angina, ischemic ST segment changes, or excess dyspnea are generally at low risk for cardiac events with sexual activity; those at high risk or if risk classification has not been deter-

mined, exercise stress testing is recommended (Lange & Levine, 2014; Levine et al, 2012). **EBN:** If a cardiac patient is able to engage in physical activity at the rate of 3 to 5 METS or 3 to 4 miles per hour on a treadmill, or climb two flights of stairs briskly, sexual activity can generally be resumed (Steinke & Jaarsma, 2014).

- Include the client's partner in discussing sexual concerns and in providing sexual counseling. **EBN:** Information provided to partners is often inadequate, and discussing sexual issues increases partner understanding and may minimize overprotectiveness by the partner; in post-MI patients and partners, patient knowledge about sex after MI improved at 1 year, while partners' knowledge did not change (Brännström et al, 2014). **EBN:** Partners' ratings of their intimate relationships were high both before and after the patient's MI, with women providing somewhat lower ratings before MI and improved ratings at 1 year, while men's ratings declined somewhat, illustrating the need to discuss sexual concerns with patients and their partners, and to encourage open communication by the couple (Fransson et al, 2013; Dalteg et al, 2011).
- Encourage the client to discuss concerns with his or her partner. **EBN:** Not communicating sexual concerns as a couple can lead to stress and deterioration in the relationship, while open and honest discussions with one's partner can promote sexual intimacy; an ideal time for such discussions might be during a daily walk together (Steinke et al, 2013a; Steinke, 2013).
- Explore attitudes about sexual intimacy and changes in sexuality patterns. **EBN:** Patients with chronic heart failure and their partners reported considerable changes in sexual activity (65%), sexual interest, pleasure and sexual satisfaction, and decline in sexual performance, illustrating the importance of nurses discussing changes in sexual function, considering both psychological and physical perspectives (van Driel et al, 2014). **EB:** Adults burned as children felt sexually attractive and confident about sexual activity, showing that sexual attitudes and behaviors may not be negatively affected by prior burn injury (Meyer et al, 2011).
- Assess psychosocial function such as anxiety, fear, depression, and low self-esteem. **EBN:** Cardiac patients who were sexually active had less sexual anxiety and depression, and higher sexual self-efficacy and satisfaction, when compared to those not sexually active, who reported negative effects on sexual function for these variables (Steinke et al, 2013b). **EB:** Women experiencing sexual distress was significantly associated with decreased pleasure, sexual frequency, and negative partner emotions, and greater distress was experienced by older women and those in unsatisfying relationships (Stephenson & Meston, 2012). (Additional relevant research: Mosack et al, 2011.)
- Discuss alternative sexual expressions for altered body functioning or structure, including closeness and sexual and nonsexual touching as other forms of expression. **EBN:** The meaning of sex and sexuality is individually defined, with some engaging in sexual intercourse, whereas others may prefer touching, holding one another, or kissing (Steinke, 2013). **EB:** Most sexually active older women reported sexual satisfaction, and sexual satisfaction increased with age, although being sexually active was not contingent on sexual activity (Trompeter et al, 2012).
- Some clients choose masturbation for sexual release, an acceptable form of sexual expression, and for some with chronic illnesses, it may be an alternative to sexual intercourse when exercise tolerance is low. **EBN:** Discuss sexual activities in the context of exercise tolerance and suggest acceptable alternatives to the client when sexual intercourse is not possible (Steinke, 2013; Steinke et al, 2013a). **CEB:** For some clients with severe heart failure, activities such as mutual masturbation, oral sex, or sexual intercourse may not be possible if exercise capacity is compromised, making other expressions of intimacy of greater importance (Medina et al, 2009).
- Assess the client's sexual orientation and usual pattern of sexual activities, and discuss prevention of illnesses for which the client may be at increased risk (e.g., anorectal cancer), asking specific questions about sexual orientation, for example, "Do you have sexual relationships with men, women, or both?" Assess use of safer sex practices (e.g., condom use); the frequency of anal intercourse; number of sexual partners in the last year; last HIV screening/results; and use of medications, alcohol, and illicit drugs. **EB:** Among young men who identified themselves as gay, bisexual, or other men who had sex with men, risk behaviors were highest among those with lower socioeconomic status and foreign-born individuals living in the United States, illustrating that assessment beyond race and ethnicity is important to reach those at risk (Halkitis & Figueroa, 2013). **EB:** A sexual genogram is a useful tool to assess issues related to sex and sexuality and to frame intervention, as well as to explore overt and covert messages about sexual behaviors, communication patterns about intimacy, sexual secrets, missing information, and partner communication and perceptions (Belous et al, 2012).

- Specific guidelines for sexual activity for clients who have had total hip arthroplasty include the following: sexual activity can be generally resumed 1 to 2 months after surgery, and a supine position (“missionary”) at maximum abduction in extension to prevent hip dislocation, avoiding the lateral decubitus positions, which carry a higher risk of adduction and internal rotation of the hip. **EBN:** *Although literature supports the use of the supine position and a passive role for the patient, others suggestions include the man and woman standing, with the woman’s legs slightly bent and the man approaching the woman from behind (McFadden, 2013).* **EB:** *In degenerative osteoarthritis patients undergoing total hip or knee replacement, improvements occurred for sexual self-image (55%), improved libido (42%), and increased intercourse duration (36%) and frequency (41%), although fear of damaging the replaced joint (10%) affected sexual function in some patients (Rathod et al, 2013).* (Other relevant research: Wall et al, 2011.)
- Specific guidelines for those who have had a myocardial infarction (MI) include the following: sexual activity can generally be resumed within a few weeks after MI unless complications are experienced, such as arrhythmias or cardiac arrest; engaging in sexual activity in familiar surroundings with the usual partner; a comfortable room temperature, when well rested to minimize cardiac stress; avoiding heavy meals or alcohol for 2 to 3 hours before sexual activity, and choosing a position of comfort to minimize stress of the cardiac client. **EB:** *Guidelines from the American Heart Association and the European Society of Cardiology suggest that resumption of sexual activity after MI is safe for most patients, and occurrence of MI with sexual activity is estimated to be less than 1% (Levine et al, 2012; Steinke et al, 2013a).* **EB:** *Studies of cardiac nurses reveal that increased attention is needed for sexual counseling by cardiac nurses, including cardiac rehabilitation nurses (Barnason et al, 2011; Steinke et al, 2011).*
- Specific guidelines for those who had complete coronary revascularization, in addition to those mentioned with MI, include those with successful percutaneous cardiovascular revascularization without complication can resume sex within a few days; those who have had coronary artery bypass grafting (CABG) or noncoronary open heart surgery may resume sex in 6 to 8 weeks; incisional pain with sexual activity can be managed by premedicating with a mild pain reliever; and reassurance should be provided to the partner that sexual activity will not harm the sternum as long as direct pressure is avoided. **EB:** *Women, particularly those with large breasts, may report more issues related to pain in the breast, chest numbness, and difficulty healing; therefore, encourage the woman to choose a position of comfort, support with pillows, and take a pain reliever such as acetaminophen before sexual activity (Steinke & Jaarsma, 2014).*
- Specific guidelines for those with an implantable cardioverter defibrillator (ICD) include assuring the client and partner that fears about being shocked during sexual activity are normal, and sex can be resumed after the ICD is placed as long as strain on the implant site is avoided; if the ICD discharges with sexual activity, the client should stop, rest, and later notify the health care provider that the device fired so that a determination can be made if this was an appropriate shock or not. The client should be instructed to report any dyspnea, chest pain, or dizziness with sexual activity. **EBN:** *In a randomized controlled trial of 196 patients who received exercise training and psychoeducational follow-up, the greatest reported concerns were lack of interest in sex, erectile dysfunction, and an overprotective partner; sexual activity had declined from pre- to post-ICD implantation; and sexual concerns and sexual activity did not differ between the intervention and usual care groups (Berg et al, 2013).* **EB:** *A high level of shock-related anxiety in patients with congenital heart disease with an ICD was associated with poor sexual function scores in both men and women and with depressive symptoms (Cook et al, 2013).*
- Specific guidelines for those with chronic lung disease include planning for sexual activity when energy level is highest; use of controlled breathing techniques; avoiding physical exertion prior to sexual activity; using positions that minimize shortness of breath, such as a semi-reclining position; engaging in sexual activity when medications are at peak effectiveness; and use of an oxygen cannula, if prescribed, to provide oxygen before, during, or after sex (Steinke, 2013). **CEB/EBN:** *In patients with COPD and post-lung transplantation, sexual desire was improved, but continued problems with breathing capacity and fears were a barrier to sexual activity. Openly discussing sexual fears, assessing fitness for sexual activity, and discussing different positions and other strategies to minimize breathing problems is helpful (Thomsen & Jensen, 2009; Steinke, 2013).* **EB:** *In women living with lung cancer, those who had regular sexual activity had closer couple relationships; satisfaction with information provided by health professionals and psychological support played a role for both men and women (Préau et al, 2011).*
- Specific guidelines for those with multiple sclerosis include treatment of symptoms with prescribed medications, assessing changes in body image, and supportive therapies to assist with a more satisfying sexual experience, including treatment of neuropathic pain, sexual positions that are most supportive,

discussing changes in sensation and stimulation with the partner, use of stretching exercise for tight muscles prior to sexual activity, and avoiding a distended bowl or bladder that may cause discomfort.

EB: Clients experiencing pain from MS had reduced sexual function and body image dissatisfaction; therefore, nonpharmacological and pharmacological management of pain may be helpful to enhance sexual function (Knafo et al, 2011; Ward-Abel & Hall, 2012). **EB:** Both positive and negative partner support yielded significant improvements in sexual satisfaction over time in women with systemic sclerosis (Blackmore et al, 2011).

- Refer to the care plan **Sexual dysfunction** for additional interventions.

Pediatric

- Provide age-appropriate information for adolescents regarding HIV/AIDS and sexual behavior, and discuss sexually transmitted infections, particularly human papillomavirus, including the risks of perinatal transmission and methods to reduce risks among HIV-infected adolescents. **EBN:** Knowledge of sexually transmitted diseases and HIV and discussion of gender roles were identified as important elements of prevention program for Latino adolescents, as well as privacy and confidentiality (Lee et al, 2013). **EB:** African American female adolescents who participated in an HIV prevention intervention with specific sexual health telephone counseling contacts had greater improvement in depressive symptoms than the comparison group; more than 40% had moderate to severe depression at baseline, illustrating the importance of addressing depression in intervention programs (Brown et al, 2014).
- Encourage client and partner communication in HIV prevention strategies. **EB:** In African American adolescent females, partner communication frequency was an important mediator for consistent use and condom protected sex; therefore, strategies to empower adolescent communication with their sexual partner about safe-sex practices are needed (Sales et al, 2012). **EB:** Teenagers and young adults who are identified as “straight” may also engage in homosexual activity, making addressing preventive strategies widely to all youth of importance (McCabe et al, 2011).
- Provide age-appropriate information regarding potential for sexual abuse. **EBN:** Women and adolescents after sexual assault experienced poorer physical health (e.g., STIs, genitourinary complaints) and mental health (e.g., depression, post-traumatic stress disorder), and engaged in greater unhealthy behaviors such as alcohol and drug abuse, illustrating the importance of discussing and screening for potential sexual abuse with adolescents (Wadsworth & Records, 2013).

Geriatric

- Carefully assess the sexuality needs of the older client and refer for counseling if needed; the ability to form satisfying social relationships and to be intimate with others, including building strong emotional intimate connections, contributes to adaptation and successful aging (Steinke, 2013). **EB:** Older adults continue to have sexual feelings, and while sexual functioning may be affected by age, the sexual response cycle is the same as in other adults, and many continue to be sexually active (Hartmans et al, 2013). **EB:** The emphasis in older adults’ sexuality should be focused on sharing pleasure as a couple, with more emphasis on sexual desire and satisfaction, and less on orgasm and intercourse; engaging in sexual play provides a more realistic focus with less emphasis on performance (McCarthy et al, 2013).
- ▲ Explore possible changes in sexuality related to health status, menopause, medications, and sexual risk, and make appropriate referrals. **EB:** In community dwelling older adults, the absence of cognitive impairment is an important consideration for maintaining sexual interest, and conversely continuing to be sexually active may be associated with better overall cognitive functioning (Hartmans et al, 2013). **EB:** The number of older adults who are HIV-positive continues to grow due to advances in medical treatment; however, older adults have increased risk related to multiple comorbidities, social isolation, and multiple effects from long-term retroviral therapy. It is important for health care providers to be well educated in managing the long-term health of this population (Cahill & Valadéz, 2013).
- Allow the client to verbalize feelings regarding loss of sexual partner, and acknowledge problems such as disapproving children, lack of available partner for women, and environmental variables that make forming new relationships difficult. **EBN:** Lack of an available partner, negative media portrayals, few studies with sufficient representation of older adults, and fears about entering new relationships are a few of the factors influencing sexuality in older ages (Garrett, 2014).
- ▲ Provide a milieu that allows for discussion of sexual issues and a higher level of sexual satisfaction, including allowing couples to room together and the provision of privacy. **EB:** Negative attitudes by long-term care facility staff in regard to older adults’ sexuality may result in sexual needs being overlooked or sexual

expression actively discouraged. Although keeping residents safe is important, their right to decision-making regarding intimacy must be considered (Tarzia et al, 2012).

- See care plan for **Sexual** dysfunction.

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on client's perceptions of normal sexual behavior. **EB:** Mexican migrant women in Mexico and the U.S. reported access to reproductive health care and lack of control over their sexual health as barriers to self-care, as well as sociocultural expectations of when seeking health care is appropriate, and perceived trust and confidentiality concerns (Espinoza et al, 2014). **EBN:** Interviews with Mexican American and African American young men revealed that they struggled to maintain physical and psychological closeness to their partners, and they distanced themselves because of their own unmet psychological needs (Collins & Champion, 2011).

Home Care

- Previously discussed interventions may be adapted for home care use. Also see care plan for **Sexual** dysfunction.
- Help the client and significant other identify a place and time in the home and daily living for privacy in sharing sexual or relationship activity, and if necessary, help the client communicate the need for privacy to family members. **EBN:** Staff in care homes often influence resident perceptions about the appropriateness of sexual expression and may view normal sexual expression as problem behavior; education of staff is important to ensure that acceptance of sexual rights and the dignity of the individual is maintained, while at the same time being of aware of resident safety and sexual abuse (Doll, 2013).
- Confirm that physical reasons for dysfunction have been addressed, and provide support for coping behaviors, including participation in support groups or therapy if appropriate. **EBN:** A 1-day retreat for men with prostate cancer and their partners increased level of knowledge about strategies for sexual recovery, and peer support was rated as an important component of the intervention, although it did not yield better communication among couples or increase sexual activity as hypothesized (Wittmann et al, 2013). **EB:** A pilot study of a Web-based support group for women with gynecologic cancer was well received, with women reporting satisfaction with the intervention and lowered sexual distress (Classen et al, 2013).
- Reinforce or teach about sexual functioning, alternative sexual practices, and necessary sexual precautions, and update teaching as client status changes. **EB:** A couple-focused HIV prevention intervention in young Latino parents reduced the proportion of unprotected sex episodes and increased the intent to use condoms at 6 months, but the results were not sustained at 12 months, although knowledge about AIDS was increased at 6 months and maintained at 12 months (Koniak-Griffin et al, 2011).

Client/Family Teaching and Discharge Planning

- ▲ Refer to appropriate community agencies (e.g., certified sex counselor, Reach to Recovery, Ostomy Association, American Association of Sex Educators, Counselors, and Therapists). **EBN:** Sexuality concerns should be addressed with all clients for whom sexual function might be affected due to an acute or chronic condition (Steinke, 2013).
- Sexuality education is important to all populations, whether hearing or deaf, sighted or blind, disabled or not disabled. Discuss contraceptive choices as appropriate, and refer to a health professional (e.g., gynecologist, urologist, nurse practitioner). **EB:** Sexuality education of older adults is often overlooked, and they may have less knowledge regarding sexual health risks, such as HIV transmission or use of condoms (Cahill & Valdéz, 2013).
- ▲ Teach safe sex to all clients including older adults, including using latex condoms, washing with soap immediately after sexual contact, not ingesting semen, avoiding oral-genital contact, not exchanging saliva, avoiding multiple partners, abstaining from sexual activity when ill, and avoiding recreational drugs and alcohol when engaging in sexual activity. **EB:** Suspicion of self-infection during penile-vaginal intercourse among a clinic sample resulted in 63% reporting condom use; nurses helping clients to realistically assess risk may result in greater protective behaviors (Crosby et al, 2014).

Risk for Shock June M. Como, EdD, RN, CNS

NANDA-I

Definition

Vulnerable to an inadequate blood flow to the body's tissues that may lead to life-threatening cellular dysfunction, which may compromise health

Risk Factors

Hypotension; hypovolemia; hypoxemia; hypoxia; infection; sepsis; systemic inflammatory response syndrome (SIRS)

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cardiac Pump Effectiveness; Fluid Balance; Infection Severity; Respiratory Status: Gas Exchange; Neurological Status: Autonomic; Tissue Perfusion: Cellular

Example NOC Outcome with Indicators

Neurological Status: Autonomic as evidenced by the following indicators: Apical heart rate/Systolic blood pressure/Urinary elimination pattern/Thermoregulation. (Rate the outcome and indicators of **Neurological Status: Autonomic**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Discuss precautions to prevent complications of disease
- Maintain adherence to agreed upon medication regimens
- Maintain adequate hydration
- Monitor for infection signs and symptoms
- Maintain a mean arterial pressure above 65 mm Hg
- Maintain a heart rate between 60 and 100 with a normal rhythm
- Maintain urine output greater than 0.5 mL/kg/hr
- Maintain warm, dry skin

NIC (Nursing Intervention Classification)

Suggested NIC Interventions

Admission Care; Allergy Management; Cardiac Care; Cerebral Perfusion Promotion; Electrolyte Monitoring; Fever Treatment; Fluid Management; Hemodynamic Regulation; Infection Precaution; Medication

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Management; Oxygen Therapy; Postanesthesia Care; Risk Identification; Shock Prevention; Teaching; Disease Process; Temperature Regulation; Vital Signs Monitoring

Example NIC Activities—Shock Prevention

Monitor circulatory status; Monitor for signs of inadequate tissue oxygenation; Administer oxygen and/or mechanical ventilation, as appropriate; Instruct client and/or family on precipitating factors of shock

Nursing Interventions and Rationales

- Review data pertaining to client risk status including age, primary diseases, immunosuppression, antibiotic use, and presence of hemodynamic alterations. **EB:** Administration of calcium-channel blockers and macrolide antibiotics such as erythromycin and clarithromycin may potentially cause significant hypotension and shock (Henneman & Thornby, 2012). Many clients who develop shock have underlying circumstances that predispose them to shock states as evidenced by hypotension and inadequate organ perfusion (Aitken et al, 2011; Kalil, 2014).
- Review client's medical and surgical history, noting conditions that place the client at higher risk for shock, including trauma, myocardial infarction, pulmonary embolism, head injury, dehydration, infection, and complicated pregnancy. **EB:** Certain clinical conditions place clients at higher risk for shock, which requires prompt identification and treatment to improve morbidity and mortality outcomes (Delgado et al, 2013; American Heart Association [AHA], 2011).
- Complete a full nursing physical examination. A full nursing physical examination is crucial in identifying all factors that might place that client at risk for the development of shock, such as hypoperfusion of internal organs (manifesting as decreases in bowel sounds and urinary output, and shortness of breath); tissue hypoperfusion (manifesting as cool, clammy, mottled skin, diminished pulses). **EBN/QSEN:** Educational strategies aimed at improving nurse's role in recognizing and responding to patient deterioration include use of clinical decision-making models, use of competency development in management of clinical deterioration and inclusion of such content in nursing education (Liaw et al, 2011). A systematic review published by Johanna Briggs International indicates that the use of extremity skin temperatures cannot be validated or supported due to a lack of consensus in the studies reviewed (Woo & Childs, 2012). **CEBN:** A systematic review found that capillary refill may not be helpful in the assessment of hypoperfusion states; use of vital signs, pulse oximetry, Doppler ultrasound, grading of peripheral pulses, color, and warmth of skin are more sensitive measures (Dufalt et al, 2008).
- Monitor circulatory status (e.g., blood pressure [BP], mean arterial pressure [MAP], skin color, skin temperature, heart sounds, heart rate and rhythm, presence and quality of peripheral pulses, Doppler ultrasound, and pulse oximetry). **EB:** The initial phase of shock is characterized by decreased cardiac output and tissue perfusion, which results in immediate compensatory changes evidenced by changes in blood pressure, increased heart rate, and shunting of blood away from the periphery, resulting in pale, cooler, damp skin, with reduced peripheral pulses (Kalil, 2014).
- Maintain intravenous (IV) access and provide isotonic IV fluids such as 0.9% normal saline or Ringer's lactate as ordered; these fluids are commonly used in the prevention and treatment of shock. **EB:** Restrictive fluid resuscitation and permissive hypotension (achievement of systolic pressure around 90 mm Hg) may have an advantage over standard higher volume fluid resuscitation in regards to overall and early intraoperative survival benefit (Duke et al, 2012; Sweeney, 2013). In a retrospective review of 778 clients the highest mortality rates were seen in those clients with positive fluid balances and with central venous pressures greater than 12 mm Hg (Boyd et al, 2011). **EB:** A Cochrane review found no difference in risk of dying in the use of colloids compared to crystalloids in trauma, burns, or surgery (Perel & Roberts, 2011).
- Monitor for inadequate tissue oxygenation (e.g., apprehension, increased anxiety, changes in mental status, agitation, oliguria, cool/mottled periphery) and determinants of tissue oxygen delivery (e.g., PaO₂, SpO₂, ScvO₂/SvO₂, MAP, hemoglobin levels, lactate levels, cardiac output [CO]). Assessment of tissue oxygen delivery and oxygenation patterns provides data to assess trends in client's status and evaluates treatment responses (Kalil, 2014). **EBN:** Tissue oxygenation endpoints, including central venous oxygen saturation (ScvO₂), tissue oxygenation (StO₂), and lactate levels, provide data on microcirculation, a key factor in the management of hemodynamic alterations in shock, especially in sepsis (Aitken et al, 2011). **EB:** Lactate or base deficit levels were found to not be correlated with triage vital signs in a study of 75 clients; however, the odds of surgical intervention were found to be four times greater in clients with higher lactate levels (Caputo et al, 2013).

- ▲ Maintain vital signs (BP, pulse, respirations, and temperature), and pulse oximetry within normal parameters. **EB:** *Unrecognized shock based on the typical presentation of vital signs that are interpreted as being within acceptable boundaries may result in inappropriate triage of clients resulting in delays in treatment (Yeh & Velmahos, 2012).* **EB:** *Increased heart rate (above 90 beats/min), hypotension (BP below 90 mm Hg systolic), tachypnea (greater than 20 breaths/min), hypoxia (SpO₂ below 90%), and lactate levels (above 2 mmol/L) are indicators of shock (Dellinger et al, 2013, Kalil, 2014).* *Temperature greater than 38°C or less than 36°C with white blood cell count greater than 12,000/mm³ or less than 4000/mm³ plus symptoms listed earlier are indicators of SIRS (Dellinger et al, 2013).*
- ▲ Administer oxygen immediately to maintain SpO₂ greater than 90% and antibiotics and other medications as prescribed to any client presenting with symptoms of early shock. **EBN:** *The experienced nurse has an important role in the implementation of the Surviving Sepsis Campaign (SSC), which includes specific early goal-directed therapies that enhance client survival (Turi & Von Ah, 2013; Kleinpell et al, 2013).* **EB:** *Administration of high-flow oxygen, hydration, antibiotics, insulin, and vasoactive medications provides early correction of risks for shock and improves survival of shock. Antibiotics as prescribed administered within 1 hour of diagnosis of a sepsis state facilitates a better rate of survival. For each hour in delayed antibiotic administration, survival decreases by 7.6% (Aitken et al, 2011; Havel et al, 2011).* **EB:** *A prospective study on compliance with the hemodynamic components of the sepsis resuscitation bundle found that there was a lower mortality rate in clients who were placed on the protocol sooner (Coba et al, 2011).* **EB:** *Emergency medical services personnel may serve as an important resource for the early diagnosis and treatment of sepsis in the field before hospitalization (Wang et al, 2010).*
- ▲ Monitor trends in noninvasive hemodynamic parameters (e.g., MAP) as appropriate. **EB:** *Identification of alterations in hemodynamic parameters provides data necessary for early and immediate implementation of prescribed therapies for prompt stabilization, preventing progression of and treating early onset of shock (Werdan et al, 2012).* **EB:** *Restoring MAP to desired levels (above 65 mm Hg) facilitates adequate perfusion to organs; however, initial impaired tissue oxygenation has been associated with impaired organ function over 24 hours in 33 intensive care unit clients (Dellinger et al, 2013; Mesquida et al, 2012).* **CEB:** *An overarching goal of cardiovascular support is optimization of blood flow to tissues; however, there is no single optimum MAP that can be applied to all (Jones et al, 2010).* *Monitor hydration status including skin turgor, daily weights, postural blood pressure changes, serum electrolytes (sodium, potassium, chloride, and blood urea nitrogen), and intake and output. Consider insertion of an indwelling urinary catheter as ordered to measure hourly output.* **EB:** *Daily weights are an important indicator of fluid status; however, the feasibility of obtaining accurate daily weights and correlating them to fluid balance in the critically ill is challenging (Schneider et al, 2012).* **EBN:** *Skin turgor is a measure of hydration, as are intake and output. Serum electrolyte levels help monitor fluid status (Schneider et al, 2012).*
- ▲ Monitor serum lactate levels, interpreting them within the context of each client. **EB:** *Elevations in serum lactate (above 2 mmol/L) may indicate circulatory failure and resultant tissue hypoxia from anaerobic metabolism that results in toxin accumulation, cellular inflammation, and cellular death. Progression to shock may result as characterized by the onset of systemic inflammatory response syndrome (SIRS). Two or more of the following indicators suggest SIRS: altered temperatures, heart rates above 90 beats/min, tachypnea or hypocarbia, and/or leukocytosis/leukopenia, which may or may not be related to infection as other causative factors exists (Kaplan & Pinsky, 2014).* **EBN:** *The degree of serum lactate elevation correlates with morbidity and mortality in sepsis; early detection facilitates early treatment and is a more accurate triage tool than vital signs (Aitken et al, 2011).* *Monitor blood glucose levels frequently and administer insulin as prescribed to maintain normal blood sugar levels (blood glucose levels of 70 to 110 mg/dL [3.9 to 6.1 mmol/L]).* **EB:** *Research suggests that tight glycemic control decreases mortality and morbidity in surgical clients; the Surviving Sepsis Campaign and clinical practice guidelines for cardiogenic shock suggests maintaining blood glucose below 150 mg/dL (8.3 mmol/L) (Dellinger et al, 2013; Werdan et al, 2012).*

Critical Care

- ▲ Prepare the client for the placement of an additional IV line, central line, and/or a pulmonary artery catheter as prescribed. *Adequate IV and central line access may be required for fluid resuscitation and medication delivery. Maintaining more than one IV access ensures rapid IV medication and fluid delivery in a crisis situation. Large amounts of fluid can be delivered more efficiently through centrally placed vascular access sites. Most vasoactive agents, especially vasopressors, should be delivered only through central lines because of risk of tissue sloughing.* **EB:** *A Cochrane systematic review of 13 studies on 5686 clients found no difference in mortality rates or days spent in an ICU between those clients with a pulmonary artery catheter*

and those without (Rajaram et al, 2013). **EBN:** Stroke volume assessment offers more precise evaluation of fluid and inotrope therapies in shock management (Aitken et al, 2011). **CEB:** Monitoring of hemodynamic parameters such as CVP, CO, cardiac index (CI), systemic vascular resistance (SVR), stroke volume (SV), and pulmonary artery pressure (PAP) through a pulmonary artery line can facilitate rapid assessment of physiological changes associated with the onset of shock (Wilmont, 2010).

- ▲ Monitor trends in hemodynamic parameters (e.g., CVP, CO, CI, SVR, PAP, and MAP) as appropriate. Hemodynamic indices will be altered depending on the underlying form of shock (hypovolemic, distributive, or cardiogenic). Dehydration will result in reduced CVP, CO, PAP, and ultimately MAP due to hypovolemia. Vasodilation as seen in distributive shock patterns (forms of third spacing as in neurogenic, anaphylactic, and septic shock states) will decrease CVP (a surrogate for intravascular volume) and other hemodynamic indices. Cardiogenic shock will result in low CO and MAP with higher PAP and CVP indices due to heart failure and subsequent congestion of the cardiopulmonary systems. Compensatory mechanisms to address reductions in CO and MAP include tachycardia and reduced urinary output (less than 0.5 mL/kg/hr). Both CO and SVR may temporarily increase with the onset of shock because of compensatory mechanisms; however, as shock progresses, both CO and SVR decline (Dellinger et al, 2013; Kalil, 2014; Werdan et al, 2012).
- ▲ Monitor electrocardiography. Tachycardia may be present as a result of decreased fluid volume, which will be seen before a decrease in blood pressure as a compensatory mechanism. **EB:** As oxygen demands increase, cardiac dysrhythmias may be evident, such as premature ventricular contractions (Dellinger et al, 2013).
- ▲ Monitor arterial blood gases, coagulation, chemistries, point-of-care blood glucose, cardiac enzymes, blood cultures, and hematology. **EB:** Abnormalities can identify the cause of the perfusion deficits and identify complications related to the decreased perfusion or shock state. Cardiogenic shock may be identified by elevations in cardiac enzymes as a result of myocardial infarction in association with low MAP. Elevation/reductions in white blood cell counts may be indicative of septic shock when associated with alterations in MAP (Aitken et al, 2011; Kalil, 2014).
- ▲ Administer vasopressor agents as prescribed. **EB:** A Cochrane collaborative review found that there is not sufficient evidence to prove that any one vasopressor is superior to others in the assessed doses. Choice of specific vasopressor is to be individualized based on the prescriber's discretion (Havel et al, 2011).
- ▲ If the client is in shock, refer to the following care plans: Risk for ineffective **Renal** perfusion, Risk for ineffective **Gastrointestinal** perfusion, Impaired **Gas** exchange, and Decreased **Cardiac** output.

Client/Family Teaching and Discharge Planning

- ▲ Teach client and family or significant others about any medications prescribed. Instruct the client to report any adverse side effects to his/her health care provider. Medication teaching includes the drug name, purpose, administration instructions (e.g., with or without food), and any side effects to be aware of. Provision of such information using clear communication principles and with an understanding of what the health literacy level of the client/family/significant others may be can facilitate appropriate adherence to the therapeutic regimen (Balentine, 2014; Nielsen-Bohlman et al, 2004; National Institutes of Health, 2011).
- Instruct the client and family on disease process and rationale for care. **EB:** Tailored interventions targeted to the level of the learner enhance client activation (Hibbard & Greene, 2013). Knowledge empowers clients and family members, allowing them to be active participants in their care (Finchman, 2013). **CEB:** When clients and their family members have sufficient understanding of their disease process, they can participate more fully in care and healthy behaviors (Finchman, 2013; Nielsen-Bohlman et al, 2004).
- Instruct clients and their family members on the signs and symptoms of low blood pressure to report to their health care provider (dizziness, lightheadedness, fainting, dehydration and unusual thirst, lack of concentration, blurred vision, nausea, cold, clammy, pale skin, rapid and shallow breathing, fatigue, depression). **EBN:** Teach back methods were found to be significantly associated with self-care activities and fewer hospitalizations in a sample of 276 clients with heart failure (White et al, 2013). **EB:** Use of the teach back method enhances an individual's knowledge and adherence behaviors (Negarandeh et al, 2013). Early recognition and treatment of these symptoms may avoid more serious sequelae (AHA, 2011).
- Implement educational initiatives to reduce health care-associated infections (HAIs). **EB:** Implementation of evidence-based educational interventions may considerably reduce HAIs (Aitken et al, 2011).
- Promote a culture of client safety and individual accountability. **EBN:** Health promotion related nursing interventions are considered by nurses to be an important component of their practice but may be hindered

by organizational obstacles (Kemppainen et al, 2012). **EB:** Include health literacy strategies into all aspects of client-centered care and weave into organizational values (Koh et al, 2013). Everyone involved in the health care of clients should adopt an attitude of accountability and promulgate zero tolerance in relation to HAIs (Aitken et al, 2011).

Impaired Sitting *Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CHSE, ANEF, FAAN*

NANDA-I

Definition

Limitation of ability to independently and purposefully attain and/or maintain a rest position that is supported by the buttocks and thighs, in which the torso is upright

Defining Characteristics

Impaired ability to adjust position of one or both lower limbs on uneven surface; impaired ability to attain a balanced position of the torso; impaired ability to flex or move both hips; impaired ability to flex or move both knees; impaired ability to maintain the torso in balanced position; impaired ability to stress torso with body weight; insufficient muscle strength

Related Factors

Alteration in cognitive functioning; impaired metabolic functioning; insufficient endurance; insufficient energy; malnutrition; neurological disorder; orthopedic surgery; pain; prescribed posture; psychological disorder; sarcopenia; self-imposed relief posture

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Endurance

Participate in desired activities; Meet own self-care need; Achieve measurable increased activity tolerance evidenced by ability to properly sit longer without fatigue and maintain vital signs within acceptable limits

Activity Tolerance

Demonstrate measurable increased ability to sit properly with vital signs within normal limits and skin warm, pink, and dry; Report absence of musculoskeletal pain while sitting

Pain Control

Demonstrate and initiate behavioral modifications of lifestyle and appropriate sitting posture; Report chronic lower back pain decreased in frequency, duration, and severity; Demonstrate relief of pain as evidenced by stable vital signs and absence of muscle tension and restlessness

Self-Management

Verbalize understanding of condition; Identify individual risk factors; Initiate lifestyle changes

Tissue Perfusion: Peripheral

Maintain skin integrity while sitting; Demonstrate sitting behaviors and techniques to prevent skin breakdown

Example NOC Outcome with Indicators

Increased sitting endurance as evidenced by the following indicators: participating in necessary and desired activities while sitting; reporting measurable increase in activity tolerance; and demonstrating a decrease in physiological signs of intolerance of sitting. (Rate ability to sit for 1 = 15 minutes; 2 = 30 minutes; 3 = 45 minutes; or 4 = one hour or more without difficulty.)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize importance of being able to sit as a method to engage in activities of daily living
- Understand somatic physiology of posture control

- Choose health care options that enhance ability to sit
- Engage in physical conditioning exercises to enhance sitting ability
- Understand relationship of posture and emotions
- Control pain to increase ability to sit

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Fall Prevention; Energy Management Including both Conservation and Restoration; Physical Exercise, Strength Training, Balance Training

Example NIC Activities—Exercise Therapy: Sitting

Assist client to use chair that facilitates sitting and prevents injury; Transfer safely from bed to chair; Encourage to sit in chair, as tolerated; Provide activities that can be completed while sitting

Nursing Interventions and Rationales

- Acknowledge the importance of being able to sit as a method to engage in activities of daily living. **EB:** *Niekerk et al (2014)* studied adolescents' ($N = 12$) sitting postural changes while on the computer and found that dynamic (purposeful) movement prevented musculoskeletal pain. **EBN:** *Harris and Shahid (2014)* studied getting clients ($N = 21$) out of bed early who were in the intensive care unit using an interdisciplinary plan, which included nurses, and found it a safe and cost-effective strategy to improve client outcomes.
- Understands the somatic physiology of posture control. **EB:** *Gorman et al (2014)* studied clients' ($N = 125$) scores on the Function In Sitting Test (FIST) between inpatient rehabilitation admission and discharge and compared them to balance and function indicators. The researchers found that the FIST correlated balance and function indicators and both tests demonstrated client improvement in sitting wellness. **EB:** *Curran et al (2014)* studied how clients ($N = 12$) sit and sitting's relationship to low back pain and overall body discomforts and found that forward-leaning chairs resulted in greater low back and overall body discomfort than sitting on a flat seat.
- Choose the musculoskeletal options that enhance ability to sit properly. **EBN:** *Kiraly and Gondos (2014)* analyzed the relationship between clients' ($N = 109$) total hip replacement (THR) and quality of life and found that THR improves the feeling of well-being and increases mobility of clients 5 years after the operation. **EB:** *Masahiro et al (2014)* investigated two different trunk muscle activities during sitting focusing on low back pain and found that sitting in a stable seat produced muscle imbalance, while in an unstable seat muscles were not imbalanced, demonstrating muscle control is needed for proper sitting.
- Engage in physical conditioning exercises to enhance proper sitting ability. **EBN:** *Huang et al (2014)* studied pediatric/surgical intensive care clients' ($N = 21$) pressure ulcers and developed a successful project to decrease the incidence of pressure ulcers, which included developing a series of pictures to illustrate proper sitting, lying, and changing positions. **EB:** *Sung-Jin et al (2014)* compared whole body vibration on the sitting balance of stroke clients ($N = 30$) with clients in a control group and found that the experimental participants had a significant improvement in the Modified Functional Reach Test while sitting.
- Understands the relationship of posture and somatic functioning. **EB:** *Thorp et al (2014)* studied alternating sitting and standing every 30 minutes in overweight office workers to determine if it reduced postprandial glucose, insulin, and triglyceride responses and found that it had a positive effect on postprandial glucose responses but not on insulin and triglyceride serum levels. **EB:** *Pedersen et al (2014)* studied desk-based employees ($N = 17$) with the intent of increasing workday energy by interrupting prolonged occupational sitting time with short bursts of physical activity and found a significant increase in calories expenditure when compared to a control group that did not participate in interspaced physical activity.
- Understands the relationship of posture and emotions. **EB:** *Michalak et al (2014)* studied the relationship of sitting posture of clients ($N = 30$) and depression and found that clients in a slumped (depressed) posture demonstrated more of a bias toward negative words than clients an upright (nondepressed) posture when shown words on a computer screen. **EB:** *Jussila et al (2014)* studied the relationship between psychosocial lifestyle and musculoskeletal pain in adolescence ($N = 1773$) and found an association between emotional and behavioral problems in both genders with musculoskeletal pain.

- Maintain pain levels below 3 to 4 on a 0- to 10-scale to increase ability to sit. **EBN**: Backaberg et al (2014) studied the high prevalence of musculoskeletal discomfort among nursing students (N = 348) and the most commonly reported everyday activities was prolonged sitting. **EB**: Wells et al (2014) studied using Pilates exercise for people with chronic low back pain (CLBP) by surveying physical therapists (N = 30) and it was recommended that people with CLBP should use Pilates twice a week because it involves body awareness, breathing, movement control, posture, and education.

Pediatric

- Increase cognitive and physical functioning by promoting proper sitting ability. **EB**: Surkar et al (2015) investigated children (N = 19) affected by cerebral palsy to determine if their focused attention changed as sitting postural control improved and found that sitting postural control was correlated with focused attention. **EB**: Harbourne et al (2014) investigated the relationship of developing sitting postural control using infants with motor delays (N = 16) and a control group (N = 28) and found infants with delayed sitting have a greater difficulty in looking at and focusing on objects.

Geriatric

- Increase cognitive and physical functioning by promoting proper sitting ability. **EBN**: Wallace et al (2014) measured the effectiveness of a 12-week exercise program to reduce the health risks in people older than age 60 years and found the intervention produced significant difference between intervention and comparison groups' fitness at 6 months (P >.01) and 12 months (P >.001). **EBN**: Strupeit et al (2014) did a longitudinal study of geriatric clients' mobility and their quality of life (QOL) and found that mobility and QOL increased for 6 months after rehabilitation discharge but then decreased at 12 months. Additionally, over time, men were found to have better function than women.

Multicultural

- Understand the importance of unimpaired sitting to different populations. **EB**: Wang et al (2014) studied extended computer use in Taiwan and developed a program to remind people to take a break and stretch their bodies and the program increased participants awareness of the dangers of prolonged sitting. **EB**: Watanabe et al (2014) did a study on Japanese men (N = 9) to determine the effects of slumped sitting on muscle health and found that slumped sitting decreases abdominal muscle contraction and thickness.

Home Care

- Encourage proper sitting posture in the home environment to promote health. **EB**: Ivengar et al (2014) studied post-stroke clients (N = 45) and postural control and found that head position while sitting correlated directly with sitting postural control and both were related to upper extremity stroke recovery. **EB**: Bassett et al (2014) used two monitors on adults (N = 15) that recorded sitting/lying down, standing, and stepping to determine accuracy of monitoring clients activity and found that the current method allowed researchers to obtain detailed information about posture.

Impaired Skin integrity Karen Zulkowski, DNS, RN

NANDA-I

Definition

Altered epidermis and/or dermis

Defining Characteristics

Alteration in skin integrity; foreign matter piercing skin

Related Factors

External

Chemical injury agent (e.g., burn, capsaicin, methylene chloride, mustard agent); extremes of age; humidity; hyperthermia; hypothermia; mechanical factors (e.g., shearing forces, pressure, physical immobility); moisture; pharmaceutical agent; radiation therapy

Internal

Alteration in fluid volume; alteration in metabolism; alteration in pigmentation; alteration in sensation (e.g., resulting from spinal cord injury, diabetes mellitus); alteration in skin turgor; hormonal change; immunodeficiency; impaired circulation; impaired nutrition; pressure over bony prominence

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Integrity: Skin and Mucous Membranes; Wound Healing: Primary Intention, Secondary Intention

Example NOC Outcome with Indicators

Tissue Integrity: Skin and Mucous Membranes will be intact as evidenced by the following indicators: Skin integrity/Skin lesions not present/Tissue perfusion/Skin temperature/Skin thickness. (Rate the outcome and indicators of **Tissue Integrity: Skin and Mucous Membranes**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Regain integrity of skin surface
- Report any altered sensation or pain at site of skin impairment
- Demonstrate understanding of plan to heal skin and prevent reinjury
- Describe measures to protect and heal the skin and to care for any skin lesion

NIC

(Nursing Interventions Classification)

Suggested NIC Interventions

Incision Site Care; Pain Management; Pressure Ulcer Care; Pressure Ulcer Prevention; Risk Identification; Skin Care: Topical Treatments; Skin Surveillance; Wound Care; Wound Irrigation

Example NIC Activities—Pressure Ulcer Care

Monitor color of wound bed, temperature, edema, erythema, moisture, and appearance of surrounding skin; Note characteristics of any drainage

Nursing Interventions and Rationales

- Assess site of skin impairment and determine cause or type of wound (e.g., acute or chronic wound, burn, dermatological lesion, pressure ulcer, skin tear). **EB:** *The cause of the wound must be determined before appropriate interventions can be implemented. This will provide the basis for additional testing and evaluation to start the assessment process (Baranoski & Ayello, 2012; McCulloch & Kloth, 2010).*
- Use a risk assessment tool to systematically assess client risk factors for skin breakdown due to pressure. **EB:** *A validated risk assessment tool such as the Norton or Braden scale should be used to identify clients at risk for immobility-related skin breakdown (National Pressure Ulcer Advisory Panel [NPUAP] and European Pressure Ulcer Advisory Panel [EPUAP], 2014). Targeting variables (e.g., age and Braden Scale Risk Category) can focus assessment on particular risk factors (e.g., pressure) and help guide the plan of prevention and care (McCulloch & Kloth, 2010; NPUAP/EPUAP, 2014; Sussman & Bates-Jensen, 2012).*
- Determine the extent of the skin impairment (e.g., partial-thickness wound, stage I or stage II pressure ulcer). The following classification system and definition is for pressure ulcers: Pressure ulcer: localized injury to the skin and/or underlying tissue usually over a bony prominence, as a result of pressure, or pressure in combination with shear (NOTE: Friction is not included in the definition) (NPUAP/EPUAP, 2014).
 - **Category/Stage I:** Intact skin with nonblanchable erythema of a localized area, usually over a bony prominence. Darkly pigmented skin may not have visible blanching. The area may be painful, firm, soft, warmer, or cooler than adjacent tissue. *Category/Stage I may be difficult to detect in individuals with dark skin tones and may indicate “at risk” persons.*
 - **Category/Stage II:** Partial-thickness skin loss of dermis presenting as a shallow open ulcer with a red pink wound bed, without slough, that may also present as intact or open/ruptured and serum-filled. Presents as a shiny or dry shallow ulcer without slough or bruising. *This category/stage should not be used to describe skin tears, tape burns, incontinence-associated dermatitis, maceration, or excoriation.*
 - Bruising may indicate suspected deep tissue injury; for wounds deeper into subcutaneous tissue, muscle, or bone (category/stage III or stage IV pressure ulcers), see the care plan for Impaired Tissue integrity (NPUAP/EPUAP, 2014).
- Inspect and monitor site of skin impairment at least once a day for color changes, redness, swelling, warmth, pain, or other signs of infection. Determine whether the client is experiencing changes in sensation or pain. Closely assess high-risk areas such as bony prominences, skinfolds, the sacrum, and heels. *Systematic inspection can identify impending problems early (Baranoski & Ayello, 2012; NPUAP/EPUAP, 2014).*
- Monitor the client’s skin care practices, noting type of soap or other cleansing agents used, temperature of water, and frequency of skin cleansing. *Cleansing should not compromise the skin (Baranoski & Ayello, 2012).*

- Consider using normal saline to clean the pressure ulcer or as ordered by the health care provider, but if necessary tap water suitable for drinking may be used to clean the wound. **EB:** *A Cochrane review found no evidence that using tap water to cleanse acute wounds in adults or children increases or reduces infection (Fernandez et al, 2012).*
- Individualize plan according to the client's skin condition, needs, and preferences. **EBN:** *Avoid harsh cleansing agents, hot water, extreme friction or force, or cleansing too frequently (Wound, Ostomy, and Continence Nurses Society [WOCN], 2010).*
- Monitor the client's continence status, and minimize exposure of skin impairment to other areas of moisture from perspiration or wound drainage. **EBN:** *Moisture from incontinence may contribute to pressure ulcer development by macerating the skin (Borchert et al, 2010; WOCN, 2010).*
- If the client is incontinent, implement an incontinence management plan to prevent exposure to chemicals in urine and stool that can damage the skin. Use a skin protectant cream to protect the skin after each incontinence episode. Refer to a continence care specialist, urologist, or gastroenterologist for incontinence assessment (Borchert et al, 2010). **EB:** *Implementing an incontinence prevention plan with the use of a skin protectant or a cleanser protectant can significantly decrease skin breakdown and pressure ulcer formation (Borchert et al, 2010; Scemons 2013).*
- For clients with limited mobility and activity, use a risk assessment tool to systematically assess immobility and activity-related risk factors. **EB:** *A validated risk assessment tool such as the Norton or Braden scale should be used to identify clients at risk for immobility-related skin breakdown (NPUAP/EPUAP, 2014).* **EBN:** *A study found that the most commonly reported interventions to reduce skin breakdown in acutely ill patients were protocol development, staff education, new use of a risk assessment tool, performance monitoring, development of a team approach, use of new beds/support surfaces, implementation of guidelines, providing feedback to staff, and linking staff with resources (Stotts et al, 2013).*
- Do not position the client on site of skin impairment. If consistent with overall client management goals, reposition the client as determined by individualized tissue tolerance and overall condition. Reposition and transfer the client with care to protect against the adverse effects of external mechanical forces such as pressure, friction, and shear. **EB:** *Do not position an individual directly on a pressure ulcer. Continue to turn/reposition the individual regardless of the support surface in use. Establish turning frequency based on the characteristics of the support surface and the individual's response (NPUAP/EPUAP, 2014).* *If the goal of care is to keep the client (e.g., a terminally ill client) comfortable, turning and repositioning may not be appropriate (NPUAP/EPUAP, 2014).*
- Evaluate for use of support surfaces (specialty mattresses, beds), chair cushions, or devices as appropriate. Maintain the head of the bed at the lowest possible degree of elevation to reduce shear and friction, and use lift devices, pillows, foam wedges, and pressure-reducing devices in the bed (NPUAP/EPUAP, 2014; WOCN, 2010).
- Implement a written treatment plan for topical treatment of the site of skin impairment. *A written plan ensures consistency in care and documentation (Baranoski & Ayello, 2012).*
- Select a topical treatment that will maintain a moist wound-healing environment (stage II) and that is balanced with the need to absorb exudate. Stage I pressure ulcers may be managed by keeping the client off of the area and using a protective dressing (Baranoski & Ayello, 2012). **EBN:** *Choose dressings that provide a moist environment, keep periwound skin dry, and control exudate and eliminate dead space (NPUAP/EPUAP, 2014; WOCN, 2010).*
- Avoid massaging around the site of skin impairment and over bony prominences. **EB:** *Research suggests that massage may lead to deep tissue trauma (NPUAP/EPUAP, 2014).*
- Assess the client's nutritional status. Refer for a nutritional consult and/or institute dietary supplements as necessary. **EB:** *Optimizing nutritional intake, including calories, fatty acids, protein, and vitamins, is needed to promote wound healing. Both the EPUAP and NPUAP (2014) endorse the application of reasonable nutritional assessment and treatment for clients at risk for and with pressure ulcers.*
- Identify the client's phase of wound healing (inflammation, proliferation, maturation) and stage of injury. **EBN:** *The selection of the dressing is based on the tissue in the ulcer bed (wound bed), the condition of the skin around the ulcer bed, and the goals of the person with the ulcer. Generally, maintaining a moist ulcer bed is the ideal when the ulcer bed is clean and granulating to promote healing and closure (NPUAP/EPUAP, 2014).* *No single wound dressing is appropriate for all phases of wound healing.*

Home Care

- The interventions described previously may be adapted for home care use.
- Instruct and assist the client and caregivers in how to change dressings and maintain a clean environment. Provide written instructions and observe the client completing the dressing change before hospital discharge and in the home setting.
- Educate client and caregivers on proper nutrition, signs and symptoms of infection, and when to call the agency and/or health care provider with concerns.
- It may be beneficial to initiate a consultation in a case assignment with a wound, ostomy, continence nurse (or wounds specialist) to establish a comprehensive plan for complex wounds.

Client/Family Teaching and Discharge Planning

- Teach skin and wound assessment and ways to monitor for signs and symptoms of infection, complications, and healing. Early assessment and intervention help prevent serious problems from developing. **EB:** *A home visit by a wound care specialist can provide essential in-home education, client specific plan of care, and reduce health care costs (Vrtis, 2013).*
- Teach the client why a topical treatment has been selected. **EBN:** *The type of dressing needed may change over time as the wound heals and/or deteriorates (NPUAP/EPUAP, 2014; WOCN, 2010).*
- If consistent with overall client management goals, teach how to reposition as client condition warrants. **EB:** *If the goal of care is to keep a client (e.g., terminally ill client) comfortable, turning and repositioning may not be appropriate (NPUAP/EPUAP, 2014).*
- Teach the client to use pillows, foam wedges, chair cushions, and pressure-redistribution devices to prevent pressure injury. **EB:** *The use of effective pressure-reducing seat cushions for older wheelchair users significantly prevented sitting-acquired pressure ulcers (Brienza et al, 2012).*

Risk for impaired Skin integrity Karen Zulkowski, DNS, RN

NANDA-I

Definition

Vulnerable to alteration in epidermis and/or dermis, which may compromise health

Risk Factors

External

Chemical injury agent (e.g., burn, capsaicin, methylene chloride, mustard agent); excretions; extremes of age; humidity; hyperthermia; hypothermia; mechanical factors (e.g., shearing forces, pressure, physical immobility); moisture; radiation therapy; secretions

Internal

Alteration in metabolism; alteration in pigmentation; alteration in sensation (e.g., resulting from spinal cord injury, diabetes mellitus); alteration in skin turgor; hormonal change; immunodeficiency; impaired circulation; inadequate nutrition; pharmaceutical agent; pressure over bony prominence; psychogenetic factor

NOTE: Risk should be determined by the use of a risk assessment tool (e.g., Norton scale, Braden scale).

NOC**(Nursing Outcomes Classification)****Suggested NOC Outcomes**

Immobility Consequences: Physiological; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Tissue Integrity: Skin and Mucous Membranes will be intact as evidenced by the following indicators: Skin intactness/Skin lesions not present/Tissue perfusion/Skin temperature. (Rate the outcome and indicators of **Tissue Integrity: Skin and Mucous Membranes**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

- Report altered sensation or pain at risk areas as soon as noted
- Demonstrate understanding of personal risk factors for impaired skin integrity
- Verbalize a personal plan for preventing impaired skin integrity

NIC**(Nursing Interventions Classification)****Suggested NIC Interventions**

Positioning: Pressure Management; Pressure Ulcer Care; Pressure Ulcer Prevention, Skin Surveillance

Example NIC Activities—Pressure Ulcer Care

Monitor color of wound bed, temperature, edema, erythema, moisture, and appearance of surrounding skin; Note characteristics of any drainage

Nursing Interventions and Rationales

- Identify clients at risk for impaired skin integrity as a result of immobility, chronological age, malnutrition, incontinence, compromised perfusion, immunocompromised status, or chronic medical condition, such as diabetes mellitus, spinal cord injury, or renal failure. **EB**: *These client populations are known to be at high risk for impaired skin integrity (Baranoski & Ayello, 2012). Targeting variables (e.g., age and Braden Scale Risk Category) can focus assessment on particular risk factors (e.g., pressure) and help guide the plan of prevention and care (NPUAP/EPUAP, 2014).*
- Inspect and monitor skin condition at least once a day for color or texture changes, redness, localized heat, edema or induration, pressure damage, dermatological conditions, or lesions and any incontinence-associated dermatitis. Determine whether the client is experiencing loss of sensation or pain. *Systematic inspection can identify impending problems early (NPUAP/EPUAP, 2014; Baranoski & Ayello, 2012).*
- Monitor the client's skin care practices, noting type of soap or other cleansing agents used, temperature of water, and frequency of skin cleansing. *Individualize plan according to the client's skin condition, needs, and preferences (Baranoski & Ayello, 2012).*
- Cleanse the skin gently with pH-balanced cleansers. Avoid harsh cleansing agents, hot water, extreme friction or force, or too-frequent cleansing (WOCN, 2010).
- ▲ Monitor the client's continence status and minimize exposure of the site of skin impairment (incontinence-associated dermatitis) and other areas to moisture from incontinence, perspiration, or wound drainage. If the client is incontinent, implement an incontinence management plan to prevent exposure to chemicals in urine and stool that can strip or erode the skin. Use a skin barrier product and/or moisture wicking pads to reduce risk of exposure. Refer to a health care provider (e.g., continence care specialist, urologist,

gastroenterologist) for an incontinence assessment (WOCN, 2010). **EB:** *Implementing an incontinence prevention plan with the use of a skin protectant or a cleanser protectant can significantly decrease skin breakdown and pressure ulcer formation (NPAUP/EPUAP 2014; WOCN, 2010; Baranoski & Ayello, 2012; Borchert et al, 2010).*

- For clients with limited mobility, inspect and monitor condition of skin covering bony prominences. *Pressure ulcers usually occur over bony prominences, such as the sacrum, coccyx, trochanter, and heels, as a result of unrelieved pressure between the prominence and support surface, or with shearing and friction (NPAUP/EPUAP, 2014; WOCN, 2010; Baranoski & Ayello, 2012).*
- Implement and communicate a client specific prevention plan. **EB:** *A plan of care clearly documented in the client's electronic health record will assist in ensuring consistency in care and documentation (Baranoski & Ayello, 2012).*
- At risk clients should be frequently repositioning. Frequency of repositioning will be influenced by variables concerning the individual's independent mobility and the support surface in use. Frequency of repositioning should be determined by the individual's tissue tolerance and medical condition (NPAUP/EPUAP, 2014). *Reposition the client with care to protect against the adverse effects of external mechanical forces (e.g., pressure, friction, shear) (WOCN, 2010).*
- Evaluate for use of specialty mattresses, beds, or devices as appropriate (Brienza et al, 2012; Lippoldt et al, 2014). *Maintain the head of the bed at the lowest possible degree of elevation to reduce shear and use lift devices, pillows, foam wedges, and pressure-reducing devices in the bed (WOCN, 2010; Lippoldt et al, 2014). If the goal of care is to keep the client (e.g., a terminally ill client) comfortable, turning and repositioning may not be appropriate; reposition the client for position of comfort and provide pain relief measures (Horn et al, 2014).*
- Avoid massaging over bony prominences. *Massage may lead to deep tissue trauma (WOCN, 2010; NPAUP/EPUAP, 2014).*
- ▲ Assess the client's nutritional status; refer for a nutritional consult, and/or institute dietary supplements. **EB:** *Meeting nutritional needs of the client is important to prevention of skin breakdown as well as preventing complications of illness. Adequate nutrition is important for maintaining overall homeostasis and health (O'Hanlon et al, 2015).*

Geriatric

- Limit number of complete baths to two or three per week, and alternate them with partial baths. Use a tepid water temperature (between 90°F and 105°F) for bathing or use a no rinse alternative product. **EB:** *Excessive bathing, especially in hot water, depletes aging skin of moisture and increases dryness. The ability to retain moisture is decreased in aging skin due to diminished amounts of dermal proteins. One of the most common age-related changes to the skin is damage to the stratum corneum (Baranoski & Ayello, 2012).*
- Use lotions and moisturizers to prevent skin from drying out, especially in the winter. **EB:** *Avoid skin care products that contain allergens such as lanolin, latex, and dyes (Baranoski & Ayello 2012).*
- Increase fluid intake within cardiac and renal limits to a minimum of 1500 mL per day. *Dry skin is caused by loss of fluid; increasing fluid intake hydrates the skin (Baranoski & Ayello, 2012).*
- Increase humidity in the environment, especially during the winter, by using a humidifier or placing a container of water on a warm object. *Increasing the moisture in the air helps keep moisture in the skin.*

Home Care

- Assess client and caregiver ability to recognize potential risk for skin breakdown. Provide resources for client/caregiver to contact health care provider with questions/concerns related to skin and incontinence care as needed (Vrtis, 2013).
- ▲ Initiate a consultation in a case assignment with a wound care specialist or wound, ostomy, and continence nurse to establish a comprehensive plan as soon as possible (Vrtis, 2013).
- See the care plan for Impaired Skin integrity.

Client/Family Teaching and Discharge Planning

- Teach the client skin assessment and ways to monitor for impending skin breakdown. *Early assessment and intervention help prevent the development of serious problems. EB: Basic elements of a skin assessment are assessment of temperature, color, moisture, turgor, and intact skin (Baranoski & Ayello, 2012).*
- If consistent with overall client management goals, teach how to turn and reposition the client. **EB:** *Do not position an individual directly on a pressure ulcer. Continue to turn/reposition the individual even if a*

low-airloss support surface is in use. Establish turning frequency based on the characteristics of the support surface and the individual's response (NPUAP/EPUAP, 2014). If the goal of care is to keep the client (e.g., a terminally ill client) comfortable, turning and repositioning may not be appropriate (NPUAP/EPUAP, 2014; Horn et al, 2014).

- Teach the client and or caregivers to use pillows, foam wedges, and pressure-reducing devices to prevent pressure injury (WOCN, 2010; NPUAP/EPUAP, 2014). **CEB:** The use of effective pressure-reducing seat cushions for older wheelchair users may significantly prevent sitting-acquired pressure ulcers (Brienza et al, 2012).

Readiness for enhanced Sleep Mary Beth Flynn Makic, RN, PhD, CNS, CCNS, FAAN

NANDA-I

Definition

A pattern of natural, periodic suspension of relative consciousness to provide rest and sustain a desired lifestyle, which can be strengthened

Defining Characteristics

Expresses desire to enhance sleep

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Well-Being; Rest; Sleep

Example NOC Outcome with Indicators

Sleep as evidenced by the following indicators: Hours of sleep/Sleep pattern/Sleep quality/Sleep efficiency/Feels rejuvenated after sleep/Napping appropriate for age. (Rate each indicator of **Sleep**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize an interest in what constitutes normal sleep
- Verbalize an interest in nonpharmacological approaches to sleep promotion
- Establish an environment conducive to sleep initiation and maintenance throughout the night

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Sleep Enhancement

Example NIC Activities—Sleep Enhancement

Assess client's sleep/activity pattern; Assist/encourage client to create an environment that facilitates sleep; Assist/encourage client to adopt personal practices that enhance sleep

Nursing Interventions and Rationales

- Obtain a sleep history including bedtime routines, sleep patterns, use of medications and stimulants, and use of complementary and alternative medical practices for stress management and relaxation before bedtime. *Assessment of sleep behavior and patterns is an important part of any health status examination (Gooneratne et al, 2014; Salas & Gamaldo, 2011).*
 - From the history, assess the client's ability to initiate and maintain sleep, obtain adequate amounts of sleep, and manage daytime responsibilities free from fatigue and sleepiness. **CEB:** *A systematic review found that most adults who average 8 hours of sleep per night (range of 7 to 9 hours) were at decreased risk for all-cause mortality (Gallicchio & Kalesan, 2009). CEBN:* *Gender and cultural beliefs influenced sleep patterns and sleep preferences (Sok, 2008). Difficulty sleeping is a side effect of psychoactive substances contained in foodstuffs, as well as prescription and over-the-counter medications (Kloss et al, 2011; Woodward, 2012).*
- Based on assessment, teach one or more of the listed sleep promotion practices as appropriate. **EB:** *In adult acute care settings, improved sleep quality and less use of sleeping medication was reported when multicomponent sleep promotion protocols were tested (Gooneratne et al, 2014).*
 - Establish a regular schedule for sleep, exercise, napping, and mealtimes. *Regular schedules are believed to promote sleep initiation and sleep maintenance by maintaining a circadian rhythm of alertness/drowsiness (Kloss et al, 2011; Woodward, 2012).*
 - Avoid long periods of daytime sleep. **EB:** *Whereas regular, short napping in the morning or early afternoon improved mood and performance in older adults, long periods of sleep during the day may interfere with quality nighttime sleep (Sterniczuk et al, 2014).*
 - Arise at the same time each day even if sleep was poor during the previous night. *Although many factors can interfere with falling and staying asleep, forcing a regular arise time helps establish a circadian rhythm and ensures better sleep the following night (Kloss et al, 2011; Woodward, 2012).*
 - Limit caffeine. *Caffeine, colas, teas, and chocolate contain the stimulant caffeine and can adversely affect the client's ability to fall asleep. Nicotine is also a stimulant that may result in smokers sleeping poorly (National Institutes of Health [NIH], 2012).*
 - Avoid large meals before bed. *A large meal can cause indigestion, interfering with comfort and ability to fall asleep (NIH, 2012).*
 - Limit alcohol use. **EBN:** *Limited alcohol use (one to two drinks) shortened time needed to fall asleep and increased depth of sleep the first 2 hours, but also suppressed REM sleep, which sometimes led to REM-rebound, that is, lighter, more fragmented sleep later in the night (Dean et al, 2010).*
 - Avoid long-term use of sleeping pills. *Long-term use of sleeping pills can be habit forming, and typically dependence and withdrawal symptoms occur while the therapeutic effect diminishes over time (Woelk et al, 2010; Woodward, 2012).*
 - Engage in relaxing activities before bed. **EBN:** *Several systematic reviews show that all forms of relaxation improve quantity and quality of sleep to some extent (Hellstrom et al, 2011).*
 - Provide backrub or other forms of massage. **EBN:** *Use of a back massage has been shown effective for promoting relaxation (Hellstrom et al, 2011).*
 - Teach relaxation techniques. *Engaging in relaxation and mindfulness techniques have been found to shorten time to fall asleep and enhance quality of sleep (NIH, 2012; Larouche et al, 2014).*
 - Teach complementary and alternative interventions as culturally congruent. *Using complementary and alternative medicine such as tai chi, acupuncture, acupressure, yoga, and meditation have improved sleep in clinical populations (Gooneratne et al, 2014).*

- Lower lighting in sleep area. **EB:** *Light affects hormonal secretions related to circadian rhythms of sleepiness (NIH, 2012).*
- Mask noise in sleep area when it cannot be eliminated. **EBN:** *“White noise” (i.e., sounds covering the entire range of human hearing, e.g., ocean sounds) and music decrease time needed to fall asleep and nighttime awakenings (Hellstrom et al, 2011).*
- For anxious clients, consider use of a lavender oil preparation in the health care setting. **EB:** *A multisite clinical trial found scent of lavender lowered anxiety and improved self-reported sleep (Woelk et al, 2010).*

Geriatric

- Interventions discussed previously may be adapted for use with geriatric clients.
- Counsel the older adult regarding normal age-related changes in sleep: **EB:** *As people age, increased time is needed to fall asleep; frequency and duration of waking after sleep onset increases; and, nighttime sleep amount tends to decrease (Woodward, 2012).*
- Elicit the older adult’s expectations for sleep and correct misconceptions. *The older person may be unduly concerned with normal age-related changes in sleep patterns; lighter sleep and occasional awakenings may be misconstrued as sleep disorders (Morin, 2011).*
- Assess and refer as appropriate if coexisting conditions may be disrupting sleep. **EBN:** *Depression, sleep apnea, and restless leg syndrome are commonly missed coexisting conditions in older adults (Woodward, 2012).*
- Discuss appropriate and inappropriate self-help measures for improving sleep. **EB:** *Older adults have been found to choose sleep interventions that can worsen rather than improve sleep (Gooneratne et al, 2011).*
- Encourage walking and other exercise outdoors unless contraindicated. *Exercise and exposure to natural light reinforce circadian rhythms that control sleep (Melancon et al, 2014; NIH, 2012).*
- Help older adults engage with others who enjoy similar events. *Social interactions reinforce circadian rhythms that control sleep (Gooneratne et al, 2014).*

Home Care

- Interventions discussed previously may be adapted for home care use.
- Some complementary and alternative medicine interventions may be more easily tried at home than in health care facilities. **EB:** *A multisite clinical trial found scent of lavender lowered anxiety and improved self-reported sleep (Woelk et al, 2010).*
- Assess the conduciveness of the home environment for both caregivers and clients’ sleep. *Many factors in the home environment can promote or interfere with the sleep readiness of clients/family members (Kloss et al, 2011; Woodward, 2012).* **EBN:** *A multicomponent sleep promotion program improved sleep quality in family caregivers of persons with dementia (Simpson & Carter, 2010).*

Sleep deprivation *Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN*

NANDA-I

Definition

Prolonged periods of time without sleep (sustained natural, periodic suspension of relative consciousness)

Defining Characteristics

Agitation, alteration in concentration, anxiety, apathy, combativeness, confusion, decrease in functional ability, decrease in reaction time, drowsiness, fatigue, fleeting nystagmus, hallucinations, hand tremors, heightened sensitivity to pain, irritability, lethargy, listlessness, malaise, perceptual disorders, restlessness, transient paranoia

Related Factors (r/t)

Age-related sleep stage shifts, average daily physical activity less than recommended for gender and age, conditions with periodic limb movement (e.g., restless leg syndrome, nocturnal myoclonus), dementia, environmental barrier, familial sleep paralysis, idiopathic central nervous system hypersomnolence, narcolepsy, nightmares, nonrestorative sleep pattern (e.g., due to caregiver responsibilities, parenting practices, sleep partner), overstimulating environment, prolonged discomfort (e.g., physical, psychological), sleep apnea, sleep terror, sleep walking, sleep-related enuresis, sleep-related painful erections, Sundowner syndrome, sustained circadian asynchrony, sustained inadequate sleep hygiene, treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Rest; Sleep; Symptom Severity

Example NOC Outcome with Indicators

Sleep as evidenced by the following indicators: Hours of sleep/Sleep pattern/Sleep quality/Sleep efficiency/Feels rejuvenated after sleep/Sleeps through the night consistently. (Rate the outcome and indicators of **Sleep**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize plan that provides adequate time for sleep
- Identify actions that can be taken to ensure adequate sleep time
- Awaken refreshed once adequate time is spent sleeping
- Be less sleepy during the day once adequate time is spent sleeping

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Sleep Enhancement

Example NIC Activities—Sleep Enhancement

Monitor/record client's sleep pattern and number of sleep hours; Encourage client to establish a schedule that allows age-appropriate hours of sleep with minimal environmental and personal disruptions

Nursing Interventions and Rationales

- Obtain a sleep history to identify the specific personal and environmental factors that may be depriving clients of the amount of sleep needed for optimal functioning. **EB:** *Two detailed case studies by Salas and Gamaldo (2011) showed uniquely complex combinations of personal and environmental factors contribute to sleep deprivation. EBN:* *A systematic review of 17 studies of heart surgery patients showed factors that led to insufficient sleep during hospitalization were personal factors including pain, dyspnea, nocturia, anxiety, and depression and environmental factors including noise, light, and provision of care (Liao et al, 2011).*
 - Minimize environmental factors that disturb the client's sleep. See Nursing Interventions and Rationales for Disturbed **Sleep** pattern.
 - Minimize personal factors that disturb the client's sleep. See Nursing Interventions and Rationales for **Insomnia**.
- Assess the amount of sleep obtained each night compared with the amount of sleep needed. **EB:** *A national survey of 10,896 adults found that more than one third (37.1%) sleep less than 7 hours per night, an amount at which physiological and neurobehavioral deficits manifest and become progressively worse under chronic conditions (Centers for Disease Control and Prevention, 2011).*
- Assess for hypersensitivity to pain. **EB:** *In a repeated-measures laboratory experiment with 18 adults, sleep deficiency led to increased sensitivity to pain (Roehrs et al, 2012). EB:* *In a laboratory study of 34 subjects, those with shortened sleep due to chronic insomnia were twice as likely as healthy controls with no sleep loss to report experiencing spontaneous pain; they also had lower pain thresholds for discomfort due to heat and pressure (Haack et al, 2012).*
- When daytime drowsiness occurs despite long, undisturbed periods of sleep, consider sleep apnea as a possible cause. **EB:** *In a household survey of more than 7000 adults, unexplained excessive daytime sleepiness was identified as a predictor of undiagnosed sleep apnea (Dosman et al, 2014).*
- Encourage a regular schedule of napping as a way to compensate for sleep deficiency whenever severely restricted sleep amounts cannot be avoided. **CEB:** *In a study of 92 adults, naps of no more than 45 minutes were found to supplement rather than replace nighttime sleep (Floyd, 1995). EB:* *In a pre-test/post-test study of 22 older adults, a consistent regimen of daily napping for 45 minutes enhanced waking function without negatively affecting nighttime sleep (Campbell et al, 2011).*
- Monitor caffeine intake in clients who may use caffeinated drinks to overcome sleep deficiency. **EB:** *In a double-blind, crossover study of 63 adults, even a single cup of caffeinated coffee consumed before bedtime in real-life conditions caused a deterioration in the quality of sleep in caffeine-sensitive subjects (Lloret-Linares et al, 2012). CEB:* *In an analysis of results from randomized controlled trials representing 156 subjects, caffeine abstinence for the whole day resulted in improved sleep quality at night (Sin et al, 2008).*
- If evidence-based interventions are inadequate, consider and carefully evaluate unstudied but commonly used countermeasures for fighting drowsiness. **EB:** *A descriptive study of 77 middle-aged adults identified the following unstudied strategies as possibly effective interrupters of drowsiness: (1) change physical position; (2) change in ventilation (e.g., get fresh air, turn on fan, open window); (3) reduce air temperature (e.g., turn on air conditioning; turn on fan); (4) increase auditory stimulation (e.g., play music, sing, engage in conversation, listen to debate); (5) engage in interesting visual activity (e.g., board games, watching TV sports events, watching serial TV dramas) (Davidsson, 2012).*

Pediatric

- Assess the amount of sleep obtained each night compared with the amount of sleep needed. **EB:** *An integrative review of 16 studies suggested that amount of sleep obtained in children was reduced from 9 hours in late childhood to 6 to 7 hours during adolescence, but that amount of sleep needed did not decline from childhood to young adulthood; thus, adolescents are often very sleep deprived (Carskadon, 2011).*

- Encourage daily schedules that allow for late awakening times for adolescents. **EB**: *In an integrative review of 16 studies, biological rhythms were found to shift during puberty, leading to delayed sleep initiation times and subsequent sleep deprivation if early arise times were required (Carskadon, 2011).*
- See the Pediatric section of Nursing Interventions and Rationales for: Readiness for enhanced **Sleep**, Disturbed **Sleep** pattern, and **Insomnia**.

Geriatric

- Assess the amount of sleep obtained each night compared with the amount of sleep needed. **EB**: *An integrative review of research published since 2000 suggested that sleep need in adults does not change across the lifespan, but obtaining adequate sleep becomes more difficult for older adults due to gradual changes in circadian functioning and sleep structure (Rybarczyk et al, 2013).*
- See the Geriatric section of Nursing Interventions and Rationales for disturbed **Sleep** pattern and **Insomnia**.

Multicultural

- Be aware of racial and ethnic disparities in sleep deprivation. **EB**: *A national survey of 10,896 adults found that sleep deficiency is more common among non-Hispanic blacks (53.0%) than among non-Hispanic whites (34.5%), Mexican Americans (35.2%), and persons of other races/ethnicities (41.7%) (Centers for Disease Control and Prevention, 2011).*

Home Care

- Teach family members about the short-term and long-term consequences of inadequate amounts of sleep for both clients and family caregivers. **CEB**: *In an integrative review of 10 studies, insufficient sleep was associated with poor attention, decreased performance, increased mortality and morbidity, and cardiovascular risk factors, including hypertension, insulin resistance, hormonal deregulation, and inflammation (Mullington et al, 2009).*
- Teach client/family caregivers about the need for those with chronic conditions to avoid schedules and commitments that interfere with obtaining adequate amounts of sleep. **EBN**: *In a study of 21 subjects with left-ventricular assist devices, clients obtained inadequate sleep persisting up to 6 months after surgery (Casida et al, 2011).*
- Promote adoption of behaviors that ensure adequate amounts of sleep for all family members. See Nursing Interventions and Rationales for Readiness for enhanced **Sleep**.
- Teach family members ways to avoid chronic sleep loss. See Nursing Interventions and Rationales for Disturbed **Sleep** pattern.
- Advise against the sleep deprived client's chronic use of caffeinated drinks to overcome daytime fatigue and or drowsiness; focus on elimination of factors that lead to chronic sleep loss. **CEB**: *In an integrative review of 26 controlled laboratory studies, caffeine was found helpful in the temporary management of sleepiness, but overuse and late-day use contributed to subsequent sleep disruption and caffeine habituation (Roehrs & Roth, 2008).*

Disturbed Sleep pattern *Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN*

NANDA-I

Definition

Time limited interruptions of sleep amount and quality due to external factors

Defining Characteristics

Alteration in sleep pattern; difficulty in daily functioning; difficulty initiating sleep; dissatisfaction with sleep; feeling unrested; unintentional awakening

Related Factors

Disruption caused by sleep partner; environmental barrier (e.g., ambient noise, daylight/darkness exposure, ambient temperature, humidity, unfamiliar settings); immobilization; insufficient privacy; nonrestorative sleep pattern (e.g., due to caregiver responsibilities, parenting practices, sleep partner)

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Well-Being; Rest; Sleep

Example NOC Outcome with Indicators

Sleep as evidenced by the following indicators: Hours of sleep/Sleep pattern/Sleep quality/Sleep efficiency/Feels rejuvenated after sleep. (Rate the outcome and indicators of **Sleep**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize plan to implement sleep promotion routines
- Maintain a regular schedule of sleep and waking
- Fall asleep without difficulty
- Remain asleep throughout the night
- Awaken naturally, feeling refreshed and is not fatigued during day

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Sleep Enhancement

Example NIC Activities—Sleep Enhancement

Determine external factors leading to sleep fragmentation; Reduce environmental disrupters of sleep

Nursing Interventions and Rationales

- Obtain a sleep history to identify (1) noise and light levels in the sleep environment, (2) activities occurring in the sleep environment during hours of sleep, (3) number of times awakened during the sleep period, and (4) when during the sleep period, time is available for undisturbed sleep. **EBN:** *A systematic review of 17 studies of heart surgery clients showed environmental disturbances during hospitalization were caused by noise, light, and provision of care (Liao et al, 2011).* **EB:** *Two case studies by Salas and Gamaldo (2011) illustrated how causes of sleep disruptions vary by setting.*
- Keep environment quiet during sleep periods. **EB:** *Recorded intensive care unit (ICU) noise led to more fragmented sleep, less slow-wave (deep) sleep, more arousals, and more time awake when played during sleep (N = 17) (Waye et al, 2013).* **CEB:** *A descriptive study of 48 hospitalized older adults found a median sound level of almost 50 dB(A) with peaks over 90 dB(A), which exceeds World Health Organization recommendations of 35 dB(A) or less (Missildine et al, 2010b).*
- Consider masking hospital noise that cannot be eliminated. **EBN:** *A systematic review of nine experimental studies found recorded natural sounds, music, and music videos effective for masking noise in health care settings (Hellstrom et al, 2011).*
- Offer earplugs when feasible. **EB:** *Results of a randomized controlled trial (RCT) (N = 136) showed perception of sleep in critical care improved with initial earplug use (Van Rompaey et al, 2012).* **EBN:** *Using a sequential pre-test/post-test research design, 22% of hospitalized clients who were offered earplugs (N = 50) reported that earplugs were helpful for improving sleep (Jones & Dawson, 2012).*
- Dim the lights during client sleep periods. **EB:** *A sequential pre/post study (N = 171) found the number of awakenings decreased when monitored lighting levels were part of a multicomponent program to decrease sleep disruption in intensive care (Patel et al, 2014).*
- Offer eye covers when lighting cannot be dimmed. **CEB:** *A descriptive study of 48 hospitalized adults found nighttime light levels were elevated an average of 5.25 hours per night (Missildine et al, 2010b).* **EBN:** *In a clinical evaluation study, 28% of hospitalized clients who were offered eye covers (N = 50) reported that eye covers were helpful for improving sleep (Jones & Dawson, 2012).*
- Be aware that use of eye covers in intubated clients may lead to sensory deprivation and anxiety. **EB:** *An experimental study of eye cover use in ICU clients (N = 18) reported less sleep fragmentation, but 72% of intubated clients refused eye covers or removed them prematurely due to restlessness (30%), discomfort (20%), or anxiety (11%) (Simons et al, 2012).*
- Consolidate essential care to provide opportunity for uninterrupted sleep the first 3 to 4 hours of the sleep period. Follow with periods of 90 to 110 minutes between interruptions. **CEB:** *A meta-analysis using data from 159 studies found the deepest stages of sleep occurred during the first 3 to 4 hours of the sleep period followed by several 90- to 110-minute sleep cycles that consisted of increasingly lighter percentages of sleep (Floyd, 2002).*
- If client must be disturbed the first 3 to 4 hours of the sleep period, attempt to protect 90- to 110-minute blocks of time between awakenings. **CEB:** *In three studies of hospitalized clients, researchers found that the high frequency of nocturnal care interactions left clients with no 90-minute blocks of uninterrupted time for sleep (Missildine, 2008; Missildine et al, 2010a, 2010b).* **EB:** *In an experimental study that included protocols for consolidating care, the number of client nights that contained a 3-hour window of interrupted sleep was increased (Patel et al, 2014).*
- Assess for medications and other stimulants that fragment sleep. Use caution when administering sleep medications. See Nursing Interventions and Rationales for **Insomnia**.
- Schedule newly ordered medications to avoid the need to wake the client the first few hours of the night. **EBN:** *A survey of sleep promotion protocols used by nurses in hospitals in The Netherlands (N = 68) identified the need for providers to plan ahead when initiating new medication regimens to help ensure uninterrupted sleep periods (Hofhuis et al, 2012).*
- Combine as many of the above interventions as feasible to create a sleep-promotion care bundle. **EB:** *A sequential pre/post study (N = 171) found efforts to limit noise and bright lighting along with efforts to consolidate care could successfully be combined into a care bundle effective for limiting sleep fragmentation (Patel et al, 2014).*

S

Pediatric

- Adapt interventions for pediatric clients with caution due to lack of empirical evidence regarding the effects of their use. **EB:** *A survey of 341 pediatric critical care providers worldwide found use of earplugs,*

eye masks, noise reduction, and lighting optimization for sleep promotion was uncommon (Kudchadkar et al, 2014).

Geriatric

- Use of earplugs and eye covers with ataxic clients and clients with dementia may contribute to disorientation. **EB**: A case report and integrative review of the literature suggested sensory deficits in clients with dementia, which can be augmented by use of earplugs and eye covers, decrease their quality of life, increase their risk for delirium and falls, and pose a higher risk for poor outcomes (Haque et al, 2012).

Multicultural

- Be aware that cultural sleep practices may alter the kinds of environmental sleep disruptors that require management. **EB**: An integrative review of the literature on family sleep practices demonstrated that bed sharing and other aspects of the sleep environment were influenced most by ethnic factors (Jain et al, 2011).

Home Care

- Consider the unique characteristics of each home sleep environment when addressing sleep disruption. **EBN**: A longitudinal study of postpartum women (N = 142) found new mothers' sleep was disturbed 56% of the time by their infant's cries, but other environmental disruptors included (1) family, friends, and pets in the home, (2) sleeping with the television on, (3) traffic sounds, and (4) other outside noise from neighbors and traffic (Doering, 2013). **EBN**: In two RCTs, modification of homes to promote parental sleep found that interventions were more effective for low socioeconomic status (SES) parents (N = 118) than more advantaged parents (N = 122) (Lee & Gay, 2011).
- In addition, see the Home Care section of Nursing Interventions and Rationales for Readiness for enhanced Sleep.

Impaired Social interaction *Gail B. Ladwig, MSN, RN, and Marina Martinez-Kratz, MS, RN, CNE*

NANDA-I

Definition

Insufficient or excessive quantity or ineffective quality of social exchange

Defining Characteristics

Discomfort in social situations; dissatisfaction with social engagement (e.g., belonging, caring, interest, shared history); dysfunctional interaction with others; family reports change in interaction (e.g., style, pattern); impaired social functioning

Related Factors (r/t)

Absence of significant others; communication barriers; disturbance in self-concept; disturbance in thought processes; environmental barrier; impaired mobility; insufficient knowledge about how to enhance mutuality; insufficient skills to enhance mutuality; sociocultural dissonance; therapeutic isolation

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Child Development: Middle Childhood, Adolescence; Play Participation; Role Performance; Social Interaction Skills; Social Involvement

Example NOC Outcome with Indicators

Social Involvement as evidenced by the following indicator: Interacts with close friends, neighbors, family members, and members of work groups. (Rate the outcome and indicators of **Social Involvement**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)].)

S

Client Outcomes

Client Will (Specify Time Frame)

- Identify barriers that cause impaired social interactions
- Discuss feelings that accompany impaired and successful social interactions
- Use available opportunities to practice interactions
- Use successful social interaction behaviors
- Report increased comfort in social situations
- Communicate, state feelings of belonging, demonstrate caring and interest in others
- Report effective interactions with others

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Socialization Enhancement

Example NIC Activities—Socialization Enhancement

Encourage patience in developing relationships; Help client increase awareness of strengths and limitations in communicating with others

Nursing Interventions and Rationales

- Monitor the client's use of defense mechanisms and support healthy defenses (e.g., the client focuses on the present and avoids placing blame on others for personal behavior). **CEBN:** *Solution-focused techniques have been demonstrated to be beneficial. Therapy focuses on the client's present and future, capitalizing on the strengths and resources of the client and significant others around them (Wand, 2010).*
- Spend time with the client. **EBN:** *In this study of spirituality at end of life, presence was identified as important in itself. By his/her caring presence, the nurse identifies with the client in his/her suffering and conveys dignity, respect, and compassion (Milligan, 2011).*
- Encourage physical activity, such as aerobics or stretching and toning. **EB:** *A Cochrane Systematic Review indicated that physical activity was beneficial to the social functioning of cancer survivors (Mishra et al, 2012).*
- Have group members support each other in a group setting. **EB:** *Assertive community treatment is beneficial in reestablishing or maintaining bonds between family, friends, and acquaintances (Templer et al, 2012).*
- Model appropriate social interactions and use focused imitation interventions. Give positive verbal and nonverbal feedback for appropriate behavior (e.g., make statements such as, "I'm proud that you made it to work on time and did all the tasks assigned to you"; make eye contact). If not contraindicated, touch the client's arm or hand when speaking. **CEBN:** *Shared feelings increased communication with stroke and aphasia clients without words (Sundin et al, 2000).* *Use of focused imitation interventions improved social functioning in children with autism spectrum disorders (Ingersoll, 2012).*
- Consider use of social cognition and interaction training (SCIT) combined with social mentoring to improve social functioning. **EB:** *A randomized controlled trial using SCIT and social mentoring demonstrated improved social cognition and social functioning in individuals with severe mental illness living in the community (Hasson-Ohayon et al, 2014).*
- Use client-centered humor as appropriate. **EB:** *Humor may be helpful in working with clients with depression (Bokarius et al, 2011).*
- Consider use of animal therapy; arrange for visitation. **EB:** *Equine-facilitated therapy (working with horses) is described as a parallel experience to working in groups, "social interaction" (Akaltun & Banning, 2012).*
- Consider use of videophone or other visual communication devices to promote social interaction in clients with visual impairments. **EB:** *The use of videophone technology increased accessibility to social interaction including cultivation and maintenance of friendships with peers (Emerson & Bishop, 2012).*
- ▲ Refer client for social cognition training to increase social skills. **EB:** *Social cognition training using targeted programs are most effective at improving social functioning in clients with a diagnosis of psychosis or schizophrenia (Henderson, 2013).*
- ▲ Refer rehabilitation clients for assistive technologies to increase therapeutic engagement and promote social engagement. **EB:** *Rehabilitation clients' desire to use mainstream technologies (cell phones, tablets, computers) underscores the need for accessible options that will provide opportunities to engage in therapeutically meaningful activities and promote social interaction (Fager & Burnfield, 2014).*
- Refer to care plans for Risk for **Loneliness** and **Social** isolation for additional interventions.

Pediatric

- Encourage social support and counseling for clients with visual and hearing impairments. **EB:** *Social support is needed for mothers of children with hearing impairment, because it is a "hidden" disability (Dehkordi et al, 2011).* *Emotional support and counseling were both effective in improving social functioning in clients with visual impairment.*
- Provide supervised interaction opportunities for children of chronically ill parents. **EBN:** *Research has identified that social isolation is a challenge for children with parents who experience chronic disabling pain (Umberger et al, 2015).*
- Provide computers and Internet access to children with chronic disabilities that limit socialization. **EB:** *Children with autism showed more active other-awareness using a technology with a supportive interface and when collaborating with a peer (Holt & Yuill, 2014).*
- ▲ Refer overweight adolescents to group based weight loss programs. **EB:** *Overweight adolescents who participated in group based weight loss programs showed improvements in social functioning that were related to increases in self-concept dimensions (Jelalian et al, 2011).*

- ▲ Refer children with autism for family-centered music therapy (FCMT). **EB:** *Research demonstrated that family participation in FCMT improved social interactions in the home and community as well as the parent-child relationship (Thompson et al, 2014).*
- Consider the use of animal-assisted activities for children on the autistic spectrum. **EB:** *Research demonstrated significant improvements in social functioning and decreases in social withdrawal behaviors after 8 weeks of animal exposure in a school classroom in addition to sixteen 20-minute animal-interaction sessions (O'Haire et al, 2014).*
- Consider the use of a theater skills training to facilitate social skills. **EB:** *Brain injured youth showed improvements in social skills and participation with the use of an arts based intervention (Agnihotri et al, 2012).*

Geriatric

- Encourage socialization through education, support groups, and programs for older adults in the community. **EB:** *Neighborhood social cohesion may be protective against stroke mortality (Clark et al, 2011).*
- Assess for depression in clients with impaired social functioning. **EB:** *Research shows higher depressive symptoms were associated with smaller numbers of close, inner circle relationships (Shouse et al, 2013).*
- Assess cognitive functioning in clients who present with decreased social interaction. **EB:** *Researchers identified a link between decreased social interaction and a decline in cognitive abilities (Dickinson et al, 2011).*
- Assess the communication patterns of clients with verbal domain problems for enactment strategies, paralinguistic features, and nonvocal communication. **EBN:** *Research has demonstrated that clients with semantic dementia spontaneously use enactment (acting out scenes), paralinguistic features (pitch and volume of tone), and nonvocal communication (e.g., body posture, pointing, and facial expression) to compensate for loss of verbal abilities (Kindell et al, 2013).*
- Consider having clients participate in playing Wii. **EB:** *This study of older adults who played with the Wii experienced well-being, particularly social connection and enjoyment (Kahlbaugh et al, 2011).*
- ▲ Refer depressed clients to services for cognitive behavioral therapy (CBT). **EB:** *A systematic review indicated that CBT was likely to be efficacious for depression and accompanying symptoms such as impaired social functioning in older people (Jayasekara et al, 2015).*
- Refer to care plans for **Frail Elderly** syndrome, Risk for **Loneliness**, and **Social** isolation for additional interventions.

Multicultural

- Assess for the effect of racism on the client's perceptions of social interactions. **EB:** *In this study of clients in group drug treatment plans, women, but not men, of different races acted differently in mixed-race, mixed-gender cocaine treatment groups, with African American women exhibiting fewer of several behaviors (Johnson et al, 2011).*
- Approach individuals of color with respect, warmth, and professional courtesy. **EBN:** *To provide client- and family-centered care, nurses must acknowledge their cultural differences, be willing to incorporate their beliefs within the health care treatment plan, and respect their values and lifeways of differing cultures (Hart & Mareno, 2015).*
- Use interpreters as needed. **EB:** *Primary care nurses act as gatekeepers to interpreting services (McCarthy et al, 2013).*
- Refer to care plan for **Social** isolation for additional interventions.

Home Care

- Previously discussed interventions may be adapted for home care use.
- ▲ Refer clients to or support involvement in supportive groups and counseling. **EBN:** *Clients who received direct support and resources had better outcomes with improvement of psychiatric symptoms, social functioning, and self-efficacy (Sono et al, 2012).*

Client/Family Teaching and Discharge Planning

- ▲ Refer to appropriate social agencies for assistance (e.g., family therapy, self-help groups, creative activities, crisis intervention), especially individuals who are seriously ill. **EB:** *Clients who received direct*

support and resources had better outcomes with improvement of psychiatric symptoms, social functioning, and self-efficacy (Sono et al, 2012). Music therapy as an addition to standard care helps people with schizophrenia improve their global state, mental state (including negative symptoms), and social functioning, if a sufficient number of music therapy sessions are provided by qualified music therapists (Mössler et al, 2011).

Social Isolation *Julianne E. Doubet, BSN, RN, CEN, NREMT-P*

NANDA-I

Definition

Aloneness experienced by the individual and perceived as imposed by others and as a negative or threatening state

Defining Characteristics

Absence of support system; aloneness imposed by others; cultural incongruence; desire to be alone; development delay; developmentally inappropriate interests; disabling condition; feeling different from others; flat affect; history of rejection; hostility; illness; inability to meet expectations of others; insecurity in public; meaningless actions; member of a subculture; poor eye contact; preoccupation with own thoughts; purposelessness; repetitive actions; sad affect; values incongruent with cultural norms; withdrawn

Related Factors (r/t)

Alterations in mental status; alterations in physical appearance; altered state of wellness; developmentally inappropriate interests; factors impacting satisfying personal relationships (e.g., developmental delay); inability to engage in satisfying personal relationships; insufficient personal resources (e.g., poor achievement, poor insight, affect unavailable and poorly controlled); social behavior incongruent with norms; values incongruent with cultural norms; may be present but is not required; pain may be of unknown etiology

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Loneliness Severity; Mood Equilibrium; Personal Well-Being; Play Participation; Social Anxiety Level; Social Interaction Skills; Social Involvement; Social Support

Example NOC Outcome with Indicators

Social Involvement as evidenced by the following indicator: Interacts with close friends, neighbors, family members, and members of work groups. (Rate the outcome and indicators of **Social Involvement**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)].)

S

Client Outcomes

Client Will (Specify Time Frame)

- Identify feelings of isolation
- Practice social and communication skills needed to interact with others
- Initiate interactions with others; set and meet goals
- Participate in activities and programs at level of ability and desire
- Describe feelings of self-worth

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Socialization Enhancement

Example NIC Activities—Socialization Enhancement

Encourage patience in developing relationships; Help patient increase awareness of strengths and limitations in communicating with others

Nursing Interventions and Rationales

- Establish a therapeutic relationship with the client. **EBN**: *In her study, Skingley (2013) suggests that many of the circumstances that contribute to social isolation are amendable and that the community nurse is in*

• = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

the position to affect changes by using one-to-one interventions, by involving the client in group activities, and by community engagement. **EBN:** Nurses are one of the fundamental client advocate groups that promote the prevention of social isolation (Wilson et al, 2011).

- Observe for barriers to social interaction. **EBN:** This study by Drury (2014) states that social isolation can be measured by objective indicators, such as the client's social network, and his/her participation in community activities, and by subjective indicators, including a client's self-rating of loneliness and perception of support. **EB:** Ohayon and Roberts (2014) maintain that stress and social isolation were important influences for depression among young adults.
- Discuss/assess causes of perceived or actual isolation. **EBN:** Some variables that were recognized by Nicholson et al (2014) as precursors to diminished social interaction included severe health problems, symptoms of depression, smoking, and decreased religious participation. **EB:** Social isolation is a known risk factor for morbidity and mortality in human beings, according to Cacioppo et al (2014).
- Allow the client opportunities to describe his/her daily life and to introduce any issues that may be of concern. **EBN:** McDonald (2014) surmises that the biggest problem in health care today is lack of communication skills, which can then be related to poor client outcomes; she maintains that the nurse of today must be proficient in effective communication. **EBN:** Therapeutic communication consists of certain techniques that promote a relationship involving mutual trust and respect between nurse and client (Thomas et al, 2013).
- Promote social interactions. **EB:** Positive social interactions may act as a basis for the client to establish new social group relationships (Cruwys et al, 2014). **EB:** In recent studies, it was found that the quality of social interactions, whether positive or negative, impact physical health and the feeling of well-being (Cyranowski et al, 2013).
- Assist the client in identifying specific health and social problems; involve him/her in their resolution. **EBN:** Pearce (2013) maintains that interventions customized to fit a client's disorganized lifestyle reduce their social isolation. **EBN:** Intervention programs that are meant to prevent or reduce loneliness in older adults may be valuable in safeguarding the client from future mental health problems (Bekhet & Zauszniewski, 2012).
- Assist the client in identifying activities that encourage socialization. **EB:** According to this study, the sooner the older client is supported in mobility and social participation, the sooner he/she is able to experience a sense of well-being and lessening of the feelings of social isolation (Elbasan et al, 2013). **EB:** Studies have shown that people with regular social connections present with significantly less cognitive decline when compared to those who are lonely and/or isolated (Ristau, 2011).
- Identify available support systems and involve those individuals in the client's care. **EBN:** According to Mattila et al (2014), nurse support of clients and their families is effective in establishing a positive outlook, mental well-being, and thoughts of getting well. **EB:** "Clinicians should be aware of social isolation and loneliness in late life and discuss nonpharmacologic treatment options with their aging patients" (Canham, 2014).
- ▲ Refer clients and caregivers to support groups as necessary. **EB:** Webster et al (2013) maintain that the family is no longer as strong a force in the struggle to reduce social isolation and that interventions should be based in the community. **EB:** Caring for a family member who is physically and/or mentally challenged can be a drain on caregivers, causing a negative effect both on the client and the caregiver: effective outside assistance might be a factor in modifying the challenges confronted by these families (Thompson et al, 2014).
- Encourage interactions with others with similar interests. **EBN:** Culley et al (2013) believe that their study is the forerunner to understanding the potential for improving connectiveness and alleviating isolation by the use of technology. **EBN:** According to this research study, a community integrative therapy program will allow those involved to form new relationships, gather emotional support, reinforce ties, and reduce social isolation (da Roche et al, 2013).
- See the care plan for Risk for Loneliness.

Pediatric

- ▲ Refer obese adolescents for diet, exercise and psychosocial support. **EB:** Nesbit et al (2014) suggest that to combat adolescent obesity, interventions should target sedentary behavior and promote the increase of physical activity, but also should address parental concerns about neighborhood safety and access to safe areas for physical activity development. **EBN:** This study found that family meals two to three times per week during adolescence is an important factor in preventing obesity in young adulthood (Berge et al, 2015).

- ▲ Assess socially isolated adolescents. Refer to appropriate rehabilitation programs as needed. **EB:** A study by *Plaiser and Konijn (2013)* implies that both peers and media have a firm influence on adolescents and that peer rejection may be cause for the adolescent to turn to antisocial media content. **EB:** This study suggests that there are racial/ethnic, gender, and socioeconomic differences in substance abuse types of treatment (*Lo & Ching, 2013*).

Geriatric

- ▲ Assess physical and mental status to establish an early baseline for referring at-risk individuals to community resources. **EBN:** In this study, *Nicholson (2012)* states that health professionals have the opportunity to take measures that will allow early detection of social isolation in at-risk, older clients and match them to suitable community resources; this may serve to prevent negative health outcomes. **EB:** Older individuals should be routinely screened for depression, as it may be an important factor in giving rise to later social isolation (*Pritchard et al, 2014*).
- Assess for hearing. **EB:** It is well-documented that hearing loss is common in older adults: it is also considered a known factor in the cause of social isolation, depression, and dementia (*Genther et al, 2014*). **EB:** Because hearing loss is more prevalent with aging, it is important that the nurse be aware of options open to older adults with hearing impairment; early detection is essential (*Jupiter, 2012*).
- Involve client in planning activities. **EBN:** Assessment of an older person's goals, as identified by the individual in need of home care, allows the health care provider to personalize the client's activities, which then leads to betterment of the client's quality of life (*Parsons et al, 2012*). **EB:** "Regular and structured physical activity is known to be effective in preventing and/or reducing the physical and mental decline associated with aging," according to *Marini et al (2014)*.
- Involve nonprofessionals in activities and projects with the client. **EBN:** Group music therapy relieved agitated activity in older adults who suffer from dementia and promoted emotional relaxation, encouraged interpersonal interactions, and appeared to reduce further agitated episodes (*Lin et al, 2011*). **EB:** *Pettigrew et al (2014)* write that both group activities and a focused approach to those clients who are at risk for social isolation may be the way to manage the problem.
- Suggest varied social activities that would decrease isolation and encourage participation. **EB:** Leisure activities can play a significant part in an older person's social life and improve their quality of life; these could include volunteer work, cultural activities, sports, reading books, hobbies, and shopping (*Toepoel, 2013*). **EB:** According to *Morrow-Howell et al (2014)*, there are community volunteer programs that have been shown to open new social, civic, and work-related paths for older adults.
- ▲ Consider the use of simulated presence therapy (see the care plan for **Hopelessness**). **EB:** A video of the simulated presence of a family member appeared to reduce unwillingness of the adult with dementia to involve himself in basic, everyday self-care tasks (*O'Connor et al, 2011*). **EB:** *Obdrzalek et al (2013)* promote an automated exercise coaching system for older adults living in assisted homes: this technique is designed to allow remote interaction with a coach and to strengthen the social aspects of exercise.
- Consider using computers and the Internet to alleviate or reduce loneliness and social isolation. **EB:** The use of technology that is tailored to older people may aid in better self-management of health conditions and thus, may produce an increased improvement in social connectedness (*Morris et al, 2014*). **EB:** According to *Gitlow (2014)*, many older adults are socializing through technological devices (phones, email, surfing the net), but there are still numerous barriers that keep them from fully using technology to its fullest; these include lack of knowledge, negativity, and age-related changes in vision and hearing.

Multicultural

- Acknowledge racial/ethnic differences at the onset of care. **EBN:** It is necessary for nurses to be aware of cultural differences, be responsive to clients' needs, and include them in the plan of care (*Kwok & White, 2011*). **EB:** Every client has a unique culture that has many aspects, is vibrant, and cannot be labeled by race or language group (*Hawes & Viera, 2014*).
- Assess for the influence of cultural beliefs, norms, values, and the client's personal cultural needs. **EB:** Cultural standpoints concerning medical decision-making and the client's expectations of his/her children, may cause the medical surrogate (who in many cultures is the firstborn) to experience stress, family conflict, and difficulty coping; health care professionals should support the surrogate in communication with the client and with his/her extended family (*Su et al, 2014*). **EBN:** Culturally responsive caregiver involvement is necessary to make certain that people of culturally and linguistically dissimilar backgrounds have the proper skills to self-manage their multifaceted medical conditions (*Williams et al, 2014*).

- Use a culturally competent, professional approach when working with clients of various ethnic groups. **EBN:** *Today's professional nurse must be aware of the role of cultural competency and cultural safety in his or her practice (Rowan et al, 2013).* **EBN:** *Miller et al (2013) found that interventions to reduce depression in an immigrant couple required, not only the lessening of immigration-related problems, but also concentration on gender diversity and promoting family and social support.*
- Promote a sense of ethnic attachment. **EBN:** *Provide care in a way that respects and considers the client's cultural and religious needs (Black, 2011).* **EB:** *According to Enguidanos et al (2014), there is a need for client-centered intervention and prevention standards that incorporate the client's cultural background, health care requirements, and individual preferences.*
- Assess the client's feelings regarding social isolation. **EBN:** *In this study of African American women with breast cancer, it is suggested that personal stress can be measured by the level of the client's isolation and proposed that nurses should generate interventions to decrease that isolation and assist clients in developing supportive bonds with other clients and community members (Heiney et al, 2011).* **EB:** *Cooley and Garcia (2012) suggest that the client's past history and diverse relationship experiences will determine their approach to interactions with others.*
- Assist those ethnic minorities who are underserved to access essential health care. **EBN:** *Jeffreys and Dogan (2013) maintain that a comprehensive nursing assessment is the first step necessary in providing culturally specialized care, recognition of high risk groups, and reduction of health care inequality.* **EBN:** *According to Waite et al (2014), it is vital that clinicians recognize the necessity of cultural competence in their practice to both improve and maintain health care for their clients.*

Home Care

- The interventions described previously may be adapted for home care use.
- Confirm that the home setting has health-safety systems in place. **EB:** *Those older persons who are socially isolated and have no support are especially vulnerable in an emergency, and their preparation to react to a disaster is questionable (Staley et al, 2011).* **EB:** *The medical and safety goals for older adults should be taken into account when redesigning an approach for home care delivery (Depuccio & Hoff, 2014).*
- Consider the use of the computer and Internet to decrease isolation. **EB:** *Older adults who use the Internet may derive benefits, such as a reduction in loneliness and an improvement in social interaction (Cotton et al, 2013).* **EBN:** *A study by Culley et al (2013) illustrated the ability of technology to develop connectedness and diminish the feeling of isolation in community-dwelling older adults.*
- Assess options for living that allow the client privacy, but not isolation. **EB:** *The medical community must respect the client's values of autonomy, safety, privacy and health and consider their unique sociocultural and historical dynamics (Weber et al, 2012).* **EBN:** *Rulliere (2014) explains that a person's dignity and privacy must be preserved, regardless of his/her cognitive ability, not only when receiving nursing care but also in all phases of life.*
- Assist clients to interact with neighbors in the community when they move to supported housing. **EB:** *The participants in this study, residents of supported housing, reported that it was important to them to feel a part of the community when interacting with their neighbors, especially in regard to neighbor relations, community safety, neighborhood satisfaction, and tolerance of mental illness (Townley & Kloos, 2011).* **EB:** *Results of a study by Cho et al (2012) found that housing professionals should consider a supportive neighborhood and social opportunities when promoting community housing for older adults.*

Client/Family Teaching and Discharge Planning

- Assist the client in initiating contacts with self-help groups, counselors, and therapists. **EBN:** *Appropriate interventions are needed to educate the client concerning the problems caused by loneliness; the proper management of chronic disease; referrals, not only to monitor physical status, but also to enhance social networking; and referrals to social services to address personal needs (Jarve & Dool, 2011).* **EBN:** *Seebom et al (2013) advise as a result of their study that policy-makers might partner with the local population to provide support for diverse types of residents to facilitate their own self-help/mutual aid groups.*
- Provide information to the client about senior citizen services and community resources. **EB:** *Those who are Spanish-speaking and those older adults who are living independently are the populations most in need for increased senior center outreach programs, according to Schneider et al (2014).* **EB:** *Senior centers are excellent locations to deliver evidence-based health support programs that will bolster this rapidly growing age group in remaining healthy and independent (Felix et al, 2014).*

- Refer socially isolated caregivers to appropriate support groups. **EBN**: Nurses demonstrate a keen knowledge of the needs of relatives and reported efficacious interventions in supporting those needs (Buckley & Andrews, 2011). **EBN**: Eriksson et al (2013) maintain that woman who are 24/7 caregivers need choices that can be recommended by health care professionals who will not disregard their ethical concerns.
- See the care plan for **Caregiver Role Strain**.

Chronic Sorrow Betty Ackley, MSN, EdS, RN, and Tracy P. George, DNP, APRN-BC, CNE

NANDA-I

Definition

Cyclical, recurring, and potentially progressive pattern of pervasive sadness experienced (by parent, caregiver, individual with chronic illness or disability) in response to continual loss throughout the trajectory of an illness or disability

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Defining Characteristics

Reports feelings of sadness (e.g., periodic, recurrent); reports feelings that interfere with ability to reach highest level of personal well-being; reports feelings that interfere with ability to reach highest level of social well-being; reports negative feelings (e.g., anger, being misunderstood, confusion, depression, disappointment, emptiness, fear, frustration, guilt, helplessness, hopelessness, low self-esteem, being overwhelmed, recurring loss, self-blame)

Related Factors (r/t)

Crisis in management of the disability; crises in management of the illness; crises related to developmental stages; death of a loved one; experiences chronic disability (e.g., physical or mental); experiences chronic illness (e.g., physical or mental); missed opportunities; missed milestones; unending caregiving

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Acceptance: Health Status; Depression Level; Depression Self-Control; Grief Resolution; Hope; Mood Equilibrium

Example NOC Outcome with Indicators

Grief Resolution with plans for a positive future as evidenced by the following indicators: Describes meaning of loss or death/Reports decreased preoccupation with loss/Reports adequate nutritional intake/Reports adequate sleep/Expresses positive expectations about the future. (Rate the outcome and indicators of **Grief Resolution**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section 1].)

Client Outcomes

Client Will (Specify Time Frame)

- Express appropriate feelings of guilt, fear, anger, or sadness
- Identify problems associated with sorrow (e.g., changes in appetite, insomnia, nightmares, loss of libido, decreased energy, alteration in activity levels)
- Seek help in dealing with grief-associated problems
- Plan for the future one day at a time
- Function at normal developmental level

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Grief Work Facilitation; Grief Work Facilitation: Perinatal Death

Example NIC Activities—Grief Work Facilitation

Encourage client to verbalize memories of loss, both past and current; Assist client in identifying personal coping strategies

Nursing Interventions and Rationales

- Determine the client's degree of sorrow. **EBN**: Use the Adapted Burke Questionnaire for the individual or caregiver as appropriate. *The Adapted Burke Questionnaire is designed to measure chronic sorrow, and it assesses eight mood states including grief, shock, anger, disbelief, sadness, hopelessness, fear, and guilt on a four-point scale (Whittingham et al, 2013).*
- Assess for the four discrete stages of grieving in chronic obstructive pulmonary disease (COPD) clients. **EB**: *The four stages of grief for clients with COPD can be assessed by the Acceptance of Disease and Impairments Questionnaire (Boer et al, 2014).*
- Provide coping strategies for caregivers who may experience chronic sorrow. **EBN**: *Coping strategies for the caregivers of clients with schizophrenia may include discussing their feelings about the situation with*

others, reading, praying, being physically active; emotional strategies like crying; and cognitive strategies like thinking positively about the situation (Olwit et al, 2015). See care plan for **Caregiver Role Strain**.

- Assess clients for chronic sorrow and provide them with coping strategies. **EBN:** Clients who come to the emergency department frequently may be at an increased risk for chronic sorrow (Joseph, 2012).
- Develop a trusting relationship with the client by using empathetic therapeutic communication techniques. **CEB:** An empathetic person who takes the time to listen, offers support and reassurance, recognizes and focuses on feelings, and appreciates the uniqueness of each individual and family is helpful to clients experiencing chronic sorrow (Isaksson & Ahlstrom, 2008).
- Help the client understand that sorrow may be ongoing. **CEB:** Studies have demonstrated that feelings of sadness, guilt, anger, frustration, and fear occur periodically throughout the lives of people experiencing chronic loss, resulting in chronic sorrow (Isaksson & Ahlstrom, 2008).
- Help the client recognize that, although sadness will occur at intervals for the rest of his/her life, it will become bearable. **CEB:** In time the client may develop a relationship with grief that is lifelong but livable, and as much filled with comfort as it is with sorrow (Moules et al, 2007).
- Urge the client to use positive coping techniques:
 - **EBN:** Encourage the client to participate in a support group, talk with others, or communicate via an online support group (Vitale & Falco, 2014). **CEB:** Social support has been shown to help bereaved individuals as they put their lives back together and find new meaning in life (Isaksson & Ahlstrom, 2008).
 - **EBN:** Encourage the client to participate in a support group, talk with others, or communicate via an online support group (Vitale & Falco, 2014). **CEB:** Social support has been shown to help bereaved individuals as they put their lives back together and find new meaning in life (Isaksson & Ahlstrom, 2008).
 - **EBN:** Encourage the client to engage in a hobby or physical activity (Vitale & Falco, 2014).
 - **EBN:** Encourage the client to think positively about the situation (Vitale & Falco, 2014).
 - **EBN:** Encourage the client to discuss his/her situation with a health care practitioner, such as a nurse, physician, or social worker (Vitale & Falco, 2014).
 - **EBN:** Discuss the need for the client to anticipate triggers that may increase chronic sorrow (Vitale & Falco, 2014). **EB:** Triggers for parents of children with cerebral palsy may include times in which there is awareness of the actual versus expected achievements of the child or during times of medical intervention (Whittingham et al, 2013).
 - **CEB:** Refer for professional counseling or spiritual or pastoral support if needed (Gordon, 2009).
- ▲ **CEB:** Consider the need for medications for anxiety and depression if needed (Gordon, 2009).
- **CEB:** Refer clients for financial assistance with equipment and supplies if needed (Gordon, 2009).

Pediatric

- Encourage the parents of children with uncommon diseases to use online resources to manage their chronic sorrow. **EBN:** In a study of 16 mothers of children with a rare disease, online communication was used effectively to manage chronic sorrow (Glenn, 2015).
- Educate parents that an increase in chronic sorrow can occur after stressful events. **EB:** An increase in chronic sorrow was noted in parents with children who have cerebral palsy after triggering events, indicating that recurring grieving can occur after the diagnosis is made. Triggers can include when the child would have met a developmental milestone or started school (Whittingham et al, 2013).
- Nurses should assess for chronic sorrow and discuss coping strategies for parents of children who have been in the neonatal intensive care unit (NICU). **EBN:** Chronic sorrow is a useful framework for families impacted by an NICU stay (Vitale & Falco, 2014).
- Allow children the opportunity to talk about the impending death of a parent or loved one. **EB:** In a qualitative study of seven children whose parent was dying, children often were not encouraged to discuss their feelings, developed anxiety, and developed ways to deal with the stress (Buchwald et al, 2012).
- Encourage parents to listen to their child's expression of grief. **EB:** It is important for parents whose child is grieving to listen to their child's concerns and create a balance between making new memories while holding onto the old memories (Bugge et al, 2014).
- Consider the use of art for children in hospice care who are dying or dealing with the death of a parent, sibling, or other family member. **CEB:** Art can be used in both children and adults to communicate feelings, especially when clients are unable to verbally discuss their feelings (Devlin, 2006).
- ▲ Refer grieving children and parents to a program to help facilitate grieving. **EB:** Parents and families who have lost a child should be referred to peer-led support groups and grief counseling if desired (Wender, 2012).

- Encourage children experiencing grief to participate in bereavement activities and camps. **EB:** *In children who participated in a ropes course as activities based counseling during bereavement camp, five themes were noted: grief as a process, expression of feelings, support, coping, and empowerment and hope (Swank, 2013).*
- Help the adolescent with chronic sorrow determine sources of support and refer for counseling if needed. **EB:** *Cognitive behavioral therapy along with parental counseling has been useful in adolescents who experience prolonged grief (Spuij et al, 2015).*
- Provide family-centered care to parents of children with disabilities, and encourage parents to attend support groups. **EB:** *Caring for a child with cerebral palsy impacts the quality of life for families and is related to anticipatory grieving among parents (Al-Gamal, 2013).*
- Encourage parents with chronic sorrow to participate in a support group and learn coping strategies. **EB:** *Bereavement support groups for parents who have lost children can be helpful for managing grief (Grinyer, 2012).*
- Recognize that mothers who have a miscarriage grieve and experience sorrow because of loss of the child. *Understanding, listening, providing respect, and being supportive are important interventions for women who have experienced the loss of a pregnancy (Ancker et al, 2012).*

Geriatric

- Identify previous losses and assess the client for depression. **EB:** *Bereavement may result in major depression in some older adults, and participation support groups can be helpful in depression management (Ghesquiere et al, 2013).*
- Evaluate the social support system of the older client and refer for bereavement counseling if needed. **EB:** *In a study of 28 geriatric clients who had recently experienced a death, older adults often used family and friends as a support network following death, but community-based organizations also play an important role in bereavement support (Bellamy et al, 2014).*

Home Care

- In-home bereavement follow-up by nurses should be considered if available. **EBN:** *In Australia, home health nurses provide bereavement visits in which they provide comfort, counseling, client education, and encouragement and also evaluate the client who has recently experienced a loss (Brownhill et al, 2013).*
- Assess the client for depression. **EB:** *Clients experiencing bereavement are at risk for depression, so assessment for depression is necessary (Ghesquiere et al, 2013).*
- Refer for mental health services and counseling as indicated. **CEB:** *It is important to refer clients for mental health services and counseling when needed (Gordon, 2009).*
- Encourage the client to participate in activities that are diversionary and uplifting as tolerated (e.g., outdoor activities, hobby groups, church-related activities, pet care). **EBN:** *Diversionary activities decrease the time spent in sorrow, can give meaning to life, and provide a sense of well-being (Vitale & Falco, 2014).*
- Encourage the client to participate in support groups appropriate to the area of loss or illness. **EBN:** *Support groups can increase an individual's sense of belonging (Vitale & Falco, 2014).*
- Provide empathetic communication for family/caregivers. **CEB:** *Family/caregivers who feel supported are often able to provide greater and more consistent support to the affected person (Isaksson & Ahlstrom, 2008).*
- The interventions described previously may be adapted for home care use.
- See the care plans for Chronic low **Self-Esteem**, Risk for **Loneliness**, and **Hopelessness**.

Spiritual distress *Lisa Burkhart, PhD, RN, ANEF, and Barbara Baele Vincensi, PhD, RN, FNP*

NANDA-I

Definition

A state of suffering related to the impaired ability to experience meaning in life through connectedness with self, others, world, or a superior being

Defining Characteristics

Anxiety; crying; fatigue; fear; insomnia; questioning identity; questioning meaning of life; questioning meaning of suffering.

Connections to Self

Anger; decrease in serenity; feeling of being unloved; guilt; inadequate acceptance; ineffective coping strategies; insufficient courage; perceived insufficient meaning in life

Connections with Others

Alienation; refuses to interact with spiritual leader; refuses to interact with significant other; separation from support system

Connections with Art, Music, Literature, and Nature

Decrease in expression of previous pattern of creativity; disinterest in nature; disinterest in reading spiritual literature

Connections with Power Greater Than Self

Anger toward power greater than self; feeling abandoned; hopelessness; inability for introspection; inability to experience the transcendent; inability to participate in religious activities; inability to pray; perceived suffering; request for a spiritual leader; sudden change in spiritual practice

Related Factors

Actively dying; aging; birth of a child; death of significant other; exposure to death; illness; imminent death; increasing dependence on another; life transition; loneliness; loss of a body part; loss of function of a body part; pain; perception of having unfinished business; receiving bad news; self-alienation; social alienation; sociocultural deprivation; treatment regimen; unexpected life event

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Dignified Life Closure; Grief Resolution; Hope; Spiritual Health; Stress Level

Example NOC Outcome with Indicators

Spiritual Health as evidenced by the following indicators: Quality of faith, hope, meaning, and purpose in life/ Connectedness with inner-self and with others to share thoughts, feelings, and beliefs. (Rate each indicator of **Spiritual Health**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Express meaning and purpose in life
- Express sense of hope in the future
- Express sense of connectedness with self
- Express sense of connectedness with family/friends
- Express ability to forgive
- Express acceptance of health status
- Find meaning in relationships with others
- Find meaning in relationship with higher power
- Find meaning in personal and health care treatment choices

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening; Forgiveness Facilitation; Grief Work Facilitation; Hope Inspiration; Humor; Music Therapy; Presence; Referral; Reminiscence Therapy; Self-Awareness Enhancement; Simple Guided Imagery; Simple Massage; Simple Relaxation Therapy; Spiritual Support; Therapeutic Touch; Touch

Example NIC Activities—Spiritual Support

Encourage use of spiritual resources if desired; Be available to listen to client's feelings

Nursing Interventions and Rationales

- Observe clients for cues indicating difficulties in finding meaning, purpose, or hope in life. **CEB**: *In a grounded theory study, spiritual care begins by recognizing a client cue for needing spiritual care (Burkhart & Hogan, 2008).* **EBN**: *In this cross-sectional study involving 202 cognitively intact nursing home residents, Haugan (2014) found a significant relationship between the nurse-patient interaction on patients' development of hope, meaning in life, and self-transcendence, which were found to be important resources for health and global well-being.*
- Observe clients with chronic illness, poor prognosis, or life-changing conditions for loss of meaning, purpose, and hope in life. **EB**: *In a retrospective study, meaninglessness, helplessness, brokenness, and despair were reported, indicating spiritual distress in younger adult patients with advanced cancer admitted to an acute palliative care unit (Hui et al, 2011).* **EBN**: *In a metasynthesis, Lin et al (2011) discovered that quality of life often reflected spiritual well-being in those living with rheumatoid arthritis.*
- Offer spiritual care in disaster relief. **EB**: *In a case study of Hurricane Katrina survivors, spirituality and religion were found to be important sources of resilience and coping in disaster relief, particularly for the African American community (Alawiyah et al, 2011).*
- Promote a sense of love, caring, and compassion in nursing encounters. **EBN**: *In a cross-sectional, descriptive study of 202 cognitively intact nursing home residents, the nurse-patient interaction had a significant impact on the development of meaning in life, hope, and self-transcendence, potentially promoting health and well-being in this population (Haugan, 2014).*

- Be physically present and actively listen to the client. **CEB:** *In a grounded theory study, spiritual care included promoting client connectedness with self (Burkhart & Hogan, 2008).* **EBN:** *In a cross-sectional correlational study by Haugan et al (2014), nurses were found to facilitate both interpersonal and intrapersonal transcendence for long-term nursing home residents by their presence and by encouraging connections with oneself and others in meaningful ways.*
- Help the client find a reason for living, be available for support and promote hope. **EBN:** *A cross-sectional descriptive study in 44 different nursing homes found nurse-resident interaction was a resource for hope, meaning in life, and self-transcendence for residents (Haugan, 2014).*
- Listen to the client's feelings about suffering and/or death. Be nonjudgmental and allow time for grieving. **EBN:** *In a cross-sectional descriptive study of 120 patients with chronic renal insufficiency, 25.7% were able to self-identify as having spiritual distress while another 25.8% were identified by expert nurses as such; however, patients were reluctant to discuss their spiritual needs because of fear of judgment by the nurses or disinterest of the health care team (Chaves et al, 2011).*
- Respect the client's beliefs; avoid imposing your own spiritual beliefs on the client. Be aware of your own belief systems and accept the client's spirituality. **EB:** *In a systematic literature review, assuring an adequate religious, spiritual, and cultural assessment has been made of children, adolescents, and their families regarding their need for spiritual and religious care before referral decreased potential for stereotyping by the nurse and assured specific needs, rituals, and desires of the patient and family were met (Wiener et al, 2013).* **CEB:** *Taylor and Mamier (2005) reported that most cancer clients and caregivers welcomed interventions that were less intimate, commonly used, and not overtly religious.*
- Monitor and promote supportive social contacts. **EB:** *In a correlational descriptive study by Dalmida et al (2013), the three variables found to play an important role in mitigating depression in people living with HIV/AIDS were social support and religious and spiritual coping interventions.*
- Integrate family into spiritual practices as appropriate. **CEB:** *In a phenomenological study, lung cancer clients identified maintaining contact with family and friends for support and prayer as helpful self-care strategies (John, 2010).* **EB:** *In a cross-sectional, descriptive study, high levels of participation in religious practices and use of social supports were found to improve the general well-being of Korean adult immigrants in the United States (Lee & Woo, 2013).*
- Assist family in searching for meaning in client's health care situation. **CEB:** *A qualitative study of young adult daughters with parents experiencing cancer identified exploring meaning as a theme (Puterman & Cadell, 2008).* **EB:** *In a cross-sectional descriptive study of the spirituality of 129 parents whose children had a life-limiting illness, Knapp et al (2011) found higher scores for spirituality and meaning/peace in non-Caucasian parents, parents who were married, and children who had higher hearing and vision scores; recommendations included incorporating the family's spirituality and search for meaning in illness into the palliative care team's routine care. Offer spiritual support to caregivers.* **EBN:** *In a descriptive study, individual spiritual well-being predicted higher levels of better mental health in cancer survivor/caregiver dyad couples (Kim et al, 2011).*
- ▲ Refer the client to a support group or counseling. **EB:** *In a cross-sectional randomized study by Lyon et al (2011), a relationship was found between providing family support within a support group, on the spirituality of adolescents living with HIV and adherence to highly active antiretroviral therapy.*
- Support meditation, guided imagery, journaling, relaxation, and involvement in art, music, or poetry. Support outdoor activities. **EB:** *In a randomized clinical study comparing differences between groups of participants with metastatic carcinoma who used either spiritual or secular meditation techniques, Cole et al (2012) found those who used spiritual meditation had significantly reduced depression and increased physical and psychological well-being than those who used the secular method.* **CEB:** *In a qualitative study of stroke caregivers, being one with nature emerged as a theme (Pierce et al, 2008).*
- ▲ Offer or suggest visits with spiritual and/or religious advisors. **CEB:** *In a grounded theory study, spiritual care included promoting connectedness with others, including chaplains (Burkhart & Hogan, 2008).* **EBN:** *In a descriptive clinical study to improve quality of care for oncology patients, Blanchard et al (2012) found adequate assessment of patients' spiritual care needs by nurses allowed for appropriate referrals to chaplains or religious/spiritual leaders, improving patients' perception of their overall care and meeting the patients' religious/spiritual needs while hospitalized.*
- Provide privacy or a "sacred space." **CEB:** *In a qualitative survey of chronically ill individuals, participants wanted access to a garden and a quiet space available in the hospital to think through decisions (Dale & Hunt, 2008).* **EBN:** *In educating college students on cultural awareness, Walton (2011) used mixed methods research of qualitative and quantitative (descriptive) design to identify five themes that had significant*

differences in findings before and after an education program; a primary theme was the development of sacred space on the dialysis unit to encourage participation in dialysis by Native Americans.

- Allow time and a place for prayer. **EBN:** In a grounded theory study, spiritual care included promoting religious rituals and prayer and was validated in a psychometric study (Burkhart et al, 2011). **CEB:** In a quantitative study of 156 clients with cancer and 68 caregivers, Taylor (2006) found that one of the most prevalent spiritual needs was understanding or relating to God.
- Coordinate or encourage attending spiritual retreats, courses, or programming. **CEB:** In a study of 128 male clients who expressed interest in attending an informational intervention, topics included spirituality (Manii & Ammerman, 2008). **EBN:** In a qualitative study, Baldacchino (2011) identified that the nurse's awareness of patients' spiritual needs, and the ability of the nurse to meet patients' spiritual needs, increased after attending a specific learning module on Spiritual Coping During Illness.

Geriatric

- Identify the client's past spiritual practices that have been helpful. Help the client explore his/her life and identify those experiences that are noteworthy. **EBN:** In a systematic literature review, past spiritual rituals helped patients with dementia connect to deeply rooted memories and provided a centering experience that promoted a sense of control and connection for the patient (Enis & Kazer, 2013). **EBN:** A cross-sectional study of 202 cognitively intact nursing home residents revealed a significant relationship between promotion of intrapersonal and interpersonal self-transcendence and meaning in life for the resident and the type of nurse-resident interaction (Haugan, 2014).
- Offer opportunities to practice one's religion. **EB:** Eighty percent of patients involved in the National Emphysema Treatment Trial, a randomized longitudinal study, used religious practices or spiritual interventions to cope with their disease (Green et al, 2011). **CEB:** In a descriptive cross-sectional study, the geriatric population uses religious services in naturally occurring retirement communities (Lun, 2010).

Pediatric

- Offer adolescents opportunities for reflection and storytelling to express their spirituality. **EB:** In a systematic literature review, Bryant-Davis et al (2012) found incorporating stories, songs, or passages from sacred script allowed children and adolescents to use their spirituality and religion as a means of coping with distress.

Multicultural

- Recognize the importance of spirituality and provide culturally competent spiritual care to specific populations:
 - Arab Muslims. **EBN:** In a phenomenological qualitative study of Jordanian Muslim men with coronary artery disease (CAD), participants believed that their illness was fate or God's will, their faith directed them to make sound health decisions, and their spirituality provided the support to accept their illness and suffering (Nabolsi & Carson, 2011).
 - Chinese elders. **EBN:** Using a life review program with Chinese elders with advanced cancer improved psychosocial well-being and enabled elders to make preparations for death, reconcile past conflicts, and make peace within themselves and with others (Xiao et al, 2011).
 - Korean immigrants. **EB:** In a cross-sectional exploratory study, high social support, and religious and spiritual practices were significantly associated with high general well-being in 147 adult Korean immigrants in the United States (Lee & Woo, 2013).
 - Latinos. **EB:** Faith based approaches to coping with cancer were found to be an important part of identity for Latinos in a cross-sectional descriptive study by Canada et al (2013).
 - African Americans. **EB:** In a descriptive study by Canada et al (2013), African Americans were found to use spirituality to cope with advanced cancer more than Hispanics or Caucasians. **EB:** A descriptive study with 100 African Americans with cancer identified positive affect and emotional functioning were influenced by religious and spiritual well-being, with religious beliefs and behaviors significant predictors of finding meaning in life, a positive affect, and use of religious coping interventions (Holt et al, 2011).
 - Thai. **EBN:** In a randomized controlled study of 79 Buddhist Thai elders in Thailand, those participants in the groups who practiced Vipassana meditation or only chanting had significantly improved spiritual well-being and sleep quality compared to the control group who practiced neither (Wiriyasombat et al, 2011).

- African women. **EBN:** *In an ethnographic study in Ghana, the belief that pregnancy makes women's souls vulnerable to spiritual illnesses is the reason many seek spiritual protection through their spiritual or religious leaders during pregnancy (Farnes et al, 2011).* **CEB:** *In Uganda, 85% of African women with HIV/AIDS use spirituality as a coping mechanism, including support from other believers, prayer, and trusting in God (Hodge & Roby, 2010).*

Veterans of Armed Services

- Recognize the unique spiritual needs of veterans and provide spiritual support or appropriate referrals. **EB:** *In a grounded theory developed by Chang et al (2012), feelings of guilt and seeking forgiveness as well as finding peace within themselves and with others were spiritual needs of veterans that were discovered.*

Home Care

- All of the nursing interventions described previously apply in the home setting.

Risk for Spiritual distress *Gail B. Ladwig, MSN, RN*

NANDA-I

Definition

Vulnerable to an impaired ability to experience and integrate meaning and purpose in life through connectedness within self, literature, nature, and/or a power greater than oneself, which may compromise health

Risk Factors

Developmental

Life transition

Environmental

Environmental change; natural disaster

Physical

Chronic illness; physical illness; substance abuse

Psychosocial

Anxiety; barrier to experiencing love; change in religious ritual; change in spiritual practice; cultural conflict; depression; inability to forgive; ineffective relationships; loss; low self-esteem; racial conflict; separation from support system; stressors

NIC, NOC, Client Outcomes, Nursing Interventions, Rationales, and References

Refer to care plan for **Spiritual Distress**.

Readiness for enhanced Spiritual well-being

Lisa Burkhart, PhD, RN, ANEF, and Barbara Baele Vincensi, PhD, RN, FNP

NANDA-I

Definition

A pattern of experiencing and integrating meaning and purpose in life through connectedness with self, others, art, music, literature, nature, and/or a power greater than oneself, which can be strengthened

Defining Characteristics

Connections to Self

Expresses desire to enhance acceptance; expresses desire to enhance coping; expresses desire to enhance courage; expresses desire to enhance hope; expresses desire to enhance joy; expresses desire to enhance love; expresses desire to enhance meaning in life; expresses desire to enhance meditative practice; expresses desire to enhance purpose in life; expresses desire to enhance satisfaction with philosophy of life; expresses desire to enhance self-forgiveness; expresses desire to enhance serenity (e.g., peace); expresses desire to enhance surrender; meditation

Connections with Others

Expresses desire to enhance forgiveness from other; expresses desire to enhance interaction with significant other; expresses desire to enhance interaction with spiritual leaders; expresses desire to enhance service to others

Connections with Art, Music, Literature, and Nature

Expresses desire to enhance creative energy (e.g., writing, poetry, music); expresses desire to enhance spiritual reading; expresses desire to enhance time outdoors

Connections with Power Greater Than Self

Expresses desire to enhance mystical experiences; expresses desire to enhance participation in religious activity; expresses desire to enhance prayerfulness; expresses desire to enhance reverence

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Health Status; Coping; Dignified Life Closure; Grief Resolution; Hope; Personal Health Status; Psychosocial Adjustment: Life Change; Quality of Life; Social Involvement; Spiritual Health

Example NOC Outcome with Indicators

Hope as evidenced by the following indicators: Expresses expectation of a positive future/Faith/Optimism/Belief in self/Sense of meaning in life/Belief in others/Inner peace. (Rate each indicator of **Hope**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = constantly demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Express hope
- Express sense of meaning and purpose in life
- Express peace and serenity
- Express love
- Express acceptance
- Express surrender
- Express forgiveness of self and others
- Express satisfaction with philosophy of life
- Express joy
- Express courage
- Describe being able to cope
- Describe use of spiritual practices
- Describe providing service to others
- Describe interaction with spiritual leaders, friends, and family
- Describe appreciation for art, music, literature, and nature

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening; Coping Enhancement; Counseling; Crisis Intervention; Decision-Making Support; Grief Work Facilitation; Hope Instillation; Meditation Facilitation; Mutual Goal Setting; Presence; Religious Ritual Enhancement; Imagery; Simple Relaxation Therapy; Socialization Enhancement; Spiritual Growth Facilitation; Spiritual Support; Support System Enhancement; Touch; Values Clarification

Example NIC Activities—Spiritual Support

Encourage use of spiritual resources if desired; Be available to listen to client's expression of feelings

Nursing Interventions and Rationales

- Perform a spiritual assessment that includes the client's relationship with God, meaning and purpose in life, religious affiliation, and any other significant beliefs. **EBN:** *A descriptive cross-sectional study examining the relationship between spiritual well-being, perceived stress, coping, and smoking in 125 African American women (smokers, ex-smokers, non-smokers) found increased spiritual well-being and a supportive faith community offered a protective quality against stress and smoking (Franklin, 2011).*
- Be present and actively listen to the client. **EBN:** *In a grounded theory study, spiritual care included promoting client connectedness with self, and was validated in a psychometric study (Burkhart et al, 2011).*
- Encourage the client to pray or engage in other spiritual meditative practices. **EB:** *In a descriptive, correlational study, spiritual and religious practices were a coping mechanism utilized by those with chronic disease (Green et al, 2011).* **CEB:** *Meraviglia (2006) found that prayer was associated with higher psychological well-being.*
- Coordinate or encourage attending spiritual retreats or courses. **EBN:** *In a qualitative study, Baldacchino (2011) identified nurses' awareness of patients' spiritual needs, and their ability to meet these needs increased after attending a specific learning module on Spiritual Coping During Illness.*
- Promote hope. **EBN:** *Using a cross-sectional descriptive design, Haugan (2014) found important factors for health in cognitively intact nursing home patients were nurse-patient interactions, which promoted hope and self-transcendence.*
- Encourage clients to reflect on what is meaningful to them in life. **EBN:** *In a descriptive, cross-sectional design of 202 cognitively intact nursing home patients, the ability to use reflection to discover meaning in life was enhanced by patients' interactions with the nurse (Haugan, 2014).*
- Encourage increased quality of life through social support and family relationships. **EB:** *Providing family support was one way to enhance the spirituality of adolescents in a quasi-experimental study by Lyon et al (2011).*
- Assist the client in identifying religious or spiritual beliefs that encourage integration of meaning and purpose in the client's life. **EBN:** *Religion and religious support were identified in a hermeneutic study of 17 participants as part of one's spirituality and caring (Rykkje et al, 2013).* **EBN:** *Haugan (2014) discovered in a cross-sectional descriptive study that nurses' interactions with the patient positively affect hope, meaning in life, and intrapersonal self-transcendence of the patient.*
- Support meditation, guided imagery, journaling, relaxation, and involvement in art, music, or poetry. Support outdoor activities. **EB:** *In a systematic literature review, Guerin et al (2011) identified music and other arts promote the spiritual connections to self, others, and community.* **CEB:** *In a randomized controlled trial, a spiritual meditation intervention was associated with fewer migraine headaches, less anxiety and a greater pain tolerance, headache-related self-efficacy, daily spiritual experiences, and existential well-being (Wachholtz & Pargament, 2008).*
- Encourage outdoor activities. **CEB:** *In a qualitative study of stroke caregivers, being one with nature emerged as a theme (Pierce et al, 2008).*
- Encourage expressions of spirituality. **EB:** *Kristeller et al (2011) used a cross-sectional exploratory design in their study of 114 individuals receiving cancer care and found higher levels of religious and spiritual engagement contributed to more positive adjustment to a cancer diagnosis.*

- Encourage integration of spirituality in healthy lifestyle choices. **EB:** *In a cross-sectional study of 100 adults, higher levels of spiritual well-being were found to be cardioprotective with a significant relationship to lowered blood pressure, C-reactive protein, triglycerides, fasting blood sugars, body mass index, stress, and depression (Holt-Lunstad et al, 2011).*

Geriatric

- Identify the client's past spiritual practices that have been growth-filled. Help the client explore his or her life and identify those experiences that are noteworthy. **EB:** *In a descriptive correlational study in which participants fell into two of four groups, those with higher levels of spirituality with or without high levels of religion, had higher levels of self-actualization and higher levels of growth initiative; both groups also had higher scores on meaning in life measures (Ivtzan et al, 2013).*
- Offer opportunities to practice one's religion. **EB: Freeze and DiTommaso (2014)** identified in their descriptive study and development of a structural equation model (SEM) that a secure connection to God through religious behaviors and prayers lessened emotional distress and increased a sense of purpose in life. **EBN:** *In a systematic literature review on improving outcomes in older adults with dementia through spiritual nursing care, spiritual and religious rituals such as praying, attending church, and paying tribute to God were found to be deeply embedded memories and helped to enhance reality orientation and emotional calming while decreasing agitation in this population (Enis & Kazer, 2013).*

Pediatric

- Offer adolescents opportunities for reflection and storytelling to express their spirituality. **EBN:** *In a cross-sectional correlational study of 310 African American adolescents, there was a relationship between frequency of participation in activities to promote spiritual well-being and positive self-reported health status (Powell-Young, 2012).*

Multicultural

- Recognize the importance of spirituality and provide culturally competent spiritual care to specific populations:
 - Arab/Jordanian Muslims. **EB:** *Jordanian Muslim men living with coronary artery disease (CAD) shared a belief in this phenomenological study that their disease was God's will but their faith directed them to make sound health decisions while their spirituality enabled them to accept their illness and suffering (Nabolsi & Carson, 2011).*
 - Thai. **EBN:** *In a randomized controlled study of 79 Buddhist Thai elders in Thailand, those in the groups who practiced Vipassana meditation or chanting had significantly improved spiritual well-being and sleep quality compared to the control group who practiced neither (Wiriyaombat et al, 2011).*
 - Latinos. **EB:** *In a cross-sectional study examining racial/ethnic differences in spiritual well-being among cancer survivors, 80% of Latinos used their spirituality or faith to help them cope with their cancer experiences (Canada et al, 2013).* **CEB:** *Latinos may identify spirituality, religiousness, prayer, and church-based approaches as coping resources (Simoni et al, 2006).*
 - African Americans. **EBN:** *Spirituality was used as a coping mechanism to decrease perceptions of stress and the urge to smoke in a cross-sectional study of 125 AA women who were smokers, ex-smokers, and non-smokers (Franklin, 2011).* Integrate spiritual practices in health-promoting programs, particularly within the African American community. **EB:** *A cross-sectional study revealed that African Americans use spirituality and religion more than Hispanics and Caucasians to cope as a cancer survivor (Canada et al, 2013).* **EB:** *A study of African American breast cancer survivors indicated that spirituality may facilitate cancer adjustment (Lewis et al, 2012).*
 - Sheltered homeless. **EBN:** *In a cross-sectional correlational study examining the relationship between spirituality and health-promoting behaviors in 90 sheltered homeless women, a significant relationship was found between higher levels of spirituality and health-promoting behaviors (physical activity, nutrition, spiritual growth, interpersonal relations, and stress management) (Hurlbut et al, 2011).*
 - Chinese. **EBN:** *In a descriptive qualitative study, Chinese patients with advanced cancer were found to have improved psycho-spiritual well-being after participating in a life-review program (Xiao et al, 2011).*

Home Care

- All of the nursing interventions described previously apply in the home setting.

Impaired Standing Tracy P. George, DNP, APRN-BC, CNE

NANDA-I

Definition

Limitation of ability to independently and purposefully attain and/or maintain the body in an upright position from feet to head

Defining Characteristics

Impaired ability to adjust position of one or both lower limbs on uneven surface; impaired ability to attain a balanced position of the torso; impaired ability to extend one or both hips; impaired ability to extend one or both knees; impaired ability to flex one or both hips; impaired ability to flex one or both knees; impaired ability to maintain the torso in balanced position; impaired ability to stress torso with body weight; insufficient muscle strength

Related Factors

Circulatory perfusion disorder; emotional disturbance; impaired metabolic functioning; injury to lower extremity; insufficient endurance; insufficient energy; malnutrition; neurological disorder; obesity; pain; prescribed posture; sarcopenia; self-imposed relief posture; surgical procedure

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Body mechanics performance

Uses correct standing posture

Body Positioning: Self-Initiated

Moves from sitting to standing

Comfort Status: Physical

Comfortable position

Risk Control Hypotension

Monitors for orthostatic hypotension when changing position

Example NOC Outcome with Indicators

Client will use personal actions to maintain proper body alignment and to prevent musculoskeletal strain by using correct standing posture 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated (see [Section I](#)).

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate optimal independence and safety when standing
- Demonstrate the proper use of assistive devices
- State benefits of standing

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Body mechanics promotion

Example NIC Activities

Instruct client on structure and functioned spine and optimal posture for moving and using the body

Nursing Interventions and Rationales

- Encourage clients to stand at intervals throughout the day. **EB:** *In a randomized control trial of overweight or obese Australian office workers, participants who completed work while alternating between sitting and standing at 30-minute intervals throughout the day demonstrated a 11.1% decrease in glucose levels after meals (Thorp et al, 2014).*
- Advise patients of the physical and psychological benefits of being upright and active. **EB:** *In patients 1 to 3 years after suffering a stroke, depression, left hemisphere infarction, visual neglect, and difficulty with mobility and balance were associated with being less active (Kunkel et al, 2015).*

Geriatric

- Advise older clients who have difficulty standing to use assistive devices. **EB:** *In a Swedish study using the Psychosocial Impact of Assistive Devices Scale, Nordström et al (2014) found that the frequent use of standing assistive devices was associated with higher psychosocial scores in older adults.*

- Encourage trunk exercises after clients have had strokes. **EB**: In a meta-analysis of six randomized controlled studies, trunk exercises were associated with improvements in standing and walking for clients following strokes (Sorinola et al, 2014).
- Encourage clients post-stroke to participate in rehabilitation interventions that promote standing. **EB**: In a meta-analysis using 11 studies, interventions used following strokes to improve standing were associated with faster sitting to standing position times and improved lateral symmetry during sitting to standing position changes (Pollock et al, 2014). **EB**: A study of seven participants found that a home-based intervention, Rehab@home, can be used effectively to improve the rehabilitation of balance and the movement from the sitting to standing position in patients with neurological deficits, without the presence of a physical therapist (Faria et al, 2015).
- Raise the height of the bed and encourage the use of the client's hands when an older adult is rising from a sitting to standing position. **EB**: In a study of 24 older clients, Lindemann et al (2014) found that raising the bed height and using the hands while transferring from a sitting to standing position resulted in less effort.
- Educate older adults who have fallen about the need for balance and muscle training of the ankle joint. **EB**: In a randomized controlled trial of 26 older clients who were at risk of falling and had fallen previously, Jung-Hyun and Nyeon-Jun (2015) found that balance and ankle muscle training resulted in improvements in the gait of older adults.
- Educate adults older than age 80 years on the need for vitamin D. **EB**: Low serum 25-hydroxyvitamin D (25OHD) levels were associated with orthostatic hypotension in a study involving community-dwelling clients 80 years of age and older (N = 329) (Annweiler et al, 2014).

Client/Family Teaching and Discharge Planning

- Educate clients that standing can be beneficial for their health. **EB**: In a Canadian prospective cohort study in which participants were followed for a mean duration of 12 years, Katzmarzyk (2014) found that increased daily standing times was associated with decreased cardiovascular and all-cause mortality rates. **EB**: In a study of participants with chronic pain (N = 18) and participants without chronic pain (N = 19), Raijmakers et al (2015) found that patients with chronic pain spent more time lying and less time sitting and standing over a 1-week period.
- Teach clients about the need to take frequent breaks when standing for long periods. **EB**: With 45 minutes of standing to 15 minutes of sitting (3:1 ratio), 55% of participants experienced low back pain while standing, so this ratio may be not be adequate and alternate rest activities may be needed (Gallagher et al, 2014).
- Instruct clients about the use of yoga for individuals who have difficulty with standing balance. **EB**: In a randomized control of obese adults with poor standing balance, participation in yoga classes three times per week was associated with improved static and dynamic standing balance (Chaiyong et al, 2015).

Stress overload *June M. Como, EdD, RN, CNS*

NANDA-I

Definition

Excessive amounts and types of demands that require action

Defining Characteristics

Excessive stress; feeling of pressure; impaired decision-making; impaired functioning; increase in anger; increase in anger behavior; increase in impatience; negative impact from stress (e.g., physical symptoms, psychological distress, feeling sick); tension

Related Factors (r/t)

Excessive stress; insufficient resources (e.g., financial, social, knowledge); repeated stressors; stressors

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Anxiety Level; Caregiver Stressors; Stress Level; Health-Promoting Behavior; Knowledge: Stress Management

Example NOC Outcome with Indicators

Stress Level as evidenced by the following indicators: Increased blood pressure, restlessness, emotional outbursts, anxiety, diminished attention to detail. (Rate the outcome and indicators of **Stress Level**: 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Review the amounts and types of stressors in daily living
- Identify stressors that can be modified or eliminated
- Mobilize social supports to facilitate lower stress levels
- Reduce stress levels through use of health promoting behaviors and other strategies

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening; Anger Control Assistance; Anxiety Reduction; Aroma Therapy; Counseling; Crisis Intervention; Emotional Support; Family Integrity Promotion; Presence; Support System Enhancement

Example NIC Activities—Support System Enhancement

Identify psychological response to situation and availability of support system; Determine adequacy of social networks; Explain to concerned others how they can help; Refer to a self-help group or Internet-based resource as appropriate; Provide services in a caring and supportive manner

Nursing Interventions and Rationales

- Assist client in identification of stress overload during vulnerable life events. **EBN**: Research suggests that role overload, associated with high stress levels, among nurses and volunteer caregivers may negatively impact health, well-being, and job performance (Kath et al, 2013; Akintola et al, 2013). **EB**: In a systematic review of 40 studies it was found that at least 33% of surrogates experience stressful emotional burden on making treatment decisions for others (Wendler & Rid, 2011). **CEB**: Women with breast cancer who were involved in group therapy focusing on stress reduction and muscle relaxation were 56% less likely to succumb to the

disease and 45% less likely to experience a recurrence (Andersen et al, 2008). Men with high stress have higher all-cause mortality, the effects being more pronounced among middle-aged men (Nielsen et al, 2008).

- Listen actively to descriptions of stressors and the stress response. **EBN:** In a recent longitudinal study of clients with heart failure, researchers found that clients with high anxiety experienced shorter periods of event-free (hospitalization, mortality) survival than those with lower anxiety ($P = .03$) (Dejong et al, 2011). **EB:** Adolescents exposed to daily stress demonstrate increased risky decision-making compared to those with low stress (Galván, 2012).
- In younger adult women, assess interpersonal stressors. **EB:** In a sample of 127 spouse caregivers of clients with Alzheimer's disease who were predominantly female (71%), greater stress was associated with more depressive symptoms and these symptoms were significantly associated with decreased personal mastery ($P = .006$), self-efficacy ($P < .001$), increased avoidance coping ($P < .001$), and activity restriction ($P = .040$) (Mausbach et al, 2012). **CEB:** A systematic review and meta-analysis of 30 studies found that maternal exposure to the stress of domestic violence results in significantly increased risk of low birth weight and preterm birth (Shah & Shah, 2010).
- Categorize stressors as modifiable or nonmodifiable. **EB:** Strategizing on nonavoidance coping and increased socialization along with enhanced personal mastery and self-efficacy in use of problem-solving coping may minimize depression symptoms in Alzheimer's disease caregivers (Mausbach et al, 2012). **CEBN:** Removing or minimizing some stressors, changing responses to stressors, and modifying the long-term effects of stress are all actions that can assist those with chronic illnesses and stress (Upton & Solowiej, 2010).
- Help clients modify or mitigate stressors identified as modifiable. **EBN:** In a sample of 480 nurse managers from 36 hospitals in Southwestern United States, role overload was found to be the most significant predictor of work-related stress followed by organizational constraints and role conflict (all $P < .01$ [two-tailed]); all three are areas that organizational leaders need to be aware of to mitigate stress overload in managerial staff (Kath et al, 2013). **CEB:** There are numerous possible strategies to modify stressors, including time management, improved organizational skills, problem solving, changing perceptions of stress, breathing, relaxation techniques, visual imagery, and soothing rituals (Lloyd et al, 2005).
- Help clients distinguish among short-term, chronic, and secondary stressors. **EB:** Cellular aging, identified by leukocyte telomere length (TL), was found to be different in a sample of 36 ethnically diverse, older adults between four pain/stress groups ($P = .01$) where those with chronic pain/higher stress had the shortest TL indicative of cellular aging (Sibille, 2012). **CEBN:** Social support is a critical dimension of health and health promotion and serves as a buffer in the stress response (Pender et al, 2010).
- Provide information as needed to reduce stress responses to acute and chronic illnesses. **EBN:** Nursing interventions including strategies to deal with child behavior, a focus on physical health, and planning to meet resource needs may enhance the well-being of African American grandmothers raising grandchildren (Kelley, 2013). Pro-active nursing interventions including assessment of caregiver needs for support and preparedness including early psycho-educational interventions can enhance caregiver ability to navigate the challenges associated with caring for a relative with Alzheimer's disease (Ducharme, 2011).
- ▲ Explore possible therapeutic approaches such as cognitive-behavioral therapy, biofeedback, neurofeedback, acupuncture, pharmacological agents, and complementary and alternative therapies. **EBN:** Non-pharmacological nursing interventions through the use of nature-based sounds played through headsets was found to effectively decrease the stress response in mechanically-ventilated clients in a sample of 60 Iranian clients aged 18-65 (Saadatmand, 2013). **EB:** In a sample of 111 healthy adults, those who exercised regularly were more resistant to acute stress (Childs, 2014). Mindfulness techniques have been suggested as an effective means of reducing stress in adolescents (Broderick, 2012), nursing personnel (Zeller, 2013), and older adults (Gallegos, 2013).
- Help the client to reframe his or her perceptions of some of the stressors. **EBN:** A study on 335 Thai nursing students found that coping mediated the effects of stress on physical and psychological health (Klainin-Yobas, 2014). Researchers found that nursing students with higher anxiety states were 62% less optimistic, findings supporting that individuals with pessimistic outlooks perceive situations as more threatening (Warning, 2011).
- Assist the client to mobilize social supports for dealing with recent stressors. **CEBN:** Emotional support in Taiwanese caregivers is suggested as a moderator of stressors experienced by caregivers of clients with Alzheimer's disease or stroke, particularly in caregivers with lower household incomes (Huang et al, 2009). **EB:** In a sample of 79 German adults a predicted association between needed and received emotional support and well-being was found in younger adults (aged 23-34) (Wolff, 2013).

Pediatric

- With children, nurses should work with parents to help them to reduce children's stressors. **EB:** A longitudinal study on 115 children aged 7 to 12 suggests that early life stress and trauma may result in increased limbic activity, a biomarker that may have implications as a risk for later psychiatric diagnoses (Suzuki, 2014). A study on 181 18- to 20-year-olds suggests that more positive parenting behaviors are statistically significantly ($P < 0.01$) associated with more adaptive cognitions in the emerging adult which may impact stress/health outcomes (Donnelly, 2013).
- Help children to manage their feelings related to self-concept. **CEB:** Perceived isolation as experienced in high school associated with victimization results in higher stress and longer-lasting negative psychological outcomes (Newman, Holden, & Delville, 2005).
- Help children to deal with bullies and other sources of violence in schools and neighborhoods. **EB:** In a sample of 1,420 children and adolescents the number of times that the individual was bullied predicted higher levels of C-reactive protein (CRP) (a risk factor for negative health consequences later in life) where those who bullied had lower levels of CRP (Copeland, 2014). Violence in schools and neighborhoods has significant effects on children's stress. In a recent study of college-aged respondents ($N = 1339$), researchers found that a history of being bullied (victimized) was associated with both increased stress and use of avoidant behaviors (Newman, Holden, & Delville, 2011).
- Help children to manage the complexities of chronic illnesses. **EB:** Individuals who grow up with a chronic illness have lower odds of graduating college, being employed, having a good income, and a higher need for public assistance although do succeed socially as evident by similar odds of marriage, having children, and living with their parents when compared to those without chronic illness (Maslow, 2011). **CEB:** Teenagers who had recently been diagnosed with diabetes described high levels of stress that often related to the complexities of managing the illness (Davidson et al, 2004).

Geriatric

- Assess for chronic stress with older adults and provide a variety of stress relief techniques. **EB:** In a sample of over 9,000 U.S. adults over the age of 60 lifetime post-traumatic stress disorder (PTSD) was found to be associated with greater odds of being diagnosed with hypertension, angina pectoris, tachycardia, other heart disease, stomach ulcer, gastritis, and arthritis (Pietrzak, 2012).
- ▲ Encourage older adults to seek appropriate counseling. **EB:** Treatment modalities for PTSD in older adults may vary dependent on whether the PTSD was experienced early or late in life; however, trauma confrontation and cognitive restructuring combined with age-specific life review in cognitive behavioral therapy may hold the most promise (Böttche, 2012). **CEB:** Bereavement-related major depression differs from major depression seen in other stressful life events only in relation to older age at onset, individuals are more likely to be female, lower levels of treatment-seeking, higher levels of guilt, fatigue, and loss of interest and therefore should not be excluded from a diagnosis of major depression (Kendler, Myers, & Zisook, 2008).

Multicultural

- Review cultural beliefs and acculturation level in relation to perceived stressors. **EBN:** A study done to assess how the type of premigration trauma, postmigration stressors and resources predicted PTSD and major depressive disorder (MDD) symptoms it was found that postmigration-related stressors greatly increased the odds (nearly 16-fold) of being in a comorbid group (PTSD or MDD) (Norris, 2011). **EB:** A review of qualitative studies found that organizational constraints, work overload, and interpersonal conflict were universally experienced stressors in studies that assessed occupational stress on an international perspective (Mazzola et al, 2011). Assess families for whether they experience high stress or low stress. **EB:** In a sample of 97 native Norwegian adolescents and 59 immigrant adolescents from an urban Norwegian secondary school, global victimization was found to be higher in the immigrant group compared to the native group although there was no difference in the report of depressive symptoms (Fandrem et al, 2012). **CEB:** Stress related to racial microaggressions experienced by African Americans may have a negative cumulative effect on health outcomes (Sue et al, 2007).

Home Care

- The preceding interventions may be adapted for home care use.
- Develop community-based programs for stress management as needed for groups with increased risk of stress overload (e.g., firefighters, policemen, military personnel, and nurses). **CEB:** Some situations have

higher risks of stress overload. Stress management interventions may prevent or modify the experience of stress overload (McNulty, 2005).

- Support and encourage neighborhood stability. **CEB**: A “significant proportion of health differentials across neighborhoods is due to disparate stress levels across [Detroit] neighborhoods” and neighborhood stability was a buffer to reduce the negative effects of high stress (Boardman, 2004).

Client/Family Teaching and Discharge Planning

- Diagnose the possibility of stress overload before teaching.
- Establish readiness for learning.
- Provide manageable amounts of information at the appropriate educational level.
- Evaluate the need for additional teaching and learning experiences.

Risk for Sudden Infant Death syndrome Betty Ackley, MSN, EdS, RN

NANDA-I

Definition

Vulnerable to unpredicted death of an infant

Risk Factors

Modifiable

Delay in prenatal care; infant overheating; infant overwrapping; infant placed to sleep in the prone position; infants placed to sleep in the side-lying position; bed sharing; lack of prenatal care; smoke exposure; soft underlayment (loose items in the sleep environment)

Potentially Modifiable

Low birth weight, prematurity, young parental age

Nonmodifiable

Ethnicity (e.g., African American or Native American), male gender, season of the year (i.e., winter and fall), infant age of 2 to 4 months

S

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Knowledge: Infant Care; Parenting Performance; Safe Home Environment; Safe Sleep Environment

Example NOC Outcome with Indicators

Knowledge: Infant Care as evidenced by the following indicators: Proper infant positioning/Age-appropriate cardiopulmonary resuscitation techniques. (Rate the outcome and indicators of **Knowledge: Infant Care**: 1 = no knowledge, 2 = limited knowledge 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Explain appropriate measures to prevent sudden infant death syndrome (SIDS)
- Demonstrate correct techniques for positioning and blanketing the infant, protecting the infant from harm

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Infant Care; Teaching: Infant Safety 0 to 3 Months

Example NIC Activities—Teaching: Infant Safety

Instruct parent/caregiver to place infant on back to sleep and keep loose bedding, pillows, and toys out of crib; Instruct parent/caregiver to avoid holding infant while smoking or holding hot liquids

Nursing Interventions and Rationales

- Position the infant supine to sleep during naps and night; do not position in the prone position or side-lying position (American Academy of Pediatrics [AAP], 2014a). **CEB/EB:** *In a retrospective review of hundreds of SIDS cases, more than 70% of the incidences happened when the infant was in a prone or side-lying position (Ostfeld et al, 2010). In two case studies, infants who were lying on their side during breast-feeding in the maternity ward apparently suffocated (Feldman & Whyte, 2013).*
- Avoid use of bedding, such as blankets and loose sheets for sleeping. Also keep quilts, pillows, bumpers, sheepskins and soft toys out of the infant's bed. Dress the child in one-piece sleepers or wearable blankets (AAP, 2014b). *Infants can suffocate from close proximity to these soft items.*
- Avoid overbundling, overheating, and swaddling the infant. The infant should not feel hot to touch. *Overheating the infant has been associated with increased risk of SIDS. The head is often covered preceding death (AAP, 2014a).* **EB:** *Swaddling has been associated with infant death, especially when the infant has shown the ability to roll over (McDonnell & Moon, 2014).*
- Provide the infant a certain amount of time in prone position while the infant is awake and observed. Change the direction that the baby lies in the crib from one week to the next; avoid too much time in car seats and carriers. *Prolonged time in the supine position can result in a flat head shape and decreased strength of the neck and shoulder muscles (AAP, 2014a).*
- Consider offering the infant a pacifier during sleep times. **EB:** *Use of a pacifier was associated with a decreased incidence of SIDS (Moon et al, 2012). Another study found that many infant caregivers were not aware that use of pacifiers was associated with decreased incidence of SIDS (Walsh et al, 2014).*
- ▲ Use electronic respiratory or cardiac monitors to detect cardiorespiratory arrest only if ordered by the health care provider. *There is no evidence that use of such home monitors decreases the incidence of SIDS (AAP, 2014a).*

Home Care

- Most of the interventions and client teaching information are relevant to home care.
- Evaluate home for potential safety hazards, such as inappropriate cribs, cradles, or strollers.
- Determine where and how the child sleeps, and provide instructions on safe sleeping positions and environments as needed.

Multicultural

- Encourage pregnant American Indian mothers and native Alaskan Indian mothers to avoid drinking alcohol and to avoid wrapping infants in excessive blankets or clothing. **EB:** *A study of death rate of infants of Indian mothers found an increased rate of SIDS, as compared with the white population, which was thought to be associated with alcohol ingestion and excessive clothing and blankets used by the mothers (Wong et al, 2014).*
- Encourage Hispanic and black mothers to find alternatives to bed sharing or placing infants for sleep on adult beds, sofas, or cots, and to avoid placing pillows, soft toys, and soft bedding in the sleep

environment. **EB**: A study found that both Hispanic and black mothers were more likely to share a bed with an infant, and as a result there is an increasing rate of SIDS in their infants (Colson et al, 2013).

Client/Family Teaching and Discharge Planning

- Teach the safety guidelines for infant care in the previous interventions.
- Recommend breastfeeding. **EB**: A meta-analysis demonstrated that breastfeeding was protective against SIDS, especially with exclusive breastfeeding (Hauck et al, 2011).
- Teach parents the need to obtain a crib that conforms to the safety standards of the Consumer Product Safety Commission (CPSC). *Drop-side rail cribs are now prohibited; cribs need stronger slats and mattress supports, and better quality hardware* (CPSC, 2013).
- Teach the need to stop smoking during pregnancy and to not smoke around the infant. Do not allow the infant to be exposed to any secondhand smoke **EB**: Both prenatal and postnatal smoking was shown to have a significant association with SIDS in a large retrospective meta-analysis (Zhang & Wang, 2013; Behm et al, 2012).
- Teach parents, especially mothers, not to use alcohol, medications, or illicit drugs while caring for or bed sharing with an infant. **EB**: Research has shown that mothers who were previously diagnosed with alcoholism had infants with a significant risk for SIDS (O'Leary et al, 2013; Phillips et al, 2011).
- Teach parents not to sleep in the same bed with the infant, regardless of alcohol, medications, smoking, or illicit drug use. **EB/CEB**: A study of more than 1000 SIDS cases found that bed sharing with an infant resulted in an increased incidence of SIDS even without illicit drugs, alcohol, or smoking (Carpenter et al, 2013). Another study of mothers of infants found that 39 of almost 300 mothers reported incidences when they had rolled partially or fully over the infant in the bed (Ateah & Hamelin, 2008).
- Teach parents not to place the infant on a cushion to sleep, or a sofa chair or other soft surface. Infants should sleep in a crib (AAP, 2014a).
- Recommend an alternative to sleeping with an infant of placing the infant's crib near their bed to allow for more convenient breastfeeding and parent contact. *Parents should be advised to place the baby in his/her own crib next to the parent's bed* (AAP, 2014a).
- Recommend that parents with infants in child care make it very clear to the employees that the infant must always be placed in the supine position to sleep, not prone or in a side-lying position (AAP, 2014a).

Risk for Suffocation

Melodie Cannon, DNP, MSc/FNP, BHScN, RN(EC), NP-PHC, CEN, GNC(C), and Betty Ackley, MSN, EdS, RN

NANDA-I

Definition

Vulnerable to inadequate air availability for inhalation, which may compromise health

Risk Factors

External

Access to empty refrigerator/freezer; eating large mouthfuls of food; gas leak; low-strung clothesline; pacifier around infant's neck; playing with plastic bag; propped bottle placed in infant's crib; small object in airway; smoking in bed; soft underlayment (e.g., loose items placed near infant); unattended in water; unvented fuel-burning heater; vehicle running in closed garage

Internal

Alteration in cognitive functioning; alteration in olfactory function; emotional disturbance; face/neck disease; face/neck injury; impaired motor functioning; insufficient knowledge of safety precautions

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Knowledge: Infant Care; Personal Safety; Parenting: Adolescent Physical Safety, Early/Middle Childhood Physical Safety; Infant/Toddler Physical Safety; Risk Control; Risk Detection; Safe Home Environment; Substance Addiction Consequences

Example NOC Outcome with Indicators

Knowledge: Infant Care as evidenced by the following indicators: Strategies to prevent choking/Appropriate activities for child's developmental level/First aid techniques. (Rate the outcome and indicators of **Knowledge: Infant Care**: 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section 1].)

Client Outcomes

Client Will (Specify Time Frame)

- Undertake appropriate measures to prevent suffocation
- Demonstrate correct techniques for emergency rescue maneuvers (e.g., Heimlich maneuver, rescue breathing, cardiopulmonary resuscitation [CPR]) and describe situations that require them

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Aspiration Precautions; Environmental Management: Safety; Infant Care; Positioning; Security Enhancement; Surveillance; Surveillance: Safety; Teaching: Infant Safety

Example NIC Activities—Environmental Management: Safety

Identify safety hazards in the environment (i.e., physical, biological, and chemical); Remove hazards from the environment, when possible

Nursing Interventions and Rationales

- Identify hospitalized clients at particular risk for suffocation, including the following:
 - Clients with altered levels of consciousness
 - Infants or young children
 - Clients with developmental delays
 - Clients with mental illness, especially schizophrenia
 - Clients who have been physically or chemically restrained

Restraint use has been associated with chest compression and death by strangulation. If use of restraints is unavoidable, proper application and close client monitoring is essential (Berzlanovich et al, 2012).

*Institute safety measures such as proper positioning and feeding precautions. See the care plans for Risk for Aspiration and Impaired Swallowing for additional interventions. Vigilance and special protective measures are necessary for clients at greater risk for suffocation. **CEB:** Mental health clients have an increased incidence of choking and suffocation incidents (Corcoran & Walsh, 2003).*

Pediatric

- Counsel families on the following for care of an infant:
 - Position infants on their back to sleep; do not position them on their side or prone (*Registered Nurses' Association of Ontario, 2014*).
 - Obtain a new crib that conforms to the safety standards of the Federal Safety Commission. *Drop-side rail cribs are now prohibited; cribs need stronger slats and mattress supports, and better quality hardware (American Academy of Pediatrics [AAP], 2011).*
 - Place the infant in the crib with a properly fitted mattress, only to sleep, not on an adult bed, sofa, chair, baby seats, swings, or playpen. *Babies can suffocate when their faces become wedged against or buried in a mattress, pillow, bumper pads, infant cushion, or other soft bedding or when someone in the same bed rolls over onto them (Parachute Preventing Injuries Saving Lives, 2012).* **EB:** A study demonstrated that bed sharing was a risk factor for sudden infant death syndrome, especially for very young infants, or a parent who smoked (Vennemann et al, 2012).
 - Avoid use of loose bedding such as blankets and sheets for sleeping. If blankets are used, they should be tucked in around the crib mattress so the infant's face is less likely to become covered by bedding. The blanket should end at the level of the infant's chest. **EB:** Evidence exists that that a firm sleep surface and the absence of soft items and loose bedding has a net benefit in reducing the risk of sudden unexpected infant death (AAP, 2011). See care plan Risk for Sudden Infant Death syndrome for further interventions.
- Assess for signs and symptoms of abuse such as Munchausen syndrome by proxy (MSBP). **CEB:** Suffocation in MSBP is one important differential diagnosis in suspected cases of SIDS (Vennemann et al, 2005)
- Conduct risk factor identification, noting special circumstances in which preventive or protective measures are indicated. Note the presence of environmental hazards, including the following: plastic bags; cribs with slats wider than 2 inches; ill-fitting crib mattresses that can allow the infant to become wedged between the mattress and crib; pillows/loose bedding in cribs; placement of crib near windows with blinds or cords; co-sleeping; abandoned large appliances such as refrigerators, dishwashers, or freezers; clothing with cords or hoods that can become entangled; bibs; pacifiers on a string; necklaces in infants and children; drapery cords; pull-toy strings. *Suffocation by airway obstruction is a leading cause of death in children younger than 6 years of age. Families need to be taught child protection.* **EB:** Home visits, safety education, and injury prevention kits have proven effective in reducing home hazards and injuries, including choking and suffocation (Cyr, 2012).
- Counsel families to evaluate household furniture for safety, including large dressers, televisions, book shelves, and appliances that may need to be anchored to the wall, to prevent the child from climbing on the furniture, and it falling forward and suffocating the child. **EB:** A review of nine deaths of children demonstrated that they could have been prevented by attaching large pieces of furniture to the wall or by better supervision of the child (Wolf & Harding, 2011).
- Counsel families to not serve these foods to the child younger than 4 years of age: nuts, seeds, hot dogs, popcorn, pretzels, chips, chunks of meat, hard pieces of fruit or vegetables, raisins, whole grapes, hard candies gum, chewable vitamins, fish with bones, snacks on toothpicks, and marshmallows. **EB:** A meta-analysis found that nuts, magnets, and small toys are the most common items associated with fatal choking

incidences in children (Foltran et al, 2012). **EB:** Most foods implicated are small and round and conform to the contours of a child's airway (Cyr, 2012).

- Counsel families to keep the following items away from the sight and reach of infants and toddlers:
 - Buttons, beads, jewelry, pins, nails, marbles, coins, stones, magnets, balloons. Choose age appropriate toys and games for children and check for any small parts that may be a choking hazard because children have the need to put everyday objects in their mouths (safekids.org, 2013). A project that collects data on child safety found that pearls, balls, marbles, and coins were observed most commonly as a cause of aspiration and suffocation (Susy Safe Working Group, 2012).
- Stress water and pool safety precautions, including vigilant, uninterrupted parental supervision. **EB:** Recognize that small portable pools can also be a source of danger for drowning in children younger than 5 years of age (Shields et al, 2011). **EB:** The majority of pediatric immersion-related deaths could be prevented with supervision (Bamber et al, 2014). An intense drive for exploration combined with a lack of awareness of danger makes drowning a threat to small children. A child's high center of gravity and poor coordination make buckets and toilets a threat because a child looking inside can fall over and become lodged (Shields et al, 2011). Pools should be surrounded completely by fencing that is difficult to climb and regularly assessed for structural defects, and has self-closing latches.
- Underscore the necessity of not allowing children to play with or near electric garage doors and of keeping garage door openers out of the reach of young children. Children close to the ground may not be large enough to trigger reversal mechanisms on the door and may become trapped.
- For adolescents, watch for signs of depression that could result in suicide by suffocation. **EB:** A study in Canada found that suffocation was a common method for female children and adolescents to commit suicide (Skinner & McFaul, 2012).

Geriatric

- Assess the status of the swallow reflex. Offer appropriate foods and beverages accordingly. Older adults, especially those receiving antipsychotic medications, have an increased incidence of choking. Refer to **Impaired Swallowing**. **EB:** Dysphagia is a common problem in adults with mental health illness and has a significant mortality risk due to choking asphyxiation (Aldridge & Taylor, 2012).
- Use care in pillow placement when positioning frail older clients who are on bed rest. Frail older clients are at risk for suffocation if the head becomes lodged against pillows and the client cannot reposition himself or herself because of weakness. Older adults who are cognitively impaired require assessment of the safety of their sleep environment for potential hazards similar to sleeping risks for the very young (Byard & Gilbert, 2011).
- Recognize that older adults in depression may use hanging, strangulation, and suffocation as a means of suicide (Shah & Buckley, 2011).

Home Care

- Assess the home for potential safety hazards in systems that are not likely to be fixed (e.g., faulty pilot lights or gas leaks in gas stoves, carbon monoxide release from heating systems, kerosene fumes from portable heaters).
- Assist the family in having these areas assessed and making appropriate safety arrangements (e.g., installing detectors, making repairs, home safety inspections). *Assessment and correction of system problems prevent accidental suffocation.*

Client/Family Teaching and Discharge Planning

- Recommend that families who are seeking day care or in-home care for children, geriatric family members, or at-risk family members with developmental or functional disabilities inspect the environment for hazards and examine the first aid preparation and vigilance of providers. *Many working families must trust others to care for family members.*
- Ensure family members learn and practice rescue techniques, including treatment of choking and lack of breathing, as well as CPR. *Family members need preparation to deal with emergency situations and should take part in the American Heart Association Basic Lifesaving Course or the American Red Cross Infant/Child CPR Course.*
- Use client/family encounters to provide age appropriate anticipatory guidance for safety precautions for infants and children, and education regarding risk reduction for suffocation for vulnerable older adults or clients with physical or mental disabilities.

Risk for Suicide Kathleen L. Patusky, MA, PhD, RN, CNS

NANDA-I

Definition

Vulnerable to self-inflicted, life threatening injury

Related Factors (r/t)

Behavioral

Changing a will; giving away possessions; history of suicide attempt; impulsiveness; making a will; marked change in attitude; marked change in behavior; marked change in school performance; purchase of a gun; stockpiling medication; sudden euphoric recovery from major depression

Demographic

Age (e.g., older people, young adult males, adolescents); divorced status; ethnicity (e.g., white, Native American); male gender; widowed

Physical

Chronic pain; physical illness; terminal illness

Psychological

Family history of suicide; guilt; history of childhood abuse (e.g., physical, psychological, sexual); homosexual youth; psychiatric disorder; substance abuse

Situational

Access to weapon; adolescents living in nontraditional settings (e.g., juvenile detention center, prison, halfway house, group home); economically disadvantaged; institutionalization; living alone; loss of autonomy; loss of independence; relocation; retired

Social

Cluster suicides; disciplinary problems; disrupted family life; grieving; helplessness; hopelessness; insufficient social support; legal difficulty; loneliness; loss of important relationship; social isolation

Verbal

Reports desire to die; threats of killing self

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Depression Level; Impulse Self-Control; Loneliness Severity; Mood Equilibrium; Risk Detection; Suicide Self-Restraint

Example NOC Outcome with Indicators

Suicide Self-Restraint as evidenced by the following indicators: Expresses feelings/Refrains from attempting suicide/Verbalizes suicidal ideas/Controls impulses. (Rate the outcome and indicators of **Suicide Self-Restraint**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Consider using one of the measures of suicide risk that are available for clients: Nurses' Global Assessment of Suicide Risk (Cutcliffe & Barker, 2004); Center for Epidemiological Studies Depression Scale measures depressed mood level (Chiu et al, 2010); Beck Suicide Intent Scale identifies a strong intent to die (Astruc et al, 2004); Suicide Assessment Checklist (Rogers et al, 2002).

Client Outcomes**Client Will (Specify Time Frame)**

- Not harm self
- Maintain connectedness in relationships
- Disclose and discuss suicidal ideas if present; seek help
- Express decreased anxiety and control of impulses
- Talk about feelings; express anger appropriately
- Refrain from using mood-altering substances
- Obtain no access to harmful objects
- Yield access to harmful objects
- Maintain self-control without supervision

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Anxiety Reduction; Coping Enhancement; Crisis Intervention; Delusion Management; Mood Management; Substance Use Prevention; Suicide Prevention; Support System Enhancement; Surveillance

Example NIC Activities—Suicide Prevention

Determine presence and degree of suicidal risk; Encourage patient to seek out care providers to talk as urge to harm self occurs

Nursing Interventions and Rationales

The American Psychiatric Nurses Association (APNA, 2015) has adapted a set of essential competencies for psychiatric nurses, all of which can be useful for generalist nurses. These competencies have been incorporated below.

- = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

- Before implementing interventions in the face of suicidal behavior, nurses should examine their own emotional responses to incidents of suicide to ensure that interventions will not be based on countertransference reactions. **EBN:** *Understanding of nurses' responses to suicidal clients can facilitate suicide prevention and recovery* (Talseth & Gilje, 2011; APNA, 2015).
- Pursue an understanding of suicide as a phenomenon at all levels of nursing practice. Elements to be considered include the terminology used with suicidality and self-harm phenomena, the epidemiology of suicide, the risk and protective influences on suicide, and the evidence-based best practices in preventing and responding to suicidality (APNA, 2015).
- Assess for suicidal ideation when the history reveals the following: depression, substance abuse; bipolar disorder, schizophrenia, anxiety disorders, post-traumatic stress disorder, dissociative disorder, eating disorders, substance use disorders, antisocial or other personality disorders; attempted suicide, current or past; recent stressful life events (divorce and/or separation, relocation, problems with children); recent unemployment; recent bereavement; adult or childhood physical or sexual abuse; gay, lesbian, or bisexual gender orientation; family history of suicide, history of chronic trauma. *Clinicians should be alert for suicide when the aforementioned factors are present in asymptomatic persons* (APA, 2015; Li et al, 2011). **EB:** *In a 10-year longitudinal study, 83% of persons who committed suicide received health care within the previous year; only 24% had been diagnosed with a mental disorder in the 4 weeks prior to death. Medical specialty and primary care accounted for the most common visits* (Ahmedani et al, 2014). Assess all medical clients and clients with chronic illnesses, traumatic injuries, or pain for their perception of health status and suicidal ideation. *Medical clients who perceived their health to be poor or who were in chronic pain were significantly more likely to report current suicidal ideation.* **EB:** *Research, including systematic review, support the association of both type 1 and type 2 diabetes with an increase in suicidal ideation* (Ceretta et al, 2012; Pompili et al, 2014). *Myocardial infarction has been connected with higher suicide rates, especially during the first month after discharge, and with impaired prognosis* (Larsen, 2013). *Persons living with HIV/AIDS who had depressive symptoms and low life satisfaction were at significantly higher risk of suicide* (Davis et al, 2011).
- Assess the client's ability to enter into a no-suicide contract. Contract (verbally or in writing) with the client for no self-harm if the client is appropriate for a contract; recontract at appropriate intervals. *Discussing feelings of self-harm with a trusted person provides relief for the client. A contract gets the subject out in the open and places some of the responsibility for safety with the client.* **CEB:** *Some clients are not appropriate for a contract: those under the influence of drugs or alcohol or unwilling to abstain from substance use, and those who are isolated or alone without assistance to keep the environment safe* (Hauenstein, 2002). *If the client will not contract, the risk of suicide should be considered higher.* **CEBN:** *Note: Although contracting is a common practice in psychiatric care settings, research has suggested that self-harm is not prevented by contracts. Thorough, ongoing assessment of suicide risk is necessary, whether or not the client has entered into a no-self-harm contract. Contracts may not be appropriate in community settings* (McMyler & Prymachuk, 2008).
- Be alert for warning signs of suicide: making statements such as, "I can't go on," "Nothing matters anymore," "I wish I were dead"; becoming depressed or withdrawn; behaving recklessly; getting affairs in order and giving away valued possessions; showing a marked change in behavior, attitudes, or appearance; abusing drugs or alcohol; suffering a major loss or life change. *Suicide is rarely a spontaneous decision. In the days and hours before people kill themselves, clues and warning signs usually appear.*
- Take suicide notes seriously and ask if a note was left in any previous suicide attempts. Consider themes of notes in determining appropriate interventions. *Clients who leave a suicide note may be at higher risk of future completed suicide in the future. A note should be viewed as indication of a failed but serious attempt.*
- Question family members regarding the preparatory actions mentioned. *Clinicians should be alert for suicide when these factors are present in asymptomatic persons* (APA, 2015).
- Determine the presence and degree of suicidal risk. A number of questions will elicit the necessary information: Have you been thinking about hurting or killing yourself? How often do you have these thoughts and how long do they last? Do you have a plan? What is it? Do you have access to the means to carry out that plan? How likely is it that you could carry out the plan? Are there people or things that could prevent you from hurting yourself? What do you see in your future a year from now? Five years from now? What do you expect would happen if you died? What has kept you alive up to now? **CEB:** *Using the acronym SAL, the nurse can evaluate the client's suicide plan for its specificity (how detailed and clear is the plan?), availability (does the client have immediate access to the planned means?), and lethality*

(could the plan be fatal, or does the client believe it would be fatal?). Assessment of reasons for living is another important part of evaluating suicidal clients (Malone et al, 2000).

- Observe, record, and report any changes in mood or behavior that may signify increasing suicide risk and document results of regular surveillance checks. **EB:** Suicidal ideation often is not continuous; it may decrease, then increase in response to negative thinking or exposure to stressors (e.g., family visits). Documentation of surveillance will alert all members of the health care team to changes in the clients' potential risk for suicide so they may be prepared to respond in the event of suicidal behavior (APNA, 2015).
- Develop a positive therapeutic relationship with the clients; do not make promises that may not be kept. Be aware that some clients may offer to self-disclose if the nurse will promise not to tell anyone what they have said. Clarify with the clients that anything they share will be communicated only to other staff but that secrets cannot be kept. **EBN:** Nurses reconnect suicidal clients with humanity by guiding the client, helping them learn how to live, and helping them connect appropriately with others. Positive support can buffer against suicide, whereas conflictual interactions can increase suicide risk (Hirsch & Barton, 2011; APNA, 2015).
- Express desire to help client. Provide education about suicide and the effectiveness of intervention. Validate the client's experience of psychological pain while maintaining a safe environment for the client. The nurse must reconcile their goal of preventing suicide with a recognition of the client's goal to alleviate their psychological pain (APNA, 2015).
- ▲ Refer for mental health counseling and possible hospitalization if evidence of suicidal intent exists, which may include evidence of preparatory actions (e.g., obtaining a weapon, making a plan, putting affairs in order, giving away prized possessions, preparing a suicide note). **EB:** Clients vary in the preparation for suicide attempts, and professional assessment is required to determine the need for hospitalization (APA, 2015). The following interventions may be instituted.
- Perform risk assessment for possible suicidality on admission to the hospital and thereafter during hospitalization. Alert treatment team to level of risk. Risk assessment includes evaluating each client's risk factors, ameliorating factors, stated suicidal intent, mental status, history of physical or psychological trauma, triggers that prompt distress, tendency to minimize or exaggerate symptoms, sources of assistance, warning signs of acute risk, and history of previous suicidal or self-harm behavior (APNA, 2015).
- Determine client's need for supervision and assign a hospitalized client to a room located near the nursing station. Close assignment increases ease of observation and availability for a rapid response in the event of a suicide attempt (APNA, 2015).
- Search the newly hospitalized client and the client's personal belongings for weapons or potential weapons and hoarded medications during the inpatient admission procedure, as appropriate. Remove dangerous items. Clients who are intent on suicide may bring the means with them. Action is necessary to maintain a hazard-free environment and client safety (APNA, 2015).
- Limit access to windows and exits unless locked and shatterproof, as appropriate. Suicidal behavior may include attempts to jump out of windows or to escape the unit to find other means of suicide (e.g., gaining roof access for a jump). Hospitals should ensure that exits are secure.
- Monitor the client during the use of potential weapons (e.g., razor, scissors). Clients with suicidal intent may take advantage of any opportunity to harm themselves (APNA, 2015).
- Increase surveillance of a hospitalized client at times when staffing is predictably low (e.g., staff meetings, change of shift report, periods of unit disruption). Clients who remain intent on suicide will be watchful of periods when staff surveillance lessens to permit completion of a suicide plan.
- Ensure that all oncoming staff members have adequate information to assist the client, using the acronym SBARR: situation (current status, observations), background (relevant client history), assessment (including nurse's current risk assessment and relevant lab findings), recommendations (what the nurse believes is necessary going forward), and response feedback (verification of oncoming staff member's understanding) (APNA, 2015).
- ▲ If imminent suicide is suspected or an attempt has occurred, call for assistance and do not leave the client alone. Client and staff safety will be served by assistance in the response. The client may attempt additional self-harm if left alone.
- Place the client in the least restrictive, safe, and monitored environment that allows for the necessary level of observation. Assess suicidal risk at least daily and more frequently as warranted. Close observation of the client is necessary for safety as long as intent remains high. Suicide risk should be assessed at frequent intervals to adjust suicide precautions and limitations on the client's freedom of movement and to ensure

that restrictions continue to be appropriate. **EB:** Inpatient root cause analyses of suicide attempts and environmental safety checklists for units can be helpful in maintaining safety (Mills et al, 2008; APNA, 2015).

- Consider strategies to decrease isolation and opportunity to act on harmful thoughts (e.g., use of a sitter). **CEB:** Clients have reported feeling safe and having their hope restored in response to close observation (Bowers & Park, 2001).
- Explain suicide precautions and relevant safety issues to the client and family (e.g., purpose, duration, behavioral expectations, and behavioral consequences). **CEB:** Suicide precautions may be viewed as restrictive. Clients have reported the loss of privacy as distressing (Bowers & Park, 2001).
- ▲ Refer for treatment and participate in the management of any psychiatric illness or symptoms that may be contributing to the client's suicidal ideation or behavior. *Psychiatric disorders have been associated with suicidal behavior. Symptoms of the disorder may require treatment with antidepressant, antipsychotic, or antianxiety medications.* **EB:** A systematic review has shown a highly significant effect for cognitive behavior therapy in reducing suicidal behavior (Tarrier et al, 2008).
- ▲ Verify that the client has taken medications as ordered (e.g., conduct mouth checks after medication administration). *The client may attempt to hoard medications for a later suicide attempt.*
- ▲ Maintain increased surveillance of the client whenever use of an antidepressant has been initiated or the dose increased. Antidepressant medications take anywhere from 2 to 6 weeks to achieve full efficacy. *During that period the client's energy level may increase, although the depression has not yet lifted, which increases the potential for suicide.*
- Involve the client in treatment planning and self-care management of psychiatric disorders. *Self-care management promotes feelings of self-efficacy, particularly for clients with depression. Suicidal ideation may occur in response to a sense of hopelessness, a sense that the client has no control over life circumstances. The more clients participate in their own care, the less powerless and hopeless they feel.* Refer to the care plan for **Powerlessness**.
- Explore with the client all circumstances and motivations related to the suicidality. Listen to the client's own views on his or her problems. **EB:** Primary reasons for suicide attempts were found to be feelings of loneliness or hopelessness, and mental illness/psychological problems (APA, 2015).
- Explore with the client all perceived consequences that could act as a barrier to suicide (e.g., effect on family, religious beliefs). **CEB:** The most common barrier to suicide is consequences to family members (Bell, 2000).
- Keep discussion oriented to the present and future. *Clients under stress have difficulty focusing their thoughts, which leads to a sense of being overwhelmed by problems. Focusing on the present and future helps the client to address problem solving with regard to current stressors.*
- Discuss plans for dealing with suicidal ideation in the future (e.g., how to identify precipitating factors, whom to contact, where to go for help, how to respond to desire for self-harm). *Clients are supported in self-care management when they are helped to identify actions they can take if suicidal ideation recurs.*
- Assist the client in identifying a network of supportive persons and resources (e.g., clergy, family, care providers). **EB:** Social support and positive events were found to have a protective support against suicidal ideation (Kleiman et al, 2014).
- ▲ Refer family members and friends to local mental health agencies and crisis intervention centers if the client has suicidal ideation or a suspicion of suicidal thoughts exists. *Clients at risk should receive evaluation and help (APA, 2015).*
- ▲ Document client behavior in detail to support outpatient commitment or an overnight psychiatric observation program for an actively suicidal client. *Involuntary outpatient commitment can improve treatment, reduce the likelihood of hospital readmission, and reduce episodes of violent behavior in persons with severe psychiatric illnesses. Overnight psychiatric observation followed by outpatient referral also can be an effective alternative to traditional hospitalization without leading to an increase in suicide gestures or attempts.*
- Utilize cognitive-behavioral techniques that help the client to modify thinking styles that promote depression, hopelessness, and a belief that suicide is a valid means of escaping the current situation. *Suicide has been shown to be associated with constriction in cognitive style, leading to decreased problem solving and information processing.* **EB:** Cognitive behavioral therapy has been shown to be effective in decreasing suicide attempts with improvement in problem-solving skills (Ghahramanlou-Holloway et al, 2012).
- Engage the client in group interventions that can be useful to address recurrent suicide attempts. *Group therapy was shown to decrease suicidality.*
- With the client's consent, facilitate family-oriented crisis intervention. Family-oriented crisis intervention can clarify stresses and allow assessment of family dynamics. **EBN:** An educational intervention addressing

ability to care, stress levels, and attitudes toward the suicidal family member was effective in promoting attitudes toward and ability to care for a suicidal family member (Sun et al, 2014).

- Involve the family in discharge planning (e.g., illness/medication teaching, recognition of increasing suicidal risk, client's plan for dealing with recurring suicidal thoughts, community resources). *Suicidal clients often are ambivalent about hurting themselves; they may not want to die so much as to escape an intolerable situation. Consequently they often leave clues about their state of mind.* **EBN:** Family members must learn before clients leave the hospital how to respond to clues early, support the treatment regimen, and encourage the client to initiate the emergency plan. Nurses help in guiding families through the process (Sun et al, 2014).
- ▲ Before discharge from the hospital, ensure that the client has a supply of ordered medications, has a plan for outpatient follow-up, understands the plan or has a caregiver able and willing to follow the plan, and has the ability to access outpatient treatment. *Clients may be discharged before they have recovered substantial functional ability and may have difficulty concentrating on the plan for follow-up. They may need the assistance of others to ensure that prescriptions are filled, that they attend appointments, or that they have transportation to the outpatient care setting.*
- ▲ In the event of successful suicide, refer the family to a therapy group for survivors of suicide. Recommended clinical interventions include addressing psychological distress, normalizing denial as an effective coping strategy, working with concerns about family disintegration, and helping families deal with stigmatization. **EB:** Psychoeducational support group participants found relief in sharing a personal narrative of their suicide bereavement with others (Feigelman & Feigelman, 2011a, 2011b).
- See the care plans for Risk for self-directed **Violence**, **Hopelessness**, and Risk for **Self-Mutilation**. *Clients with suicidal ideation often are reacting to a feeling of hopelessness.*

Pediatric

- The preceding interventions may be appropriate for pediatric clients.
- Use brief self-report measures to improve clinical management of at-risk cases. **CEBN:** *The Home, Education, Activities, Drug use and abuse, Sexual behavior, and Suicidality and depression (HEADSS) instrument has been found useful in suicide risk assessment of adolescents (Biddle et al, 2010).*
- Recognize that the developmental issues of childhood and adolescence may heighten suicide risks and involve different issues from those with adults. Assess specific stressors for the pediatric client, including bullying. **EBN:** *The experience of being bullied can contribute to suicidality (Cooper et al, 2012).* **CEBN:** *A model accounting for 41.9% of adolescents' suicide risk showed that negative life events and rumination contributed to suicidal risk behaviors, whereas resilience and social support could decrease the risk (Thanoi et al, 2010).*
- Assess for exposure to suicide of a significant other. **CEB:** *Among risk factors of previous psychiatric history, poor psychosocial function, dysphoric mood, and psychomotor restlessness, suicide of a significant other was shown to create risk for adolescents diagnosed with adjustment disorder (Pelkonen et al, 2005).*
- Be alert to the presence of school victimization around lesbian, gay, bisexual, and transgender issues and be prepared to advocate for the client. **EBN/EB:** *Male adolescents experience greater levels of depression and suicidal ideation in response to high rates of LGBT school victimization (Hatzenbuehler, 2011; Russell et al, 2011; Lea et al, 2014).*
- Evaluate for the presence of self-mutilation and related risk factors. Refer to care plan for Risk for **Self-Mutilation** for additional information. *Self-mutilation and suicidality may co-occur.*
- Be aware that complete overlap does not exist between suicidal behavior and self-mutilation. The motivation may be different (ending life rather than coping with difficult feelings), and the method is usually different. **CEB:** *In one study, about half of the participants reported both attempted suicide and self-mutilation; in the other half there was no overlap in types of acts (Bolognini et al, 2003).*
- Involve the adolescent in multimodal treatment programs. **CEBN:** *A systematic review identified individual, family, group, and psychopharmacological therapies as being used for treatment; however, limited research exists to determine which are most effective (Prymachuk & Trainor, 2010). Cognitive behavior therapy was cited as showing promise in one study included in a systematic review, but further study was recommended (Robinson et al, 2011).*
- Before discharge from the hospital, ensure that the client's parent has a supply of ordered medications, has a plan for outpatient follow-up, has a caregiver who understands the plan or is able and willing to follow the plan, and has the ability to access outpatient treatment. **CEB:** *A compliance enhancement intervention (including contracting interviews with parent and adolescent and telephone contacts) improved*

attendance at follow-up appointments only when barriers to service were controlled (e.g., delays in getting appointments, placement on a waiting list, inability to switch therapists, problems with insurance coverage) (Spirito et al, 2002).

- Parental education groups can influence suicide risk factors. **CEB**: A program of parent education groups focused on improved communication skills and relationships with adolescents. Students in the intervention group reported increased maternal care, decreased conflict with parents, decreased substance abuse, and decreased delinquency (Toumbourou & Gregg, 2002).
- Support the implementation of school-based suicide prevention programs. School nurses can be key to early intervention. **EB**: School-based suicide prevention programs have been shown in systematic review to improve knowledge, attitude, and help-seeking behavior, with some reports of decreased suicidal ideation (Cusimano & Sameem, 2011). A randomized controlled trial including more than 11,000 students in the European Union were divided into three groups: a question and refer group, a mental health awareness group, and a professional screening group. No differences between the groups showed up at 3 months. At 12 months the mental health awareness group showed significant reduction in suicide attempts and severe suicidal ideation (Wasserman et al, 2015).

Geriatric

- Evaluate the older client's mental and physical health status and financial stressors. **EB**: Depression in particular is more prevalent in persons with chronic medical conditions, including cardiac disease, diabetes mellitus, cancer, and more. Psychological distress, daily hassles, and marital status, along with chronic illnesses and substance abuse, have been associated with suicidal ideation (Bosse et al, 2011; Shelef et al, 2014).
- Explore with client any concerns or pressures (physical and financial) regarding ability to secure support of medical care, especially perceived pressures about being a burden on family. **EB**: "Perceived burdensomeness" has been found to be a risk factor of older adults' suicidality, whether clinical depression is present or not, accounting for 68.3% of variance of suicidal ideation (Jahn et al, 2011). The presence of stressful life events in the previous year and the presence of untreated major depression were also found to increase suicidal behavior (Pompili et al, 2014).
- Conduct a thorough assessment of clients' medications. **EB**: The use of psychotropic medications, especially long-term use and high doses of benzodiazepines, has been significantly associated with suicidal ideation or death thoughts (Bosse et al, 2011).
- When assessing suicide risk factors, incorporate a higher degree of risk for older men and for some older adults who have lost a loved one in the previous year. **CEB**: Although mortality for oldest old adults (80+) has increased, the suicide mortality has not decreased. In one study, oldest old men had the highest increase in suicide risk after death of a partner (more so than oldest old women) and took a longer time to recover from the death of a spouse (Erlangsen et al, 2004). Suicide rate may be rising among men older than age 65, and marriage may no longer be the protective factor it was once considered to be (Lamprecht et al, 2005).
- Explore triggers of and barriers to suicidal behavior, with particular attention to real and perceived losses (e.g., professional role, health). **EB**: A qualitative study found that older adults' reflections preceding their suicide attempt included loss of a significant other, loneliness, loss of control, and unwillingness to live under these conditions (Bonnewyn et al, 2014). "Perceived burdensomeness" has been found to be a risk factor of older adults' suicidality, whether clinical depression is present or not, accounting for 68.3% of variance of suicidal ideation (Jahn et al, 2011).
- An older adult who shows self-destructive behaviors should be evaluated for dementia. **EB**: Reviews of older adult psychiatric care for both the medical and psychiatric communities emphasize the possible overlap of depression, dementia, and suicidality (DeMers et al, 2013).
- ▲ Advocate for the older client with other professionals in securing treatment for suicidal states. Primary care providers have been noted to underrecognize and undertreat older adult clients with depression. **EB**: In a 10-year longitudinal study, 83% of persons who committed suicide received health care within the previous year; only 24% had been diagnosed with a mental disorder in the 4 weeks prior to death. Medical specialty and primary care accounted for the most common visits (Ahmedani et al, 2014).
- Encourage physical activity in older adults. **EB**: Suicide and sleep disturbances have been linked. Exercise has been associated with improved sleep and lower suicide risk (Davidson et al, 2013).
- ▲ Refer older adults in primary care settings for care management. **EBN**: The Depression Care for Patients at Home (Depression CAREPATH) program provided assistance for medical and surgical homebound clients as a routine part of clinical practice (Bruce et al, 2011).

- Consider telephone contacts as an effective intervention for suicidal older adults. **EB:** *One study predicted that, over a 10-year period, telephone and chat services could avoid about 36% of suicides and attempts in a high-risk population with a modest effect on quality-adjusted-life-years (Pil et al, 2013).*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's perceptions of suicide, as well as on the nurse's perception and approach to suicide. **EBN:** *A qualitative study of suicidal ideation in Korean college students found that the facilitators of suicidal ideation included physical, psychological, and societal factors. Inhibitors were religious and cultural factors. Buddhism and Confucianism influenced reason not to attempt suicide (Jo et al, 2011).* **EB:** *A systematic review of psychological autopsies across multiple countries concluded that cultural influences in the diagnosis of a mental disorder might account for the variance in cases without a psychiatric diagnosis (Milner et al, 2013).*
- Identify and acknowledge the stresses unique to culturally diverse individuals. *Financial difficulties and maintaining cultural values are two of the most common family stressors in women of color.* **EB:** *Acculturative stress and perceived discrimination, moderated by hopelessness, can increase vulnerability to suicide. A strong ethnic identity can serve as a buffer (Polanco-Roman & Miranda, 2013).*
- Identify and acknowledge unique cultural responses to stressors in determining sensitive interventions to prevent suicide. **CEB:** *In a randomized controlled trial, the Mexican American Problem Solving (MAPS) program addressed depression symptoms of immigrant Mexican women and their fourth- and fifth-grade children using home visits and after-school programs. Family problem-solving communication improved, and children's depression symptoms decreased (Cowell et al, 2009).* Encourage family members to demonstrate and offer caring and support to each other. **EB:** *Connectedness had been identified as a culture-based protective factor against suicide among young Alaska natives (Mohatt et al, 2011).*
- Validate the individual's feelings regarding concerns about the current crisis and family functioning. *Validation lets the client know that the nurse has heard and understood what was said, and it promotes the nurse-client relationship (APNA, 2015).*

Home Care

- Communicate the degree of risk to family and caregivers; assess the family and caregiving situation for ability to protect the client and to understand the client's suicidal behavior. Provide the family and caregivers with guidelines on how to manage self-harm behaviors in the home environment. *Client safety between home visits is a nursing priority. Family and caregivers may become frightened by the client's suicidal ideation, may be angry at the client's perceived lack of self-control, or may feel as if they are walking on eggshells awaiting another suicide attempt.*
- Assess risk factors in the home. *The presence of a gun must be determined. Safe gun ownership should address the five Ls: locked, loaded, little children, feeling low, learned owner (Pinholt et al, 2014).*
- If the client's suicidal ideation intensifies, or if a suicide plan with access to means becomes evident, institute an emergency plan for mental health intervention. **CEB:** *More than a quarter (29%) of clients who had previously self-harmed died within 3 months of discharge from psychiatric care and 36% had missed their last service appointment. Measures that may prevent suicide pacts in the mentally ill include the effective treatment of depression and closer supervision in both inpatient and community settings (Hunt et al, 2009).*
- Identify the client's concerns and implement interventions to address the consequences of disability in a client with medical illness. **EB:** *Depression, perceived social support, and disability have been found to be predictors of suicidal ideation. Lower levels of family support have been implicated in higher levels of suicidal ideation (Park et al, 2014).* Refer to the care plans for **Hopelessness** and **Powerlessness**.
- ▲ Refer for homemaker or psychiatric home health care services for respite, client reassurance, and implementation of a therapeutic regimen. *Respite decreases the high degree of caregiver stress that goes with the responsibility of caring for a person at risk for suicide.* **EBN:** *The Depression Care for Patients at Home (Depression CAREPATH) program provided assistance for medical and surgical homebound clients as a routine part of clinical practice (Bruce et al, 2011).*
- ▲ If the client is on psychotropic medications, assess the client's and family's knowledge of medication administration and side effects. Teach as necessary. *Knowledge of the medical regimen promotes compliance and promotes safe use of medications.*
- ▲ Evaluate the effectiveness and side effects of medications and adherence to the medication regimen. Review with the client and family all medications kept in the home; encourage discarding of old

prescriptions. Monitor the amount of medications ordered/provided by the health care provider; limiting the amount of medications to which the client has access may be necessary. *Accurate clinical feedback improves the health care provider's ability to prescribe an effective medical regimen specific to the client's needs. At home, clients may have greater access to medications, including old prescriptions that may be used to overdose.*

Client/Family Teaching and Discharge Planning

- Establish a supportive relationship with family members. **EBN:** *Family members experience a great deal of stress around suicidal ideation and benefit from nurses' support (Sun et al, 2014).*
- Explain all relevant symptoms, procedures, treatments, and expected outcomes for suicidal ideation that is illness based (e.g., depression, bipolar disorder). **CEBN:** *The Health Belief Model identifies perceived barriers and perceived susceptibility to disease as powerful predictors of clients' motivation in taking action to prevent disease and participate in self-care management (Pender et al, 2010).*
- Teach the family how to recognize that the client is at increased risk for suicide (changes in behavior and verbal and nonverbal communication, withdrawal, depression, or sudden lifting of depression). **EBN:** *A client may be at peace because a suicide plan has been made and the client has the energy to carry it out. Therefore, when depression lifts, increased vigilance is necessary (Sun et al, 2014).*
- Provide written instructions for treatments and procedures for which the client will be responsible. **EBN:** *A written record provides a concrete reference so that the client and family can clarify any verbal information that was given (Sun et al, 2014).*
- Instruct the client in coping strategies (assertiveness training, impulse control training, deep breathing, progressive muscle relaxation). **CEBN:** *Suicidal ideation may be triggered by stress and painful emotions. Once clients are able to identify these triggers, they need to learn how to respond to them more effectively through assertiveness, impulse control, or relaxation techniques, as appropriate (Lakeman & FitzGerald, 2008).*
- Teach cognitive-behavioral activities, such as active problem solving, reframing (reappraising the situation from a different perspective), or thought stopping (in response to a negative thought, picturing a large stop sign and replacing the image with a prearranged positive alternative). Teach the client to confront his or her own negative thought patterns (or cognitive distortions), such as catastrophizing (expecting the very worst), dichotomous thinking (perceiving events in only one of two opposite categories), or magnification (placing distorted emphasis on a single event). *Cognitive-behavioral activities address clients' assumptions, beliefs, and attitudes about their situations and foster modification of these elements to be as realistic and optimistic as possible. Through cognitive-behavioral interventions, clients become more aware of their cognitive choices in adopting and maintaining their belief systems and thereby exercise greater control over their own reactions (Hagerty & Patuskay, 2011).*
- Provide the client and family with phone numbers of appropriate community agencies for therapy and counseling. The National Alliance on Mental Illness (NAMI) is an excellent resource for client and family support. *Continuous follow-up care should be implemented; therefore, the method to access this care must be given to the client (NAMI, 2012).*

Delayed Surgical recovery *Nicole Jones, MSN, FNP-BC*

NANDA-I

Definition

Extension of the number of postoperative days required to initiate and perform activities that maintain life, health, and well-being

Defining Characteristics

Discomfort; evidence of interrupted healing of surgical area; excessive time required for recuperation; impaired mobility; inability to resume employment; loss of appetite; postpones resumption of work; requires assistance for self-care

Related Factors (r/t)

American Society of Anesthesiologists Physical Status classification score ≥ 3 ; diabetes mellitus; edema at surgical site; extensive surgical procedure; extremes of age; history of delayed wound healing; impaired mobility; malnutrition; obesity; pain; perioperative surgical site infection; persistent nausea; persistent vomiting; pharmaceutical agent; postoperative emotional response; prolonged surgical procedure; psychological disorder in postoperative period; surgical site contamination; trauma at surgical site

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Endurance; Infection Severity; Mobility; Pain Control; Self-Care: Activities of Daily Living (ADLs); Wound Healing: Primary Intention; Surgical Recovery: Convalescence/Immediate Postoperative

Example NOC Outcome with Indicators

Surgical Recovery/Convalescence as evidenced by the following indicators: Extent of physiological, psychological, and role function following discharge from postanesthesia care to the final postoperative clinic visit/Vital signs/Performance of normal activities, self-care activities. (Rate the outcome and indicators of **Surgical Recovery**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Have surgical area that shows evidence of healing: no redness, induration, draining, or immobility
- State that appetite is regained
- State that no nausea is present
- Demonstrate ability to move about
- Demonstrate ability to complete self-care activities
- State that no fatigue is present
- State that pain is controlled or relieved after nursing interventions
- Resume employment activities/activities of daily living (ADLs)
- State no depression or anxiety related to surgical procedure

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Incision Site Care; Nutrition Management; Pain Management; Self-Care Assistance; Surgical Assistance

Example NIC Activities—Incision Site Care

Teach the client and/or the family how to care for the incision, including signs and symptoms of infection; Inspect the incision site for redness, swelling, or signs of dehiscence or evisceration

Nursing Interventions and Rationales

- Encourage smoking cessation prior to surgery. **EB:** *Smoking cessation improves tissue oxygenation and improves pulmonary function. A meta-analysis shows that smoking cessation leads to improved surgical recovery and fewer complications (Mills et al, 2011).*
- Preoperatively, perform a thorough assessment of the client, including risk factors. Allow time to be with the client, and actively listen to client's concerns and questions about care, functional status, and recovery. **CEB:** *Assessment of clients preoperatively by nursing and medical staff is an important part of the surgical experience to ensure that appropriate interventions are used and recovery from surgery is as quick as possible (Layzell, 2008).* **EB:** *Clients with higher presurgery levels of emotional distress appear to be at greater risk for experiencing higher levels of postsurgery side effects (Sadati et al, 2013).* Assess for the presence of medical conditions and treat appropriately before surgery. If the client is diabetic, maintain normal blood glucose levels before surgery. **CEB:** *High blood glucose levels slow healing and increase risk of infection. The American Diabetes Association (ADA) recommends that blood glucose should be less than 180 mg/dL for people in the hospital or having surgery. For some, the goal is less than 110 mg/dL (ADA, 2014).* **EB:** *In some cases, complications and poor client satisfaction and joint function can be directly attributable to obesity (Choong & Dowsey, 2011).*
- Carefully assess client's use of dietary supplements such as feverfew, fish oil, ginkgo biloba, garlic, ginseng, ginger, valerian, kava, St. John's wort, ephedra (Ma huang or metabolite), and echinacea. It is recommended that all clients be advised to stop all dietary supplements at least 1 week before major surgical or diagnostic procedures. **EB:** *Due to increasingly complicated medication regimens and polypharmacy, it is important to assess client's use of herbal and dietary supplements, because they can cause medication reactions or have unintended medical side effects (Nieva et al, 2012).* **EB:** *Herbal remedies are common in clients presenting for anesthesia. Because of the potential interactions between anesthetic drugs or techniques and such medication, it is important for anesthetists to be aware of their use (Bajwa & Panda, 2012; Kaye, 2014).* Assess and treat for depression and anxiety in a client before surgery and postoperatively. **EB:** *Clients with depression or anxiety are less likely to regain former level of functioning or following surgery (Barry et al, 2011).* **CEB:** *Clients with higher levels of preoperative anxiety and depression report increased postoperative pain, nausea, and fatigue (Montgomery et al, 2010).* **EB:** *Early identification of clients with high preoperative anxiety allows the nurse to prepare postoperative interventions and support systems that may lessen or alleviate client suffering (Yilmaz et al, 2012).*
- Play music of the client's choice preoperatively, intraoperatively, and postoperatively. **EBN:** *Listening to self-selected music during the preoperative period can effectively reduce anxiety levels and should be a useful*

tool for preoperative nursing (Ni et al, 2012). **EBN:** Results of this research provide evidence to support the use of music and/or a quiet rest period to decrease pain and anxiety. The interventions pose no risks and have the benefits of improved pain reports and decreased anxiety (Pittman & Kridli, 2011).

- Consider using healing touch and other mind-body-spirit interventions such as stress control, therapeutic massage, and imagery in the perianesthesia setting. **EBN:** Research shows that use of holistic therapies in the perioperative setting can decrease pain, surgical trauma, and anesthesia complications, leading to increased client satisfaction with health care (Selimen & Andsoy, 2011). **EB:** Therapeutic touch may help restore client's integrity by providing consolation and a sense of safety (Airoso et al, 2013). Use warmed cotton blankets to reduce heat loss during surgery. **EB:** Monitoring of body temperature and avoidance of unintended perioperative hypothermia through active and passive warming measures are the keys to preventing its complications (Hart et al, 2011).
- Postoperatively, discuss with surgeon vital sign parameters, signs, and symptoms that could indicate early postoperative infection. **EB:** Surgical site infections are a leading cause of prolonged hospitalization, which increase cost of care and are associated with poorer outcomes (Tanner et al, 2013).
- Use careful aseptic technique when caring for wounds. **EBN:** Handwashing continues to be the most important factor in reducing health care-associated infection, but the use of an aseptic technique will further cut the risk of infection (Harrington, 2014). **EBN:** Dressings should be changed by nurses who are trained in antiseptic, non-touch technique.
- Clients should be allowed to shower after surgery to maintain cleanliness if not contraindicated because of the presence of pacemaker wires. **EB:** In an analysis of existing studies, it was determined that there was no statistically significant increase in wound infection related to early bathing. Avoiding washing may have an adverse effect on the wound due to accumulation of sweat or dirt at the site. The decision to bathe the client immediately postoperatively should be specific to surgical type and site (Toon et al, 2013). Promote early ambulation and deep breathing. **CEB:** When looking across all of the intervention types, the most frequently reported positive outcomes were associated with measures of ambulatory ability (Chudyk et al, 2009). Deep breathing clears the lungs and prevents pneumonia.
- The client should be provided with a complete, balanced therapeutic diet after the immediately postoperative period (24 to 48 hours). **EBN:** Optimal wound healing requires adequate nutrition. Nutrition deficiencies impede the normal processes that allow progression through stages of wound healing. Malnutrition has also been related to decreased wound tensile strength and increased infection rates (Collins & Sloan, 2013).
- Encourage the client to use prayer as a form of spiritual coping if this is comfortable for the client. **EB:** Prayer has been shown to reduce pain intensity and provide a stabilizing effect on cardiovascular measurements (Jegindø et al, 2013).
- Carefully assess functional status of client postoperatively using a fall-risk stratification tool such as the Morse Fall Scale to identify clients at high risk for fall. **EBN:** The Morse Fall Scale has been validated in numerous studies, and helps to identify clients at high risk for falls. All clients identified as high risk should have increased monitoring and nursing and be placed under increased safety precautions until discharge, regardless of functional improvement (Baek et al, 2014).
- See the care plans for **Anxiety**, Acute **Pain**, **Fatigue**, Risk for deficient **Fluid** volume, Risk for **Perioperative Positioning** injury, Impaired physical **Mobility**, and **Nausea**.

Pediatric

- Encourage children to ask questions about their procedures and postoperative expectations regarding pain, function, and long-term social and emotional care needs. **EBN:** Children often report having little input or understanding of their medical conditions and requirements for surgical and functional interventions. Parents and children report higher levels of satisfaction, decreased preoperative anxiety, and better experiences if they are given the opportunity preoperatively to discuss all aspects of the surgery, including realistic postoperative expectations (Bray et al, 2012; Alanazi, 2014).
- Teach imagery and encourage distraction for children for postsurgical pain relief. **EBN:** Distraction decreases pain in children undergoing painful procedures (Helgadottir & Wilson, 2014; Ha & Kim, 2013).

Geriatric

- Perform a thorough preoperative assessment, including a cardiac, social support, and skin assessment. **EB:** The condition of the client's skin should be noted before and after the procedure and should be fully documented using an objective evaluation tool such as the Braden scale to allow early identification of older

clients at higher risk for developing surgical site infections or other skin breakdown (Cohen et al, 2012). **CEB:** Older clients, those with preoperative comorbidities, and those without a caregiver at home experience delays in functional recovery and discharge. These findings support the addition of functional recovery and social support risk items to the preoperative cardiac surgery risk assessment (Anderson et al, 2006).

- Routinely assess pain in postoperative clients using a pain scale that is appropriate for clients with impaired cognition or inability to verbalize. **EB:** *The Pain Assessment in Advanced Dementia (PAINAD) and Pain Assessment Checklist for Seniors with Limited Ability to Communicate (PACSLAC) have been validated for reliability (Herr, 2011).*
- Serially evaluate the client's vital signs, including temperature. Know what is normal and abnormal for each client. Check baseline vital signs and monitor trends. **EB:** *Physiologic changes of aging often result in lower baseline body temperatures and decreased heart rates, and prevent the older client from developing fever. Medications, such as blood pressure agents, may prevent client from having an increased heart rate (Gonik et al, 2011).*
- Provide tools such as clocks, calendars, and other orientation tools to help prevent delirium in the postoperative or extended-stay client. Ensure that hearing aids and glasses are also available as needed. **EB:** *Older adults are at higher risk for developing delirium following anesthesia or prolonged hospitalization. Delirious clients are at higher risk for falls or other adverse events, have longer inpatient stays, and have higher mortality rates (Mouchoux et al, 2011).*
- Offer spiritual support. **EB:** *Religiousness is related to significantly fewer depressive symptoms, better quality of life, less cognitive impairment, and less perceived pain. Clinicians should consider taking a spiritual history and ensuring that spiritual needs are addressed among older clients in rehabilitation settings (Lucchetti et al, 2011).*

Home Care

- The preceding interventions may be adapted for the home setting.
- Provide supportive telephone calls from nurse to client as a means of decreasing anxiety and providing the psychosocial support necessary for recovery from surgery. **CEB:** *A study of clients who underwent surgery for breast cancer showed that a telephone intervention 1 week after surgery was helpful and the timing was appropriate. The intervention group showed significantly better body image, worried less about the future, and had fewer postoperative side effects than the control group (Salonen et al, 2009).*

Client/Family Teaching and Discharge Planning

- Provide discharge planning and teaching in language that is appropriate to the client and caregiver's education and literacy level. **EBN:** *Do not use technical or medical jargon, and be aware that clients and caregivers may be reluctant to ask for explanation or clarification due to embarrassment and may verbalize dishonestly understanding. Allow the client to repeat their understanding of the discharge plan (Ross, 2013).*
- Meet with client and caregivers to create a discharge plan that includes measurable goals for functional activities of daily living and pain levels, discuss expectations for recovery, and address signs and symptoms of postoperative complications. **EBN:** *In a study on successful discharge planning, it was found that plans that were detailed and precise, and addressed client and caregiver feedback, situations, preferences, and agreement with the care plan had greater satisfaction and plan adherence (Tomura et al, 2011).*
- Provide individualized teaching plans for the client with an ostomy. Assess client's ability to manage basic needs: (1) maintenance of a pouching seal for a consistent, predictable wear time; (2) maintenance of peristomal skin integrity; and (3) social and professional support of the client. Referrals for home wound care or nursing visits may be necessary to help client maintain hygiene and prevent readmission for complications. **EBN:** *Careful assessment of client's ability to manage colostomy will help the nurse anticipate possible problems with routine care requiring close follow-up and referrals for skilled care following discharge (Walker & Lachman, 2013).*

Risk for delayed Surgical recovery *Nicole Jones, MSN, FNP-BC*

NANDA-I

Definition

Vulnerable to an extension of the number of postoperative days required to initiate and perform activities that maintain life, health, and well-being, which may compromise health

Risk Factors

American Society of Anesthesiologists Physical Status classification score ≥ 3 ; diabetes mellitus; edema at surgical site; extensive surgical procedure; extremes of age; history of delayed wound healing; impaired mobility; malnutrition; obesity; pain; perioperative surgical site infection; persistent nausea; persistent vomiting; pharmaceutical agent; postoperative emotional response; prolonged surgical procedure; psychological disorder in postoperative period; surgical site contamination; trauma at surgical site

NIC, NOC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

See the care plan for Delayed **Surgical** recovery.

Impaired Swallowing

Dennis C. Tanner, PhD, Stephanie C. Christensen, PhD, CCC-SLP, and Betty J. Ackley, MSN, EdS, RN

NANDA-I

Definition

Abnormal functioning of the swallowing mechanism associated with deficits in oral, pharyngeal, or esophageal structure or function

Defining Characteristics

First Stage: Oral

Abnormal oral phase of swallow study; choking prior to swallowing; coughing prior to swallowing; drooling; food falls from mouth; food pushed out of mouth; gagging prior to swallowing; inability to clear oral cavity; incomplete lip closure; inefficient nipple; inefficient suck; insufficient chewing; nasal reflux; piecemeal deglutition; pooling of bolus in lateral sulci; premature entry of bolus; prolonged bolus formation; prolonged mealtime with inefficient consumption; tongue action ineffective in forming bolus

Second Stage: Pharyngeal

Abnormal pharyngeal phase of swallow study; alteration in head position; choking; coughing; delayed swallowing; fevers of unknown etiology; food refusal; gagging sensation; gurgling voice quality; inadequate laryngeal elevation; nasal reflux; recurrent pulmonary infection; repetitive swallowing

Third Stage: Esophageal

Abnormal esophageal phase of swallow study; acidic-smelling breath; bruxism; difficulty swallowing; epigastric pain; food refusal; heartburn; hematemesis; hyperextension of head; nighttime awakening; nighttime coughing; odynophagia; regurgitation; repetitive swallowing; reports "something stuck;" unexplained irritability surrounding mealtimes; volume limiting; vomiting; vomitus on pillow

Related Factors

Congenital Defects

Behavioral feeding problem; conditions with significant hypotonia; congenital heart disease; failure to thrive; history of enteral feeding; mechanical obstruction; neuromuscular impairment; protein-energy malnutrition; respiratory condition; self-injurious behavior; upper airway abnormality

Neurological Problems

Achalia; acquired anatomic defects; brain injury (e.g., cerebrovascular impairment, neurological illness, trauma, tumor); cerebral palsy; cranial nerve involvement; developmental delay; esophageal reflux disease; laryngeal abnormality; laryngeal defect; nasal defect; nasopharyngeal cavity defect; neurological problems; oropharynx abnormality; prematurity; tracheal defect; trauma; upper airway anomaly

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Swallowing Status: Esophageal Phase, Oral Phase, Pharyngeal Phase

Example NOC Outcome with Indicators

Swallowing Status as evidenced by the following indicators: Delivery of bolus to hypopharynx is timed with swallow reflex/Ability to clear oral cavity/Number of swallows appropriate for bolus size and texture/Voice quality/Choking, coughing, gagging/Normal swallow effort. (Rate the outcome and indicators of **Swallowing Status**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

- Demonstrate effective swallowing without signs of aspiration (see defining characteristics above)
- Remain free from aspiration (e.g., lungs clear, temperature within normal range)

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Aspiration Precautions; Swallowing Therapy

Example NIC Activities—Swallowing Therapy

Assist client to sit in erect position (as close to 90 degrees as possible) for feeding/exercise; Instruct client not to talk during eating, if appropriate

Nursing Interventions and Rationales

- ▲ Do not feed clients with impaired swallowing orally until an appropriate diagnostic workup is completed. *Feeding a client who cannot adequately swallow can result in aspiration and possibly death (Forster et al, 2011).*
- ▲ Ensure proper nutrition by consulting with a health care provider regarding alternative nutrition and hydration when oral nutrition is not safe/adequate. **EB:** *Nasogastric tube feedings (NGT) and percutaneous endoscopic gastrostomy (PEG) tubes after stroke may reduce death rates (Geeganage et al, 2012). PEG feedings are preferable to NGT when longer term feeding is required (Geeganage et al, 2012).*
- ▲ Refer to a speech-language pathologist for evaluation and diagnostic evaluation of swallowing to determine swallowing problems and solutions as soon as oral and/or pharyngeal dysphagia is suspected. *Safe nursing care includes a consultation with a speech-language pathologist whenever doubts arise regarding a client's ability to tolerate oral-supported nutrition in any form (Tanner, 2013).*
- ▲ *To manage impaired swallowing, use a multidisciplinary dysphagia team composed of a speech pathologist, dietitian, nursing, health care provider, and medical staff. A comprehensive assessment from a multidisciplinary dysphagia team can lead to personalized therapeutic interventions that can help the client learn to swallow safely and maintain a good nutritional status (Forster et al, 2011).*
- ▲ *Observe the following feeding guidelines:*
 - Before giving oral feedings, determine the client's readiness to eat (e.g., alert, able to hold head erect, follow instructions, move tongue in mouth, and manage oral secretions). *If one of these elements is missing, it may be advisable to withhold oral feeding and use enteral feeding for nourishment.*
 - Monitor client during oral feedings and provide cueing as needed to ensure client follows swallowing guidelines/aspiration precautions recommended by speech language pathologist or dysphagia

specialist. NOTE: General aspiration precautions include the following: sit at 90 degrees for all oral feedings; take small bites/sips, slow rate, no straws. However, client specific strategies will be determined via bedside and/or instrumental swallowing evaluation performed by dysphagia specialist. *Postural changes, sensory enhancements, swallow maneuvers, or voluntary controls exerted over the swallow can improve swallow but the use and effectiveness of these treatments will vary systematically with the client's medical diagnosis (Logemann & Larsen, 2012).*

- If the client is older or has gastroesophageal reflux disease, ensure the client is kept in an upright posture for an hour after eating. **CEB:** *An upright posture after eating has been associated with a decreased incidence of pneumonia in older adults (Coleman, 2004).*
- During meals and all oral intake, observe for signs associated with swallowing problems such as coughing, choking, spitting of food, drooling, difficulty handling oral secretions, double swallowing or delay in swallowing, watering eyes, nasal discharge, wet or gurgling voice, decreased ability to move the tongue and lips, decreased mastication of food, decreased ability to move food to the back of the pharynx, slow or scanning speech. **CEB:** *Perceptual judgments of a clear post-swallow voice quality provided reasonable evidence that aspiration and dysphagia were absent as measured by videofluoroscopy (Waito et al, 2011).*
- ▲ Watch for uncoordinated chewing or swallowing; coughing immediately after eating or delayed coughing; pocketing of food; wet-sounding voice; sneezing when eating; delay of more than 1 second in swallowing; or a change in respiratory patterns. If any of these signs of dysphagia and/or aspiration is present, remove all food from the oral cavity, stop feedings, and consult with speech and language pathologist and dysphagia team. *Placing a client with suspected dysphagia on NPO (nothing by mouth) status is the strongest measure that can be taken to prevent choking and aspiration (Tanner & Culbertson, 2014).*
- ▲ If signs of aspiration or pneumonia are present, auscultate lung sounds after feeding. Note new onset of crackles or wheezing, or elevated temperature. **CEB:** *Bronchial auscultation of lung sounds was shown to be specific in identifying clients at risk for aspiration (Shaw et al, 2004).*
- ▲ Watch for signs of malnutrition and dehydration and keep a record of food intake. *Clients with dysphagia are at serious risk for malnutrition and dehydration, which can lead to aspiration pneumonia resulting from depressed immune function and weakness, lethargy, and decreased cough.*
- ▲ Evaluate nutritional status daily. Weigh the client weekly to help evaluate nutritional status. If the client is not adequately nourished, work with the dysphagia team to determine whether the client needs therapeutic feeding only or needs enteral feedings until the client can swallow adequately. **CEB:** *PEG feedings are preferable to NGT when longer term feeding is required (Geenganage et al, 2010).*
- ▲ Assist client in following dysphagia specialist's recommendations and provide open, accurate, and effective communication with dysphagia team regarding client's diet tolerance. *Understanding and following dysphagia specialist's recommendations is a pivotal role that nurses play in helping ensure positive dysphagia management outcomes (Tanner & Culbertson, 2014).*
- ▲ Document and notify the health care provider and dysphagia team of changes in medical, nutritional, or swallowing status. *Many negative dysphagia management outcomes can be avoided by ensuring dysphagia communication is accurate, complete, and disseminated among and between health care professionals; nurses are pivotal in this process (Tanner & Culbertson, 2014).*
- ▲ Work with the client on swallowing exercises prescribed by the dysphagia team. **EB:** *Exercise programs can improve airway closure, the range of oral or pharyngeal structure movement during swallow, cricopharyngeal opening, and tongue strength (Logemann & Larsen, 2012).*
- ▲ If needed, provide meals in a quiet environment away from excessive stimuli, such as a community dining room, for some clients who are easily distracted. *A noisy environment can be an aversive stimulus and can decrease effective chewing and swallowing.*
- ▲ For many adult clients, avoid the use of straws if recommended by the speech pathologist. *Use of straws can increase the risk of aspiration, because straws can result in spilling of a bolus of fluid rapidly in the posterior pharynx.*
- ▲ Recognize that the client can aspirate oral feedings, even if there are no symptoms of coughing or distress. *This phenomenon is called silent aspiration and is common. EB: It is estimated that up to 60% of stroke clients with dysphagia have silent aspiration (Ickenstein et al, 2012).*
- ▲ Ensure oral hygiene is maintained. **EB:** *Oral health care including tooth brushing after each meal, cleaning dentures once a day, and consistent professional oral health care reduces the incidence of aspiration pneumonia (van der Maarel-Wierink et al, 2013).*
- ▲ Check the oral cavity for proper emptying after the client swallows and after the client finishes the meal. Provide oral care at the end of the meal. It may be necessary to manually remove food from the client's

mouth. If this is the case, use gloves and keep the client's teeth apart with a padded tongue blade. *Food may become pocketed on the affected side and cause stomatitis, tooth decay, and possible later aspiration.*

- ▲ Praise the client for successfully following directions and swallowing appropriately. *Praise reinforces behavior and sets up a positive atmosphere in which learning takes place.*
- ▲ Keep the client in an upright position for 45 minutes to an hour after a meal. **CEB:** *Matsui and colleagues (2002) found the number of older clients who developed a fever was significantly reduced when clients were kept sitting upright after eating.*
- ▲ Recognize that impaired swallowing may be caused by the medications the client is taking. Side effects of medications include xerostomia (antidepressants, anticholinergics, antihistamines, bronchodilators, antineoplastic, anti-Parkinson), central nervous system depression (anticonvulsants, benzodiazepines, antispasmodics, antidepressants, antipsychotics), myopathy (corticosteroids, lipid-lowering agents, colchicines), and decreased esophageal sphincter tone (antihistamines, diuretics, opiates, antipsychotics, antihypertensives, anticholinergics). *Medications can cause impaired swallowing in multiple ways.*
- ▲ For clients receiving mechanical ventilation with a tracheostomy tube, request a referral to speech language pathologist or dysphagia specialist for an instrumental swallowing evaluation before beginning oral diet. *Dysphagia occurs in approximately 50% of clients with a tracheostomy receiving mechanical ventilation; objective swallowing studies are the best way to determine safest oral intake and rule out silent aspiration in these clients (Seckel & Schulenburg, 2011).*

Pediatric

- ▲ Refer a child who has difficulty swallowing and symptoms such as difficulty manipulating food, delayed swallow response, and pocketing of a bolus of food to speech-language pathologist (or dysphagia specialist) and a dietitian. *Adequate nutrition is extremely important for children to ensure sufficient growth and development of all body systems.*
- ▲ Consult with speech-language pathologist or dysphagia specialist regarding modifications to nipple; appropriate positioning and feeding strategies; and other therapeutic activities deemed most appropriate based on bedside and instrumental swallowing evaluation. *Speech-language pathologists are trained to evaluate and treat pediatric dysphagia. Consultation with a speech-language pathologist or feeding therapist with pediatric expertise improves the diagnostic utility of a feeding assessment and can result in better outcomes.*
- ▲ The following are general feeding guidelines. Specific strategies to eliminate aspiration and maximize intake should be individualized and determined by swallowing specialist through bedside and instrumental swallowing evaluation.
 - Attempt feedings when infant is in an optimal behavioral feeding state (e.g., awake, alert, and not agitated) and halt feedings if infant is not able to maintain or regain a proper feeding state. *Infants' feeding state can fluctuate rapidly and caregiver's attention to this state can influence feedings (Lau, 2014).*
 - In preterm infant, provide opportunities for patterned nonnutritive sucking (NNS). **EB:** *Although adequate NNS is not sufficient to predict adequacy of oral feeding (Lau, 2014), providing skilled training in patterned NNS has been demonstrated to accelerate the transition from NNS to oral feeding (Lau et al, 2012).*
 - In preterm infant, alter nipple flow rate to one that is easily managed by infant to facilitate intake while achieving physiologic stability. **CEB:** *Increased flow rate should only be considered when doing so assists the infant in obtaining adequate intake while maintaining physiologic stability. Aspiration risk is increased with faster flow rates.*
 - Watch for indicators of aspiration and physiologic instability during feeding: coughing, a change in vocal quality or wet vocal quality, perspiration and color changes, sneezing, apnea, and/or increased heart rate and breathing. Infants and children with silent aspiration may only have indicators of increased respiratory mucous, congestion and chronic wheeze or rhonchi, recurrent bronchitis, or recurrent pneumonia (Tutor & Gosa, 2012).
 - Watch for warning signs of reflux: sour-smelling breath after eating, sneezing, lack of interest in feeding, crying and fussing extraordinarily when feeding, pained expressions when feeding, and excessive chewing and swallowing after eating. *Many premature and medically fragile children experience growth deficits and respiratory problems from an underlying dysphagia. Some infants may need to work harder to breathe than others and as a result develop a decreased tolerance for food intake. They also demonstrate inconsistent arousal and poor/uncoordinated suck-swallow-breath synchrony. Many of these infants require supplemental tube feedings and the use of special nipples or bottles to boost oral intake.*

- Observe infant's behavior and cues and adjust feeding to promote a safe pleasurable feeding experience while eliminating aspiration and maximizing intake. *Individualize interventions based on infant's cues related to swallowing, breathing, physiologic stability, postural control, and state regulation to help infant maintain or regain stability. Some approaches include reducing noise/light levels, adjusting feeding position, letting infant regulate milk flow, and varying number and/or duration of feedings to reduce adverse events (Lau, 2014).*

Geriatric

- ▲ Recognize that age-related changes can impact swallowing and these changes have a more pronounced effect when superimposed on disease such as neurological and other chronic medical problems. *Subtle motor changes and age-related decrements in oral moisture, taste, and smell can contribute to less efficient and effective swallowing in older adults (Sura et al, 2012).*
- ▲ Evaluate medications the client is presently taking and consult with the pharmacist for assistance in monitoring for incorrect doses and drug interactions that could result in dysphagia. *Most older clients take numerous medications, which when taken individually can slow motor function, cause anxiety and depression, and reduce salivary flow. When taken together, these medications can interact, resulting in impaired swallowing function.*
- ▲ Ensure all nursing home residents are screened for swallowing problems. *It is estimated that up to 40% to 60% of nursing home residents have swallowing problems (Tanner, 2013).*
- ▲ Encourage and provide good oral hygiene when indicated. **EB:** *Good oral health care reduces the incidence of aspiration pneumonia (van der Maarel-Wierink et al, 2013).*
- ▲ Consult with occupational therapist for adaptive equipment when appropriate. *The use of adaptive equipment such as cups without rims and angled utensils can improve outcomes for older clients with dysphagia (Sura et al, 2012).*
- ▲ Recognize that the older client with dementia may need a longer time to eat and is often easily distracted. Help optimize hydration and nutrition using the following techniques:
 - Encourage six small meals and hydration breaks per day.
 - Offer foods that are sweet, spicy, or sour to increase sensory input.
 - Allow clients to touch food and self-feed, if necessary (Tanner, 2013).
 - Eliminate from the tray or table nonfoods such as salt and pepper, or anything that can be distracting. *Dementia clients are often impulsive and easily distracted.*
 - Keep desserts out of sight until the end of the meal.
 - Offer finger foods to the client who has trouble holding still to eat.
 - Allow clients to eat immediately when they come for the meal.
 - Recognize that the client with advanced dementia, who is unable to swallow, may or may not benefit from enteral tube feedings. *Some dementia clients enter into a catabolic state with negative protein balance, and it may be irreversible. In addition, there is often an increased risk for aspiration pneumonia in the tube fed client.*

S

Home Care

- ▲ Refer to speech therapy. Speech-language pathologists can work with clients to enhance swallowing ability and teach compensatory strategies.

Client/Family Teaching and Discharge Planning

- ▲ Teach the client and family exercises prescribed by the dysphagia team.
- ▲ Teach the client a systematic method of swallowing effectively as prescribed by the dysphagia team.
- Educate the client, family, and all caregivers about rationales for food consistency and choices. *It is common for family members to disregard necessary dietary restrictions and give the client inappropriate foods that predispose to aspiration.*
- Teach the family how to monitor the client to prevent and detect aspiration during eating.

Risk for imbalanced body Temperature

Betty J. Ackley, MSN, EdS, RN, and Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

NANDA-I

Definition

Vulnerable to failure to maintain body temperature within normal parameters, which may compromise health

Risk Factors

Acute brain injury; alteration in metabolic rate; condition affecting temperature regulation; decreased sweat response; dehydration; extremes of age; extremes of environmental temperature; extremes of weight; inactivity; inappropriate clothing for environmental temperature; increase in oxygen demand; increased body surface area to weight ratio; insufficient nonshivering thermogenesis; insufficient supply of subcutaneous fat; pharmaceutical agent; sedation; sepsis; vigorous activity

NOC, NIC, Client Outcomes, Nursing Interventions, Rationales, Client/Family Teaching and Discharge Planning, and References

Refer to care plans for Ineffective **Thermoregulation** (fever), **Hyperthermia**, or **Hypothermia**.

Risk for Thermal injury

Wendie A. Howland, MN, RN-BC, CRRN, CCM, CNLCP, LNCC

NANDA-I

Definition

Vulnerable to extreme temperature damage to skin and mucous membranes, which may compromise health

Risk Factors

Alteration in cognitive functioning; extremes of age; extremes of environmental temperature; fatigue; inadequate protective clothing (e.g., flame-retardant sleepwear, gloves, ear covering); inadequate supervision; inattentiveness; insufficient knowledge of safety precautions (client, caregiver); intoxication (alcohol, drug); neuromuscular impairment; neuropathy; smoking; treatment regimen; unsafe environment

List of Nursing Diagnoses by Letter: T

Risk for imbalanced body Temperature	Risk for Thermal injury	Ineffective Thermoregulation
Impaired Tissue integrity	Risk for Impaired Tissue integrity	Ineffective peripheral Tissue Perfusion
Risk for ineffective peripheral Tissue Perfusion	Impaired Transfer ability	Risk for Trauma

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Safe Home Environment; Parenting: Early/Middle/Adolescent Physical Safety

Client Outcomes**Client Will (Specify Time Frame)**

- Be free of thermal injury to skin or tissue
- Explain actions he or she can take to protect self and family from thermal injury
- Explain actions he or she can take to protect self and others in the work environment

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Environmental Management: Safety

Example NIC Activities—Environmental Management: Safety

Identify safety hazards in the environment; Modify the environment to minimize hazards and risk

Nursing Interventions and Rationales

- Teach the following interventions to prevent fires in the home, to handle any possible fire, and to have a readily available exit from the home:
 - Avoid plugging several appliance cords into the same electrical socket.
 - Do not use open candles or allow smoking in the home.
 - Keep a fire extinguisher within reach in case a fire should occur.
 - Install smoke alarms on every level of the home and in every sleeping area.
 - Keep furniture and other heavy objects out of the way of doors and windows.
 - Develop a fire escape plan that includes two ways out of every room and an outside meeting place. Practice the escape plan at least twice a year.
- Teach the following activities to homes with small children:
 - Lock up matches and lighters out of sight and reach.
 - Do not leave a hot stove unattended.
 - Do not allow small children to use the microwave until they are at least 7 or 8 years of age.
 - Keep all portable heaters out of children's reach and at least 3 feet away from anything that can burn.
 - Install thermostatic mixer valves in hot water system to prevent extreme hot water causing scalding burns. **EB:** *A study of the effects of the devices installed in public housing in Scotland identified a lower rate of scalding burns, which saved money (Phillips et al, 2011). Children ages 5 and younger are more than twice as likely to die in a fire as the rest of the population (Safe Kids USA, 2012). In the United States, burns are the third leading cause of unintentional injury death in children aged 1 to 14 years (Bowman et al, 2011).*
- Apply sunscreen as directed on the container when out in the sun. Use sun-blocking clothing, and stay in the shade if possible. *Sunburn predisposes to skin cancer development and premature skin aging. Up to 50% of children have at least one sunburn by the time they are 11 years of age and generally have another sunburn 3 years later (Dusza et al, 2012).*
- Teach the following to prevent fires in the home where medical oxygen is in use:
 - Never smoke in a home where medical oxygen is in use. "No smoking" signs should be posted inside and outside the home.
 - All ignition sources (e.g., matches, lighters, candles, gas stoves, appliances, electric razors, and hair dryers) should be kept at least 10 feet away from the point where the oxygen comes out.
 - Do not wear oxygen while cooking. Oils, grease, and petroleum products can spontaneously ignite when exposed to high levels of oxygen. Also, do not use oil-based lotions, lip balm, or aerosol sprays.
 - Homes with medical oxygen must have working smoke alarms that are tested monthly.
 - Keep a fire extinguisher within reach. If a fire occurs, turn off the oxygen and leave the home.

- Develop a fire escape plan that includes two ways out of every room and an outside meeting place. Practice the escape plan at least twice a year. **EB**; *A study of people who smoked while having medical oxygen in the home found that many of the clients died, and most of them lost their independence following the burn accident augmented by the presence of oxygen* (Murabit & Tredget, 2012; Joyner, 2012).
- Be aware that thermal injury also includes injury from cold materials and environmental conditions, including freezing injury, nonfreezing injury, and hypothermia (Kiss, 2012).
- Provide adequate environmental temperatures. Older clients and others at risk for temperature dysregulation can easily become hypothermic in air-conditioned environments (e.g., a surgical suite) or with inadequate clothing (e.g., patient gowns). *Inadvertent hypothermia is common in surgical procedures* (Moola & Lockwood, 2011).
 - Monitor temperature in vulnerable clients. Core temperature is the best measure to assess for hypothermia. If a pulmonary artery catheter is not available, use a thermometer calibrated for lower body temperature (Moola & Lockwood, 2011).
 - Use active warming measures to help clients maintain body temperature (e.g., warming blankets, warm intravenous fluids, forced warm air warming devices, foil wraps, and radiant warmers) as indicated. *Passive devices such as socks or reflective blankets do not impart heat to body tissues* (Moola & Lockwood, 2011).
- Ensure that exposed skin is protected from cold with adequate clothing.
- Monitor for developing cold thermal injury by checking peripheral circulation, temperature, sensation, and fine motor coordination, which decreases as a very early sign of hypothermia. *Preventing progression of thermal injury is critical to client outcomes. Shivering is a late sign and consumes considerable metabolic energy* (Soreide, 2014).
- Check the temperature of all equipment and other materials before allowing them to contact client skin especially if client has increased risk factors for thermal injury.

Ineffective Thermoregulation

Mary Beth Flynn Makic, PhD, RN, CNS, CCRN, FAAN, and Betty J. Ackley, MSN, EdS, RN

NANDA-I

Definition

Temperature fluctuation between hypothermia and hyperthermia

Defining Characteristics

Cyanotic nail beds; fluctuations in body temperature above and below the normal range; flushed skin; hypertension; increase in body temperature above normal range; increase in respiratory rate; mild shivering; moderate pallor; piloerection; reduction in body temperature below normal range; seizures; skin cool to touch; skin warm to touch; slow capillary refill; tachycardia

Related Factors (r/t)

Extremes of age; fluctuating environmental temperature; illness; trauma

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Thermoregulation; Thermoregulation: Newborn

Example NOC Outcome with Indicators

Thermoregulation as evidenced by the following indicators: Body temperature/Skin temperature/Skin color changes/Hydration/Reported thermal comfort. (Rate the outcome and indicators of **Thermoregulation**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see [Section 1](#)].)

Client Outcomes**Client Will (Specify Time Frame)**

- Maintain temperature within normal range
- Explain measures needed to maintain normal temperature
- Describe two to four symptoms of hypothermia or hyperthermia
- List two or three self-care measures to treat hypothermia or hyperthermia

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Temperature Regulation; Temperature Regulation: Inoperative

Example NIC Activities—Temperature Regulation

Institute use of a continuous core temperature-monitoring device, as appropriate; Promote adequate fluid and nutritional intake

Nursing Interventions and Rationales**Temperature Measurement**

- Measure and record the client's temperature using a consistent method of temperature measurement every 1 to 4 hours depending on severity of the situation or whenever a change in condition occurs (e.g., chills, change in mental status). **CEB/EB**: Errors in accurate temperature measurement are most often associated with instrument related errors, choice of temperature site chosen for monitoring, and operator error (Barnason et al, 2012; Bridges & Thomas, 2009; Makic et al, 2011; Sessler, 2008). **EBN**: A consistent mode of temperature measurement for accurate trending of body temperature is important for accurate treatment decisions (Davie & Amoore, 2010; Barnason et al, 2012; Hooper et al, 2009). If different devices are used to obtain temperature measurements, the results should not vary more than 0.3° C to 0.5° C (Bridges & Thomas, 2009; Makic et al, 2011).
- Select core, near core, or peripheral temperature monitoring mode based on ability to obtain an accurate temperature from that site and clinical situation dictating the need for mode of temperature monitoring required for clinical treatment decisions. **CEB/EB**: Core temperature is obtained by pulmonary artery catheter and distal esophagus; near core temperature measurements include oral, bladder, rectal, and temporal artery; and peripheral measurements are obtained by skin surface measurements such as measurement in the axilla (Barnason et al, 2012; Jefferies et al, 2011; Davie & Amoore, 2010; Hooper et al, 2009; Sessler, 2008).
- Caution should be taken in interpreting extreme values of temperature (less than 35° C or greater than 39° C) from a near core temperature site device. **EB/EBN**: Accurate oral temperature measurement requires the probe to be placed in the posterior sublingual pocket to provide a reliable near core temperature measurement (Jefferies et al, 2011; Barnason et al, 2012; Ring et al, 2010; Hooper et al, 2009; Sessler, 2008; Torossian, 2008). Evidence is limited in testing the accuracy of temperature measurement devices outside of normal temperature ranges. Research has demonstrated the accuracy of temperature measurement from most

accurate to least accurate are intravascular (pulmonary artery), distal esophageal, bladder thermistor, rectal, and oral. Research is limited on accuracy of temporal artery measurements outside normal ranges; axillary temperature is accurate in neonates but is not well supported in adults; tympanic membrane measurements and chemical dot thermometers are least accurate and should be avoided in caring for the acutely ill adult client (Barnason et al, 2012; Adam, 2013; Calonder et al, 2010; Davie & Amoores, 2010; Hooper et al, 2009; Makic et al, 2011; O'Grady et al, 2008; Wollerich et al, 2012).

- Evaluate the significance of a decreased or increased temperature. Normal adult temperature is usually identified as 98.6° F (37°C), but in actuality the normal temperature fluctuates throughout the day. In the early morning it may be as low as 96.4° F (35.8° C) and in the late afternoon or evening as high as 99.1° F (37.3° C) (Becker & Wu, 2010). Disease, injury, or pharmacological agents may impair regulation of body temperature (Dinarello & Porat, 2011; Hooper et al, 2009; Sessler, 2008).
- ▲ Notify the health care provider of temperature according to institutional standards or written orders, or when temperature reaches 100.5° F (38.3° C) and above (Saltzberg 2013; O'Grady et al, 2008). Also notify the health care provider of the presence of a change in mental status and temperature greater than 38.3° C or less than 36° C. A change in mental status may indicate the onset of septic shock (Saltzberg 2013; Dellinger et al, 2013).

Fever (Pyrexia)

- Recognize that fever is characterized as a temporary elevation in internal body temperature 1° C to 2° C higher than the client's normal body temperature. A rise in body temperature is an innate immune response to a perceived threat and is regulated by the hypothalamus. Hyperthermia may occur when a client gains heat through either an increase in the body's heat production or is unable to effectively dissipate heat. Hypothermia occurs when a client loses heat or cannot generate heat (Rehman & deBoisblanc, 2013; Kenney et al, 2014; Pitoni et al, 2011; Scrase & Tranter, 2011).
- Recognize that fever is a normal physiological response to a perceived threat by the body, frequently in response to an infection. **EB:** Fever is a deliberate, active thermoregulatory defense action by the body (Kenney et al, 2014). Metabolic heat accelerates the body's antibody production to defend the body and assists the body's cellular repair processes (Scrase & Tranter, 2011). Nursing care should focus on supporting the body's normal physiological response (fever), locating the cause for the fever, and providing comfort (Rehman & deBoisblanc, 2013; Scrase & Tranter, 2011).
- ▲ Review client history to include current medical diagnosis, medications, recent procedures/interventions, and review of laboratory analysis for cause of ineffective thermoregulation. **EB:** Changes in body temperature, fever, should be explored for possible problems associated with a client's health status (Rehman & deBoisblanc, 2013).
- Recognize that fever may be low grade (36° C to 38° C) in response to an inflammatory process such as infection, allergy, trauma, illness, or surgery. Moderate to high-grade fever (38° C to 40° C) indicates a more concerted inflammatory response from a systemic infection. Hyperpyrexia (40° C and higher) occurs as a result of damage of the hypothalamus, bacteremia, or an extremely overheated room (Scrase & Tranter, 2011; Kenney et al, 2014). **EB:** Interventions to treat fever focus on client comfort, allowing the body to progress through the natural course of fever. Exceptions may exist with the client with hyperpyrexia (Carey, 2010; Scrase & Tranter, 2011).
- Recognize that fever has a predictable physiological pattern. The initial phase (cold or chill stage) presents with an increased heart rate, respiratory rate, shivering, pale, cold skin, absence of sweat, and piloerection. As the hypothalamus adjusts, the body temperature shivering ceases, skin becomes warm, and heart rate and respiratory rate remain elevated. The client may complain of thirst, poor appetite, painful muscles, exhaustion, and lethargy. The resolution phase presents with warm, flushed, sweaty skin, reduced shivering, and possible signs of dehydration (Kenney et al, 2014; Rehman & deBoisblanc, 2013; Carey, 2010; Pitoni, et al, 2011; Scrase et al, 2011).
- Monitor and intervene to provide comfort during a fever by:
 - Obtaining vital signs and accurate intake and output
 - Checking laboratory analysis trends of white blood cell counts and other markers of infection
 - Providing blankets when the client complains of being cold, but removing surplus of blankets when the client is too warm
 - Encouraging fluid and nutrition
 - Limiting activity to conserve energy
 - Providing frequent oral care (Scrase et al, 2011)

- ▲ **EBN/EB:** Current evidence that examined the evidence of antipyretic therapies used to treat fever such as administration of antipyretic medications, cooling blankets, and sponge baths found these therapies did not reduce the duration of illness and may even prolong it (Carey, 2010; Hammond & Boyle, 2011; Niven et al, 2013).

Hypothermia

- Take vital signs frequently, noting changes associated with hypothermia: increased blood pressure, pulse, and respirations that then advance to decreased values as hypothermia progresses. *Mild hypothermia activates the sympathetic nervous system, which can increase the levels of vital signs; as hypothermia progresses, the heart becomes suppressed, with decreased cardiac output and lowering of vital sign readings (Dinarello et al, 2011).*
- Monitor the client for signs of hypothermia (e.g., shivering, cool skin, piloerection, pallor, slow capillary refill, cyanotic nailbeds, decreased mentation, dysrhythmias) (Pitoni et al, 2011).
- See the care plan for **Hypothermia** as appropriate.

Hyperthermia

- Note changes in vital signs associated with hyperthermia: rapid, bounding pulse; increased respiratory rate; and decreased blood pressure, accompanied by orthostatic hypotension, and signs and symptoms of dehydration (Rehman & deBoisblanc, 2013; Dinarello et al, 2011). *Consistent monitoring promotes prevention and early intervention in clients with altered cardiopulmonary status associated with hyperthermia. Hyperthermia is a different etiology than fever, and the cause of the elevated body temperature should be explored for definitive treatment (Rehman & deBoisblanc, 2013).*
- Monitor the client for signs of hyperthermia (e.g., headache, nausea and vomiting, weakness, extreme fatigue, delirium, and coma). *Monitoring for the defining characteristics of hyperthermia allows for early intervention.*
- Adjust clothing to facilitate passive warming or cooling as appropriate.
- See the care plan for **Hyperthermia** as appropriate.

Pediatric

- For routine measurement of temperature, use an electronic thermometer in the axilla in infants younger than 4 weeks; for a child up to 5 years of age, use an electronic thermometer in the axilla or an infrared temporal artery thermometer. **EB:** *Oral and rectal routes should not be used routinely to measure the temperature of infants to children of 5 years of age (National Institute for Health and Clinical Excellence [NICE], 2013). Tympanic thermometers often provide inaccurate temperature from incorrect placement in the ear canal and presence of cerumen adversely affecting temperature reading (Adam, 2013). Fever strips and pacifier thermometers often provide inaccurate readings (Adam, 2013).*
- Recognize that pediatric clients have a decreased ability to adapt to temperature extremes. Take the following actions to maintain body temperature in the infant/child:
 - Keep the head covered.
 - Use blankets to keep the client warm.
 - Keep the client covered during procedures, transport, and diagnostic testing.
 - Keep the room temperature at 72° F (22.2° C).

The combination of a relatively smaller body surface area, smaller body fluid volume, less well-developed temperature control mechanisms, and smaller amount of protective body fat limits the infant's and child's ability to maintain normal temperatures (NICE, 2013).

- Recognize that the infant and small child are both vulnerable to develop heat stroke in hot weather; ensure that they receive sufficient fluids and are protected from hot environments. *Infants and young children are at risk for heat stroke for many reasons, including a decreased thermoregulatory ability in the young body and the inability to obtain their own fluids.*
- Antipyretic treatments typically are not indicated unless the child's temperature is higher than 38.3° C and may be given to provide comfort. **EB:** *The use of antipyretics in febrile children should be examined in light of the therapeutic goal for treatment, which may be primarily to improve the child's discomfort (Sullivan & Farrar, 2011; Adam, 2013). A systematic review found combination treatment with ibuprofen and acetaminophen in children older than 6 months may be beneficial in treatment of fever symptoms over one agent alone (Malya, 2013; Pursell, 2011).*

Geriatric

- Do not allow an older client to become chilled. Keep the client covered when giving a bath and offer socks to wear in bed. Be aware of factors such as room temperature (heating/air conditioning), clothing (layered/loose), and fluid intake. *Older adults have a decreased ability to adapt to temperature extremes and need protection from extreme environmental temperatures. The response to cold environment is also compromised with the cutaneous vasoconstrictor response, the shivering process being less effective, and decreased ability to feel cold (McLafferty et al, 2009; Outzen, 2009). Research indicates that this can be traced in part to medications used to treat chronic age-associated diseases and physiology of aging.*
- Recognize that the older client may have an infection without a significant rise in body temperature. *Febrile response to infection was found to be reduced with increasing age, and baseline temperatures were generally lower in older clients (Rehman & deBoisblanc, 2013; Barakzai & Fraser, 2008). This blunted febrile response may lead to delayed diagnosis and treatment; therefore, reviewing all data to include a change in temperature, rather than fever, is important in the care of older clients (Outzen, 2009).*
- Fever does not put the older adult at risk for long-term complications; thus, fever should not be treated with antipyretic agents or other external methods of cooling, unless there is serious heart disease present. **CEB:** *Exceptions in treating fever should be considered in some older clients with significant cardiovascular disease, because fever may increase metabolic rate by 10% and shivering may double the metabolic rate, greatly increasing the oxygen consumption requirements of the body and creating significant stress on the cardiovascular system (Outzen, 2009).*
- Ensure that older clients receive sufficient fluids during hot days and stay out of the sun. *Older adults may have trouble walking independently to obtain fluids, have decreased thirst sensation, and have chronic illnesses that predispose them to heat stroke, a hyperthermic condition (Wotton et al, 2008).*
- Assess the medication profile for the potential risk of drug-related altered body temperature. *Anesthetics, barbiturates, salicylates, nonsteroidal antiinflammatory drugs, diuretics, antihistamines, anticholinergics, beta-blockers, and thyroid hormones have been linked to decreased body temperature (American Geriatric Society, 2012).*

Home Care

Treating Fever

- Instruct client/parents on the physiological benefits of fever and provide interventions to treat fever symptoms, avoiding antipyretic agents and external cooling interventions.
- Ensure that client/parents know when to contact a health care provider for fever-related concerns.

Prevention of Hypothermia in Cold Weather

See the care plan **Hypothermia**.

Prevention of Hyperthermia in Hot Weather

See the care plan **Hyperthermia**.

Client/Family Teaching and Discharge Planning

- Teach the client and family the signs of fever, hypothermia, and hyperthermia and appropriate actions to take if either condition develops.
- Teach the client and family an age-appropriate method for taking the temperature.
- Teach the client to avoid alcohol and medications that depress cerebral function. *When the client is sedated or under the influence of alcohol, mentation is depressed, which results in decreased activities to maintain an adequate body temperature.*

Impaired Tissue integrity Karen Zulkowski, DNS, RN

NANDA-I

Definition

Damage to the mucous membrane, cornea, integumentary system, muscular fascia, muscle, tendon, bone, cartilage, joint capsule, and/or ligament

Defining Characteristics

Damaged tissue; destroyed tissue

Related Factors

Alteration in metabolism; alteration in sensation; chemical injury agent (e.g., burn, capsaicin, methylene chloride, mustard agent); excess fluid volume; extremes of age; extremes of environmental temperature; high

voltage power supply; humidity; imbalanced nutritional state (e.g., obesity, malnutrition); impaired circulation; impaired mobility; insufficient fluid volume; insufficient knowledge about maintain tissue integrity; insufficient knowledge about protecting tissue integrity; mechanical factor; peripheral neuropathy; pharmaceutical agent; radiation; surgical procedure

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Integrity: Skin and Mucous Membranes; Wound Healing: Primary Intention, Secondary Intention

Example NOC Outcome with Indicators

Intact **Tissue Integrity: Skin and Mucous Membranes** as evidenced by the following indicators: Skin intactness/Skin lesions absent/Tissue perfusion/Skin temperature. (Rate the outcome and indicators of **Tissue Integrity: Skin and Mucous Membranes**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Report any altered sensation or pain at site of tissue impairment
- Demonstrate understanding of plan to heal tissue and prevent reinjury
- Describe measures to protect and heal the tissue, including wound care
- Experience a wound that decreases in size and has increased granulation tissue

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Incision Site Care; Pain Management; Pressure Ulcer Care; Risk Identification; Skin Care: Topical Treatments; Skin Surveillance; Wound Care; Wound Irrigation

Example NIC Activities—Pressure Ulcer Care

Monitor color of wound bed, temperature, edema, erythema, moisture, and appearance of surrounding skin; Note characteristics of any drainage

Nursing Interventions and Rationales

- Assess the site of impaired tissue integrity and determine the cause and type of wound (e.g., acute or chronic wound, burn, dermatological lesion, pressure ulcer, leg ulcer, skin failure). **EB**: *The etiology or cause of the wound must be determined before appropriate interventions can be implemented. This provides the basis for additional testing and evaluation to start the treatment process (Baranoski & Ayello, 2012).*
- Determine the size (length, width) and depth of the wound (e.g., full-thickness wound, deep tissue injury, stage III or IV pressure ulcer). *Consistency and accuracy in how the wound (tissue integrity) is measured are important for determining changes in the wound over time and for comparing effectiveness of various treatments (Baranoski & Ayello, 2012).*
- ▲ Classify pressure ulcers using national guidelines and definitions (<http://www.npuap.org/resources/educational-and-clinical-resources/npuap-pressure-ulcer-stagescategories>)
 - Pressure ulcer: localized injury to the skin and/or underlying tissue usually over a bony prominence, as a result of pressure, or pressure in combination with shear (note: friction is not included in the definition) (National Pressure Ulcer Advisory Panel [NPUAP] and European Pressure Ulcer Advisory Panel [EPUAP], 2014).
 - **Category/Stage III**: Full-thickness tissue loss. Subcutaneous fat may be visible but bone, tendon, or muscle is not exposed. Slough may be present but does not obscure the depth of tissue loss. May include undermining and tunneling. The depth of a category/stage III pressure ulcer varies by anatomical location. The bridge of the nose, ear, occiput and malleolus do not have (adipose) subcutaneous tissue and can be shallow. In contrast, areas of significant adiposity can develop extremely deep category/stage III pressure ulcers. Bone/tendon is not visible or directly palpable.

- **Category/Stage IV:** Full-thickness tissue loss with exposed bone, tendon, or muscle. Slough or eschar may be present on some parts of the wound bed. Often includes undermining and tunneling. The depth of a category/stage IV pressure ulcer varies by anatomical location. The bridge of the nose, ear, occiput, and malleolus do not have (adipose) subcutaneous tissue and can be shallow. Category IV ulcers can extend into muscle and/or supporting structures (e.g., fascia, tendon, or joint capsule), making osteomyelitis possible. Exposed bone/tendon is visible or directly palpable.
- **Suspected Deep Tissue Injury:** Purple or maroon localized area of discolored intact skin or blood-filled blister due to damage of underlying soft tissue from pressure and/or shear. The area may be preceded by tissue that is painful, firm, mushy, boggy, warmer, or cooler as compared to adjacent tissue. Suspected deep tissue injury may be difficult to detect in individuals with dark skin tones. Evolution may include a thin blister over a dark wound bed. The wound may further evolve and become covered by thin eschar. Evolution may be rapid, exposing additional layers of tissue even with optimal treatment.
- **Unstageable (Depth Unknown):** Full-thickness tissue loss in which the base of the ulcer is covered by slough (yellow, tan, gray, green, or brown) and/or eschar (tan, brown, or black) in the wound bed. Until enough slough and/or eschar is removed to expose the base of the wound, the true depth and, therefore, category/stage cannot be determined. Stable (dry, adherent, intact without erythema or fluctuance) eschar on the heels serves as a natural cover and should not be removed.
- Inspect and monitor the site of impaired tissue integrity at least once daily for color changes, redness, swelling, warmth, pain, or other signs of infection or per facility/agency policy. Determine whether the client is experiencing changes in sensation or pain. Pay special attention to all high-risk areas such as bony prominences, skin folds, sacrum, and heels. *Systematic inspection can identify impending problems early.* **EB:** *Pain secondary to dressing changes can be managed by interventions aimed at reducing trauma and other sources of wound pain (Wounds International, 2009).*
- Monitor the status of the skin around the wound. Monitor the client's skin care practices, noting type of soap or other cleansing agents used, temperature of water, and frequency of skin cleansing. *Individualize the plan according to the client's skin condition, needs, and preferences. Avoid harsh cleansing agents, hot water, extreme friction or force, or too-frequent cleansing (Baranoski & Ayello, 2012).*
- Monitor the client's continence status and minimize exposure of the skin impairment site and other areas to moisture from urine or stool, perspiration, or wound drainage. *If the client is incontinent, implement an incontinence management plan to prevent exposure to chemicals in urine and stool that can strip or erode the skin. Refer to a continence care specialist, urologist, or gastroenterologist for incontinence assessment (Borchert et al, 2010; Wound, Ostomy, and Continence Nurses Society [WOCN], 2010).* **EB:** *Implementing an incontinence prevention plan with the use of a skin or cleanser protectant can significantly decrease skin breakdown and pressure ulcer formation (Borchert et al, 2010).*
- Monitor for correct placement of tubes, catheters, and other devices. Assess the skin and tissue affected by the pressure of the devices and tape used to secure these devices. **EB:** *Mechanical damage to skin and tissues as a result of pressure, friction, or shear is often associated with external devices (NPUAP/EPUAP, 2014).* A medical device related pressure ulcer is defined as a localized injury to the skin or underlying tissue as a result of sustained pressure from a medical device and the skin/tissue injury will often have the same configuration as the device (NPUAP/EPUAP, 2014; Black et al, 2010).
- Assess frequently for correct placement of foot boards, restraints, traction, casts, or other devices, and assess skin and tissue integrity. Frequently assess for signs and symptoms of compartment syndrome (refer to the care plan for Risk for **Peripheral Neurovascular** dysfunction). *Mechanical damage to skin and tissues (pressure or shear) is often associated with external devices.*
- Implement and communicate a comprehensive treatment plan for the topical treatment of the skin impairment site. *A clearly stated treatment plan ensures consistency in care and documentation (Baranoski & Ayello, 2012).*
- ▲ Identify a plan for debridement if necrotic tissue (eschar or slough) is present and if consistent with overall client management goals. (i.e., curative vs. palliative care). **EB:** *Debride devitalized tissue within the wound bed or edge of pressure ulcers when appropriate to individual's condition and consistent with overall goals of care. Do not debride stable, hard, dry eschar in ischemic limbs or heels (NPUAP/EPUAP, 2014).*
- Select a topical treatment that maintains a moist, wound-healing environment and also allows absorption of exudate and filling of dead space. *No single wound care product provides the optimal environment for healing all wounds.* **EB:** *Choose dressings that provide a moist healing environment, keep periwound skin*

dry, and control exudate and eliminate dead space (Baranoski & Ayello, 2012; NPUAP/EPUAP, 2014; WOCN, 2010).

- Avoid positioning the client on the site of impaired tissue integrity. **EB:** *If it is consistent with overall client management goals, reposition the client based on level of tissue tolerance and overall condition, and transfer or reposition the client carefully to avoid adverse effects of external mechanical forces (pressure, friction, and shear) (NPUAP/EPUAP, 2014; WOCN, 2010).*
- Evaluate for the use of support surfaces (specialty mattresses, beds) chair cushion, or devices as appropriate (Brienza et al, 2012; Lippoldt et al, 2014).
- If the goal of care is to keep the client comfortable (e.g., for a terminally ill client), repositioning may not be appropriate. *Position the client in position of optimal comfort (Horn et al, 2014). Maintain the head of the bed at the lowest degree of elevation possible to reduce shear and friction and use lift devices, pillows, foam wedges, and pressure-reducing devices in the bed (Baranoski & Ayello, 2012; NPUAP/EPUAP, 2014, WOCN, 2010).*
- ▲ Assess the client's nutritional status. Refer for a nutritional consult and/or institute dietary supplements as necessary. *Optimizing nutritional intake, including calories, fatty acids, protein, and vitamins, is needed to promote wound healing (NPUAP/EPUAP, 2014; O'Hanlon et al, 2015).*
- ▲ Develop a comprehensive plan of care that includes a thorough wound assessment, treatment interventions, support surfaces, nutritional products, adjunctive therapies, and evaluation of the outcome of care. *Documentation of these essential elements is paramount to establishing a framework for quality care.*

Home Care

- Some of the interventions previously described may be adapted for home care use.
- ▲ Assess the client's current phase of wound healing (inflammation, proliferation, maturation) and stage of injury; initiate appropriate wound management. **EB:** *Accurate understanding of tissue status combined with knowledge of underlying diagnoses and product validity provide a basis for determining appropriate treatment objectives (Baranoski & Ayello, 2012).*
- Instruct and assist the client and caregivers in understanding how to change dressings and in the importance of maintaining a clean environment. Provide written instructions and observe them completing the dressing change.
- ▲ Initiate a consultation in a case assignment with a wound specialist or wound, ostomy, and continence nurse to establish a comprehensive plan as soon as possible. Plan case conferencing to promote optimal wound care. *Case conferencing ensures that cases are regularly reviewed to discuss and implement the most effective wound care management to meet client needs.*
- ▲ Consult with other health care disciplines to provide a thorough, comprehensive assessment. *Consider referring to a dietitian, physical therapist, occupational therapist, and social worker/case manager as needed. Early engagement of wound care specialists can enhance overall care and reduce health care costs (Vrtis, 2013).*

Client/Family Teaching and Discharge Planning

- Teach skin and wound assessment and ways to monitor for signs and symptoms of infection, complications, and healing. *Early assessment and intervention help prevent serious problems from developing.*
- Teach the client why a topical treatment has been selected. Explain wound bed changes that the caregiver can expect to see. Instruct on when the dressing needs to be changed. **EB:** *The type of wound dressing needed may change over time as the wound heals and/or deteriorates (Baranoski & Ayello, 2012; NPUAP/EPUAP, 2014).*
- ▲ Teach the use of pillows, foam wedges, and pressure-reducing devices to prevent pressure injury. The use of effective pressure-reducing seat cushions for older wheelchair users significantly prevented sitting-acquired pressure ulcers (Brienza et al, 2012).

Risk for Impaired Tissue integrity

Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN, and Karen Zulkowski, DNS, RN

NANDA-I

Definition

Vulnerable to damage to the mucous membrane, cornea, integumentary system, muscular fascia, muscle, tendon, bone, cartilage, joint capsule, and/or ligament, which may compromise health

Risk Factors

Alteration in metabolism; alteration in sensation; chemical injury agent (e.g., burn, capsaicin, methylene chloride, mustard agent); excessive fluid volume; extremes of age; extremes of environmental temperature; high voltage power supply; humidity; imbalanced nutritional state (e.g., obesity, malnutrition); impaired circulation; impaired mobility; insufficient fluid volume; insufficient knowledge about maintaining tissue integrity; insufficient knowledge about protecting tissue integrity; mechanical factor; peripheral neuropathy; pharmaceutical agent; radiation therapy; surgical procedure

NOC, NIC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan for Impaired **Tissue** integrity.

T

Ineffective peripheral Tissue Perfusion *Lorraine Duggan, MSN, ACNP-BC*

NANDA-I

Definition

Decrease in blood circulation to the periphery, which may compromise health

Defining Characteristics

Absence of peripheral pulses; alteration in motor function; altered skin characteristics (e.g., color, elasticity, hair, moisture, nails, sensation, temperature); ankle-brachial index (ABI) <0.90; capillary refill time >3 seconds; color does not return to lowered limb after 1 minute of leg elevation; decrease in blood pressure in extremities; decrease in pain-free distances achieved in the 6-minute walk test; decrease in peripheral pulses; delay in peripheral wound healing; distance in the 6-minute walk test below normal range (400 m to 700 m in adults); edema; extremity pain; femoral bruit; intermittent claudication; paresthesia; skin color pales with limb elevation

Related Factors

Diabetes mellitus; hypertension; insufficient knowledge of aggravating factors (e.g., smoking, sedentary lifestyle, trauma, obesity, salt intake, immobility); insufficient knowledge of disease process; sedentary lifestyle; smoking

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Circulation Status; Fluid Balance; Hydration; Tissue Perfusion: Peripheral

Example NOC Outcome with Indicators

Demonstrates adequate **Circulation Status** as evidenced by the following indicators: Peripheral pulses strong/Peripheral pulses symmetrical/Skin color and temperature/Peripheral edema not present. (Rate the outcome and indicators of **Circulation Status**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

- Demonstrate adequate tissue perfusion as evidenced by palpable peripheral pulses, warm and dry skin, adequate urine output, and absence of respiratory distress
- Verbalize knowledge of treatment regimen, including appropriate exercise and medications and their actions and possible side effects
- Identify changes in lifestyle needed to increase tissue perfusion

NIC (Nursing Interventions Classification)**Suggested NIC Intervention**

Circulatory Care: Arterial Insufficiency

Example NIC Activities—Circulatory Care: Arterial Insufficiency

Evaluate peripheral edema and pulses; inspect skin for arterial ulcers and tissue breakdown

Nursing Interventions and Rationales

- ▲ Check the brachial, radial, dorsalis pedis, posterior tibial, and popliteal pulses bilaterally. If unable to find them, use a Doppler stethoscope and notify the health care provider immediately if new onset of absence of pulses along with a cold extremity. *Diminished or absent peripheral pulses indicate arterial insufficiency with resultant ischemia (White, 2011).*
- Note skin color and feel the temperature of the skin. *Skin pallor or mottling, cool or cold skin temperature, or an absent pulse can signal arterial obstruction, which is an emergency that requires immediate intervention (White, 2011). Rubor (reddish blue color accompanied by dependency) indicates dilated or damaged vessels. Brownish discoloration of the skin on the anterior tibia indicates chronic venous insufficiency (Jarvis, 2012).*
- Assess for pain in the extremities, noting severity, quality, timing, and exacerbating and alleviating factors. Differentiate venous from arterial disease. *In clients with venous insufficiency, the pain lessens with elevation of the legs and exercise. In clients with arterial insufficiency, the pain increases with elevation of the legs and exercise (Longo, 2011). Some clients have both arterial and venous insufficiency. Arterial insufficiency is associated with pain when walking (claudication) that is relieved by rest. Clients with severe arterial disease have pain while at rest, which keeps them awake at night. Venous insufficiency is associated with aching, cramping, and discomfort (White, 2011).*
- Check capillary refill. **EBN:** *Nail beds usually return to a pinkish color within 1 to 2 seconds after compression; a capillary refilling time greater than 3 seconds is abnormal (Jarvis, 2012).*
- Note skin texture and the presence of hair, ulcers, or gangrenous areas on the legs or feet. *Thin, shiny, dry skin with hair loss; brittle nails; and gangrene or ulcerations on toes and anterior surfaces of the feet are seen in clients with arterial insufficiency. If ulcerations are on the side of the leg, they are usually associated with venous insufficiency (Jarvis, 2012).*
- Note the presence of edema in the extremities and rate severity on a four-point scale. Measure the circumference of the ankle and calf at the same time each day in the early morning (White, 2011).

Arterial Insufficiency

- ▲ Monitor peripheral pulses. If there is new onset of loss of pulses with bluish, purple, or black areas and extreme pain, notify the health care provider immediately. *These are symptoms of arterial obstruction that can result in loss of a limb if not immediately reversed.* **CEB:** *A classic study concluded that (1) if pulses are palpable on both feet of a client, the prognosis for progression is relatively good regarding the client's peripheral arterial disease (PAD); (2) if pedal pulse is palpable, an arteriosclerotic ulcer on the foot will heal; (3) clients lacking palpable pulses in both feet actually suffer from PAD (Christensen, 1989).*
- ▲ Measure ABI via Doppler imaging. **EB:** *Automated ABI measurement using a professional blood pressure monitor allowing simultaneous arm-leg blood pressure measurements appears to be a reliable and faster alternative to Doppler measurement (Kollias et al, 2011).*
- Avoid elevating the legs above the level of the heart. With arterial insufficiency, leg elevation decreases arterial blood supply to the legs.
- ▲ For early arterial insufficiency, encourage exercise such as walking or riding an exercise bicycle from 30 to 60 minutes per day as ordered by the health care provider. **EB:** *Exercise was the most common non-pharmacological option recommended by health care providers for PAD (Bozkurk, 2011).*
- Keep the client warm and have the client wear socks and shoes or sheepskin-lined slippers when mobile. Do not apply heat. Clients with arterial insufficiency report being constantly cold; keep extremities warm to maintain vasodilation and blood supply. Heat application can easily damage ischemic tissues.
- ▲ Pay meticulous attention to foot care. Refer to a podiatrist if the client has a foot or nail abnormality. Ischemic feet are vulnerable to injury; meticulous foot care can prevent further injury. **EBN:** *Clients with diabetes and high risk for development of foot ulcer constitute a fragile group that needs special foot protective attention (Annersten Gershatner, 2011).*
- If the client has ischemic arterial ulcers, refer to the care plan for Impaired **Tissue** integrity.
- ▲ If the client smokes, aggressively counsel the client to stop smoking and refer to the health care provider for medications to support nicotine withdrawal and a smoking withdrawal program. **EB:** *Smoking cessation substantially reduces risk for PAD in women, but an increased occurrence of PAD persists even among former smokers who maintain abstinence (Conen, 2011).*

Venous Insufficiency

- ▲ Elevate edematous legs as ordered and ensure no pressure under the knee and heels to prevent pressure ulcers. *Elevation increases venous return, helps decrease edema, and can help heal venous leg ulcers (Longo et al, 2011).* *Pressure under the knee decreases venous circulation.* **EBN:** *Results indicate that leg elevation, compression hosiery, high levels of self-efficacy, and strong social support will help prevent recurrence (Finlayson et al, 2011).*
- ▲ Apply graduated compression stockings as ordered. Ensure proper fit by measuring accurately. Remove the stockings at least twice a day, in the morning with the bath and in the evening, to assess the condition of the extremity, then reapply. Knee length is preferred rather than thigh length. **EB:** *Hosiery is a dominant treatment—that is, on average it results in higher quality-adjusted life-years and lower costs than do bandages (Rebecca, 2014).*
- Encourage the client to walk with compression stockings on and perform toe-up and point-flex exercises. *Exercise helps increase venous return, builds up collateral circulation, and strengthens the calf muscles.* **EBN:** *Physical therapy modalities improves ABI, Doppler flow velocity, and blood parameters in clients with type 2 diabetes (Castro-Sanchez, 2013).*
- If the client is overweight, encourage weight loss to decrease venous disease. *Obesity is a risk factor for development of both deep vein thrombosis (DVT) and pulmonary embolism (PE) (Weitz, 2011).*
- If the client has venous leg ulcers, encourage the client to avoid prolonged sitting, standing, and elevation of the involved leg. Encourage proper use of compression stockings. Pain may prevent compliance. **EBN:** *A study shows a high incidence of ulcer pain, confirming that pain has a great impact on clients with venous leg ulcers (Akessonrut et al, 2014).*
- Discuss lifestyle with the client to determine if the client's occupation requires prolonged standing or sitting, which can result in chronic venous disease (Longo et al, 2011).
- ▲ If the client is mostly immobile, consult with the health care provider regarding use of a calf-high pneumatic compression device for prevention of DVT. **EB:** *Superficial venous surgery in addition to compression therapy is the most efficient treatment of venous leg ulcers. The compression therapy should be continued in both surgically and conservatively treated clients with healed ulcers (Taradaj et al, 2011).*

- Observe for signs of DVT, including pain, tenderness, swelling in the calf and thigh, and redness in the involved extremity. Take serial leg measurements of the thigh and calf circumferences. In some clients a tender venous cord can be felt in the popliteal fossa. Do not rely on Homan's sign. *Thrombosis with clot formation is usually first detected as swelling of the involved leg and then as pain. Symptoms of existing DVT are nonspecific and cannot be used alone to determine the presence of DVT (Ginsberg, 2011).*
- ▲ Note the results of a D-dimer test and ultrasounds. *High levels of D-dimer, a fibrin degradation fragment, are found in DVT and pulmonary embolism, but results should be confirmed with a duplex venous ultrasound (Ginsberg, 2011).*
- If DVT is present, observe for symptoms of a pulmonary embolism, including dyspnea, pleuritic chest pain, cough, and sometimes hemoptysis, especially with a history of trauma (Weitz, 2011).
- ▲ If the client develops DVT, after treatment and hospital discharge, recommend client wear below-the-knee elastic compression stockings during the day on the involved extremity. **EBN:** *Client education for post-thrombotic syndrome prevention compliance may be enhanced by specifically addressing individual risk factors and barriers to stocking application (Crumley, 2011).*

Geriatric

- Complete a thorough lower extremity assessment. Documenting the smallest change from previous assessment, and implement a plan immediately. **EB:** *Complete and accurate assessment is essential to guide health care providers in formulating efficacious plans of care. The prevalence of peripheral arterial disease increases with age. The elevated risk of ulcerations leading to amputation among older adults reflects not only increased rates of peripheral arterial disease and diabetic pathologies but also age-related changes of the integument (Hakim & Heitzman, 2013).*
- Change the client's position slowly when getting the client out of bed because of possible syncope. **EB:** *A study has confirmed a changing pattern in the etiology of syncope as a person ages. The burden of disease is greatest in older adults (Cooke et al, 2011).*
- Recognize that older adults have an increased risk for development of pulmonary embolism; if pulmonary embolism is present, the symptoms are nonspecific and often mimic those of heart failure or pneumonia (Weitz, 2011). **EB:** *A diagnostic review demonstrates an increase of prevalence of PE with age and a strong decrease of specificity and efficiency for clinical decision rules of VTE in older clients (Siccama et al, 2011).*

Home Care

- The interventions previously described may be adapted for home care use.
- If arterial disease is present and the client smokes, aggressively encourage smoking cessation.
- Examine the feet carefully at frequent intervals for changes and new ulcerations. **CEB:** *Lower Extremity Amputation Prevention (LEAP) Program documentation forms are available at <http://www.hrsa.gov/leap> (Health Resources and Service Administration, 2012).*
- ▲ Assess the client's nutritional status, paying special attention to obesity, hyperlipidemia, and malnutrition. Refer to a dietitian if appropriate. *Malnutrition contributes to anemia, which further compounds the lack of oxygenation to tissues. Obese clients have poor circulation in adipose tissue and increased coagulability (Weitz, 2011).*
- Monitor for development of gangrene, venous ulceration, and symptoms of cellulitis (redness, pain, and increased swelling in an extremity). *Cellulitis often accompanies peripheral vascular disease, especially with development of wounds on the leg (Longo et al, 2011).*

Client/Family Teaching and Discharge Planning

- Explain the importance of good foot care. Teach the client and family to wash and inspect the feet daily. Recommend that the diabetic client wear comfortable shoes and break them in slowly, watching for blisters (National Diabetes Information Clearing House, 2014).
- ▲ Teach the diabetic client that he or she should have a comprehensive foot examination at least annually (which includes an analysis for predicting foot ulceration risk), also including assessment of sensation using the Semmes-Weinstein monofilaments. If good sensation is not present, refer to a footwear professional for fitting of therapeutic shoes and inserts, the cost of which is covered by Medicare. **EBN:** *In a study, the strongest predictors of foot ulceration were prior ulcer, insulin treatment, absent monofilaments, structural abnormality, proteinuria, and retinopathy (Leese, 2011).*
- For arterial disease, stress the importance of not smoking, following a weight loss program (if the client is obese), carefully controlling a diabetic condition, controlling hyperlipidemia and hypertension,

maintaining intake of antiplatelet therapy, and reducing stress. *All these risk factors for atherosclerosis can be modified (White, 2011).* **EB:** *Intermittent claudication due to PAD causes substantial impairment in quality of life and is strongly associated with increased cardiovascular morbidity and mortality. Management focuses on reducing cardiovascular events, preventing progression of underlying PAD (e.g., limb loss), and improving symptoms. Aggressive secondary prevention strategies (e.g., statins and smoking cessation) are of critical importance (Vodnala et al, 2011).*

- Teach the client to avoid exposure to cold; limit exposure to brief periods if going out in cold weather and wear warm clothing.
- For venous disease, teach the importance of wearing compression stockings as ordered, elevating the legs at intervals, and watching for skin breakdown on the legs. **EB:** *Difficulties regarding putting on and removal of the compression stockings remain significant but are counterbalanced by better comfort when they are on (Carpentier et al, 2011).*
- Teach the client to recognize the signs and symptoms that should be reported to a health care provider (e.g., change in skin temperature, color, or sensation or the presence of a new lesion on the foot).
- Provide clear, simple instructions about plan of care.
- Instruct and provide emotional support for client undergoing hyperoxygenation treatment. **EB:** *Hyperbaric oxygen may be associated with ulcer healing in selected diabetic foot ulcers (Oliveira et al, 2014).*

Risk for ineffective peripheral Tissue Perfusion

Betty J. Ackley, MSN, EdS, RN, and Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

NANDA-I

Definition

Vulnerable to a decrease in blood circulation to the periphery, which may compromise health

Risk Factors

Diabetes mellitus; endovascular procedure; excessive sodium intake; hypertension; insufficient knowledge of aggravating factors (e.g., smoking, sedentary lifestyle, trauma, obesity, salt intake, immobility); insufficient knowledge of disease process; insufficient knowledge of risk factors; sedentary lifestyle; smoking; trauma

NOC, NIC, Client Outcomes, Nursing Interventions, Client/Family Teaching and Discharge Planning, Rationales, and References

Refer to care plan for Ineffective peripheral **Tissue Perfusion**.

Impaired Transfer ability *Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN*

NANDA-I

Definition

Limitation of independent movement between two nearby surfaces

Defining Characteristics

Impaired ability to transfer between bed and chair; impaired ability to transfer between bed and standing position; impaired ability to transfer between car and chair; impaired ability to transfer between chair and floor; impaired ability to transfer between chair and standing position; impaired ability to transfer between floor and standing position; impaired ability to transfer between uneven levels; impaired ability to transfer in or out of bath tub; impaired ability to transfer in or out of shower; impaired ability to transfer on or off a commode; impaired ability to transfer on or off a toilet

Related Factors (r/t)

Alteration in cognitive functioning; environmental barrier (e.g., bed height, inadequate space, wheelchair type, treatment equipment, restraints); impaired balance; impaired vision; insufficient knowledge of transfer techniques; insufficient muscle strength; musculoskeletal impairment; neuromuscular impairment; obesity; pain; physical deconditioning

NOTE: Specify level of Independence using a standardized functional scale.

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Balance; Body Positioning; Self-Initiated; Transfer Performance

Example NOC Outcome with Indicators

Transfer Performance as evidenced by the following indicators: Transfers from bed to chair and back/Transfers from wheelchair to toilet and back/Transfers from wheelchair to vehicle and back. (Rate the outcome and indicators of **Transfer Performance**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Transfer from bed to chair and back successfully
- Transfer from chair to chair successfully
- Transfer from wheelchair to toilet and back successfully
- Transfer from wheelchair to car and back successfully

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Exercise Promotion: Strength Training; Exercise Therapy: Muscle Control

Example NIC Activities—Exercise Promotion: Strength Training

Obtain medical clearance for initiating a strength-training program, as appropriate; Assist to set realistic short- and long-term goals and to take ownership of the exercise plan

Nursing Interventions and Rationales

- ▲ Request consult for a physical and/or occupational therapist (PT and OT) to develop exercise and strengthening program early in the client's recovery. *Leg/trunk strength is key for standing transfers; arm/trunk strength is key for slide-board transfers.* **EB:** *Progressive mobility earlier and more aggressively in the hospital stay, as early as in the ICU, decreases mechanical ventilation days and decreases complications such as weakness from disuse and contractures (Vollman, 2010; Kalisch et al, 2013).* **EB:** *Voet and colleagues (2010), via a Cochrane review, reported that strength training and aerobic exercise training for muscle disease may optimize function.*
- ▲ Obtain a consult for a PT, OT, or orthotist to evaluate and fit clients with proper orthoses, braces, collars, and walking aids before helping them stand. *Equipment helps clients move and function safely, comfortably, and independently (Hoeman et al, 2008).*
- Help client put on/take off collars, braces, prostheses in bed, as well as antiembolism stockings and abdominal binders. Applying antiembolism stockings while the client is in bed may reduce the risk of the client developing a deep vein thrombosis (DVT). **EB:** *A literature review reported knee-high stockings were as effective as above-the-knee stockings in preventing DVT in immobile medical/surgical inpatients, and compliance was better (Gordon et al, 2012).*
- Assess client's dependence, weight, strength, balance, tolerance to position change, cooperation, fatigue level, and cognition plus available equipment and staff ratio/experience to decide whether to do a manual or device-assisted transfer (Nelson et al, 2008; Cohen et al, 2010).
- ▲ Collaborate with PT and OT to use algorithms to identify technological aids to handle and transfer dependent and obese clients; do not use under-axilla method (Cohen et al, 2010). *Assess the client for appropriate use of assistive devices to include powered stand-assist devices, mechanical lifts, stretchers to chairs, and friction-reducing devices prevent musculoskeletal injuries of staff and allow safe client handling (Centers for Disease Control and Prevention, 2015).*
- Implement and document type of transfer (e.g., slide board, pivot), weight-bearing status (non-weight-bearing, partial), equipment (walker, sling lift), and level of assistance (standby, moderate) on care plan, white board in room, and/or electronic medical record.
- Apply a gait belt with handles before transferring clients with partial weight-bearing abilities; keep the belt and client close to provider during the transfer. *If used incorrectly, such as at arm's length, it prevents support of client and places staff at risk for back and arm injuries (Hallmark et al, 2015; Kalisch et al, 2013).*
- Help clients with wearing shoes with nonskid soles and socks/hose. *Proper shoes help prevent slips/pain/pressure and improve balance.* **EB:** *Suggest trying a running shoe that is comfortable and lightweight, because a recent study found that participants unable to see the type of shoe (control shoe, running shoe, or orthopedic shoe) chose the running shoe based on comfort and weight (Riskowski et al, 2011).*

- Remove or swivel wheelchair armrests, leg rests, and footplates to the side, especially with squat or slide board transfers. *This gives clients and nurses feet space to maneuver in and provides fewer obstacles to trip over.*
- Adjust transfer surfaces so they are similar in height. For example, lower a hospital bed to about an inch higher than commode height. **EB:** *Similar heights between seat surfaces require less upper extremity muscular effort during transfers (Hoeman et al, 2008; Cohen et al, 2010).*
- Place wheelchair and commode at a slight angle toward the surface onto which client will transfer. *The two surfaces are close together yet allow room for the caregiver to adjust the client's movements during the transfer (Hoeman et al, 2008).*
- Teach client to consistently lock brakes on wheelchair/commode/shower chair before transferring. *Wheels will roll if not locked, thus creating risk for falls. Pneumatic wheelchair tires must be adequately inflated for brakes to lock effectively (LaPlante et al, 2010).*
- Give clear, simple instructions, allow client time to process information, and let him/her do as much of the transfer as possible. *Over-assistance by staff and family may decrease client learning, independence, self-care, and self-esteem.*
- ▲ Remind clients to comply with weight-bearing restrictions ordered by their health care provider. *Weight bearing may retard healing in fractured bones.*
- Place client in set position before standing him or her—for example, sitting on edge of surface with bilateral weight bearing on buttocks and hips, with knees flexed, balls of feet aligned under knees, and head in midline. *This position prepares individuals for bearing weight and permits shifting of weight from pelvis to feet as the center of gravity changes while rising.*
- Support and stabilize client's weak knees by placing one or both of your knees next to or encircling client's knees, rather than blocking them. *This allows client to flex his/her knees and lean forward to stand and transfer.*
 - Squat transfer: client leans well forward, slightly raises flexed hips off the surface, pivots, and sits down on new surface. *This is beneficial for clients with slight weight-bearing ability.*
 - Standing pivot transfer: client leans forward with hips flexed and pushes up with hands from seat surface (or arms of chair), then stands erect, pivots, and sits down on new surface. *This is beneficial for clients who have fair weight-bearing ability.*
 - Slide board transfer: client should have on pants or have a pillowcase over the board. Remove arm and leg rest from wheelchair on one side, then slightly angle chair toward new surface. Help client lean sideways, thus shifting his/her weight so transfer board can be placed well under the upper thigh of the leg next to new surface. Make sure board is safely angled across both surfaces. Help client to sit upright and place one hand on board and the other hand on surface. Remind and help client perform a series of pushups with arms while leaning slightly forward and lifting (not sliding) hips in small increments across board with each pushup. *This benefits clients with little to no weight-bearing ability (Hoeman et al, 2008; Cohen et al, 2010; Hallmark et al, 2015).*
- Position walking aids appropriately so a standing client can grasp and use them once he/she is upright. *These aids help provide support, balance, and stability to help client stand and step safely (Kalisch et al, 2013; Mayeda-Letourneau, 2014).*
- Reinforce to clients who use walkers to place one hand on walker and push with opposite hand against chair arm or surface from which they are arising to stand up. *Placing both hands on the walker may cause it to tip and the client to lose balance and fall.*
- Use ceiling-mounted or bedside mechanical bariatric lifts to transfer dependent bariatric (extremely obese) clients. *Equipment prevents client/staff injury and is essential for clients who require a moderate/maximum assist transfer (Cohen et al, 2010).*
- Use bariatric devices and use available safe client handling equipment for lifting, transferring, positioning, and sliding client (Cohen et al, 2010).
- Place a mechanical lift sling in the wheelchair preventively. Place two transfer sheets or a slide board under bariatric client. Reinforce that head should be leaning forward and that knees should be level with hips; help hold wheelchair in place as therapist directs/helps client with a scoot transfer. *Client may be too fatigued to do a manual transfer back to bed after sitting, so sling/lift can be used.*
- Perform initial and subsequent fall risk assessment. *Use standardized tools for fall risk assessment and interdisciplinary multifactorial interventions to reduce falls and risk of falling in hospitals (Cameron et al, 2010).*

- ▲ Collaborate with PT, OT, and pharmacist for individualized preventive/postfall plans, for example, scheduled toileting, balance and strength training, removal of hazards, chair alarms, call system/phone in reach, and review of medications. **EB:** *Results from a study showed low-intensity exercise and incontinence care in residents in nursing homes reduced falls (Cameron et al, 2010). More than five drugs indicates polypharmacy and puts the client at risk for adverse drug reactions, drug-drug interactions, and overall low adherence to drug therapy due to taking too many drugs (Hovstadius et al, 2010).*
- Encourage an exercise component such as tai chi, physical therapy, or other exercise for balance, gait, and strength training in group programs or at home.
- Modify environment for safety; recommend vision assessment and consideration for cataract removal.
- Recommend polypharmacy assessment with special consideration to sedatives, antidepressants, and drugs affecting the central nervous system; recommend evaluation for orthostatic hypotension and irregular heartbeats; and recommend vitamin D supplementation 800 IU per day (Barclay, 2011).

Home Care

- ▲ Obtain referral for OT and PT to teach home exercises and balance as well as fall prevention and recovery. They also evaluate for potential modifications such as an entry ramp, elevated toilet seat/toilevator (raised base under toilet), tub seat or shower chair, need for shower stall with built-in seat or wheel-in shower stall without a curb/threshold, handheld flexible shower head, lever-type facets, pull-out drawers with loop handles versus cupboards, standing lift, and so on. **CEB:** *Petersson et al (2008) reported study subjects self-ratings for everyday life, especially in terms of safety and less difficulty in the bathroom and transfers in/out of the home, increased after home modifications.*
- Assess for adequate lighting and hazards such as throw/area rugs, clutter, cords, and unfitted bedspreads. Suggest safe floor surfaces, such as use of adhesive nonslip strips in tubs/thresholds/areas where floor height changes; removal of wax from slippery floors; and installing low-pile carpet/nonglazed or nonglossy tiles/wood/linoleum coverings. Stress relocating commonly used items to shelves/drawers in reach, applying remote controls to appliances, and optimizing furniture placement for function, maneuverability, and stability. *Barrier removal promotes safety and accessibility; steady furniture can be used to steady or pull oneself up with if a fall occurs (Petersson et al, 2008).*
- Nurses can provide further safety assessments by suggesting installing hand rails in bathrooms and by stairs, ensuring client's slippers and clothes fit properly, and recommending repairing or discarding broken equipment in the home (Taylor et al, 2011).
- ▲ Involve social worker or case manager to educate clients about potential assistive technology, financial cost and benefits, regulations of payers, and local resources. *Information helps clients understand options and cost of services and aids to make informed decisions.*
- ▲ Implement approaches for home care staff and family to safely handle and transfer clients. *Risk of injury is high because people often work alone, without mechanical aids or adjustable beds and in crowded spaces while giving care (Mayeda-Letourneau, 2014).*
- For further information, refer to care plans for Impaired physical **Mobility** and Impaired **Walking**.

Client/Family Teaching and Discharge Planning

- Assess for readiness to learn and use teaching modalities conducive to personal learning styles, including written instructions for home use.
- Supervise practice sessions in which client and family apply items such as gait belts, braces, and orthoses. Check skin once aids are removed. *Repetition reinforces motor learning for safety and sound skin integrity.*
- Teach and monitor client/family for consistent use of safety precautions for transfers (e.g., nonskid shoes, correctly placed equipment/chairs, locked brakes, leg rests swiveled away) and for correct performance of transfer or use of lifts/slings. *Promotes safety.*
- Teach client/family how to check brakes on chairs to ensure they engage and how to check tires for adequate air pressure; advise routine inspection and annual tune-up of devices. *Long-term use may loosen brakes or cause them to slip; brakes work only if they make sound contact with tire or wheel. Pneumatic tires must be adequately inflated.*
- Offer information on safe use of shower and commode chairs to prevent discomfort, pressure, and falls during transfer, transport, care, and hygiene.
- For further information, refer to the care plans for Impaired physical **Mobility**, Impaired **Walking**, and Impaired wheelchair **Mobility**.

Risk for Trauma *Julianne E. Doubet, BSN, RN, CEN, NREMT-P*

NANDA-I

Definition

Vulnerable to accidental tissue injury (e.g., wound, burn, fracture), which may compromise health

Risk Factors

External

Absence of call for aid device; absence of stairway gate; absence of window guard; access to weapon; bathing in very hot water; bed in high position; children riding in front seat of car; defective appliance; delay in ignition of gas appliance; dysfunctional call for aid device; electrical hazard (e.g., faulty plug, frayed wire, overloaded outlet/fuse box; exposure to corrosive product; exposure to dangerous machinery; exposure to radiation; exposure to toxic chemical; extremes of environmental temperature; flammable object (e.g., clothing, toys); gas leak; grease on stove; high crime neighborhood; icicles hanging from roof; inadequate stair rails; inadequately stored combustible (e.g., matches, oily rags); inadequately stored corrosive (e.g., lye); insufficient lighting; insufficient protection from heat source; misuse of headgear (e.g., hard hat, motorcycle helmet); misuse of seat restraint; insufficient anti-slip material in bathroom; nonuse of seat restraints; obstructed passageway; playing with dangerous object; playing with explosive; pot handle facing front of stove; proximity to vehicle pathway (e.g., driveway, railroad track); slippery floor; smoking in bed; smoking near oxygen; struggling with restraints; unanchored electric wires; unsafe operation of heavy equipment (e.g., excessive speed while intoxicated with required eyewear); unsafe road; unsafe walkway; use of cracked dishware; use of throw rugs; use of unstable chair; use of unstable ladder; wearing loose clothing around open flame

Internal

Alteration in cognitive functioning; alteration in sensation (e.g., resulting from spinal cord injury, diabetes mellitus); decrease in eye-hand coordination; decrease in muscle coordination; economically disadvantaged; emotional disturbance; history of trauma (e.g., physical, psychological, sexual); impaired balance; insufficient knowledge of safety precautions; insufficient vision; weakness

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Risk Control; Fall Prevention Behavior

Example NOC Outcome with Indicators

Accomplishes **Risk Control** as evidenced by the following indicators: Acknowledges risk/Develops effective risk-control strategies/Follows selected risk control strategies. (Rate the outcome and indicators of **Risk Control**: 1 = never demonstrated; 2 = rarely demonstrated; 3 = sometimes demonstrated; 4 = often demonstrated; 5 = consistently demonstrated [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

- Remain free from trauma
- Explain actions that can be taken to prevent trauma

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Environmental Management: Safety; Skin Surveillance

Example NIC Activities—Environmental Management

Provide family/significant other with information about making home environment safe for client; Remove harmful objects from the environment

Nursing Interventions and Rationales

- Provide vision aids for visually impaired clients. **EB**: *Low-vision rehabilitation enables people to restart and/or maintain the capability of performing the tasks of daily living (Virgili et al, 2013).* **EB**: *This study proposes that a person with diagnosed visual impairments might again have enhanced independence and a better quality of life after rehabilitative efforts using visual aids and training, to restore reading abilities and improve orientation (Trauzettel-Klosinski, 2012).*
- Assist the client with ambulation. Encourage the client to use assistive devices in activities of daily living (ADLs) as needed. **EB**: *Studies reviewed by Edelstein (2013) have shown the advantages—if used correctly—of employing time-honored assistive devices (e.g., crutches, walker).*
- Evaluate client's risk for burn injury. **EBN**: *Grant (2013) states that the very young and the elderly are at an increased risk for burn injuries when compared with any other age group.* **EBN**: *It is apparent to Goodarzi et al (2014) in their research that there is a continuing need for further safety education and the utilization of environmental safety measures to reduce burn trauma.*
- Assess the client for causes of impaired cognition. **EB**: *Adults with intellectual disabilities are likely to have an elevated risk for traumatic injury in comparison to the general populace (Finlayson et al, 2014).*
- Provide assistive devices in the home. **EB**: *Those who are disabled should have access to assistive technology devices and services, so as to continue their inclusion and participation in society (Office of Special Education and Rehabilitative Service, Department of Education, 2014).* **EBN**: *According to Johnston et al (2014), shared conclusions between the health care giver and the client with disabilities allows the client to choose the best assistive devices and services that are vital to achieving their goals of education, community living, and employment, among others.*
- ▲ Question the client concerning his/her sense of safety. **EB**: *Future functional decline in older adults may have a basis in their observations of neighborhood safety (Sun et al, 2012).* **EBN**: *In their study, Edwards et al (2014) state that clients who wish to remain at home at the end of life are at increased risk for trauma due to declining cognitive and/or physical capabilities, environmental dangers, and concerns with caregivers.*

- ▲ Assess for a substance abuse problem and refer to appropriate resources for drug and alcohol education. **EB:** According to *Choi et al (2014)*, older adults who abuse alcohol and/or illicit drugs should be sent to the most appropriate service that meets his/her needs, both for rehabilitation and any mental health challenges that may be involved. **EB:** Although drinking and driving among student drivers has declined in recent years, driving after the use of marijuana has increased; therefore, *O'Malley and Johnston (2013)* believe that more attention should be focused on preventing those under the influence of illicit drugs from driving.
- Review drug profile for potential side effects that may inhibit performance of ADLs. **EB:** Health care providers should assess systemic (e.g., cognition) or drug-specific characteristics such as side effects on a regular basis when dealing with the client on multiple medications (*Tsai et al, 2012*).
- See care plans for Risk for **Aspiration**, Risk for **Falls**, Impaired **Home** maintenance, Risk for **Injury**, Risk for **Poisoning**, and Risk for **Suffocation**.

Pediatric

- Assess the client's socioeconomic status. **CEB:** Pediatric clients living in poverty are at higher risk for injury (*Shenessa et al, 2004*). **EB:** The presently used evaluations that measure evidence of adverse childhood experiences (ACEs) may be insufficient to recognize the extent of adversity to which low-income urban children are exposed, so state *Wade et al (2014)*.
- Never leave young children unsupervised. **EB:** According to *van Beelen et al (2014)*, the death, disability, and loss of quality of life among young children is directly related to injuries that occur in the home. **EB:** "Drowning is a leading cause of child mortality globally," write *Morrongiello et al (2013)*; to reduce this risk, more strategies are necessary to include increased parental awareness of children's drowning risk and their need for adult supervision when swimming.
- Keep flammable and potentially flammable articles out of reach of young children. **EB:** Infants and toddlers who scald themselves by spilling hot liquids on themselves or touching irons and hair straighteners are a main cause for concern for targeted prevention (*Kemp et al, 2014*). **EBN:** *Hollywood and O'Neill (2014)* maintain that nurses working with children in hospitals, schools, and the community can connect with parents, families, school staff, and children to offer professional advice, plus health and safety guidance for burn prevention.
- Lock up harmful objects such as guns. **EB:** Easy access to firearms in the home is responsible for injury to thousands of children in the United States (*Barton & Kologi, 2014*). **EB:** There is an increased risk for childhood injury when firearms are left loaded and unlocked (*Schwebel et al, 2014*).

Geriatric

- Assess the geriatric client's cognitive level of functioning. **EB:** Because some disease processes (e.g., Alzheimer's, Parkinson's) alter the integrity of that part of the brain that controls communication and cognitive ability, it is important to focus on a cognitive assessment that would include the evaluation of attention, memory, and executive functioning capabilities (*Murray, 2012*). **EB:** *Patel et al (2014)* agree that the occurrence of neurocognitive disorders can be an obstacle to the capability of older adults to carry out ADLs and this deficit will continue to escalate with age.
- Assess for routine eye examinations. **EBN:** The older client may find it difficult to adjust to vision loss and aging, due to the psychological, functional, social, and health implications that play a significant role in the process (*Mac Cobb, 2013*). **EB:** *Addis et al (2013)* maintain that vision loss in older adults due to cataracts, glaucoma, and/or stroke threaten their independence and may be a defining moment in their lives.
- Perform a home safety assessment and recommend the following preventive measures: keep electrical cords out of the flow of traffic; remove small rugs or make sure they are slip resistant; increase lighting in hallways and other dark areas; place a light in the bathroom; keep towels, curtains, and other items that might catch fire away from the stove; store harmful products away from food products; provide at least one grab bar in tubs and showers; check prescribed medications for appropriate labels; store medications in original containers or in a dispenser of some type (e.g., egg carton, 7-day plastic dispenser). If the client cannot administer medications according to directions, secure someone to administer medications. Mark stove knobs with bright colors (yellow or red) and outline the borders of steps. **EB:** The capability of older adults to use a home appliance depends on the client's comprehension of the appliance's operation (*Soares et al, 2012b*). **EBN:** As part of a person-centered, evidenced-based approach, a professional case manager/care coordinator is able to perform a thorough assessment of the client's needs and will design and put into operation an all-inclusive care plan to meet the clinical, psychosocial, and environmental requirements of the client (*Johansson & Harkey, 2014*).

- Discourage driving at night. **EB:** *Driving is a complicated task, placing substantial demands on perceptual, cognitive, and motor capabilities, so it would seem that age-related decreases in these capabilities are negatively reflected in driving performance (Soares et al, 2012a).* **EB:** *Gruber et al (2013) suggest that there is an increasing number of older adults who continue to drive, and the population of drivers who are affected by deteriorating night vision is increasing.*
- Encourage the client to participate in resistance and impact exercise programs as tolerated. **EB:** *Graham and Connolly (2013) found that exercise plans for older adults were more successful if the exercise is enjoyable and familiar to them: the program is also more successful if the exercise is connected to training and strategies that relate to chronic conditions and offer potential health benefits.* **EB:** *In their review of current evidence, Carvalho et al (2014) suggest that physical activity may not only aid in improving cognitive function in older adults, but also could play a part in delaying the development of cognitive impairment in the older adult.*

Client/Family Teaching and Discharge Planning

- Educate the family regarding age-appropriate child safety precautions, environmental safety precautions, and intervention in an emergency. **EB:** *Safety education for parents of young children is essential in the prevention of accidental injuries in and/or around the home (van Beelen et al, 2013).* **EB:** *In their study, Morrongiello et al (2014) found that to decrease a child's risk of harm, the child must first understand the safety issue.*
- Teach the family to assess the child care provider's knowledge regarding child safety. **EB:** *Home safety interventions not only aid in reducing children's injuries, but also enhance the general safety of the home (Kendrick et al, 2013).*
- Educate the client and family regarding helmet use during recreation and sports activities. **EB:** *This study states that helmet use decreases bicycle-related head injuries, especially in single vehicle crashes and those in which the head strikes the ground (Owen et al, 2011).* **EB:** *It has been proven time and time again that wearing a bicycle helmet has averted or reduced the risk of serious head injuries (Basch et al, 2014).*
- Encourage the proper use of car seats and safety belts. **EB:** *Health care professionals who care for children must make every effort to impart to the child's caregiver the importance of using the size-appropriate restraint for every child on every trip (Macy et al, 2012).* **EB:** *Himle and Wright (2014) state that child passenger safety restraint, when used correctly, can diminish the risk of serious injury and/or death in motor vehicle crashes.*
- Teach parents to restrict driving for teens. **EB:** *Williams and Tefft (2013) found that in most fatal teen crashes, the passengers were the same sex and about the same age as the driver: risk factors include speeding, alcohol use, late-night driving, lack of a valid license, seat belt non-use, and multiple passengers.* **EB:** *According to Taubman et al (2014), research studies have shown that parents are the most important influence on young people's driving conduct.*
- Teach parents the importance of monitoring children after school. **EB:** *In a study by Freisthler et al (2014), children who are not supervised appropriately, either by inattentive parents and/or caregivers, could be considered neglected.* **EB:** *It is important to monitor teens' activities and behaviors, so that they have assistance in making important decisions (Cox et al, 2014).*
- Teach firearm safety. **EB:** *According to Schwebel et al (2014), firearms in the home that are loaded and unlocked are sources of increased risks for trauma.* **EB:** *Health care professionals must have knowledge and skills to address safe gun ownership in older adults (Pinholt et al, 2014).*
- For further information, refer to care plans for Risk for **Aspiration**, Risk for **Falls**, Impaired **Home** maintenance, Risk for **Injury**, Risk for **Poisoning**, and Risk for **Suffocation**.

List of Nursing Diagnoses by Letter: U

Unilateral Neglect	Impaired Urinary elimination	Readiness for enhanced Urinary elimination
Urinary Retention		

Unilateral Neglect *Lori M. Rhudy, PhD, RN, CNRN, ACNS-BC*

NANDA-I

Definition

Impairment in sensory and motor response, mental representation, and spatial attention of the body and the corresponding environment characterized by inattention to one side and overattention to the opposite side; left-side neglect is more severe and persistent than right-side neglect

Defining Characteristics

Alteration in safety behavior on neglected side; disturbance of sound lateralization; failure to dress neglected side; failure to eat food from portion of plate on neglected side; failure to groom neglected side; failure to move eyes in the neglected hemisphere; failure to move head in the neglected hemisphere; failure to move limbs in the neglected hemisphere; failure to move trunk in the neglected hemisphere; failure to notice people approaching from the neglected side; hemianopia; impaired performance on line cancellation, line bisection, and target cancellation tests; left hemiplegia from cerebrovascular accident; marked deviation of the eyes to stimuli on the non-neglected side; marked deviation of the trunk to stimuli on the non-neglected side; omission of drawing on the neglected side; perseveration; representational neglect (e.g., distortion of drawing on the neglected side; substitution of letters to form alternative words when reading; transfer of pain sensation to the non-neglected side; unaware of positioning of neglected limb; unilateral visuospatial neglect; use of vertical half of page only when writing

Related Factors (r/t)

Brain injury (e.g., cerebrovascular impairment, neurological illness, trauma, tumor)

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Body Image; Body Positioning: Self-Initiated; Mobility; Self-Care: Activities of Daily Living (ADLs)

Example NOC Outcome with Indicators

Mobility as evidenced by the following indicators: Balance/Coordination/Gait/Muscle movement. (Rate the outcome and indicators of **Mobility**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see [Section I](#)].)

U

Client Outcomes

Client Will (Specify Time Frame)

- Use techniques that can be used to minimize unilateral neglect
- Care for both sides of the body appropriately and keep affected side free from harm
- Return to the highest functioning level possible based on personal goals and abilities
- Remain free from injury

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Unilateral Neglect Management

Example NIC Activities—Unilateral Neglect Management

Ensure that affected extremities are properly and safely and positioned; Rearrange the environment to use the right or left visual field

Nursing Interventions and Rationales

- Assess the client for signs of unilateral neglect (UN; e.g., not washing, shaving, or dressing one side of the body; sitting or lying inappropriately on affected arm or leg; failing to respond to environmental stimuli contralateral to the side of lesion; eating food on only one side of plate; or failing to look to one side of the body). *Many tests for UN exist, but there is no consensus about which is the most valid. Joint assessments of UN that include both clinical observation and precise testing perform better than either used alone (Jepson et al, 2008).* **EB:** *There is no difference in gender and UN in a sample of 155 women and 157 men with acute stroke (Kleinman et al, 2008).* **EB:** *UN was identified in 70 of 71 clients using National Institutes of Health Stroke Scale (NIHSS).*
- ▲ Collaborate with health care provider for referral to a rehabilitation team (including, but not limited to, rehabilitation clinical nurse specialist, physical medicine and rehabilitation health care provider, neuropsychologist, occupational therapist, physical therapist, and speech and language pathologist) for continued help in dealing with UN. **EB:** *There is some evidence that rehabilitation for unilateral spatial neglect using tools such as visual scanning and prism adaptation improves performance, but its effect on disability is not clear. Further studies are needed (Ting et al, 2011).*
- Use the principles of rehabilitation to progressively increase the client's ability to compensate for UN by using assistive devices, feedback, and support. **EB:** *Studies demonstrate that recovery from UN generally occurs in first 4 weeks after stroke with much more gradual recovery after that (Osawa & Maeshima, 2009).*
- Set up the environment so that essential activity is on the unaffected side:
 - Place the client's personal items within view and on the unaffected side.
 - Position the bed so that client is approached from the unaffected side.
 - Monitor and assist the client to achieve adequate food and fluid intake.

Helps in focusing attention and aids in maintenance of safety.

- Implement fall prevention interventions. Clients with right hemisphere brain damage are twice as likely to fall as those with left hemisphere damage (Jepson et al, 2008).
- Position affected extremity in a safe and functional manner. **EB:** *A study found that clients with UN had higher rates of shoulder-hand complications than those without UN (Wee & Hopman, 2008).* **EB:** *Clients with neglect had significantly lower FIM (functional independence measure) motor scores than those with aphasia (Gialanella & Ferlucci, 2010).*
- Teach the client to be aware of the problem and modify behavior and environment. **EB:** *Awareness of the environment decreases risk of injury. There is some evidence that use of scanning techniques may decrease visual neglect (Ting et al, 2011).*

Home Care

- Many of the previously listed interventions may be adapted for use in the home care setting.
- Position bed at home so that client gets out of bed on unaffected side. *Positioning the bed so that the client gets out on the unaffected side can increase safety.*

Client/Family Teaching and Discharge Planning

- Engage discharge planning specialists for comprehensive assessment and planning early in the client's stay. **EB:** *A study demonstrated that clients with UN have longer length of stay and less likelihood of discharge to home than subjects without UN (Cumming et al, 2009).*
- Encourage family participation in care and exercise. **EB:** *UN improved in clients who participated in exercise training with their family members (Osawa & Maeshima, 2009).*
- Explain pathology and symptoms of unilateral neglect to both the client and family.
- Teach the client how to scan regularly to check the position of body parts and to regularly turn head from side to side for safety when ambulating, using a wheelchair, or doing self-care tasks.
- Reinforce the client's use of adaptive devices such as prisms prescribed by rehabilitation professionals (Shiraishi et al, 2008).
- Teach caregivers to cue the client to the environment.

Impaired Urinary elimination

Michelle Acorn, DNP, NP PHC-Adult, BA, BScN/PHCNP, MN/ACNP, ENC(C), GNC(C), CAP, CGP, and Betty J. Ackley, MSN, EdS, RN

NANDA-I

Definition

Dysfunction in urine elimination

Defining Characteristics

Dysuria; frequent voiding; hesitancy; nocturia; urinary incontinence; urinary retention; urinary urgency

Related Factors

Anatomic obstruction; multiple causality; sensory motor impairment; urinary tract infection (UTI)

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Urinary Elimination

Example NOC Outcome with Indicators

Urinary Elimination as evidenced by the following indicators: Urine clarity/urine odor, fluid intake, pain with urination. (Rate the outcome and indicators of **Urinary Elimination**: 1 = severely compromised 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- State absence of pain or excessive urgency during urination
- Demonstrate voiding frequency no more than every 2 hours

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Urinary Elimination Management

Example NIC Activities—Urinary Elimination Management

Monitor urinary elimination, including frequency, consistency, odor, volume, and color, as appropriate; Teach client signs and symptoms of UTI

Nursing Interventions and Rationales

- Ask the client about urinary elimination patterns and concerns. *Urinary elimination problems have many presenting signs and symptoms. Asking the client questions may help understand the subtle signs and symptoms associated with urinary elimination (Mayo Clinic, 2012).*
- Question the client regarding the following:
 - Presence of symptoms such as incontinence, dribbling, frequency, urgency, dysuria, and nocturia
 - Presence of pain in the area of the bladder
 - The pattern of urination and approximate amount
 - Possible aggravating and alleviating factors for urinary problems
- Ask the client to keep a bladder diary/bladder log. **EB:** *Use of a bladder diary may reduce client discrepancies in recall and is a valuable tool for assessment; short (24-hour) duration of the bladder diary may yield inadequate data, and excessive diary duration reduces compliance (Bright et al, 2011).*
- For interventions on urinary incontinence, refer to the following nursing diagnosis care plans as appropriate: Stress urinary **Incontinence**, Urge urinary **Incontinence**, Reflex urinary **Incontinence**, Overflow urinary **Incontinence**, or Functional urinary **Incontinence**.
- ▲ Perform a focused physical assessment including inspecting the perineal skin integrity, percussion, and palpation of the lower abdomen looking for obvious bladder distention or an enlarged kidney. *A palpable kidney or bladder provides direct evidence of a dilated urinary collection system (Policastro et al, 2014).* If signs of urinary obstruction are present, refer client to a urologist. *Unrelieved obstruction of urine can result in renal damage, and if severe, renal failure (Policastro et al, 2011).* Refer to the nursing care plan for **Urinary Retention** if retention is present.
- ▲ Check for costovertebral tenderness. *Costovertebral tenderness is seen with pyelonephritis and kidney stones (Gupta & Trautner, 2011).*
- ▲ Review results of urinalysis for the presence of urinary infection: white blood cells, red blood cells, bacteria, positive nitrites. If urinalysis results are not available, request a midstream specimen of urine (urine obtained during voiding, discarding the first and last portions) for a urinalysis (Norrby, 2011).
- ▲ If blood or protein is present in the urine, recognize that both hematuria and proteinuria are serious symptoms, and the client should be referred to a urologist to receive a workup to rule out pathology.
- Inquire about the client's history of smoking. **EB:** *Smoking and bladder symptoms in women found that urgency and frequency are three times more common among current than never smokers. Parallel associations suggest dose-related response associations. Nocturia and stress urinary incontinence (SUI) are not associated with smoking. Smoking cessation recommended (Tahtinen et al, 2011).*

Urinary Tract Infection

- ▲ Consult the provider for a culture and sensitivity testing and antibiotic treatment in the individual with evidence of a symptomatic UTI. *UTI is a transient, reversible condition that is usually associated with urgency or urge urinary incontinence (Norrby, 2011).* Eradication of UTI will alleviate or reverse symptoms of suprapubic pressure and discomfort, urgency, daytime voiding frequency, and dysuria (Norrby, 2011).
- ▲ Teach the client to recognize symptoms of UTI: dysuria that crescendos as the bladder nears complete evacuation; urgency to urinate followed by micturition of only a few drops; suprapubic aching discomfort; malaise; voiding frequency; sudden exacerbation of urinary incontinence with or without fever, chills, and flank pain. Recognize that a cloudy or malodorous urine, in the absence of other lower urinary tract symptoms, may not indicate the presence of a UTI and that asymptomatic bacteriuria in the older adult does not justify a course of antibiotics. *Asymptomatic bacteriuria may be associated with cloudy or malodorous urine, but these signs alone do not justify antimicrobial therapy when balanced against the potential adverse effects of treatment, including adverse side effects of the various antibiotics and encouragement of colonization of the urine with antibiotic-resistant bacterial strains (Ariathianto, 2011; Norrby, 2011).*
- ▲ Refer the individual with chronic lower urinary tract pain to a urologist or specialist in the management of pelvic pain. *Bladder pain and storage symptoms, in the absence of an acute urinary infection, may indicate the presence of interstitial cystitis, a chronic condition requiring ongoing treatment (Interstitial Cystitis Association, 2015).*

Geriatric

- ▲ Perform urinalysis in all older adults who experience a sudden change in urine elimination patterns such as new-onset incontinence, lower abdominal discomfort, acute confusion, or a fever of unclear origin. *Older adults often experience atypical symptoms with a UTI or pyelonephritis (Nazarko, 2009).*
- Encourage older women consume one to two servings of fresh blueberries and consider drinking at least 10 oz of cranberry juice daily or supplement the diet with cranberry concentrate capsules as ordered. **EB:** *While the evidence supporting the consumption of cranberry juice or tablets to reduce UTIs is inconclusive (Jepson et al, 2012), some evidence does suggest that the consumption of 8 to 10 oz of cranberry juice, ascorbic acid (vitamin C) supplement, or an equivalent portion of foods containing whole cranberries or blueberries exerts a bacteriostatic effect on Escherichia coli, the most common pathogen associated with urinary infection among community-dwelling adult women (Masson et al, 2009; Aydin et al, 2014).*
- ▲ Refer the older woman with recurrent UTIs to her health care provider for possible use of topical estrogen creams for treatment of atrophic vaginal mucosa from decreased hormonal stimulation, which can predispose to UTIs (Buhr et al, 2011; Norrby, 2011; Aydin et al, 2014).
- ▲ Recognize that UTIs in older men are typically associated with prostatic hyperplasia or strictures of the urethra. Refer to a urologist (Norrby, 2011).

Client/Family Teaching and Discharge Planning

- Teach the client/family methods to keep the urinary tract healthy. Refer to Client/Family Teaching in the care plan for Readiness for enhanced **Urinary** elimination.
- Teach the following measures to women to decrease the incidence of UTIs:
 - Urinate at appropriate intervals. Do not ignore need to void, which can result in stasis of urine.
 - Drink plenty of liquids, especially water. *Drinking water helps dilute the urine, allowing bacteria to be flushed from the urinary tract before an infection can begin (Norrby, 2011).*
 - Wipe from front to back. *This helps prevent bacteria in the anal region from spreading to the vagina and urethra.*
 - Wear underpants that have a cotton crotch. *This allows air to circulate in the area and decreases moisture in the area, which predisposes to infection.*
 - Avoid potentially irritating feminine products. *Using deodorant sprays, bubble baths, or other feminine products, such as douches and powders, in the genital area can irritate the urethra. There are multiple common sense measures that can be used to decrease the incidence of UTIs (Gupta & Trautner, 2011; Mayo Clinic, 2012).*
- Teach the sexually active woman with recurrent UTIs prevention measures including:
 - Void after intercourse to flush bacteria out of the urethra and bladder.
 - Use a lubricating agent as needed during intercourse to protect the vagina from trauma and decrease the incidence of vaginitis.
 - Watch for signs of vaginitis and seek treatment as needed.
 - Avoid use of diaphragms with spermicide.

Sexually active women have the highest incidence of UTIs (Norrby, 2011). The vagina and periurethral area can become colonized with organisms from the intestinal flora, such as E. coli, and increase the risk for UTIs (Gupta & Trautner, 2011).

- Teach clients with spinal cord injury and neurogenic bladder dysfunction to consider adding cranberry extract tablets or cranberry juice, or fruits containing D-mannose (e.g., apples, oranges, peaches, blueberries) on a daily basis, monitor fluid intake. The client is encouraged to discuss the use of probiotics and antibiotic therapy with the provider for frequent recurrent symptomatic UTIs. **EB:** *Limited evidence suggests that clients who regularly consume cranberry extract tablets experience fewer UTIs than clients who do not routinely consume cranberry extract tablets (Hess et al, 2008; Jepson et al, 2012; Keifer, 2013; Shmueli, 2012; Barbosa-Cesnik et al, 2011). Additionally, clients with spinal cord injury and neurogenic bladder dysfunction are at higher risk for UTI, and more frequent monitoring of symptomatic infection is necessary (Goetz & Klausner, 2014).*
- Teach all persons to recognize hematuria and to promptly seek care if this symptom occurs.

Readiness for enhanced Urinary elimination

Michelle Acorn, DNP, NP PHC-Adult, BA, BScN/PHCNP, MN/ACNP, ENC(C), GNC(C), CAP, CGP, and Betty J. Ackley, MSN, EdS, RN

NANDA-I

Definition

A pattern of urinary functions for meeting eliminatory needs, which can be strengthened

Defining Characteristics

Expresses desire to enhance urinary elimination

NOC

(Nursing Outcomes Classification)

Suggested NOC Outcome

Urinary Elimination

Example NOC Outcome with Indicators

Urinary Elimination as evidenced by the following indicators: Urine clarity/urine odor, fluid intake, pain with urination. (Rate the outcome and indicators of **Urinary Elimination**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Urinate every 3 to 4 hours while awake
- Remain free of undetected symptoms of a urinary tract infection (UTI) or cancer of the kidney or bladder
- Drink fluids at a sufficient level to have light yellow (e.g., straw-colored) urine

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Urinary Elimination Management

Example NIC Activities—Urinary Elimination Management

Monitor urinary elimination, including frequency, consistency, odor, volume, and color, as appropriate; Teach client signs and symptoms of UTI

Nursing Interventions and Rationales

- Ask the client questions regarding any bothersome or concerning urinary symptoms such as frequency, nocturia, urgency, dysuria, or retention of urine.
- Question the client regarding presence of incontinence. If incontinence is present, refer to the appropriate care plan: Stress urinary **Incontinence**, Urge urinary **Incontinence**, Functional urinary **Incontinence**, or Reflex urinary **Incontinence**.
- Question the client regarding history of urinary tract infections UTIs. If the client has had UTIs in the past, provide teaching for prevention as outlined in the care plan for Impaired **Urinary** elimination.
- Ask the client to complete a bladder diary of diurnal and nocturnal urine elimination patterns and patterns of urinary leakage. **CEB:** *A study demonstrated that women overestimated daytime urinary frequency from recall. Use of a bladder diary results in increased accuracy of reporting of bladder symptoms (Stay et al, 2009).*

Pediatric

- Encourage children and adolescents to maintain normal weight because obesity has been related to cancers of the urinary tract. **EB:** *A large study found an increase in cancer of the bladder, ureter, and renal pelvis in adolescents who were obese at the age of 17 and developed cancer years later (Leiba et al, 2012). Refer to care plan for **Obesity and Overweight**.*

Geriatric

- Encourage older women to consume one to two servings of fresh blueberries and consider drinking at least 10 oz of cranberry juice daily or supplement the diet with cranberry concentrate capsules as ordered. **EB:** *While the evidence supporting the consumption of cranberry juice or tablets to reduce UTIs is inconclusive (Jepson et al, 2012), some evidence does suggest that the consumption of 8 to 10 oz of cranberry juice, ascorbic acid (vitamin C) supplement, or an equivalent portion of foods containing whole cranberries or blueberries exerts a bacteriostatic effect on Escherichia coli, the most common pathogen associated with urinary infection among community-dwelling adult women (Masson et al, 2009; Aydin et al, 2014).*
- Older adults with toileting disability have increased care costs and dependency. *Prevention efforts include physical activity programs targeting impairments with walking, standing, sitting, stooping, reaching, and grasping. Therapy should improve dressing, bathing, and transferring skills (Tally et al, 2014).*

Client/Family Teaching and Discharge Planning

- Teach the client general guidelines for health of the urinary system:
 - ▲ Ensure good hydration. Total daily fluid intake should be approximately 2.7 L per day for women and 3.7 L per day for men (Newman & Willson, 2011). *Adequate fluid helps wash out bacteria from the urethra to prevent UTIs, helps prevent kidney stones, and potentially protects the client from development of cancer of the bladder from exposure to carcinogens concentrated in the urine (Newman & Willson, 2011).*
 - ▲ Recommend the client have a physical exam, a metabolic panel of laboratory tests, and a urinalysis done yearly. *A urinalysis includes tests for red blood cells and white blood cells, which can help identify cancer of the bladder and infection in the urinary tract, respectively. The urinalysis also includes testing for proteinuria, which can be found with damage to the kidney. The metabolic panel includes tests of blood urea nitrogen and serum creatinine, which, if elevated, indicate that the client has early kidney damage (Lin & Denker, 2011).*
 - ▲ Recommend that the client not hold urine for long periods of time before emptying the bladder. It is normal to urinate every 3 to 4 hours. *Stasis of urine in the bladder leads to an increased chance of a UTI*

and may predispose to stone formation (Seifert, 2011). NOTE: Health care professionals frequently are busy with clients and forget or ignore the urge to urinate. This can predispose individuals to UTIs.

- ▲ Recommend that the client with frequency, urgency in the morning, or possible incontinence consider reducing or eliminating caffeine intake.
- If the client has constipation at intervals, share measures to alleviate or prevent constipation, including adequate consumption of dietary fluids, dietary fiber, exercise, and regular bowel elimination patterns. *Constipation predisposes the individual to urinary retention and increases the risk for UTI. See care plan for Constipation.*
- Advise clients to stop smoking because of the association with damage to the kidney and bladder, including chronic kidney disease, bladder cancer, urinary incontinence, and bothersome lower urinary tract symptoms in men. *Smoking is a known risk factor for chronic kidney disease (Rezonzew et al, 2012). CEB: Smoking may increase the severity and risk of urinary incontinence, and it is clearly linked with an increased risk for bladder cancer (Lodovici & Bigagli, 2009). EB: Smoking and bladder symptoms in women found that urgency and frequency are three times more common among current smokers than never smokers. Parallel associations suggest dose-related response associations. Nocturia and symptomatic UTI are not associated with smoking. Smoking cessation recommended (Tahtinen et al, 2011).*
- ▲ Encourage the client to eat a healthy diet, avoiding processed meats, with sodium nitrate as a preservative, to decrease incidence of cancer of the bladder. *EB: A study demonstrated that people who ate more processed meats had an increased risk for development of cancer of the bladder (Wu et al, 2012).*

Urinary Retention

Michelle Acorn, DNP, NP PHC-Adult, BA, BScN/PHCNP, MNI/ACNP, ENC(C), GNC(C), CAP, CGP, and Betty J. Ackley, MSN, EdS, RN

NANDA-I

Definition

Incomplete emptying of the bladder

Defining Characteristics

Absent urinary output; bladder distention; dribbling of urine; dysuria; frequent voiding; overflow incontinence; residual urine; sensation of bladder fullness; small voiding

Related Factors

Blockage in urinary tract; high urethral pressure; reflex arc inhibition; strong sphincter

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

NOC (Nursing Outcomes Classification)**Suggested NOC Outcome**

Urinary Elimination

Example NOC Outcome with Indicators

Urinary Elimination as evidenced by the following indicators: Empties bladder completely/Absence of urinary leakage/ Urine clarity. (Rate the outcome and indicators of **Urinary Elimination**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

- Demonstrate consistent ability to urinate when desire to void is perceived
- Have measured urinary residual volume of less than 200 to 250 mL
- Experience correction or relief from dysuria, nocturia, postvoid dribbling, and voiding frequently
- Be free of a urinary tract infection

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Urinary Catheterization; Urinary Retention Care

Example NIC Activities—Urinary Retention Care

Perform a comprehensive urinary assessment focusing on incontinence (e.g., urinary output, urinary voiding pattern, cognitive function, and preexistent urinary problems); Use the power of suggestion by running water or flushing toilet

Nursing Interventions and Rationales

- Obtain a focused urinary history including questioning the client about episodes of acute urinary retention (complete inability to void) or chronic retention (documented elevated postvoid residual volumes), as well as symptoms such as dysuria, nocturia, postvoid dribbling, and voiding frequently. *A history of difficulty voiding, pain, infection, or decreased urine volume is common in clients with urinary obstruction (Seifter, 2012).*
- Question the client concerning specific risk factors for urinary retention including:
 - Spinal cord injuries
 - Ischemic stroke
 - Metabolic disorders such as diabetes mellitus, chronic alcoholism, and related conditions associated with polyuria and peripheral polyneuropathies
 - Herpetic infection
 - Heavy-metal poisoning (lead, mercury) causing peripheral polyneuropathies
 - Advanced stage human immunodeficiency virus (HIV) infection
 - Medications including antispasmodics/parasympatholytics, alpha-adrenergic agonists, antidepressants, sedatives, narcotics, psychotropic medications, illicit drugs
 - Recent surgery requiring general or spinal anesthesia
 - Vaginal delivery within the past 48 hours
 - Bowel elimination patterns, history of fecal impaction, encopresis
 - Recent surgical procedures
 - Recent prostatic biopsy

Urinary retention is related to multiple factors affecting either detrusor contraction strength or urethral resistance to urinary outflow (Policastro et al, 2011).

- Complete a pain assessment including pain intensity using a self-report pain tool, such as the 0 to 10 numerical pain rating scale. Also determine location, quality, onset/duration, intensity, aggravating/

alleviating factors, and effects of pain on function and quality of life. *Acute onset of obstruction with inability to void is associated with significant pain; partial obstruction causes minimal pain, which may delay diagnosis (Policastro et al, 2011). Bladder distention is associated with pain overlying the bladder (Seifter, 2012).*

- Perform a focused physical assessment including perineal skin integrity and inspection, percussion, and palpation of the lower abdomen, looking for obvious bladder distention or an enlarged kidney. *A palpable kidney or bladder provides direct evidence of a dilated urinary collection system (Policastro et al, 2011).*
- Recognize that unrelieved obstruction of urine can result in kidney damage and, if severe, kidney failure. Urinary retention can be a medical emergency and should be reported to the primary provider as soon as possible. **EB:** *As urine backs up in the urinary tract, the pressure increases inside the ureters, which results in pressure on the nephrons, damaging the nephrons and decreasing glomerular blood flow (Policastro et al, 2011).*
- Review laboratory test results including serum electrolytes, blood urea nitrogen (BUN) and creatinine, along with calcium, phosphate, magnesium, uric acid, and albumin. *Serum electrolytes (sodium, potassium, chloride, bicarbonate, BUN, creatinine) as well as calcium, phosphate, magnesium, uric acid, and albumin should be measured. Elevations of BUN and creatinine and changes in electrolytes may be caused by kidney failure secondary to obstruction (Policastro et al, 2011).*
- Monitor for signs of dehydration, peripheral edema, elevating blood pressure, and heart failure. *The kidney can develop concentrating defects associated with partial obstruction of urine flow, resulting in symptoms that indicate kidney insufficiency (Policastro et al, 2011).*
- Ask the client to complete a bladder diary including patterns of urine elimination, urine loss (if present), nocturia, and volume and type of fluids consumed for a period of 3 to 7 days. **CEB:** *A study demonstrated that women overestimated daytime urinary frequency from recall. Use of a bladder diary results in increased accuracy of reporting of bladder symptoms (Stav et al, 2009).*
- Consult with the provider concerning eliminating or altering medications suspected of producing or exacerbating urinary retention. **CEB:** *Observational studies suggest that medications may play a role in approximately 10% of all cases of urinary retention. The most commonly implicated drug classes include antipsychotics, antidepressants, anticholinergic respiratory agents, opioid analgesics, alpha-adrenergic agonists, benzodiazepines, nonsteroidal antiinflammatory drugs, antimuscarinics, and calcium channel blockers (Verhamme et al, 2008).*
- Advise the male client with urinary retention related to benign prostatic hyperplasia (BPH) to avoid risk factors associated with acute urinary retention:
 - Avoid over-the-counter cold remedies containing a decongestant (alpha-adrenergic agonist) or antihistamine such as diphenhydramine that has anticholinergic effects.
 - Avoid taking over-the-counter dietary medications (frequently contain alpha-adrenergic agonists).
 - Discuss voiding problems with a health care provider before beginning new prescription medications.
 - After prolonged exposure to cool weather, warm the body before attempting to urinate.
 - Avoid overfilling the bladder by regular urination patterns and refrain from excessive intake of alcohol.

These modifiable factors predispose the client to acute urinary retention by overdistinging the bladder and decreasing muscle contraction (Mayo Clinic, 2011).

- Advise the client who is unable to void specific strategies to manage this potential medical emergency as follows:
 - Attempt urination in complete privacy.
 - Place the feet solidly on the floor.
 - If unable to void using these strategies, take a warm sitz bath or shower and void (if possible) while still in the tub or shower.
 - Drink a warm cup of caffeinated coffee or tea to stimulate the bladder, which may promote voiding.
- If unable to void within 6 hours or if bladder distention is producing significant pain, seek urgent or emergency care. *Attempting urination in complete privacy and placing the feet solidly on the floor help relax the pelvic muscles and may encourage voiding. Warm water also stimulates the bladder and may produce voiding; the cooling experienced by leaving the tub or shower may again inhibit the bladder (Joanna Briggs Institute, 2013).*

- Perform sterile (in acute care) or clean intermittent catheterization at home as ordered for clients with urinary retention. Refer to care plan for Reflex urinary **Incontinence** for more information about intermittent catheterization.
- ▲ Insert an indwelling catheter only as ordered by a health care provider. Catheter-associated urinary tract infections (CAUTI) are among the most common health care–associated infections. Each CAUTI episode is estimated to cost \$600, rising to \$2800 per episode when a CAUTI leads to a bloodstream infection. While certain conditions among hospitalized clients may require the use of a urinary catheter, limiting their use and decreasing the length of use are the most effective methods of reducing clients’ exposure to CAUTIs ([Choosing wisely.org](http://Choosingwisely.org), 2014).
- Nurse-led and computer-based reminders are both successful in reducing how long urinary catheters remain in place ([Bernard et al, 2012](#)).
- Nurse-driven practice recommendations to reduce CAUTI risk include securing catheters, maintaining drainage bags lower than level of bladder, and emptying drainage bags every 8 hours, when two-thirds full and before any transfer, daily evaluation of catheter indication/need to promote removal, and use of bladder scanner to prevent reinsertion. **EB**: *Incorporating nurse-driven catheter practices was found to reduce catheter days, decrease length of hospital stay, increase use of bladder scanners, and decrease reinsertions* ([Oman et al, 2012](#)).
- Current practice recommendations support aseptic catheter insertions, while the use of hydrophilic-coated catheters for clean intermittent catheters can reduce the rate of CAUTIs. Suprapubic catheterization is not more effective than urethral catheterization in reducing the incidence of catheter-related bacteremia. **EB**: *Evidence does not support routine use of antimicrobial-impregnated catheters to prevent CAUTIs* ([Tenke et al, 2014](#); [Beattie et al, 2011](#)).
- For the individual with urinary retention who is not a suitable candidate for intermittent catheterization, recognize that the catheter can be a significant cause of harm to the client through development of a CAUTI or through genitourinary trauma when the catheter is pulled. *An indwelling catheter provides continuous drainage of urine; however, the risks for serious urinary complications, such as chronic CAUTIs, with prolonged use are significant.* **EB**: *One study found that the risk for genitourinary trauma was as common as symptomatic urinary tract infection when clients were repeatedly catheterized* ([Leuck et al, 2012](#)). **EBN**: *Indwelling urinary catheters are associated with up to 80% of hospital acquired CAUTIs. Appropriate use of bladder ultrasonography can reduce the rate of bladder damage as well as the need to use catheters. Incorporating bladder ultrasonography into the client’s assessment can lead to decreased use of urinary catheter and rate of CAUTIs, lower risk for spread of multiresistant gram-negative bacteria, and lower hospital costs* ([Johansson et al, 2013](#)).
- Advise clients with indwelling catheters that bacteria in the urine is an almost universal finding after the catheter has remained in place for more than 1 week and that only symptomatic infections warrant treatment. *The long-term indwelling catheter is inevitably associated with bacterial colonization, with formation of biofilm on the catheter surfaces* ([Norrby, 2011](#)). **CEB**: *Most bacteriuria does not produce significant infection, and attempts to eradicate bacteriuria often produce subsequent morbidity because resistant bacteria are encouraged to reproduce while more easily managed strains are eradicated. Intermittent catheterization was preferred in a rehabilitation setting because it improves client quality of life and diminishes the time required to recover spontaneous voiding with a postvoid residual volume less than 150 mL* ([Tang et al, 2006](#)).
- Use the following strategies to reduce the risk for CAUTI whenever feasible:
 - Insert the indwelling catheter with sterile technique, only when insertion is indicated.
 - Remove the indwelling catheter as soon as possible; acute care facilities should institute a policy for regular review of the necessity of an indwelling catheter.
 - Maintain a closed drainage system whenever feasible.
 - Maintain unobstructed urine flow, avoiding kinks in the tubing and keeping the collecting bag below the level of the bladder at all times.
 - Regularly cleanse the urethral meatus with a gentle cleanser to remove apparent soiling.
 - Change the long-term catheter every 4 weeks; more frequent catheter changes should be reserved for clients who experience catheter encrustation and blockage.
- Educate staff about the risks for CAUTI development and specific strategies to reduce these risks. **CEB**: *These strategies are supported by sufficient evidence to recommend routine use* ([Gould et al, 2010](#)). *Numerous nursing studies have demonstrated that nurse-controlled methods to decrease the length of catheterization such as chart reminders and computerized interventions lead to decreased incidences of CAUTI* ([Andriessen et al, 2012](#)).

Postoperative Urinary Retention

- Urinary retention is a common complication of surgery, anesthesia, and advancing age. If conservative measures do not help the client pass urine, the bladder needs to be drained using either an intermittent catheter or indwelling urethral catheter, which places the client at risk for development of CAUTI (Steggall et al, 2013). **CEB:** *Factors associated with an increased risk for postoperative urinary retention included preoperative voiding difficulty, advanced age, total amount of fluid replacement during a 24-hour postoperative period, type of anesthesia, pain management medications, and route and length of medication administration (Baldini et al, 2009).* **EBN:** *A study demonstrated increased urinary retention after trans-urethral resection of the prostate in clients with preoperative increased prostate size, urinary tract infection, and clot retention (McKinnon et al, 2011).*
- Remove the indwelling urethral catheter at midnight in the hospitalized postoperative client to reduce the risk for acute urinary retention. **CEB:** *Removal of indwelling catheters at midnight in clients undergoing urologic surgery offers several advantages over morning removal, including a larger initial voided volume and earlier hospital discharge with no increased risk for readmission compared with those undergoing morning removal (Griffiths et al, 2004).*
- Perform a bladder scan before considering inserting a catheter to determine postvoid residual volume following surgery. **EBN:** *A study demonstrated a significant decrease in the number of catheterizations when ultrasonic bladder scanning was done to monitor postoperative urinary retention (Cutright, 2011).* **CEB:** *Another study found that in hip fracture clients, use of bladder scanning and intermittent catheterization resulted in less retention after surgery than in clients in whom a retention catheter was inserted (Johansson & Christensson, 2010).* **CEB:** *A meta-analysis found that performing bladder scanning was effective in decreasing urinary catheterization and development of urinary tract infection (Palese et al, 2010).*

Geriatric

- Aggressively assess older clients, particularly those with dribbling urinary incontinence, urinary tract infection, and related conditions for urinary retention. **CEB:** *Older women and men may experience urinary retention with few or no apparent symptoms; a urinary residual volume and related assessments are necessary to determine the presence of retention in this population (Johansson & Christensson, 2010).*
- Assess older clients for impaction when urinary retention is documented or suspected. **CEB:** *Fecal impaction and urinary retention frequently coexist in older clients and, unless reversed, may lead to acute delirium, urinary tract infection, or renal insufficiency (Waardenburg, 2008).*
- Monitor older male clients for retention related to BPH or prostate cancer. *Prostate enlargement in older men increases the risk for acute and chronic urinary retention.*

Home Care

- Encourage the client to report any inability to void.
- Maintain an up-to-date medication list; evaluate side effect profiles for risk of urinary retention. *New medications or changes in dose may cause urinary retention.*
- Refer the client for health care provider evaluation if urinary retention occurs. *Identification of cause is important. Left untreated, urinary retention may lead to urinary tract infection or kidney failure.*

Client/Family Teaching and Discharge Planning

- Teach the client with mild to moderate obstructive symptoms to double void by urinating, resting in the bathroom for 3 to 5 minutes, and then trying again to urinate. *Double voiding promotes more efficient bladder evacuation by allowing the detrusor to contract initially and then rest and contract again (Mayo Clinic, 2011).*
- Teach the client with urinary retention and infrequent voiding to urinate by the clock. *Timed or scheduled voiding may reduce urinary retention by preventing bladder overdistention (Mayo Clinic, 2011).*
- Teach the client with an indwelling catheter to assess the tube for patency, maintain the drainage system below the level of the symphysis pubis, and routinely cleanse the bedside bag as directed.
- Teach the client with an indwelling catheter or undergoing intermittent catheterization the symptoms of a significant urinary infection, including hematuria, acute-onset incontinence, dysuria, flank pain, fever, or acute confusion.

Risk for Vascular Trauma

Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN

NANDA-I

Definition

Vulnerable to damage to vein and its surrounding tissues related to the presence of a catheter and/or infusion solutions, which may compromise health

Risk Factors

Difficulty visualizing artery or vein; inadequate anchoring of catheter; inappropriate catheter type; inappropriate catheter width; insertion site; irritating solution (e.g., concentration, temperature, pH); length of time catheter is in place; rapid infusion rate

NOC

(Nursing Outcomes Classification)

Suggested NOC Outcomes

Risk Control; Tissue Integrity: Skin and Mucous Membranes

• = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

List of Nursing Diagnoses by Letter: V

Risk for Vascular Trauma	Impaired spontaneous Ventilation	Dysfunctional Ventilatory weaning response
Risk for other-directed Violence	Risk for self-directed Violence	

Example NOC Outcome with Indicators

Accomplishes **Risk Control** as evidenced by the following indicators: Monitors environmental risk factors/Develops effective risk control strategies/Modifies lifestyle to reduce risk. (Rate the outcome and indicators of **Risk Control**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free from vascular trauma
- Remain free from signs and symptoms that indicate vascular trauma
- Remain free from impaired tissue and/or skin
- Maintain skin integrity, tissue perfusion, usual tissue temperature, color and pigment
- Report any altered sensation or pain
- State site is comfortable

NIC

(Nursing Interventions Classification)

Suggested NIC Interventions

Intravenous (IV) Therapy; Medication Administration: Intravenous

Example NIC Activities—Intravenous (IV) Therapy

Monitor intravenous flow rate and IV site during infusion; Perform IV site care according to agency protocol

Nursing Interventions and Rationales

Client Preparation

- ▲ Verify objective and estimate duration of treatment. Check health care provider's order. *Verify if client will remain hospitalized during the whole treatment or will go home with the device (Phillips, 2014).*
- Assess client's clinical situation when venous infusion is indicated. *Consider possible clinical conditions that cause changes in temperature, color, and sensitivity of the possible venous access site. Verify situations that alter venous return (e.g., mastectomy, stroke) (Phillips, 2014). The site of catheter insertion influences the risk of infection and phlebitis, such as preexisting catheters, anatomic deformity, and bleeding diathesis (Xue, 2014).*
- Assess if client is prepared for an intravenous (IV) procedure. Explain the procedure if necessary to decrease stress. *Stress may cause vasoconstriction that can interfere in the visualization of the vein and flow of the infused solution (Xue, 2014).*
- Provide privacy and make the client comfortable during the intravenous insertion. *Privacy and comfort help decrease stress (Phillips, 2014). The nurse should minimize discomfort to the client and utilize measures to reduce the fear, pain, and anxiety associated with intravenous insertion (Royal College of Nursing [RCN], 2010).*
- Teach the client what symptoms of possible vascular trauma he should be alert to and to immediately inform staff if any of these symptoms are noticed. *Prompt attention to adverse changes decreases chance of adverse effects from complications.*

Insertion

- Wash hands before and after touching the client, as well as when inserting, replacing, accessing, repairing, or dressing an intravascular catheter (O'Grady et al, 2011; Society for Health Care Epidemiology of America, 2014).
- Maintain aseptic technique for the insertion and care of intravascular catheters. *Using an approved anti-septic solution, wearing gloves during insertion of an intravenous catheter, and immediately covering the insertion site with a transparent sterile semipermeable dressing are important interventions to reduce the risk of infection (Xue, 2014; McGowan, 2014).*

- Assess the condition of the client's veins, possible age-related influence, and previous intravenous site use. *To minimize the risk of complications, thorough client assessment and careful catheter management are essential (McCallum & Higgins, 2012).*
- In cases of hard-to-access veins, consider strategies such as the use of ultrasound to assist in vein localization and safe venipuncture. *Ultrasound-guided cannulations have a high success rate in clients with difficult venous access (Elia et al, 2012).*
- Avoid areas of joint flexion or bony prominences. *Movement in these sites can cause mechanical trauma in veins (RCN, 2010; McGowan 2014).*
- Choose an appropriate vascular access device (VAD) based on the types and characteristics of the devices and insertion site. Consider the following:
 - Peripheral cannulae: short devices that are placed into a peripheral vein; can be straight, winged, or ported and winged
 - Midline catheters or peripherally inserted central catheters (PICCs) with ranges from 7.5 to 20 cm
 - Central venous access devices (CVADs) are terminated in the central venous circulation and are available in a range of gauge sizes; they can be nontunneled catheters, skin-tunneled catheters, implantable injection ports, or PICCs.
 - Polyurethane venous devices and silicone rubber may cause less friction and consequently may reduce the risk of mechanical phlebitis (Phillips, 2014).
- ▲ Choose a device with consideration of the nature, volume, and flow of prescribed solution. **EBN:** *Choosing the right gauge size reduces the risk of vascular trauma (McGowan, 2014). Verify that the osmolarity of the solution to be infused is compatible with the available access site and device (Phillips, 2014; Loubani & Green, 2015).*
- If possible, choose the venous access site considering the client's preference. Engaging the client in choosing venous access site, when possible, may facilitate line patency.
- Select the gauge of the venous device according to the duration of treatment, purpose of the procedure, and size of the vein. *Emergency situations require short, large-bore cannulae. Hydration fluids and antibiotics can be delivered through much smaller cannulae (Loubani & Green, 2015). Select the smallest gauge necessary to achieve the prescribed flow rate (Infusion Nurses Society [INS], 2013). The time of infusion of the drug, especially chemotherapy and vasoactive agents, can contribute to the occurrence of phlebitis (Loubani & Green, 2015).*
- Verify whether client is allergic to fixation or device material.
- Disinfect the venipuncture site. Assess that skin is dry before puncturing to achieve maximal benefit of disinfection agent.
- Provide a comfortable, safe, hypoallergenic, easily removable stabilization dressing, allowing for visualization of the access site. *Catheter stabilization should be used to preserve the integrity of the access device, to minimize catheter movement at the hub, and to prevent catheter migration and loss of access (INS, 2013). Some peripheral cannulae have stabilization wings (which increase the external surface area) and/or ports (which are used to administer bolus medication) incorporated into their design.*
- Peripheral catheter intended dwell time is 72 to 96 hours and central catheters is 7 days (Helm et al, 2015).
- Use sterile, transparent, semipermeable dressing to cover catheter site. *Replace dressing with catheter change, or at a minimum every 7 days for transparent dressings (INS, 2013; O'Grady et al, 2011). The use of a transparent occlusive dressing can facilitate regular monitoring by visually inspecting the vascular access device (Xue, 2014; McGowan, 2014). If the client has local tenderness or signs of possible catheter-related bloodstream infection, the site should be visually inspected and the catheter removed (O'Grady et al, 2011). Use of gauze may be necessary if the client is diaphoretic, if the site is oozing or bleeding, or if it becomes damp; if gauze is used, it should be changed every 2 days (INS, 2013; O'Grady et al, 2011).*
- Document insertion date, site, type of VAD, number of punctures performed, other occurrences, and measures/arrangements.
- Always decontaminate the device before infusing medication or manipulating IV equipment (Xue, 2014; Helm et al, 2015).
- ▲ Verify the sequence of drugs to be administered. Vesicants should always be administered first in a sequence of drugs (Loubani & Green, 2015).

Monitoring Infusion

- Monitor permeability and flow rate at regular intervals.
- Monitor catheter-skin junction and surrounding tissues at regular intervals, observing possible appearance of burning, pain, erythema, altered local temperature, infiltration, extravasation, edema, secretion, tenderness, or induration. Remove promptly. *The infusion should be discontinued at the first sign of infiltration or extravasation, the administration set disconnected, and all fluid aspirated from the catheter with a small syringe (INS, 2013).*
- ▲ Replace device according to institution protocol. **EB:** *There are variations regarding catheter permanence (dwell) time in the literature. Recommended catheter permanence time varies from 72 to 96 hours or less for peripheral catheters (O'Grady et al, 2011; Helm et al, 2015); catheter should be removed sooner if there are any clinical signs (Xue, 2014; McGowan, 2014). EBN:* *In a systematic review including five trials (3408 participants) on the replacement of peripheral venous catheters, authors did not identify evidence of the benefit of the replacement of catheters between 72 and 96 hours; thus, its authors recommended that catheters be replaced only in the presence of clinical signs (Webster et al, 2010).*
- ▲ Flush vascular access according to organizational policies and procedures, and as recommended by the manufacturer. *Vascular access devices should be flushed after each infusion to clear the infused medication from the catheter lumen, preventing contact between incompatible medications (INS, 2013). Sodium chloride 0.9% or heparinized sodium chloride has been studied to determine optimal solution for catheter patency. A recent Cochrane review found little difference in catheter patency between either solution; thus, given the cost and possible client risks to heparin exposure, sodium chloride flush solution is recommended (López-Briz et al, 2014).*
- Remove catheter on suspected contamination, if the client develops signs of phlebitis, infection, or a malfunctioning catheter, or when no longer required. *Vascular access devices should be removed on unresolved complication, therapy discontinuation, or if deemed unnecessary (INS, 2013). Replace any catheter inserted under emergency conditions within 24 hours because sterility of procedure may have been compromised.*
- Encourage clients to report any discomfort such as pain, burning, swelling, or bleeding (Xue, 2014).

Pediatric

- The preceding interventions may be adapted for the pediatric client. *Consider age, culture, development level, health literacy, and language preferences (INS, 2013; American Nurses Association, 2015). Consider the anatomic characteristics of the child or newborn in choice of VAD, equipment, and procedures for insertion and maintenance of infusion (Frey & Pettit, 2010). Consider the risk for dislodging the catheter when replacing the dressing in pediatric clients (O'Grady et al, 2011).*
- Inform the client and family about the IV procedure; obtain permissions, maintain client's comfort, and perform appropriate assessment prior to venipuncture. Assess the client for any allergies or sensitivities to tape, antiseptics, or latex. *Choose a healthy vein and appropriate site for insertion of selected device (Abolfotouh et al, 2014).*
- The use of an appropriate device to obtain blood samples reduces discomfort in the pediatric client. *Accessing a pediatric client's vein successfully can be difficult and measures to optimize the health care provider's skill is important to ensure successful venous cannulation (Goff et al, 2013; Frey, 2010).*
- Avoid areas of joint flexion or bony prominences. *Cannulae inserted away from joints remain patent for longer periods of time (McGowan, 2014).*
- ▲ Consider whether sedation or the use of local anesthetic is suitable for insertion of a catheter, taking into consideration the age of the pediatric client. *The use of effective local anesthetic methods and agents before each painful dermal procedure should be discussed with the health care provider (INS, 2013).*
- ▲ Use diversion while carrying out the procedure. *Diversion reduces anxiety (Goff et al, 2013).*

Geriatric

- The preceding interventions may be adapted for the geriatric client.
- Consider the physical, emotional, and cognitive changes related to older adults.
- Use strict aseptic technique for venipuncture of older clients. **EB:** *Older clients are at a higher risk for nosocomial and other health care-acquired complications due to defective host defenses that compromise their ability to ward off infectious agents (Laurent et al, 2012).*

Home Care

- Some devices may remain after discharge. Provide device-specific education to the client and family members about care of the selected device.
- Help in the choice of actions that support self-care. The nurse can provide valuable information that can be used to guide decision-making to maximize the self-care abilities of clients receiving home infusion therapy.
- Select, with the client, the insertion site most compatible with the development of activities of daily living (Xue, 2014; McGowan, 2014).
- Minimize the use of continuous IV therapy whenever possible. **CEBN:** *Clients who received intermittent IV therapy via a saline lock were more independent with regard to ability to perform self-care ADLs than those who received continuous IV therapy. The need for assistive mobility devices was also an independent predictor of ability to perform self-care ADLs (O'Halloran et al, 2008).*

Impaired spontaneous Ventilation

Debra Siela, PhD, RN, CCNS, ACNS-BC, CCRN-K, CNE, RRT

NANDA-I

Definition

Decreased energy reserves resulting in an inability to maintain independent breathing that is adequate to support life

• = Independent **CEB** = Classic Research ▲ = Collaborative **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Defining Characteristics

Alteration in metabolism; apprehensiveness; decrease in arterial oxygen saturation; decrease in cooperation; decrease in partial pressure of oxygen; decrease in tidal volume; dyspnea; increase in accessory muscle use; increase in heart rate; increase in partial pressure of carbon dioxide; restlessness

Related Factors

Alteration in metabolism; respiratory muscle fatigue

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Neurological Status: Central Motor Control; Respiratory Status: Gas Exchange, Ventilation

Example NOC Outcome with Indicators

Achieves appropriate **Respiratory Status: Ventilation** as evidenced by the following indicators: Respiratory rate/Respiratory rhythm/Depth of inspiration/Symmetrical chest expansion/Ease of breathing/Moves sputum out of airway/Accessory muscle use not present/Adventitious breath sounds not present/Chest retraction not present/Tidal volume/Vital capacity. (Rate the outcome and indicators of **Respiratory Status: Ventilation**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain arterial blood gases within safe parameters
- Remain free of dyspnea or restlessness
- Effectively maintain airway
- Effectively mobilize secretions

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Artificial Airway Management; Mechanical Ventilation: Invasive; Respiratory Monitoring; Resuscitation: Neonate; Ventilation Assistance; Mechanical Ventilation Management: Noninvasive

Example NIC Activities—Mechanical Ventilation Management: Invasive

Monitor for conditions indicating a need for ventilation support (e.g., respiratory muscle fatigue, neurological dysfunction second to trauma, anesthesia, drug overdose, refractory respiratory acidosis); Consult with other health care personnel in selection of a ventilator mode

Nursing Interventions and Rationales

- ▲ Collaborate with the client, family, and health care provider regarding possible intubation and ventilation. Ask whether the client has advanced directives and, if so, integrate them into the plan of care with clinical data regarding overall health and reversibility of the medical condition. **EB**: *Client preferences and goals of care need to be acknowledged and discussed when planning care. Advanced directives protect client autonomy and help ensure that the client's wishes are respected (Siela, 2010; You et al, 2014).*
- Assess and respond to changes in the client's respiratory status. Monitor the client for dyspnea, increase in respiratory rate, use of accessory muscles, retraction of intercostal muscles, flaring of nostrils, decrease in O₂ saturation, cyanosis, and subjective complaints (Burns, 2011; Parshall et al, 2011).
- Have the client use a numerical scale (0-10) or visual analog scale to self-report dyspnea before and after interventions. *The numerical rating scale is a valid measure of dyspnea and has been found to be easiest for clients to use. Incorporating client self-report of dyspnea assists with assessment of symptom intensity, distress, progression, impact, and resolution of dyspnea (Grossbach et al, 2011; Mahler & O'Donnell, 2015).*

Determine intensity, unpleasantness, or distress of dyspnea using a rating scale such as an intensity-focused modified Borg scale or visual analog scale (Parshall et al, 2011).

- Assess for history of chronic respiratory disorders when administering oxygen. *When managing acute respiratory failure in clients with chronic obstructive pulmonary disease (COPD), continually assess the client's oxygenation needs. Long-term administration of oxygen (>15 hours per day) has been shown to increase survival in clients with severe, resting hypoxemia. (GOLD, 2015).*
- ▲ Collaborate with the health care provider and respiratory therapists in determining the appropriateness of noninvasive positive pressure ventilation (NPPV/NIV) for the decompensated client with COPD. Ventilatory support in a COPD exacerbation can be provided by either noninvasive or invasive ventilation (Burns, 2011; GOLD, 2015). NIV improves respiratory acidosis and decreases respiratory rate, severity of breathlessness, incidence of ventilator-associated pneumonia (VAP), and hospital length of stay (GOLD, 2015; Mas & Masip, 2014).
- ▲ Assist with implementation, client support, and monitoring if NPPV is used. **EB/CEB:** *In a client with exacerbation of COPD, NPPV can be as effective as intubation with use of a ventilator. NPPV has also been found to improve outcomes in clients with acute cardiogenic pulmonary edema (Mas et al, 2014). It can also be used if the client has other complications, such as hypotension or severely impaired mental status. The use of continuous positive airway pressure and bi-level positive airway pressure has been shown to improve oxygenation and decrease the rate of endotracheal intubation in clients with acute pulmonary edema (Burns, 2011; GOLD, 2015).*
- If the client has apnea, respiratory muscle fatigue, somnolence, hypoxemia, and/or acute respiratory acidosis prepare the client for possible intubation and mechanical ventilation. **EB:** *These indicators may predict the need for invasive mechanical ventilation to support the client's respiratory efforts (Burns, 2011; Stacy, 2013). The indications for initiating invasive mechanical ventilation during a COPD exacerbation include a failure of an initial trial of NIV (Burns, 2011; GOLD, 2015).*
- *If a client with acute respiratory failure (ARF) has a Rapid Shallow Breathing Index (RSBI) >105, endotracheal intubation is likely needed with invasive mechanical ventilation. A client with ARF with an RSBI of <105 may require only noninvasive ventilation (Berg et al, 2012).*

Ventilator Support

- ▲ Explain the endotracheal intubation and mechanical ventilation process to the client and family as appropriate, and during intubation administer sedation for client comfort according to the health care provider's orders. **EBCN:** *Explanation of the procedure decreases anxiety and reinforces information; pre-medication allows for a more controlled intubation with decreased incidence of insertion problems (Burns, 2011; Joanna Briggs Institute, 2013).*
- Secure the endotracheal tube in place using either tape or a commercially available device, auscultate bilateral breath sounds, use a CO₂ detector, and obtain a chest radiograph to confirm endotracheal tube placement. **CEBN:** *Secure taping is needed to prevent inadvertent extubation. Nursing studies have shown conflicting results regarding the preferable way to secure the endotracheal tube (Goodrich, 2011a).* **EB:** *Auscultation alone is an unreliable method for checking endotracheal tube placement. A CO₂ detector can be used to confirm tube placement in the trachea (Goodrich, 2011; Stacy, 2013); however, correct position of the endotracheal tube in the trachea (3 to 5 cm above the carina) must be confirmed by chest radiograph (Goodrich, 2011b; Stacy, 2013). Calormetric CO₂ detectors have also been used successfully to detect inadvertent airway intubation during gastric tube placement (Goodrich, 2011a).*
- Review ventilator settings with the health care provider and respiratory therapy to ensure support is appropriate to meet the client's minute ventilation requirements (Grossbach, et al, 2011; Stacy, 2013; Chacko et al, 2015). *Ventilator settings should be adjusted to prevent hyperventilation or hypoventilation. A variety of new modes of ventilation are currently available that are responsive to client effort (pressure support).*
- ▲ Suction as needed and hyperoxygenate according to facility policy. Refer to the care plan for Ineffective Airway clearance for further information on suctioning.
- Check that monitor alarms are set appropriately at the start of each shift. *This action helps ensure client safety (Burns, 2011).*
- Respond to ventilator alarms promptly. *If unable to immediately locate the source/cause of an alarm, use a manual self-inflating resuscitation bag to ventilate the client while waiting for assistance. Common causes of a high-pressure alarm include secretions, condensation in the tubing, biting of the endotracheal tube, decreased compliance of the lungs, and compression of the tubing. Common causes of a low-pressure*

alarm are ventilator disconnection, leaks in the circuit, and changing compliance. Using a manual self-inflating resuscitation bag with supplemental oxygen, the nurse can provide immediate ventilation and oxygenation as needed (Burns, 2011; Goodrich, 2011; Grossbach et al, 2011).

- Prevent unplanned extubation by maintaining stability of endotracheal tube. **EB:** Prevent unplanned extubation with use of weaning protocol (Jarachovic et al, 2011).
- Drain collected fluid from condensation out of ventilator tubing as needed. *This action reduces the risk for infection by decreasing inhalation of contaminated water droplets (Burns, 2011).*
- Note ventilator settings of flow of inspired oxygen, peak inspiratory pressure, tidal volume, and alarm activation at intervals and when removing the client from the ventilator for any reason (Burns, 2011; Grossbach et al, 2011). *Checking the settings ensures that safety measures are taken and that the client is not left on 100% oxygen after suctioning (Burns, 2011).*
- ▲ Administer analgesics and sedatives as needed to facilitate client comfort and rest. Use behavioral and sedation scales for nonverbal clients to provide a consistent way of monitoring pain and sedation levels and ensuring that therapeutic outcomes are being met (Balas et al, 2012; Barr et al, 2013). Clients receiving mechanical ventilation frequently require sedation to help attenuate the anxiety, pain, and agitation associated with this intervention (Balas et al, 2012; Barr et al, 2013). The overall goal of sedation during mechanical ventilation is to provide physiological stability, ventilator synchrony, and comfort for clients.
- Tools such as the Riker Sedation-Agitation Scale, the Motor Activity Assessment Scale, the Ramsey Scale, or the Richmond Agitation-Sedation Scale may be useful in monitoring levels of sedation. *Each of these instruments has established reliability and validity and can be used to monitor the effect of sedative therapy (Balas et al, 2012; Barr et al, 2013).*
- Alternatives to medications for decreasing anxiety should be attempted, such as music therapy with selections of the client's choice played on headphones at intervals. **EBN/EB:** *Music therapy has been reported to decrease anxiety and reduce heart and respiratory rate in critically ill and intubated clients (Hunter et al, 2010; Tracy & Chlan, 2011; Gelinas et al, 2013).*
- Analyze and respond to arterial blood gas results, end-tidal CO₂ levels, and pulse oximetry values. *Ventilatory support must be closely monitored to ensure adequate oxygenation and acid-base balance. **EBN:** End-tidal CO₂ monitoring is best used as an adjunct to direct client observation and is used to monitor a client's ventilatory status and pulmonary blood flow (Burns, 2011; Raseria et al, 2011).*
- Use an effective means of verbal and nonverbal communication with the client. Barriers to communication include endotracheal tubes, sedation, and general weakness associated with a critical illness. Basic technologies should be readily available to the client, including eyeglasses and hearing aids (Grossbach et al, 2011; Khalaila et al, 2011). A variety of communication devices are available, including electronic voice output communication aids, alphabet boards, picture boards, computers, and writing slate. Ask the client for input into their care as appropriate (Grossbach et al, 2011; Khalaila et al, 2011). **CEB:** *Inadequate communication with the client and family may increase the risk for medical errors and adverse events (Klempell et al, 2008).*
- Move the endotracheal tube from side to side at least every 24 hours, and tape it or secure it with a commercially available device. Assess and document client's skin condition, and ensure correct tube placement at lip line (National Pressure Ulcer Advisory Panel, 2013).
- Implement steps to prevent ventilator-associated events (VAE), such as ventilator-associated pneumonia (VAP), including continuous removal of subglottic secretions, elevation of the head of bed to 30 to 45 degrees (Siela, 2010; Hospital Quality Institute, 2015) unless medically contraindicated, change of the ventilator circuit no more than every 48 hours, and handwashing before and after contact with each client.
- *The accumulation of contaminated oropharyngeal secretions above the endotracheal tube may contribute to the risk of aspiration. Use endotracheal tubes that allow for the continuous aspiration of subglottic secretions (Siela, 2010; Frost et al, 2013). **EB:** Subglottic secretion drainage during mechanical ventilation results in a significant reduction in VAE, including late-onset VAP (Frost et al, 2013). Use of continuous subglottic suctioning endotracheal tubes for intubation in clients who are predicted to require more than 48 hours likely results in decreased incidence of VAP and costs of care (Speroni et al, 2011).*
- Position the client in a semirecumbent position with the head of the bed at a 30 to 45 degree angle to decrease the aspiration of gastric, oral, and nasal secretions (Siela, 2010; Bell, 2011; Hospital Quality Institute, 2015). Consider use of kinetic therapy, using a kinetic bed that slowly moves the client with 40 degree turns. *Rotational therapy may decrease the incidence of pulmonary complications in high-risk clients with increasing ventilator support requirements, at risk for ventilator-associated pneumonia, and clinical*

indications for acute lung injury or acute respiratory distress syndrome with worsening PaO₂:FIO₂ ratio, presence of fluffy infiltrates via chest radiograph concomitant with pulmonary edema, and refractory hypoxemia (Johnson, 2011; Bein et al, 2012; Joanna Briggs Institute, 2014).

- Perform handwashing using both soap and water and alcohol-based solution before and after all mechanically ventilated client contact to prevent spread of infections (Makic et al, 2013; Centers for Disease Control and Prevention, 2014).
- Provide routine oral care using tooth brushing and oral rinsing with an antimicrobial agent if needed (Siela, 2010; Martin, 2010; Joanna Briggs Institute, 2014; Ames, 2011). **EB:** Reducing bacterial colonization of oral cavity includes interventions of daily oral assessment, deep suctioning every 4 hours, tooth brushing twice per day with a plaque reducer, oral tissue cleaning with peroxide every 4 hours. A Cochrane review found that routine oral care that included chlorhexidine mouthwash or gel resulted in a 40% reduction in development of VAP (Shi et al, 2013).
- Maintain proper cuff inflation for both endotracheal tubes and cuffed tracheostomy tubes with minimal leak volume or minimal occlusion volume to decrease risk of aspiration and reduce incidence of VAP (Siela, 2010; Bell, 2011; Skillings & Curtis, 2011; Stacy, 2013).
- Reposition the client as needed. Use rotational bed or kinetic bed therapy in clients for whom side-to-side turning is contraindicated or difficult. **EBN:** Changing position frequently decreases the incidence of atelectasis, pooling of secretions, and resultant VAP (Burns, 2011; Johnson, 2011). **EB/EBN:** Continuous, lateral rotational therapy has been shown to improve oxygenation and decrease the incidence of VAP (Burns, 2011; Johnson, 2011; Bein et al, 2012; Joanna Briggs Institute 2014).
- ▲ If the client is intubated and is stable, consider getting the client up to sit at the edge of the bed, transfer to a chair, or walk as appropriate, if an effective interdisciplinary team is developed to keep the client safe (Gosselink et al, 2008; Balas et al, 2012). For every week of bed rest, muscle strength can decrease 20%, early ambulation helped clients develop a positive outlook (Perme & Chandrashekar, 2009).
- Assess bilateral anterior and posterior breath sounds every 2 to 4 hours and as needed; respond to any relevant changes (Burns, 2011).
- Assess responsiveness to ventilator support; monitor for subjective complaints and sensation of dyspnea (Burns, 2011).
- ▲ Collaborate with the interdisciplinary team in treating clients with acute respiratory failure (Grap, 2009, Balas et al, 2012). Collaborate with the health care team to meet the client's ventilator care needs and avoid complications (Grossbach et al, 2011). **CEB:** A collaborative approach to caring for mechanically ventilated clients has been demonstrated to reduce length of time on the ventilator and length of stay in the intensive care unit (Grap, 2009).
- Document assessments and interventions according to policy.

Geriatric

- Recognize that critically ill older adults have a high rate of morbidity when mechanically ventilated.
- ▲ NPPV may be used during acute treatment of older clients with impaired ventilation. **EB:** A recent study found that older immunocompromised clients admitted with pneumonia had decreased morbidity and mortality when NPPV compared to mechanical ventilation was used to support impaired ventilation (Johnson et al, 2014).

Home Care

- ▲ Some of the interventions listed previously may be adapted for home care use. Begin discharge planning as soon as possible with the case manager or social worker to assess the need for home support systems, assistive devices, and community or home health services.
- ▲ With help from a medical social worker, assist the client and family to determine the fiscal effect of care in the home versus an extended care facility.
- Assess the home setting during the discharge process to ensure the home can safely accommodate ventilator support (e.g., adequate space and electricity).
- Have the family contact the electric company and place the client residence on a high-risk list in case of a power outage. *Some home-based care requires special conditions for safe home administration.*
- Assess the caregivers for commitment to supporting a ventilator-dependent client in the home.
- Be sure that the client and family or caregivers are familiar with operation of all ventilation devices, know how to suction secretions if needed, are competent in doing tracheostomy care, and know schedules for

cleaning equipment. Have the designated caregiver or caregivers demonstrate care before discharge. *Some home-based care involves specialized technology and requires specific skills for safe and appropriate care.*

- Assess client and caregiver knowledge of the disease, client needs, and medications to be administered via ventilation-assistive devices. Avoid analgesics. Assess knowledge of how to use equipment. Teach as necessary. *A client receiving ventilation support may not be able to articulate needs. Respiratory medications can have side effects that change the client's respiration or level of consciousness.*
- Establish an emergency plan and criteria for use. Identify emergency procedures to be used until medical assistance arrives. Teach and role play emergency care. *A prepared emergency plan reassures the client and family and ensures client safety.*

Client/Family Teaching and Discharge Planning

- Explain to the client the potential sensations that will be experienced, including relief of dyspnea, the feeling of lung inflations, the noise of the ventilator, and the reality of alarms. **EBN:** *Knowledge of potential sensations and experiences before they are encountered can decrease anxiety. Administration of sedatives and/or narcotics may be needed to provide adequate oxygenation and ventilation in some clients (Barr et al, 2013).*
- Explain to the client and family about being unable to speak, and work out an alternative system of communication. See previously mentioned interventions.
- Demonstrate to the family how to perform simple procedures, such as suctioning secretions in the mouth with a tonsil-tip catheter, providing range-of-motion exercises, and reconnecting the ventilator immediately if it becomes disconnected. *Families are a critical part of the client's care, may be present at the bedside for prolonged periods of time, and need information about the plan of care (Burns, 2011).*
- Offer both the client and family explanations of how the ventilator works and answer any questions. *Having questions answered is often cited as an important need of clients and families when a client is on a ventilator (Burns, 2011).*

V

Dysfunctional Ventilatory weaning response

Debra Siela, PhD, RN, CCNS, ACNS-BC, CCRN-K, CNE, RRT

NANDA-I**Definition**

Inability to adjust to lowered levels of mechanical ventilator support that interrupts and prolongs the weaning process

Defining Characteristics**Mild**

Breathing discomfort; fatigue; fear of machine malfunction; increase in focus on breathing; mild increase of respiratory rate over baseline; perceived need for increased in oxygen; restlessness; warmth

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

Moderate

Abnormal skin color (e.g., pale, dusky, cyanosis); apprehensiveness; decrease in air entry on auscultation; diaphoresis; facial expression of fear; hyperfocused on activities; impaired ability to cooperate; impaired ability to respond to coaching; increase in blood pressure from baseline (<20 mm Hg); increase in heart rate from baseline (<20 beats/min); minimal use of respiratory accessory muscles; moderate increase in respiratory rate over baseline

Severe

Abnormal skin color (e.g., pale, dusky, cyanosis); adventitious breath sounds; agitation; asynchronized breathing with the ventilator; decrease in level of consciousness; deterioration in arterial blood gases from baseline; gasping breaths; increase in blood pressure from baseline (≥ 20 mm Hg); increase in heart rate from baseline (≥ 20 beats/min); paradoxical abdominal breathing; profuse diaphoresis; shallow breathing; significant increase in respiratory rate above baseline; use of significant respiratory accessory muscles

Related Factors (r/t)**Physiological**

Alteration in sleep pattern; ineffective airway clearance; inadequate nutrition; pain

Psychological

Anxiety; decrease in motivation; fear; hopelessness; insufficient knowledge of weaning process; insufficient trust in health care professional; low self-esteem; powerlessness; uncertainty about ability to wean

Situational

Environmental barrier (e.g., distractions, low nurse to client ratio, unfamiliar health care staff); history of unsuccessful weaning attempt; history of ventilator dependence greater than 4 days; inappropriate pace of weaning process; insufficient social support; uncontrolled episodic energy demands

NOC (Nursing Outcomes Classification)**Suggested NOC Outcomes**

Respiratory Status: Gas Exchange; Ventilation

Example NOC Outcome with Indicators

Achieves appropriate **Respiratory Status: Ventilation** as evidenced by the following indicators: Respiratory rate/Respiratory rhythm/Depth of inspiration/Symmetrical chest expansion/Ease of breathing/Moves sputum out of airway/Accessory muscle use not present/Adventitious breath sounds not present/Chest retraction not present/Tidal volume/Vital capacity. (Rate the outcome and indicators of **Respiratory Status: Ventilation**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes**Client Will (Specify Time Frame)**

- Wean from ventilator with adequate arterial blood gases
- Remain free of unresolved dyspnea or restlessness
- Effectively clear secretions

NIC (Nursing Interventions Classification)**Suggested NIC Interventions**

Mechanical Ventilation Management: Invasive; Mechanical Ventilatory Weaning

Example NIC Activities—Mechanical Ventilatory Weaning

Monitor for optimal fluid and electrolyte status; Monitor to ensure client is free of significant infection before weaning

Nursing Interventions and Rationales

- Assess client's readiness for weaning as evidenced by the following:
 - Physiological and psychological readiness. There has been little research devoted to the study of psychological readiness to wean. **EBN:** *Assess fears and anxieties that can contribute to prolonged and repeated failure of ventilator weaning (Chen et al, 2011).* **EBN:** *Clinical assessment of comfort and anxiety are important predictors of ventilator weaning success (Grap, 2009).*
 - Resolution of initial medical problem that led to ventilator dependence
 - Hemodynamic stability
 - Normal hemoglobin levels
 - Absence of fever
 - Normal state of consciousness
 - Metabolic, fluid, and electrolyte balance
 - Adequate nutritional status with serum albumin levels >2.5 g/dL
 - Adequate sleep
 - Adequate pain management and minimal sedation

Adequate respiratory parameters historically include the following: adequate gas exchange (P_{aO_2}/F_{iO_2} ratio >200), respiratory rate ≤ 35 breaths/min, a negative inspiratory pressure <20 cm, positive expiratory pressure >30 cm H_2O , spontaneous tidal volume >5 mL/kg, vital capacity >10 to 15 mL/kg (Burns, 2011a).

EB: *A spontaneous awakening trial in conjunction with a daily weaning assessment has a great impact on ventilator liberation outcomes (Haas & Loik, 2012; MacIntyre, 2012; Jones et al, 2014).* Predictors of extubation failure include disease severity, secretion burden, higher minute ventilation, and lower oxygenation (Miu et al, 2014). **EBN:** *Systematic tracking of weaning factors may be helpful in care planning and management and determining weaning potential (Burns et al, 2010; Grap, 2009).*

- For successful weaning, ensure that the client is in an optimal physiological and psychological state before introducing the stress of weaning (Burns, 2011a). *For more information on weaning assessment, please refer to the Burns Weaning Assessment Program (Burns et al, 2010; Burns, 2011d).*
- *An early mobility and walking program can promote weaning from ventilator support as a client's overall strength and endurance improve (Gosselink et al, 2008; Perme & Chandrashekar, 2009).* If the client is intubated and is stable, consider getting the client up to sit at the edge of the bed, transfer to a chair, or walk as appropriate, if an effective interdisciplinary team is developed to keep the client safe. *For every week of bed rest, muscle strength can decrease 20%, early ambulation also helped clients develop a positive outlook (Perme & Chandrashekar, 2009).* Prolonged mechanical ventilation results in long periods of inactivity with deep sedation that results in disuse atrophy of skeletal and diaphragmatic muscles.
- *Early mobility and physical rehabilitation can reduce muscle weakness, mechanical ventilation duration, ICU stay, and hospital stay (Mendez-Tellez & Needham, 2012, Spruit et al, 2013).* The Awakening and Breathing Coordination, Delirium Monitoring and Management, and Early Mobility (ABCDE) bundle has criteria to determine when clients are candidates for early mobility (Balas, 2012).
- Involve family as appropriate to help the client provide a maximal effort during weaning readiness measurements (Burns, 2011a).
- Provide adequate nutrition to ventilated clients, using enteral feeding when possible. **EB:** *Protein malnutrition results in decreased muscle strength, which impairs the weaning process. Enteral nutrition is preferred to total parenteral nutrition because it provides an equal number of calories at lower cost and with fewer complications, while preserving gut integrity (McClave et al, 2009).* Parenteral nutrition should be initiated in any client in whom enteral nutrition cannot be used because of gut dysfunction (McClave et al, 2009).
- Use evidence-based weaning and extubation protocols as appropriate. **EBN/EB:** *The duration of treatment with mechanical ventilation and ventilation utilization ratio (VUR) were reduced in clients who received a spontaneous breathing trial (SBT) protocol (Jones et al, 2014).* Daily spontaneous breathing trials are superior to gradual ventilator-reduction strategies (Grap, 2009). *Protocol-directed weaning has been demonstrated to be safe and effective but not superior to other weaning methods that used structured rounds and other processes that allow for timely and ongoing clinical decision-making by expert nurses and health care providers (Arias-Rivera et al, 2008; Burns, 2011a; Grap, 2009; Navalesi et al, 2008; Robertson et al, 2008, Balas et al, 2012).*
- Identify reasons for previous unsuccessful weaning attempts, and include that information in development of the weaning plan. **EBN:** *Analyzing client responses after each weaning attempt prevents repeated unsuccessful weaning trials (Burns, 2011d; Burns et al, 2010; Chen et al, 2011; Grap, 2009).* Reducing the

size of artificial airways can increase airway resistance and overly increase energy expenditures of the diaphragm (MacIntyre, 2012).

- ▲ Collaborate with an interdisciplinary team (health care provider, nurse, respiratory therapist, physical therapist, and dietitian) to develop a weaning plan with a timeline and goals; revise this plan throughout the weaning period. Use a communication device, such as a weaning board or flow sheet (Burns, 2011b; Grossbach et al, 2011). **EBN:** *Effective interdisciplinary collaboration can positively affect client outcomes (Grap, 2009). Decisions related to weaning trials should be made in conjunction with members of the interdisciplinary team (Grap, 2009; Haas & Loik, 2012, Balas et al, 2012; Rose et al, 2014).*
- In clients with chronic obstructive pulmonary disease who fail extubation, noninvasive ventilation (NIV) facilitates weaning, prevents reintubation, and reduces mortality. Early NIV after extubation reduces the risk for respiratory failure and lowers 90-day mortality in clients with hypercapnia during a spontaneous breathing trial (Epstein, 2009; Mas & Masip, 2014).
- Assist client to identify personal strategies that result in relaxation and comfort (e.g., music, visualization, relaxation techniques, reading, television, family visits). Support implementation of these strategies (Pattison & Watson, 2009). Music intervention can be used to allay anxiety and can be a powerful distractor from distressful sounds and thoughts in the intensive care unit (ICU) (Tracy & Chlan, 2011). **EB:** *Music therapy appears to reduce the physiologic signs of anxiety, which can be a major deterrent to successful liberation from mechanical ventilation (Hunter et al, 2010). EBN:* *A study found that use of music was beneficial as a relaxation technique for clients if they were willing to accept it and were able to choose the selection of music (Chan et al, 2009; Hunter et al, 2010).*
- Provide a safe and comfortable environment. **EBN:** *Stay with the client during weaning if possible (Pattison & Watson, 2009).*
- If unable to stay, make the call light button readily available and assure the client that needs will be met responsively. **EBN:** *Presence entails a focus by the nurse to engage attentively with the client (Tracy & Chlan, 2011). EBN:* *A client who feels safe and trusts the health care providers can focus on the immediate work of weaning; support from the nurse helps decrease anxiety (Burns et al, 2010). Knowing the client in association with objective clinical data helps individualize the weaning process (Rose et al, 2014).*
- ▲ Coordinate pain and sedation medications to minimize sedative effects. *Appropriate levels of sedation may be key to successful weaning. EBN:* *Nursing implemented sedation protocols have been used effectively to improve the probability of successful extubation (Arias-Rivera et al, 2008; Balas et al, 2012). Of note is that a recent study in Australia reported that sedation and analgesia scales did not reduce the duration of mechanical ventilation (Williams et al, 2008). This may be due, in part, to the nurse's autonomy in making decisions about the appropriate level of sedation for any given client. Wake up and breathe protocols that pair daily spontaneous awakening trials with daily spontaneous breathing trials result in better outcomes for mechanically ventilated clients in intensive care (Girad et al, 2008; Balas, 2012; Haas & Liok, 2012). Daily interruption of sedation (DIS) is safe in mechanically ventilated medical ICU clients. Further information is needed to determine benefits in other client populations. Current practice evidence suggests that sedation should be client specific to avoid overuse of sedating agents. DIS may not reduce the duration of mechanical ventilation (Makic et al, 2015).*
- Administer analgesics and sedatives as needed to facilitate client comfort and rest. Use behavioral and sedation scales for nonverbal clients to provide a consistent way of monitoring pain and sedation levels and ensuring that therapeutic outcomes are being met (Barr et al, 2013). *Clients receiving mechanical ventilation frequently require sedation to help attenuate the anxiety, pain, and agitation associated with this intervention (Barr et al, 2013; Balas, 2012). The overall goal of sedation during mechanical ventilation is to provide physiological stability, ventilator synchrony, and comfort for clients (Balas, 2012; Makic et al, 2015).*
- Tools such as the Riker Sedation-Agitation Scale, the Motor Activity Assessment Scale, the Ramsey Scale, or the Richmond Agitation-Sedation Scale may be useful in monitoring levels of sedation (Balas et al, 2012; Barr et al, 2013).
- Schedule weaning periods for the time of day when the client is most rested. Cluster care activities to promote successful weaning. Avoid other procedures during weaning; keep the environment quiet and promote restful activities between weaning periods.
- Promote a normal sleep-wake cycle, allowing uninterrupted periods of nighttime sleep. *Limit visitors during weaning to close and supportive persons; ask visitors to leave if they are negatively affecting the weaning process. EB:* *Communication with a client and/or the client's family is important to assess the client's typical pattern of sleep (Tracy & Chlan, 2011).*

- During weaning, monitor the client's physiological and psychological responses; acknowledge and respond to fears and subjective complaints. Validate the client's efforts during the weaning process. **EBN:** *Weaning is a stressful experience that requires active participation by the client. The client's work needs to be understood and supported by health care providers to facilitate recovery from mechanical ventilation and weaning* (Burns, 2011c; Grap, 2009).
- Monitor subjective and objective data (breath sounds, respiratory pattern, respiratory effort, heart rate, blood pressure, oxygen saturation per oximetry, amount and type of secretions, anxiety, and energy level) throughout weaning to determine client tolerance and responses (Burns, 2011c; Grap, 2009).
- Involve the client and family in the weaning plan. Inform them of the weaning plan and possible client responses to the weaning process (e.g., potential feelings of dyspnea). Foster a partnership between clients and nurses in care planning for weaning (Pattison & Watson, 2009). **EBN:** *Consider the experience of client and client's family members to develop interventions for weaning success* (Rose et al, 2014).
- Coach the client through episodes of increased anxiety. Remain with the client or place a supportive and calm significant other in this role. Give positive reinforcement, and with permission use touch to communicate support and concern. *It is not unusual for a client with lung disease to experience self-limiting episodes of increased shortness of breath. Supporting and coaching a client through such episodes allows weaning to continue* (Pattison & Watson, 2009; Tracy & Chlan, 2011).
- Terminate weaning when the client demonstrates predetermined criteria or when the following signs of weaning intolerance occur:
 - Tachypnea, dyspnea, or chest and abdominal asynchrony
 - Agitation or mental status changes
 - Decreased oxygen saturation: SaO₂ <90%
 - Increased PaCO₂ or ETCO₂
 - Change in pulse rate or blood pressure or onset of new dysrhythmias
- ▲ If the dysfunctional weaning response is severe, consider slowing weaning to brief periods (e.g., 5 minutes). Continue to collaborate with the team to determine whether an untreated physiological cause for the dysfunctional weaning pattern remains. Consult with health care provider regarding use of non-invasive ventilation immediately after discontinuing ventilation. Consider an alternative care setting (subacute, rehabilitation facility, home) for clients with prolonged ventilator dependence as a strategy that can positively affect outcomes. *Use of noninvasive ventilation has been effective for the client who is difficult to wean from a ventilator* (Epstein, 2009).

Geriatric

- Recognize that older clients may require longer periods to wean.

Home Care

- Weaning from a ventilator at home should be based on client stability and comfort of the client and caregivers under an intermittent care plan. *Generally the client will be safer weaning in a hospital environment.*

Risk for other-directed Violence Kathleen L. Patuskay, MA, PhD, RN, CNS

V

NANDA-I

Definition

Vulnerable to behaviors in which an individual demonstrates that he or she can be physically, emotionally, and/or sexually harmful to others

Risk Factors

Access to weapon; alteration in cognitive functioning; cruelty to animals; fire setting; history of childhood abuse (e.g., physical, psychological, sexual); history of substance abuse; history of witnessing family violence; impulsiveness; motor vehicle offense (e.g., traffic violations, use of a motor vehicle to release anger); negative body language (e.g., rigid posture, clenching of fists/jaw, hyperactivity, pacing threatening stances); neurological impairment (e.g., positive electroencephalogram, head trauma, seizure disorders); pathological intoxication; pattern of indirect violence (e.g., tearing objects off walls, urinating/defecating on floor, stamping feet, temper tantrum, throwing objects, breaking a window, slamming doors, sexual advances); pattern of

other directed violence (e.g., hitting/kicking/spitting/scratching others, throwing objects/biting someone, attempted rape, rape sexual molestation, urinating/defecating on a person); pattern of threatening violence (e.g., verbal threats against property/people, social threats cursing, threatening notes/gestures, sexual threats); pattern of violent anti-social behavior (e.g., stealing, insistent borrowing, insistent demands for privileges, insistent interrupting, refusal to eat/take medication, ignoring instructions); perinatal complications; prenatal complications; psychotic disorder; suicidal behavior.

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Cessation; Abusive Behavior Self-Restraint; Aggression Self-Restraint; Distorted Thought Self-Control; Impulse Self-Control; Risk Detection

Example NOC Outcome with Indicators

Aggression Self-Restraint as evidenced by the following indicators: Refrains from harming others/Expresses/Vents needs and negative feelings in a nondestructive manner/Identifies when angry. (Rate the outcome and indicators of **Aggression Self-Restraint**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Stop all forms of abuse (physical, emotional, sexual; neglect; financial exploitation)
- Have cessation of abuse reported by victim
- Display no aggressive activity
- Refrain from verbal outbursts
- Refrain from violating others' personal space
- Refrain from antisocial behaviors
- Maintain relaxed body language and decreased motor activity
- Identify factors contributing to abusive/aggressive behavior
- Demonstrate impulse control or state feelings of control
- Identify impulsive behaviors
- Identify feelings/behaviors that lead to impulsive actions
- Identify consequences of impulsive actions to self or others
- Avoid high-risk environments and situations
- Identify and talk about feelings; express anger appropriately
- Express decreased anxiety and control of hallucinations as applicable
- Displace anger to meaningful activities
- Communicate needs appropriately
- Identify responsibility to maintain control
- Express empathy for victim
- Obtain no access or yield access to harmful objects
- Use alternative coping mechanisms for stress
- Obtain and follow through with counseling
- Demonstrate knowledge of correct role behaviors

Victim (and Children if Applicable) Will (Specify Time Frame)

- Have safe plan for leaving situation or avoiding abuse
- Resolve depression or traumatic response

Parent Will (Specify Time Frame)

- Monitor social/play contacts
- Provide supervision and nurturing environment
- Intervene to prevent high-risk social behaviors

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Abuse Protection Support; Anger Control Assistance; Behavior Management; Calming Technique; Coping Enhancement; Crisis Intervention; Delusion Management; Dementia Management; Distraction; Environmental Management: Violence Prevention; Mood Management; Physical Restraint; Seclusion; Substance Use Prevention

Example NIC Intervention—Environmental Management: Violence Prevention

Remove other individuals from the vicinity of a violent or potentially violent client; Provide ongoing surveillance of all client access areas to maintain client safety and therapeutically intervene as needed

Nursing Interventions and Rationales

Client Violence

- ▲ Monitor the environment, evaluate situations that could become violent, and intervene early to de-escalate the situation. Know and follow institutional policies and procedures concerning violence. Consider that family members or other staff may initiate violence in all settings. Enlist support from other staff rather than attempting to handle situations alone. **EBN:** *American Psychiatric Nurses Association (APNA) guidelines (2008) and workgroup report (Cafaro et al, 2012) warn that workplace violence can occur in all settings, from a variety of sources. Nurses need to be aware and informed of department policies and procedures. Policies should be developed and training programs should be provided in proper use and application of restraints. All nursing units should develop a proactive plan for dealing with violent situations.*
- Assess causes of aggression: social versus biological. **EB:** *Knowing the client, having experience with similar clients, paying attention, and planning interventions are expert practices used by clinicians to predict and respond to aggressive behavior effectively. A nonconfrontational approach is the most effective (APA, 2014).*
- Assess the client for risk factors of violence, including those in the following categories: personal history (e.g., past violent behavior, especially violent behavior in the community within 2 weeks of admission); psychiatric disorders (particularly psychoses, paranoid or bipolar disorders, substance abuse, post-traumatic stress disorder [PTSD], antisocial personality, or borderline personality disorder); neurological disorders (e.g., head injury, temporal lobe epilepsy, cardiovascular accident, dementia or senility), medical disorders (e.g., hypoxia, hypoglycemia, or hyperglycemia), psychological precursors (e.g., low tolerance for stress, impulsivity, hostility), coping difficulties (e.g., inability to plan solutions or see long-term consequences of behavior), younger age, risk of suicide, and childhood or adolescent disorders (e.g., conduct disorders, hyperactivity, autism, learning disability). **EBN/EB:** *All of these risk factors have been implicated in aggressive, agitated, or violent behavior, with prior history being a key indicator (American Psychiatric Association [APA], 2014; APNA, 2014a, b; Battaglini, 2014a).*
- Measures of violence may be useful in predicting or tracking behavior, and serving as outcome measures. **EBN:** *The Broset Violence Checklist (BVC) and the Kennedy Axis V have been shown to help identify clients at risk for seclusion (Sande et al, 2013).* **EB:** *The Alert System identifies potential violent incidents (odds ratio = 7.74, 95% CI = 4.81-12.47), but should be combined with resources and procedures to prevent escalation of behavior (Kling et al, 2011).*
- Assess the client with a history of previous assaults, especially violent behavior in the community within 2 weeks of admission. Listen to and acknowledge feelings of anger, observe for increased motor activity, and prepare to intervene if the client becomes aggressive. **EBN/EB:** *The most significant risk factor for physical violence is a past history of physically aggressive behavior (APA, 2014; Battaglini, 2014).*
- Assess the client for physiological signs and external signs of anger. Internal signs of anger include increased pulse rate, respiration rate, and blood pressure; chills; prickly sensations; numbness; choking sensation; nausea; and vertigo. External signs include increased muscle tone, changes in body posture (clenched fists, set jaw), eye changes (eyebrows lower and drawn together, eyelids tense, eyes assuming a “hard” appearance), lips pressed together, flushing or pallor, goose bumps, twitching, and sweating. **EBN/EB:** *Anger is an early warning sign of possible violence (APA, 2014).*
- Assess for the presence of hallucinations. **EB:** *Command hallucinations may direct the client to behave violently (APA, 2014).*

- Apply STAMPEDAR as an acronym for assessing the immediate potential for violence. **CEBN:** *A study of nurses experienced in workplace violence identified the following as factors and behaviors indicating the likelihood of a violent episode: staring, tone of voice, anxiety, mumbling, pacing, emotions, disease process, assertive/nonassertive behavior, and access to resources that might be used for violent behavior (Chapman et al, 2009).*
- Determine the presence and degree of homicidal or suicidal risk. A number of questions will elicit the necessary information: Have you been thinking about harming someone? If yes, who? How often do you have these thoughts, and how long do they last? Do you have a plan? What is it? Do you have access to the means to carry out that plan? What has kept you from hurting the person until now? Refer to the care plan for Risk for **Suicide**. Psychotherapists are required to report harm or threats of harm to another person, referred to as the “duty to warn.” State laws and mental health codes should be checked to determine local mandates for threat reporting by specific health care professionals.
- Take action to minimize personal risk: use nonthreatening body language. Respect personal space and boundaries. Maintain at least an arm’s length distance from the client; do not touch the client without permission (unless physical restraint is the goal). Do not allow the client to block access to an exit. If speaking with the client alone, keep the door to the room open. Be aware of where other staff is at all times. Notify other staff of where you are at all times. Take verbal threats seriously and notify other staff. Wear clothing and accessories that are not restricting and that will not be dangerous (e.g., sandals or shoes with heels can lead to twisted ankles; necklaces or dangling earrings could be grabbed). Ensure staff training to deal with violence. **EBN/EB:** *Aggression management training has been identified as a critical need (Battaglini, 2014a; Chu, 2014a). Programs for violence prevention have been implemented that reduce workplace violence. For OSHA guidelines, visit <https://www.osha.gov/SLTC/workplaceviolence/index.html>.*
- Remove potential weapons from the environment. Be prepared to remove obstructions to staff response from the environment. Search the client and his or her belongings for weapons or potential weapons on admission to the hospital as appropriate. **EBN:** *Preventive strategies are important (Chu, 2014a; Zhili, 2013). Clients prone to violence may use available weapons opportunistically. If client restraint becomes necessary, environmental hazards (e.g., chairs, wastebaskets) should be moved out of the way to prevent injuries.*
- Inform the client of unit expectations for appropriate behavior and the consequences of not meeting these expectations. Emphasize that the client must comply with the rules of the unit. Give positive reinforcement for compliance. Increase surveillance of the hospitalized client at smoking, meal, and medication times. **CEB/EBN:** *Clients benefit from clear guidance and positive reinforcement regarding behavioral expectations and consequences, providing much needed structure and emphasizing client responsibility for his/her own behavior (APNA, 2011; APNA, 2014a, b). The unit serves as a microcosm of the client’s outside world, so adherence to social norms while on the unit models adherence on discharge and provides the client with staff support to learn appropriate coping skills and alternative behaviors.*
- Assign a single room to the client with a potential for violence toward others. The client will be able to take time away from unit stimulation to calm self as needed. Another client will not be placed at risk as a roommate.
- Maintain a calm attitude in response to the client. Provide a low level of stimulation in the client’s environment; place the client in a safe, quiet place, and speak slowly and quietly. Anxiety is contagious. **EBN/EB:** *Maintenance of a calm environment contributes to the prevention of aggression (APA, 2011; APNA, 2014a, b). Harmony among staff can help prevent violence, in that disharmony transmits itself to clients’ emotional state (Battaglini, 2014a). Music therapy may help (Chu, 2014b).*
- Redirect possible violent behaviors into physical activities (e.g., walking, jogging) if the client is physically able. Using a punching bag or hitting a pillow is not indicated, because these are not calming activities and they continue patterning violent behavior. However, activities that distract while draining excess energy help build a repertoire of alternative behaviors for stress reduction.
- Provide sufficient staff if a show of force is necessary to demonstrate control to the client. **EBN:** *When staff respond to an escalating or violent situation, it can reassure clients that they will not be allowed to lose control. On the other hand, leave immediately if the client becomes violent and you are not trained to handle it (APNA, 2011).*
- De-escalation is the first and most important action in response to anger, hostility. Constant special observation may be implemented. **EBN:** *Response to hostility should be appropriate, measured, and*

reasonable. Constant special observation should be used to prevent acutely disturbed clients from harming self or others (Battaglini, 2014a).

- Protect other clients in the environment from harm. Remove other individuals from the vicinity of a violent or potentially violent client. Follow safety protocols of the department. The risk of a violent client to others in the area (other clients, visitors) should be anticipated, even as efforts proceed to de-escalate the situation with the client. **EBN:** *Clients exposed to violence need timely support and assistance (Chu, 2014a).*
- Maintain a secluded area for the client to be placed when violent. Ensure that staff are continuously present and available to client during seclusion. **EBN:** *Staff presence is necessary to prevent the harmful effects of social isolation and to honor clients' motivation to connect with staff (APNA, 2014a, b). Seclusion should be short and should be reviewed at least every 2 hours (Zhili, 2013).*
- ▲ Recognize legal requirements that the least restrictive alternative of treatment should be used with aggressive clients. The hierarchy of intervention is as follows: promote a milieu that provides structure and calmness, with negotiation and collaboration taking precedence over control; maintain vigilance of the unit and respond to behavioral changes early; talk with client to calm and promote understanding of emotional state; use chemical restraints as ordered; increase to manual restraint if needed; increase to mechanical restraint and seclusion as a last resort. **EBN:** *APNA guidelines (2014a, b) support early assessment and intervention to prevent aggression, with nursing actions to reduce stimulation, divert client from aggressive thought patterns, set appropriate limits on behavior, and provide medications as needed. Chemical restraints are useful, but clients must be monitored for response, side effects (Chu, 2014b). Physical restraints should be avoided and used for short periods when necessary (Battaglini, 2014a; Chu, 2014b).*
- ▲ Use mechanical restraints if ordered and as necessary. Physical restraint can be therapeutic to keep the client and others safe. **EBN:** *Physical restraints should be avoided and used for short periods when necessary (Battaglini, 2014a; Chu, 2014b). Restraint skill training, audits of adverse events, and examination of the safe use of restraints and medications are important to safe restraint practices (APNA, 2014a, b).*
- ▲ Follow the institutional protocol for releasing restraints. Observe the client closely, remain calm, and provide positive feedback as the client's behavior becomes controlled. **EBN:** *The period during which restraints are removed can be dangerous for staff if they do not recognize that the client may choose to reinitiate violence. Protocols will specify safe procedures for removing restraints (APNA, 2014a, b).*
- ▲ After a violent event on a unit, debriefing and support of both staff and clients should be made available. Allowing discussion of a violent episode, either individually or in a group, among other clients present reveals clients' responses to the event and provides the opportunity for staff to offer reassurance and support. Clients may have concerns that staff will attempt to restrain them without reason or may feel uncertain whether staff can keep them safe. **EBN:** *A study of the impact of serious events on psychiatric units found that staff reported a variety of negative emotional responses, levels of containment increased, the provision of care could be affected, and client reactions were largely ignored (APNA, 2014a, b; Lim, 2011). Injury after violence has a strong negative influence on influence on staff and calls for treatment (Chu, 2014a).*
- Form a therapeutic alliance with the client, remaining calm, identifying the source of anger as external to both nurse and client, and using the therapeutic relationship to prevent the need for seclusion or restraint. The development of a therapeutic relationship before aggressive behavior occurs provides an alternative for working through anger and frustration. Assisting the client to identify a source of anger or frustration that is external to both the nurse and client prevents the need for defensiveness by both and directs energy at solving an external problem. **EBN:** *A therapeutic environment has a mitigating effect against violence (Zhili, 2013).*
- Allow, encourage, and assist the client to verbalize feelings appropriately either one-on-one or in a group setting. Actively listen to the client; explore the source of the client's anger, and negotiate resolution when possible. Teach healthy ways to express feelings/anger, appropriate gender roles, and how to communicate needs appropriately. **CEBN:** *When clients' feelings are not addressed, when an individual feels threatened, or when gratification is delayed or denied, violence may be used as a manifestation of the internal feeling state (APNA, 2008).*
- Identify with client the stimuli that initiate violence and the means of dealing with the stimuli. Have the client keep an anger diary and discuss alternative responses together. Teach cognitive behavioral techniques. Assisting the client to identify situations and people that upset him/her provides information needed for problem solving. The client may then identify alternative responses (e.g., leaving the stimulus; using relaxation techniques, such as deep breathing; initiating thought stopping; initiating a distracting activity; responding assertively rather than aggressively).

- ▲ Initiate and promote staff attendance at aggression management training programs. **EBN:** *Aggression management training programs have a positive influence on the ability and confidence of nurses in responding to aggressive or violent behavior (APNA, 2011).*

Intimate Partner Violence (IPV)/Domestic Violence

NOTE: Before implementation of interventions in the face of domestic violence, nurses should examine their own emotional responses to abuse, their knowledge base about abuse, and systemic elements within the emergency department (ED) to ensure that interventions will be compassionate and appropriate. **EBN:** *A metasynthesis of health care provider studies identified a strong therapeutic relationship and the ability to hear what the client is not saying as facilitators of IPV screening (LoGiudice, 2015).*

- Screen for possible abuse in women or children with a pattern of multiple injuries, particularly if any suspicion exists that the physical findings are inconsistent with the explanation of how the injuries were incurred. **CEBN:** *IPV/domestic violence is recognized as a nationwide public health issue. In one study, nurses cited insufficient evidence as a reason for not reporting IPV. Nurses with a personal history of IPV were more likely to report (Smith et al, 2008).*
- ▲ Report suspected child abuse to Child Protective Services. Refer women suspected of being in a spousal abuse situation to an area crisis center and provide phone number of area crisis hotline. *Rapid screening tools are helpful to identify IPV. All nurses are required by law to report suspected child abuse. CEB:* *Child and spouse maltreatment often occur together; all family members should be evaluated and provided with assistance as needed (Taylor et al, 2009).*
- Assess for physical and mental concerns of women, including risk of HIV. **CEB:** *Major health needs of women with a history of IPV were found to include chronic pain, chronic diseases, and mental illness, as well as concerns regarding risk of HIV. Barriers to health care created by the IPV may prevent these concerns from being addressed (Cole et al, 2008).*
- Assist the client in negotiating the health care system and overcoming barriers. **CEBN:** *Victims of IPV were found to experience barriers, including inappropriate responses from providers, when attempting to access health care services (Robinson & Spilsbury, 2008).*
- With women who repeatedly experience injuries from domestic violence, maintain a nonjudgmental approach and continue to offer resources/referrals. If the woman voices a willingness to leave her situation, assist with developing an emergency plan that will consider all contingencies possible (e.g., safe location, financial resources, care of children, when to leave safely). A woman in a domestic violence situation may change her mind several times before actually leaving. Proactive organization of an emergency plan helps increase the possibility that women will be able to leave safely. The most dangerous time of a domestic violence situation is when the spouse tries to leave.
- Maintain a nonjudgmental response when clients return to husbands or refuse to leave them. Women have many reasons for remaining in an abusive relationship, including economic concerns (especially with children), socialization about the woman's role, political or legal obstacles, powerlessness, and a realistic fear of retaliation or death. Refer to the care plan for **Powerlessness**. Experienced nurses working with abused women define success as client personal growth over time, rather than the woman leaving the relationship.
- Focus on providing support, ensuring safety, and promoting self-efficacy while encouraging disclosure about IPV events. **CEB:** *A review of evidence concluded that nursing care should focus on providing physical, psychological, and emotional support; ensuring safety of the client and family; and promoting the self-efficacy of the woman (Olive, 2007).*
- Screen pregnant women for the potential for domestic violence during pregnancy, especially in teenage pregnancies. **CEBN:** *In a study of high-risk teen mothers, IPV was reported by 61% of the participants, with 37.5% reporting IPV during pregnancy (Mylant & Mann, 2008). Psychological health was found to be predicted by a history of abuse among women in a high-risk prenatal care clinic (Svavarsdottir & Orlygsdottir, 2008). CEB:* *Pregnant women will remain in an abusive relationship if they perceive it to be in the best interest of the child, part of a process of "double-binding" with child and abusive spouse (Lutz et al, 2006). Systematic screening of pregnant women is recommended, and choking is a danger that should be added to routine screening (Jeanjot et al, 2008). Screen women and children for effects of domestic violence during the postpartum period. CEB:* *Less educated women, women who reported substance abuse by spouse, and women who reported unwanted pregnancies were at risk for IPV both during and after pregnancy. Violence during pregnancy predicted postpartum violence. U.S. women employed during pregnancy were most likely to leave an abusive partner at 1 year postpartum (Charles & Pereira,*

2007). In cases of high IPV, less than optimal infant health and difficult temperament were found (Burke et al, 2008).

- Women with physical or mental disabilities require extended assessment, including a comprehensive functional assessment, with attention to cultural issues, the nature of the disability, and needed resources. Women with disabilities may experience abuse from multiple sources, and particular attention should be paid to the additional emotional stressors present. Difficulties leaving home, physical needs that shelter may not be able to accommodate, and the undesirability of nursing home placement are just a few stressors. Personal assistance providers may be abusive or take advantage financially. **CEB:** *Women with disabilities may follow a unique model of IPV progression, requiring adaptation of the usual interventions, and may be slower in returning to usual routines (Copel, 2006; Focht-New et al, 2008). Women with schizophrenia are especially vulnerable and have complex needs (Bengtsson-Tops & Tops, 2007; Rice, 2006).*
- ▲ Referral for spiritual counseling may be considered, but be aware that clergy vary in their helpfulness. **CEBN:** *Survivors of sexual violence described being able to cope with their situation through spiritual connection, spiritual journey, and spiritual transformation (Knapik et al, 2008). A study of women in abusive relationships who sought spiritual guidance from male clergy revealed themes of spiritual suffering, devaluation, loss, and powerlessness consistent with old societal biases. The authors noted that conclusions could not be drawn regarding the helpfulness of female clergy (Copel, 2008).*
- Identify risk factors such as ongoing mental illness of a parent, and monitor family closely. **CEB:** *Concern for the children of parents with a mental illness has been identified in light of the potential for family dysfunction and violence among the mentally ill (Copeland, 2007; Mason et al, 2007).*
- Be aware that IPV may arise or continue under circumstances of medical illness. **EBN:** *Older women with breast cancer reported they experienced negative relationship changes and IPV (Sawin & Parker, 2011).*
- Consider risk versus benefit when deciding if, when, and in how great a depth to explore client responses to abuse or violence. **EB:** *A systematic review of research on violence and abuse concluded that risks as well as benefits may derive from clients talking about such experiences (Appollis et al, 2015).*
- ▲ When spouse or child abuse accompanies substance abuse, refer the abusive client to a substance abuse treatment program. Refer the spouse receiving abuse to Al-Anon and the children to Alateen. **CEB:** *Use of drugs or alcohol may decrease impulse control and aggravate abusive behavior, depending on specific drug used and culture (Caetano et al, 2008; Stalans & Ritchie, 2008).*
- ▲ When an adult reveals a history of unresolved/untreated sexual abuse as a child, referral to a local Adults Molested as Children (AMAC) group may be helpful. **CEB:** *Childhood sexual abuse has been associated with adult depression, attempted suicide, self-harm, and higher risk for later interpersonal violence (Murrell et al, 2007). Interventions tailored to the AMAC experience may be helpful. Refer to the care plans for Risk for **Suicide, Self-Mutilation**, and Risk for **Self-Mutilation**.*
- ▲ Referral of women for psychiatric/psychological treatment or parenting classes should be considered as an appropriate intervention. **CEB:** *Overcoming shame, building a stable sense of identity, and becoming less dependent on others' approval should be addressed, along with physical health and PTSD symptoms (Woods et al, 2008). **EB:** In a study of 3429 women enrolled in an HMO, 46% reported a lifetime history and 14.7% reported a history within the previous 5 years of physical, sexual, and/or nonphysical abuse, with PTSD being a potential outcome (Dutton, 2009). Self-blame was associated with all factors involved in IPV, with outcomes of PTSD, depression, suicidality, and substance abuse (Campbell et al, 2009).*
- ▲ Referral of children for psychiatric/psychological treatment should be considered as an appropriate intervention. **CEB:** *Children living with domestic violence were found to express fear and anxiety, self-esteem issues, ambivalent relationships with the abuser, and a sense of a lost childhood (Buckley et al, 2007).*
- ▲ Refer to batterer intervention programs that are often available and may be court mandated. **CEB:** *Batterers believe behaviors toward them are not justified, and their behaviors toward others are justified and minimized. Treatment should include emotional skills training that addresses these areas (Smith, 2007).*

Social Violence

- Assess for acute stress disorder (ASD) and PTSD among victims of violence. **CEB:** *In the acute phase following an assault, women reported high rates of ASD symptoms. Four months after an attack, dissatisfaction with previous life, prior mental health problems, recent life events, and earlier abuse were risk factors for PTSD (Renck, 2006).*
- ▲ Assess the support network of women who become victims of violent crime and refer for appropriate levels of assistance. Of particular concern would be women who do not have family or friends to provide support or who have difficulty accessing other types of assistance.

- Be aware that hate crime is increasing, particularly toward gay and transgendered individuals, and it requires support and advocacy for victims. **CEB:** *Gay men who experienced antigay abuse reported that the events affected their self-image. In addition to verbal and physical abuse, spiritual abuse emerged as the men internalized schemas of outcast and sinner (Lucies & Yick, 2007).*
- ▲ Victims of violence seen in the ED should receive an assessment for needed services and assignment to case management. *Establishment of linkages with social service agencies can provide important services for referral.*

Rape-Trauma Syndrome

- Assist client to cope with potential stalking activity. **EBN:** *The usual coping of college students in response to stalking was found to include ignoring or minimizing the problem; distancing or depersonalizing; using verbal escape strategies, attempting to end the relationship; and restricting availability (Amar & Alexy, 2010). Emphasizing the need to take stalking behavior seriously and problem-solving interventions may prevent a rape situation.*
- Approach client with sensitivity. **CEBN:** *Using Peplau's theory of nursing roles, researchers found that the roles of counselor and technical expert were most helpful, with interpersonal sensitivity important to clients (Courey et al, 2008).*
- ▲ Monitor for paradoxical drug reactions, and report any to the health care provider. Violent behavior can be stimulated by a medication intended to calm the client.
- Assess for brain insults, such as recent falls or injuries, strokes, or transient ischemic attacks. Clients with brain injuries may respond to stimulus control, problem solving, social skills training, relaxation training, and anger management to reduce aggressive behaviors. Brain injuries, lowered impulse control, and reduced coping can cause violent reactions to self or others. Brain injury symptoms may be mistaken for mental illness.
- Decrease environmental stimuli if violence is directed at others. Removal of the client to a quiet area can reduce violent impulses. Use a calm voice to “talk down” the client.
- Assess holistic needs of the client. **CEBN:** *Risk factors for negative mental health outcomes following sexual violence were found to be low income, low education level, lack of social support, and poor health promotion (Vandemark & Mueller, 2008).*
- Discuss with client her wishes regarding use of an emergency contraceptive. **CEBN:** *If emergency contraception was offered to every female victim of sexual assault, researchers concluded that unintended pregnancies would decline. However, the findings are limited, in that only 15% of women who are raped seek health care promptly (Womack, 2008).*
- ▲ If abuse or neglect of an older client is suspected, report the suspicion to an adult protective services agency with jurisdiction over the geographical area where the client lives.

Pediatric

- Assess for predictors of anger that can lead to violent behavior. **EBN:** *A meta-analysis of adolescent anger predictors identified trait anger, anxiety, depression, stress, and exposure to violence as moderate to substantial predictors of anger; victim of violence, hostility, self-esteem, and social support were low to moderate predictors (Mahon et al, 2010).*
- Be alert for both shaken baby syndrome and exposure of children to violence. *In homes where domestic violence exists, children are involved as either witnesses or victims. Such children tend not to seek help and need care providers to elicit actively the need for assistance (Lepisto et al, 2010).*
- Pregnant teens should be assessed for abuse, particularly if they are with an older partner. **CEB:** *In a study of predominantly African American pregnant teens, 13% reported domestic violence during pregnancy. Teens with adult partners (4 or more years older) were twice as likely to report abuse as teens with similar-age partners (Harner, 2004).*
- ▲ In the case of child abuse or neglect, refer for early childhood home visitation. **CEB:** *Home visits during a child's first 2 years of life have been found to be effective in preventing child abuse and neglect (Hahn et al, 2003).*

Geriatric

- Be alert to the potential for elder abuse in clients, including the possibility of psychological abuse. **EBN:** *Abuse may be physical, sexual, psychological, financial, or may appear as neglect. Look for signs of bruising, malnutrition, and fearful responses to or around caregivers (Battaglini, 2014b). Cognitive impairment,*

behavioral problems, and psychiatric illness in the client are risk factors for becoming recipients of abuse (Battaglini, 2014c). Assess for changes in physiological functions (e.g., constipation, dehydration) or impairment of the ability to meet basic needs (e.g., inadequate toileting, decreased mobility). Observe for signs of fear, anxiety, anger, and agitation, and intervene immediately. In older adults, subtle physiological changes, interruptions of or changes in routine, or fears about medical disorders or potential loss of independence can be transformed into anger, irritability, or agitation. **EBN:** A comprehensive physical exam should include a neurological exam and x-rays as needed (Battaglini, 2014b).

- Assess for presence or client history of mental illness or treatment. **EBN:** There is a high likelihood of elder abuse in the presence of mental illness, even if receiving psychiatric treatment (Battaglini, 2014c).
- Assess and observe for aggressive behavior in older clients at long-term care facilities. **EBN:** Between 25% and 50% of clients with dementia have demonstrated aggressive behavior. Knowledge of the client's history and risk factors is important. Treatment with antipsychotics should be individualized and carefully monitored. Use of restraints should be avoided, used for a short time, and removed at the earliest possible time. Staff should receive training in aggression management (Battaglini, 2014d).
- Observe clients for dementia and delirium. **EBN:** Between 25% and 50% of clients with dementia have demonstrated aggressive behavior. Clients with dementia or delirium may strike out if they are frustrated or if they have the sense that their personal space is being violated. The competency of the client should be assessed to determine if he/she possesses a cognitive capacity that permits discussion of the behavior (Battaglini, 2014c, d).
- Be aware of laws and regulations in the appropriate jurisdiction where client is located. **EBN:** Confidentiality, consent, and information sharing are sensitive issues that are determined by federal as well as local regulation (Battaglini, 2014b; Goh, 2014a).
- Document and record suspected elder abuse according to mandatory regulations. **EBN:** Incidents of abuse should be recorded with date, time, chronology of abuse, family history, potential indicators of abuse, details regarding care planning and decision-making process, and actual care provided. Photographic evidence of abuse should be obtained. The police may be requested to take forensic pictures (Goh, 2014b).
- Apart from mandated requirements, abide by the older client's wishes regarding action to be taken in response to abuse. Avoid interventions that increase the risk of abuse. **EBN:** Discuss with client their reasons for refusing to disclose abuse. There may be a fear that the only available caregiver will withdraw, leaving the client helpless. Allow adequate time for the discussion; respect the client's pace and need for a sense of control. Corroborate events as possible (Battaglini, 2014b). Avoid the use of antidepressants or sedatives without a thorough abuse assessment; the recommendation of family counseling without intervention for the abuser; blaming the victim; colluding with the abuser; or minimizing the possible danger (Goh, 2014c).
- Develop a safety plan and provide referrals to all relevant agencies or services. **EBN:** Discuss safety options for both client and provider. Contact police if there is a concern regarding the availability of a gun. RN should debrief with manager as necessary (Battaglini, 2014c). Multidisciplinary and interagency collaboration is important to meet client needs (Goh, 2014c).

Multicultural

- Exercise cultural competence when dealing with domestic violence. **CEBN:** Battered Latina women reported protecting their partner, preventing their mother from worrying, and fear of losing their children as barriers to disclosing IPV (Montalvo-Liendo et al, 2009).
- Identify and respond to unique needs of immigrant women who experience IPV. **EBN:** A study of Sri Lankan immigrants to Canada revealed that violence prior to the immigration, gender inequity in the marriage, changes in social networks and supports, and changes in socioeconomic status were identified by the women as factors involved in IPV (Guruge et al, 2010). Filipina women focused on keeping their family together and did not realize that IPV has a negative influence on the mental health of the women and their children (Shoultz et al, 2010).
- Assist with acculturation and activating social support. **CEB:** Type of support and acculturation helped promote resiliency and improved mood among Hispanic women in IPV situations (Shoultz, et al, 2009).

Home Care

- Be alert to the potential for violent behavior in the home setting. Respond to verbal aggression with interventions to deescalate negative emotional states. Violence is a process that can be recognized early. Deescalation involves reducing client stressors, responding to the client with respect, acknowledging the

client's feeling state, and assisting the client to regain control. If deescalation does not work, the nurse should leave the home.

- Assess family members or caregivers for their ability to protect the client and themselves. The safety of the client between home visits is a nursing priority. Caregivers often need assistance with recognizing or admitting fear of or danger from a loved one.
- Include an initial and ongoing assessment and evaluation of potential abuse and neglect. Photograph evidence of abuse or neglect when possible. *Victims of abuse perceive themselves to be powerless to change the situation. Indeed, the abuser fosters this perception and may threaten violence or death if the victim attempts to leave. Chronic abuse and neglect by a spouse or other family among older adults is often hidden until home care is actively involved.* Refer to the care plan for **Powerlessness**.
- ▲ If neglect or abuse is suspected, identify an emergency plan that addresses the problem immediately, ensures client safety, and includes a report to the appropriate authorities. Discuss when to use hotlines and 911. Role-play access to emergency resources with the client and caregivers. *Client safety is a nursing priority. An emergency plan should address either immediate removal to a safe environment or identification of appropriate steps to take in the event of abuse and the securing of resources for the anticipated action (e.g., available phone, packed bag, alternative living arrangements). Reporting is a legal requirement for health care workers.*
- Encourage appropriate safety behaviors in abused women; call the client at intervals during a 6-month period to determine whether safety behaviors are being carried out. **CEB:** *A study of telephone contacts to women who sought help through the district attorney's office demonstrated that safety behaviors increased dramatically. Safety behaviors included hiding money; hiding an extra set of house and car keys; establishing a code for abuse occurrence with family or friends; asking neighbors to call police if violence occurs; removing weapons; keeping available family social security numbers, rent and utility receipts, family birth certificates, identification or driver licenses, bank account numbers, insurance policies and numbers, marriage license, valuable jewelry, important phone numbers, and a hidden bag with extra clothing (McFarlane et al, 2002).*
- Assess the home environment for harmful objects. Have the family remove or lock objects as able. *The safety of the client and caregivers is a nursing priority.*
- ▲ Refer for homemaker or psychiatric home health care services for respite, client reassurance, and implementation of a therapeutic regimen. Responsibility for a person who may become violent provides high caregiver stress. Respite decreases caregiver stress. The presence of caring individuals is reassuring to both the client and caregivers, especially during periods of client anxiety. Individuals exhibiting violent behaviors can respond to the interventions described previously, modified for the home setting.
- ▲ If the client is taking psychotropic medications, assess client and family knowledge of medication and its administration and side effects. Teach as necessary. Knowledge of the medical regimen supports compliance.
- ▲ Evaluate effectiveness and side effects of medications. Accurate clinical feedback improves the health care provider's ability to prescribe an effective medical regimen specific to a client's needs.
- If client displays mildly intensifying aggressive behavior, attempt to diffuse anger or violence (e.g., ask for a glass of water to distract client). Later in the visit, explain that aggressive behavior is not acceptable and present consequences of continued aggressive behavior (i.e., right of agency to discontinue services). *Mild aggression can be defused safely. Confronting the client before severe aggression is evident places responsibility on the client and family for respectful partnership in care.*
- Document all acts or verbalizations of aggression. Safety of the staff is a primary responsibility of home health agencies. Law enforcement intervention may be necessary.
- ▲ If client verbalizes or displays threatening behavior, notify your supervisor and plan to make joint visits with another staff person or a security escort. *Having a second person at the visit is a show of power and control used to subdue aggressive behavior.*
- If the client's behavior is not overtly threatening but makes the nurse uncomfortable, a meeting may be held outside the home in sight of others (e.g., front porch). *The nurse should trust a "gut" reaction that prompts concern regarding the client's potential for aggressive or violent behavior. Such intuitive reactions are often the result of subliminal cues that are not readily voiced.*
- Never enter a home or remain in a home if aggression threatens your well-being.
- ▲ Never challenge a show of force, such as a gun threat. Leave and notify your supervisor and the appropriate authorities. Document the incident. *Safety of the staff is a primary responsibility of home health agencies. Law enforcement intervention may be necessary.*

- ▲ If client behaviors intensify, refer for immediate mental health intervention. The degree of disturbance and ability to manage care safely at home determines the level of services needed to protect the client.

Client/Family Teaching and Discharge Planning

- Instruct victims of IPV in the dynamics and prognosis of domestic violence behavior, as well as the effect on children who witness or are victims of domestic violence. *Victims of IPV feel alone and isolated. They can begin to take back control of their circumstances once they better understand what is happening within the interpersonal relationship, what their options are, and what the consequences of inaction may be. Do not expect an immediate change in the victim's behavior.*
- Teach relaxation and exercise as ways to release anger and deal with stress. **CEB:** *IPV and parenting stress were found to be risk factors for child maltreatment (Taylor et al, 2009).*
- Teach cognitive behavioral activities, such as active problem solving, reframing (reappraising the situation from a different perspective), or thought stopping (in response to a negative thought, picture a large stop sign and replace the image with a prearranged positive alternative). Teach the client to confront his or her own negative thought patterns (or cognitive distortions), such as catastrophizing (expecting the very worst), dichotomous thinking (perceiving events in only one of two opposite categories), magnification (placing distorted emphasis on a single event), or unrealistic expectations (e.g., “should get what I want when I want it”). *Cognitive behavioral activities address clients' assumptions, beliefs, and attitudes about their situations, fostering modification of these elements to be as realistic as possible. Through cognitive behavioral interventions, clients become more aware of their cognitive choices in adopting and maintaining their belief systems, thereby exercising greater control over their own reactions (Hagerty & Patusky, 2011).*
- ▲ Refer to individual or group therapy.
- Teach the adolescent client violence prevention, and encourage him/her to become involved in community service activities. School programs that couple community service with classroom health instruction can have a measurable effect on violent behaviors of young adolescents at high risk for being both the perpetrators and victims of peer violence. Community service programs may be a valuable part of multicomponent violence prevention programs.
- Teach the use of appropriate community resources in emergency situations (e.g., hotline, community mental health agency, ED, 911 in most places in the United States, the toll-free National Domestic Violence Hotline [1-800-799-SAFE]). Internet resources are increasing and should be made available to clients. It is necessary to get immediate help when violence occurs.
- Encourage the use of self-help groups in nonemergency situations.
- Inform the client and family about any applicable medication actions, side effects, target symptoms, and toxic reactions.

Risk for self-directed Violence Kathleen L. Patusky, MA, PhD, RN, CNS

NANDA-I

Definition

Vulnerable to behaviors in which an individual demonstrates that he or she can be physically, emotionally and/or sexually harmful to self

Risk Factors

Age \geq 45 years; age 15 to 19 years; behavioral cues (e.g., writing forlorn love notes, directing angry messages at a significant other who has rejected the person, giving away personal items, taking out a large life insurance policy); conflict about sexual orientation; conflict in interpersonal relationships; employment concern (e.g., unemployed, recent job loss/failure); engagement in autoerotic sexual acts; history of multiple suicide attempts; insufficient personal resources (e.g., achievement, insight, affect unavailable and poorly controlled); marital status (e.g., single, widowed, divorced); mental health issue (e.g., depression, psychosis, personality disorder, substance abuse); occupation (e.g., executive, administrator/owner of business, professional, semi-skilled worker); pattern of difficulties in family background (e.g., chaotic or conflictual, history of suicide); physical health issue; psychological disorder; social isolation; suicidal ideation; suicidal plan; verbal cues (e.g., talking about death, "better off without me," asking about lethal dosage of medication)

NOC, NIC, Client Outcomes, Nursing Interventions and Rationales, Client/Family Teaching and Discharge Planning, and References

Refer to care plans for Risk for **Suicide**, **Self-Mutilation**, and Risk for **Self-Mutilation**.

Impaired Walking Wendie A. Howland, MN, RN-BC, CRRN, CCM, CNLCP, LNCC

NANDA-I

Definition

Limitation of independent movement within the environment on foot

● = Independent CEB = Classic Research ▲ = Collaborative EBN = Evidence-Based Nursing EB = Evidence-Based

List of Nursing Diagnoses by Letter: W

Impaired Walking

Wandering

Defining Characteristics

Impaired ability to climb stairs; impaired ability to navigate curbs; impaired ability to walk on decline; impaired ability to walk on incline; impaired ability to walk on uneven surface; impaired ability to walk required distance

Related Factors

Alteration in cognitive functioning; alteration in mood; decrease in endurance; environmental barriers (e.g., stairs, inclines, uneven surfaces, obstacles, distances, lack of assistive device); fear of falling; impaired balance; impaired vision; insufficient knowledge of mobility strategies; insufficient muscle strength; musculoskeletal impairment; neuromuscular impairment; obesity; pain; physical deconditioning

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Ambulation; Mobility

Example NOC Outcome with Indicators

Ambulation as evidenced by the following indicators: Walks with effective gait/Walks at moderate pace/Walks up and down steps/Walks moderate distance. (Rate the outcome and indicators of **Ambulation**: 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate optimal independence and safety in walking
- Demonstrate the ability to direct others on how to assist with walking
- Demonstrate the ability to properly and safely use and care for assistive walking devices

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Exercise Therapy: Ambulation

Example NIC Activities—Exercise Therapy: Ambulation

Assist client to use footwear that facilitates walking and prevents injury; Encourage to sit in bed, on side of bed (“dangle”), or in chair, as tolerated

Nursing Interventions and Rationales

- Progressively mobilize clients (e.g., gradual elevation of head of bed [HOB], sitting in reclined chair, standing). *Limited mobility is an independent predictor of negative outcomes for hospitalized older clients (Doherty-King et al, 2014).*
- Assist clients to apply orthosis, immobilizers, splints, and braces as prescribed before walking. **EB:** *Assistive devices are prescribed for specific reasons and should be used correctly to help prevent falls (Boelens et al, 2013).*
- Apply thromboembolic deterrent stockings (TEDs) and/or elastic leg wraps; raise HOB slowly in small increments to sitting, have clients move feet/legs up and down then stand slowly; avoid prolonged standing. *Movement promotes venous return and decreases edema. EB: Sleeping with the HOB elevated produces minor improvement in postural hypotension; compression bandages have been found to improve postural drop by more than 10 mm Hg (Logan & Witham, 2012; Anthony, 2013).*
- Carefully monitor blood pressure of older adults at least from 30 to 90 minutes after meals before walking. There are significant differences in systolic and diastolic pressure over time, with the biggest drop in systolic and diastolic blood pressure occurring at 45 minutes after a meal (Son & Lee, 2012; Lee, 2013).
- Maintain partial head elevation when resting in bed to help decrease orthostatic hypotension. *HOB elevation stimulates baroreceptors and decreases nocturnal diuresis (Feldstein & Weder, 2012).*

- Compare morning lying/sitting/standing blood pressures. If systolic pressure falls 20 mm Hg or diastolic pressure falls 10 mm Hg from lying to standing within 3 minutes, and/or if lightheadedness, dizziness, syncope, or unexplained falls occur, consult a health care provider (Lee, 2013).
- Detection of orthostatic hypotension is key to fall prevention. **EB:** Review medication for possible contributing factors. Give prescribed hydration and medications to treat orthostatic hypotension. Consider leg wraps. Client should perform warm-up bed exercises (Lee, 2013). Cerebral hypoperfusion is a common cause of orthostatic intolerance and hypotension (Lee, 2013). Severe spinal cord injury above T6-8 is a risk factor for orthostatic hypotension due to reduced efferent sympathetic nervous activity and loss of reflex vasoconstriction at arterial baroreceptors below the level of injury (Phillips et al, 2012).
- Use a formalized screening tool to identify persons at high risk for thromboembolism (deep venous thrombosis). Best clinical practice is supported by use of a clinical decision model that determines risk based on predisposing factors and certain clinical signs and symptoms (Anthony, 2013).
- ▲ Implement thromboembolism prophylaxis/treatment as prescribed (e.g., anticoagulants, antiembolic stockings, elastic leg wraps, sequential compression devices, feet/ankle exercises, and hydration). Refer to care plan for Ineffective peripheral **Tissue Perfusion**.
- Reinforce correct use of prescribed mobility devices and remind clients of weight-bearing restrictions. Canes provide stability in persons with hemiparesis; canes are prescribed to improve gait, balance and alleviate joint pain and are usually used on the contralateral side of the affected limb.
 - Teach clients with leg amputations to correctly don stump socks, liner, immediate postoperative prostheses or traditional prosthesis before standing/walking.
 - Teach client importance of avoiding prolonged hip and knee flexion. If contractures occur, the client may have difficulty with prosthesis fit and use. *Limit amount of time the client is permitted to sit to no more than 40 minutes of each hour, ensure when client sits, stands or is recumbent, the hip and knee are in extension and periodic prone lying is recommended (Pierson & Fairchild, 2008).*
- Emphasize the importance of wearing properly fitting, low-heeled shoes with nonskid soles, and socks/hose, and of seeking medical care for foot pain or problems with abnormal toenails, corns, calluses, or diabetes. *Suggest trying a running shoe that is comfortable and lightweight, in that a recent study found participants unable to see the type of shoe (control shoe, running shoe, or orthopedic shoe) chose the running shoe based on comfort and weight (Ambrosea et al, 2013).*
- Use a snug gait belt with handles and assistive devices while walking clients, as recommended by the physical therapist (PT). *A gait belt must be applied before and during all ambulation and functional gait activities. It should be applied securely around the waist. Do not use client's clothing, upper extremity, or personal belt for control because these items are not strong or secure to provide a safe grasp (Pierson & Fairchild, 2008).*
- Walk clients frequently with an appropriate number of people; have one team member state short, simple motor instructions. *Standing/weight bearing benefits gut motility, spasticity, and respiratory/bowel/bladder function, and promotes muscle stretching (Doherty-King et al, 2014).*
- Cue and manually guide clients with unilateral neglect to prevent clients from bumping into objects/people. **EB:** *Research subjects with left neglect veered left when driving a powered wheelchair, whereas when walking, they veered right (Turton et al, 2009).*
- Document the number of helpers, level of assistance (e.g., maximum, standby), type of assistance, and devices needed on the care plan and room white board (if used). *Communication and consistency promote client learning/safety, help prevent staff injury, and use all client handling and movement equipment as possible (Cohen et al, 2010).*
- Take pulse rate/rhythm and pulse oximetry before walking clients, and reassess within 5 minutes of walking, then ongoing as needed. If either is abnormal, have the client sit 5 minutes, then reassess. If still abnormal, walk clients more slowly and with more help, or for a shorter time or notify the health care provider.
- If uncontrolled diabetes/angina/arrhythmias/tachycardia (≥ 100 bpm) or resting systolic blood pressure ≥ 200 mm Hg or diastolic blood pressure ≥ 110 mm Hg occur, do not initiate walking exercise without consulting the health care prescriber. *Pulse rate and arterial blood oxygenation indicate cardiac/exercise tolerance. Tachycardia and low pulse oximetry readings, generally $< 88\%$, are indicators of unstable hemodynamic status; rest the client and apply oxygen (Ambrosea et al, 2013).*

Refer to the care plan for **Activity intolerance**.

- Perform initial/ongoing screening for risk of falling and perform postfall assessments including medications and lab results to prevent further falls. *Nurses must assess fall risk; in a Medicare review, fewer than*

60% of older adults who reported falls talked to a health care provider about the problem (Matsuda et al, 2011).

- Individualize interventions to prevent falls, e.g., scheduled toileting, monitored rooms, bed alarms, wheelchair alarms, balance/strength training, sleep hygiene, education on risk of medication/alcohol use, removal of hazards and attention to safe handling during any transfers, wound care, toileting, showering/bathing (Cohen et al, 2010). **EB:** Root cause analysis can be an effective tool to decrease rate of falls in facilities with challenge to keep personnel trained in the process. The fall prevention program should include fall prevention interventions as well as assessment of risk and assessment of a fall (Boelens et al, 2013).

Geriatric

- ▲ Assess for swaying, poor balance, weakness, and fear of falling while older adults stand/walk. If present, refer to PT. *Fear of falling and repeat fallers are common. Balance rehabilitation provides individualized treatment for persons with various diseases/deficits (Ambrosea et al, 2013). Assess all geriatric clients and have heightened awareness for risk of fall in clients with chronic diseases such as multiple sclerosis, Parkinson's disease or parkinsonism, or stroke (Matsuda et al, 2011).*
- ▲ Review medications for polypharmacy and those that place older adults at risk for falls; consult with pharmacy as needed. More than five drugs indicates polypharmacy and puts the client at risk for adverse drug reactions, drug-drug interactions, and overall low adherence to drug therapy due to too many drugs to take (Hovstadius et al, 2010).
- ▲ Encourage an exercise component such as tai chi, physical therapy, or other exercise for balance, gait, and strength training in group programs or at home; modify environment for safety; recommend vision assessment for corrective lenses and consideration for cataract removal; conduct polypharmacy assessment with special consideration to sedatives, antidepressants, and drugs affecting the central nervous system; evaluate for orthostatic hypotension and dysrhythmia; recommend vitamin D supplementation 800 IU per day (National Institutes of Health, 2014).
- Assess fall risk, then implement fall precautions, such as clearing obstacles, reviewing medications, and using a visual identifier on clients starting exercise/education programs. *Previous falls, physiological changes, and adverse effects from multiple medications put older adults at risk for falls (Ambrosea et al, 2013).*

Home Care

- ▲ Establish a support system for emergency and contingency care (e.g., remote monitoring, emergency call system, alert local EMS). *Impaired walking may pose a life threat during a crisis (e.g., fall, fire, orthostatic episode).*
- ▲ Assess for and modify any barriers to walking in the home environment to promote safety. **EB:** *Effective precautions for ambulation safety in the home are removal of small rugs or mats that may slip or slide, use of extreme caution when using a bath mat, avoidance of waxing floors or use of nonskid wax, and immediate clearance of spills from non-carpeted floors (Ambrosea et al, 2013).*
- ▲ Obtain prescription for PT home visits for individualized strength, balance retraining, and an exercise plan. **EB:** *Original research shows the use of simple stretching program for older clients counteracts age-related decline in gait function (Watt et al, 2011).*
- ▲ Make referrals for home health services for support and assistance with activities of daily living (ADLs). *This is a key component of discharge planning.* Listen to and support client/caregivers; refer to support groups that meet or are online. Refer to care plan for **Caregiver Role Strain**.

Client/Family Teaching and Discharge Planning

- Teach clients to check ambulation devices weekly for cracks, loose nuts, or worn tips; clean dust and dirt on tips; remove all items from stairways; be certain hand rails are strong and secure; position furniture to allow a 36-inch wide unobstructed pathway when possible, and remove electrical cords or loose objects from walking paths (Boelens et al, 2013).
- Teach clients with diabetes that they are at risk for foot ulcers and train them in preventive interventions. **EB:** *Literature continues to address risk factors for foot ulcers, previous amputation, foot ulcer history, peripheral neuropathy, foot deformity, peripheral vascular disease, visual impairment, diabetic nephropathy, poor glycemic control, and cigarette smoking; clients with diabetes need education on these risk factors (National Diabetes Information Clearing House, 2014).*

- Instruct anyone at risk for osteoporosis or hip fractures to bear weight, walk, engage in resistance exercise (with appropriate adjustments for conditions), take good nutrition, especially adequate intake of calcium and vitamin D, stop smoking, monitor alcohol intake, and consult a health care provider for antiresorptive therapy. **EB:** *Supplementation with vitamin D3 (cholecalciferol) and calcium reduced the risk of hip fracture by 43%. The National Osteoporosis Foundation recommends daily calcium intake of at least 1200 mg with diet plus supplements, if needed, for postmenopausal women and men aged 50 years and older intake of vitamin D3 800 to 1000 IU per day (Cotton D, 2011).*
- For more information, refer to the care plans for Impaired **Transfer** ability and Impaired wheelchair **Mobility**.

Wandering Laura May Struble, PhD, GNP-BC

NANDA-I

Definition

Meandering: aimless or repetitive locomotion that exposes the individual to harm; frequently incongruent with boundaries, limits, or obstacles

Defining Characteristics

Continuous movement from place to place; eloping behavior; frequent movement from place to place; fretful locomotion; haphazard locomotion; hyperactivity; impaired ability to locate landmarks in a familiar setting; locomotion into unauthorized spaces; locomotion resulting in getting lost; locomotion that cannot be easily dissuaded; long periods of locomotion without an apparent destination; pacing; periods of locomotion interspersed with periods of non-locomotion (e.g., sitting, standing, sleeping); persistent locomotion in search of something; scanning behavior; searching behavior; shadowing a caregiver's locomotion; trespassing

Related Factors (r/t)

Alteration in cognitive functioning; cortical atrophy; overstimulating environment; physiological state (e.g., hunger, thirst, pain, need to urinate); premorbid behavior (e.g., outgoing, sociable personality); psychological disorder; sedation; separation from familiar environment; time of day

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Safe Wandering; Caregiver Home Care Readiness; Fall Prevention Behavior; Falls Occurrence

Example NOC Outcome with Indicators

Safe Wandering as evidenced by the following indicators: Moves about without harming self or others/Sits for more than 5 minutes at a time/Paces a given route/Appears content in environment/Distracts easily/Can be redirected from unsafe activities. (Rate the outcome and indicators of **Safe Wandering**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section 1].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain psychological well-being and reduce any felt need to wander
- Decrease the amount of time getting lost
- Engage in meaningful activities daily
- Remain safe and free from falls and elopement
- Maintain physical activity and remain comfortable and free of pain
- Maintain appropriate body weight and be well nourished and well hydrated
- Be physically well rested and demonstrate absence of fatigue

Caregiver Will (Specify Time Frame)

- Be able to explain interventions he/she can use to provide a safe environment for a care receiver who displays wandering behavior
- Develop strategies to reduce caregiver stress levels

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Dementia Management

Example NIC Activities—Dementia Management

Place identification bracelet on the client; Provide space for safe pacing and wandering

Nursing Interventions and Rationales

Acute Care Hospital: Wandering

- Screen clients with cognitive impairment at the time of admission and when the client is transferred to another unit in the hospital. Assess for concerns that the client will wander from family members and other health professionals. In addition, assess for the client's ability to walk independently or with minimal assistance. **EB**: *A two-question assessment tool was developed by a multidisciplinary team that identified clients at risk for wandering. The tool used electronic health records and initiated a list of wandering interventions required once a client was identified as a wandering risk (Sheth et al, 2014).*
- If the client is at risk for wandering in the hospital setting, the following interventions may be implemented: dress the client in a brightly colored hospital gown that is easily identifiable, provide appropriate supervision and surveillance of the at risk client, identify in the chart (electronic record) the client's risk for wandering, discuss with the client and family the risks of wandering, set up appropriate alarm systems, consult with geriatric or mental health advanced practice nurse regarding wandering risks and individualized interventions, and have a current client photograph on file to help with identification in case the client leaves unattended. **EBN**: *The suggested interventions may reduce the risk of clients getting injured or lost, or wandering into restricted areas in the hospital setting (Sheth et al, 2014).*

Nursing Care Facilities: Wandering

- Assess and document the amount (frequency and duration), percentage of hours with wandering, and 24-hour distribution of wandering behavior over 3 days. **EBN:** *Assessment over time provides a baseline against which behavioral change can be evaluated and targets the time of day when behavioral interventions are most necessary (Algase et al, 2009).*
- Assess and document the quantity and qualities of wandering behaviors (e.g., persistent walking, repetitive walking, eloping behaviors, spatial disorientation, goal directed, negative outcomes). **CEB:** *Instruments such as the Revised Algase Wandering Scale indicate whether the behavior is persistent or spatially disordered, or if the client is prone to elopement. A recent review of 34 wandering instruments concluded that the Algase tool had the most in-depth description of wandering behaviors (White & Montgomery, 2014).*
- Obtain a history of personality characteristics and behavioral responses to stress. **EBN:** *Premorbid personality traits (e.g., history of a physically active job or leisure activities) and behavioral responses to stress (e.g., history of responding to stress with psychomotor activity) may reveal circumstances under which wandering will occur and can aid in interpreting both positive and negative meanings of wandering behavior (Song & Algase, 2008).*
- Evaluate for neurocognitive strengths and limitations, particularly language, attention, and visuospatial skills. **CEB:** *Wanderers may have expressive language deficits that hamper their ability to communicate needs (Algase, 1992).* **CEB:** *Knowledge of attentional and visuospatial deficits, which may account for certain patterns of wandering or way-finding deficits, can lead to identification of appropriate environmental modifications that could enhance functional ambulation, such as elimination of distractions and enhancement of cues marking desired destinations (Chiu et al, 2004).*
- Assess for level of cognitive and emotional status and age. **CEB:** *In a secondary analysis of a multisite study, higher rates of wandering were related to younger age and severe cognitive impairment. In addition, positive emotional expressions were related to higher rates of wandering and should be considered a positive result of wandering behavior (Lee et al, 2014).*
- Assess for changes in cognition and signs and symptoms of medical illness such as pneumonia or cardiovascular disease. **EB:** *A large longitudinal study found advancing dementia and/or an undiagnosed medical event that affects cognition but spares mobility are associated with the onset of wandering (King-Kallimanis et al, 2010).*
- Assess and monitor for drug-induced akathisia (motor restlessness). **CEB:** *Although wandering has not been specifically linked to akathisia, medications such as antipsychotics, selective serotonin reuptake inhibitors, antiemetics, and dopamine antagonist drugs may increase restlessness, pacing, and the urge to move (Molinari et al, 2008; Schneider et al, 2006).* **CEB:** *The occurrence of akathisia can be assessed with the Barnes Akathisia Rating Scale (Barnes, 1989).*
- Discontinue use of medications and physical restraints that are used for the sole purpose of controlling wandering behavior. **CEB:** *The Omnibus Budget Reconciliation Act (OBRA) of 1978 requirements specify that wandering behavior is not an appropriate target symptom for the use of psychotropic medications or physical restraints. In addition, there is no evidence that psychotropic medications should be used to treat any type of wandering behavior (Sink et al, 2005; Rosenberg et al, 2012).*
- Assess for emotional or psychological distress, such as anxiety, fear, or feeling lost. **EB:** *Anxiety, loneliness, and separation may be related to restlessness and wandering (Ata et al, 2010).*
- Assess for physical distress or unmet needs (e.g., hunger, thirst, pain discomfort, elimination) with the Need-Driven Dementia-Compromised Behaviors (NBD) model. **EBN:** *The NBD model may help explain reasons for wandering and offers direction in the development of management strategies (Futrell et al, 2010; Miranda-Castillo et al, 2010).*
- Observe wandering episodes for antecedents and consequences. **CEB:** *Triggers for wanderers include being placed in an unfamiliar environment, seeing a coat and hat, experiencing an argumentative or confrontational situation, a change in schedule or routine, and recent relocation to a care facility (Silverstein & Flaherty, 2003).*
- Observe the location where and environmental conditions in which wandering is occurring and modify those that appear to induce wandering. **EBN:** *In a recent observational study, wanderers were less likely to wander from where the likelihood of social interaction was greater (i.e., activities room, dayroom, staff area); where the environment was more soothing (i.e., their own room); or where rooms had a designated purpose (e.g., dayrooms, the wanderer's own room, activities and staff areas), and wandering was less likely when lighting was low and variation in sound levels was small (Algase et al, 2010).*

- Assess regularly for the presence of or potential for negative outcomes of wandering (e.g., elopement, declining social skills, onset of falls, becoming lost, and injuries). **CEB:** *Wanderers are at great risk for falls and other adverse events (Nelson & Algase, 2007).*
- Weigh the client at defined intervals to detect onset of weight loss, and watch for symptoms associated with inadequate food intake, including constipation, dehydration, muscle wasting, and starvation. **CEB:** *Wandering behavior can affect the client's ability to eat, when the client is unable to sit at a table for the time needed to eat a meal (Beattie & Algase, 2002).*
- For the client who displays wandering behavior during mealtimes, use behavioral interventions to shape behavior, including verbal statements, nonverbal social behavior, and systematic extinguishing of undesirable client behavior. **CEB:** *Results of a study using behavior interventions demonstrated that they were effective in increasing the time the client sat at the table and the amount of food the client ate (Beattie et al, 2004).*
- Provide for safe ambulation with comfortable and well-fitting clothes, shoes with nonskid soles and foot support, and any necessary walking aids (e.g., a cane or walker). **CEB:** *Wanderers are at increased risk for falls (Katz et al, 2004).*
- Refer to physical therapy for core therapeutic exercise, balance, gait, and assistive device training. **EB:** *In a case study, physical therapy demonstrated positive functional outcomes using fall prevention interventions modified for the client's cognition, communication deficits, and behavior problems (Mirolsky-Scala & Kraemer, 2009).*
- Provide safe and secure surroundings that deter accidental elopements, using perimeter control devices or electronic tracking systems. **CEB:** *A review of technology identified boundary alarms activated by wrist bands, alarms alerting caregivers of wandering behavior, and electronic monitoring and tracking systems, such as global positioning systems (GPS), as effective in improving client safety (Lauriks et al, 2007).*
- There are ethical concerns in the use of tracking technologies. **EB:** *Qualitative and quantitative results from a large study recommend that clients with dementia should be part of the decision process related to the use of monitoring systems as early as possible in the dementia disease process (Landau & Werner, 2012). In an ethnographic field study, the themes that emerged suggested that technology may contribute to the client's autonomy if a person-centered approach is used and the client's experience with devices is evaluated (Niemeijer et al, 2014).*
- During periods of inactivity, position the wanderer so that desirable destinations (e.g., bathroom) are within the client's line of vision and undesirable destinations (e.g., exits or stairwells) are out of sight. **CEB:** *Functional, nonwandering ambulation is possible even into late-stage dementia and may be facilitated by keeping appropriate visual cues accessible (Passini et al, 2000).*
- Facilitate way-finding through therapeutic environmental design. **EB:** *Thirty nursing homes were analyzed for architectural characteristics, and the significant characteristics that impact spatial orientation included limiting the number of people with dementia per living area, providing straight layouts without changes in direction to important locations, and providing only one living/dining room (Marquardt & Schmiege, 2009).*
- Enhance the physical environment by increasing visual appeal and provide interesting views and opportunities to sit. **CEB:** *In a cross-sectional study, environmental ambience influenced walking frequencies, walking duration, and sitting duration (Yao & Algase, 2006).*
- Engage wanderers in social interaction and structured activity such as painting or coloring, especially when wanderers appear distressed or otherwise uncomfortable, or their wandering presents a challenge to others in the setting. **EB:** *In a case study, simple leisure activities such as picture coloring significantly reduced wandering behavior (Giulio et al, 2011).*
- Provide headphones and iPod with individualized preferred music while the person with dementia is wandering, or encourage the person to participate in a music group. **EBN:** *In an intervention nursing home study in Taiwan, researchers found preferred music listening had a positive impact by reducing the level of anxiety in older residents with dementia (Sung et al, 2010).*
- If wandering has a pacing quality, attempt to identify and address any underlying problems or concerns. Offer stress-reducing approaches, such as music, massage, or rocking. Attempts to distract or redirect the pacing wanderer may worsen wandering. **EB:** *In a field study, the researchers found a close relationship between wandering and restlessness (Ata et al, 2010).*
- Provide a regularly scheduled and supervised exercise or walking program, particularly if wandering occurs excessively during the night or at times that are inconvenient in the setting. **CEB:** *Although exercise or walking programs do not reduce daytime wandering, they have been shown to reduce or eliminate nighttime wandering (Carillon Nursing and Rehabilitation Center, 2000).*

- Use soft tactile hand massage before the times of day or events that induce wandering. **EB:** *In an intervention study, soft hand massage for 20 minutes reduced aggressiveness and stress in clients with dementia (Suzuki et al, 2010).*

Multicultural

- Recognize that wandering occurs with little variation in expression among individuals with dementia regardless of culture or ethnicity. **CEB/EB:** *Wandering has been reported in multiple populations and varies little by cultural group (Greiner et al, 2007; Young et al, 2008).*
- Assess for the influence of cultural beliefs, norms, and values on the family's understanding of wandering behavior. **CEB:** *Latina caregivers of people with dementia delay institutionalization significantly longer than female Caucasian caregivers because of Latino cultural values and positive views of the caregiving role (Mausbach et al, 2004; Sink et al, 2004).*
- ▲ Refer the family to social services or other supportive services to assist with the impact of caregiving for the wandering client.
- Encourage the family to use support groups or other service programs.

Home Care

- Help the caregiver set up a plan to deal with wandering behavior using the interventions mentioned earlier.
- Assess the home environment for modifications that will protect the client and prevent elopement. *Security devices are available to notify the caregiver of the client's movements such as alarms at doors, bed alarms, and ongoing surveillance (McKenzie et al, 2013).*
- Assist the family to set up a plan of exercise for the client, including safe walking. *Walking is a valuable source of exercise, even for clients with dementia.*
- Enroll wanderers in the Safe Return Program of the Alzheimer's Association, and help the caregiver develop a plan of action to use if the client elopes. **CEB:** *The Safe Return Program has assisted in locating numerous persons who have eloped from their homes or other residential care settings. Mortality rates are high if there is failure to locate elopers within the first 24 hours (Rowe & Glover, 2001).*
- Help the caregiver develop a plan of action to use if the client elopes.
- Refer for homemaker or psychiatric home health care services for respite, client reassurance, and implementation of a therapeutic regimen. Refer to the care plan for **Caregiver Role Strain**. *Responsibility for a person at high risk for wandering provides high caregiver stress. Respite care decreases caregiver stress. The presence of caring individuals is reassuring to both the client and caregivers, especially during periods of client anxiety. Wandering behavior can make use of the interventions described previously, modified for the home setting.*

Client/Family Teaching and Discharge Planning

- Use a broad range of descriptions for the term "wandering" to enhance caregivers' understanding. **EB:** *In structured interviews, it was found that informal caregivers rarely used the term "wandering," which could lead to miscommunication with health care providers (Houston et al, 2011).*
- Inform the client and family of the meaning of and reasons for wandering behavior. An understanding of wandering behavior will enable the client and family to provide the client with a safe environment.
- Teach the caregiver/family methods to deal with wandering behavior using the interventions mentioned in Nursing Interventions and Rationales.

APPENDIX A

Nursing Diagnoses Arranged by Maslow's Hierarchy of Needs

Because human beings adapt in many ways to establish and maintain the self, health problems are much more than simple physical matters. Maslow's Hierarchy of Needs (see diagram below) is a system of classifying human needs. Maslow's hierarchy is based on the idea that lower-level physiological needs must be met before higher-level, abstract needs can be met.

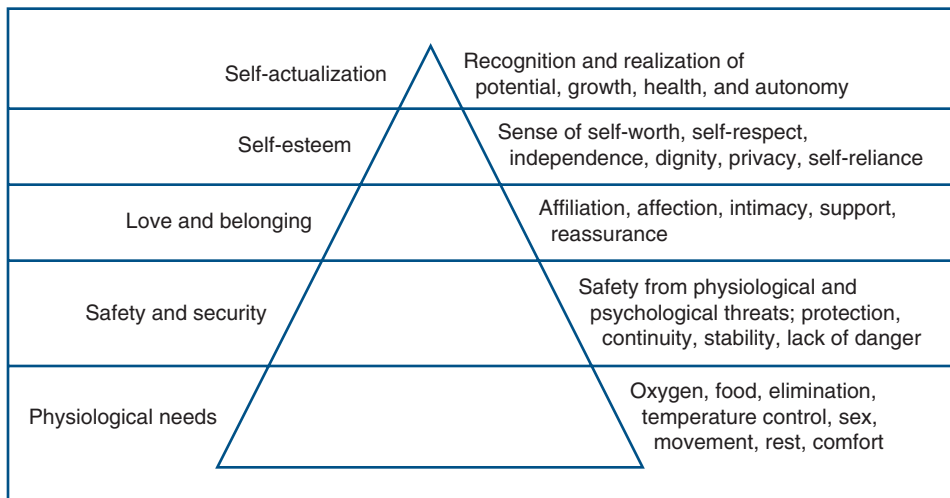

For nurses, Maslow's hierarchy has special significance in decision-making and planning for care. By considering need categories as you identify client

problems, you will be able to provide more holistic care. For example, a client who demands frequent attention for a seemingly trivial matter may require help with self-esteem needs. Need levels vary from client to client. If a client is short of breath, the client is probably not interested in or capable of discussing spirituality. In addition, a client's need level may change throughout planning and intervention, so you will need to be vigilant in your assessment.

All needs are relevant. Too many times, physiological problems are caused

by unmet psychological problems. For example, poor self-esteem or unmet needs for love can result in use of food as a source of comfort, leading to obesity and resultant heart disease.

Read the descriptions of each category in the diagram and see how you would relate them to nursing diagnoses. Compare your evaluation with how the authors categorized the nursing diagnoses according to this hierarchy. Be sure to assess clients for potential problems at all levels of the pyramid, regardless of their initial complaint.

Spiritual well-being, readiness for enhanced

APPENDIX B

Nursing Diagnoses Arranged by Gordon's Functional Health Patterns

Diagnoses currently accepted by NANDA-I (North American Nursing Diagnosis Association—International).

HEALTH-PERCEPTION— HEALTH-MANAGEMENT PATTERN

Ineffective **Airway** clearance
Risk for **Allergy** response
Risk for **Aspiration**
Autonomic Dysreflexia
Risk for **Autonomic Dysreflexia**
Risk for **Bleeding**
Contamination
Risk for **Contamination**
Risk for adverse reaction to iodinated **Contrast Media**
Risk for dry **Eye**
Risk for **Falls**
Frail Elderly syndrome
Risk for **Frail Elderly** syndrome
Deficient community **Health**
Ineffective **Health** maintenance
Ineffective **Health** management
Risk-prone **Health** behavior
Readiness for enhanced **Health** management
Risk for **Infection**
Risk for **Injury**
Risk for corneal **Injury**
Risk for urinary tract **Injury**
Latex Allergy Response
Risk for **Latex Allergy** Response
Noncompliance
Risk for **Perioperative Positioning** injury
Risk for **Poisoning**
Ineffective **Protection**
Self-Neglect
Risk for **Shock**
Impaired **Skin** integrity
Risk for impaired **Skin** integrity
Risk for **Suffocation**
Risk for **Thermal** injury
Impaired **Tissue** integrity
Risk for impaired **Tissue** integrity
Risk for **Trauma**
Risk for **Vascular Trauma**
Impaired spontaneous **Ventilation**
Dysfunctional **Ventilatory** weaning response

NUTRITIONAL-METABOLIC PATTERN

Risk for **Aspiration**
Insufficient **Breast Milk**

Ineffective **Breastfeeding**
Interrupted **Breastfeeding**
Readiness for enhanced **Breastfeeding**
Impaired **Dentition**
Risk for **Electrolyte** imbalance
Ineffective infant **Feeding** pattern
Deficient **Fluid** volume
Excess **Fluid** volume
Readiness for enhanced **Fluid** balance
Risk for deficient **Fluid** volume
Risk for imbalanced **Fluid** volume
Dysfunctional **Gastrointestinal** motility
Risk for dysfunctional **Gastrointestinal** motility
Risk for ineffective **Gastrointestinal** perfusion
Risk for unstable blood **Glucose** level
Hyperthermia
Hypothermia
Risk for **Hypothermia**
Neonatal **Jaundice**
Risk for neonatal **Jaundice**
Latex Allergy response
Risk for impaired **Liver** function
Nausea
Imbalanced **Nutrition**: less than body requirements
Readiness for enhanced **Nutrition**
Obesity
Overweight
Risk for **Overweight**
Impaired **Oral Mucous Membrane**
Risk for **Perioperative Hypothermia**
Risk for **Pressure** ulcer
Impaired **Skin** integrity
Risk for impaired **Skin** integrity
Risk for **Sudden Infant Death** syndrome
Impaired **Swallowing**
Risk for imbalanced body **Temperature**
Ineffective **Thermoregulation**
Impaired **Tissue** integrity
Risk for impaired **Tissue** integrity

ELIMINATION PATTERN

Chronic functional **Constipation**
Perceived **Constipation**
Risk for chronic functional **Constipation**
Diarrhea
Bowel **Incontinence**
Functional urinary **Incontinence**
Overflow urinary **Incontinence**
Reflex urinary **Incontinence**

Risk for urge urinary **Incontinence**
 Stress urinary **Incontinence**
 Urge urinary **Incontinence**
 Risk for ineffective **Renal** perfusion
 Impaired **Urinary** elimination
 Readiness for enhanced **Urinary** elimination
Urinary Retention

ACTIVITY-EXERCISE PATTERN

Activity intolerance
 Risk for **Activity** intolerance
 Ineffective **Breathing** pattern
 Risk for decreased **Cardiac** tissue perfusion
 Decreased **Cardiac** output
 Risk for decreased **Cardiac** output
 Risk for impaired **Cardiovascular** function
 Risk for delayed **Development**
 Risk for **Disuse** syndrome
 Deficient **Diversional** activity
Fatigue
 Impaired **Gas** exchange
 Risk for disproportionate **Growth**
 Impaired **Home** maintenance
 Disorganized **Infant** behavior
 Readiness for enhanced organized **Infant** behavior
 Risk for disorganized **Infant** behavior
 Impaired bed **Mobility**
 Impaired physical **Mobility**
 Impaired wheelchair **Mobility**
 Risk for **Peripheral Neurovascular** dysfunction
Sedentary lifestyle
 Bathing **Self-Care** deficit
 Dressing **Self-Care** deficit
 Feeding **Self-Care** deficit
 Readiness for enhanced **Self-Care**
 Toileting **Self-Care** deficit
 Impaired **Sitting**
 Impaired **Standing**
 Delayed **Surgical** recovery
 Risk for delayed **Surgical** recovery
 Ineffective peripheral **Tissue Perfusion**
 Risk for ineffective peripheral **Tissue Perfusion**
 Impaired **Transfer** ability
Unilateral Neglect
 Risk for **Unilateral Neglect**
 Impaired **Walking**
Wandering

SLEEP-REST PATTERN

Insomnia
 Disturbed **Sleep** pattern
 Readiness for enhanced **Sleep**
Sleep deprivation

COGNITIVE-PERCEPTUAL PATTERN

Ineffective **Activity** planning
 Risk for ineffective **Activity** planning
 Risk for ineffective **Cerebral** tissue perfusion
 Impaired **Comfort**
 Readiness for enhanced **Comfort**
 Acute **Confusion**
 Chronic **Confusion**
 Risk for acute **Confusion**
 Readiness for enhanced **Decision-Making**
Decisional Conflict
 Labile **Emotional Control**
 Ineffective **Impulse** control
 Decreased **Intracranial** adaptive capacity
 Deficient **Knowledge**
 Readiness for enhanced **Knowledge**
 Impaired **Memory**
 Acute **Pain**
 Chronic **Pain**
 Chronic **Pain** syndrome
 Labor **Pain**
Unilateral Neglect

SELF-PERCEPTION— SELF-CONCEPT PATTERN

Anxiety
 Death **Anxiety**
 Disturbed **Body Image**
Fear
 Readiness for enhanced **Hope**
Hopelessness
 Risk for compromised **Human Dignity**
 Disturbed personal **Identity**
 Risk for disturbed personal **Identity**
 Risk for **Loneliness**
 Readiness for enhanced **Power**
Powerlessness
 Risk for **Powerlessness**
 Readiness for enhanced **Self-Concept**
 Chronic low **Self-Esteem**
 Risk for chronic low **Self-Esteem**
 Situational low **Self-Esteem**
 Risk for situational low **Self-Esteem**
 Risk for self-directed **Violence**

ROLE-RELATIONSHIP PATTERN

Risk for impaired **Attachment**
Caregiver Role Strain
 Risk for **Caregiver Role Strain**
 Impaired verbal **Communication**

Readiness for enhanced **Communication**
 Dysfunctional **Family** processes
 Ineffective Family **Health** management
 Interrupted **Family** processes
 Readiness for enhanced **Family** processes
Grieving
 Complicated **Grieving**
 Risk for complicated **Grieving**
 Risk for disturbed **Maternal–Fetal** dyad
 Impaired **Parenting**
 Readiness for enhanced **Parenting**
 Risk for impaired **Parenting**
 Ineffective **Relationship**
 Risk for ineffective **Relationship**
 Readiness for enhanced **Relationship**
 Ineffective **Role** performance
 Parental **Role** conflict
 Impaired **Social** interaction
Social isolation
 Chronic **Sorrow**

SEXUALITY-REPRODUCTIVE PATTERN

Ineffective **Childbearing** process
 Readiness for enhanced **Childbearing** process
 Risk for ineffective **Childbearing** process
 Risk for disturbed **Maternal–Fetal** dyad
Sexual dysfunction
 Ineffective **Sexuality** pattern

COPING—STRESS-TOLERANCE PATTERN

Compromised family **Coping**
 Defensive **Coping**

Disabled family **Coping**
 Ineffective community **Coping**
 Ineffective **Coping**
 Readiness for enhanced community **Coping**
 Readiness for enhanced **Coping**
 Readiness for enhanced family **Coping**
 Ineffective **Denial**
 Risk-prone **Health** behavior
 Impaired **Mood** regulation
Post-Trauma syndrome
 Risk for **Post-Trauma** syndrome
Rape-Trauma syndrome
Relocation stress syndrome
 Risk for **Relocation** stress syndrome
 Impaired **Resilience**
 Readiness for enhanced **Resilience**
 Risk for impaired **Resilience**
Self-Mutilation
 Risk for **Self-Mutilation**
Stress overload
 Risk for **Suicide**
 Risk for other-directed **Violence**

VALUE-BELIEF PATTERN

Impaired emancipated **Decision-Making**
 Readiness for enhanced emancipated **Decision-Making**
 Risk for impaired emancipated **Decision-Making**
Moral Distress
 Impaired **Religiosity**
 Readiness for enhanced **Religiosity**
 Risk for impaired **Religiosity**
Spiritual distress
 Risk for **Spiritual** distress
 Readiness for enhanced **Spiritual** well-being

Motivational Interviewing for Nurses

Mary P. Mancuso, MA

Motivational interviewing (MI) is an evidenced-based interpersonal style used with individuals who would benefit from changes in their behaviors. Nurses may find this approach helpful in guiding clients toward making positive lifestyle changes and adhering to recommended treatment regimens. Unlike other aspects of nursing, MI does not involve *directing* clients to engage in certain behaviors. Rather, it involves *guiding* clients to take steps toward making a behavioral change through collaboration, support, and inspiration (Miller & Rollnick, 2013).

The origins of MI are in the field of psychology, but this technique has been applied in a variety of settings including health care. A recent systematic review and meta-analysis found MI to be effective in helping clients make a number of behavioral changes leading to positive health outcomes including body weight, cholesterol level, blood pressure, reduction in alcohol consumption, smoking cessation, and lowering HIV viral load (Lundahl et al, 2013). These studies took place in medical care settings and involved brief consultations with a variety of clients with different characteristics demonstrating that MI can be a successful approach for health care providers working with clients. Further evidence is being compiled, but single studies demonstrate promising findings that MI can be effective in helping clients adhere to treatment regimens, particularly clients with chronic disease (Moral et al, 2015).

As individuals begin to take steps toward making a behavioral change, they often experience ambivalence; individuals both want to change and do not want to change at the same time. Clients may express agreement about the benefits of changing (*change talk*) as well as argue against making a change (*sustain talk*) (Miller & Rollnick, 2013). The central concept of MI is an approach

to communication that motivates the client to change by resolving ambivalence and unresolved feelings. The nurse who uses MI does not directly confront the client's ambivalence or resort to using methods that try to coerce the client into changing behaviors. Rather, the nurse recognizes the client's autonomy and understands that clients will only make a change when they are ready. Ideally, the client will voice his/her own reasons to change; if the nurse provides the client with reasons to change (e.g., "You will be more healthy if you exercise more"), the client may argue against it. People are more convinced to change when they formulate their own arguments (Miller & Rollnick, 2013).

At the heart of MI are four interrelated elements: collaboration, acceptance, compassion, and evocation. The nurse and client collaborate to move toward change; the nurse accepts where the client is in the process of change, feels and demonstrates compassion for the client, and helps call forth change from within the client himself (Miller & Rollnick, 2013). The nurse, over time, helps the client focus on the hope of success in making a change as well as recognizing and using the resources the client already has supporting change (Csillik, 2015). Four principles of MI help the nurse accomplish collaboration with the client to achieve positive change: (1) expressing empathy, (2) supporting self-efficacy, (3) allowing for resistance, and (4) developing discrepancy. Expressing empathy involves reflecting what the client is feeling and experiencing. Supporting self-efficacy encompasses the understanding that clients are the experts on their own lives and facilitating hope for change. Allowing for resistance involves seeking to understand the client while not arguing for change or offering solutions for change. Developing discrepancy entails

cultivating the client's perception of the gap between current behaviors and the values he/she holds deeply (Miller & Rollnick, 2013).

Case example: A female client is admitted to an inpatient unit; she is experiencing multiple medical conditions secondary to obesity. Her provider has ordered a low-calorie diet while she is in the hospital. The client makes angry comments during meal times and refuses to adhere to the diet, asking friends and family to sneak in prohibited snacks. Nurses not educated about MI may use logical expressions when communicating with this client. An example of this approach would be, "Eating foods high in calories will increase your risk for continued weight gain, resulting in further medical problems." In contrast, MI requires that a therapeutic rapport be established between the nurse and the client and that logical expressions that confront the client be avoided. The nurse using MI uses empathy statements, expressing an understanding of the client's ambivalence, for example, "You are frustrated about being on a low-calorie diet." Establishing rapport facilitates trust in the nurse-client relationship and allows for future collaboration.

After developing a collaborative relationship, the nurse uses the process of evocation to expose the client's own thoughts and ideas. The client may exhibit varying levels of resistance to change. During these periods, the nurse must not confront the resistance; rather, the nurse should allow the client to express himself or herself freely. Allowing for this resistance prevents a power struggle between the nurse and the client. The client may say, "I know I'm fat and unhealthy. I see myself in the mirror every day, but that doesn't mean I need to be on a diet." Instead of presenting the low-calorie diet as the recommended strategy, the nurse

reflects back the client's statements and encourages his or her own ideas for change (e.g., "It sounds like being overweight frustrates you; what are some weight loss strategies that might work for you?"). Although not all of the client's suggestions may be appropriate, recognizing the client's own motivation for change by using reflective listening is important. The nurse must refrain from instructing the client, using persuasion, or minimizing feelings by saying, for example, "You just have to try the diet; it won't be that bad." During this phase of MI, the nurse continues with open-ended statements and positive affirmations in an attempt to get the client to recognize the need for a change: "I am impressed that you realize it takes a lot of work to get healthy; tell me how that makes you feel."

Last, when MI is consistently used, the client begins to examine discrepancies between his or her future goals and his or her current patterns of behavior. During this phase of MI, the nurse uses the technique of exploration and clarification in an attempt to get the client to recognize the need for a change. "In what ways do you feel like being overweight affects your health?" As the client

begins to expose discrepancies between his or her current behavior and future goals, the impetus for change will emerge. The nurse then provides positive affirmations to empower the client to make changes: "You seem very determined to get healthy. I think your plan is definitely achievable."

When the client begins to make statements that express the intent to change, the nurse uses an MI summary to reinforce what has been discussed. The summary communicates a mutual interest and understanding of the significant elements that were addressed. This summary serves as a platform to move the client toward implementing change and typically reveals the client's ambivalence, discrepancy, and self-empowerment; however, it is up to the nurse to recognize what aspects should be included to encourage the client to move forward. An example summary statement is, "You get frustrated and sad about being overweight but realize that change is a hard thing. You have decided to increase your exercise once a week to help you get healthier. You have made changes like that in the past with much success. Your plan is very doable and a step in the right direction."

Motivating clients to make behavioral changes is an important nursing task and requires diligence and patience. Motivational Interviewing is a fluid method that does not always follow a direct formula, so it is essential for nurses to be flexible and allow the principles of MI to evolve differently, depending on the individual and the situation.

APPENDIX D

Wellness-Oriented Diagnostic Categories

This is a list of NANDA-I diagnoses in a wellness format. When available, readiness diagnoses are listed first in each category. Risk diagnoses are listed next. The goal is to support wellness, prevent illness, and intervene when illness is present.

Diagnoses are arranged first by priority according to the ABCs (airway, breathing, circulation). They are then arranged according to possible priority physiological needs and then psychosocial needs. Diagnoses dealing with family, infant, and child are grouped together. It is the responsibility of the nurse to individualize and reorder based on the client's assessment data.

This list refers to adult care plans. Asterisked diagnoses have pediatric interventions in the care plans.

PHYSIOLOGICAL

Airway/Breathing

- Risk for **Aspiration**
- Risk for **Suffocation**
- Impaired **Swallowing**
- Ineffective **Airway** clearance
- Ineffective **Breathing** pattern
- Impaired **Gas** exchange
- Impaired spontaneous **Ventilation**
- Dysfunctional **Ventilatory** weaning response

Circulation

- Risk for **Bleeding**
- Risk for decreased **Cardiac** output
- Risk for impaired **Cardiovascular** function
- Risk for decreased **Cardiac** tissue perfusion
- Risk for ineffective **Cerebral** tissue perfusion
- Risk for ineffective **Gastrointestinal** tissue perfusion
- Risk for **Peripheral Neurovascular** dysfunction
- Risk for ineffective **Renal** perfusion

- Risk for **Shock**
- Decreased **Cardiac** output
- Ineffective peripheral **Tissue Perfusion**

COGNITION/SENSORY PERCEPTION

- Risk for acute **Confusion**
- Risk for **Autonomic Dysreflexia**
- Ineffective **Activity** planning
- **Autonomic Dysreflexia**
- Decreased **Intracranial** adaptive capacity
- Acute **Confusion**
- Chronic **Confusion**
- Impaired **Memory**

INJURY: FALLS/ INFECTION/POISONING/ TRAUMA

- Readiness for Enhanced **Health** management
- Risk for **Contamination**
- Risk for corneal **Injury**
- Risk for **Falls**
- Risk for **Injury***
- Risk for **Infection***
- Risk for **Latex Allergy** response
- Risk for **Perioperative Positioning** injury
- Risk for **Poisoning***
- Risk for delayed **Surgical** recovery
- Risk for **Trauma**
- Risk for urinary tract **Injury**
- Risk for **Vascular Trauma***
- Acute **Pain*** (psychosocial)
- Chronic **Pain*** (psychosocial)
- **Contamination**
- Delayed **Surgical** recovery
- Ineffective **Protection**
- **Latex Allergy** response
- **Rape-Trauma** syndrome

HOMEOSTASIS

- Risk for **Hypothermia**
- Risk for impaired **Liver** function
- Risk for unstable blood **Glucose** level
- Risk for imbalanced body **Temperature***
- Risk for **Electrolyte** imbalance
- Risk for **Perioperative Hypothermia**
- **Hyperthermia**
- **Hypothermia***
- Ineffective **Thermoregulation**

FLUID/NUTRITION/ GASTROINTESTINAL/ ORAL/DENTAL MANAGEMENT

- Readiness for enhanced **Fluid** balance
- Readiness for enhanced **Nutrition**
- Risk for dysfunctional **Gastrointestinal** motility
- Risk for **Overweight**
- Risk for impaired **Oral Mucous Membrane**
- Risk for imbalanced **Fluid** volume
- Risk for deficient **Fluid** volume
- Dysfunctional **Gastrointestinal** motility
- **Nausea**
- Imbalanced **Nutrition**: less than body requirements
- Deficient **Fluid** volume*
- Excess **Fluid** volume
- **Obesity**
- **Overweight**
- Impaired **Oral Mucous Membrane**
- Impaired **Dentition**

ELIMINATION

Urinary Elimination

- Readiness for enhanced **Urinary** elimination

- Impaired **Urinary** elimination
- **Urinary Retention**

INCONTINENCE, BOWEL

- Bowel **Incontinence**

INCONTINENCE, BLADDER

- Risk for urge urinary **Incontinence**
- Functional urinary **Incontinence**
- Overflow urinary **Incontinence**
- Reflex urinary **Incontinence**
- Stress urinary **Incontinence**
- Urge urinary **Incontinence**

BOWEL ELIMINATION

Constipation

- Risk for chronic functional **Constipation**
- Risk for **Constipation**
- Perceived **Constipation**
- Chronic functional **Constipation**
- **Constipation**

Diarrhea

- Diarrhea*

ACTIVITY/MOVEMENT/ SELF-CARE

- Readiness for enhanced **Self-Care**
- Risk for **Activity** intolerance
- Risk for **Disuse** syndrome
- **Sedentary** lifestyle*
- Deficient **Diversional** activity*
- **Activity** intolerance
- **Fatigue**
- Impaired physical **Mobility**
- Bathing **Self-Care** deficit
- Dressing **Self-Care** deficit
- Feeding **Self-Care** deficit
- Toileting **Self-Care** deficit
- **Self-Neglect**
- Impaired **Sitting**
- Impaired **Standing**
- Impaired **Walking**
- Impaired **Transfer** ability

- Impaired bed **Mobility**
- Impaired wheelchair **Mobility**
- **Unilateral Neglect**
- **Wandering**

SKIN/TISSUE

- Risk for **Pressure** ulcer
- Risk for impaired **Skin** integrity
- Risk for impaired **Tissue** integrity
- Impaired **Skin** integrity
- Impaired **Tissue** integrity

SLEEP

- Readiness for enhanced **Sleep**
- Disturbed **Sleep** pattern
- **Insomnia**
- **Sleep** deprivation

PSYCHOSOCIAL

Comfort

- Readiness for enhanced **Comfort**
- Impaired **Comfort**
- Acute **Pain*** (physiological)
- Chronic **Pain*** (physiological)
- Chronic **Pain** syndrome
- Labor **Pain**

COMMUNICATION/ HEALTHY BEHAVIORS/ THERAPEUTIC REGIMEN/ KNOWLEDGE

Individual

- Readiness for enhanced **Communication***
- Readiness for enhanced **Health** management
- Readiness for enhanced **Knowledge***
- Risk-prone **Health** behavior
- Impaired verbal **Communication***
- Ineffective **Health** management
- Deficient **Knowledge***
- Ineffective **Health** maintenance

Family

- Ineffective Family **Health** management

SPIRITUALITY/ RELIGIOUS BELIEFS

- Readiness for enhanced **Spiritual** well-being
- Readiness for enhanced **Religiosity***
- Readiness for enhanced **Hope**
- Risk for **Spiritual** distress
- Risk for impaired **Religiosity**
- Impaired **Religiosity**
- **Spiritual** distress
- **Hopelessness**

HARM: SELF AND OTHERS

- Risk for **Suicide**
- Risk for **Self-Mutilation**
- Risk for other-directed **Violence**
- Risk for self-directed **Violence**
- **Self-Mutilation**

ANXIETY/STRESS

- Readiness for enhanced **Decision-Making**
- Risk for **Relocation** stress syndrome
- Risk for compromised **Human Dignity**
- **Anxiety**
- Death **Anxiety**
- Ineffective **Denial**
- **Decisional Conflict**
- Dysfunctional **Family** processes*
- **Fear***
- **Noncompliance**
- **Relocation** stress syndrome*
- **Stress** overload

COPING

Individual

- Readiness for enhanced **Coping***
- Readiness for enhanced emancipated **Decision-Making**
- Readiness for enhanced **Power**
- Readiness for enhanced **Resilience**
- Risk for impaired emancipated **Decision-Making**
- Risk for **Caregiver Role Strain**
- Risk for impaired **Resilience**
- Risk for **Powerlessness**

- Risk for **Loneliness***
- Risk for **Post-Trauma** syndrome*
- Ineffective **Activity** planning
- Defensive **Coping**
- Ineffective **Coping**
- **Caregiver Role Strain**
- Impaired emancipated **Decision-Making**
- Labile **Emotional Control**
- Impaired **Mood** regulation
- Impaired **Resilience**
- Impaired **Social** interaction
- **Post-Trauma** syndrome
- **Powerlessness**
- Ineffective **Role** performance*
- **Social** isolation

Community

- Readiness for enhanced community **Coping**
- Ineffective community **Coping**

SEXUALITY/BODY IMAGE

- Disturbed **Body Image**
- **Sexual** dysfunction
- Ineffective **Sexuality** pattern*

GRIEF/SORROW

- Risk for complicated **Grieving***
- **Grieving***
- Complicated **Grieving***
- Chronic **Sorrow**

SELF-CONCEPT/SELF-ESTEEM/PERSONAL IDENTITY

- Readiness for enhanced **Self-Concept***
- Risk for situational low **Self-Esteem**
- Disturbed personal **Identity**
- Situational low **Self-Esteem**
- Chronic low **Self-Esteem**

ELDERLY

- Risk for **Frail Elderly** syndrome
- **Frail Elderly** syndrome

FAMILY/INFANT/CHILD

Sudden Infant Death

- Risk for **Sudden Infant Death** syndrome

Development/Growth

- Risk for delayed **Development**
- Risk for disproportionate **Growth**

Neonate

- Neonatal **Jaundice**

Infant Care

- Readiness for enhanced organized **Infant** behavior
- Risk for disorganized **Infant** behavior

- Risk for impaired **Attachment**
- Disorganized **Infant** behavior
- Ineffective infant **Feeding** pattern

Parenting

- Readiness for enhanced **Parenting**
- Risk for impaired **Parenting**
- Impaired **Parenting**
- Parental **Role** conflict

Breastfeeding

- Readiness for enhanced **Breastfeeding**
- Interrupted **Breastfeeding**
- Ineffective **Breastfeeding**

Coping/Family

- Readiness for enhanced family **Coping**
- Readiness for enhanced **Relationship**
- Risk for disturbed **Maternal–Fetal** dyad
- Compromised family **Coping**
- Disabled family **Coping**
- Ineffective Family **Health** management

Family Processes

- Readiness for enhanced **Childbearing** process
- Readiness for enhanced **Family** processes
- Interrupted **Family** processes
- Dysfunctional **Family** processes

APPENDIX E

Nursing Care Plans for Hearing Loss and Vision Loss

Hearing Loss *Betty J. Ackley, MSN, EdS, RN, and Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, FAAN*

NANDA-I

Definition

A condition where there is the inability to detect some or all frequencies of sound and may involve complete or partial impairment of the ability to hear.

NOTE: **Hearing Loss** is not a NANDA-I accepted diagnosis, but is included here because of the frequency of occurrence of hearing loss, especially in the geriatric population.

Defining Characteristics

Inability to hear in noisy environments, difficulty following conversations with more than one person, change in speech, change in usual response to stimuli; disorientation; impaired communication; irritability; poor concentration; restlessness; sensory distortions

Related Factors (r/t)

Altered sensory integration; altered sensory reception; altered sensory transmission; biochemical imbalance; electrolyte imbalance; excessive noise exposure; psychological stress

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes (Auditory)

Cognitive Orientation; Communication: Receptive; Distorted Thought Self-Control; Hearing Compensation Behavior

Example NOC Outcome with Indicators

Hearing Compensation Behavior as evidenced by the following indicators: Monitors symptoms of hearing deterioration/Positions self to advantage hearing/Reminds others to use techniques that advantage hearing/Eliminates background noise/Uses sign language/Uses lip reading/Uses closed captioning for television viewing/Uses hearing assistive devices/Uses hearing aid(s) correctly. (Rate the outcome and indicators of **Hearing Compensation Behavior**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see [Section I](#)].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate understanding by a verbal, written, or signed response
- Demonstrate relaxed body movements and facial expressions
- Explain plan to modify lifestyle to accommodate hearing impairment
- Demonstrate familiarity with hearing assistive devices

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cognitive Stimulation; Communication Enhancement: Hearing Deficit, Visual Deficit; Environmental Management

Example NIC Activities—Communication Enhancement: Visual Deficit

Identify yourself when you enter the client's space; Build on client's remaining vision, as appropriate

Nursing Interventions and Rationales

- Observe for signs of a hearing loss, especially in people exposed to loud noise and people older than 60 years of age. *Signs include the following: miscommunication, difficulty understanding words in a noisy environment or when in a crowd of people, frequently asking others to speak more slowly, clearly, or loudly, listening to the television or radio at a loud volume, withdrawal from conversations, and social isolation (Mayo Clinic, 2014).*
- Use the National Institutes of Health (NIH) Toolbox to test hearing as available. *The toolbox is an automated procedure that allows nonspecialists to administer the hearing test reliably. In addition, conductive hearing loss can be differentiated from sensorineural loss, the ability to hear in a noisy environment is tested, and the effects of a hearing loss on the emotional and social life of a hearing impaired person can be determined (Zecker et al, 2013).*
- Recognize that certain populations are especially vulnerable to noise-induced hearing loss, including farmers, industrial workers, firefighters, construction workers, musicians, and music lovers using personal listening devices.
- ▲ Refer to otolaryngologist and/or audiologist. *Conductive hearing loss can be ameliorated by treatment such as removal of ear wax or surgical treatment for hearing disorders. Sensorineural hearing loss is generally permanent; hearing aids can be helpful (Baloh & Jen, 2011).*
- Keep background noise to a minimum. Turn off the television and radio when communicating with the client. If in a noisy environment, take the client to a private room and shut the door. *Background noise significantly interferes with hearing in the hearing impaired client (Harkin & Kelleher, 2011).*
- Stand or sit directly in front of the client when communicating. Make sure adequate light is on the nurse's face, avoid chewing gum or covering mouth or face with hands while speaking, establish eye contact, and use nonverbal gestures. *Clients with hearing impairment read lips and also interpret nonverbal communication, which is a significant part of communication. To increase communication, it is important that the client be able to clearly see the face of the person speaking (Harkin & Kelleher, 2011; Spyridakou, 2012).*
- Speak clearly in lower voice tones if possible. Do not overenunciate or shout at the client. *In many kinds of hearing loss, clients lose the ability to hear higher-pitched tones but can still hear lower-pitched tones. Overenunciating makes it difficult to read lips. Shouting makes the words less clear and is seen as aggressive (Harkin & Kelleher, 2011; Spyridakou, 2012).*
- Verify that the client understands critical information by asking the client to repeat the information. *Hearing impaired clients will often smile or nod when asked if they understand to avoid embarrassment; asking them to repeat the information is the best way to verify they understand what is being said.*
- If necessary, provide a communication board, personnel who know sign language, or any method helpful to increase understanding for the hearing impaired client. *Health care institutions are required to provide and pay for qualified interpreters under the Americans with Disabilities Act.*
- Prepare pictures or diagrams depicting tests or procedures; have books with relevant pictures available for more detailed discussions. *The use of visual aids can improve communication when hearing is impaired.*
- Watch for signs of depression such as withdrawal, impaired sleep, flat affect, and refer for treatment if needed. **EB:** *A large study found that hearing loss was significantly associated with depression, especially in women (Li et al, 2014).*
- Encourage the client to wear a hearing aid if available. **EB:** *A study demonstrated that use of a hearing aid was associated with a reduced chance of developing a major depressive disorder in older adults (Mener et al, 2013).*
- Recognize that clients with a hearing aid may choose to wear a hearing aid intermittently because hearing aids can create distortion of speech and extraneous noise that is bothersome (Shah & Lotke, 2013).

Critical Care

- Develop a communication cart to foster communication with hearing impaired clients. Contents can include spiral notebooks, felt tip markers, clipboards, communication boards (picture, word, whole phrases, alphabet), hearing aid batteries, and electronic speech generators.
- Develop good communication skills to interact with hearing impaired clients. It is unfair to expect critically ill older adults to understand what is being said to them only through auditory means. **EBN:** *A study of nurses receiving training in basic communication skills found them to be helpful, but also found advanced communication skills utilizing electronic speech generating devices time consuming (Radtko et al, 2012).*

Pediatric

- ▲ Refer infants or children for hearing tests as indicated so that treatment/therapy begins early as needed. *Early treatment of a hearing loss can decrease the effects of a hearing loss on social, emotional, and academic development of a child (Shah & Lotke, 2013).*
- In the child, recommend parents watch for signs of hearing loss including worsening speech or school performance, withdrawal from social activities, playing alone, and playing the television and music increasingly louder (Shah & Lotke, 2013).
- Refer the child to the use of a language wizard player with Baldi, a computer-animated tutor for teaching vocabulary. **CEB:** *A study demonstrated that use of the computer system resulted in excellent retention of learned words 4 weeks after the end of the experiment (Massaro & Light, 2004).*
- Recognize that children who are deaf or hard of hearing are particularly vulnerable to abuse, both by parents/caregivers and by sexual predators. *Parental abuse may be caused by frustration dealing with the child; sexual abuse may be associated with increased isolation of the child and decreased ability to report abuse to others (Shah & Lotke, 2013).*
- Recommend that teenagers avoid use of personal listening devices, or try to keep the volume down. Use culturally appropriate teaching materials. *There is an increased rate of hearing loss in teenagers 12 to 19 years of age (Shah & Lakte, 2013).* **EB:** *A study found that more than half of young people using personal listening devices had the volume at a level that could damage hearing. In addition, African American participants listened to music at the highest volume (Fligor et al, 2014).*

Geriatric

- ▲ Routinely screen geriatric clients for presence of hearing loss because up to two thirds of all people 70 or older have a hearing loss (Bainbridge & Wallhagen, 2014).
- ▲ Inspect the ear canal for wax buildup in the ears. *Older adults have drier wax and slower than normal movement of skin and debris out of the ear. Ear hairs at the entrance can sometimes block the movement of wax out of the ear (Harkin & Kelleher, 2011).* **EB:** *Removal of wax from the ear was found to significantly improve the well-being of older clients (Oron et al, 2011).*
- Work with the client to ensure contact with others and maintenance of meaningful activities to strengthen the social network and maintain cognitive abilities. **EB:** *A large observational study found that hearing loss predicted loss of cognition in older adults (Lin et al, 2013).*

Home Care

- The previously listed interventions are applicable in the home care setting.
- Recommend that the client change the home environment if needed for better acoustics. Avoid glossy walls, high and reflective ceilings, reflective glass counters, and tiled floors. Use acoustic paneling if needed. *The goal is to reduce noise reverberating off the walls, floors, and surfaces of the home.*
- Suggest installation of devices such as strobe lights for the telephone, alarm clock, fire alarms, and doorbell; sensors that detect an infant's cry; alarm clocks that vibrate the bed; and closed caption decoders for television sets. Other helpful devices include telephone amplifiers, speakerphones, cell phones with text messaging or instant messaging, pocket talker personal listening systems, and FM and infrared amplification systems that connect directly to a TV or audio output jack. Also available is a telecommunication device, a typewriter keyboard with an alphanumeric display that allows the hearing impaired person to send typed messages over the telephone line. Use of hearing ear dogs (dogs specially trained to alert their owners to specific sounds) may also be helpful. *These methods can be helpful to increase communication and safety for the hearing impaired client (Shah & Lotke, 2013).*

Client/Family Teaching and Discharge Planning

- Teach client to avoid excessive noise at work or at home and to wear hearing protection when necessary. *Any noise that hurts the ears or is above 90 decibels is excessive. Sources of noise that can cause hearing loss include motorcycles, firecrackers, and small firearms, all emitting sounds from 120 to 150 decibels. Long or repeated exposure to sounds at or above 85 decibels can cause hearing loss; music, lawnmowers, leaf blowers, and shop tools may contribute to hearing loss (NIH, 2011).*
- Teach the client to avoid inserting objects such as cotton-tipped swabs or bobby pins into the ears. *The ear is self cleaning, and using devices can interfere with the process and also damage the ear structures (Harkin & Kelleher, 2011).*

Vision Loss Michelle Acorn, DNP, NP PHC-Adult, BA, BScN/PHCNP, MNI/ACNP, ENC(C), GNC(C), CAP, CGP, and Betty J. Ackley, MSN, EdS, RN

Definition

Decreased or absence of vision when it existed previously; vision loss can be either acute in onset or occur as a slow progressive chronic visual loss

NOTE: This is not a NANDA-I nursing diagnosis. The authors have identified this health problem because vision loss is commonly seen in nursing practice.

Defining Characteristics

Change in behavior pattern; change in problem-solving abilities; disorientation; decreased visual acuity; loss of vision; visual hallucinations

Related Factors

Aging; diabetes mellitus; exposure to UV light; impaired visual function; impaired visual integration; impaired visual reception; impaired visual transmission; nutritional deficiency
(Adapted from the work of NANDA-I)

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes (Visual)

Sensory Function: Vision; Vision Compensation Behavior

Example NOC Outcome with Indicators

Vision Compensation Behavior as evidenced by the following indicators: Uses adequate light for activity being performed/Wears eyeglasses correctly/Uses vision assistive devices/Uses computer assistive devices/Uses support services for low vision. (Rate each indicator of **Vision Compensation Behavior**: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate relaxed body movements and facial expressions
- Remain as independent as possible

- Explain plan to modify lifestyle to accommodate visual impairment
- Incorporate use of lighting to maximize visual abilities
- Demonstrate familiarity with vision assistive devices
- Remain free of physical harm resulting from loss of vision

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cognitive Stimulation; Visual Deficit; Environmental Management

Example NIC Activities—Communication Enhancement: Visual Deficit

Identify yourself when you enter the client's space; Build on client's remaining vision, as appropriate

Nursing Interventions and Rationales

- Identify yourself immediately whenever you enter the client's area. *Effective communication assists in the development of trust and decreases fear (Lawrence, 2011).*
- Provide environmental predictability. Consistently remind staff, family members, and visitors to tell the client when something is added or removed from the environment. *Consistency in placement of furniture and personal items aids in location detection and independence, and decreases chances of injury (Cattan, 2011; Lawrence, 2011).*
- Assist with feeding at mealtimes if blindness is temporary.
- Keep side rails up using half rails; maintain bed in a low position.
- Converse with and touch the client frequently during care if frequent touch is within the client's cultural norm. *Appropriate touch can decrease social isolation.*
- Walk the client by having the client grasp nurse's elbow or shoulder and walk partially behind nurse.
- Walk a frightened or confused client by having the client place both hands on the nurse's shoulders or waist. Then the nurse backs up in the desired direction while holding the client around the waist. This method helps the client feel secure and ensures safety.
- Keep the call light within the client's reach; check location of call light before leaving the room. **CEB:** *A study demonstrated that a large percentage of hospitalized clients are unable to use the call light button and feel vulnerable as a result (Duffy et al, 2005).*
- Provide good lighting in rooms, task lights, and night lights. **CEB:** *Good overall lighting is essential for safety, and task lighting makes everyday activities easier. Night lights allow safer navigation in the dark (Lighthouse International, 2015).*
- Make doorframes and light switches a contrasting color to the walls. **CEB:** *Contrast increases the likelihood of identifying them during navigation (Lighthouse International, 2015).*
- Ensure access to eyeglasses or magnifying devices as needed. Vision aid devices include readers, microscopes, handheld magnifiers, and stand magnifiers (Ventocilla, 2013).
- Encourage expression of feelings and expect grieving behavior if onset of blindness is new. Blind people grieve the loss of vision and experience a loss of identity and control over their lives. **CEB:** *Anxiety and depression are common in people with decreased vision (Watkinson, 2010).* **CEB:** *A study of clients with age-related macular degeneration found that a problem-focused group was effective in helping clients (Wahl et al, 2006).*
- Recommend client have vision evaluated by an optometrist or ophthalmologist as appropriate to determine whether an improvement in visual acuity is possible. *Clients may not have the correct prescription for their visual acuity; for some clients, the correct prescription of glasses may restore visual acuity (Goldman & Schafer, 2011).*
- Question the client regarding the presence of visual hallucinations. If present, reassure the client that the experience is common and does not mean he or she has a mental illness. It is helpful for the client to know that this is common and usually does not require treatment. **CEB:** *Up to half of all severely visually impaired persons have visual hallucinations, that is, fully formed images in their mind (Ricard, 2009; Watkinson, 2010).*
- Provide a CD player, radio, or books on tape as desired. These provide sensory stimulation and can help deal with the boredom of hospitalization.

- Take protective measures to prevent falls. Refer to the care plan for Risk for Falls.
- Explore and enhance available support systems to ensure a safe discharge. Caregivers and/or family may not have the ability to assist the client after discharge. See care plan for Risk for Injury or Risk for Falls.
- Assess the client's visual and other sensory loss using valid and reliable tools. **EB:** *The Severe Dual Sensory Loss Screening Tool for hearing and visual impairment is a valid and reliable tool, enabling nurses to identify impairment among older adults (Roets-Merken, 2014).* **EB:** *The vision-target HRQOL measure provides a comprehensive assessment of the impact of eye disease on daily functioning and well-being in adults (Paz et al, 2013).*
- Encourage the client to implement lifestyle strategies that promote avoidance of cardiovascular disease and diabetes to prevent vision loss. **CEB:** *Lifestyle strategies for the prevention of vision loss are important by promoting the avoidance of cardiovascular disease and diabetes (Sharts-Hopko, 2010).*

Multicultural

- Consider race/ethnicity as a possible related factor to vision loss. **EB:** *African Americans are at higher risk for rapid worsening of glaucoma than Caucasians (Lee et al, 2014).*

Geriatric

- Keep environment quiet, soothing, and familiar. Use consistent caregivers. These measures are comforting to older adults with a sensory loss and help decrease confusion (Lawrence, 2011).
- Increase the amount of light in the environment for older eyes; ensure it is nonglare lighting. **CEB:** *Increased lighting can help compensate for some of the visual changes of aging, including reduced visual acuity, reduced contrast sensitivity, and reduced color discrimination (Boyce, 2003).*
- ▲ Determine origin of vision loss if possible. *There are five main causes of vision loss in older adults: macular degeneration, cataracts, glaucoma, diabetic retinopathy, and refractive error (Horton, 2012).*
- Cataract is a leading cause of reversible vision impairment and may increase the risk for falls in older adults. *Use appropriate refractive management between timely surgeries (Meulders et al, 2014).*
- Hearing and vision rehabilitation services need to screen for dual sensory impairment. **EB:** *If audiologists are made aware of visual conditions affecting their clients, they can facilitate access to technologies for aid retention and benefit (Schneider et al, 2014).*
- ▲ Refer to a comprehensive vision rehabilitation center early in the disease process of macular degeneration to prevent some of the negative consequences of vision loss (Maturi, 2011).
- Teach the client methods to preserve remaining vision as much as possible, including not smoking or breathing second-hand smoke, protecting the eyes from sunlight, and including fish and leafy green vegetables in the diet (Maturi, 2011).
- Vision impairment is independently associated with malnutrition. **EB:** *Older assisted living residents with visual impairment were more often female, had lower body mass index, suffered more dementia, and had more chewing problems (Murrinen et al, 2014).*
- Monitor for signs of new onset of increased vision loss, such as not recognizing familiar people, difficulty seeing in bright light or low light, new problems with reading, the client complains of tired eyes, and/or verbalizes vision problems with current glasses facilitating effective vision (Ventocilla, 2013).
- Age-related visual problems can also occur with stroke (Pollock et al, 2011). If vision loss is from a stroke, watch for hemianopia, an ability to see to one side only. Encourage clients to scan environment by turning head from side to side. Also assess for visual spatial misconception.
- ▲ **EB:** *A Cochrane study found that there was evidence supporting scanning to improve reading ability, but scanning techniques were not helpful for improved visual field outcomes, and there was insufficient evidence to demonstrate effectiveness in improving activities of daily living ability (Pollock et al, 2011).*
- ▲ Refer client to low-vision clinics or independent living programs, which are designed for individuals who are vision impaired or blind to help maintain independence. *Clients with vision loss should be referred to clinics early, preferably before vision is gone, for help dealing with the loss (Kalinowski, 2008).* **EB:** *A study demonstrated that mobility function improved after blind rehabilitation training for a group of older veterans (Kuyk & Elliot, 2004).*
- Work with the client to ensure contact with others, to maintain meaningful activities, and to strengthen the social network. **CEB:** *Severe loneliness can accompany sensory loss in older adults as a result of self-imposed isolation (Girdler et al, 2008).*

- Watch for signs of depression: decreased appetite, withdrawal from usual life activities, flat affect, excessive time in bed, and somatization. **CEB:** *In one study, clients with severe vision loss identified their reality as a cause for feelings of despair (Girdler et al, 2008).*
- For the client with both vision loss and dementia, provide nursing care including:
 - Recognize that vision loss can increase problems for the client with dementia, including decreased orientation, decreased recognition of others, less recall, impaired judgment, and possibly aggression (Barrand, 2011).
 - Use one-to-one conversations to maintain socialization. *These clients often cannot process conversations with a group; communication is enhanced with one-to-one communication (Lawrence, 2011).*
 - Obtain and use visual aids to help maintain orientation and contact with the environment, including such things as talking clocks, speaking Freeview digital boxes to give an auditory version of what is on the television, and use of memory photo dial pads so that clients can use the telephone to maintain contact with others (Barrand, 2011).

Home Care

- Most of the listed interventions are applicable in the home care setting.
- Monitor home care clients for recent visual loss and resulting decrease in social activity. **CEB:** *A study found that recent visual loss commonly resulted in decreased socialization and decrease in outdoor activities due to a fear of falling (Grue et al, 2010).*
- Enable the visually impaired client to do things for himself/herself to maintain independence as long as possible (Cattan, 2011).

Client/Family Teaching and Discharge Planning

Low Vision

- Use contrast to increase visibility of items; for example, place a dark background around the light switch so that it can be located more easily. *Improving the contrast between images results in better visual recognition (Ventocilla et al, 2013).*
- Place red, yellow, or orange identifiers on important items that need to be seen, such as a red strip at the edge of steps, red behind a light switch, or a red dot on a stove or washing machine to indicate how far to turn knob, or use a dial marker that will offer a tactile cue to the client to turn on ovens, stoves, and washing machines. *Color cues can improve the legibility of the environment and increase the ability to target objects quickly.*
- Use a watch or clock that verbally tells time, and a phone with large numerals and emergency numbers programmed into it (Ventocilla et al, 2013).
- Teach blind clients how to feed self; associate food on plate with hours on a clock so that the client can identify location of food.
- Use low-vision aids including magnifying devices for near vision and telescopes for seeing objects at a distance, a closed-circuit television that magnifies print, and guides for writing checks and envelopes. *Low vision aids can improve vision in clients with limited sight (Ventocilla et al, 2013).*
- Teach the client with vision loss to do the following:
 - Use a magnifying mirror to shave or apply makeup. Use an electric razor only.
 - Put personal care products in brightly colored pump containers (red, yellow, or orange) for identification.
 - Use tactile clues such as safety pins or buttons placed in hems to help client match clothing. Or place matching outfits of clothing in separate plastic bags.
 - Use a prefilled medication organizer with large lettering or three-dimensional (3D) markers. *These methods can help maintain the independence of the client (Ventocilla et al, 2013).*
- Increase lighting in the home to help vision in the following ways:
 - Ensure adequate illumination of the entire home, adding light fixtures and increasing wattage of existing bulbs as needed.
 - Decrease glare; where light reflects on shiny surfaces, move or cover object.
 - Use nonglare wax on the floor.
 - Use motion lights that turn on automatically when a person enters the room for nighttime use.
 - Add indoor strip or “runway”-type lighting to baseboards.

Visual acuity can be improved by taking steps to overcome age-related changes in vision (American Federation for the Blind, 2011).

- ▲ Refer the client to an occupational therapist for assistance in dealing with vision loss and learning how to meet personal needs to maintain maximum independence.

Occupational therapists can help with a large number of problems for the visually impaired client, including safety, independence, quality of life, and agencies for support (Ventocilla et al, 2013).

- Encourage the client to wear a hat and sunglasses when out in the sun. *Direct sunlight and glare have been associated with vision loss.*
- Work with the client to find rewarding recreational pursuits. *Recognize that advancing vision loss can often discourage people from participating in the recreational pursuits they enjoyed in the past. When an activity becomes too much of a struggle, it simply is no longer fun. However, vision loss does not erase the basic need for the physical and mental rewards of play and relaxation.*
